- The NetScaler supports not-so-stubby-areas (NSSAs). An NSSA is similar to an OSPF stub area but allows injection of external routes in a limited fashion into the stub area. To support NSSAs, a new option bit (the N bit) and a new type (Type 7) of Link State Advertisement (LSA) area have been defined. Type 7 LSAs support external route information within an NSSA. An NSSA area border router (ABR) translates a type 7 LSA into a type 5 LSA that is propagated into the OSPF domain. The OSPF specification defines only the following general classes of area configuration:
  - Type 5 LSA: Originated by routers internal to the area are flooded into the domain by AS boarder routers (ASBRs).
  - Stub: Allows no type 5 LSAs to be propagated into/throughout the area and instead depends on default routing to external destinations.

After enabling OSPF, you need to configure advertisement of OSPF routes. For troubleshooting, you can limit OSPF propagation. You can display OSPF settings to verify the configuration.

Enabling and Disabling OSPF

Updated: 2013-09-05

To enable or disable OSPF, you must use either the command line interface or the configuration utility. When OSPF is enabled, the NetScaler starts the OSPF process. When OSPF is disabled, the NetScaler stops the OSPF routing process.

To enable or disable OSPF routing by using the command line interface

At the command prompt, type one of the following commands:

1. enable ns feature OSPF
2. disable ns feature OSPF

To enable or disable OSPF routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the OSPF Routing option.

Advertising OSPF Routes

Updated: 2013-08-30

OSPF enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure OSPF to advertise routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enters global configuration mode.
router OSPF	Start OSPF routing process and enter configuration mode for the routing process.
network A.B.C.D/M area <0-4294967295>	Enable routing on an IP network.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router OSPF
NS(config-router)# network 10.102.29.0/24 area 0
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting OSPF Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you can configure listen-only mode on any given VLAN.

To limit OSPF propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router OSPF	Start OSPF routing process and enters configuration mode for the routing process.

Command	Specifies
passive-interface < vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router OSPF
NS(config-router)# passive-interface VLAN0
```

Verifying the OSPF Configuration

Updated: 2013-08-30

You can display current OSPF neighbors, and OSPF routes.

To view the OSPF settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh OSPF neighbor	Displays current neighbors.
sh OSPF route	Displays OSPF routes.

Example

```
>VTYSH
NS# sh OSPF neighbor
NS# sh OSPF route
```

Configuring BGP

Mar 20, 2012

The NetScaler appliance supports BGP (RFC 4271). The features of BGP on the NetScaler are:

- The NetScaler advertises routes to BGP peers.
- The NetScaler injects host routes to virtual IP addresses (VIPs), as determined by the health of the underlying virtual servers.
- The NetScaler generates configuration files for running BGP on the secondary node after failover in an HA configuration.
- This protocol supports IPv6 route exchanges.

After enabling BGP, you need to configure advertisement of BGP routes. For troubleshooting, you can limit BGP propagation. You can display BGP settings to verify the configuration.

Prerequisites for IPv6 BGP

Before you begin configuring IPv6 BGP, do the following:

- Make sure that you understand the IPv6 BGP protocol.
- Install the IPv6PT license on the NetScaler appliance.
- After installing the IPv6PT license, enable the IPv6 feature.

Enabling and Disabling BGP

Updated: 2013-09-05

To enable or disable BGP, you must use either the command line interface or the configuration utility. When BGP is enabled, the NetScaler appliance starts the BGP process. When BGP is disabled, the appliance stops the BGP process.

To enable or disable BGP routing by using the command line interface

At the command prompt, type one of the following commands:

- enable ns feature BGP
- disable ns feature BGP

To enable or disable BGP routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the BGP Routing option.

Advertising IPv4 Routes

Updated: 2013-08-30

You can configure the NetScaler appliance to advertise host routes to VIPs and to advertise routes to downstream networks.

To configure BGP to advertise IPv4 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
Neighbor < IPv4 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the link local IPv4 address of the neighbor in the specified autonomous system.
Address-family ipv4	Enter address family configuration mode.
Neighbor < IPv4 address> activate	Exchange prefixes for the IPv4 router family between the peer and the local node by using the link local address.
redistribute kernel	Redistribute kernel routes.
redistribute static	Redistribute static routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router BGP 5
NS(config-router)# Neighbor a1bc::102 remote-as 100
NS(config-router)# Address-family ipv4
NS(config-router-af)# Neighbor 10.102.29.170 activate
NS(config-router)# redistribute kernel
NS(config-router)# redistribute static
```

Advertising IPv6 BGP Routes

Updated: 2013-08-30

Border Gateway Protocol (BGP) enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure BGP to advertise IPv6 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
Neighbor < IPv6 address> remote-as < as-number>	Update the IPv6 BGP neighbor table with the link local IPv6 address of the neighbor in the specified autonomous system.
Address-family ipv6	Enter address family configuration mode.
Neighbor < IPv6 address> activate	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address.
redistribute kernel	Redistribute kernel routes.
redistribute static	Redistribute static routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router BGP 5
NS(config-router)# Neighbor a1bc::102 remote-as 100
NS(config-router)# Address-family ipv6
NS(config-router-af)# Neighbor a1bc::102 activate
NS(config-router)# redistribute kernel
NS(config-router)# redistribute static
```

Verifying the BGP Configuration

Updated: 2013-08-30

You can use VTYSH to display BGP settings.

To view the BGP settings using the VTYSH command line

At the command prompt, type:

```
VTYSH
You are now in the VTYSH command prompt. An output similar to the following appears:
NS170#
At the VTYSH command prompt, type:
```

```
NS170# sh ip BGP
NS170# sh BGP
NS170# sh ip BGP neighbors
NS170# sh ip BGP summary
NS170# sh ip BGP route-map <map-tag>
```

Configuring IPv6 RIP

Mar 20, 2012

IPv6 Routing Information Protocol (RIP) or RIPng is a Distance Vector protocol. This protocol is an extension of RIP to support IPv6. After enabling IPv6 RIP, you need to configure advertisement of IPv6 RIP routes. For troubleshooting, you can limit IPv6 RIP propagation. You can display IPv6 RIP settings to verify the configuration.

Prerequisites for IPv6 RIP

Before you begin configuring IPv6 RIP, do the following:

- Make sure that you understand the IPv6 RIP protocol.
- Install the IPv6PT license on the NetScaler appliance.
- Enable the IPv6 feature.

Enabling IPv6 RIP

Updated: 2013-08-30

You can enable or disable IPv6 RIP by using VTYSH. After you enable IPv6 RIP, the NetScaler starts the IPv6 RIP daemon. After you disable IPv6 RIP, the NetScaler stops the RIP daemon.

To enable IPv6 RIP by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
ns IPv6-routing	Start IPv6 dynamic routing daemon.
interface < vlan_name>	Enter VLAN configuration mode.
router ipv6 RIP	Start IPv6 RIP routing process on the VLAN.

Example

```
> VTYSH
NS# configure terminal
NS(config)# ns IPv6-routing
NS(config)# interface vlan0
NS(config-if)# router ipv6 RIP
```

Advertising IPv6 RIP Routes

Updated: 2013-08-30

IPv6 RIP enables an upstream router to load balance traffic between two identical vservers hosted on two standalone NetScaler devices. Route advertisement enables an upstream router to track network entities located behind the NetScaler.

To configure IPv6 RIP to advertise IPv6 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 rip	Start IPv6 RIP routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 rip
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting IPv6 RIP Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given interface.

To limit IPv6 RIP propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.

Command	Specifies
router ipv6 rip	Start IPv6 RIP routing process and enter configuration mode for the routing process.
passive-interface < vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 rip
NS(config-router)# passive-interface VLAN0
```

Verifying the IPv6 RIP Configuration

Updated: 2013-08-30

You can use VTYSH to display the IPv6 RIP routing table and IPv6 RIP information for a specified VLAN.

To view the IPv6 RIP settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
sh ipv6 rip	Display updated IPv6 RIP routing table.
sh ipv6 rip interface <vlan_name>	Display IPv6 RIP information for the specified VLAN.

Example

```
NS# VTYSH
NS# sh ipv6 rip
NS# sh ipv6 rip interface VLAN0
```

Configuring IPv6 OSPF

Mar 20, 2012

IPv6 OSPF or OSPF version 3 (OSPF v3) is a link state protocol that is used to exchange IPv6 routing information. After enabling IPv6 OSPF, you need to configure advertisement of IPv6 OSPF routes. For troubleshooting, you can limit IPv6 OSPF propagation. You can display IPv6 OSPF settings to verify the configuration.

Prerequisites for IPv6 OSPF

Before you begin configuring IPv6 OSPF, do the following:

- Make sure that you understand the IPv6 OSPF protocol.
- Install the IPv6PT license on the NetScaler appliance.
- Enable the IPv6 feature.

Enabling IPv6 OSPF

Updated: 2013-08-30

To enable IPv6 OSPF, you must use the VTYSH command line. When IPv6 OSPF is enabled, the NetScaler appliance starts the IPv6 OSPF daemon. When IPv6 OSPF is disabled, the appliance stops the IPv6 OSPF daemon.

To enable IPv6 OSPF by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
ns IPv6-routing	Start IPv6 dynamic routing process.
interface < vlan_name>	Enter the VLAN configuration mode.
ipv6 router OSPF area <area-id>	Start IPv6 OSPF routing process on a VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# ns IPv6-routing
NS(config)# interface vlan0
NS(config-if)# ipv6 router OSPF area 3
```

Advertising IPv6 Routes

Updated: 2013-08-30

IPv6 OSPF enables an upstream router to load balance traffic between two identical vservers hosted on two standalone NetScaler devices. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure IPv6 OSPF to advertise IPv6 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 OSPF	Start IPv6 OSPF routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 OSPF
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting IPv6 OSPF Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you use VTYSH to configure listen-only mode on any given VLAN.

To limit IPv6 OSPF propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.

Commands	Specifies
router ipv6 OSPF	Start IPv6 OSPF routing process and enter configuration mode for the routing process.
passive-interface < vlan_name >	Suppress routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 OSPF
NS(config-router)# passive-interface VLAN0
```

Verifying the IPv6 OSPF Configuration

Updated: 2013-08-30

You use VTYSH to display IPv6 OSPF current neighbors and IPv6 OSPF routes.

To view the IPv6 OSPF settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh ipv6 OSPF neighbor	Display current neighbors.
sh ipv6 OSPF route	Display IPv6 OSPF routes.

Example

```
>VTYSH
NS# sh ipv6 OSPF neighbor
NS# sh ipv6 OSPF route
```

Configuring ISIS

Aug 28, 2013

The NetScaler appliance supports the Intermediate System-to-Intermediate System (IS-IS or ISIS) dynamic routing protocol. This protocol supports IPv4 as well as IPv6 route exchanges. IS-IS is a link state protocol and is therefore less prone to routing loops. With the advantages of faster convergence and the ability to support larger networks, ISIS can be very useful in Internet Service Provider (ISP) networks.

Prerequisites for configuring ISIS

Before you begin configuring ISIS, do the following:

- Make sure that you understand the ISIS protocol.
- For IPV6 routes, enable:
  - IPv6 protocol translation feature.
  - IPv6 Dynamic Routing option on the VLANs on which you want to run ISIS protocol.

Enabling ISIS

Updated: 2013-08-30

Use either of the following procedures to enable the ISIS routing feature on the NetScaler appliance.

To enable ISIS routing by using the command line interface

At the command prompt, type:

```
enable ns feature ISIS
```

To enable ISIS routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the ISIS Routing option.

Creating an ISIS Routing Process and Starting It on a VLAN

Updated: 2013-08-30

To create an ISIS routing process, you must use the VTYSH command line.

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Creates an ISIS routing process and configuration mode for the routing process.

Command	Description
net XX....XXXX.YYYY.YYYY.YYYY.00	Specifies a NET value for the routing process, where: ● · XX. .. .XXXX is the Area Address (can be 1-13 bytes) ● · YYYY.YYYY.YYYY is the System ID (6 bytes) ● · 00 is the N-selector (1 byte) A NET value can be 8 to 20 bytes in length. The last byte is always the n-selector, and must be zero. The n-selector indicates that there is no transport entity and means that the packet is for the routing software of the appliance. The six bytes directly preceding the n-selector are the system ID. The system ID length is fixed and cannot be changed. The system ID must be unique throughout each area (Level 1) and throughout the backbone (Level 2). The bytes preceding the system ID are the area ID, which can be from 1 to 13 bytes in length. A maximum of three NETs per routing process are allowed with different area ID, but the system ID should be the same for all NETs.
is-type (level-1|level-1-2|level-2-only)	Sets the ISIS routing process to the specified level of routing. Default: level-1-2.
ns IPv6-routing	Starts the IPv6 dynamic routing daemon.
interface <vlan_name>	Enters the VLAN configuration mode.
ip router ISIS	Enables the ISIS routing process on the VLAN for IPv4 route exchanges.
ipv6 router ISIS	Enables the ISIS routing process on the VLAN for IPv6 route exchanges.

Example

```
> VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# net 15.aabb.ccdd.0097.00
NS(config-router)# is-type level-1
NS(config-router)# exit
NS(config)# ns IPv6-routing
NS(config)# interface vlan0
NS(config-if)#  ip router isis 11
NS(config-if)# ipv6 router isis 11
```

Advertising Routes

Updated: 2013-08-30

Route advertisement enables an upstream router to track network entities located behind the NetScaler appliance.

To configure ISIS to advertise routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Description

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Starts the ISIS routing instance and enter configuration mode for the routing process.
redistribute connected (level-1|level-1-2|level-2)	Redistributes connected routes, where • **level-1** : Redistribute connected routes into Level-1. • **level-1-2** : Redistribute connected routes into Level-1 and Level-2. • **level-2** : Redistribute connected routes into Level-2.
redistribute kernel(level-1|level-1-2|level-2)	Redistributes kernel routes, where: • **level-1** : Redistribute kernel routes into Level-1. • **level-1-2** : Redistribute kernel routes into Level-1 and Level-2. • **level-2** : Redistribute kernel routes into Level-2.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# redistribute connected level-1
NS(config-router)# redistribute kernel level-1
```

Limiting ISIS Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given VLAN.

To limit ISIS propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router isis [tag]	Enters the configuration mode for the routing process.
passive-interface <vlan_name>	Suppresses routing updates on interfaces bound to the specified VLAN.

Example

>VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# passive-interface VLAN0
Verifying the ISIS Configuration

Updated: 2013-08-30

You can use VTYSH to display the ISIS routing table and ISIS information for a specified VLAN.

To view the ISIS settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Description
VTYSH	Displays the VTYSH command prompt.
show ip isis route	Displays updated IPv4 ISIS routing table.
show ipv6 isis route	Displays updated IPv6 ISIS routing table.
sh isis interface <vlan_name>	Displays IPv6 ISIS information for the specified VLAN.

Example
NS# VTYSH
NS# show ip isis route
NS# show ipv6 isis route
NS# sh isis interface VLAN0

Installing Routes to the NetScaler Routing Table

Aug 30, 2013

The NetScaler appliance can use routes learned by various routing protocols after you install the routes in the appliance's routing table.

To install various routes to the internal routing table by using the VTYSH command line

At the command prompt, type the following commands as appropriate for the routes that you want to install:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
ns route-install Default	Install IPv4 default routes to the internal routing table.
ns route-install RIP	Install IPv4 RIP specific routes to the internal routing table.
ns route-install BGP	Install IPv4 BGP specific routes to the internal routing table.
ns route-install OSPF	Install IPv4 OSPF specific routes to the internal routing table.
ns route-install IPv6 Default	Install IPv6 default routes to the internal routing table.
ns route-install IPv6 RIP	Install IPv6 RIP specific routes to the internal routing table.
ns route-install IPv6 BGP	Install IPv6 BGP specific routes to the internal routing table.
ns route-install IPv6 OSPF	Install IPv6 OSPF specific routes to the internal routing table.

Example

```
>VTYSH
NS# configure terminal
NS# ns route-install Default
NS(config)# ns route-install RIP
NS(config)# ns route-install BGP
NS(config)# ns route-install OSPF
NS# ns route-install IPv6 Default
NS(config)# ns route-install IPv6 RIP
```

```
NS(config)# ns route-install IPv6 BGP
NS(config)# ns route-install IPv6 OSPF
```

Configuring Static Routes

Sep 06, 2013

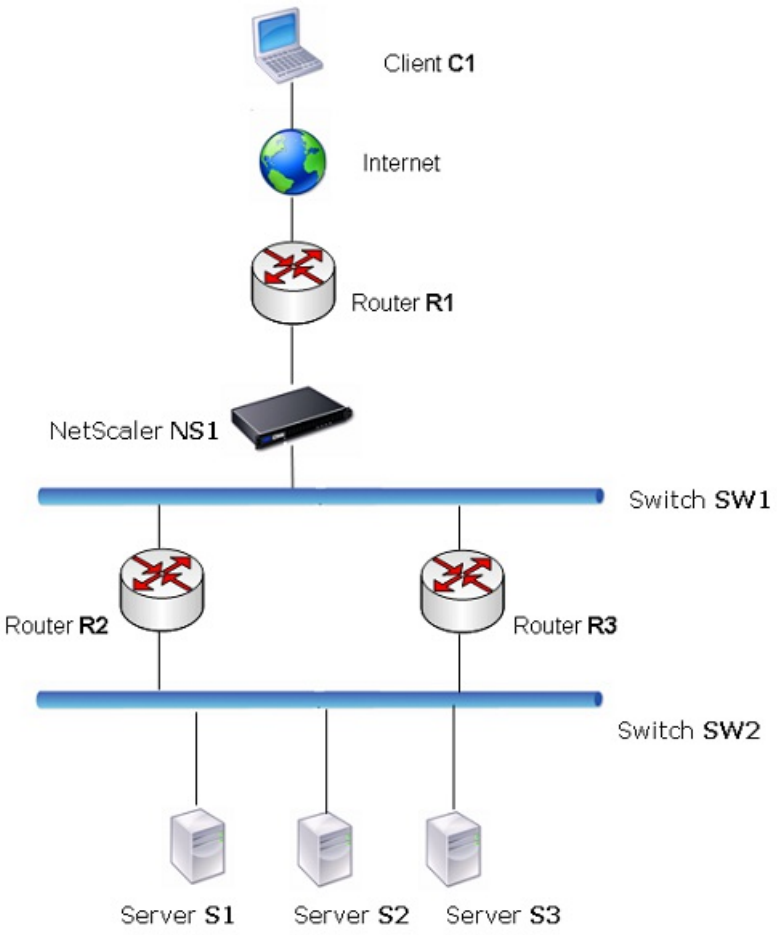
Static routes are manually created to improve the performance of your network. You can monitor static routes to avoid service disruptions. Also, you can assign weights to ECMP routes, and you can create null routes to prevent routing loops.

Monitored Static Routes

If a manually created (static) route goes down, a backup route is not automatically activated. You must manually delete the inactive primary static route. However, if you configure the static route as a monitored route, the NetScaler appliance can automatically activate a backup route.

Static route monitoring can also be based on the accessibility of the subnet. A subnet is usually connected to a single interface, but it can be logically accessed through other interfaces. Subnets bound to a VLAN are accessible only if the VLAN is up. VLANs are logical interfaces through which packets are transmitted and received by the NetScaler. A static route is marked as DOWN if the next hop resides on a subnet that is unreachable.

Note: In a high availability (HA) setup, the default value for monitored state routes (MSRs) on the secondary node is UP. The value is set to avoid a state transition gap upon failover, which could result in dropping packets on those routes.
Consider the following simple topology, in which a NetScaler is load balancing traffic to a site across multiple servers.



Router R1 moves traffic between the client and the NetScaler appliance. The appliance can reach servers S1 and S2 through routers R2 or R3. It has two static routes through which to reach the servers' subnet, one with R2 as the gateway and another with R3 as the gateway. Both these routes have monitoring enabled. The administrative distance of the static route with gateway R2 is lower than that of the static route with gateway R3. Therefore, R2 is preferred over R3 to forward traffic to the servers. Also, the default route on the NetScaler points to R1 so that all Internet traffic exits properly.

If R2 fails while monitoring is enabled on the static route, which uses R2 as the gateway, the NetScaler marks it as DOWN. The NetScaler now uses the static route with R3 as the gateway and forwards the traffic to the servers through R3.

The NetScaler supports monitoring of IPv4 and IPv6 static routes. You can configure the NetScaler to monitor an IPv4 static route either by creating a new ARP or PING monitor or by using existing ARP or PING monitors. You can configure the NetScaler to monitor an IPv6 static route either by creating a new Neighbor discovery for IPv6 (ND6) or PING monitor or by using the existing ND6 or PING monitors.

Weighted Static Routes

When the NetScaler appliance makes routing decisions involving routes with equal distance and cost, that is, Equal Cost Multi-Path (ECMP) routes, it balances the load between them by using a hashing mechanism based on the source and destination IP addresses. For an ECMP route, however, you can configure a weight value. The NetScaler then uses both the weight and the hashed value for balancing the load.

Null Routes

If the route chosen in a routing decision is inactive, the NetScaler appliance chooses a backup route. If all the backup routes become inaccessible, the appliance might reroute the packet to the sender, which could result in a routing loop leading to network congestion. To prevent this situation, you can create a null route, which adds a null interface as a gateway. The null route is never the preferred route, because it has a higher administrative distance than the other static routes. But it is selected if the other static routes become inaccessible. In that case, the appliance drops the packet and prevents a routing loop.

This section includes the following details:

- Configuring IPv4 Static Routes
- Configuring IPv6 Static Routes

Configuring IPv4 Static Routes

Updated: 2013-09-06

You can add a simple static route or a null route by setting a few parameters, or you can set additional parameters to configure a monitored or monitored and weighted static route. You can change the parameters of a static route. For example, you might want to assign a weight to an unweighted route, or you might want to disable monitoring on a monitored route.

To create a static route by using the command line interface

At the command prompt, type the following commands to create a static route and verify the configuration:

- add route <network> <netmask> <gateway>[-cost <positive_integer>] [-advertise (DISABLED | ENABLED)]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

Example

```
> add route 10.102.29.0 255.255.255.0 10.102.29.2 -cost 2 -advertise ENABLED
 Done
```

To create a monitored static route by using the command line interface

At the command prompt, type the following commands to create a monitored static route and verify the configuration:

- add route <network> <netmask> <gateway> [-distance <positive_integer>] [-weight <positive_integer>][-msr (ENABLED | DISABLED) [-monitor <string>]]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

Example

```
> add route 10.102.29.0 255.255.255.0 10.102.29.3 -distance 5 -weight 6 -msr ENBLED -monitor PING
 Done
```

To create a null route by using the command line interface

At the command prompt type:

- add route <network> <netmask> null
- show route <network> <netmask>

Example

```
> add route 10.102.29.0 255.255.255.0 null
 Done
```

To remove a static route by using the command line interface

At the command prompt, type:

rm route <network> <netmask> <gateway>

Example

```
> rm route 10.102.29.0 255.255.255.0 10.102.29.3
 Done
```

To configure a static route by using the configuration utility

Navigate to System > Network > Routes and, on the Basic tab, add a new static route, or edit an existing static route.

To remove a route by using the configuration utility

Navigate to System > Network > Routes and, on the Basic tab, delete the static route.

Configuring IPv6 Static Routes

Updated: 2013-09-06

You can configure a maximum of six default IPv6 static routes. IPv6 routes are selected on the basis of whether the MAC address of the destination device is reachable. This can be determined by using the IPv6 Neighbor Discovery feature. Routes are load balanced and only source/destination-based hash mechanisms are used. Therefore, route selection mechanisms such as round robin are not supported. The next hop address in the default route need not belong to the NSIP subnet.

To create an IPv6 route by using the command line interface

At the command prompt, type the following commands to create an IPv6 route and verify the configuration:

- add route6 <network> <gateway> [-vlan <positive_integer>]
- show route6 [<network> [<gateway>]

Example

```
> add route6 ::/0 FE80::67 -vlan 5
 Done
```

To create a monitored IPv6 static route by using the command line interface

At the command prompt, type the following commands to create a monitored IPv6 static route and verify the

configuration:

- add route6 <network> <gateway> [-msr (ENABLED | DISABLED) [-monitor <string>]
- show route6 [<network> [<gateway>]

Example

```
> add route6 ::/0 2004::1 -msr ENABLED -monitor PING
 Done
```

To remove an IPv6 route by using the command line interface

At the command prompt, type:

rm route6 <network> <gateway>

Example

```
> rm route6 ::/0 FE80::67
 Done
```

To configure an IPv6 route by using the configuration utility

Navigate to System > Network > Routes and, on the IPV6 tab, add a new IPv6 route, or edit an existing IPv6 route.

To remove an IPv6 route by using the configuration utility

Navigate to System > Network > Routes and, on the IPV6 tab, delete the IPv6 route.

Configuring Policy-Based Routes

Jun 11, 2012

Policy-based routing bases routing decisions on criteria that you specify. A policy-based route (PBR) specifies criteria for selecting packets and, typically, a next hop to which to send the selected packets. For example, you can configure the NetScaler appliance to route outgoing packets from a specific IP address or range to a particular next hop router. Each packet is matched against each configured PBR, in the order determined by the specified priorities, until a match is found. If no match is found, or if the matching PBR specifies a DENY action, the NetScaler applies the routing table for normal destination-based routing.

A PBR bases routing decisions for the data packets on parameters such as source IP address, source port, destination IP address, destination port, protocol, and source MAC address. A PBR defines the conditions that a packet must satisfy for the NetScaler to route the packet. These actions are known as "processing modes." The processing modes are:

- ALLOW - The NetScaler sends the packet to the designated next-hop router.
- DENY - The NetScaler applies the routing table for normal destination-based routing.

You can create PBRs for outgoing IPv4 and IPv6 traffic.

Many users begin by creating PBRs and then modifying them. To activate a new PBR, you must apply it. To deactivate a PBR, you can either remove or disable it. You can change the priority number of a PBR to give it a higher or lower precedence.

This document includes the following information:

- Configuring a Policy-Based Routes (PBR) for IPv4 Traffic
- Configuring a Policy-Based Routes (PBR6) for IPv6 Traffic

Configuring a Policy-Based Routes (PBR) for IPv4 Traffic

Mar 20, 2012

Configuring PBRs involves the following tasks:

- Create a PBR.
- Apply PBRs.
- (Optional) Disable or enable a PBR.
- (Optional) Renumber the priority of the PBR.

Creating or Modifying a PBR

Updated: 2013-10-31

You cannot create two PBRs with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR. The priority (an integer value) defines the order in which the NetScaler appliance evaluates PBRs. When you create a PBR without specifying a priority, the NetScaler automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR, the NetScaler performs an action. If the packet does not match the condition defined by the PBR, the NetScaler compares the packet against the PBR with the next highest priority.

Instead of sending the selected packets to a next hop router, you can configure the PBR to send them to a link load balancing virtual server to which you have bound multiple next hops. This configuration can provide a backup if a next hop link fails.

Consider the following example. Two PBRs, p1 and p2, are configured on the NetScaler and automatically assigned priorities 20 and 30. You need to add a third PBR, p3, to be evaluated immediately after the first PBR, p1. The new PBR, p3, must have a priority between 20 and 30. In this case, you can specify the priority as 25.

To create a PBR by using the command line interface

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-state (ENABLED | DISABLED)]
- show ns pbr

Example

```
> add ns pbr pbr1  allow -srcip 10.102.37.252 -destip 10.10.10.2 -nexthop 10.102.29.77
 Done
```

To modify the priority of a PBR by using the command line interface

At the command prompt, type the following commands to modify the priority and verify the configuration:

- set ns pbr <name> [-action (ALLOW | DENY)] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-state (ENABLED | DISABLED)]
- show ns pbr [<name>]

Example

```
> set ns pbr pbr1 -priority 23
 Done
```

To remove one or all PBRs by using the command line interface

At the command prompt, type one of the following commands:

- rm ns pbr <name>
- clear ns pbrs

Example

```
> rm ns pbr pbr1
 Done
> clear ns PBRs
 Done
```

To create a PBR by using the configuration utility

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR, or edit an existing PBR.

To remove one or all PBRs by using the configuration utility

Navigate to System > Network > PBRs, on the PBRs tab, delete the PBR.

Applying a PBR

Updated: 2013-08-30

You must apply a PBR to activate it. The following procedure reapplies all PBRs that you have not disabled. The PBRs constitute a memory tree (lookup table). For example, if you create 10 PBRs (p1 - p10), and then you create another PBR (p11) and apply it, all of the PBRs (p1 - p11) are freshly applied and a new lookup table is created. If a session has a DENY PBR related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR. For example, you must follow this procedure after disabling a PBR.

Note: PBRs created on the NetScaler appliance do not work until they are applied.

To apply a PBR by using the command line interface

At the command prompt, type:

apply ns PBRs

To apply a PBR by using the configuration utility

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Apply.

Enabling or Disabling PBRs

Updated: 2013-08-30

By default, the PBRs are enabled. This means that when PBRs are applied, the NetScaler appliance automatically compares incoming packets against the configured PBRs. If a PBR is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBRs are applied. After the PBRs are applied, the NetScaler does not compare incoming packets against disabled PBRs.

To enable or disable a PBR by using the command line interface

At the command prompt, type one of the following commands:

- enable ns pbr <name>
- disable ns pbr <name>

Examples

```
> enable ns PBR pbr1
 Done
> show ns PBR pbr1
1)     Name: pbr1
       Action: ALLOW                  Hits: 0
       srcIP = 10.102.37.252
       destIP = 10.10.10.2
       srcMac:                     Protocol:
       Vlan:                      Interface:
       Active Status: ENABLED           Applied Status: APPLIED
       Priority: 10
       NextHop: 10.102.29.77

 Done

> disable ns PBR pbr1
Warning: PBR modified, use 'apply pbrs' to commit this operation
> apply pbrs
 Done
> show ns PBR pbr1
1)     Name: pbr1
       Action: ALLOW                  Hits: 0
       srcIP = 10.102.37.252
```

```
    destIP = 10.10.10.2
    srcMac:                 Protocol:
    Vlan:                   Interface:
    Active Status: DISABLED         Applied Status: NOTAPPLIED
    Priority: 10
    NextHop: 10.102.29.77
Done
```

To enable or disable a PBR by using the configuration utility

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Enable or Disable.

Renumbering PBRs

Updated: 2013-08-30

You can automatically renumber the PBRs to set their priorities to multiples of 10.

To renumber PBRs by using the command line interface

At the command prompt, type:

```
renumber ns pbrs
```

To renumber PBRs by using the configuration utility

Navigate to System > Network > PBRs, on the PBRs tab, in the Action list, select Renumber Priority (s).

Use Case - PBR with Multiple Hops

Updated: 2013-08-30

Consider a scenario in which two PBRs, PBR1 and PBR2, are configured on NetScaler appliance NS1. PBR1 routes all the outgoing packets, with source IP address as 10.102.29.30, to next hop router R1. PBR2 routes all the outgoing packets, with source IP address as 10.102.29.90, to next hop router R2. R3 is another next hop router connected to NS1.

If router R1 fails, all the outgoing packets that matched against PBR1 are dropped. To avoid this situation, you can specify a link load balancing (LLB) virtual server in the next hop field while creating or modifying a PBR. Multiple next hops are bound to the LLB virtual server as services (for example R1, R2, and R3). Now, if R1 fails, all the packets that matched against PBR1 are routed to R2 or R3 as determined by the LB method configured on the LLB virtual server.

The NetScaler appliance throws an error if you attempt to create a PBR with an LLB virtual server as the next hop in the following cases:

- Adding another PBR with the same LLB virtual server.
- Specifying a nonexistent LLB virtual server.
- Specifying an LLB virtual server for which the bound services are not next hops.
- Specifying an LLB virtual server for which the LB method is not set to one of the following:
  - LEASTPACKETS
  - LEASTBANDWIDTH
  - DESTIPHASH
  - SOURCEIPHASH

- WEIGHTDRR
- SRCIPDESTIP_HASH
- LTRM
- CUSTOM LOAD

- Specifying an LLB virtual server for which the LB persistence type is not set to one of the following:
  - DESTIP
  - SOURCEIP
  - SRCDSTIP

The following table lists the names and values of the entities configured on the NetScaler appliance:

Table 1. Sample Values for Creating Entities

Entity Type	Name	IP Address
Link load balancing virtual server	LLB1	NA
Services (next hops)	Router1	1.1.1.254
	Router2	2.2.2.254
	Router3	3.3.3.254
PBRs	PBR1	NA
	PBR2	NA

To implement the configuration described above, you need to:

1. Create services Router1, Router2, and Router3 that represent next hop routers R1, R2, and R3.
2. Create link load balancing virtual server LLB1 and bind services Router1, Router2, and Router3 to it.
3. Create PBRs PBR1 and PBR2, with next hop fields set as LLB1 and 2.2.2.254 (IP address of the router R2), respectively.

To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port>
- show service <name>

Example

```
> add service Router1 1.1.1.254 ANY *
 Done
> add service Router2 2.2.2.254 ANY *
 Done
> add service Router3 3.3.3.254 ANY *
```

```
Done
```

To create a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create a link load balancing virtual server and bind a service by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType>
- bind lb vserver < name> <serviceName>
- show lb vserver < name>

Example

```
> add lb vserver LLB1 ANY
 Done
> bind lb vserver LLB1 Router1 Router2 Router3
 Done
```

To create a link load balancing virtual server and bind a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.
   Note: Make sure that **Directly Addressable** is unchecked.
2. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

To create a PBR by using the command line interface

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-nextHop <nextHopVal>]
- show ns pbr

Example

```
> add pbr PBR1 ALLOW -srcIP 10.102.29.30 -nextHop LLB1
 Done
> add pbr PBR2 ALLOW -srcIP 10.102.29.90 -nextHop 2.2.2.254
 Done
```

To create a PBR by using the configuration utility

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR.

Configuring a Policy-Based Routes (PBR6) for IPv6 Traffic

Mar 20, 2012

Configuring PBR6s involves the following tasks:

- Create a PBR6.
- Apply PBR6s.
- (Optional) Disable or enable a PBR6.
- (Optional) Renumber the priority of the PBR6.

Creating or Modifying a PBR6

Updated: 2013-09-06

You cannot create two PBR6s with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR6. The priority (an integer value) defines the order in which the NetScaler appliance evaluates PBR6s. When you create a PBR6 without specifying a priority, the NetScaler automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR6, the NetScaler performs an action. If the packet does not match the condition defined by the PBR6, the NetScaler compares the packet against the PBR6 with the next highest priority.

To create a PBR6 by using the command line interface

At the command prompt, type:

- add ns pbr6 <name> <action> [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>] [-srcMac <mac_addr>] [-protocol <protocol> |-protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-state (ENABLED | DISABLED)] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-nextHop <nextHopVal>] [-nextHopVlan <positive_integer>]
- show ns pbr

To modify or remove a PBR6 by using the command line interface

To modify a PBR6, type the set pbr6 <name> command and the parameters to be changed, with their new values.

To remove one or all PBR6s by using the command line interface

At the command prompt, type one of the following commands:

- rm ns pbr6 <name>
- clear ns pbr6

To create or modify a PBR6 by using the configuration utility

Navigate to System > Network > PBRs and, on the PBR6s tab, add a new PBR6, or edit an existing PBR6.

To remove one or all PBR6s by using the configuration utility

Navigate to System > Network > PBRs and, on the PBR6s tab, delete the PBR6.

Applying PBR6s

Updated: 2013-08-30

You must apply a PBR6 to activate it. The following procedure reapplies all PBR6s that you have not disabled. The PBR6s constitute a memory tree (lookup table). For example, if you create 10 PBR6s (p6_1 - p6_10), and then you create another PBR6 (p6_11) and apply it, all of the PBR6s (p6_1 - p6_11) are freshly applied and a new lookup table is created. If a session has a DENY PBR6 related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR6. For example, you must follow this procedure after disabling a PBR6.

Note: PBR6s created on the NetScaler appliance do not work until they are applied.

To apply PBR6s by using the command line interface

At the command prompt, type:

apply ns PBR6

To apply PBR6s by using the configuration utility

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Apply.

Enabling or Disabling a PBR6

Updated: 2013-08-30

By default, the PBR6s are enabled. This means that when PBR6s are applied, the NetScaler appliance automatically compares outgoing IPv6 packets against the configured PBR6s. If a PBR6 is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBR6s are applied. After the PBR6s are applied, the NetScaler does not compare incoming packets against disabled PBR6s.

To enable or disable a PBR6 by using the command line interface

At the command prompt, type one of the following commands:

- enable ns pbr <name>
- disable ns pbr <name>

To enable or disable a PBR6 by using the configuration utility

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Enable or Disable.

Renumbering PBR6s

Updated: 2013-08-30

You can automatically renumber the PBR6s to set their priorities to multiples of 10.

To renumber PBR6s by using the command line interface

At the command prompt, type:

renumber ns pbr6

To renumber PBR6s by using the configuration utility

Navigate to System > Network > PBRs, on the PBR6s tab, in the Action list, select Renumber Priority (s).

Troubleshooting Routing Issues

May 11, 2012

To make your troubleshooting process as efficient as possible, begin by gathering information about your network. You need to obtain the following information about the NetScaler appliance and other systems in the Network:

- Complete Topology diagram, including interface connectivity and intermediate switch details.
- Running Configuration. You can use the show running command to get the running configuration for ns.conf and ZebOS.conf.
- Output of the History command, to determine whether any configuration changes were made when the issue arose.
- Output of the Top and ps -ax commands, to determine whether any routing daemon is over utilizing the CPU or is misbehaving.
- Any routing related core files in /var/core - nsm, bgpd, ospfd, or ripd. Check the time stamp to see if they are relevant.
- dr_error.log and dr_info.log files from /var/log.
- Output of the date command and time details for all relevant systems. Print dates across all devices one after another, so that the times on the log messages can be correlated with various events.
- Relevant ns.log, newnslog files.
- Configuration files, log files and command history details from upstream and downstream routers.

This document includes the following information:

- Generic Routing FAQs
- Troubleshooting OSPF-Specific Issues

Generic Routing FAQs

Mar 20, 2012

Users typically have the following questions about how to troubleshoot generic routing issues:

- How do I save the config files?

  The write command from VTYSH saves only ZebOS.conf. Run the save ns config command from NetScaler CLI to save both ns.conf and ZebOS.conf files.
- If I have configured both a static default route and a dynamically learned default route, which is the preferred default route?

  The dynamically learned route is the preferred default route. This behavior is unique to default routes. However, in case of the Network Services Module (NSM), unless the administrative distances are modified, a statically configured route in the RIB is preferred over a dynamic route. The route that is downloaded to the NSM FIB is the static route.
- How do I block the advertisement of default routes?

  After release 7.0, the default route is not injected into ZebOS.

  However, if you are working with 7.0 or an earlier release, you must apply a suitable route map with the

  However, if you are working with 7.0 or an earlier release, you must apply a suitable route map with the redistribute kernel command for each protocol to block default route advertisement. For example:

```
ns(config)#access-list 1 deny 0.0.0.0
ns(config)#access-list 2 permit any
ns(config)#route-map redist-kernel permit 5
ns(config-route-map)#match ip address 1
ns(config)#route-map redist-kernel permit 10
ns(config-route-map)#match ip address 2
ns(config-route-map)#q
ns(config)#router ospf 1
ns(config-router)#redistribute kernel route-map redist-kernel
ns(config-router)#q
ns(config)#q
ns#show route-map
route-map redist-kernel, permit, sequence 5
  Match clauses:
    ip address 1
  Set clauses:
route-map redist-kernel, permit, sequence 10
  Match clauses:
    ip address 2
  Set clauses:
ns#show access-list
Standard IP access list 1
```

```
    deny 0.0.0.0
Standard IP access list 2
    permit any
ns#
```

- How do I view the debug output of networking daemons?

  You can write debugging output from networking daemons to a file by entering the following log file command from the global configuration view in VTYSH:

  ```
  ns(config)#log file /var/ZebOS.log
  ```

  With release 8.1, you can direct debug output to the console by entering the terminal monitor command from VTYSH user view:

  ```
  ns#terminal monitor
  ```

- How do I collect cores of running daemons?

  You can use the gcore utility to collect cores of running daemons for processing by gdb. This might be helpful in debugging misbehaving daemons without bringing the whole routing operation to a standstill.

  ```
  gcore [-s] [-c core] [executable] pid
  ```

  The -s option temporarily stops the daemon while gathering the core image. This is a recommended option, because it guarantees that the resulting image shows the core in a consistent state.

  ```
  root@ns#gcore -s -c nsm.core /netscaler/nsm 342
  ```

- How do I run a batch of ZebOS commands?

  You can run a batch of ZebOS commands from a file by entering the VTYSH -f <file-name> command. This does not replace the running configuration, but appends to it. However, by including commands to delete the existing configuration in the batch file and then add those for the new, desired configuration, you can use this mechanism to replace a specific configuration:

  ```
  !
  router bgp 234
  network 1.1.1.1 255.255.255.0
  !
  route-map bgp-out2 permit 10
   set metric 9900
   set community 8602:300
  !
  ```

Troubleshooting OSPF-Specific Issues

Mar 20, 2012

Before you start debugging any OSPF specific issue, you must collect information from the NetScaler appliance and all systems in the affected LAN, including upstream and downstream routers. To begin, enter the following commands:

1. show interface from both nscli and VTYSH
2. show ip ospf interface
3. show ip ospf neighbor detail
4. show ip route
5. show ip ospf route
6. show ip ospf database summary
    1. If there are only few LSAs in the database, then enter show ip ospf database router, show ip ospf database A. network, show ip ospf database external, and other commands to get the full details of LSAs.
    2. If there are a large number of LSAs in the database, enter the show ip ospf database self-originated command.
7. show ip ospf
8. show ns ip. This ensures that the details of all VIPs of interest are included.
9. Get the logs from peering devices and run the following command:

    gcore -s -c xyz.core /netscaler/ospfd <pid>

Note: The gcore command is non-disruptive.

Collect additional information from the NetScaler as follows:

1. Enable logging of error messages by entering the following command from the global configuration view in VTYSH:

    ns(config)#log file /var/ospf.log

2. Enable debugging ospf events and log them by using the following command:

    ns(config)#log file /var/ospf.log

    Enable debug ospf lsa packet only if the number of LSAs in the database is relatively small (< 500).

Internet Protocol version 6 (IPv6)

Mar 20, 2012

A NetScaler appliance supports both server-side and client-side IPv6 and can therefore function as an IPv6 node. It can accept connections from IPv6 nodes (both hosts and routers) and from IPv4 nodes, and can perform Protocol Translation (RFC 2765) before sending traffic to the services. You have to license the IPv6 feature before you can implement it.

The following table lists some of the IPv6 features that the NetScaler appliance supports.

Table 1. Some Supported IPv6 Features

IPv6 features
IPv6 addresses for SNIPs (NSIP6, VIP6, and SNIP6)
Neighbor Discovery (Address Resolution, Duplicated Address Detection, Neighbor Unreachability Detection, Router Discovery)
Management Applications (ping6, telnet6, ssh6)
Static Routing and Dynamic routing (OSPF)
Port Based VLANs
Access Control Lists for IPv6 addresses (ACL6)
IPv6 Protocols (TCP6, UDP6, ICMP6)
Server Side Support (IPv6 addresses for vservers, services)
USIP (Use source IP) and DSR (Direct Server Return) for IPv6
SNMP and CVPN for IPv6
HA with native IPv6 node address
IPv6 addresses for MIPs
Path-MTU discovery for IPv6

The following table lists NetScaler components that support IPv6 addresses and provides references to the topics that

document the components.

Table 2. NetScaler Components That Support IPv6 Addresses and the Corresponding Documentation

NetScaler component	Topic that documents IPv6 support
Network	Adding, Customizing, Removing, Removing all, and Viewing routes.
SSL Offload	Creating IPv6 vservers for SSL Offload
SSL Offload	Specifying IPv6 SSL Offload Monitors
SSL Offload	Creating IPv6 SSL Offload Servers
Load Balancing	Creating IPv6 vservers for Load Balancing
Load Balancing	Specifying IPv6 Load Balancing Monitors
Load Balancing	Creating IPv6 Load Balancing Servers
DNS	Creating AAAA Records

You can configure IPv6 support for the above features after implementing the IPv6 feature on your NetScaler appliance. You can configure both tagged and prefix-based VLANs for IPv6. You can also map IPv4 addresses to IPv6 addresses.

Implementing IPv6 Support

IPv6 support is a licensed feature, which you have to enable before you can use or configure it. If IPv6 is disabled, the NetScaler does not process IPv6 packets. It displays the following warning when you run an unsupported command:

"Warning: Feature(s) not enabled [IPv6PT]"

The following message appears if you attempt to run IPv6 commands without the appropriate license:

"ERROR: Feature(s) not licensed"

After licensing the feature, use either of the following procedures to enable or disable IPv6.

To enable or disable IPv6 by using the command line interface

At the command prompt, type one of the following commands:

- enable ns feature ipv6pt
- disable ns feature ipv6pt

To enable or disable IPv6 by using the configuration utility

1. Navigate to System > Settings, in the Modes and Features group, click Configure Advanced Features.
2. Select or clear the IPv6 Protocol Translation option.

VLAN Support

Updated: 2013-08-30

If you need to send broadcast or multicast packets without identifying the VLAN (for example, during DAD for NSIP, or ND6 for the next hop of the route), you can configure the NetScaler appliance to send the packet on all the interfaces with appropriate tagging. The VLAN is identified by ND6, and a data packet is sent only on the VLAN.

For more information about ND6 and VLANs, see "Configuring Neighbor Discovery."

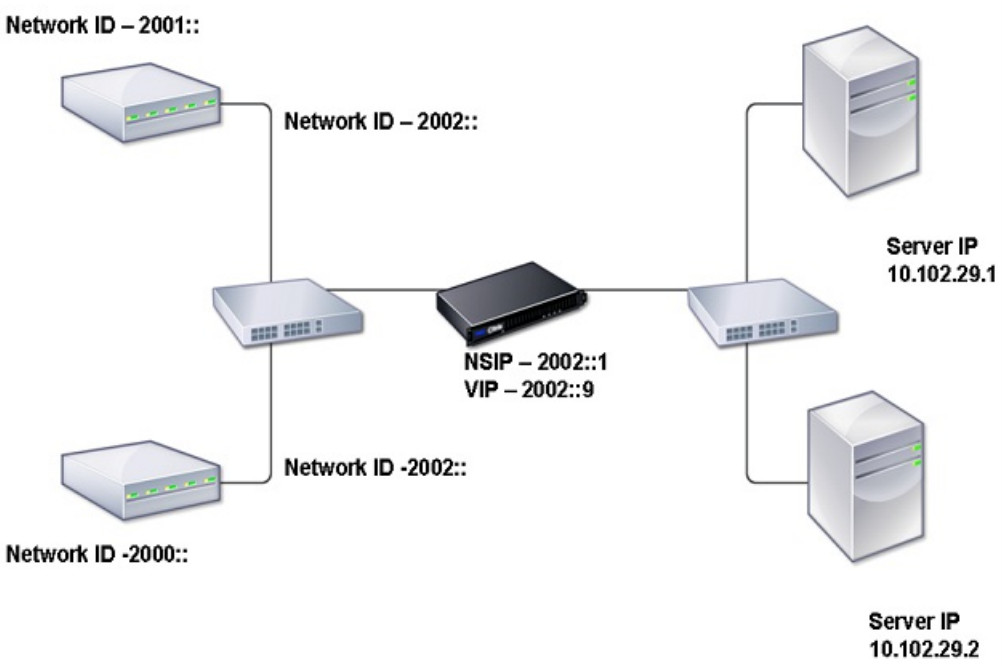
Port-based VLANs are common for IPv4 and IPv6. Prefix-based VLANs are supported for IPv6.

Simple Deployment Scenario

Updated: 2013-08-30

Following is an example of a simple load balancing set-up consisting of an IPv6 vserver and IPv4 services, as illustrated in the following topology diagram.

Figure 1. IPv6 Sample Topology



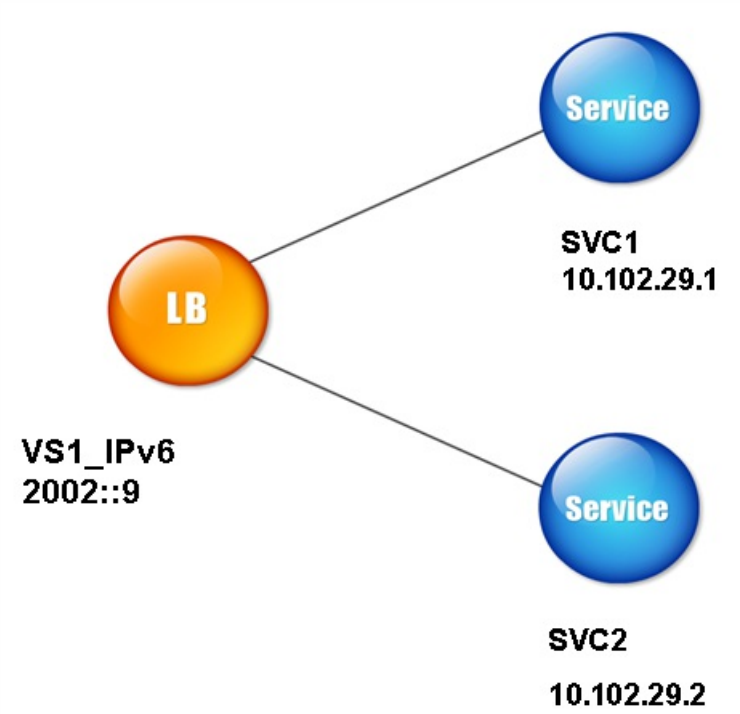
The following table summarizes the names and values of the entities that must be configured on the NetScaler.

Table 3. Sample Values for Creating Entities

Entity type	Name	Value
LB Vserver	VS1_IPv6	2002::9
Services	SVC1	10.102.29.1

Entity type	Name	Value
	SVC2	10.102.29.2

The following figure shows the entities and values of the parameters to be configured on the NetScaler.
Figure 2. IPv6 Entity Diagram



To configure this deployment scenario, you need to do the following:

1. Create an IPv6 service.
2. Create an IPv6 LB vserver.
3. Bind the services to the vserver.

To create IPv4 services by using the command line interface

At the command prompt, type:

add service <Name> <IPAddress> <Protocol> <Port>

Example

```
add service SVC1 10.102.29.1 HTTP 80
add service SVC2 10.102.29.2 HTTP 80
```

To create IPv4 services by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, click Add, and then set the following parameters:

- Service Name
- IP Address
- Protocol
- Port

To create IPv6 vserver by using the command line interface

At the command prompt, type:

add lb vserver <Name> <IPAddress> <Protocol> <Port>
Example

add lb vserver VS1_IPv6 2002::9 HTTP 80

To create IPv6 vserver by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, click Add, and select the IPv6 check box.
2. Set the following parameters:
   - Name
   - Protocol
   - IP Address Type
   - IP Address
   - Port

To bind a service to an LB vserver by using the command line interface

At the command prompt, type:

bind lb vserver <name> <service>
Example

bind lb vserver VS1_IPv6 SVC1
The vservers receive IPv6 packets and the NetScaler performs Protocol Translation (RFC 2765) before sending traffic to the IPv4-based services.

To bind a service to an LB vserver by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers page, select the vserver for which you want to bind the service (for example, VS1_IPv6).
3. Click Open.
4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box corresponding to the service that you want to bind to the vserver (for example, SVC1).
5. Click OK.
6. Repeat Steps 1-4 to bind the service (for example, SVC2 to the vserver).

Host Header Modification

Updated: 2013-08-30

When an HTTP request has an IPv6 address in the host header, and the server does not understand the IPv6 address, you must map the IPv6 address to an IPv4 address. The IPv4 address is then used in the host header of the HTTP request sent to the vserver.

To change the IPv6 address in the host header to an IPv4 address by using the command line interface

At the command prompt, type:

set ns ip6 <IPv6Address> -map <IPAddress>
Example

```
set ns ip6 2002::9 -map 200.200.200.200
```

To change the IPv6 address in the host header to an IPv4 address by using the configuration utility

1. Navigate to System > Network > IPs and, on the IPV6s tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:0:9, and click Open.
2. In the Mapped IP text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

VIP Insertion

Updated: 2013-08-30

If an IPv6 address is sent to an IPv4-based server, the server may not understand the IP address in the HTTP header, and may generate an error. To avoid this, you can map an IPv4 address to the IPv6 VIP and enable VIP insertion.

To configure a mapped IPv6 address by using the command line interface

At the command prompt, type:

set ns ip6 <IPv6Address> -map <IPAddress>
Example

```
> set ns ip6 2002::9 -map 200.200.200.200
 Done
```

To configure a mapped IPv6 address by using the configuration utility

1. Navigate to System > Network > IPs, on the IPV6s tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:0:9, and click Open.
2. In the Mapped IP text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

Use either of the following procedures to enable insertion of an Ipv4 VIP address and port number in the HTTP requests sent to the servers.

To enable VIP insertion by using the command line interface

At the command prompt, type:

set lb vserver <name> -insertVserverIPPort <Value>
Example

```
> set lb vserver VS1_IPv6 -insertVserverIPPort ON
 Done
```

To enable VIP insertion by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, select the vserver that you want to enable port insertion, and click Open.
2. In the Advanced tab, under Traffic Settings, in the Vserver IP Port Insertion drop-down list box, select VIPADDR.
3. In the Vserver IP Port Insertion text box, type the vip header.

Traffic Domains

Jun 23, 2016

> **Important**
>
> Citrix recommends you to use Admin Partitioning over Traffic Domains. For more information about Admin Partitions, see Admin Partitioning page.

Traffic domains are a way to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments within a NetScaler appliance. An application belonging to a specific traffic domain communicates with entities and processes traffic within that domain. The traffic belonging to one traffic domain cannot cross the boundary of another traffic domain.

Benefits of using Traffic Domains

The main benefits of using traffic domains on a NetScaler appliance are the following:

- **Use of duplicate IP addresses in a Network**. Traffic domains allow you to use duplicate IP address on the network. You can assign the same IP address or network address to multiple devices on a network, or multiple entities on a NetScaler appliance, as long as each of the duplicate address belongs to a different traffic domain.
- **Use of Duplicate entities on the NetScaler appliance**. Traffic domains also allow you to use duplicate NetScaler feature entities on the appliance. You can create entities with the same settings as long as each entity is assigned to a separate traffic domain.
  Note: Duplicate entities with same name is not supported.
- **Multitenancy**. Using traffic domains, you can provide hosting services for multiple customers by isolating each customer's type of application traffic within a defined address space on the network.

A traffic domain is uniquely identified by an identifier, which is an integer value. Each traffic domain needs a VLAN or a set of VLANs. The isolation functionality of the traffic domain depends on the VLANs bound to the traffic domain. More than one VLAN can be bound to a traffic domain, but the same VLAN cannot be a part of multiple traffic domains. Therefore, the maximum number of traffic domains that can be created depends on the number of VLANS configured on the appliance.

Default Traffic Domain

A NetScaler appliance has a preconfigured traffic domain, called the *default traffic domain*, which has an ID of 0. All factory settings and configurations are part of the default traffic domain. You can create other traffic domains and then segment traffic between the default traffic domain and each of the other traffic domains. You cannot remove the default traffic domain from the NetScaler appliance. Any feature entity that you create without setting the traffic domain ID is automatically associated with the default traffic domain.
Note: Some features and configurations are supported only in the default traffic domain. They do not work in nondefault traffic domains. For a list of the features supported in all traffic domains, see "Supported NetScaler Features in Traffic Domains ."
This section includes the following details:

- How Traffic Domains Work
- Supported NetScaler Features in Traffic Domains
- Configuring Traffic Domains

How Traffic Domains Work

As an illustration of traffic domains, consider an example in which two traffic domains, with IDs 1 and 2, are configured on NetScaler appliance NS1.

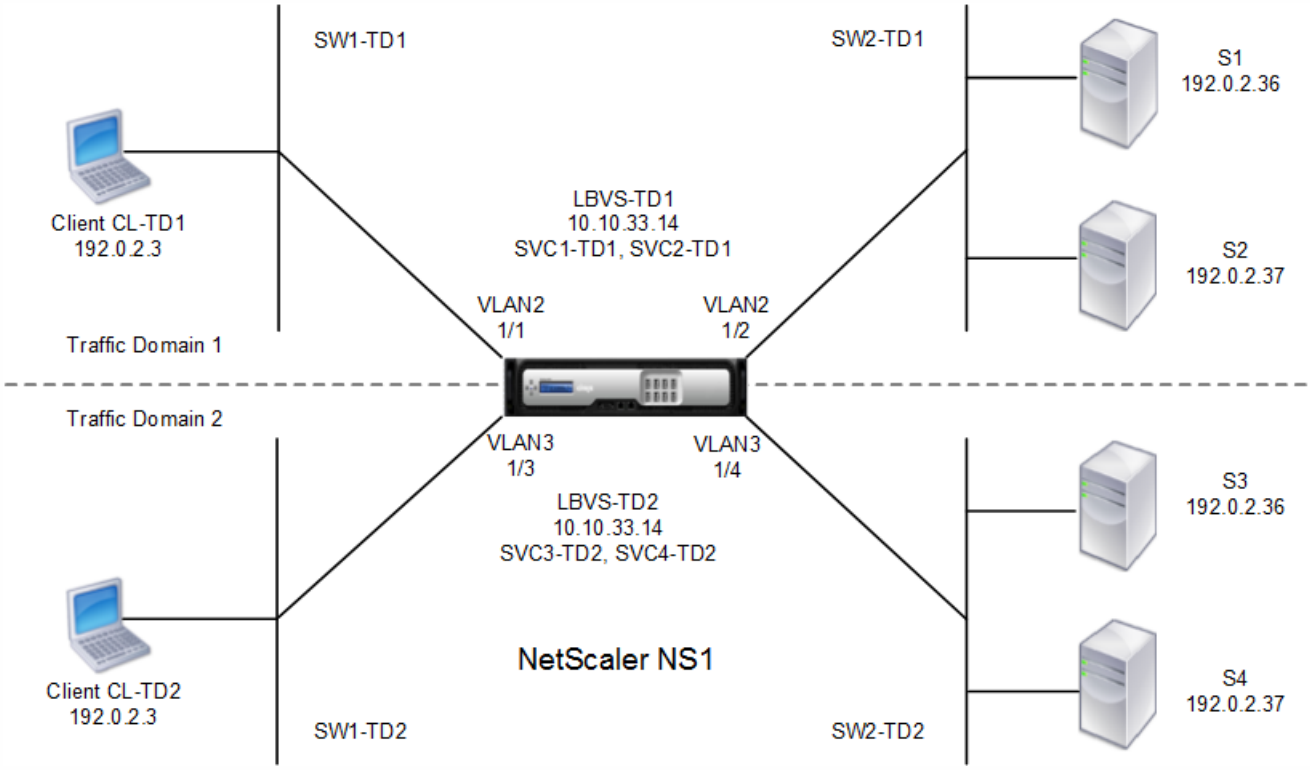
In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the NetScaler appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. Servers S1 and S2 are connected to NS1 through L2 switch SW2-TD1. Client CL-TD1 is on a private network connected to NS1 through L2 switch SW1-TD1. SW1-TD1 and SW2-TD1 are connected to VLAN 2 of NS1. VLAN 2 is bound to traffic domain 1, which means that client CL-TD1 and servers S1 and S2 are part of traffic domain 1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the NetScaler appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. Servers S3 and S4 are connected to NS1 through L2 switch SW2-TD2. Client CL-TD2 is on a private network connected to NS1 through L2 switch SW1-TD2. SW1-TD2 and SW2-TD2 are connected to VLAN 3 of NS1. VLAN 3 is bound to traffic domain 2, which means that client CL-TD2 and servers S3 and S4 are part of traffic domain 2.

On the NetScaler appliance, entities LBVS-TD1 and LBVS-TD2 share the same settings, including the IP address. The same is true for SVC1-TD1 and SVC3-TD2, and for SVC2-TD1 and SVC4-TD2. This is possible because these entities are in different traffic domains.

Similarly, servers S1 and S3, S2 and S4 share the same IP address, and clients CL-TD1 and CL-TD2 each have the same IP address.

Figure 1. How traffic domains work



The following table lists the settings used in the example.

Entity	Name	Details
Settings in traffic domain 1		
VLANs bound to traffic domain 1	VLAN 2	VLAN Id: 2 Interfaces bound: 1/1, 1/2
Client connected to TD1	CL-TD1 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD1	LBVS-TD1	IP address: 192.0.2.15
Service bound to virtual server LBVS-TD1	SVC1-TD1	IP address: 192.0.2.36
	SVC2-TD1	IP address: 192.0.2.37
SNIP	SNIP-TD1 (for reference purposes only)	IP address: 192.0.2.27
Settings in traffic domain 2		
VLAN bound to traffic domain 2	VLAN 3	VLAN Id: 3 Interfaces bound: 1/3, 1/4
Client connected to TD2	CL-TD2 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD2	LBVS-TD2	IP address: 192.0.2.15
Service bound to virtual server LBVS-TD2	SVC3-TD2	IP address: 192.0.2.36
	SVC4-TD2	IP address: 192.0.2.37
SNIP in TD2	SNIP-TD2 (for reference purposes only)	IP address: 192.0.2.29

Following is the traffic flow in traffic domain 1:

1. Client CL-TD1 broadcasts an ARP request for the IP address of 192.0.2.15.
2. The ARP request reaches NS1 on interface 1/1, which is bound to VLAN 2. Because VLAN 2 is bound to traffic domain 1, NS1 updates the ARP table of traffic domain 1 for the IP address of client CL-TD1.
3. Because the ARP request is received on traffic domain 1, NS1 looks for an entity configured on traffic domain 1 that has an IP address of 192.0.2.15. NS1 finds that a load balancing virtual server LBVS-TD1 is configured on traffic domain 1 and has the IP address 192.0.2.15.
4. NS1 sends an ARP response with the MAC address of interface 1/1.

5. The ARP reply reaches CL-TD1. CL-TD1 updates its ARP table for the IP address of LBVS-TD1 with the MAC address of interface 1/1 of NS1.
6. Client CL-TD1 sends a request to 192.0.2.15. The request is received by LBVS-TD1 on port 1/1 of NS1.
7. LBVS-TD1's load balancing algorithm selects server S2, and NS1 opens a connection between a SNIP in traffic domain 1 (192.0.2.27) and S2.
8. S2 replies to SNIP 192.0.2.27 on NS1.
9. NS1 sends S2's reply to client CL-TD1.

Following is the traffic flow in traffic domain 2:

1. Client CL-TD2 broadcasts an ARP request for the IP address of 192.0.2.15.
2. The ARP request reaches NS1 on interface 1/3, which is bound to VLAN 3. Because VLAN 3 is bound to traffic domain 2, NS1 updates traffic-domain 2's ARP-table entry for the IP address of client CL-TD2, even though an ARP entry for the same IP address (CL-TD1) is already present in the ARP table of traffic domain 1.
3. Because the ARP request is received in traffic domain 2, NS1 searches traffic domain 2 for an entity that has an IP address of 192.0.2.15. NS1 finds that load balancing virtual server LBVS-TD2 is configured in traffic domain 2 and has the IP address 192.0.2.15. NS1 ignores LBVS-TD1 in traffic domain 1, even though it has the same IP address as LBVS-TD2.
4. NS1 sends an ARP response with the MAC address of interface 1/3.
5. The ARP reply reaches CL-TD2. CL-TD2 updates its ARP table entry for the IP address of LBVS-TD2 with the MAC address of interface 1/3 of NS1.
6. Client CL-TD2 sends a request to 192.0.2.15. The request is received by LBVS-TD2 on interface 1/3 of NS1.
7. LBVS-TD2's load balancing algorithm selects server S3, and NS1 opens a connection between a SNIP in traffic domain 2 (192.0.2.29) and S3.
8. S2 replies to SNIP 192.0.2.29 on NS1.
9. NS1 sends S2's reply to client CL-TD2.

Supported NetScaler Features in Traffic Domains

The NetScaler features in the following list are supported in all traffic domains.

- ARP table
- ND6 table
- Bridge table
- All types of IPv4 and IPv6 addresses
- IPv4 and IPv6 routes
- ACL and ACL6
- PBR & PBR6
- INAT
- RNAT
- RNAT6
- MSR
- MSR6
- Net profiles
- SNMP MIBs
- Fragmentation
- Monitors (Scriptable Monitors are not supported)
- Content Switching
- Persistency
- Service (Domain based services are not supported)
- Servicegroup (Domain based service groups are not supported)
- Policies (*)
- PING
- TRACEROUTE
- PMTU
- High Availability (connection mirroring is not supported)
- Cluster (Supported on L2 clusters. Not supported on L3 clusters)
- Cookie Persistency
- MSS
- Logging
- Priority Queuing
- Surge Protection
- HTTP DOSP (*)
- Load balancing (The following types are not supported:
  - TFTP

• Cache Redirection	• RTSP • Diameter • SIP) • NAT46 • NAT64 • DNS64 • Forwarding Session Rules • SNMP

Important

Any NetScaler feature not listed above is supported only in the default traffic domain. Traffic domains are not supported in a cluster configuration.

Note

Global Server Loading Balancing (GSLB) and ADNS features in NetScaler are not aware of Traffic Domains. If the GSLB configuration needs to be shared across all traffic domains then GSLB methods Static Proximity and Round Trip Time (RTT) do not work. As a workaround in this scenario, you can use GSLB methods other than RTT and Static Proximity. For more information, see http://support.citrix.com/article/CTX202277.

Configuring Traffic Domains

Configuring a traffic domain on the NetScaler appliance consists of the following tasks:

- **Add VLANs.** Create VLANs and bind specified interfaces to them.
- **Create a traffic domain entity and bind VLANs to it.** This involves the following two tasks:
  - Create a traffic domain entity uniquely identified by an ID, which is an integer value.
  - Bind the specified VLANs to the traffic domain entity. All the interfaces that are bound to the specified VLANs are associated with the traffic domain. More than one VLAN can be bound to a traffic domain, but a VLAN cannot be a part of multiple traffic domains.
- **Create feature entities on the traffic domain**. Create the required feature entities in the traffic domain. The CLI commands and configuration dialog boxes of all the supported features in a nondefault traffic domain include a parameter called a *traffic domain identifier* (td). When configuring a feature entity, if you want the entity to be associated with a particular traffic domain, you must specify the td. Any feature entity that you create without setting the td is automatically associated with the default traffic domain.

To give you an idea of how feature entities are associated with a traffic domain, this topic covers the procedures for configuring all the entities mentioned in the figure titled "How Traffic Domains Work."

The command line interface has two commands for these two tasks, but the configuration utility combines them in a single dialog box.

To create a VLAN and bind interfaces to it by using the command line interface

At the command prompt, type:

- add vlan <id>
- bind vlan <id> -ifnum <slot/port>
- show vlan <id>

To create a traffic domain entity and bind VLANs to it by using the command line interface

At the command prompt, type:

- add ns trafficdomain <td>
- bind ns trafficdomain <td> -vlan <id>
- show ns trafficdomain <td>

To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> -td <id>
- show service <name>

To create a load balancing virtual server and bind services to it by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType> <IPAddress> <port> -td <id>
- bind lb vserver <name> <serviceName>
- show lb vserver <name>

To create a VLAN by using the configuration utility

Navigate to System > Network > VLANs, click Add, and set the parameters.

To create a traffic domain entity by using the configuration utility

Navigate to System > Network > Traffic Domains, click Add, and in the Create Traffic Domain dialog box, set the parameters.

To create a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, click Add, and set the parameters.

To create a load balancing virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, click Add, and set the parameters.

AppExpert

Jan 07, 2014

The following topics provide a conceptual reference and configuration instructions for the AppExpert and other features of the NetScaler appliance.

Action Analytics	Collects run-time statistics on the basis of pre-defined criteria. When used with policies, the feature also provides you with the infrastructure for automatic, real-time traffic optimization.
AppExpert Applications and Templates	Simplify configuration steps for the Citrix® NetScaler® appliance by using applications, application templates, NetScaler Gateway applications, and entity templates.
Entity Templates	Describes how to use entity templates to set up and configure individual NetScaler entities, such as a policy or virtual server. An entity template provides a specification and a set of defaults for the object.
AppQoE	Application level Quality of Experience (AppQoE) integrates several existing policy-based security features of the NetScaler appliance into a single integrated feature that takes advantage of a new queuing mechanism, fair queuing.
HTTP Callouts	An HTTP request that the NetScaler appliance generates and sends to an external application when certain criteria are met during policy evaluation.
Pattern Sets	Allow string matching during the evaluation of a default syntax policy.
Policies and Expressions	Rules that determine the operations that the NetScaler appliance must perform.
Rate Limiting	Defines the maximum load for a given network entity or virtual entity on the NetScaler appliance.
Responder	Bases responses on who sends the request, where it is sent from, and other criteria with security and system management implications.
Rewrite	Rewrites information in the requests or responses handled by the NetScaler appliance.
String Maps	Perform pattern matching in all NetScaler features that use the default policy syntax.

Action Analytics

Sep 16, 2013

The performance of your website or application depends on how well you optimize the delivery of the most frequently requested content. Techniques such as caching and compression help accelerate the delivery of services to clients, but you need to be able to identify the resources that are requested most frequently, and then cache or compress those resources. You can identify the most frequently used resources by aggregating real-time statistics about website or application traffic. Statistics such as how frequently a resource is accessed relative to other resources and how much bandwidth is consumed by those resources help you determine whether those resources need to be cached or compressed to improve server performance and network utilization. Statistics such as response times and the number of concurrent connections to the application help you determine whether you must enhance server-side resources.

If the website or application does not change frequently, you can use products that collect statistical data, and then manually analyze the statistics and optimize the delivery of content. However, if you do not want to perform manual optimizations, or if your website or application is dynamic in nature, you need infrastructure that can not only collect statistical data but can also automatically optimize the delivery of resources on the basis of the statistics. On the NetScaler appliance, this functionality is provided by the action analytics feature. The feature operates on a single NetScaler appliance and collects run-time statistics on the basis of criteria that you define. When used with NetScaler policies, the feature also provides you with the infrastructure that you need for automatic, real-time traffic optimization.

When configuring the action analytics feature, you specify the request attributes for which you want to collect statistical data (for example, URLs and HTTP methods) by configuring default syntax expressions in an entity called a selector. Then, you configure an identifier to configure settings such as the sampling interval and sample count. You also configure a policy that enables the appliance to evaluate traffic as specified by the selector-identifier pair. Finally, you bind the policy to a bind point to begin collecting statistics.

The appliance also provides you with a set of built-in selectors, identifiers, and responder policies that you can use to get started with the feature.

The appliance aggregates the following statistics:

- The number of requests.
- The bandwidth consumed by the requests.
- The response time.
- The number of concurrent connections.

You can configure the feature to perform run-time sorting of the records on an attribute of your choice. You can view the statistical data by using either the command-line interface or the Stream Sessions tool in the configuration utility.

Configuring a Selector

Sep 16, 2013

A selector is a filter for identifying requests. It consists of up to five individual default syntax expressions that identify request attributes such as the client IP address and the URL in the request. Each expression is a non-compound default syntax expression and is considered to be in an AND relationship with the other expressions. Following are some examples of selector expressions:

- HTTP.REQ.URL
- CLIENT.IP.SRC
- HTTP.RES.BODY(1000).AFTER_STR(\"<string>\").BEFORE_STR(\"<string>\")"
- CLIENT.IP.SRC.SUBNET(24)

Selectors are used in rate limiting and action analytics configurations. A selector is optional in a rate limiting configuration, but is required in a action analytics configuration.

The order in which you specify parameters is significant. For example, if you configure an IP address and a domain (in that order) in one selector, and then specify the domain and the IP address (in the reverse order) in another selector, the NetScaler considers these values to be unique. This can lead to the same transaction being counted twice. Also, if multiple policies invoke the same selector, the NetScaler, again, can count the same transaction more than once.

If you modify an expression in a selector, you may get an error if any policy that invokes it is bound to a new policy label or bind point. For example, suppose that you create a selector named myLimitSelector1, invoke it from myLimitID1, and invoke the identifier from a DNS policy named dnsRateLimit1. If you change the expression in myLimitSelector1, you might receive an error when binding dnsRateLimit1 to a new bind point. The workaround is to modify these expressions before creating the policies that invoke them.

The NetScaler appliance provides the following built-in selectors for some of the most common use cases:

Table 1. Built-in Selectors

Selector	Selector Expressions
Top_URL	HTTP.REQ.URL
Top_CLIENTS	CLIENT.IP.SRC
Top_URL_CLIENTS_LBVSERVER	1. HTTP.REQ.URL 2. CLIENT.IP.SRC 3. HTTP.REQ.LB_VSERVER.NAME
Top_URL_CLIENTS_CSVSERVER	1. HTTP.REQ.URL 2. CLIENT.IP.SRC 3. HTTP.REQ.CS_VSERVER.NAME
Top_MSSQL_QUERY_DB_LBVSERVER	1. MSSQL.REQ.QUERY.TEXT 2. MSSQL.REQ.LB_VSERVER.NAME

Selector	Selector Expressions
Top_MYSQL_QUERY_DB_LBVSERVER	1. MYSQL.REQ.QUERY.TEXT 2. MYSQL.REQ.LB_VSERVER.NAME

You can also configure a selector with expressions that identify the request attributes of your choice. For example, you might want to create a record for a request that arrives with a specific header. To evaluate the header, you can add HTTP.REQ.HEADER("<header_name>") to the selector that you intend to use.

To configure a selector by using the command line interface

At the command prompt, type the following commands to configure a selector and verify the configuration:

- add stream selector <name> <rule> ...
- show stream selector

Example

```
> add stream selector myselector HTTP.REQ.URL CLIENT.IP.SRC
 Done
> show stream selector myselector
 Name: myselector
 Expressions:
  1) HTTP.REQ.URL
  2) CLIENT.IP.SRC
 Done
>
```

To modify or remove a selector by using the command line interface

- To modify a selector, type the set stream selector command, the name of the selector, and the rule parameter with the expressions. Enter the existing expressions that you want to retain, along with the new expressions that you want to add.
- To remove a selector, type the rm stream selector command and the name of the selector.

To configure a selector by using the configuration utility

1. Navigate to AppExpert > Action Analytics > Selectors.
2. In the details pane, do one of the following:
   - To create a selector, click Add.
   - To modify a selector, select the selector, and then click Open.
3. In the Create Limit Selector or Configure Limit Selector dialog box, set one or more of the following parameters:
   - Name
   - Expressions
     To add the expression to the selector configuration, click Add. To remove an expression from the selector configuration, in the Expression box, select the expression, and then click Remove.
     Note: In the Expressions box, enter a valid parameter. For example, enter HTTP. Then, enter a period after this parameter. A drop-down menu appears. The contents of this menu provide the keywords that can follow the initial keyword that you entered. To select the next keyword in this expression prefix, double-click the selection in the drop-down menu. The Expressions text box displays both the first and second keywords for the expression prefix, for

example, HTTP.REQ. Continue adding expression components until the complete expression is formed.

4. Click Add.
5. Continue adding up to five non-compound expressions.
6. Click Create or OK.

Configuring a Stream Identifier

Aug 30, 2013

You configure a stream identifier to specify parameters for collecting statistical data from requests identified by a given selector. An identifier specifies the selector to be used, the statistics collection interval, the sample count, and the field on which the records are to be sorted.

The NetScaler appliance includes the following built-in stream identifiers for common use cases. All the built-in identifiers specify a sample count of 1 and an interval of 1 minute. Additionally, they sort the data on the REQUESTS attribute. They differ only in being associated with different built-in selectors. Each built-in identifier is associated with a built-in selector of the same name (for example, the built in identifier Top_URL is associated with the built-in selector Top_URL). Following are the built-in identifiers:

- Top_URL
- Top_CLIENTS
- Top_URL_CLIENTS_LBVSERVER
- Top_URL_CLIENTS_CSVSERVER
- Top_MSSQL_QUERY_DB_LBVSERVER
- Top_MYSQL_QUERY_DB_LBVSERVER

For more information about the built-in selectors, see "Configuring a Selector."

Note: The maximum length for storing string results of selectors (for example, HTTP.REQ.URL) is 60 characters. If the string (for example, URL) is 1000 characters long, of which 50 characters are enough to uniquely identify a string, use an expression to extract only the required 50 characters.
You cannot modify a built-in identifier's configuration. However, you can create an identifier with a configuration of your choice.

To configure a stream identifier by using the command line interface

At the command prompt, type the following commands to configure a stream identifier and verify the configuration:

- add stream identifier <name> <selectorName> [-interval <positive_integer>] [-SampleCount <positive_integer>] [-sort <sort>]
- show stream identifier <name>

Example

```
> add stream identifier myidentifier Top_URL -interval 10 -sampleCount 100
 Done
```

To configure a stream identifier by using the configuration utility

1. Navigate to AppExpert > Action Analytics > Stream Identifiers.
2. In the details pane, do one of the following:
   - To create a stream identifier, click Add.
   - To modify a stream identifier, select the identifier, and then click Open.
3. In the Configure Stream Identifier dialog box, set one or more of the following parameters:
   - Name
   - Selector
   - Interval

- Sample Count
- Sort

4. Click Create or OK, and then click Close.

Viewing Statistics

Aug 30, 2013

You can view the collected statistics in tabular format in the command-line interface and in graphical format in the configuration utility.

The following table describes the collected statistics:

Table 1. Statistical Information Displayed for a Stream Identifier

Statistics	Column name in the output of the stat stream identifier <identifier name> command	Description
Number of requests	Req	The number of requests for which records were created in the last <interval> number of minutes.
Bandwidth consumed	BandW	The total bandwidth consumed by the requests that were received in the last <interval> number of minutes. The total bandwidth of a request is the bandwidth consumed by the request and its response. The value is rounded off to the next higher or next lower integer value. Consequently, it might differ slightly from the expected value. For example, if a request's total bandwidth consumption is 2.2 KB, one instance of the request might be shown as having consumed 2 KB and two instances might be shown as having consumed 4 KB, but three instances might be shown as having consumed 7 KB.
Response time	RspTime	The average response time for all the requests received in the last <interval> number of minutes.
Concurrent connections	Conn	The total number of concurrent connections that are currently open.

To view the statistical data collected for a stream identifier by using the command line

At the command prompt, type:

stat stream identifier <name> [<pattern> ...] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-sortBy <sortBy> [<sortOrder>]

Examples

Example 1 sorts the output on the BandW column, in the descending order. Example 2 sorts the output in Example 1, on the Req column, and in the ascending order

Example 1

```
> stat stream identifier myidentifier -sortBy BandW Descending -fullValues
Stream Session statistics
            Req          BandW
User1        508         125924
User2       5020          12692
User3       2025           4316

          RspTime          Conn
User1       5694             0
User2        109             0
User3          3             0
 Done
```

Example 2

```
> stat stream identifier myidentifier -sortBy Req Ascending –fullValues
Stream Session statistics
            Req          BandW
User1        508         125924
User3       2025           4316
User2       5020          12692

          RspTime          Conn
User1       5694             0
User3          3             0
User2        109             0
 Done
```

To view the statistical data collected for a stream identifier by using the configuration utility

1. Navigate to AppExpert > Action Analytics > Stream Identifiers.
2. Select the stream identifier whose sessions you want to view, and then click Stream Sessions. For information about how you can group the output on the basis of the values collected for various selector expressions, see "Grouping Records on Attribute Values."

Grouping Records on Attribute Values

Sep 30, 2013

Statistical information such as the number of times a particular URL has been accessed overall and per client, and the total number of GET and POST requests per client can provide valuable insights into whether any of your resources need to be expanded to meet the demand or be optimized for delivery. To obtain such statistics, you must use an appropriate set of selector expressions, and then use the pattern parameter in the stat stream identifier command. The grouping is based on the pattern that is specified in the command. Grouping can be performed concurrently on the values of multiple expressions.

In the command-line interface, you can group the output by using patterns of your choice. In the configuration utility, the pattern depends on the choices you make when drilling down through the values of various selector expressions. For example, consider a selector that has the expressions HTTP.REQ.URL, CLIENT.IP.SRC, and HTTP.REQ.LB_VSERVER.NAME, in that order. The statistics home page displays icons for each of these expressions. If you click the icon for CLIENT.IP.SRC, the output is based on the patterns * ? *. The output displays statistics for each client IP address. If you click an IP address, the output is based on the patterns * <IP address> ? and ? <IP address> * where <IP address> is the IP address you selected. In the resulting output, if you click a URL, the pattern used is <URL> <IP address> ?.

To group the records on the values of selector expressions by using the command line interface

At the command prompt, enter the following command to group the records on the basis of a selector expression:

stat stream identifier <name> [<pattern> ...]

Examples

Each example uses a different pattern to demonstrate the effect of the pattern on the output of the stat stream identifier command. The selector expressions are HTTP.REQ.URL and HTTP.REQ.HEADER("UserHeader"), in that order. The requests contain a custom header whose name is UserHeader. Note that in the examples, a given statistical value changes as determined by the grouping, but the sum total of the values for a given field remains the same.

Example 1

In the following command, the pattern used is ? ?. The appliance groups the output on the values collected for both selector expressions. The row headers consist of the expression values separated by a question mark (?). The row with the header /mysite/mypage1.html?Ed displays statistics for requests made by user Ed for the URL /mysite/mypage1.html.

```
> stat stream identifier myidentifier ? ? -fullValues
Stream Session statistics
                          Req          BandW
/mysite/mypage2.html?Grace          1           2553
/mysite/mypage1.html?Grace          2             4
/mysite/mypage1.html?Ed             8            16
/mysite/mypage2.html?Joe            1          2554
/mysite/mypage1.html?Joe            5            10
/mysite/?Joe                    1           4

                       RspTime          Conn
```

```
/mysite/mypage2.html?Grace              0              0
/mysite/mypage1.html?Grace              0              0
/mysite/mypage1.html?Ed                 0              0
/mysite/mypage2.html?Joe                0              0
/mysite/mypage1.html?Joe                0              0
/mysite/?Joe                        6              0
 Done
```

Example 2

In the following command, the pattern used is * ?. The appliance groups the output on the values accumulated for the second expression HTTP.REQ.HEADER("UserHeader"). The rows display statistics for all requests made by users Grace, Ed, and Joe.

```
> stat stream identifier myidentifier * ?
Stream Session statistics
          Req   BandW  RspTime    Conn
Grace       3    2557      0      0
Ed          8      16      0      0
Joe         7    2568      6      0
 Done
```

Example 3

In the following command, the pattern used is ? *, which is the default pattern. The output is grouped on the values collected for the first selector expression. Each row displays statistics for one URL.

```
> stat stream identifier myidentifier ? * -fullValues
Stream Session statistics
                        Req           BandW
/mysite/mypage2.html              2            5107
/mysite/mypage1.html             15              30
/mysite/                      1             4

                      RspTime           Conn
/mysite/mypage2.html              0             0
/mysite/mypage1.html              0             0
/mysite/                      6             0
 Done
```

Example 4

In the following command, the pattern used is * *. The appliance displays one set of collective statistics for all the requests received, with no row title.

```
> stat stream identifier myidentifier * *
Stream Session statistics
          Req   BandW  RspTime    Conn
           18    5141      6      0
 Done
```

Example 5

In the following command, the pattern is /mysite/mypage1.html *. The appliance displays one set of collective statistics

for all the requests received for the URL /mysite/mypage1.html, with no row title.

```
> stat stream identifier myidentifier /mysite/mypage1.html *
Stream Session statistics
          Req    BandW  RspTime    Conn
           15      30       0       0
 Done
```

To group the records on the values of selector expressions by using the configuration utility

1. Navigate to AppExpert > Action Analytics > Stream Identifiers.
2. In the details pane, click the stream identifier for which you want to view statistics, and then click Stream Sessions.
3. On the Home page, click the icon for the stream selector by which you want to group the output.
4. To return to the Home page from the statistics page for a selector expression, click Home.
5. To view statistics for the value of a given selector expression, click the value. You can repeat this step for a selector expression value in each subsequent output until you obtain the statistics you want.

Clearing a Stream Session

Aug 30, 2013

You can flush all the records that have been accumulated for a stream identifier.

To clear a stream session by using the command line interface

At the command prompt, enter the following commands to clear a stream session and verify the results:

- clear stream session <name>
- stat stream identifier <name>

Example

This example uses the stat stream identifier command first, so that a comparison can be made with the stat stream identifier command that is used for verifying the result of the clear stream session command.

```
>stat stream identifier myidentifier
Stream Session statistics
            Req    BandW  RspTime    Conn
/aed....html      2       0       0       0
/             636     303      12       0
 Done
>clear stream session myidentifier
 Done
>stat stream identifier myidentifier
 Done
```

To clear a stream session by using the configuration utility

1. Navigate to AppExpert > Action Analytics > Stream Identifiers.
2. Select the stream identifier whose sessions you want to clear, and then click Clear Sessions.

Configuring a Policy for Analyzing and Optimizing Traffic

Sep 16, 2013

To put the selector-identifier pair in your action analytics configuration into effect, you must associate the pair with the point in the traffic flow at which you want to collect statistics. You can do so by configuring a default syntax policy and referencing the stream identifier from the policy rule. You can use compression policies, caching policies, rewrite policies, application firewall policies, responder policies, and any other policies whose action is based on a Boolean expression.

The action analytics feature introduces a set of default syntax expressions and functions for collecting and evaluating data. The expression ANALYTICS.STREAM(<identifier_name>) is used for referencing the identifier that you want to use. The expression COLLECT_STATS is used to collect statistical data. Functions such as IS_TOP(<uint>) and IS_TOP_FREQUENTS(<uint>) are used for making automatic, real-time traffic optimization decisions.

- **IS_TOP(<number>).** Finds if a given object is in the top <number> of elements. For example, is the element among the top 10 elements. When multiple elements have the count, they are considered to be similar in nature. The sort function must be turned on to avoid an undef condition.
- **IS_TOP_FREQUENTS(<frequency>).** Finds if a given object is in the top <frequency> of the elements that are in the top elements. For example, is the element among the top 50% of all the top elements maintained. Elements having the same values are considered similar in nature. The sort function must be turned on to avoid an undef condition.

It is your policy configuration that determines whether the NetScaler appliance must only collect data from traffic or also perform an action. If the appliance must only collect statistical data, you can configure a policy with the rule ANALYTICS.STREAM(<identifier_name>).COLLECT_STATS and the action NOOP. The NOOP policy must be the policy with the highest priority at the bind point. This policy is sufficient if you are only collecting statistics. Traffic optimization decisions, such as what to compress or cache, must be based on manual, periodic evaluation of the statistical data.

If, in addition to collecting statistics, the appliance must also perform an action on the traffic, you must configure the gotoPriorityExpression parameter of the NOOP policy such that another policy that has the desired rule and action is evaluated subsequently. This second policy must have a rule that begins with the ANALYTICS.STREAM(<identifier_name>) prefix and a function that evaluates the data.

Following is an example of two responder policies that are configured and bound globally. The policy responder_stat_collection enables the appliance to collect statistics based on the identifier, myidentifier. The policy responder_notify evaluates the data that is collected.

Example

```
> add responder action send_notification respondwith '"You are in the Top 10 list for bandwidth consumption"'
 Done
> add responder policy responder_stat_collection' ANALYTICS.STREAM("myidentifier").COLLECT_STATS' NOOP
Done
> add responder policy responder_notify 'ANALYTICS.STREAM("myidentifier").BANDWIDTH.IS_TOP(10)' send_notification
 Done
> bind responder global responder_stat_collection 10 NEXT
 Done
> bind responder global responder_notify 20 END
 Done
```

Use Case: Limiting Bandwidth Consumption per User or Client Device

Sep 16, 2013

Your web site, application, or file hosting service has finite network and server resources available to it to serve all its users. One of the most important resources is bandwidth. Substantial bandwidth consumption by only a subset of the user base can result in network congestion and reduced resource availability to other users. To prevent network congestion, you might have to limit a client's bandwidth consumption by using temporary service denial techniques such as responding to a client request with an HTML page if it has exceeded a preconfigured bandwidth value over a fixed time period leading up to the request.

In general, you can regulate bandwidth consumption either per client device or per user. This use case demonstrates how you can limit bandwidth consumption per client to 100 MB over a time period of one hour. The use case also demonstrates how you can regulate bandwidth consumption per user to 100 MB over a time period of one hour, by using a custom header that provides the user name. In both cases, the tracking of bandwidth consumption over a moving time period of one hour is achieved by setting the interval parameter in the stream identifier to 60 minutes. The use cases also demonstrate how you can import an HTML page to send to a client that has exceeded the limit. Importing an HTML page not only simplifies the configuration of the responder action in these use cases, but also simplifies the configuration of all responder actions that need the same response.

To limit bandwidth consumption per user or client device by using the command line interface

In the command-line interface, perform the following tasks to configure action analytics for limiting a client's or user's bandwidth consumption. Each step includes sample commands and their output.

1. **Set up your load balancing configuration.** Configure load balancing virtual server mysitevip, and then configure all the services that you need. Bind the services to the virtual server. The following example creates ten services and binds the services to mysitevip.

   ```
   > add lb vserver mysitevip HTTP 192.0.2.17 80
    Done
   > add service service[1-10] 192.0.2.[240-249] HTTP 80
   service "service1" added
   service "service2" added
   service "service3" added
   .
   .
   .
   service "service10" added
    Done
   > bind lb vserver vserver1 service[1-10]
   service "service1" bound
   service "service2" bound
   service "service3" bound
   .
   .
   .
   service "service10" bound
    Done
   ```

2. **Configure the stream selector.** Configure one of the following stream selectors:
   - To limit bandwidth consumption per client, configure a stream selector that identifies the client IP address.

     ```
     > add stream selector myselector CLIENT.IP.SRC
      Done
     ```

- To limit bandwidth consumption per user on the basis of the value of a request header that provides the user name, configure a stream selector that identifies the header. In the following example, the name of the header is UserHeader.

  ```
  > add stream selector myselector HTTP.REQ.HEADER("UserHeader")
   Done
  ```

3. **Configure a stream identifier.** Configure a stream identifier that uses the stream selector. Set the interval parameter to 60 minutes.

   ```
   > add stream identifier myidentifier myselector -interval 60 -sampleCount 1 -sort BANDWIDTH
    Done
   ```

4. **Configure the responder action.** Import the HTML page that you want to send to users or clients that have exceeded the bandwidth consumption limit, and then use the page in responder action crossed_limits.

   ```
   > import responder htmlpage http://192.0.2.20:80/stdpages/wait.html crossed-limits.html
   This operation may take some time, Please wait...

    Done
   > add responder action crossed_limits respondwithhtmlpage crossed-limits.html
    Done
   ```

5. **Configure the responder policies.** Configure responder policy myrespol1 with the rule ANALYTICS.STREAM("myidentifier").COLLECT_STATS and the action NOOP. Then, configure policy myrespol2 for determining whether a client or user has crossed the 100 MB limit. The policy myrespol2 is configured with the responder action crossed_limits.

   ```
   > add responder policy myrespol1 'ANALYTICS.STREAM("myidentifier").COLLECT_STATS' NOOP
    Done
   > add responder policy myrespol2 'ANALYTICS.STREAM("myidentifier").BANDWIDTH.GT(1048576)' crossed_limits
    Done
   ```

6. **Bind the responder policies to the load balancing virtual server.** The policy myrespol1, which only collects statistical data, must have the higher priority and a GOTO expression of NEXT.

   ```
   > bind lb vserver mysitevip -policyName myrespol1 -priority 1 -gotoPriorityExpression NEXT
    Done
   > bind lb vserver mysitevip -policyName myrespol2 -priority 2 -gotoPriorityExpression END
    Done
   ```

7. **Test the configuration.** Test the configuration by sending test HTTP requests, from multiple clients or users, to the load balancing virtual server and using the stat stream identifier command to view the statistics that are collected for the specified identifier. The following output displays statistics for clients.

   ```
   > stat stream identifier myidentifier -sortBy BandW –fullValues
   Stream Session statistics
                     Req        BandW
   192.0.2.30          5000       3761
   192.0.2.31          29         2602
   192.0.2.32          25         51

                     RspTime      Conn
   192.0.2.30          2          0
   192.0.2.31          0          0
   192.0.2.32          0          0
    Done
   >
   ```

AppExpert Applications and Templates

May 21, 2015

An AppExpert application is a collection of configuration information that you set up on the Citrix NetScaler appliance for securing and optimizing traffic for a Web application, such as Microsoft SharePoint. Managing AppExpert applications is simplified by a graphical user interface (GUI) that allows you to specify application traffic subsets and a distinct set of security and optimization policies for processing each traffic subset. Additionally, it consolidates all deployment tasks in one view, so you can quickly configure target IP addresses for clients and specify host servers.

Prebuilt application templates for widely used Web applications, such as Microsoft Outlook Web Access and Microsoft SharePoint, are available on the AppExpert Templates page of the Citrix Community website at "http://community.citrix.com/display/ns/AppExpert+Templates."

Each prebuilt template provides you with an initial configuration for managing the associated Web application. You can customize prebuilt application templates for your organization. If a prebuilt application template does not suit your requirements, you can create a custom application without using a template.

Regardless of whether you use a prebuilt application template or you create a custom application, you can export the configuration to a template file. You can then share the template with other administrators or import the template to other NetScaler appliances that require a similar AppExpert application configuration.

To get started with an AppExpert application, you must first obtain the appropriate application template and import the template to the NetScaler appliance. After the AppExpert application is set up, you must verify that the application is working correctly. If required, you can customize the configuration to suit your requirements.

Periodically, you can verify and monitor the configuration by viewing the hit counters for various application components, statistics, and the Application Visualizer. You can also configure authentication, authorization, and auditing (AAA) policies for the application.

Updated: 2013-08-30

Following are the terms used in the AppExpert applications feature and the descriptions of the entities for which the terms are used:

Public Endpoint. The IP address and port combination at which the NetScaler appliance receives client requests for the associated web application. A public endpoint can be configured to receive either HTTP or secure HTTP (HTTPS) traffic. All client requests for the web application must be sent to a public endpoint. An AppExpert application can be assigned multiple endpoints. You configure public endpoints after you import a template.

Application Unit. An AppExpert application entity that processes a subset of web application traffic and load balances a set of services that host the associated content. The subset of traffic that an application unit must manage is defined by a rule. Each application unit also defines its own set of traffic optimization and security policies for the requests and responses that it manages. The NetScaler services associated with these policies are Compression, Caching, Rewrite, Responder, and application firewall.

By default, every AppExpert application with at least one application unit includes a default application unit, which cannot be deleted. The default application unit is not associated with a rule for identifying requests and is always placed last in the

order of application units. It defines a set of policies for processing any request that does not match the rules that are configured for the other application units, thereby ensuring that all client requests are processed.

Application units and their associated rules, policies, and actions are included in AppExpert application templates.

Service. The combination of the IP address of the server that hosts the web application instance and the port to which the application is mapped on the server, in the format <IP address>:<Port>. A web application that serves a large number of requests is usually hosted on multiple servers. Each server is said to host an instance of the web application, and each such instance of the web application is represented by a service on the NetScaler appliance. Services are deployment-specific, and are therefore not included in templates. You must configure services after you import a template.

Application Unit Rule. Either a classic expression or a default syntax expression that defines the characteristics of a traffic subset for an application unit. The following example rule is a default syntax expression that identifies a traffic subset that consists of four image types:

```
HTTP.REQ.URL.SUFFIX.EQ("bmp") || HTTP.REQ.URL.SUFFIX.EQ("gif") || HTTP.REQ.URL.SUFFIX.EQ("png") || HTTP.REQ.URL.SUFFIX.EQ("jpg")
```

For more information about default syntax expressions and classic policy expressions, see "Policies and Expressions."

Traffic Subset. A set of client requests that require a common set of traffic optimization and security policies. A traffic subset is managed by an application unit and is defined by a rule.

When the endpoint receives a client request, the NetScaler appliance evaluates the request against the rule that is configured for the topmost application unit. If the request satisfies this rule, the request is processed by the policies that are configured for the application unit, and then forwarded to a service. The choice of service depends on which services are configured for the application, and on settings such as the load balancing algorithm and persistence method configured for the application unit.

If the request does not satisfy the rule, the request is evaluated against the rule for the next topmost application unit. In this order, the request is evaluated against each application unit rule until the request satisfies a rule. If the request does not satisfy any of the configured rules, it is processed by the default application unit, which is always the last application unit.

You can configure multiple public endpoints for an AppExpert application. In such a configuration, by default, each application unit processes requests received by all the public endpoints and load balances all the services that are configured for the application. However, you can specify that an application unit processes traffic from only a subset of the public endpoints and load balances only a subset of the services that are configured for the AppExpert application.

Getting Started with an AppExpert Application

Aug 30, 2013

The process of setting up an AppExpert application begins with downloading the appropriate AppExpert application template from the Citrix Community Web site at "http://community.citrix.com/display/ns/AppExpert+Templates." The template that you need depends on the NetScaler release running on your appliance.

After you download the template, you must import the template to the NetScaler appliance, configure deployment settings, and then verify the configuration to make sure that the AppExpert application is working as expected.

Updated: 2013-08-30

You can either import the template file directly from your local computer or upload the template to the appliance and then import it. For more information about uploading a template to the NetScaler appliance, see "Uploading and Downloading Template Files."

During import, along with the template file that you specify in the AppExpert Template Wizard, you can include a deployment file that contains deployment details. If you choose to include a deployment file, you do not have to provide any additional information. All application-configuration information is imported from the template file, and all deployment-specific information for the application is imported from the deployment file. The NetScaler appliance imports all configuration settings from the deployment file through the NITRO API, and the wizard displays the configuration summary screen for your verification. If you do not include a deployment file, the wizard displays screens on which you can specify deployment information. During import, if an error occurs, any changes are automatically rolled back, preserving the configuration that was in place before you attempted to import the AppExpert application. For more information about the format of application templates and deployment files, see "Understanding NetScaler Application Templates and Deployment Files." For more information about how the template and deployment files are imported through the NITRO API, see "NITRO API."

AppExpert applications and the deployment files created from them support two or more endpoints. However, when importing an AppExpert template file, if you do not include a deployment file, the AppExpert Template Wizard displays a screen on which you can configure a maximum of two public endpoints—one endpoint of type HTTP and one endpoint of type HTTPS—for the application. So, if you want more than two endpoints, you have to configure additional endpoints after you create the application. You can then export the application to obtain a deployment file that contains all the configured endpoints.

If the public endpoint that you configure during import uses the HTTPS protocol, and you are not providing a deployment file, you must also specify a server certificate for the public endpoint. Additionally, if variables have been configured for the template, a Specify Variable Values page appears in the wizard. On this page, you can choose to specify new values for the variables. Configuring deployment settings (a minimum of one public endpoint and one or more services) during template import is not mandatory; you can choose to skip these steps during import and, instead, configure these settings after you import the template. Note, however, that you can configure additional AppExpert application features, such as AAA, only after you specify at least one public endpoint.

For more information about configuring endpoints after you import a template, see "Configuring Public Endpoints." For more information about configuring services and service groups after you import a template, see "Configuring Services and Service Groups." For more information about configuring variables for a NetScaler application, see "Creating Variables in

Application Templates."

To import an AppExpert application template to the NetScaler appliance

1. Navigate to AppExpert > Applications.
2. In the details pane, click Applications, and then click Import.
3. Follow the instructions in the AppExpert Template Wizard.

Updated: 2013-08-30

Verification is an important step in the process of setting up the NetScaler application. Before you proceed with other configuration tasks, you must verify that the state of the entities, such as endpoints and application units, are UP, and then test the entities for correct processing.

Verifying the Configuration

The graphical user interface (GUI) includes icons that indicate the states of the entities in the AppExpert application. These icons are displayed for applications and application units and are based on the health checks that the NetScaler appliance performs periodically on services and entities. The following table lists the icons and describes their meanings.

Table 1. Descriptions of State Indicator Icons

Icon	Entity	Indicates that
	Application	At least one public endpoint is up. The application will accept client requests from the public endpoints that are up.
	Application unit	The application unit is up. The application unit is up when at least one service or service group is up.
	Application	The public endpoint is out of service (disabled). This indicator is displayed when only one public endpoint is configured for the AppExpert application.
	Application	All the endpoints that are configured for the application are out of service. This indicator is displayed only when multiple endpoints are configured for the application.
	Application unit	All the services configured for the application unit are down.

You must ensure that the icons for each application and its application units are green at all times. If the icon that is displayed for an application is not green, verify that you have configured the public endpoints correctly. If the icon that is displayed for an application unit is not green, verify that the services are configured correctly. However, note that a green indicator does not mean that the state of all associated entities is UP. It only means that the application has sufficient

resources (endpoints and services) to serve client requests. To verify that the state of all associated entities is UP, check the health of all the entities on the statistics page for the application. For more information about viewing the application statistics page, see "Viewing Application Statistics."

Testing the Configuration by Using Hit Counters

You can test the configuration by sending test HTTP requests for web application content through the NetScaler appliance, and then verifying that the requests are being processed by the right application units, by viewing the hit counters for the various AppExpert application entities. For example, to verify that the endpoint is receiving requests, you can view the hit counter for the AppExpert application. To verify that the configured application unit rules are being matched as expected, you can view the hit counters for the AppExpert application units.

Note: To view hit counters for policies and actions that are configured for AppExpert applications, you must go to the associated feature node. For example, to view the hit counter for a Rewrite policy that is configured for an AppExpert application, you must go to the Rewrite feature node in the NetScaler configuration utility.
For a test example, consider an AppExpert application that includes an application unit called "WebPages" for processing web page content, and an application unit called "Images" for processing images. In this example, the rule that is configured for the WebPages application unit includes an expression that checks whether an HTML file is being requested. The Images application unit includes an expression that checks whether an image file is being requested.

Consider an HTML file called sitehome.html, located at /var/www/html/myapplicationpages/, on a backend server with an IP address of 192.0.2.10. In addition to HTML content, the HTML file also references images stored on the server. An HTTP request for the HTML file, sent directly to the server, would be as follows:

http://192.0.2.10/myapplicationpages/sitehome.html

To send a test request for this file through the NetScaler appliance, in the URL, replace the IP address of the server with the IP address of the public endpoint that is configured for the AppExpert application. For example, if the IP address of the public endpoint is 192.0.2.11, your test URL would be as follows:

http://192.0.2.11/myapplicationpages/sitehome.html

After you send the request, you must view the hit counter for the application to verify that the public endpoint received the request, view the hit counter for the WebPages application unit to verify that the request for the HTML file matched the rule configured for the application unit, and view the hit counter for the Images application unit to verify that the requests for the images matched the rule configured for the application unit.

For the application, the Hits dialog box displays the total number of requests received by each configured public endpoint. For an application unit, the Hits dialog box displays the number of requests that the application unit processed from each of the public endpoints, and the total hit count.

1. Navigate to AppExpert > Applications.
2. In the details pane, click the application or application unit for which you want to view the hit counter.
3. Click Hits.

Customizing the Configuration

Mar 28, 2012

After you verify that the AppExpert application is working correctly, you can customize the configuration to suit your requirements.

You can configure public endpoints and services for the AppExpert application and specify only a subset of the endpoints and services for each application unit. When you want the AppExpert application to manage a traffic subset that is not included in the template, you can either add an application unit for the new traffic subset or modify an existing application unit rule. You can also specify the order of evaluation of the traffic subsets that the AppExpert application manages.

Finally, you can modify the policies that the template provided. If the AppExpert application template does not include policies for a particular NetScaler feature, such as Rewrite or application firewall, you can configure your own policies.

The order in which you perform these tasks depends on your requirement. However, before you configure a service for an application, you must configure the service for the parent application.

Configuring Public Endpoints

Aug 30, 2013

If you did not specify a public endpoint when importing an AppExpert application, you can specify public endpoints after you create the application. You can configure one public endpoint of type HTTP and one public endpoint of type HTTPS for your AppExpert application.

If endpoints are already configured for the application, you can dissociate endpoints from the AppExpert application and delete any endpoints that you no longer need. Note that when you dissociate a public endpoint from the AppExpert application, the endpoint is automatically unbound from the associated application unit, but it is not deleted from the system.

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application for which you want to configure public endpoints, and then click Configure Public Endpoints.
3. In the Choose Public Endpoints dialog box for the application, do one of the following:
   - If the endpoints you want are listed in the dialog box, click the corresponding check boxes.
   - If you want to specify all the public endpoints, click Activate All.
   - If you want to dissociate endpoints from the AppExpert application, clear the corresponding check boxes.
   - If you want to create a new public endpoint, click Add. Then, in the Create public endpoint dialog box, configure endpoint settings, and then click OK.

     In the Create public endpoint dialog box, you can specify only the name, IP address, port, and protocol for the endpoint. You can specify additional endpoint settings after you create the public endpoint. To specify additional endpoint settings, after you create the endpoint, in the Choose Public Endpoints dialog box, click the endpoint, and then click Open. Then, in the Configure Public Endpoint dialog box, provide additional settings, and then click OK.

     For more information about the parameters in the Create public endpoint and Configure Public Endpoint dialog boxes, see "Content Switching."

   - If you want to modify a public endpoint, click the endpoint, and then click Open. Then, in the Configure Public Endpoint dialog box, modify settings for the endpoint, and then click OK.

     For more information about the parameters in the Configure Public Endpoint dialog box, see "Content Switching."
4. Click Close.

Configuring Endpoints for an Application Unit

Aug 30, 2013

When you configure multiple public endpoints for an AppExpert application, by default, all endpoints are bound to each application unit, and each application unit processes the requests received by all the endpoints. However, you can specify that a given application unit manages the traffic that is received by only a subset of the endpoints that are configured for the AppExpert application.

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application unit for which you want to specify public endpoints, and then click Configure Public Endpoints.
3. In the Choose Public Endpoints dialog box for the application unit, do one of the following:
   - If you are specifying endpoints for the application unit for the first time, clear the check boxes that correspond to the endpoints that you do not want to be bound to the application unit.
   - If you want to specify endpoints that are listed in the dialog box but not currently bound to the application unit, click the corresponding check boxes.
4. Click OK.

Configuring Services and Service Groups

Aug 30, 2013

When you configure a service or service group, you either modify an existing service or service group, or add new services to the AppExpert application. You add services or service groups if you did not specify them when you imported the application template. You also add services and service groups when you increase the number of servers that host instances of the application. You can configure a service and service group for an application unit only after you configure the service or service group for the AppExpert application.

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application for which you want to configure services or service groups, and then click Configure Backend Services.
3. In the Configure Backend Services dialog box, do one of the following:
   - To configure services, click the Services tab.
   - To configure service groups, click the Service Groups tab.
4. On the Service or Service Groups tab, do one of the following:
   - If the services or service groups that you want are listed on the tab, click the corresponding check boxes.
   - If you want to specify all the services or service groups, click Activate All.
   - If you want to create a new service or service group, click Add. Then, in the Create Service dialog box or Create Service Group dialog box, configure settings for the service or service group, respectively, and then click Create.
   - If you want to modify a service, click the service, and then click Open. Then, in the Configure Service dialog box or Create Service Group dialog box, configure settings for the service or service group, respectively, and then click OK.

For information about the settings in the Create Service, Configure Service, and Create Service Group dialog boxes, see "Load Balancing."

Configuring Services, Service Groups, and Load Balancing Parameters for an Application Unit

Aug 30, 2013

When you configure services and service groups for an AppExpert application, by default, all the services and service groups are bound to each application unit. However, depending on how you have configured your web application, the application resources that are managed by an application unit might be hosted on only some of the servers that are configured as services for the AppExpert application. Or, a set of servers might host content that is meant for the requests received at one or more specific public endpoints. In such scenarios, if all the services and service groups that are configured for the AppExpert application are associated with the application unit, a request that is forwarded to a server that does not host the requested content might not be served or might be served incorrect content. Therefore, you must ensure that each application unit is configured to manage only those services that can serve the requested content.

When configuring services and service groups for an application unit, you might choose to specify load balancing settings such as the weights that services must be assigned and the desired load balancing, persistence, and spillover methods. For more information about these settings, see Load Balancing.

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application unit for which you want to configure a service or service group, and then click Configure Backend Services.
3. In the Configure Backend Services dialog box, do one of the following:
   - To configure services, click the Services tab.
   - To configure service groups, click the Service Groups tab.
4. In the Services or Service Groups tab, do one of the following:
   - Clear the check boxes that correspond to the services or service groups that you do not want configured for the application unit. Make sure that the check boxes that correspond to the services or service groups that you want configured for the application unit are selected. Then, in the Weight column, specify the weight that you want to assign to each configured service.
   - To specify all services or service groups, click Activate All.
5. On the Method and Persistence and Advanced tabs, specify the desired parameters.
6. Click OK.

Creating Application Units

Aug 30, 2013

You might need to add application units for traffic subsets that are either specific to your web application implementation or not defined in the template. When creating an application unit, you must configure a rule for the application unit.

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application for which you want to add an application unit, and then click Add.
3. Click Create.

Configuring Application Unit Rules

Aug 30, 2013

You might want to configure an application unit rule to include or exclude certain types of traffic. When you configure the rule, you can also define the syntax of the expression.

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Applications.
2. In the details pane, right-click the application unit for which you want to modify the rule, and then click Open.
3. In the Configure Application Unit dialog box, do the following:
   1. To specify the format of the new expression, do one of the following:
      - To specify that you want to configure a classic expression in the Rule box, click Classic Syntax.
      - To specify that you want to configure an advanced expression in the Rule box, click Default Syntax.
   2. In the Rule box, configure the expression.
4. Click OK.

Specifying the Order of Evaluation of Application Units

Aug 30, 2013

Application unit rules are evaluated in the order in which they are placed in the graphical user interface (GUI). The rule that is configured for the topmost application unit is always configured first, followed by the rule that is configured for the second topmost application unit, and so on. The default application unit is always evaluated last.

When a request matches the rule that is configured for an application unit, the request is processed by the application unit, and no further matching is performed. Therefore, the order of evaluation of application units becomes an important factor if the traffic subsets for two or more application units overlap. If the traffic subsets for two or more application units overlap, you must specify the order in which an incoming request is matched against the application unit rules.

1. Navigate to AppExpert > Applications.
2. In the details pane, do the following:
   - To move an application unit up by one step, right-click the application unit, and then click Move Up.
   - To move an application unit down by one step, right-click the application unit, and then click Move Down.

Configuring Policies for Application Units

Apr 24, 2014

For an AppExpert application, you can configure policies for Compression, Caching, Rewrite, Responder, and Application Firewall. The templates that you download from the Citrix Community web site provide you with a set of policies that fulfill the most common application management requirements. You might want to fine-tune or customize these policies. If the set of policies provided for a given application unit does not include policies for a particular feature, you can create and bind your own policies for that feature.

If you create an AppExpert application without using a template, you must configure all the policies that the web application needs.

The GUI uses various icons to indicate whether or not policies are configured for a feature. For an application unit, if a policy is configured for a given feature, an icon that represents the feature is displayed. For example, if a compression policy is configured for an application unit, a compression icon is displayed in the Compression column for the application unit. For features for which no policy is configured, an icon depicting a plus sign (+) is displayed.

Note: When configuring policies for application units, you might need to configure policies and expressions that are either in the classic or default syntax. Additionally, when you configure default syntax policies, you might need to specify parameters such as Goto expressions and invoke policy banks. For information about configuring policies and expressions in both formats, see "Policies and Expressions."

You can use either classic policies or advanced policies to configure compression, but you cannot bind compression policies of both types to the same application unit.

To configure a compression policy for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, in the row for the application unit you want to configure, click the icon provided in the Compression column.
3. In the Configure Compression Policies dialog box, do one or more of the following, depending on the configuration tasks you want to perform:
   - Click Switch to Default Syntax if you want to configure a default syntax compression policy. If you want to bind or configure classic compression policies, and if you are in the default syntax view, you can click Switch to Classic Syntax to return to the classic policy view and begin modifying bound classic policies or create and bind new classic compression policies.
     Important: This setting also determines what policies are displayed when you want to insert a policy. For example, if you are in the default syntax view, when you click Insert Policy, the list that appears in the Policy Name column will include only default syntax policies. You cannot bind policies of both types to an application unit.
   - If you want to configure classic policies, click either Request or Response, depending on whether you want the policy to be evaluated at request-time or at response-time.
     You can configure both request-time and response-time classic compression policies for an application unit. After evaluating all of the request-time policies, if no match is found, the appliance evaluates response-time policies.
   - To modify a compression policy that is already bound to the application unit, click the name of the policy, and then click Modify Policy. Then, in the Configure Compression Policy dialog box, modify the policy, and then click OK.

For information about modifying a compression policy, see "Compression."

- To unbind a policy, click the name of the policy, and then click Unbind Policy.
- To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
- To regenerate assigned priorities, click Regenerate Priorities.
- To insert a new policy, click Insert Policy and, in the list that is displayed in the Policy Name column, click New Policy. Then, in the Create Compression Policy dialog box, configure the policy, and then click Create.

  For information about modifying a compression policy, see "Compression."

- If you are configuring a default syntax expression, do the following:
  - In the Goto Expression column, select a Goto expression.
  - In the Invoke column, specify the policy bank that you want to invoke if the current policy evaluates to TRUE.

4. Click Apply Changes, and then click Close.

You can use only default syntax policies and expressions to configure Caching policies.

To configure Caching policies for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, in the row for the application unit you want to configure, click the icon provided in the Caching column.
3. In the Configure Cache Policies dialog box, do one or more of the following, depending on the configuration tasks you want to perform:
   - Click either Request or Response, depending on whether you want the policy to be evaluated at request-time or at response-time.

     You can configure both request-time and response-time Caching policies for an application unit. After evaluating all of the request-time policies, if no match is found, the appliance evaluates response-time policies.

   - To modify a Caching policy that is already bound to the application unit, click the name of the policy, and then click Modify Policy. Then, in the Configure Cache Policy dialog box, modify the policy, and then click OK.

     For information about modifying a Caching policy, see "Integrated Caching."

   - To unbind a policy, click the name of the policy, and then click Unbind Policy.
   - To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
   - To regenerate assigned priorities, click Regenerate Priorities.
   - To insert a new policy, click Insert Policy and, in the list that is displayed in the Policy Name column, click New Policy. Then, in the Create Cache Policy dialog box, configure the policy, and then click Create.

     For information about modifying a Caching policy, see "Integrated Caching."

   - In the Goto Expression column, select a Goto expression.
   - In the Invoke column, specify the policy bank that you want to invoke if the current policy evaluates to TRUE.

4. Click Apply Changes, and then click Close.

You can use only default syntax policies and expressions to configure Rewrite policies.

To configure Rewrite policies for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, in the row for the application unit you want to configure, click the icon provided in the Rewrite column.
3. In the Configure Rewrite Policies dialog box, do one or more of the following, depending on the configuration tasks you want to perform:
   - Click either Request or Response, depending on whether you want the policy to be evaluated at request-time or at response-time.

     You can configure both request-time and response-time Rewrite policies for an application unit. After evaluating all of the request-time policies, if no match is found, the appliance evaluates response-time policies.

   - To modify a Rewrite policy that is already bound to the application unit, click the name of the policy, and then click Modify Policy. Then, in the Configure Rewrite Policy dialog box, modify the policy, and then click OK.

     For information about modifying a Rewrite policy, see "Rewrite."

   - To unbind a policy, click the name of the policy, and then click Unbind Policy.
   - To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
   - To regenerate assigned priorities, click Regenerate Priorities.
   - To insert a new policy, click Insert Policy and, in the list that is displayed in the Policy Name column, click New Policy. Then, in the Create Rewrite Policy dialog box, configure the policy, and then click Create.

     For information about modifying a Rewrite policy, see "Rewrite."

   - In the Goto Expression column, select a Goto expression.
   - In the Invoke column, specify the policy bank that you want to invoke if the current policy evaluates to TRUE.
4. Click Apply Changes, and then click Close.

You can use only default syntax policies and expressions to configure Responder policies.

To configure Responder policies for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, in the row for the application unit you want to configure, click the icon provided in the Responder column.
3. In the Configure Responder Policies dialog box, do one or more of the following, depending on the configuration tasks you want to perform:
   - To modify a Filter policy that is already bound to the application unit, click the name of the policy, and then click Modify Policy. Then, in the Configure Responder Policy dialog box, modify the policy, and then click OK.

     For information about modifying a Responder policy, see "Responder."

   - To unbind a policy, click the name of the policy, and then click Unbind Policy.
   - To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
   - To regenerate assigned priorities, click Regenerate Priorities.

- To insert a new policy, click Insert Policy and, in the list that is displayed in the Policy Name column, click New Policy. Then, in the Create Responder Policy dialog box, configure the policy, and then click Create.

  For information about modifying a Responder policy, see "Responder."

- In the Goto Expression column, select a Goto expression.
- In the Invoke column, specify the policy bank that you want to invoke if the current policy evaluates to TRUE.

4. Click Apply Changes, and then click Close.

You can configure both classic and default syntax policies and expressions for Application Firewall. However, if a policy of one type is already bound globally or to a virtual server that is configured on the appliance, you cannot bind a policy of the other type to an application unit. For example, if a default syntax policy is already bound either globally or to a virtual server, you cannot bind a classic policy to an application unit.

To configure Application Firewall policies for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, in the row for the application unit you want to configure, click the icon provided in the Application Firewall column.
3. In the Configure Application Firewall Policies dialog box, do one or more of the following, depending on the configuration tasks you want to perform:
   - Click either Classic Expression or Advanced Expression depending on the type of expression you want to configure for the Application Firewall policy.
     Important: This setting also determines what policies are displayed when you want to insert a policy. For example, if you select Advanced Expression, when you click Insert Policy, the list that appears in the Policy Name column will include only default syntax policies. You cannot bind policies of both types to an application unit. This option is not available if a policy of either type is already bound either globally or to a virtual server.
   - To modify an application firewall policy that is already bound to the application unit, click the name of the policy, and then click Modify Policy. Then, in the Configure Application Firewall Policy dialog box, modify the policy, and then click OK.
     For information about modifying a application firewall policy, see "Policies."

   - To unbind a policy, click the name of the policy, and then click Unbind Policy.
   - To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
   - To regenerate assigned priorities, click Regenerate Priorities.
   - To insert a new policy, click Insert Policy and, in the list that is displayed in the Policy Name column, click New Policy. Then, in the Create Application Firewall Policy dialog box, configure the policy, and then click Create.
     For information about modifying a application firewall policy, see "Policies."

4. Click Apply Changes, and then click Close.

Configuring Persistency Groups for Application Units

Aug 30, 2013

You can configure a persistency group for the application units in an AppExpert application. In the context of an AppExpert application, a persistency group is a group of application units that you can treat as a single entity for the purpose of applying common persistence settings. When the application is exported to an application template file, the persistency group settings are included, and they are automatically applied to the application units when you import the AppExpert application.

1. Navigate to AppExpert > Applications.
2. In the Applications View dialog box, click the name of the application for whose application units you want to configure a persistency group, and then click Configure Persistency Groups.
3. In the Configure Persistency Groups dialog box, do one of the following:
   - To add a persistency group, click Add.
   - To modify a persistency group, click Open.
4. In the Create Persistency Group or Configure Persistency Group dialog box, set the following parameters:
   - Group Name*—Name of the persistency group. For the NetScaler appliance to recognize the persistency group as part of the application's configuration, the name of the AppExpert application must be included in the name of the persistency group, as a prefix. Therefore, by default, the appliance displays the prefix in the Group Name box, and you cannot remove that prefix. Enter a name of your choice after the prefix.
   - Persistence—Type of persistence for the virtual server. If you select SOURCEIP, in the IPv4 Netmask box, enter a network mask that specifies the number of bits that the appliance must consider when creating persistence sessions. If you select COOKIEINSERT, in the Cookie Domain and Cookie Name boxes, specify a domain attribute to send in the Set-Cookie directive, and a name for the cookie, respectively.
   - Timeout—Time period for which a persistence session is in effect.
   - Backup Persistence—Type of backup persistence for the group.
   - Backup Timeout—Time period, in minutes, for which backup persistence is in effect.
   - Application Units—To add an application unit to the persistency group, in the Available Application Units box, click the application unit, and then click Add. To remove an application unit from the persistency group, in the Configured Application Units box, click the application unit, and then click Remove.
5. Click OK.

Viewing AppExpert Applications and Configuring Entities by Using the Application Visualizer

Aug 30, 2013

The Application Visualizer is a graphical representation of an AppExpert application. The Visualizer displays the public endpoints, application units, backend services, and policies that are configured for the application. You can use the Visualizer to obtain a visual overview of an AppExpert application's configuration and configure some of the displayed entities. By default, the Visualizer displays application units, services, and monitors for the selected application.

1. Navigate to AppExpert > Applications.
2. In the details pane, click the name of the application that you want to view, and then click Visualizer.
3. Do one or more of the following:
   - To optimize the display area, choose Best Fit, Zoom In, or Zoom out. If an item that you want to see disappears from view after zooming in, you can click and drag the viewable area.
   - To save the graph as an image file, click Save Image.
   - To find a particular entity, in the Search in field, type an entity name. In the view area, the entity names that begin with the search string are highlighted. To restrict the search, click the drop-down menu and select the specific entity that you want to search for.
   - To view the policies that an application uses, click one or more icons to display feature-specific policies. The policy types are Compression, Filter, Rewrite, Responder, Cache, application firewall, Authorization, Auditing, HTML Injection, SureConnect, Priority Queuing, and Traffic.
   - To view the rule that is configured for an application unit, click the curve that connects the public endpoint to the application unit. The rule is displayed on the Related Tasks tab.
   - To view the binding information for an application unit, policy, or monitor, click the displayed icon, click the Related Tasks tab, and then click Show Bindings
   - To view member services, click the icon for the service, click the Related Tasks tab, and then click Show Member Services.
   - To view detailed statistics for a public endpoint or application unit, click the icon that is displayed, click the Related Tasks tab, and then click Statistics.
   - To view the Load Balancing Visualizer for an application unit, click the application unit, click Related Tasks, and then click Visualizer.
   - To view the number of requests received per second at a given point in time by the load balancing virtual server and the number of hits per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time and has to be refreshed manually. To refresh this information, click Refresh Stats.

1. Navigate to AppExpert > Applications.
2. In the details pane, click the name of the application that you want to configure or view, and then click Visualizer.
3. Do one or more of the following:
   - To configure an entity that is displayed in the viewing area, click the icon for the entity, click the Related Tasks tab, and then click Modify public endpoint.
     In the Application Visualizer, you can modify only public endpoints and services.

- To bind additional monitors to a service, click the Available Resources tab, select Monitors from the drop-down list, and then click and drag a monitor to a service.
- To unbind a service from an application unit, click the curve that connects the application unit and the service, click Related Tasks, and then click Unbind.
- To unbind a monitor from a service, click the curve that connects the service and the monitor, click Related Tasks, and then click Unbind.
- To modify a monitor, click the monitor, click Related Tasks, and then click Open.
- To modify the binding parameters for a monitor, click the curve that connects the monitor to the associated service, click Related Tasks, and then click Modify Parameters.
- To apply a common service configuration across multiple service containers that are displayed when the services bound to a vserver do not have the same configuration, click the service container whose configuration you want to apply to all the containers, and then, in Related Tasks, click Apply Configuration.
- To view a comparative list of the parameters whose values differ across service containers, click the icon for a container, click the Related Tasks tab, and then click Service Attributes Diff. The comparative list helps you determine which service container has the service configuration that you want to apply to all the containers. After you determine which service container has the configuration you want, right-click the container, and then click Apply this Configuration.
- To copy the configuration of an entity (other than the configuration of the AppExpert application) to the local computer's clipboard, click the entity, click the Related Tasks tab, and then click Copy Properties. You can then paste the configuration information in a word processing document or spreadsheet.

Monitoring a NetScaler Application

Mar 18, 2011

After you customize the AppExpert application, you can view application statistics to make sure that the application and all its entities are working correctly. You can also use the Application Visualizer to monitor statistics associated with certain entities such as policies and virtual servers.

You can also view the hit counters for various entities at regular intervals to make sure that counters are being updated.

Updated: 2013-08-30

In the Applications node, you can select an application and view the Statistics page for the application. On the Statistics page, you can monitor the health and states of public endpoints and application units, and view the following statistical information:

- Requests and responses per second for each of the public endpoints and application units.
- Bytes per second, at each endpoint, for incoming and outgoing traffic.
- Application unit hit counters and the number of client and server connections for each application unit.
- Statistics for the services that are bound to the application units.

On the Statistics page, you can also view CPU usage, memory usage, and system logs.

To view statistics for an application

1. Navigate to AppExpert > Applications.
2. In the details pane, click the application for which you want to view statistics, and then click Statistics.

Updated: 2013-08-30

You can use the Application Visualizer to monitor the number of requests received per second at a given point in time by the vservers and the number of hits per second at a given point in time for Rewrite, Responder, and Cache policies.

To view statistical information for vservers, Rewrite policies, Responder policies, and Cache policies in the Visualizer

1. Navigate to AppExpert > Applications.
2. In the details pane, select the application for which you want to view statistical information, and then click Visualizer.
3. In the Application Visualizer window, do the following:
   - To view the statistics, click Show Stats.

     The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time and has to be refreshed manually.

   - To refresh the statistical information, click Refresh Stats.

Updated: 2013-08-30

The hit counters that are provided for various AppExpert application entities enable you to monitor the functioning of public endpoints and application units. For an application, the Hits dialog box displays the total number of requests received by each configured public endpoint. For an application unit, the Hits dialog box displays the number of requests that the application unit processed from each of the public endpoints and the total hit count. For instructions on viewing hit counters, see "Verifying and Testing the Configuration."

Deleting an Application

Aug 30, 2013

If you no longer need an application and its application units, you can delete it. When you delete an AppExpert application, backend services are not deleted, and any public endpoints that the application used become available for use by other applications.

When deleting an application, you are also prompted to specify whether you want to delete any bound policies and actions that are not used elsewhere.

1. Navigate to AppExpert > Applications.
2. In the details pane, click the name of the application that you want to delete, and then click Remove.

Configuring Authentication, Authorization, and Auditing

May 21, 2015

You can configure Authentication, Authorization, and Auditing (AAA) for the applications that you configure on the appliance. An authentication policy that is configured for an application defines the type of authentication to apply when a user or group attempts to access the application. If external authentication is used, the policy also specifies the external authentication server. Authorization policies configured for an application specify whether a particular user or group can access the application. Auditing policies define the audit log type, the level at which logging is performed, and other audit server settings. Authentication and auditing policies use the classic policy format.

Authentication policies, authorization policies, and auditing policies can be configured in any order. However, before you configure AAA for an application, you must configure a public endpoint for the application.

This document includes the following deatils:

- Configuring Authentication
- Configuring Authorization
- Configuring Auditing
- Disabling AAA for an Application

Updated: 2013-08-30

Configuring authentication for an application involves specifying an authentication FQDN, an authentication virtual server, a server certificate, and authentication and session policies. Authentication policies are automatically bound to the authentication virtual server specified for the application.

To configure authentication for an AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, click the name of the application for which you want to configure authentication, and then click Authentication.
3. In the Authentication Wizard, on the Introduction page, click Next.
4. Follow the instructions in the Authentication Wizard.

Updated: 2013-08-30

You can configure authorization for users and groups to enable then to access an AppExpert application. If the AAA user or group for which you want to configure permissions has not already been created, you can create it from AppExpert and then configure permissions for application access.

To configure permissions for a AAA user or group to access an AppExpert application

1. Navigate to AppExpert > Applications.

2. In the details pane, click the AppExpert application for which you want to configure user or group access, and then click Authorization.
3. Do one of the following:
   - If the AAA user or group for which you want to configure permissions is already in the Groups/Users tree, drag the user or group from the Groups/Users tree to the Users or Groups node in the application tree. Then, right-click the user or group and click Allow.
   - If the AAA user or group for which you want to configure permissions is not configured on the appliance, in the application tree, right-click Users or Groups, and then click Add. In the Create AAA Group or Create AAA User dialog box, fill in the values, click Create, and then click Close.

     The user or group is created with the permission set to Allow. To change the permission setting, right-click the group or user, and then click the permission setting.
4. Click Close.

Updated: 2013-08-30

When you configure auditing policies for an application, you must specify the server to which the log messages must be directed, the format of the messages logged, and the log level. Optionally, you can configure other settings, such as the log facility and date format. Auditing policies are automatically bound to all the AppExpert application's public endpoints.

To configure auditing policies for an application

1. Navigate to AppExpert > Applications.
2. In the details pane, click the application for which you want to configure auditing policies, and then click Auditing.
3. In the Configure Auditing Policies dialog box, click Insert Policy.
   - To specify an existing auditing policy, under Policy Name, click the name of the policy, and then do the following:
     - To modify the priority that is assigned to the policy by default, under Priority, double-click the priority, and then type a new priority value.
     - To modify the settings of the audit server, under Server, double-click the name of the server, and then, in the Configure Auditing Server dialog box, modify the settings as appropriate. You can modify all the settings in this dialog box except the name of the audit server and the audit type. For more information about the settings in the Configure Auditing Server dialog box, see "Auditing Policies."
   - To create a new auditing policy, under Policy Name, click New Policy, and then, in the Create Auditing Policy dialog box, do the following:
     - In the Name box, type a name for the policy.
     - The Name box already contains the string that is required at the beginning of the server name. You cannot modify the string.
     - From the Auditing Type list, select the auditing type (either SYSLOG or NSLOG).
     - If the audit server you want to specify is already listed in the Server list, select the server from the list, and then, if you want to modify the server settings, click Modify. In the Configure Auditing Server dialog box, modify the settings as appropriate, and then click OK. For more information about the settings in the Configure Auditing Server dialog box, see "Auditing Policies."
     - If you want to configure a new audit server, click New, and then, in the Create Auditing Server dialog box, type a name for the server, specify the server IP address, port number, and other settings as appropriate. When finished,

click OK.
    - Click Create.
- To change the priorities for the new auditing policies you created, under Priority, for each policy for which you want to change the priority, double-click the priority value and type new priority value.
- To regenerate priorities, click Regenerate Priorities.
- To unbind a policy, click the policy, and then click Unbind Policy.
- To modify a policy, click the policy, and then click Modify Policy.

4. Click Apply Changes, and then click Close.

Updated: 2013-08-30

After you configure AAA for an application, you can disable the AAA configuration for that application. When you disable AAA for an application, the configuration is not lost. You can enable AAA for the application when you want to reapply the configuration.

To enable or disable AAA for an application

1. Navigate to AppExpert > Applications.
2. In the details pane, click the application for which you want to enable or disable AAA, and then do one of the following:
    - To disable AAA for the application, click Turn Off AAA.
    - To enable AAA for the application, click Turn On AAA.

Setting Up a Custom NetScaler Application

May 21, 2015

If an AppExpert application template is not available for the Web application that you want to manage through the NetScaler appliance, or if available AppExpert application templates do not suit your requirements, you can create an AppExpert application without a template.

To create an AppExpert application without a template, you must first create an application and application units. Then, you configure public endpoints, services, and service groups. Finally, you configure the policies that determine how application traffic is evaluated and processed.

After you create the application and application units and configure policies, you must verify the configuration and test it to make sure that it is working correctly, just as you would when you configure an application by using a prebuilt AppExpert application template. Then, you must monitor the application to make sure that the application and its entities are working correctly.

This document includes the following details:

- Creating an Application
- Creating Application Units
- Configuring Public Endpoints for an AppExpert Application
- Configuring Public Endpoints for an Application Unit
- Configuring Services and Service Groups for an AppExpert Application
- Configuring Services and Service Groups for an Application Unit
- Configuring Policies

Updated: 2013-08-30

When you create an AppExpert application, the appliance creates a container to which you can add application units. The default application unit is not created until you create the first application unit.

To create an AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click Applications, and then click Add.
3. In the Create Application dialog box, in Name, enter a name for the application, and then click OK.

Updated: 2013-08-30

For each subset of traffic associated with your web application, you must create an application unit.

To create an application unit for the AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application for which you want to add an application unit, and then click Add.
3. Click Create.

Updated: 2013-08-30

After you have created all the application units that you require, you must configure one or more public endpoints to enable clients to access the web application through the NetScaler appliance.

To configure public endpoints for an AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application for which you want to configure public endpoints, and then click Configure Public Endpoints.
3. In the Choose Public Endpoints dialog box for the application, do one of the following:
   - If the endpoints you want are listed in the dialog box, click the corresponding check boxes.
   - If you want to specify all the public endpoints, click Activate All.
   - If you want to dissociate endpoints from the AppExpert application, clear the corresponding check boxes.
   - If you want to create a new public endpoint, click Add. Then, in the Create public endpoint dialog box, configure endpoint settings, and then click OK.

     In the Create public endpoint dialog box, you can specify only the name, IP address, port, and protocol for the endpoint. You can specify additional endpoint settings after you create the public endpoint. To specify additional endpoint settings, after you create the endpoint, in the Choose Public Endpoints dialog box, click the endpoint, and then click Open. Then, in the Configure Public Endpoint dialog box, provide additional settings, and then click OK.

     For more information about the parameters in the Create public endpoint and Configure Public Endpoint dialog boxes, see "Content Switching."

   - If you want to modify a public endpoint, click the endpoint, and then click Open. Then, in the Configure Public Endpoint dialog box, modify settings for the endpoint, and then click OK.

     For more information about the parameters in the Configure Public Endpoint dialog box, see "Content Switching."

4. Click Close.

Updated: 2013-08-30

For an application unit, you specify public endpoints in the same way as you would specify public endpoints for an application that is created from an AppExpert application template. For more information about specifying a subset of the endpoints for an application unit, see "Configuring Endpoints for an Application Unit."

To configure endpoints for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application unit for which you want to specify public endpoints, and then click Configure Public Endpoints.
3. In the Choose Public Endpoints dialog box for the application unit, do one of the following:
   - If you are specifying endpoints for the application unit for the first time, clear the check boxes that correspond to the endpoints that you do not want to be bound to the application unit.
   - If you want to specify endpoints that are listed in the dialog box but not currently bound to the application unit, click

the corresponding check boxes.
4. Click OK.

Updated: 2013-08-30

Services and service groups are available for application units only after you configure the services and service groups for the AppExpert application. Therefore, you must configure services and service groups for the AppExpert application before you configure the services for the application units. All the services and service groups that you configure for an AppExpert application must use the same protocol (either HTTP or HTTPS). The procedure for configuring services and service groups for an AppExpert application that is not created from a template is the same as that for an application created from a template.

To configure a service or service group for the AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application for which you want to configure services or service groups, and then click Configure Backend Services.
3. In the Configure Backend Services dialog box, do one of the following:
   - To configure services, click the Services tab.
   - To configure service groups, click the Service Groups tab.
4. On the Service or Service Groups tab, do one of the following:
   - If the services or service groups that you want are listed on the tab, click the corresponding check boxes.
   - If you want to specify all the services or service groups, click Activate All.
   - If you want to create a new service or service group, click Add. Then, in the Create Service dialog box or Create Service Group dialog box, configure settings for the service or service group, respectively, and then click Create.
   - If you want to modify a service, click the service, and then click Open. Then, in the Configure Service dialog box or Create Service Group dialog box, configure settings for the service or service group, respectively, and then click OK.

For information about the settings in the Create Service, Configure Service, and Create Service Group dialog boxes, see "Load Balancing."

Updated: 2013-08-30

After you configure services and service groups, you must configure services and service groups for each application unit. However, this step is not necessary if each backend service hosts all the content associated with the web application. You configure services and service groups for an application unit if the content associated with the application unit is hosted on only a subset of the backend servers.

To configure services or service groups for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application unit for which you want to configure a service or service group, and then click Configure Backend Services.
3. In the Configure Backend Services dialog box, do one of the following:
   - To configure services, click the Services tab.
   - To configure service groups, click the Service Groups tab.

4. In the Services or Service Groups tab, do one of the following:
   - Clear the check boxes that correspond to the services or service groups that you do not want configured for the application unit. Make sure that the check boxes that correspond to the services or service groups that you want configured for the application unit are selected. Then, in the Weight column, specify the weight that you want to assign to each configured service.
   - To specify all services or service groups, click Activate All.
5. On the Method and Persistence and Advanced tabs, specify the desired parameters.
6. Click OK.

Updated: 2013-08-30

The procedures for configuring policies for an AppExpert application that is created without using a template are the same as those for an AppExpert application that was created from a template. For more information, see "Configuring Policies for Application Units."

Creating and Managing Template Files

May 10, 2012

After you set up an AppExpert application and customize it to suit your requirements, you can create a template from the application and then share the template with other administrators. Or, you can create a template and then import the template to other NetScaler appliances that require a similar AppExpert application configuration. This simplifies and expedites the process of setting up similar applications on other appliances. You can also export a content switching configuration to a template file. When creating a template file, you can configure variables in the policy expressions and actions that are configured for an application.

AppExpert application template files can be exported either to the template directory on the NetScaler appliance or to a folder on your local computer. You can then upload and download the templates to and from the NetScaler appliance and rename the templates that are stored in the AppExpert application templates directory on your appliance.

This document includes the following information:

- Exporting an AppExpert Application to a Template File
- Exporting a Content Switching Virtual Server Configuration to a Template File
- Creating Variables in Application Templates
- Uploading and Downloading Template Files
- Understanding NetScaler Application Templates and Deployment Files

Exporting an AppExpert Application to a Template File

Sep 30, 2013

When you export an AppExpert application, all application-configuration information is exported to a template file and all deployment-specific information is exported to a deployment file. The string _deployment is automatically appended to the name of the template file to create the name of the deployment file. Both files are in XML format. If you choose to export the application template file to the NetScaler appliance, the template file is stored in the /nsconfig/nstemplates/applications directory on the NetScaler appliance and the deployment file is stored in the /nsconfig/nstemplates/applications/deployment_files/ directory. For more information about the format of application templates and deployment files, see "Understanding NetScaler Application Templates and Deployment Files". If you have configured NetScaler Gateway application, when you export the AppExpert configuration, you can choose to include the NetScaler Gateway policies in the template.

1. Navigate to AppExpert > Applications.
2. In the details pane, click the name of the application that you want to export as a template file, and then click Export.
3. In the Export...as Template dialog box, do the following:
   1. In the Name box, modify the name of the template, if necessary.
   2. If you want to configure variables for the template, click Configure Variables, and then, in the Configure Variables dialog box, configure the variables that you want.
      For more information about configuring variables in application templates, see "Creating Variables in Application Templates".
   3. If you want to export the template file to the application templates directory on the appliance, make sure that Browse (Appliance) is displayed.
   4. If you want to export the template file to your computer, click the Browse (Appliance) drop-down menu, click Local, browse to the location to which you want to save the file, and then click Save.
   5. Provide the following information:
      - **Introduction Description**—Any text that introduces the AppExpert application template during import. This text is displayed on the Specify Application Name page of the AppExpert Template Wizard when the template is imported.
      - **Summary Description**—Any summary that you might want to display on the Summary page of the AppExpert Template Wizard when the template is imported.
      - **Author**—The name of the author of the template.
      - **Major**—The major version number of the template.
      - **Minor**—The minor version number of the template. This number is appended to the major version number and displayed on the Summary page of the AppExpert Template Wizard, during import, in the format Major.Minor.
   6. Click OK.
      If NetScaler Gateway policies have been configured for the application, you will be prompted to include the NetScaler Gateway configuration in the application template. If you want to include the NetScaler Gateway configuration in the template, at the prompt, click Yes.

Exporting a Content Switching Virtual Server Configuration to a Template File

Aug 30, 2013

You can also export a content switching configuration as an application template. You can export a content switching virtual server configuration to an application template either from the Content Switching Virtual Servers pane or from the Content Switching Visualizer. Configuration information, which includes the content switching virtual server, all associated load balancing virtual servers, services, service groups, and policies, is exported to a template file and all deployment-specific information is exported to a deployment file. The string "_deployment" is automatically appended to the name of the template file to create the name of the deployment file. Both files are in XML format. If you choose to export the application template file to the NetScaler appliance, the template file is stored in the /nsconfig/nstemplates/applications directory on the NetScaler appliance and the deployment file is stored in the /nsconfig/nstemplates/applications/deployment_files/ directory. For more information about the format of application templates and deployment files, see "Understanding NetScaler Application Templates and Deployment Files." The configuration information that is exported includes the content switching virtual server, all associated load balancing virtual servers, services, service groups, and policies.

However, if the content switching virtual server is already configured as the public endpoint for an AppExpert application, you cannot export the configuration to a template file . In this scenario, you must export the associated AppExpert application to a template. For more information about exporting an AppExpert application to a template file, see "Exporting an AppExpert Application to a Template File."

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, click the name of the content switching virtual server whose configuration you want to export as a template file, and then click Visualizer.
3. In the Content Switching Visualizer, click the icon for the content switching vserver, click Related Tasks, and then click Create Template.
4. In the Export...as Template dialog box, enter a name for the template file, and then do one of the following:
   - To export the template file to the appliance, make sure that Browse (Appliance) is displayed.
   - To export the template file to your computer, click the Browse (Appliance) drop-down menu, click Local, browse to the location to which you want to save the file, and then click Save.
5. Provide the following information:
   - **Introduction Description**—Any text that introduces the AppExpert application template during import. This text is displayed on the Specify Application Name page of the AppExpert Template Wizard when the template is imported.
   - **Summary Description**—Any summary that you might want to display on the Summary page of the AppExpert Template Wizard when the template is imported.
   - **Author**—The name of the author of the template.
   - **Major**—The major version number of the template.
   - **Minor**—The minor version number of the template. This number is appended to the major version number and displayed on the Summary page of the AppExpert Template Wizard, during import, in the format `Major.Minor`.
6. Click OK.

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, click the name of the content switching virtual server whose configuration you want to export as a template file, and then click Create AppExpert Template.
3. Perform steps 4 through 6 described in "To export a content switching configuration to an application template file from the Content Switching Visualizer".

Creating Variables in Application Templates

Aug 30, 2013

Application templates support the declaration of variables in the policy expressions and actions that are configured for an application. The ability to declare variables in policy expressions and actions enables you to replace preconfigured values in expressions (for example, configurable parameters such as the host name of a server or the target for a Rewrite action) with values that suit the environment into which you are importing the template. If variables have been configured for an AppExpert application template, the AppExpert Template Wizard, which appears when you import an AppExpert application template, includes a Specify Variable Values page on which you can specify appropriate values for the variables that are configured for the template.

As an example, consider the following policy expression that is configured to evaluate the value of the Host header in an HTTP request:

```
HTTP.REQ.HEADER("Host").CONTAINS("server1")
```

If you want the server name to be configurable at import time, you can specify the string "server1" as a variable. When importing the template, you can specify a new value for the variable on the Variables tab.

After you create a variable, you can do the following:

- Assign additional strings to an existing variable. After you create a variable for a string, you can select and assign other parts of the same or different expression to the variable. The strings you assign to a variable need not be the same. At import time, all the strings that are assigned to the variable are replaced with the value that you provide.
- View the string or strings that are assigned to the variable.
- View a list of all the entities and parameters that use the variable.

In the export application template wizard, you can define variables in certain fields (fields with an adjacent  button) for the following entities:

- Cache policies
- Rewrite policies
- Rewrite actions
- Responder policies
- Responder actions

To configure a variable in a policy expression or action

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application that you want to export to a template file, and then click Export.
3. In the Export...as Template dialog box, modify the default template file name if required, specify the location where you want to save the template, and then click Configure Variables.
4. In the Configure Variables dialog box, click the tab that lists the policy expression or action for which you want to configure a variable, select the expression, and then click Configure Variables.
5. In the Variables dialog box, click the  button next to the expression or value in which you want to create a variable.
6. In the Variables dialog box, do the following:
   - To create a variable, in the text box that displays the configured expression or value, select the string that you want to be configurable at import time, and then click Add. In the Add Variable dialog box, specify a name and a description for the variable, and then click Create.

- The name of the variable, its value, and the description you provided appear in the Available Variables listing in the dialog box. The name you provide will be the name of the associated field in the template import wizard, and the description will appear as alt text when the user positions the mouse pointer over the field.
- To modify a variable, in the Available Variables list, click the variable, and then click Open. In the Add Variable dialog box, modify the value and the description, and then click OK.
- To view all the strings that are assigned to a given variable, in the Available Variables listing, click the name of the variable. The strings that are assigned to the variable are highlighted.
- To view a list of all the entities and parameters in which the variable is used, in the Available Variables listing, click the variable whose references you want to view, and then click Show References.
- To assign a string to an existing variable, in the text box that displays the expression you configured, select the string you want to assign to an existing variable, right-click the selection, click Use Existing Selection, and then click the name of the variable to which you want to assign the string.

  If a variable has multiple strings assigned to it, when you specify a new value for the variable during import, all strings assigned to the variable are replaced with the new value.

7. Click Close.

Uploading and Downloading Template Files

Aug 30, 2013

Template files can be uploaded from your local computer to the NetScaler appliance or downloaded from the appliance to your local computer. On the appliance, AppExpert application templates are always stored in the AppExpert application templates directory, which is /nsconfig/nstemplates/applications/.

To upload an AppExpert application template from your local computer to the NetScaler appliance

1. Navigate to AppExpert > Templates.
2. In the details pane, click Manage Templates.
3. In the Manage Application Templates dialog box, click Application Templates, and then click Upload.
4. In the Upload Application Template dialog box, browse to the directory in which the template file is stored, click the template file, and then click Select.
   The template file is uploaded to the AppExpert application template directory on the appliance.

To download an AppExpert application template from the NetScaler appliance to your local computer

1. Navigate to AppExpert > Templates.
2. In the details pane, click Manage Templates.
3. In the Manage Application Templates dialog box, click the AppExpert application template that you want to download, and click Download.
4. In the Download Application Template dialog box, browse to the location to which you want to save the file, and then click Save.

Understanding NetScaler Application Templates and Deployment Files

Mar 28, 2012

When you export a NetScaler application, the following two files are automatically created:

- **NetScaler application template file.** Contains application-configuration information such as application units, rules, and configured policies.
- **Deployment file.** Contains deployment-specific information such as public endpoints, services, associated IP addresses, and configured variables.

In the application template and deployment file, each unit of application-configuration information is encapsulated in a specific XML element that is meant for that unit type. For example, each public endpoint and associated endpoint details are encapsulated within the <appendpoint> and </appendpoint> tags, and all the endpoint elements are encapsulated within the <appendpoint_list> and </appendpoint_list> tags.
Note: After you export a NetScaler application, you can add elements, remove elements, and modify existing elements before importing the application to a NetScaler appliance.

Example of a NetScaler Application Template

Following is an example of a template file that was created from a NetScaler application called "SharePoint_Team_Site":

```
<?xml version="1.0" encoding="UTF-8" ?>
<template>
<template_info>
  <application_name>SharePoint_Team_Site</application_name>
  <templateversion_major>1</templateversion_major>
  <templateversion_minor>1</templateversion_minor>
  <author>Ed</author>
  <introduction>An application for managing a SharePoint team site with images, reports, and, XML content.</introduction>
  <summary>This template includes variables</summary>
  <version_major>9</version_major>
  <version_minor>3</version_minor>
  <build_number>38</build_number>
</template_info>
<apptemplate>
  <rewrite>
    <rewriteaction_list>
      <rewriteaction>
        <name>Rw_name</name>
        <type>replace</type>
        <target>HTTP.REQ.BODY(10000).AFTER_REGEX(re/number/).BEFORE_REGEX(re/address/)</target>
        <stringbuilderexpr>"NA"</stringbuilderexpr>
        <allow_unsafe_pi1>NO</allow_unsafe_pi1>
      </rewriteaction>
      <rewriteaction>
        .
        .
        .
      </rewriteaction>
      .
      .
      .
    </rewriteaction_list>
    <rewritepolicy_list>
      <rewritepolicy>
        <name>Rw_number_NA</name>
        <rule>HTTP.REQ.BODY(100000).CONTAINS("admin")</rule>
        <action>Rw_name</action>
      </rewritepolicy>
      <rewritepolicy>
```

```
      .
      .
      .
    </rewritepolicy>
    .
    .
    .
  </rewritepolicy_list>
</rewrite>
<appunit_list>
  <appunit>
    <name>SharePoint_Team_Sitedefault</name>
    <rule />
    <expressiontype>PE</expressiontype>
    <servicetype>HTTP</servicetype>
    <ipv46>0.0.0.0</ipv46>
    <ipmask>*</ipmask>
    <port>0</port>
    <range>1</range>
    <persistencetype>NONE</persistencetype>
    <timeout>2</timeout>
    <persistencebackup>NONE</persistencebackup>
    <backuppersistencetimeout>2</backuppersistencetimeout>
    <lbmethod>LEASTCONNECTION</lbmethod>
    <persistmask>255.255.255.255</persistmask>
    <v6persistmasklen>128</v6persistmasklen>
    <pq>OFF</pq>
    <sc>OFF</sc>
    <m>IP</m>
    <datalength>0</datalength>
    <dataoffset>0</dataoffset>
    <sessionless>DISABLED</sessionless>
    <state>ENABLED</state>
    <connfailover>DISABLED</connfailover>
    <clttimeout>180</clttimeout>
    <somethod>NONE</somethod>
    <sopersistence>DISABLED</sopersistence>
    <redirectportrewrite>DISABLED</redirectportrewrite>
    <downstateflush>DISABLED</downstateflush>
    <gt2gb>DISABLED</gt2gb>
    <ipmapping>0.0.0.0</ipmapping>
    <disableprimaryondown>DISABLED</disableprimaryondown>
    <insertvserveripport>OFF</insertvserveripport>

```

NetScaler Gateway Applications

May 21, 2015

When you configure an AppExpert application to manage a web application through the Citrix® NetScaler® appliance, you also create a set of application units and configure a set of traffic optimization and security policies for each unit. The policies that you configure for each application unit (policies for features such as Compression, Caching, and Rewrite) evaluate traffic that is meant only for that unit. In addition to these policies, you might want to configure Access Gateway policies for the application as a whole to optimize the application traffic when accessed through the Access Gateway. The Access Gateway Applications feature enables you to configure Access Gateway policies (Authorization, Traffic, Clientless Access, and TCP Compression) for an AppExpert application. After you configure NetScaler Gateway policies for AppExpert applications, you can include the policy configuration in the AppExpert application templates that you create.

You can also configure NetScaler Gateway policies for intranet subnets, file shares, and other network resources.

Finally, you can create bookmarks for AppExpert applications and certain resources if you want users to be able to access them from the NetScaler Gateway home page.

You can configure the entities in the NetScaler Gateway Applications feature only by using the configuration utility.

How an NetScaler Gateway Application Works

Updated: 2013-07-17

When you create an AppExpert application in the Applications node in the configuration utility, a corresponding Access Gateway application is automatically created in the Access Gateway Applications node. Additionally, a rule that uses the AppExpert application's configured public endpoint is automatically created for the Access Gateway application entry. If multiple endpoints are configured for the AppExpert application, the rule includes all the configured public endpoints. The NetScaler appliance uses this rule to apply any configured Access Gateway policies to the traffic received at the AppExpert application's public endpoint. Traffic received at the AppExpert application's public endpoint is first evaluated against the NetScaler Gateway policies and then evaluated against the policies configured for AppExpert application's application units.

The rule that is created for the Clientless Access policies for an Access Gateway application is an advanced expression that also uses the public endpoint that is configured for the AppExpert application. Therefore, before you configure NetScaler Gateway policies for an AppExpert application, you must configure public endpoints for the AppExpert application.

When you include the NetScaler Gateway configuration in an application template, deployment-specific information, such as IP address and port information, and the rule that is created from this information are not included in the template.

How a NetScaler Configuration for a File Share Works

On the NetScaler appliance, you can configure Authorization policies for a file share that is hosted on your organization's network.

When you create a file share, you specify a name for the file share and the network path to the file share. In the network path, you can specify either the name of the server or the server IP address. A rule that uses the components of the file share path is automatically created for the file share. This rule enables the appliance to identify requests for files hosted on the file share server. Any Authorization policies that are configured for the file share are applied to incoming requests.

The NetScaler configuration for a file share cannot be saved in AppExpert application templates.

How a NetScaler Configuration for an Intranet Subnet Works

For the intranet subnets that form a part of your network, you can configure policies for Authorization, Traffic, and TCP Compression on the NetScaler appliance. When adding an intranet subnet, you specify the IP address and the netmask of the intranet subnet. A rule that uses these two parameters is automatically created for the intranet subnet. The appliance applies the configured policies to any request that has a destination IP address and netmask set to the subnet's IP address and netmask, respectively.

The NetScaler configuration for an intranet subnet cannot be saved in AppExpert application templates.

How the Other Resources Category Works

Updated: 2013-07-18

The Other Resources category enables you to configure Access Gateway policies for any network resource by using a rule of your choice. When you configure the NetScaler appliance to process requests for the network resource, you configure a classic expression to identify the requests that are associated with the network resource. You can configure Authorization, Traffic, Clientless Access, and TCP Compression policies for a network resource in Other Resources. The NetScaler appliance applies the configured NetScaler Gateway policies to any requests that match the configured rule.

The NetScaler configuration for a network resource in Other Resources cannot be saved in AppExpert application templates.

Entity Naming Conventions

The NetScaler Gateway Applications feature enforces a naming convention for some of the entities that you create in this feature. For example, the names of the profiles that you create for Traffic policies for an intranet subnet always begin with a string that consists of the name of the intranet subnet followed by an underscore (_). The name that you provide for the entity is appended to this string. If the name of a subnet is "subnet1," the name of the profile begins with "subnet1_." When such a naming convention is required (in the text box in which you type the name of an entity, for example), the user interface automatically inserts the string with which the name of the entity must begin and does not allow you to modify it.

Adding File Shares

Mar 28, 2012

When creating a file share, you provide the network path to the file share. Any policies that you configure for a file share use the rule that is automatically created when you created the file share.

To configure a file share

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, click File Shares, and then do one of the following:
   - To add a file share, click File Shares, and then click Add.
   - To modify a file share, click File Shares, and then click Open.
3. In the Create File Share or Configure File Share dialog box, do the following:
   1. In the Name box, type a name for the file share you are adding. This parameter cannot be changed for an existing file share.
   2. In the Path box, type the path to the file share.
      The path to the file share may use either the name of the server or the IP address of the server.
   3. In Bookmark, in the Text to Display box, type a name for the file share as you would want it to appear on the Access Gateway home page.
   4. Click Create or OK, and then click Close.

Adding Intranet Subnets

Mar 28, 2012

You can specify authorization and Traffic policies for traffic that is bound for the intranet subnets that are configured in your network. The rules for these policies are automatically created by using the parameters you specify for the subnet.

To configure an intranet subnet

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, do one of the following:
   - To add an intranet subnet, click Intranet Subnets, and then click Add.
   - To modify an intranet subnet, click an intranet subnet, and then click Open.
3. In the Create Intranet Subnet or Configure Intranet Subnet dialog box, do the following:
   1. In the Name box, type a name for the intranet subnet you are adding. This parameter cannot be changed for an existing intranet subnet.
   2. In the IP Address box, type the IP address of the intranet subnet.
   3. In the Netmask box, type the netmask that will be used for the intranet subnet.
   4. Click Create or OK, and then click Close.

Adding Other Resources

Jul 17, 2013

For a network resource that you add to Other Resources, you must configure a classic expression that identifies the subset of traffic associated with the resource. For more information about configuring a classic expression, see the Policy Configuration and Reference.

To configure a resource in Other Resources

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, do one of the following:
   - To add a resource, click Other Resources, and then click Add.
   - To modify a resource, click a resource, and then click Open.
3. In the Create Resource or Configure Resource dialog box, do the following:
   1. In the Name box, type a name for the resource you are adding. This parameter cannot be changed for an existing resource.
   2. In the Rule box, type the rule that will identify the subset of traffic that is associated with the resource you are adding.
      Alternatively, click Configure, and then create the rule in the Create Expression dialog box.
   3. Click Create or OK, and then click Close.

Configuring Authorization Policies

Mar 28, 2012

You can configure NetScaler Gateway authorization policies for AAA users and groups to access a resource.

To configure permissions for a AAA user or group to access a resource

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, in the Authorization column, click the icon for the application, file share, intranet subnet, or resource for which you want to configure authorization policies for AAA users and groups.
3. Do one of the following:
   - If the AAA user or group for which you want to configure permissions is already in the Groups/Users tree, drag the user or group from the Groups/Users tree to the Users or Groups node in the <application name> tree. Then, right-click the user or group and click Allow.
   - If the AAA user or group for which you want to configure permissions is not configured on the appliance, in the <application name> tree, right-click Users or Groups, and then click Add. In the Create AAA Group or Create AAA User dialog box, fill in the values, click Create, and then click Close.

     The user or group is created with the permission set to Allow. To change the permission setting, right-click the group or user, and then click the permission setting.
4. Click Close.

Configuring Traffic Policies

Dec 16, 2013

The traffic policies that you configure for the resources in the NetScaler Gateway Applications node control client connections to the application. You do not have to configure a rule for the resource. The rule created automatically when you create the resource. You only need to associate a request profile with the traffic policy. In the traffic profile, you specify parameters such as the protocol, application time-out, and file type association.

To configure traffic policies for a resource

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, in the Traffic column, click the icon provided for the application, file share, intranet subnet, or resource for which you want to configure traffic policies.
3. In the Configure Traffic Policies dialog box, do the following:
   - To specify an existing traffic policy, click Insert Policy, and then, in the Policy Name column, click the name of the policy.
   - To configure a new policy, click Insert Policy, and then, in the Policy Name column, click New Policy. In the Create Traffic Policy dialog box, in the Name box, after the underscore (_), type a name for the policy. Then, in Request Profile, either select an existing request profile or click New to configure a new request profile. You can also select an existing profile and then click Modify to modify the profile.

     For more information about configuring a traffic policy or profile, see NetScaler Gateway , Enterprise Edition at http://edocs.citrix.com/.

   - To modify a policy that you have inserted, in the Policy Name column, click the policy name, and then click Modify Policy. To modify only the associated profile, in the Profile column, click the name of the profile, and then click Modify Profile.
   - To regenerate the priorities assigned to the policies, click Regenerate Priorities.
   - To specify a new priority value for a policy, in the Priority column, double-click the assigned priority, and then enter the value you want.
   - To unbind a policy, click the policy, and then click Unbind Policy.
4. Click Apply Changes, and then click Close.

Configuring Clientless Access Policies

Dec 16, 2013

Clientless access, when configured for a resource on the NetScaler appliance, allows end-users to access the resource without using the NetScaler Gateway client software. Users can use web browsers to access resources such as Outlook Web Access. You configure clientless access for a resource by configuring a clientless access policy that is associated with a clientless access profile.

To configure a clientless access policy for a resource in the NetScaler Gateway Applications node

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, in the Clientless Access column, click the icon for the application, file share, intranet subnet, or resource for which you want to configure a clientless access policy.
3. In the Configure Clientless Access Policies dialog box, do the following:
   - To specify an existing clientless access policy, click Insert Policy, and then, in the Policy Name column, click the name of the policy.
   - To configure a new clientless access policy, click Insert Policy, and then, in the Policy Name column, click New Policy. In the Create Clientless Access Policy dialog box, in the Name box, after the underscore (_), type a name for the policy. Then, in Profile, either select an existing profile or click New to configure a new profile. You can also select an existing profile and then click Modify to modify the profile.

     For more information about configuring a clientless access policy or profile, see NetScaler Gateway , Enterprise Edition at http://edocs.citrix.com/.

   - To modify a policy that you have inserted, in the Policy Name column, click the policy name, and then click Modify Policy. To modify only the associated profile, in the Profile column, click the name of the profile, and then click Modify Profile.
   - To specify a new priority value for a policy, in the Priority column, double-click the assigned priority, and then enter the value you want.
   - To unbind a policy, click the policy, and then click Unbind Policy.
4. Click Apply Changes, and then click Close.

Configuring TCP Compression Policies

Dec 16, 2013

You can configure TCP compression policies for an application to increase the performance of the application. TCP compression reduces network latency, reduces bandwidth requirements, and increases the speed of transmission. When configuring a TCP compression policy, you associate a compression action with the policy. The compression action specifies either Compress, GZIP, Deflate, or NoCompress as the compression type. For more information about the compression policies, and compression actions, see NetScaler Gateway , Enterprise Edition at http://edocs.citrix.com/.

To configure a TCP compression policy for a resource in the NetScaler Gateway Applications node

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, in the TCP Compression column, click the icon for the application, file share, intranet subnet, or resource for which you want to configure a TCP compression policy.
3. In the Configure TCP Compression Policies dialog box, do the following:
   - To specify an existing TCP compression policy, click Insert Policy, and then, in the Policy Name column, click the name of the policy.
   - To create a new TCP compression policy, click Insert Policy, and then, in the Policy Name column, click New Policy. In the Create TCP Compression Policy dialog box, in the Policy Name box, after the underscore ("_"), type a name for the policy. Then, in Action, either select an existing action or click New and configure a new action. You can also click View to view the configured compression type.

     For more information about configuring a TCP compression policy or action, see NetScaler Gateway , Enterprise Edition at http://edocs.citrix.com/.

   - To modify a policy that you have inserted, in the Policy Name column, click the policy name, and then click Modify Policy.
   - To regenerate the priorities assigned to the policies, click Regenerate Priorities.
   - To specify a new priority value for a policy, in the Priority column, double-click the assigned priority, and then enter the value you want.
   - To unbind a policy, click the policy, and then click Unbind Policy.
4. Click Apply Changes, and then click Close.

Configuring Bookmarks

Dec 16, 2013

You can configure bookmarks for an application or for a resource that you configure in the Other Resources category if you want the application or resource to be accessible from the NetScaler Gateway home page.

To configure a bookmark for an NetScaler Gateway application or a resource in the Other Resources category

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, click the application or resource for which you want to configure a bookmark, and then click Configure Bookmark.
3. In the Create Bookmark dialog box, configure values for the parameters.
   For more information about the parameters in the Create Bookmark dialog box, see NetScaler Gateway , Enterprise Edition at http://edocs.citrix.com/.
4. Click Create, and then click Close.

AppQoE

Jan 07, 2014

Application level Quality of Experience (AppQoE) integrates several existing policy-based security features of the NetScaler appliance into a single integrated feature that takes advantage of a new queuing mechanism, fair queuing. Fair queuing manages requests to load-balanced web servers and applications at the virtual server level instead of at the service level, allowing it to handle queuing of all requests to a web site or application as one group before load balancing, instead of as separate streams after load balancing.

The features that are integrated into AppQoE are HTTP Denial-of-Service Protection (HDOSP), Priority Queuing (PQ), and SureConnect. Collectively these services provide protection against a number of problems:

- **Simple overload.** Any server, no matter how robust, can accept only a limited number of connections at one time. When a protected web site or application receives too many requests at once, the Surge Protection feature detects the overload and queues the excess connections til the server can accept them. The Priority Queuing feature ensures that whoever most needs access to a resource is provided access without having to wait behind other lower-priority requests. The SureConnect feature displays an alternate web page that notifies users that the resource that they requested is not available.
- **Denial-of-Service (DOS) attacks.** Any public-facing resource is vulnerable to attacks whose purpose is to bring that service down and deny legitimate users access to it. The Surge Protection, Priority Queuing, and SureConnect features help manage DOS attacks as well as other types of high load. In addition, the HTTP Denial-of-Service Protection feature targets DOS attacks against your web sites, sending challenges to suspected attackers and dropping connections if the clients do not send an appropriate response.

Until the current version of the NetScaler operating system, these features were implemented at the service level, which means that each service was assigned its own queues. While service-level queues work, they also have some disadvantages, most of which are due to the NetScaler appliance having to load balance requests before implementing any of the protection features that rely on queuing. Implementing protection features before queuing has a number of advantages, some of which are listed below:

- Absolute priority of connections as configured in the priority queuing feature can be maintained.
- Connections are not flushed if a service transitions state, as they are in a service-level queue.
- During periods of high load, such as a denial-of-service attack, HTTP DoS and SureConnect come into play before load balancing, allowing these features to detect and divert unwanted or lower-priority traffic from the load balancer before the load balancer must cope with it.

In addition to implementing fair queuing, AppQoE integrates a set of features that each provide a different set of tools to achieve a common goal: protecting your networked resources from excessive or inappropriate demand. Putting these features into a common framework enables you to configure and implement them more easily.

Enabling AppQoE

Apr 20, 2013

To configure AppQoE, you must first enable the feature.

To enable AppQoE by using the command line

At the command prompt, type the following commands:

- enable ns feature appqoe
- show ns feature

Example

```
> enable ns feature appqoe
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)    Web Logging              WL              ON
 2)    Surge Protection          SP              ON
 3)    Load Balancing           LB              ON
...
29)   AppQoE                   AppQoE           ON
 Done
```

To enable AppQoE by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, click Configure Advanced Features.
3. In the Configure Advanced Features dialog box, select the AppQoE check box.
4. Click OK.

AppQOE Actions

Oct 02, 2014

After enabling the AppQoE feature, you must configure one or more actions for handling requests.

Important: No specific individual parameters are required to create an action, but you must include at least one parameter or you cannot create the action.

To configure an AppQoE action by using the command line

At the command prompt, type the following commands:

- add appqoe action <name> [-priority <priority>] [-respondWith (ACS | NS) [<customfile>] [-altContentSvcName <string>] [-altContentPath <string>] [-maxConn <positive_integer>] [-delay <usecs>] [-polqDepth <positive_integer>] [-priqDepth <positive_integer>] [-dosTrigExpression <expression>] [-dosAction (SimpleResponse | HICResponse)]
- show appqoe action

Example

To configure priority queuing with policy queue depths of 10 and 1000 for medium and lowest priority queues, respectively:

```
> add appqoe action appqoe-act-basic-prhigh -priority HIGH
 Done

> add appqoe action appqoe-act-basic-prmedium -priority MEDIUM -polqDepth 10
 Done

> add appqoe action appqoe-act-basic-prlow -priority LOW -polqDepth 1000
 Done

> show appqoe action
1)     Name: appqoe-act-basic-prhigh
       ActionType: PRIORITY_QUEUING
       Priority: HIGH
       PolicyQdepth: 0
       Qdepth: 0

2)     Name: appqoe-act-basic-prmedium
       ActionType: PRIORITY_QUEUING
       Priority: MEDIUM
       PolicyQdepth: 10
       Qdepth: 0

3)     Name: appqoe-act-basic-prlow
       ActionType: PRIORITY_QUEUING
       Priority: LOW
       PolicyQdepth: 1000
       Qdepth: 0
Done
```

To modify an existing AppQoE action by using the command line

At the command prompt, type the following commands:

- set appqoe action <name> [-priority <priority>] [-altContentSvcName <string>] [-altContentPath <string>] [-polqDepth <positive_integer>] [-priqDepth <positive_integer>] [-maxConn <positive_integer>] [-delay <usecs>] [-dosTrigExpression <expression>] [-dosAction (SimpleResponse | HICResponse)]
- show appqoe action

To remove an AppQoE action by using the command line

At the command prompt, type the following commands:

- rm appqoe action <name>
- show appqoe action

Parameters for configuring an AppQoE action

name

A name for the new action, or the name of the existing action that you want to modify. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols.

priority

The priority queue to which the request is assigned. When a protected web server or application is heavily loaded and cannot accept additional requests, specifies the order in which waiting requests are to be fulfilled when resources are available. The choices are:

1. **HIGH.** Fulfills the request as soon as resources are available.
2. **MEDIUM.** Fulfills the request after it has fulfilled all requests in the HIGH priority queue.
3. **LOW.** Fulfills the request after it has fulfilled all requests in the HIGH and MEDIUM priority queues.
4. **LOWEST.** Fulfills the request only after it has fulfilled all requests in higher-priority queues.

If priority is not configured, then the NetScaler appliance assigns the request to the LOWEST priority queue by default.

respondWith

Configures the NetScaler ADC to take the specified Responder action when the specified threshold is reached. Must be used with one of the following settings:

- **ACS:** Serves content from an alternate content service. Threshold: maxConn (maximum connections) or delay.
- **NS:** Serves a built-in response from the NetScaler ADC. Threshold: maxConn (maximum connections) or delay.
- **NO ACTION:** Serves no alternative content. Assigns connections to the LOWEST priority queue if the maxConn (maximum connections) or delay threshold is reached.

altContentSvcName

If -responseWith ACS is specified, the name of the alternative content service, usually an absolute URL to the web server that hosts the alternate content.

altContentPath

If -responseWith (ACS | NS) is specified, the path to the alternative content.

polqDepth

Policy queue depth threshold value for the policy queue associated with this action. When the number of connections in the policy queue associated with this action increases to the specified number, subsequent requests are assigned to the LOWEST policy queue. Minimum value: 1 Maximum value: 4,294,967,294

priqDepth

Policy queue depth threshold value for the specified priority queue. If the number of requests in the specified queue on the virtual server to which the policy associated with the current action is bound increases to the specified number, subsequent requests are assigned to the LOWEST priority queue. Minimum value: 1 Maximum value: 4,294,967,294

maxConn

The maximum number of connections that can be open for requests that match the policy rule. Minimum value: 1 Maximum value: 4,294,967,294

delay

The delay threshold, in microseconds, for requests that match the policy rule. If a matching request has been delayed for longer than the threshold, the NetScaler appliance performs the specified action. If NO ACTION is specified, then the appliance assigns requests to the LOWEST priority queue. Minimum value: 1 Maximum value: 599999,999

dosTrigExpression

Adds an optional second-level check to trigger DoS actions.

dosAction

Action to take when the ADC determines that it or a protected server is under DoS attack. Possible values: SimpleResponse, HICResponse

To configure an AppQoE action by using the configuration utility

1. Navigate to App-Expert > AppQoE > Actions.
2. In the details pane, do one of the following:
   - To create a new action, click Add.
   - To modify an existing action, select the action, and then click Edit.
3. In the Create AppQoE Action or the Configure AppQoE Action screen, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring the AppQoE Action" as follows (asterisk indicates a required parameter):
   - Name—name
   - Action type—respondWith
   - Priority—priority
   - Policy Queue Depth—polqDepth
   - Queue Depth—priqDepth
   - DOS Action—dosAction
4. Click Create or OK.

AppQoE Parameters

Oct 02, 2014

In the AppQoE parameters, you configure the session life of an AppQoE session, the file name of the file containing the customized response, and the number of client connections that can be placed in a queue.

To configure the AppQoE parameter settings by using the command line

At the command prompt, type the following commands:

- set appqoe parameter [-sessionLife <secs>] [-avgwaitingclient <positive_integer>] [-MaxAltRespBandWidth <positive_integer>] [-dosAttackThresh <positive_integer>]
- show appqoe parameter

Parameters for configuring the AppQoE parameters

sessionLife

Number of seconds to wait after displaying alternate content before the ADC displays the same content again. Default value: 300 Maximum Minimum value: 1 Maximum value: 4,294,967,294

avgwaitingclient

The average number of client requests that can be in the service waiting queue. Default value: 1000000 Maximum value: 4,294,967,294

MaxAltRespBandWidth

The maximum bandwidth to consume when sending alternate responses. If the maximum is reached, the ADC quits sending the alternate content til bandwidth consumption drops. Default value: 100 Minimum value: 1 Maximum value: 4,294,967,294

dosAtckThrsh

The denial-of-service attack threshold. The number of connections that must be waiting in queues before the ADC responds with DoS protection measures. Default value: 2000 Minimum value: 0 Maximum value: 4,294,967,294

To configure the AppQoE parameter settings by using the configuration utility

1. Navigate to AppExpert > AppQoE.
2. In the details pane, click Configure AppQoE Parameters.
3. In the Configure AppQoE params screen, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring the AppQoE Parameters" as follows (asterisk indicates a required parameter):
   - Session Life (secs)—sessionLife
   - Average waiting client—avgwaitingclient
   - Alternate Response Bandwidth Limit(Mbps) —MaxAltRespBandWidth
   - DOS Attack Threshold —dosAttackThresh
4. Click OK.

AppQoE Policies

Oct 02, 2014

To implement AppQoE, you must configure at least one policy to tell your NetScaler ADC how to distinguish the connections to be queued in a specific queue.

To configure an AppQoE policy by using the command line

At the command prompt, type the following command:
add appqoe policy <name> -rule <expression> -action <string>
Example

The following example selects requests with a User-Agent header that contains "Android", and assigns them to the medium priority queue. These requests come from smartphones and tablets that run the Google Android operating system.

```
> add appqoe action appqoe-act-primd -priority MEDIUM
Done
> add appqoe policy appqoe-pol-primd -rule "HTTP.REQ.HEADER(\"User-Agent\").CONTAINS(\"Android\")" -action appqoe-act-primd
Done
> sh appqoe policy appqoe-pol-primd
      Name: appqoe-pol-primd
      Rule: HTTP.REQ.HEADER("User-Agent").CONTAINS("Android")
      Action: appqoe-act-primd
      Hits: 0

Done
```

Parameters for configuring an AppQoE policy

name

A name for the AppQoE policy. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should chose a name that helps identify the type of action.

rule

A NetScaler expression that tells the appliance which connections it should handle. For complete information about policy expressions, see the *Citrix NetScaler Policy Configuration and Reference Guide* at .

action

The AppQoE action to perform when a connection matches the policy.

To configure an AppQoE policy by using the configuration utility

1. Navigate to App-Expert > AppQoE > Policies.
2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Edit.
3. If you are creating a new policy, in the Create AppQoE Policy dialog, in the Name text box, type a name for your new policy.
   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should chose a name that helps identify the purpose and effect of this policy.

   If you are modifying an existing policy, skip this step. You cannot change the name of an existing policy.

4. In the Action drop-down list, choose the AppQoE action to perform when the policy matches a connection. Click the plus (+) to open the Add AppQoE Action dialog and add a new action.
5. In the Rule text box, either enter the policy expression directly, or click New to create a policy expression. If you click New, perform the following steps:
   1. In the Create Expression dialog box, click Add.
   2. In the Add Expression dialog box, select a common expression from the Frequently Used Expressions drop-down list, or use the Construct Expression drop-down lists to create the expression that defines which traffic to filter.
      If you choose to create your own expression, you start by selecting the first term from the first drop-down list on the left side of the Construct

Expression area. The choices in that list are:

- HTTP: All traffic to port 80 and port 443.
- SYS:
- CLIENT:
- SERVER:
- ANALYTICS:
- TEXT:

The default choice is HTTP. After you make a choice in the first drop-down list (or accept the default), you can choose the next term in your expression from the drop-down list to the right of it. The terms in that list and other lists that follow change depending on your previous choices; the lists offer only terms that are valid choices. Continue to select terms until you have finished the expression.

Use the Help and Preview Expression areas for assistance when creating the expression. For a complete description of the available choices, see the *Citrix NetScaler Policy Configuration and Reference Guide* at .

3. When you have created the expression that you want, click OK. The expression is added in the Expression text box.

6. Click Create. The expression appears in the Rule text box.

Entity Templates

May 21, 2015

An entity template is a collection of configuration information for an individual entity on a Citrix® NetScaler® appliance. It provides a specification and a set of defaults for a configurable NetScaler entity, such as a policy, virtual server, service, or action. By using a template that defines a set of defaults, you can quickly configure multiple entities that require a similar configuration while eliminating several configuration steps.

Entity templates are available only in the configuration utility. You use the NetScaler configuration utility to create, manage, and use any type of entity template. You can share entity templates with other administrators and manage local folders that contain the templates. You can also import entity templates from and export entity templates to your local computer.

Before creating a template, you should be familiar with the configuration of the entity.

Note: You use entity templates to configure individual entities. To configure multiple entities related to a particular Web application, you must use an application template. For more information, see "AppExpert Applications and Templates."

How Entity Templates Work

When you create a template for a NetScaler entity, you specify default values for the entity. You specify what values must be read-only, what values must not be displayed, and what values users can configure. You also configure the pages that compose the template import wizard. All the information and settings you provide are stored in the template file.

When a user imports the entity template to a NetScaler appliance, a wizard guides the user through the various pages that you configured for the template. The wizard displays the read-only parameter values and prompts the user to specify values for the configurable parameters. After the user follows the instructions in the wizard, the appliance creates the entity with the configured values.

For example, you can create an entity template for HTTP services that provides a text box for a service name and assigns preset values for the service protocol, timeouts, thresholds, and monitors. Later, when you use the template to create new HTTP services, a wizard prompts you for a service name and supplies the preset values that you would otherwise have configured manually.

The procedure for creating entity templates for load balancing virtual servers is different than the AppExpert procedure for creating other entity templates. For more information, see "Creating an Entity Template."

In addition, the procedure for using the template to create the load balancing virtual server entity is different. For more information, see "Creating an Entity from a Template."

Configuring an Entity Template

Mar 28, 2012

You can create or modify an entity template either from the AppExpert feature node or from the associated NetScaler feature node for the entity. For example, you can create a content switching virtual server entity template in either the AppExpert feature node or the content switching feature node in the configuration utility.

If you create a template that is not based on an existing entity, you can specify the following options and settings for the template:

- The default value of a parameter.
- Whether the default values are visible to users.
- Whether the default values can be changed by users.
- The number of pages in the entity import wizard, including the page names, text, and available parameters.
- The entities that must be bound to the entity for which the template is being created.

  For example, when you are creating a cache redirection virtual server template, you can specify the policies that you want to bind to the cache redirection virtual servers that you create from the template. However, only binding information is included in the template. The bound entities are not included. If the entity template is imported to another NetScaler appliance, the bound entities must exist on the appliance at import time for the binding to succeed. If none of the bound entities exist on the target appliance, the entity (for which the template was configured) is created without any bindings. If only a subset of the bound entities exist on the target appliance, they are bound to the entity that is created from the template.

When you create a template based on an existing entity, the configuration settings of the entity appear in the template. All bound entities are selected by default, but you can modify bindings as necessary. As in the case of a template that is not based on an existing entity, only binding information is included and not the entities. You can either save the template with the existing configuration settings or use the settings as a basis for creating a new configuration for a template.

Creating an Entity Template

Aug 30, 2013

You can create entity templates in either the AppExpert node or the NetScaler feature node that corresponds to the type of entity. For example, you can create a content switching virtual server template from the entity templates tab of the AppExpert feature's Templates node or in the Content Switching node. You can also specify the parameters that you want the template to store, and specify whether you want the template import wizard to prompt the user for certain parameter values.

However, when creating load balancing virtual servers, you do not have the option of specifying parameter values that you want stored in the template. You create a load balancing virtual server template by selecting an existing load balancing virtual server and configuring any variables that you might want to create in existing parameters and bound policies. The variables can be assigned values when you create a load balancing virtual server from the template. The template stores load balancing parameters such as the virtual server's IP address and port number, bound policies, actions, and variable definitions. A deployment file is also created, automatically, from the load balancing configuration. The deployment file stores deployment-specific information, such as information about bound services, service groups, and the name-value pairs of variables. If the bound entities that are included in the template are already configured on the NetScaler appliance to which the template is imported, duplicates are created, with names that are generated automatically in a particular format. The duplicate entities are based on the parameter information stored in the entity template.

When you create a load balancing virtual server template from the AppExpert node, the template is always saved to the /nsconfig/nstemplates/entities/lb vserver/ folder. If you want to save the template to a different folder, create the template from the Virtual Servers pane in the Load Balancing node. The deployment file is created with the name with which you save the template file, but with the string _deployment appended to the name. The deployment file is saved to the /nsconfig/nstemplates/entities/lb vserver/deployment_files/ folder. For more information about deployment files for load balancing virtual server templates, see "Understanding Load Balancing Entity Templates and Deployment Files."

Note: You can use either of the first two procedures for creating any template, except for a load balancing virtual server template. For creating a load balancing virtual server template, use the third or fourth procedure.

To create an entity template by using the AppExpert feature node

1. Navigate to AppExpert > Templates.
2. In the details pane, on the Entity Templates tab, do one of the following:
   - To create a new template, click Add. In the Select the Template Type dialog box, select the template type, and then click OK.
   - To create a duplicate of an existing entity template, in the details pane, select the entity template, and then click Add.
3. In the Create...Template dialog box, follow the instructions to create a template.
   If you are creating a duplicate of an existing entity template, in the Create...Template dialog box, on the Specify Template Name page, you must change the name of the entity template.
4. Click Finish, and then click Exit.

To create an entity template by using its corresponding feature node

1. Navigate to Traffic Management, and select the feature (for example, Content Switching), and then select the entity (for example, Virtual Servers), for which you want to create the entity template.
2. At the top of the details pane, click Entity Templates, and then click Create Template.

3. In the Create...Template dialog box, follow the instructions to create a template.
4. Click Finish, and then click Exit.

To create a load balancing virtual server template from the AppExpert node

1. Navigate to AppExpert > Templates.
2. In the details pane, on the LB Templates tab, click Add.
3. In the Select Load Balancing Virtual Server dialog box, select the load balancing virtual server whose configuration you want to save to a template file, and then click OK.
4. In the Create Template dialog box, provide the following information:
   - Name. The name of the template.
     Note: The Folder field shows the location to which the template will be saved. You cannot modify the path that is displayed.
   - Configure Variables. Configure variables for the load balancing template. For more information, see "Configuring Variables in Load Balancing Virtual Server Templates."
   - Introduction Description. A description of the virtual server for which you are creating a template.
   - Summary Description. A summary of the configuration or additional instructions for other administrators, such as a description of any additional steps that need to be followed after the entity is successfully created.
   - Author. The creator of the template.
   - Major. An optional major version number of your choice, to be specified if you want to maintain versions of your template.
   - Minor. An optional minor version number of your choice, to be specified if you want to maintain minor versions of your template.
     You can maintain versions by incrementing one or both of the version numbers each time you maintain the template. The Entity Template Wizard concatenates and displays the major and minor version numbers during import. For example, if the major version number is 1 and the minor version is 1, the Entity Template Wizard displays a version number of 1.1.
5. Click OK.

To create a load balancing virtual server template from the Load Balancing Virtual Servers pane

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server on which to base the template,, and then click Create Template. You might have to click the scroll arrow at the bottom right of the pane to bring the Create Template button into view.
3. In the Create Template dialog box, provide the following information:
   - Name. The name of the template.
   - Folder. The location to which the template will be saved.
     Note: If you want to save the template to the appliance, you can save it only to the `/nsconfig/nstemplates/entities/lb vserver/` directory (the path displayed by default in Folder. If you want to save the template file to a folder on your computer, click the down-arrow on the Browse button, click Local, and then select a folder.
   - Configure Variables. Configure variables for the load balancing template. For more information, see "Configuring Variables in Load Balancing Virtual Server Templates."
   - Introduction Description. A description of the virtual server for which you are creating a template.
   - Summary Description. A summary of the configuration or additional instructions for other administrators, such as a description of any additional steps that need to be followed after the entity is successfully created.
   - Author. The creator of the template.

- Major. An optional major version number of your choice, to be specified if you want to maintain versions of your template.
- Minor. An optional minor version number of your choice, to be specified if you want to maintain minor versions of your template.
  You can maintain versions by incrementing one or both of the version numbers each time you maintain the template. The Entity Template Wizard concatenates and displays the major and minor version numbers during import. For example, if the major version number is 1 and the minor version is 1, the Entity Template Wizard displays a version number of 1.1.

4. Click OK.

Configuring Variables in Load Balancing Virtual Server Templates

Aug 30, 2013

Load balancing virtual server templates support the declaration of variables in the configured load balancing parameters and in bound policies and actions. The ability to declare variables enables you to replace preconfigured values with values that suit the environment into which you are importing the template. The Entity Template Wizard, which appears when you import a template, includes a Specify Variable Values page on which you can specify appropriate values for the variables that are configured for the entity template. This wizard page appears only when you import a template that is configured with existing variables.

As an example, consider the following expression configured for a policy that is bound to a load balancing virtual server for which you are creating a template. The expression evaluates the value of the Accept-Language header in an HTTP request.

```
HTTP.REQ.HEADER("Accept-Language").CONTAINS("en-us")
```

If you want the value of the header to be configurable at import time, you can specify the string en-us as a variable. When importing the template, you can specify a new value for the variable on the Specify Variable Values page.

After you create a variable, you can do the following:

- Assign additional strings to an existing variable. After you create a variable for a string, you can select and assign other parts of the same or different expression to the variable. The strings you assign to a variable need not be the same. At import time, all the strings that are assigned to the variable are replaced with the value that you provide.
- View the string or strings that are assigned to the variable.
- View a list of all the entities and parameters that use the variable.

To configure variables in a load balancing virtual server template

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, right-click the virtual server that you want to export to a template file, and then click Create Template.
3. In the Create Template dialog box, modify the default template file name if required, specify the location where you want to save the template, and then click Configure Variables.
4. In the Configure Variables dialog box, click the tab that lists the entity for which you want to configure a variable, select the entity, and then click Configure Variables.
5. In the Variables for <Entity Type>: <Entity Name> dialog box, click the  button next to the parameter value or expression in which you want to create a variable.
6. In the Variables for <Field Name> dialog box, do the following:
   - To create a variable, in the text box that displays the configured expression or value, select the string that you want to be configurable at import time, and then click Add. In the Create Variable dialog box, specify a name and a description for the variable, and then click Create.

     The name of the variable, its value, and the description you provided appear in the Available Variables listing in the dialog box. The name you provide will be the name of the associated field in the template import wizard, and the description will appear as alt text when the user positions the mouse pointer over the field.

   - To modify a variable, in the Available Variables list, click the variable, and then click Open. In the Create Variable dialog

box, modify the value and the description, and then click OK.

The new value that you specify will not replace the text selected in the text box that displays the configured expression or value. However, when you import the template, the new value will be displayed as the default value for the variable in the template import wizard.

- To view all the strings that are assigned to a given variable, in the Available Variables listing, click the name of the variable. The strings that are assigned to the variable are highlighted.
- To view a list of all the parameters, expressions, and actions in which the variable is used, in the Available Variables listing, click the variable whose references you want to view, and then click Show References.
- To assign a string to an existing variable, in the text box that displays the expression you configured, select the string you want to assign to an existing variable, right-click the selection, click Use existing Variable, and then click the name of the variable to which you want to assign the string.

  If a variable has multiple strings assigned to it, when you specify a new value for the variable during import, all strings assigned to the variable are replaced with the new value.

7. Click Close.

Modifying an Entity Template

Aug 30, 2013

You can modify only the parameters, bindings, and pages configured for a template. The name and location of the template specified when the template was created cannot be changed. The NetScaler appliance does not provide you with the option of modifying a load balancing virtual server template.

To modify an entity template by using the AppExpert feature node

1. Navigate to AppExpert > Templates.
2. In the details pane, on the Entity Templates tab, select the template you want to change, and then click Open.
3. In the Modify...Template dialog box, follow the instructions to modify a template.
4. Click Finish, and then click Exit.

To modify an entity template by using its corresponding feature node

1. Navigate to Traffic Management, select the feature (for example, Content Switching), and then select the entity (for example, Virtual Servers) for which you want to modify the entity template.
2. At the top of the details pane, click Entity Templates, and then click Manage Template.
3. In the Manage <feature entity name> Entity Templates dialog box, select the template that you want to modify, and then click Modify.
4. In the Modify <template name> Template dialog box, follow the instructions to modify a template.
5. Click Finish, and then click Exit.
6. Click Close.

Deleting an Entity Template

Aug 30, 2013

Deleting an entity template does not affect any objects that have been created by using the template. You can delete a load balancing virtual server template only from the AppExpert feature node.

To delete an entity template by using the AppExpert feature node

1. Navigate to AppExpert > Templates.
2. In the details pane, on the Entity Templates tab, click the template you want to delete, and then click Remove.

To delete an entity template by using its corresponding feature node

1. Navigate to Traffic Management, and select the feature (for example, Content Switching) and then select the entity (for example, Virtual Servers), for which you want to delete the entity template.
2. At the top of the details pane, click Entity Templates, and then click Manage Template.
3. In the Manage...Entity Templates dialog box, select the template that you want to delete, and then click Delete.

Creating an Entity from a Template

Aug 30, 2013

You can create an entity from an entity template either from the AppExpert feature node in the NetScaler configuration utility or from the NetScaler feature node that corresponds to the type of entity that you want to create. For example, you can create a content switching virtual server from a template with either the AppExpert feature node or the content switching feature node in the configuration utility.

The procedure for creating a load balancing virtual server from a template is different than the AppExpert procedure for creating other entities from templates.

After you create an instance of an entity using an entity template, you can configure it in the same way that you would any other object of that type, such as by using the configuration utility or the command line.

To create an entity from a template by using the AppExpert feature node

1. Navigate to AppExpert > Templates.
2. In the details pane, do one of the following:
   1. To create any entity other than a load balancing virtual server from a template, on the Entity Templates tab, click the template that you want to use, and then click Use Template.
   2. To create a load balancing virtual server from a template, on the LB Templates tab, click the template that you want to use, and then click Use Template.
3. In the <Entity Template Name> wizard, follow the instructions to create the entity on the NetScaler.
4. Click Finish, and then click Exit.

To create an entity from a template by using its corresponding feature node

1. Navigate to Traffic Management, and expand a feature node (for example, Content Switching), and then click an entity subnode (for example, Virtual Servers).
2. At the top of the details pane, click Entity Templates, and then click Use Template.
3. Click the name of the template that you want to use.
4. In the Use <template name> Template wizard, follow the instructions to create the entity.
   Only templates that match the current context are displayed. For example, in the details pane for content switching virtual servers, only entity templates for content switching virtual servers appear, if configured.
5. Click Finish, and then click Exit.

To create a load balancing virtual server by using a load balancing virtual server template

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Use Template.
3. In the Entity Template Wizard, follow the instructions to create a load balancing virtual server on the NetScaler.
   Only templates that match the current context are displayed. For example, when you click Browse (Appliance), only entity templates for load balancing virtual servers appear, if configured.
4. Click Finish, and then click Exit.
   Note: The Entity Template Wizard includes a Specify Variable Values page on which you can specify new values for variables. For more information about configuring variables in load balancing virtual server templates, see "Configuring Variables in Load Balancing Virtual Server Templates."

Managing Entity Template Folders

Aug 30, 2013

You can organize only load balancing virtual server template folders.

To organize load balancing virtual server template folders

1. Navigate to AppExpert > Templates > LB Templates.
2. In the Manage LB Templates dialog box, do one of the following:
   - To change the name of a folder, select the folder and click Rename.

     You can also click the folder that you want to rename, and then press F2. You cannot rename the top-level default folder.

   - To remove the folder, select the folder and click Delete.

     You can also click the folder that you want to remove, and then press the Delete key. You cannot remove the top-level default folder.
3. Click Close.

Uploading and Downloading Entity Templates

Aug 30, 2013

You can import the entity templates that are stored on your local computer. You can also download entity templates from the NetScaler appliance to your local computer and then import them to other NetScaler appliances.

Note: You cannot upload or download load balancing virtual server templates.

To upload an entity template to the NetScaler appliance

1. Navigate to Traffic Management, and expand a feature node (for example, Content Switching), and then click a subnode (for example, Virtual Servers) for which you want to upload an entity template.
2. At the top of the details pane, click Entity Templates, and then click Manage Template.
3. In the Manage...Entity Templates dialog box, click the top-level folder, and then click Upload.
4. In the Upload Entity Template dialog box, navigate to the template file that you want to upload, and then click Select.
5. Click Close.

To download an entity template from the NetScaler appliance

1. Navigate to Traffic Management, and expand a feature node (for example, Content Switching), and then click a subnode (for example, Virtual Servers) for which you want to upload an entity template.
2. At the top of the details pane, click Entity Templates, and then click Manage Template.
3. In the Manage...Entity Templates dialog box, click the template that you want to download, and then click Download.
4. In the Download Entity Template dialog box, navigate to the location at which you want to save the template on your local computer, enter a file name, and then click Save.
5. Click Close.

Understanding Load Balancing Entity Templates and Deployment Files

Mar 28, 2012

Load balancing entity templates are created in the same way that NetScaler application templates are created. When you export a load balancing virtual server to a template file, the following two files are automatically created:

- **Load balancing virtual server template file.** Contains XML elements that store the values of the parameters that are configured for the load balancing virtual server. The file also contains XML elements for storing information about bound policies.
- **Deployment file.** Contains XML elements that store deployment-specific information such as services, service groups, and configured variables.

In the template and deployment files, each unit of configuration information is encapsulated in a specific XML element that is meant for that unit type. For example, the load balancing method parameter, lbMethod, is encapsulated within the <lbmethod> and </lbmethod> tags.

Note: After you export a load balancing virtual server, you can add elements, remove elements, and modify existing elements before importing the configuration information to a NetScaler appliance.

Example of a Load Balancing Virtual Server Template

Following is an example of a template file that was created from a load balancing virtual server called "Lbvip":

```
<?xml version="1.0" encoding="UTF-8" ?>
 <template>
  <template_info>
   <entity_name>Lbvip</entity_name>
   <version_major>10</version_major>
   <version_minor>0</version_minor>
   <build_number>40.406</build_number>
  </template_info>
  <entitytemplate>
   <lbvserver_list>
    <lbvserver>
     <name>Lbvip</name>
     <servicetype>HTTP</servicetype>
     <ipv46>0.0.0.0</ipv46>
     <ipmask>*</ipmask>
     <port>0</port>
     <range>1</range>
     <persistencetype>NONE</persistencetype>
     <timeout>2</timeout>
     <persistencebackup>NONE</persistencebackup>
     <backuppersistencetimeout>2</backuppersistencetimeout>
     <lbmethod>LEASTCONNECTION</lbmethod>
     <persistmask>255.255.255.255</persistmask>
     <v6persistmasklen>128</v6persistmasklen>
     <pq>OFF</pq>
```

```
        <sc>OFF</sc>
        <m>IP</m>
        <datalength>0</datalength>
        <dataoffset>0</dataoffset>
        <sessionless>DISABLED</sessionless>
        <state>ENABLED</state>
        <connfailover>DISABLED</connfailover>
        <clttimeout>180</clttimeout>
        <somethod>NONE</somethod>
        <sopersistence>DISABLED</sopersistence>
        <sopersistencetimeout>2</sopersistencetimeout>
        <redirectportrewrite>DISABLED</redirectportrewrite>
        <downstateflush>DISABLED</downstateflush>
        <gt2gb>DISABLED</gt2gb>
        <ipmapping>0.0.0.0</ipmapping>
        <disableprimaryondown>DISABLED</disableprimaryondown>
        <insertvserveripport>OFF</insertvserveripport>
        <authentication>OFF</authentication>
        <authn401>OFF</authn401>
        <push>DISABLED</push>
        <pushlabel>none</pushlabel>
        <l2conn>OFF</l2conn>
        <appflowlog>DISABLED</appflowlog>
        <icmpvsrresponse>PASSIVE</icmpvsrresponse>
        <lbvserver_cmppolicy_binding_list>
          <lbvserver_cmppolicy_binding>
            <name>Lbvip</name>
            <policyname>NOPOLICY-COMPRESSION</policyname>
            <priority>100</priority>
            <gotopriorityexpression>END</gotopriorityexpression>
            <bindpoint>REQUEST</bindpoint>
          </lbvserver_cmppolicy_binding>
        </lbvserver_cmppolicy_binding_list>
      </lbvserver>
    </lbvserver_list>
  </entitytemplate>
 </template>
```

Example of a Deployment File

Following is the deployment file associated with the virtual server in the preceding example:

```
<?xml version="1.0" encoding="UTF-8" ?>
 <template_deployment>
  <template_info>
   <entity_name>Lbvip</entity_name>
   <version_major>10</version_major>
   <version_minor>0</version_minor>
   <build_number>40.406</build_number>
  </template_info>
```

```
  <service_list>
   <service>

```

HTTP Callouts

Jan 11, 2013

For certain types of requests, or when certain criteria are met during policy evaluation, you might want to stall policy evaluation briefly, retrieve information from a server, and then perform a specific action that depends on the information that is retrieved. At other times, when you receive certain types of requests, you might want to update a database or the content hosted on a Web server. HTTP callouts enable you to perform all these tasks.

An HTTP callout is an HTTP or HTTPS request that the NetScaler appliance generates and sends to an external application when certain criteria are met during policy evaluation. The information that is retrieved from the server can be analyzed by default syntax policy expressions, and an appropriate action can be performed. You can configure HTTP callouts for HTTP content switching, TCP content switching, rewrite, responder, and for the token-based method of load balancing.

Before you configure an HTTP callout, you must set up an application on the server to which the callout will be sent. The application, which is called the *HTTP callout agent* , must be configured to respond to the HTTP callout request with the required information. The HTTP callout agent can also be a Web server that serves the data for which the NetScaler appliance sends the callout. You must make sure that the format of the response to an HTTP callout does not change from one invocation to another.

After you set up the HTTP callout agent, you configure the HTTP callout on the NetScaler appliance. Finally, to invoke the callout, you include the callout in a default syntax policy in the appropriate NetScaler feature and then bind the policy to the bind point at which you want the policy to be evaluated.

After you have configured the HTTP callout, you must verify the configuration to make sure that the callout is working correctly.

How an HTTP Callout Works

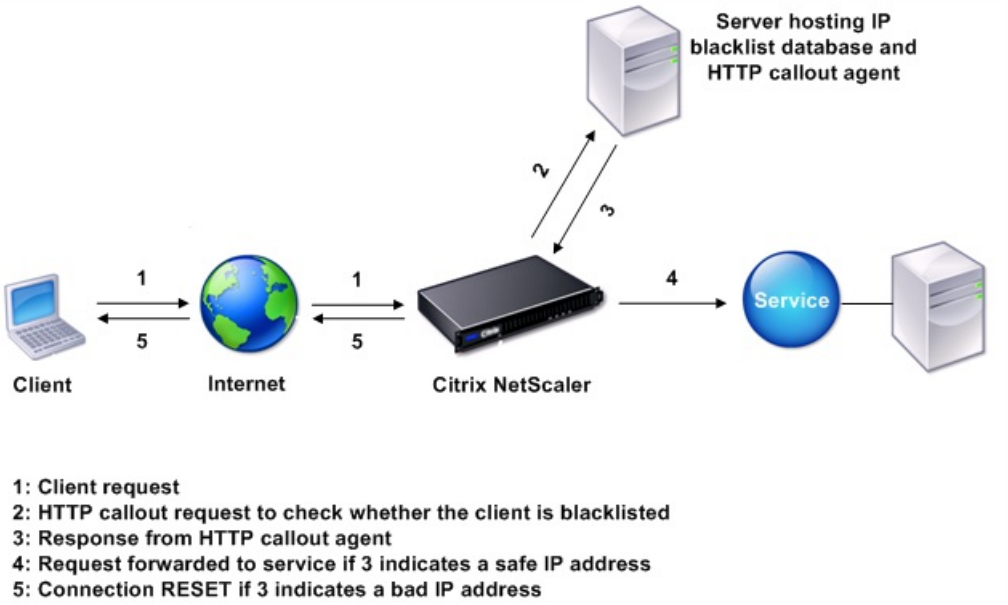
Jan 11, 2013

When the NetScaler appliance receives a client request, the appliance evaluates the request against the policies bound to various bind points. During this evaluation, if the appliance encounters the HTTP callout expression, SYS.HTTP_CALLOUT(<name>), it stalls policy evaluation briefly and sends a request to the HTTP callout agent by using the parameters configured for the specified HTTP callout. Upon receiving the response, the appliance inspects the specified portion of the response, and then either performs an action or evaluates the next policy, depending on whether the evaluation of the response from the HTTP callout agent evaluates to TRUE or FALSE, respectively. For example, if the HTTP callout is included in a responder policy, if the evaluation of the response evaluates to TRUE, the appliance performs the action associated with the responder policy.

If the HTTP callout configuration is incorrect or incomplete, or if the callout invokes itself recursively, the appliance raises an UNDEF condition, and updates the undefined hits counter.

The following figure illustrates the working of an HTTP callout that is invoked from a globally bound responder policy. The HTTP callout is configured to include the IP address of the client that is associated with an incoming request. When the NetScaler appliance receives a request from a client, the appliance generates the callout request and sends it to the callout server, which hosts a database of blacklisted IP addresses and an HTTP callout agent that checks whether the client's IP address is listed in the database. The HTTP callout agent receives the callout request, checks whether the client's IP address is listed, and sends a response that the NetScaler appliance evaluates. If the response indicates that the client's IP address is not blacklisted, the appliance forwards the response to the configured service. If the client's IP address is blacklisted, the appliance resets the client connection

Figure 1. HTTP Callout Entity Model



Notes on the Format of HTTP Requests and Responses

May 21, 2015

The NetScaler appliance does not check for the validity of the HTTP callout request. Therefore, before you configure HTTP callouts, you must know the format of an HTTP request. You must also know the format of an HTTP response, because configuring an HTTP callout involves configuring expressions that evaluate the response from the HTTP callout agent.

This document includes the following details:

- Format of an HTTP Request
- Format of an HTTP Response

Format of an HTTP Request

An HTTP request contains a series of lines that each end with a carriage return and a line feed, represented as either <CR><LF> or \r\n.

The first line of a request (the *message line*) contains the HTTP method and target. For example, a message line for a GET request contains the keyword GET and a string that represents the object that is to be fetched, as shown in the following example:

```
GET /mysite/mydirectory/index.html HTTP/1.1\r\n
```

The rest of the request contains HTTP headers, including a required Host header and, if applicable, a message body.

The request ends with a bank line (an extra <CR><LF> or \r\n).

Following is an example of a request:

```
Get /mysite/index.html HTTP/1.1\r\n
Host: 10.101.101.10\r\n
Accept: */*\r\n
\r\n
```

Format of an HTTP Response

An HTTP response contains a status message, response HTTP headers, and the requested object or, if the requested object cannot be served, an error message.

Following is an example of a response:

```
HTTP/1.1 200 OK\r\n
Content-Length: 55\r\n
Content-Type: text/html\r\n
Last-Modified: Wed, 12 Aug 1998 15:03:50 GMT\r\n
Accept-Ranges: bytes\r\n
ETag: “04f97692cbd1:377”\r\n
Date: Thu, 19 Jun 2008 19:29:07 GMT\r\n
\r\n
```

<55-character response>

Configuring an HTTP Callout

Dec 17, 2013

When configuring an HTTP callout, you specify the type of request (HTTP or HTTPS), destination and format of the request, the expected format of the response, and, finally, the portion of the response that you want to analyze.

For the destination, you either specify the IP address and port of the HTTP callout agent or engage a load balancing, content switching, or cache redirection virtual server to manage the HTTP callout requests. In the first case, the HTTP callout requests will be sent directly to the HTTP callout agent. In the second case, the HTTP callout requests will be sent to the virtual IP address (VIP) of the specified virtual server. The virtual server will then process the request in the same way as it processes a client request. For example, if you expect a large number of callouts to be generated, you can configure instances of the HTTP callout agent on multiple servers, bind these instances (as services) to a load balancing virtual server, and then specify the load balancing virtual server in the HTTP callout configuration. The load balancing virtual server then balances the load on those configured instances as determined by the load balancing algorithm.

For the format of the HTTP callout request, you can specify the individual attributes of the HTTP callout request (an attribute-based HTTP callout), or you can specify the entire HTTP callout request as a default syntax expression (an expression-based HTTP callout).
Note: The appliance does not check for the validity of the request. You must make sure that the request is a valid request. An incorrect or incomplete HTTP callout configuration results in a runtime UNDEF condition that is not associated with an action. The UNDEF condition merely updates the Undefined Hits counter, which enables you to troubleshoot an incorrectly configured HTTP callout. However, the appliance parses the HTTP callout request to enable you to configure certain NetScaler features for the callout. This can lead to an HTTP callout invoking itself. For information about callout recursion and how you can avoid it, see "Avoiding HTTP Callout Recursion."
Finally, regardless of whether you use HTTP request attributes or an expression to define the format of the HTTP callout request, you must specify the format of the response from the HTTP callout agent and the portion of the response that you want to evaluate. The response can be a Boolean value, a number, or text. The portion of the response that you want to evaluate is specified by an expression. For example, if you specify that the response contains text, you can use HTTP.RES.BODY(<unit>) to specify that the appliance must evaluate only the first <unit> bytes of the response from the callout agent.

At the command line, you first create an HTTP callout by using the add command. When you add a callout, all parameters are set to a default value of NONE, except the HTTP method, which is set to a default value of GET. You then configure the callout's parameters by using the set command. The set command is used to configure both types of callouts (attribute-based and expression-based). The difference lies in the parameters that are used for configuring the two types of callouts. Accordingly, the command-line instructions that follow include a set command for configuring an attribute-based callout and a set command for configuring an expression-based callout. In the configuration utility, all of these configuration tasks are performed in a single dialog box.
Note: Before you put an HTTP callout into a policy, you can modify all configured parameters except the return type. Once an HTTP callout is in a policy, you cannot completely modify an expression that is configured in the callout. For example, you cannot change HTTP.REQ.HEADER("myval") to CLIENT.IP.SRC. However, you can modify the operators and arguments that are passed to the expression. For example, you can change HTTP.REQ.HEADER("myVal1") to HTTP.REQ.HEADER("myVal2"), or HTTP.REQ.HEADER("myVal") to HTTP.REQ.HEADER("myVal").AFTER_STR(<string>). If the set command fails, create a new HTTP callout.
HTTP callout configuration involves configuring default syntax expressions. For more information about configuring default syntax expressions, see "Configuring Default Syntax Expressions: Getting Started."

To configure an HTTP callout by using the command line interface

At the command prompt, do the following:

1. Create a HTTP callout.
   add policy httpCallout <name>

   Example
   > add policy httpCallout mycallout
2. Configure the details of the HTTP callout.
   - To configure an attribute-based HTTP callout, type:
     set policy httpCallout <name> [-IPAddress <ip_addr|ipv6_addr|*>] [-port <port|*>] [-vServer <string>] [-returnType <returnType>] [-httpMethod (GET | POST)] [-hostExpr <string>] [-urlStemExpr <string>] [-headers <name(value)> ...] [-parameters <name(value)> ...] [-resultExpr <string>]

Example

```
> set policy httpCallout mycallout -vserver lbv1 -returnType num -httpMethod GET -hostExpr 'http.req.header("Host")'
-urlStemExpr "http.req.url" -parameters Name("My Name") -headers Name("MyHeader")
-resultExpr "http.res.body(10000).length"
```

- To configure an expression-based HTTP callout, type:
  set policy httpCallout <name> [-vServer <string>] [-returnType <returnType>] [-httpMethod (GET | POST)] [-fullReqExpr <string>] [-resultExpr <string>]

Example

```
> set policy httpCallout mycallout1 -vserver lbv1 -returnType num -httpMethod GET
-fullReqExpr q{"GET " + http.req.url + "HTTP/" + http.req.version.major + "." + http.req.version.minor.sub(1)+
"r\nHost:10.101.10.10\r\nAccept: */*\r\n\r\n"}
```

3. Verify the configurations of the HTTP callout.
   show policy httpCallout <name>

To configure an HTTP callout by using the configuration utility

1. Navigate to AppExpert > HTTP Callouts.
2. In the details pane, click Add.
3. In the Create HTTP Callout dialog box, configure the parameters of the HTTP callout. For a description of the parameter, hover the mouse cursor over the check box.
4. Click Create and then click Close.

Verifying the Configuration

Aug 30, 2013

For an HTTP callout to work correctly, all the HTTP callout parameters and the entities associated with the callout must be configured correctly. While the NetScaler appliance does not check the validity of the HTTP callout parameters, it indicates the state of the bound entities, namely the server or virtual server to which the HTTP callout is sent. The following table lists the icons and describes the conditions under which the icons are displayed.

Table 1. Icons That Indicate the States of Entities Bound to an HTTP Callout

Icon	Indicates that
	The state of the server that hosts the HTTP callout agent, or the load balancing, content switching, or cache redirection virtual server to which the HTTP callout is sent is UP.
	The state of the server that hosts the HTTP callout agent, or the load balancing, content switching, or cache redirection virtual server to which the HTTP callout is sent is OUT OF SERVICE.
	The state of the server that hosts the HTTP callout agent, or the load balancing, content switching, or cache redirection virtual server to which the HTTP callout is sent is DOWN.

For an HTTP callout to function correctly, the icon must be green at all times. If the icon is not green, check the state of the callout server or virtual server to which the HTTP callout is sent. If the HTTP callout is not working as expected even though the icon is green, check the parameters configured for the callout.

You can also verify the configuration by sending test requests that match the policy from which the HTTP callout is invoked, checking the hits counter for the policy and the HTTP callout, and verifying the responses that the NetScaler appliance sends to the client.

Note: An HTTP callout can sometimes invoke itself recursively a second time. If this happens, the hits counter is incremented by two counts for each callout that is generated by the appliance. For the hits counter to display the correct value, you must configure the HTTP callout in such a way that it does not invoke itself a second time. For more information about how you can avoid HTTP callout recursion, see "Avoiding HTTP Callout Recursion."

To view the hits counter for an HTTP callout

1. Navigate to AppExpert > HTTP Callouts.
2. In the details pane, click the HTTP callout for which you want to view the hits counter, and then view the hits in the Details area.

Invoking an HTTP Callout

Aug 30, 2013

After you configure an HTTP callout, you invoke the callout by including the SYS.HTTP_CALLOUT(<name>) expression in a default syntax policy rule. In this expression, <name> is the name of the HTTP callout that you want to invoke.

You can use default syntax expression operators with the callout expression to process the response and then perform an appropriate action. The return type of the response from the HTTP callout agent determines the set of operators that you can use on the response. If the part of the response that you want to analyze is text, you can use a text operator to analyze the response. For example, you can use the CONTAINS(<string>) operator to check whether the specified portion of the response contains a particular string, as in the following example:

```
SYS.HTTP_CALLOUT(mycallout).contains("Good IP address")
```

If you use the preceding expression in a responder policy, you can configure an appropriate responder action.

Similarly, if the part of the response that you want to evaluate is a number, you can use a numeric operator such as GT(int). If the response contains a Boolean value, you can use a Boolean operator.

Note: An HTTP callout can invoke itself recursively. HTTP callout recursion can be avoided by combining the HTTP callout expression with a default syntax expression that prevents recursion. For information about how you can avoid HTTP callout recursion, see "Avoiding HTTP Callout Recursion."

You can also cascade HTTP callouts by configuring policies that each invoke a callout after evaluating previously generated callouts. In this scenario, after one policy invokes a callout, when the NetScaler appliance is parsing the callout before sending the callout to the callout server, a second set of policies can evaluate the callout and invoke additional callouts, which can in turn be evaluated by a third set of policies, and so on. Such an implementation is described in the following example.

First, you could configure an HTTP callout called myCallout1, and then configure a responder policy, Pol1, to invoke myCallout1. Then, you could configure a second HTTP callout, myCallout2, and a responder policy, Pol2. You configure Pol2 to evaluate myCallout1 and invoke myCallout2. You bind both responder policies globally.

To avoid HTTP callout recursion, myCallout1 is configured with a unique custom HTTP header called "Request1." Pol1 is configured to avoid HTTP callout recursion by using the default syntax expression, HTTP.REQ.HEADER(\"Request1\").EQ(\"Callout Request\").NOT.

Pol2 uses the same default syntax expression, but excludes the .NOT operator so that the policy evaluates myCallout1 when the NetScaler appliance is parsing it. Note that myCallout2 identifies its own unique header called "Request2," and Pol2 includes a default syntax expression to prevent myCallout2 from invoking itself recursively.

Example

```
> add policy httpCallout myCallout1

Done

> set policy httpCallout myCallout1 -IPAddress 10.102.3.95 -port 80 -returnType TEXT -hostExpr
 "\"10.102.3.95\"" -urlStemExpr "\"/cgi-bin/check_clnt_from_database.pl\"" -headers Request1
("Callout Request") -parameters cip(CLIENT.IP.SRC) -resultExpr "HTTP.RES.BODY(100)"

Done
```

> add responder policy Pol1 "HTTP.REQ.HEADER(\"Request1\").EQ(\"Callout Request\").NOT && SYS.HTTP_CALLOUT(myCallout1).CONTAINS(\"IP Matched\")" RESET

Done

> bind responder global Pol1 100 END -type OVERRIDE

Done

> add policy httpCallout myCallout2

Done

> set policy httpCallout myCallout2 -IPAddress 10.102.3.96 -port 80 -returnType TEXT -hostExpr "\"10.102.3.96\"" -urlStemExpr "\"/cgi-bin/check_clnt_location_from_database.pl\"" -headers Request2 ("Callout Request") -parameters cip(CLIENT.IP.SRC) -resultExpr "HTTP.RES.BODY(200)"

Done

> add responder policy Pol2 "HTTP.REQ.HEADER(\"Request2\").EQ(\"Callout Request\").NOT && HTTP.REQ.HEADER(\"Request1\").EQ(\"Callout Request\") && SYS.HTTP_CALLOUT(myCallout2).CONTAINS (\"APAC\")" RESET

Done

> bind responder global Pol2 110 END -type OVERRIDE

Done

Avoiding HTTP Callout Recursion

Apr 03, 2013

Even though the NetScaler appliance does not check for the validity of the HTTP callout request, it parses the request once before it sends the request to the HTTP callout agent. This parsing allows the appliance to treat the callout request as any other incoming request, which in turn allows you to configure several useful NetScaler features (such as integrated caching, SureConnect, and Priority Queuing) to work on the callout request.

However, during this parsing, the HTTP callout request can hit the same policy and therefore invoke itself recursively. The appliance detects the recursive invocation and raises an undefined (UNDEF) condition. However, the recursive invocation results in the policy and HTTP callout hit counters being incremented by two counts each instead of one count each.

To prevent a callout from invoking itself, you must identify at least one unique characteristic of the HTTP callout request, and then exclude all requests with this characteristic from being processed by the policy rule that invokes the callout. You can do so by including another default syntax expression in the policy rule. The expression must precede the SYS.HTTP_CALLOUT(<name>) expression so that it is evaluated before the callout expression is evaluated. For example:

<Expression that prevents callout recursion> && SYS.HTTP_CALLOUT(<name>)

When you configure a policy rule in this way, when the appliance generates the request and parses it, the compound rule evaluates to FALSE, the callout is not generated a second time, and the hit counters are incremented correctly.

One way by which you can assign a unique characteristic to an HTTP callout request is to include a unique custom HTTP header when you configure the callout. Following is an example of an HTTP callout called "myCallout." The callout generates an HTTP request that checks whether a client's IP address is present in a database of blacklisted IP addresses. The callout includes a custom header called "Request," which is set to the value "Callout Request." A globally bound responder policy, "Pol1," invokes the HTTP callout but excludes all requests whose Request header is set to this value, thus preventing a second invocation of myCallout. The expression that prevents a second invocation is HTTP.REQ.HEADER(\"Request\").EQ(\"Callout Request\").NOT.

Example

```
> add policy httpCallout myCallout
 Done

> set policy httpCallout myCallout -IPAddress 10.102.3.95 -port 80 -returnType TEXT -hostExpr "\"10.102.3.95\"" -urlStemExpr "\"/cgi-bin/check_clnt_from_database.pl\"" -h
Done

> add responder policy Pol1 "HTTP.REQ.HEADER(\"Request\").EQ(\"Callout Request\").NOT && SYS.HTTP_CALLOUT(myCallout).CONTAINS(\"IP Matched\")" RESET
Done

> bind responder global Pol1 100 END -type OVERRIDE
Done
```

Note: You can also configure an expression to check whether the URL of the request includes the URL stem expression that is configured for the HTTP callout. If you want to implement this scenario, make sure that the HTTP callout agent is dedicated to respond only to HTTP callouts and not to other client requests directed through the appliance. If the HTTP callout agent is an application or Web server that serves other client requests, such an expression will prevent the appliance from processing those client requests. Instead, use a unique custom header as described earlier.

Caching HTTP Callout Responses

Apr 03, 2013

For improved performance while using callouts, you can use the integrated caching feature to cache callout responses. The responses are stored in an integrated caching content group named calloutContentGroup for a specified time duration.

Note: To cache callout responses, make sure that the integrated caching feature is enabled.

To set the cache duration by using the command line interface

At the command prompt, type:

set policy httpCallout <name> -cacheForSecs <secs>

Example

```
> set httpcallout httpcallout1 -cacheForSecs 120
```

To set the cache duration by using the configuration utility

1. Navigate to AppExpert > HTTP Callouts.
2. In the details pane, select the HTTP callout for which you want to set the cache duration and click Open.
3. In the Configure HTTP Callout dialog box, specify the Cache Expiration Time.
4. Verify that you have entered the correct time duration, and then click OK.

Use Case: Filtering Clients by Using an IP Blacklist

May 21, 2015

HTTP callouts can be used to block requests from clients that are blacklisted by the administrator. The list of clients can be a publicly known blacklist, a blacklist that you maintain for you organization, or a combination of both.

The NetScaler appliance checks the IP address of the client against the pre-configured blacklist and blocks the transaction if the IP address has been blacklisted. If the IP address is not in the list, the appliance processes the transaction.

To implement this configuration, you must perform the following tasks:

1. Enable responder on the NetScaler appliance.
2. Create an HTTP callout on the NetScaler appliance and configure it with details about the external server and other required parameters.
3. Configure a responder policy to analyze the response to the HTTP callout, and then bind the policy globally.
4. Create an HTTP callout agent on the remote server.

Enabling Responder

Updated: 2013-08-30

You must enable responder before you can use it.

To enable responder by using the configuration utility

1. Make sure that you have installed the responder license.
2. In the configuration utility, expand AppExpert, and right-click Responder, and then click Enable Responder feature.

Creating an HTTP Callout on the NetScaler Appliance

Updated: 2013-08-30

Create an HTTP callout, HTTP-Callout-1, with the parameter settings shown in the following table. For more information about creating an HTTP callout, see "Configuring an HTTP Callout."

Table 1. Parameters and Values for HTTP-Callout-1

Parameter	Value
Name	HTTP-Callout-1
Server to receive callout request	
IP Address	10.103.9.95
Port	80
Request to send to the server	
Method	GET
Host Expression	10.102.3.95
URL Stem Expression	"/cgi-bin/check_clnt_from_database.pl"
Headers	
Name	Request
Value-expression	Callout Request

Parameters Parameter	Value
Name	Cip
Value-expression	CLIENT.IP.SRC
Server Response	
Return Type	TEXT
Expression to extract data from the response	HTTP.RES.BODY(100)

Configuring a Responder Policy and Binding it Globally

Updated: 2013-08-30

After you configure the HTTP callout, verify the callout configuration, and then configure a responder policy to invoke the callout. While you can create a responder policy in the Policies sub-node and then bind it globally by using the Responder Policy Manager, this demonstration uses the Responder Policy Manager to create the responder policy and bind the policy globally.

To create a responder policy and bind it globally by using the configuration utility

1. Navigate to AppExpert > Responder.
2. In the details pane, under Policy Manager, click Policy Manager.
3. In the Responder Policy Manager dialog box, click Override Global.
4. Click Insert Policy, and then, under Policy Name, click New Policy.
5. In the Create Responder Policy dialog box, do the following:
   1. In Name, type Policy-Responder-1.
   2. In Action, select RESET.
   3. In Undefined-Result Action, select Global undefined-result action.
   4. In Expression, type the following default syntax expression:
      "HTTP.REQ.HEADER(\"Request\").EQ(\"Callout Request\").NOT && SYS.HTTP_CALLOUT(HTTP-Callout-1).CONTAINS(\"IP Matched\")"
   5. Click Create, and then click Close.
6. Click Apply Changes, and then click Close.

Creating an HTTP Callout Agent on the Remote Server

You must now create an HTTP callout agent on the remote callout server that will receive callout requests from the NetScaler appliance and respond appropriately. The HTTP callout agent is a script that is different for each deployment and must be written with the server specifications in mind, such as the type of database and the scripting language supported.

Following is a sample callout agent that verifies whether the given IP address is part of an IP blacklist. The agent has been written in the Perl scripting language and uses a MYSQL database.

The following CGI script checks for a given IP address on the callout server.

```
#!/usr/bin/perl -w
print "Content-type: text/html\n\n";
      use DBI();
      use CGI qw(:standard);
#Take the Client IP address from the request query
      my $ip_to_check = param('cip');
# Where a MYSQL database is running
      my $dsn = 'DBI:mysql:BAD_CLIENT:localhost';
# Database username to connect with
      my $db_user_name = ‘dbuser’;
# Database password to connect with
      my $db_password = 'dbpassword';
      my ($id, $password);
# Connecting to the database
      my $dbh = DBI->connect($dsn, $db_user_name, $db_password);
```

```
      my $sth = $dbh->prepare(qq{ select * from bad_clnt });
      $sth->execute();
      while (my ($ip_in_database) = $sth->fetchrow_array()) {
      chomp($ip_in_database);
# Check for IP match
      if ($ip_in_database eq $ip_to_check) {
           print "\n IP Matched\n";
           $sth->finish();
           exit;
       }
      }
      print "\n IP Failed\n";
      $sth->finish();
      exit;
```

Use Case: ESI Support for Fetching and Updating Content Dynamically

May 21, 2015

Edge Side Includes (ESI) is a markup language for edge-level dynamic Web content assembly. It helps in accelerating dynamic Web-based applications by defining a simple markup language to describe cacheable and non-cacheable Web page components that can be aggregated, assembled, and delivered at the network edge. By using HTTP callouts on the NetScaler appliance, you can read through the ESI constructs and aggregate or assemble content dynamically.

To implement this configuration, you must perform the following tasks:

1. Enable rewrite on the NetScaler appliance.
2. Create an HTTP callout on the appliance and configure it with details about the external server and other required parameters.
3. Configure a rewrite action to replace the ESI content with the callout response body.
4. Configure a rewrite policy to specify the conditions under which the action is performed, and then bind the rewrite policy globally.

Enabling Rewrite

Updated: 2013-08-30

Rewrite must be enabled before it is used on the NetScaler appliance. The following procedure describes the steps to enable the rewrite feature.

To enable rewrite by using the configuration utility

1. Make sure that you have installed the rewrite license.
2. In the configuration utility, expand AppExpert, and right-click Rewrite, and then click Enable Rewrite feature.

Creating an HTTP Callout on the NetScaler Appliance

Updated: 2013-08-30

Create an HTTP callout, HTTP-Callout-2, with the parameter settings shown in the following table. For more information about creating an HTTP callout, see "Configuring an HTTP Callout."

Table 1. Parameters and Values for HTTP-Callout-2

Parameter	Value
Name	HTTP-Callout-2
Server to receive callout request	
IP Address	10.102.56.51
Port	80

Parameter	Value
Request to send to the server	
Method	GET
Host Expression	10.102.56.51:80
URL Stem Expression	"HTTP.RES.BODY(500).AFTER_STR(\"src=\").BEFORE_STR(\"/>\")"
Headers	
Name	Name
Value-expression	Callout
Server Response	
Return Type	TEXT
Expression to extract data from the response	HTTP.RES.BODY(100)

Configuring the Rewrite Action

Updated: 2013-08-30

Create a rewrite action, Action-Rewrite-1, to replace the ESI content with the callout response body. Use the parameter settings shown in the following table.

Table 2. Parameters and Values for Action-Rewrite-1

Parameter	Value
Name	Action-Rewrite-1
Type	Replace
Expression to choose target text reference	"HTTP.RES.BODY(500).AFTER_STR (\" <example>\").BEFORE_STR (\" </example>\")"
String expression for replacement text	"SYS.HTTP_CALLOUT(HTTP-Callout-2)"

To configure the rewrite action by using the configuration utility

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, click Add.
3. In the Create Rewrite Action dialog box, in Name, type Action-Rewrite-1.
4. In Type, select REPLACE.
5. In Expression to choose target text reference, type the following default syntax expression:
   "HTTP.RES.BODY(500).AFTER_STR(\"<example>\").BEFORE_STR(\"</example>\")"
6. In the String expression for replacement text, type the following string expression:
   "SYS.HTTP_CALLOUT(HTTP-Callout-2)"
7. Click Create, and then click Close.

Creating the Rewrite Policy and Binding it Globally

Updated: 2013-08-30

Create a rewrite policy, Policy-Rewrite-1, with the parameter settings shown in the following table. You can create a rewrite policy in the Policies subnode and then bind it globally by using the Rewrite Policy Manager. Alternatively, you can use the Rewrite Policy Manager to perform both these tasks simultaneously. This demonstration uses the Rewrite Policy Manager to perform both tasks.

Table 3. Parameters and Values for Policy-Rewrite-1

Parameter	Value
Name	Policy-Rewrite-1
Action	Action_Rewrite-1
Undefined Result Action	-Global undefined-result action-
Expression	"HTTP.REQ.HEADER(\"Name\").CONTAINS (\"Callout\").NOT"

To configure a rewrite policy and bind it globally by using the configuration utility

1. Navigate to AppExpert > Rewrite.
2. In the details pane, under Policy Manager, click Rewrite Policy Manager.
3. In the Rewrite Policy Manager dialog box, click Override Global.
4. Click Insert Policy, and then, in the Policy Name column, click New Policy.
5. In the Create Rewrite Policy dialog box, do the following:
   1. In Name, type Policy-Rewrite-1.
   2. In Action, select Action-Rewrite-1.
   3. In Undefined-Result Action, select Global undefined-result action.
   4. In Expression, type the following default syntax expression:
      "HTTP.REQ.HEADER(\"Name\").CONTAINS(\"Callout\").NOT"
   5. Click Create, and then click Close.
6. Click Apply Changes, and then click Close.

Use Case: Access Control and Authentication

May 21, 2015

In high security zones, it is mandatory to externally authenticate the user before a resource is accessed by clients. On the NetScaler appliance, you can use HTTP callouts to externally authenticate the user by evaluating the credentials supplied. In this example, the assumption is that the client is sending the user name and password through HTTP headers in the request. However, the same information could be fetched from the URL or the HTTP body.

To implement this configuration, you must perform the following tasks:

1. Enable the responder feature on the NetScaler appliance.
2. Create an HTTP callout on the appliance and configure it with details about the external server and other required parameters.
3. Configure a responder policy to analyze the response, and then bind the policy globally.
4. Create a callout agent on the remote server.

Enabling Responder

Updated: 2013-08-30

The responder feature must be enabled before it is used on the NetScaler appliance.

To enable responder by using the configuration utility

1. Make sure that the responder license is installed.
2. In the configuration utility, expand AppExpert, and right-click Responder, and then click Enable Responder feature.

Creating an HTTP Callout on the NetScaler Appliance

Updated: 2013-08-30

Create an HTTP callout, HTTP-Callout-3, with the parameter settings shown in the following table. For more information about creating an HTTP callout, see "Configuring an HTTP Callout."

Table 1. Parameters and Values for HTTP-Callout-3

Parameter	Value
Name	HTTP-Callout-3
Server to receive callout request	
IP Address	10.103.9.95
Port	80
Request to send to the server	
Method	GET
Host Expression	10.102.3.95
URL Stem Expression	"/cgi-bin/authenticate.pl"
Headers	
Name	Request
Value-expression	Callout Request
Parameters	
Name	Username
Value-expression	HTTP.REQ.HEADER("Username").VALUE(0)
Name	Password
Value-expression	HTTP.REQ.HEADER("Password").VALUE(0)

Parameter Server Response	Value
Return Type	TEXT
Expression to extract data from the response	HTTP.RES.BODY(100)

Creating a Responder Policy to Analyze the Response

Updated: 2013-08-30

Create a responder policy, Policy-Responder-3, that will check the response from the callout server and RESET the connection if the source IP address has been blacklisted. Create the policy with the parameters settings shown in the following table. While you can create a responder policy in the Policies subnode and then bind it globally by using the Responder Policy Manager, this demonstration uses the Responder Policy Manager to create the responder policy and bind the policy globally.

Table 2. Parameters and Values for Policy-Responder-3

Parameter	Value
Name	Policy-Responder-3
Action	RESET
Undefined-Result-Action	-Global undefined-result action-
Expression	"HTTP.REQ.HEADER(\"Request\").EQ(\"Callout Request\").NOT && SYS.HTTP_CALLOUT(HTTP-Callout-3).CONTAINS(\"Authentication Failed\")"

To create a responder policy and bind it globally by using the configuration utility

1. Navigate to AppExpert > Responder.
2. In the details pane, under Policy Manager, click Responder Policy Manager.
3. In the Responder Policy Manger dialog box, click Override Global.
4. Click Insert Policy, and then, in the Policy Name column, click New Policy.
5. In the Create Responder Policy dialog box, do the following:
   1. In Name, type Policy-Responder-3.
   2. In Action, select RESET.
   3. In Undefined-Result Action , select Global undefined-result action.
   4. In the Expression text box, type:
      "HTTP.REQ.HEADER(\"Request\").EQ(\"Callout Request\").NOT && SYS.HTTP_CALLOUT(HTTP-Callout-3).CONTAINS(\"Authentication Failed\")"
   5. Click Create, and then click Close.
6. Click Apply Changes, and then click Close.

Creating an HTTP Callout Agent on the Remote Server

You now need to create an HTTP callout agent on the remote callout server. The HTTP callout agent receives callout requests from the NetScaler appliance and responds appropriately. The callout agent is a script that is different for each deployment and must be written with server specifications in mind, such as the type of database and the scripting language supported.

Following is sample callout agent pseudo-code that verifies whether the supplied user name and password are valid. The agent can be implemented in any programming language of your choice. The pseudo-code is to be used only as a guideline for developing the callout agent. You can build additional functionality into the program.

To verify the supplied user name and password by using pseudo-code

1. Accept the user name and password supplied in the request and format them appropriately.
2. Connect to the database that contains all the valid user names and passwords.
3. Check the supplied credentials against your database.
4. Format the response as required by the HTTP callout.
5. Send the response to the NetScaler appliance.

Use Case: OWA-Based Spam Filtering

May 21, 2015

Spam filtering is the ability to dynamically block emails that are not from a known or trusted source or that have inappropriate content. Spam filtering requires an associated business logic that indicates that a particular kind of message is spam. When the NetScaler appliance processes Outlook Web Access (OWA) messages based on the HTTP protocol, HTTP callouts can be used to filter spam.

You can use HTTP callouts to extract any portion of the incoming message and check with an external callout server that has been configured with rules that are meant for determining whether a message is legitimate or spam. In case of spam email, for security reasons, the NetScaler appliance does not notify the sender that the email is marked as spam.

The following example conducts a very basic check for various listed keywords in the email subject. These checks can be more complex in a production environment.

To implement this configuration, you must perform the following tasks:

1. Enable the responder feature on the NetScaler appliance.
2. Create an HTTP callout on the NetScaler appliance and configure it with details about the external server and other required parameters.
3. Create a responder policy to analyze the response, and then bind the policy globally.
4. Create a callout agent on the remote server.

Enabling Responder

Updated: 2013-08-30

The responder feature must be enabled before it can be used on the NetScaler appliance.

To enable responder by using the configuration utility

1. Make sure that the responder license is installed.
2. In the configuration utility, expand AppExpert, and right-click Responder, and then click Enable Responder feature.

Creating an HTTP Callout on the NetScaler Appliance

Updated: 2013-08-30

Create an HTTP callout, HTTP-Callout-4, with the parameter settings shown in the following table. For more information about creating an HTTP callout, see "Configuring an HTTP Callout."

Table 1. Parameters and Values for HTTP-Callout-4

Parameter	Value
Name	HTTP-Callout-4
Server to receive callout request	
IP Address	10.103.56.51
Port	80
Request to send to the server	
Method	POST
Host Expression	fffffff
URL Stem Expression	"/cgi-bin/Callout/spam_filter.pl"
Headers	
Name	Request
Value-expression	Callout Request
Parameters	
Name	Subject
Value-expression	("\"" + HTTP.REQ.BODY(1000).AFTER_STR("urn:schemas:httpmail:subject=").BEFORE_STR("\n").TO_LOWER + "\"")
Server Response	

Parameter	Value
Return Type	BOOL
Expression to extract data from the response	HTTP.RES.BODY(100) .CONTAINS(\"Matched\")

Creating a Responder Action

Updated: 2013-08-30

Create a responder action, Action-Responder-4. Create the action with the parameter settings shown in the following table.

Table 2. Parameters and Values for Action-Responder-4

Parameter	Value
Name	Action-Responder-4
Type	Respond with
Target	"\"HTTP/1.1 200 OK\r\nServer: Microsoft-IIS/6.0\r\nX-Powered-By: ASP.NET\r\nContent-Length: 0\r\nMS-WebStorage: 6.5.6944\r\nCache-Control: no-cache\r\n\r\n\""

To create a responder action by using the configuration utility

1. Navigate to AppExpert > Responder > Actions.
2. In the details pane, click Add.
3. In the Create Responder Action dialog box, in Name, type Action-Responder-4.
4. In Type, click Respond with.
5. In Target, type:
   "\"HTTP/1.1 200 OK\r\nServer: Microsoft-IIS/6.0\r\nX-Powered-By: ASP.NET\r\nContent-Length: 0\r\nMS-WebStorage: 6.5.6944\r\nCache-Control: no-cache\r\n\r\n\""
6. Click Create, and then click Close.

Creating a Responder Policy to Invoke the HTTP Callout

Updated: 2013-08-30

Create a responder policy, Policy-Responder-4, that will check the request body and, if the body contains the word "*subject*," invoke the HTTP callout to verify the email. Create the policy with the parameter settings shown in the following table. While you can create a responder policy in the Policies subnode and then bind it globally by using the Responder Policy Manager, this demonstration uses the Responder Policy Manager to create the responder policy and bind it globally.

Table 3. Parameters and Values for Policy-Responder-4

Parameter	Value
Name	Policy-Responder-4
Action	Action-Responder-4
Undefined-Result-Action	-Global undefined-result action-
Expression	"HTTP.REQ.BODY(1000).CONTAINS(\"urn:schemas:httpmail:subject\") && SYS.HTTP_CALLOUT(HTTP-Callout-4)"

To create a responder policy by using the configuration utility

1. Navigate to AppExpert > Responder.
2. In the details pane, under Policy Manager, click Responder policy manager.
3. In the Responder Policy Manger dialog box, click Override Global.
4. Click Insert Policy, and then, in the Policy Name column, click New Policy.
5. In the Create Responder Policy dialog box, do the following:
   1. In Name, type Policy-Responder-4.
   2. In Action, click Action-Responder-4.
   3. In Undefined-Result Action, click Global undefined-result action.
   4. In the Expression text box, type:
      "HTTP.REQ.BODY(1000).CONTAINS(\"urn:schemas:httpmail:subject\") && SYS.HTTP_CALLOUT(HTTP-Callout-4)"
   5. Click Create, and then click Close.
6. Click Apply Changes, and then click Close.

Creating an HTTP Callout Agent on the Remote Server

You will now need to create an HTTP callout agent on the remote callout server. The HTTP callout agent receives callout requests from the NetScaler appliance and responds accordingly. The callout agent is a script that is different for each deployment and must be written with server specifications in mind, such as the type of database and the scripting language supported.

The following pseudo-code provides instructions for creating a callout agent that checks a list of words that are generally understood to indicate spam mails. The agent can be implemented in any programming language of your choice. The pseudo-code is to be used only as a guideline for developing the callout agent. You can build additional functionality into the program.

To identify spam email by using pseudo-code

1. Accept the email subject provided by the NetScaler appliance.
2. Connect to the database that contains all the terms against which the email subject is checked.
3. Check the words in the email subject against the spam word list.
4. Format the response as required by the HTTP callout.
5. Send the response to the NetScaler appliance.

Use Case: Dynamic Content Switching

May 21, 2015

This use case provides dynamic content switching by using an HTTP callout to get the name of the load balancing virtual server to which the request is forwarded.

1. Add a content switching virtual server.
   > add cs vserver cs_vserver1 HTTP 10.102.29.196 80
2. Create an HTTP callout.
   > add policy httpCallout http_callout1
3. Configure the HTTP callout to respond with the name of the load balancing virtual server from a request that contains the client IP address in the HTTP header "X-CLIENT-IP".
   > set policy httpCallout http_callout1 -IPAddress 10.217.14.23 -port 80 -returnType TEXT -hostExpr "\"www.get-lbvip.com\"" -urlStemExpr "\"/index.html\"" -headers X-CL
4. Configure the content switching action to retrieve the callout response.
   > add cs action cs_action1 -targetVserverExpr 'SYS.HTTP_CALLOUT(http_callout1)'
   Note: You must bind a load balancing virtual server to the content switching virtual server to account for:
   - The non-availability of the load balancing virtual server that the callout resolves to.
   - A UNDEF condition that results from the execution of the callout.

   > bind cs vserver cs_vserver1 -lbvserver default_lbvip
5. Configure the content switching policy.
   > add cs policy cs_policy1 -rule true -action cs_action1
6. Binding the content switching policy to the content switching virtual server.
   > bind cs vserver cs_vserver1 -policyName cs_policy1 -priority 10

Pattern Sets and Data Sets

Jun 20, 2013

Policy expressions for string matching operations on a large set of string patterns tend to become long and complex. Resources consumed by the evaluation of such complex expressions are significant in terms of processing cycles, memory, and configuration size. You can create simpler, less resource-intensive expressions by using pattern matching.

Depending on the type of patterns that you want to match, you can use one of the following features to implement pattern matching:

- A pattern set is an array of indexed patterns used for string matching during default syntax policy evaluation. Example of a pattern set: imagetypes {svg, bmp, png, gif, tiff, jpg}.
- A data set is a specialized form of pattern set. It is an array of patterns of types number (integer), IPv4 address, or IPv6 address.

In many cases, you can use either pattern sets or data sets. However, in cases where you want specific matches for numerical data or IPv4 and IPv6 addresses, you must use data sets.

Note: Pattern sets and data sets can be used only in default syntax policies.
To use pattern sets or data sets, first create the pattern set or data set and bind patterns to it. Then, when you configure a policy for comparing a string in a packet, use an appropriate operator and pass the name of the pattern set or data set as an argument.

How String Matching works with Pattern Sets and Data Sets

Jul 11, 2013

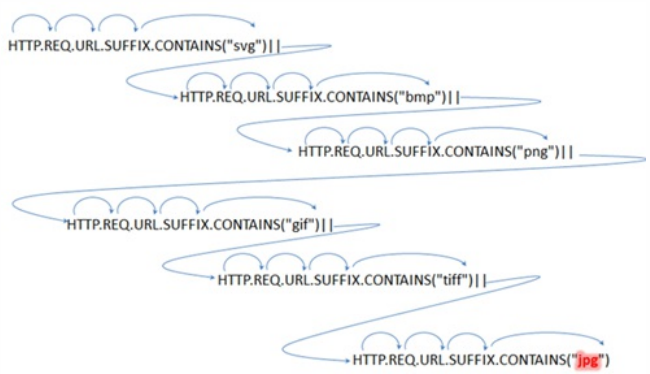
A pattern set or data set contains a set of patterns, and each pattern is assigned a unique index. When a policy is applied to a packet, an expression identifies a string to be evaluated, and the operator compares the string to the patterns defined in the pattern set or data set until a match is found or all patterns have been compared. Then, depending on its function, the operator returns either a boolean value that indicates whether or not a matching pattern was found or the index of the pattern that matches the string.

Note: This topic explains the working of a pattern set. Data sets work the same way. The only difference between pattern sets and data sets is the type of patterns defined in the set.
Consider the following use case to understand how patterns can be used for string matching.

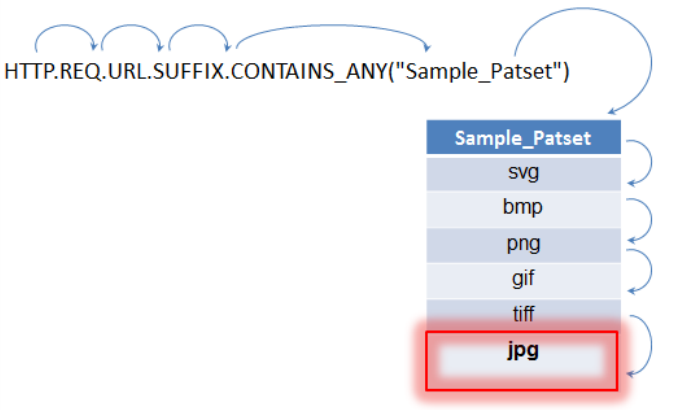
You want to determine whether the URL suffix (target text) contains any of the image file extensions. Without using pattern sets, you would have to define a complex expression, as follows:

```
HTTP.REQ.URL.SUFFIX.CONTAINS("svg") ¦¦ HTTP.REQ.URL.SUFFIX.CONTAINS("bmp") ¦¦ HTTP.REQ.URL.SUFFIX.CONTAINS("png") ¦¦ HTTP.REQ.URL.SUFFIX.CONTAINS("gif") ¦¦ HTTP.REQ.URL.SUFFIX.CONTAINS("tiff") ¦¦ HTTP.REQ.URL.SUFFIX.CONTAINS("jpg")
```

If the URL has a suffix of "jpg," with the above compound expression, the NetScaler appliance has to iterate through the entire compound expression sequentially, from one sub expression to the next, to determine that the request refers to a jpg image. The following figure shows the steps in the process.



When a compound expression includes hundreds of sub expressions, the above process is resource intensive. A better alternative is an expression that invokes a pattern set, as shown in the following figure.



During policy evaluation as shown above, the operator (CONTAINS_ANY) compares the string identified in the request with the patterns defined in the pattern set until a match is found. With the `Sample_Patset` expression, the multiple iterations through six sub expressions are reduced to just one.

By eliminating the need to configure compound expressions that perform string matching with multiple OR operations, pattern sets or data sets simplify configuration and accelerate processing of requests and responses.

Configuring a Pattern Set

Oct 29, 2013

To configure a pattern set, you must specify the strings that are to serve as patterns. You can manually assign a unique index value to each of these patterns, or you can allow the index values to be assigned automatically.

Note: Pattern sets are case sensitive (unless you specify the expression to ignore case). Therefore, the string pattern "product1," for example, is not the same as the string pattern "Product1."

Points to remember about index values

- You cannot bind the same index value to more than one pattern.
- An automatically assigned index value is one number larger than the highest index value of the existing patterns within the pattern set. For example, if the highest index value of existing patterns in a pattern set is 104, the next automatically assigned index value will be 105.
- If you do not specify an index for the first pattern, index value 1 is automatically assigned to that pattern.
- Index values are not regenerated automatically if one or more patterns are deleted or modified. For example, if the set contains five patterns, with indexes from 1 through 5, and if the pattern with an index of 3 is deleted, the other index values in the pattern set are not automatically regenerated to produce values from 1 through 4.
- The maximum index value that can be assigned to a pattern is 4294967290. If that value is already assigned to a pattern in the set, you must manually assign index values to any newly added patterns. An unused index value that is lower than a currently used value cannot be assigned automatically.

At the command prompt, do the following:

1. Create a pattern set.
   add policy patset <name>

   Example:
   ```
   > add policy patset samplepatset
   ```
2. Bind patterns to the pattern set.
   bind policy patset <name> <string> [-index <positive_integer>]

   Example:
   ```
   > bind policy patset samplepatset product1 -index 1
   ```
   Note: Repeat this step for all the patterns you want to bind to the pattern set.
3. Verify the configuration.
   show policy patset <name>

1. Navigate to AppExpert > Pattern Sets.
2. In the details pane, click Add to open the Create Pattern Set dialog box.
3. Specify a name for the pattern set in the Name text box.
4. Under Specify Pattern, type the first pattern and, optionally, specify values for the following parameters:
   - Treat back slash as escape character—Select this check box to specify that any backslash characters that you might include in the pattern are to be treated as escape characters.
   - Index—A user assigned index value, from 1 through 4294967290.

5. Verify that you have entered the correct characters, and then click Add.
6. Repeat steps 4 and 5 to add additional patterns, and then click Create.

Configuring a Data Set

Jul 30, 2014

To configure a data set, you must specify the strings that are to serve as patterns, and assign a type (number, IPv4 address, or IPv6 address) to each pattern. You can manually assign a unique index value to each of these patterns, or you can allow the index values to be assigned automatically.

Note: Data sets are case sensitive (unless you specify the expression to ignore case). Therefore, the string pattern "product1," for example, is not the same as the string pattern "Product1."

The rules applied for index values of data sets are the same as those applied for pattern sets. For information about index values, see "Configuring a Pattern Set."

At the command prompt, do the following:

1. Create a data set.
   add policy dataset <name> <type>

   Example:

   ```
   > add policy dataset sampledataset ipv4
   ```
2. Bind patterns to the data set.
   bind policy dataset <name> <value> [-index <positive_integer>]

   Example:

   ```
   > bind policy dataset sampledataset 10.102.29.1 -index 1
   ```
   Note: Repeat this step for all the patterns you want to bind to the data set.
3. Verify the configuration.
   show policy dataset <name>

Navigate to AppExpert > Data Sets, click Add and specify the relevant details.

Using Pattern Sets and Data Sets

Aug 30, 2013

Default syntax policy expressions that take pattern sets or data sets as an argument can be used to perform string matching operations.

The usage is as follows:
<text>.<operator>("<name>")
where,

- <text> is the expression that identifies a string in a packet. Example: HTTP.REQ.HEADER("Host").
- <operator> is one of the operators described in the following table.

Table 1. Operators for pattern sets and data sets

Operator	Description
<text>.CONTAINS_ANY(<name>)	Returns true if the target text contains one or more of the patterns defined in the specified pattern set or data set.
<text>.SUBSTR_ANY(<name>)	Returns the first string that matches any pattern defined in the specified pattern set or data set.
<text>.BEFORE_STR_ANY(<name>)	Returns the text that is present before the first occurrence of any of the patterns defined in the specified pattern set or data set.
<text>.AFTER_STR_ANY(<name>)	Returns the text that is present after the first occurrence of any of the patterns defined in the specified pattern set or data set.
<text>.EQUALS_ANY (<name>)	Returns true if the target text exactly matches any of the patterns defined in the specified pattern set or data set.
<text>.ENDSWITH_ANY(<name>)	Returns true if the target text ends with any of the patterns that are defined in the specified pattern set or data set.
<text>.STARTSWITH_ANY(<name>)	Returns true if the target text starts with any of the patterns that are defined in the specified pattern set or data set.
<text>.STARTSWITH_INDEX(<name>)	Evaluates whether the target text starts with any of the patterns that are defined in the specified pattern set or data set. If a match is found, the index of the matching pattern is returned. Otherwise, 0 is returned.
<text>.ENDSWITH_INDEX(<name>)	Evaluates whether the target text ends with any of the patterns that are defined in the specified pattern set or data set. If a match is found, the index of the matching pattern is returned. Otherwise, 0 is returned.
<text>.CONTAINS_INDEX(<name>)	Evaluates whether the target text contains any of the patterns that

Operator	Description
	are defined in the specified pattern set or data set. If a match is found, the index of the matching pattern is returned. Otherwise, 0 is returned.
<text>.EQUALS_INDEX(<name>)	Evaluates whether the target text exactly matches any of the patterns that are defined in the specified pattern set or data set. If an exact match is found, the index of the pattern is returned. Otherwise, 0 is returned.

- <name> is the name of the pattern set or data set

For sample usage, see "Sample Usage."

Sample Usage

Jun 13, 2013

To understand the usage of pattern sets in expressions, consider the example of a pattern set named "imagetypes."

Table 1. Pattern set "imagetypes"

Patterns	Index value
svg	1
bmp	2
png	3
gif	4
tiff	5
jpg	6

Example 1: Determine whether the suffix of an HTTP request is one of the file extensions defined in the "imagetypes" pattern set.

- **Expression.** HTTP.REQ.URL.SUFFIX.EQUALS_ANY("imagetypes")
- **Sample URL.** http://www.example.com/homepageicon.jpg
- **Result.** TRUE

Example 2: Determine whether the suffix of an HTTP request is one of the file extensions defined in the "imagetypes" pattern set, and return the index of that pattern.

- **Expression.** HTTP.REQ.URL.SUFFIX.EQUALS_INDEX("imagetypes")
- **Sample URL.** http://www.example.com/mylogo.gif
- **Result.** 4 (The index value of the pattern "gif".)

Example 3: Use the index value of a pattern to determine whether the URL suffix is within a specified index-value range.

- **Expression.** HTTP.REQ.URL.SUFFIX.EQUALS_INDEX("imagetypes").GE(3) && HTTP.REQ.URL.SUFFIX.EQUALS_INDEX("imagetypes").LE(5)
- **Sample URL.** http://www.example.com/mylogo.gif
- **Result.** TRUE (The index value of gif file types is 4.)

Example 4: Implement one set of policies for file extensions bmp, jpg, and png, and a different set of policies for gif, tiff, and svg files.

An expression that returns the index of a matched pattern can be used to define traffic subsets for a web application. The

following two expressions could be used in content switching policies for a content switching virtual server:

- HTTP.REQ.URL.SUFFIX.EQUALS_INDEX("imagetypes").LE(3)
- HTTP.REQ.URL.SUFFIX.EQUALS_INDEX("imagetypes").GE(4)

Variables

Jun 02, 2015

Note: Supported only on NetScaler release 10.1.e.

Variables are named objects that store information in the form of tokens. These tokens are used within and across different transactions on the NetScaler Appliance for internal computation and policy processing.

The NetScaler appliance supports creation of variables of the following types:

- **Singleton variables.** Can have a single value of one of the following types: ulong and text (max-size). The ulong type is an unsigned 64-bit integer, the text type is a sequence of bytes, and max-size is the maximum number of bytes in the sequence.
- **Map variables.** Maps hold values associated with keys: each key-value pair is called a map entry. The key for each entry is unique within the map. Maps are specified as follows:

  map (key_type, value_type, max-values).

  where,

  - *key_type* is the data type of the key. It is of type text (max-size).
  - *value_type* is the data type of the values of the map. It can be of type ulong or text (max-size).
  - *max-values* is the maximum number of entries that the map can contain. It is of type ulong.

Values for these variables are set using assignments which must be invoked on policy actions.

Note: Variables are not yet supported in a high-availability setup or in a cluster.

A map variable or a singleton variable can have a global scope. Alternatively, the scope of a singleton variable can be limited to a single transaction.

- **Global Scope Variable** - A variable with global scope (the default) has only one instance, and that instance has the same value(s) across all cores of a NetScaler appliance and across all nodes of a cluster or HA configuration. Global variable values exist until they are explicitly deleted, until they expire, or until a standalone appliance is restarted or all nodes of a cluster or HA configuration are restarted.
- **Transaction Scope Variable** - A variable with transaction scope has a separate instance, with its own value, for each transaction processed by the NetScaler appliance. When the transaction processing is complete, the transaction variable value is deleted.

Note: Transaction scope variables are available in NetScaler release 10.5.e or later.

Configuring and Using Variables

Mar 20, 2014

You must first create a variable and then assign a value or specify the operation that must be performed on the variable. After performing these operations, you can use the assignment as a policy action.

Note: Once configured, a variable's settings cannot be modified or reset. If the variable needs to be changed, the variable and all references to the variable (expressions and assignments) must be deleted. The variable can then be re-added with new settings, and the references (expressions and assignments) can be re-added.

1. Create a variable.
   add ns variable <name> -type <string> [-scope global] [-ifFull (undef | lru)] [-ifValueTooBig (undef | truncate)] [-ifNoValue (undef | init)] [-init <string>] [-expires <positive_integer>] [-comment <string>]

   Note: Refer to the man page "man add ns variable" for description of the command parameters.
   Example 1: Create a ulong variable named "my_counter" and initialize it to 1.
   `add ns variable my_counter –type ulong -init 1`
   Example 2: Create a map named "user_privilege_map". The map will contain keys of maximum length 15 characters and text values of maximum length 10 characters, with a maximum of 10000 entries.
   `add ns variable user_privilege_map -type map(text(15),text(10),10000)`
   Note: If the map contains 10000 unexpired entries, assignments for new keys reuse one of the least recently used entries. By default, an expression trying to get a value for a non-existent key will initialize an empty text value.
2. Assign the value or specify the operation to be performed on the variable. This is done by creating an assignment.
   add ns assignment <name> -variable <expression> [-set <expression> | -add <expression> | -sub <expression> | -append <expression> | -clear] [-comment <string>]

   Note: A variable is referenced by using the variable selector ($). Therefore, **$variable1** is used to refer to text or ulong variables. Similarly, **$variable2[key-expression]** is used to refer to map variables.
   Example 1: Define an assignment named "inc_my_counter" that automatically adds 1 to the "my_counter" variable.
   `add ns assignment inc_my_counter -variable $my_counter -add 1`
   Example 2: Define an assignment named "set_user_privilege" that adds to the "user_privilege_map" variable an entry for the client's IP address with the value returned by the "get_user_privilege" HTTP callout.
   `add ns assignment set_user_privilege -variable $user_privilege_map[client.ip.src.typecast_text_t] -set sys.http.callout(get_user_privilege)`
   Note: If an entry for that key already exists, the value will be replaced. Otherwise a new entry for the key and value will be added. Based on the previous declaration for user_privilege_map, if the map already has 10000 entries, one of the least recently used entries will be reused for the new key and value.
3. Invoke the variable assignment in a policy.
   There are two functions that can operate on map variables.

   - **$name.valueExists(key-expression).** Returns true if there is a value in the map selected by the key-expression. Otherwise returns false. This function will update the expiration and LRU information if the map entry exists, but will not create a new map entry if the value does not exist.
   - **$name.valueCount.** Returns the number of values currently held by the variable. This is the number of entries in a map. For a singleton variable, this is 0 if the variable is uninitialized or 1 otherwise.

   Example: Invoke the assignment named "set_user_privilege" with a compression policy.
   `> add cmp policy set_user_privilege_pol -rule $user_privilege_map.valueExists(client.ip.src.typecast_text_t).not -resAction set_user_privilege`

1. Navigate to AppExpert > NS Variables, to create a variable.
2. Navigate to AppExpert > NS Assignments, to assign value(s) to the variable.
3. Navigate to the appropriate feature area where you want to configure the assignment as an action.

Use Case: Caching User Privileges

Aug 13, 2014

In this use case, user privileges ("GOLD", "SILVER", and so on) must be retrieved from an external web service.

To achieve this use case, perform the following operations:

1. Create an HTTP callout to fetch the user privileges from the external web service.
   ```
   > add policy httpcallout get_user_privilege
   > set policy httpcallout get_user_privilege -ipaddress 10.217.193.84 -port 80 -returntype text -httpmethod get -urlstemexpr '"/get_user_privilege"' -resultexpr 'http.res.b
   ```
2. Store the privileges in a variable.
   ```
   > add ns variable user_privilege_map -type map(text(15),text(10),10000) -expires 1200
   > add ns assignment set_user_privilege -variable $user_privilege_map[client.ip.src] -set sys.http_callout(get_user_privilege)
   ```
3. Create a policy to check if there is already a cached entry for the client's IP address; if not, it calls the HTTP callout to set a map entry for the client.
   ```
   > add cmp policy set_user_privilege_pol -rule $user_privilege_map.valueExists(client.ip.src).not -resAction set_user_privilege
   ```
4. Create a policy that compresses if the cached privilege entry for the client is "GOLD".
   ```
   > add cmp policy compress_if_gold_privilege_pol -rule '$user_privilege_map[client.ip.src].eq("GOLD")' -resAction compress
   ```
5. Bind the compression policies globally.
   ```
   > bind cmp global set_user_privilege_pol -priority 10 NEXT
   > bind cmp global compress_if_gold_privilege_pol -priority 20 END
   ```

Use Case: Limiting the Number of Sessions

Jun 17, 2015

In this use case, the requirement is to limit the number of active backend sessions. In the deployment, each session login has login in the URL and each session logout has logout in the URL. On successful login, the backend sets a sessionid cookie with a unique 10 character value.

To achieve this use case, perform the following operations:

1. Create a map variable that can store each active session. The key of the map is the sessionid. The expiry time for the variable is set to 600 seconds (10 minutes).
   ```
   > add ns variable session_map -type map(text(10),ulong,100) -expires 600
   ```
2. Create the following assignments for the map variable:
   - Create an entry for the sessionid and set that value to 1 (this value is not actually used).
     ```
     > add ns assignment add_session -variable '$session_map[http.req.cookie.value("sessionid")]' -set 1
     ```
   - Deallocate the entry for a session ID, which implicitly decrements the value count for session_map.
     ```
     > add ns assignment delete_session -variable '$session_map[http.req.cookie.value("sessionid")]' -clear
     ```
3. Create responder policies for the following:
   - To check if a map entry exists for that sessionid in the HTTP request. The add_session assignment is executed if the map entry does not exist.
     ```
     > add responder policy add_session_pol 'http.req.url.contains("twbkwbis.P_SabanciLogin") || $session_map.valueExists(http.req.cookie.value("netsuis"))' add_sessior
     ```
     Note: The valueExists() function in the add_session_pol policy counts as a reference to the session's map entry, so each request resets the expiration timeout for its session. If no requests for a session are received after 10 minutes, the session's entry will be deallocated.
   - To check when the session is logged out. The delete_session assignment is executed.
     ```
     > add responder policy delete_session_pol "http.req.url.contains(\"Logout\")" delete_session
     ```
   - To check for login requests and if the number of active sessions exceed 100. If these conditions are satisfied, in order to limit the number of sessions, the user is redirected to a page that indicates that the server is busy.
     ```
     > add responder action redirect_too_busy redirect "/too_busy.html"
     > add responder policy check_login_pol "http.req.url.contains(\"twbkwbis.P_SabanciLogin\") && $session_map.valueCount > 1" redirect_too_busy
     ```
4. Bind the responder policies globally.
   ```
   > bind responder global add_session_pol 10 next
   > bind responder global delete_session_pol 10
   > bind responder global check_login_pol 20
   ```

Policies and Expressions

May 26, 2015

The following topics provide the conceptual and reference information that you require for configuring advanced policies on the Citrix® NetScaler® appliance.

You can also download a list of all the expressions supported on the NetScaler appliance and the hierarchical order in which they can be invoked. The reference is in a zip file which you can download from:

- For NetScaler 10.5: http://support.citrix.com/article/CTX141344
- For NetScaler 10.1: http://support.citrix.com/article/CTX137705

Introduction to Policies and Expressions	Describes the purpose of expressions, policies, and actions, and how different NetScaler applications make use of them.
Configuring Advanced Policies	Describes the structure of advanced policies and how to configure them individually and as policy banks.
Configuring Advanced Expressions: Getting Started	Describes expression syntax and semantics, and briefly introduces how to configure expressions and policies.
Advanced Expressions: Evaluating Text	Describes expressions that you configure when you want to operate on text (for example, the body of an HTTP POST request or the contents of a user certificate).
Advanced Expressions: Working with Dates, Times, and Numbers	Describes expressions that you configure when you want to operate on any type of numeric data (for example, the length of a URL, a client's IP address, or the date and time that an HTTP request was sent).
Advanced Expressions: Parsing HTTP, TCP, and UDP Data	Describes expressions for parsing IP and IPv6 addresses, MAC addresses, and data that is specific to HTTP and TCP traffic.
Advanced Expressions: Parsing SSL Certificates	Describes how to configure expressions for SSL traffic and client certificates, for example, how to retrieve the expiration date of a certificate or the certificate issuer.
Advanced Expressions: IP and MAC Addresses, Throughput, VLAN IDs	Describes expressions that you can use to work with any other client- or server-related data not discussed in other chapters.
Typecasting Data	Describes expressions for transforming data of one type to another.
Regular Expressions	Describes how to pass regular expressions as arguments to operators in advanced

	expressions.
Configuring Classic Policies and Expressions	Provides details on how to configure the simpler policies and expressions known as classic policies and classic expressions.
Expressions Reference	A reference for classic and advanced expression arguments.
Summary Examples of Advanced Expressions and Policies	Examples of classic and advanced expressions and policies, in both quick reference and tutorial format, that you can customize for your own use.
Tutorial Examples of Advanced Policies for Rewrite	Examples of advanced policies for use in the Rewrite feature.
Tutorial Examples of Classic Policies	Examples of classic policies for NetScaler features such as application firewall and SSL.
Migration of Apache mod_rewrite Rules to Advanced Policies	Examples of functions that were written using the Apache HTTP Server mod_rewrite engine, with examples of these functions after translation into Rewrite and Responder policies on the NetScaler.

Introduction to Policies and Expressions

Jun 04, 2015

For many NetScaler features, policies control how a feature evaluates data, which ultimately determines what the feature does with the data. A policy uses a logical expression, also called a rule, to evaluate requests, responses, or other data, and applies one or more actions determined by the outcome of the evaluation. Alternatively, a policy can apply a profile, which defines a complex action.

Some NetScaler features use default syntax policies, which provide greater capabilities than do the older, classic, policies. If you migrated to a newer release of the NetScaler software and have configured classic policies for features that now use default syntax policies, you might have to manually migrate policies to the default syntax.

This document contains the following details:

- Classic and Default Syntax Policies
- Classic and Default Syntax Expressions
- Converting Classic Expressions to the Newer Default Expression Syntax
- Before You Proceed

Classic and Default Syntax Policies

May 25, 2015

Classic policies evaluate basic characteristics of traffic and other data. For example, classic policies can identify whether an HTTP request or response contains a particular type of header or URL.

Default syntax policies can perform the same type of evaluations as classic policies. In addition, default syntax policies enable you to analyze more data (for example, the body of an HTTP request) and to configure more operations in the policy rule (for example, transforming data in the body of a request into an HTTP header).

In addition to assigning a policy an action or profile, you bind the policy to a particular point in the processing associated with the NetScaler features. The bind point is one factor that determines when the policy will be evaluated.

This document includes the following details:

Default syntax policies use a powerful expression language that is built on a class-object model, and they offer several options that enhance your ability to configure the behavior of various NetScaler features. With default syntax policies, you can do the following:

- Perform fine-grained analyses of network traffic from layers 2 through 7.
- Evaluate any part of the header or body of an HTTP or HTTPS request or response.
- Bind policies to the multiple bind points that the default syntax policy infrastructure supports at the default, override, and virtual server levels.
- Use goto expressions to transfer control to other policies and bind points, as determined by the result of expression evaluation.
- Use special tools such as pattern sets, policy labels, rate limit identifiers, and HTTP callouts, which enable you to configure policies effectively for complex use cases.

Additionally, the configuration utility extends robust graphical user interface support for default syntax policies and expressions and enables users who have limited knowledge of networking protocols to configure policies quickly and easily. The configuration utility also includes a policy evaluation feature for default syntax policies. You can use this feature to evaluate a default syntax policy and test its behavior before you commit it, thus reducing the risk of configuration errors.

Updated: 2013-09-02

Following are a few characteristics of both classic and default syntax policies:

Name.

Each policy has a unique name.

Rule.

The rule is a logical expression that enables the NetScaler feature to evaluate a piece of traffic or another object. For example, a rule can enable the NetScaler to determine whether an HTTP request originated from a particular IP address, or whether a Cache-Control header in an HTTP request has the value “No-Cache.”

Default syntax policies can use all of the expressions that are available in a classic policy, with the exception of classic expressions for the SSL VPN client. In addition, default syntax policies enable you to configure more complex expressions.

Bindings.

To ensure that the NetScaler can invoke a policy when it is needed, you associate the policy, or bind it, to one or more bind points.
You can bind a policy globally or to a virtual server. For more information, see "About Policy Bindings."

An associated action.

An action is a separate entity from a policy. Policy evaluation ultimately results in the NetScaler performing an action. For example, a policy in the integrated cache can identify HTTP requests for .gif or .jpeg files. An action that you associate with this policy determines that the responses to these types of requests are served from the cache.

For some features, you configure actions as part of a more complex set of instructions known as a profile. For more information, see "Order of Evaluation Based on Traffic Flow."

Updated: 2013-09-30

The NetScaler supports a variety of features that rely on policies for operation. The following table summarizes how the NetScaler features use policies.

Table 1. NetScaler Feature, Policy Type, and Policy Usage

Feature Name	Policy Type	How You Use Policies in the Feature
System	Classic	For the Authentication function, policies contain authentication schemes for different authentication methods. For example, you can configure LDAP and certificate-based authentication schemes. You also configure policies in the Auditing function.
DNS	Default	To determine how to perform DNS resolution for requests.
SSL	Classic and Default	To determine when to apply an encryption function and add certificate information to clear text. To provide end-to-end security, after a message is decrypted, the SSL feature re-encrypts clear text and uses SSL to communicate with Web servers.

Feature Name	Policy Type	How You Use Policies in the Feature
Compression	Classic and Default	To determine what type of traffic is compressed.
Integrated Caching	Default	To determine whether HTTP responses are cacheable.
Responder	Default	To configure the behavior of the Responder function.
Protection Features	Classic	To configure the behavior of the Filter, SureConnect, and Priority Queuing functions.
Content Switching	Classic and Default	To determine what server or group of servers is responsible for serving responses, based on characteristics of an incoming request. Request characteristics include device type, language, cookies, HTTP method, content type, and associated cache server.
AAA - Traffic Management	Classic Exceptions: • Traffic policies support only default syntax policies • Authorization policies support both classic and default syntax policies.	To check for client-side security before users log in and establish a session. Traffic policies, which determine whether single sign-on (SSO) is required, use only the default syntax. Authorization policies authorize users and groups that access intranet resources through the appliance.
Cache Redirection	Classic	To determine whether responses are served from a cache or from an origin server.
Rewrite	Default	To identify HTTP data that you want to modify before serving. The policies provide rules for modifying the data. For example, you can modify HTTP data to redirect a request to a new home page, or a new server, or a selected server based on the address of the incoming request, or you can modify the data to mask server information in a response for security purposes. The URL Transformer function identifies URLs in HTTP transactions and text files for the purpose of evaluating whether a URL should be transformed.

Feature Name	Policy Type	How You Use Policies in the Feature
Application Firewall	Classic and Default	To identify characteristics of traffic and data that should or should not be admitted through the firewall.
NetScaler Gateway, Clientless Access function	Default	To define rewrite rules for general Web access using the NetScaler Gateway.
NetScaler Gateway	Classic	To determine how the NetScaler Gateway performs authentication, authorization, auditing, and other functions.

Updated: 2013-09-30

Policies do not themselves take action on data. Policies provide read-only logic for evaluating traffic. To enable a feature to perform an operation based on a policy evaluation, you configure actions or profiles and associate them with policies.

Note: Actions and profiles are specific to particular features. For information about assigning actions and profiles to features, see the documentation for the individual features.

About Actions

Actions are steps that the NetScaler takes, depending on the evaluation of the expression in the policy. For example, if an expression in a policy matches a particular source IP address in a request, the action that is associated with this policy determines whether the connection is permitted.

The types of actions that the NetScaler can take are feature specific. For example, in Rewrite, actions can replace text in a request, change the destination URL for a request, and so on. In Integrated Caching, actions determine whether HTTP responses are served from the cache or an origin server.

In some NetScaler features actions are predefined, and in others they are configurable. In some cases, (for example, Rewrite), you configure the actions using the same types of expressions that you use to configure the associated policy rule.

About Profiles

Some NetScaler features enable you to associate profiles, or both actions and profiles, with a policy. A profile is a collection of settings that enable the feature to perform a complex function. For example, in the application firewall, a profile for XML data can perform multiple screening operations, such as examining the data for illegal XML syntax or evidence of SQL injection.

Use of Actions and Profiles in Particular Features

The following table summarizes the use of actions and profiles in different NetScaler features. The table is not exhaustive. For more information about specific uses of actions and profiles for a feature, see the documentation for the feature.

Table 2. Use of Actions and Profiles in Different NetScaler Features

Feature	Use of an Action	Use of a Profile
Application firewall	Synonymous with a profile	All application firewall features use profiles to define complex behaviors, including pattern-based learning. You add these profiles to policies.
NetScaler Gateway	The following features of the NetScaler Gateway use actions: • **Pre-Authentication.** Uses Allow and Deny actions. You add these actions to a profile. • **Authorization.** Uses Allow and Deny actions. You add these actions to a policy. • **TCP Compression.** Uses various actions. You add these actions to a policy.	The following features use a profile: • Pre-Authentication • Session • Traffic • Clientless Access After configuring the profiles, you add them to policies.
Rewrite	You configure URL rewrite actions and add them to a policy.	Not used.
Integrated Caching	You configure caching and invalidation actions within a policy	Not used.
AAA - Traffic Management	You select an authentication type, set an authorization action of ALLOW or DENY, or set auditing to SYSLOG or NSLOG.	You can configure session profiles with a default timeout and authorization action.
Protection Features	You configure actions within policies for the following functions: • Filter • Compression • Responder • SureConnect	Not used.
SSL	You configure actions within SSL policies	Not used.
System	The action is implied. For the Authentication function, it is either Allow or Deny. For Auditing, it is Auditing On or Auditing Off.	Not used.

Feature	Use of an Action	Use of a Profile
DNS	The action is implied. It is either Drop Packets or the location of a DNS server.	Not used.
SSL Offload	The action is implied. It is based on a policy that you associate with an SSL virtual server or a service.	Not used.
Compression	Determine the type of compression to apply to the data	Not used.
Content Switching	The action is implied. If a request matches the policy, the request is directed to the virtual server associated with the policy.	Not used.
Cache Redirection	The action is implied. If a request matches the policy, the request is directed to the origin server.	Not used.

Updated: 2013-09-30

A policy is associated with, or bound to, an entity that enables the policy to be invoked. For example, you can bind a policy to request-time evaluation that applies to all virtual servers. A collection of policies that are bound to a particular bind point constitutes a policy bank.

Following is an overview of different types of bind points for a policy:

Request time global.

A policy can be available to all components in a feature at request time.

Response time global.

A policy can be available to all components in a feature at response time.

Request time, virtual server-specific.

A policy can be bound to request-time processing for a particular virtual server. For example, you can bind a request-time policy to a cache redirection virtual server to ensure that particular requests are forwarded to a load balancing virtual server for the cache, and other requests are sent to a load balancing virtual server for the origin.

Response time, virtual server-specific.

A policy can also be bound to response-time processing for a particular virtual server.

User-defined policy label.

For default syntax policies, you can configure custom groupings of policies (policy banks) by defining a policy label and collecting a set of related policies under the policy label.

Other bind points.

The availability of additional bind points depends on type of policy (classic or default syntax), and specifics of the relevant NetScaler feature. For example, classic policies that you configure for the NetScaler Gateway have user and group bind points.

For additional information about default syntax policy bindings, see "Binding Policies That Use the Default Syntax" and Configuring a Policy Bank for a Virtual Server. For additional information about classic policy bindings, see "Configuring a Classic Policy."

For classic policies, policy groups and policies within a group are evaluated in a particular order, depending on the following:

- The bind point for the policy, for example, whether the policy is bound to request-time processing for a virtual server or global response-time processing. For example, at request time, the NetScaler evaluates all request-time classic policies before evaluating any virtual server-specific policies.
- The priority level for the policy. For each point in the evaluation process, a priority level that is assigned to a policy determines the order of evaluation relative to other policies that share the same bind point. For example, when the NetScaler evaluates a bank of request-time, virtual server-specific policies, it starts with the policy that is assigned to the lowest priority value. In classic policies, priority levels must be unique across all bind points.

For default syntax policies, as with classic policies, the NetScaler selects a grouping, or bank, of policies at a particular point in overall processing. Following is the order of evaluation of the basic groupings, or banks, of default syntax policies:

1. Request-time global override
2. Request-time, virtual server-specific (one bind point per virtual server)
3. Request-time global default
4. Response-time global override
5. Response-time virtual server-specific
6. Response-time global default

However, within any of the preceding banks of policies, the order of evaluation is more flexible than in classic policies. Within a policy bank, you can point to the next policy to be evaluated regardless of the priority level, and you can invoke policy banks that belong to other bind points and user-defined policy banks.

As traffic flows through the NetScaler and is processed by various features, each feature performs policy evaluation. Whenever a policy matches the traffic, the NetScaler stores the action and continues processing until the data is about to leave the NetScaler. At that point, the NetScaler typically applies all matching actions. Integrated Caching, which only applies a final Cache or NoCache action, is an exception.

Some policies affect the outcome of other policies. Following are examples:

- If a response is served from the integrated cache, some other NetScaler features do not process the response or the request that initiated it.
- If the Content Filtering feature prevents a response from being served, no subsequent features evaluate the response.

If the application firewall rejects an incoming request, no other features can process it.

Classic and Default Syntax Expressions

May 25, 2015

One of the most fundamental components of a policy is its rule. A policy rule is a logical expression that enables the policy to analyze traffic. Most of the policy's functionality is derived from its expression.

An expression matches characteristics of traffic or other data with one or more parameters and values. For example, an expression can enable the NetScaler to accomplish the following:

- Determine whether a request contains a certificate.
- Determine the IP address of a client that sent a TCP request.
- Identify the data that an HTTP request contains (for example, a popular spreadsheet or word processing application).
- Calculate the length of an HTTP request.

This document includes the following details:

Classic expressions enable you to evaluate basic characteristics of data. They have a structured syntax that performs string matching and other operations.

Following are a few simple examples of classic expressions:

- An HTTP response contains a particular type of Cache Control header.

res.http.header Cache-Control contains public

- An HTTP response contains image data.

res.http.header Content-Type contains image/

- An SSL request contains a certificate.

req.ssl.client.cert exists

Updated: 2013-09-02

Any feature that uses default syntax policies also uses default syntax expressions. For information about which features use default syntax policies, see the table "NetScaler Feature, Policy Type, and Policy Usage."

Default syntax expressions have a few other uses. In addition to configuring default syntax expressions in policy rules, you configure default syntax expressions in the following situations:

Integrated Caching:

You use default syntax expressions to configure a selector for a content group in the integrated cache.

Load Balancing:

You use default syntax expressions to configure token extraction for a load balancing virtual server that uses the TOKEN

method for load balancing.

Rewrite:

You use default syntax expressions to configure rewrite actions.

Rate-based policies:

You use default syntax expressions to configure limit selectors when configuring a policy to control the rate of traffic to various servers.

Following are a few simple examples of default syntax expressions:

- An HTTP request URL contains no more than 500 characters.

```
http.req.url.length <= 500
```

- An HTTP request contains a cookie that has fewer than 500 characters.

```
http.req.cookie.length < 500
```

- An HTTP request URL contains a particular text string.

```
http.req.url.contains(".html")
```

Converting Classic Expressions to the Newer Default Expression Syntax

Jun 04, 2015

You can convert a classic expression to the default expression syntax by using the nspepi conversion tool. You can also use the tool to convert all the classic expressions in the NetScaler configuration to the default syntax (with the exception of NetScaler entities that currently support only classic expressions).

The conversion tool does not convert policies configured for the following features, because the features currently support only classic policies:

- Authentication, Pre-authentication
- SSL
- Cache redirection
- VPN (session, traffic, and tunnel traffic)
- Content filtering (The responder feature not only provides you with functionality that is equivalent to that provided by the content filtering feature but also surpasses the content filtering feature in the use cases that it supports. Additionally, responder supports the more powerful default syntax for policy expressions.)

The following NetScaler features support both classic and default syntax expressions and, therefore, support the conversion of classic expressions to default syntax expressions:

- Application firewall policies
- Authorization policies
- Named expressions
- Compression policies
- Content switching policies
- User-defined, rule-based tokens/persistency (the –rule parameter value that is specified for a load balancing virtual server)

This document includes the following details:

Updated: 2013-09-02

When parsing a NetScaler configuration file, the conversion tool performs the following actions:

1. In commands that create classic named expressions, the conversion tool replaces the names of the classic expressions with default syntax expressions.
2. In commands that support only the classic syntax, if classic named expressions are used, the conversion tool replaces the names of the classic expressions with the actual classic expressions they represent. This action ensures that the names of expressions in classic-only features do not reference the default syntax expressions created from Step 1.
3. In commands associated with entities that support both the classic syntax and the default syntax, the conversion tool replaces all classic expressions in commands with default syntax expressions.

Example

Consider the following sample configuration commands:

```
add policy expression ne_c1 "METHOD == GET"
add policy expression ne_c2 "ne_c1 || URL == /*.htm "
add filter policy pol1 -rule "ne_c2" -reqAction YES
add cmp policy pol2 -rule "REQ.HTTP.HEADER Accept CONTAINS \'text/html\'" -resAction COMPRESS
add cmp policy pol3 -rule "ne_c1 || ne_c2" -resAction GZIP
```

In the commands that create the classic named expressions ne_c1 and ne_c2, the tool replaces the names of the expressions with actual default syntax expressions. This action, which corresponds to Step 1 described earlier, results in the following commands:

```
add policy expression ne_c1 "HTTP.REQ.METHOD.EQ(\"GET\")"

add policy expression ne_c2 "HTTP.REQ.URL.SUFFIX.EQ(\"htm\")"
```

The filter policy command supports only the classic syntax. Therefore, the conversion tool replaces the classic named expression ne_c1 with the actual classic expression it represents. Note that the tool replaces ne_c1 in the expression for ne_c2, and then replaces ne_c2 in the filter policy with the classic expression. This action, which corresponds to Step 2 described earlier, results in the following command:

```
add filter policy pol1 -rule "METHOD == GET || URL == /*.htm" -reqAction YES
```

The compression feature supports both classic and default syntax expressions. Therefore, in the command that creates the compression policy pol2, the conversion tool replaces the expression with a default syntax expression. This action, which corresponds to Step 3 described earlier, results in the following command:

```
add cmp policy pol2 -rule "HTTP.REQ.HEADER(\"Accept\").AFTER_STR(\"text/html\").LENGTH.GT(0)" -
resAction COMPRESS
```

The command that creates the compression policy pol3 is unaffected by the conversion process because, after the conversion process is complete, ne_c1 and ne_c2 reference the default syntax expressions that result from Step 1.

Client security messages are not supported in the newer default policy format and, therefore, are lost. The SYS.EVAL_CLASSIC_EXPR function is replaced with a default policy expression. The following entities support the SYS.EVAL_CLASSIC_EXPR function:

- DNS policies
- Rate limit selectors
- Cache selectors
- Cache policies
- Content switching policies
- Rewrite policies
- URL transformation policies
- Responder policies
- Application firewall policies
- Authorization policies
- Compression policies
- CVPN access policies

After performing the conversion, the tool saves the changes in a new configuration file. The new configuration file is created in the directory in which the input file exists. The name of the new configuration file is the same as the name of the input configuration file except for the string new_ used as a prefix. Conversion warnings are reported in a warning line at the end of the screen output. Additionally, a warning file is created in the directory in which the input configuration file resides. For more

information about the warning file and the types of warnings that are reported, see "Conversion Warnings."

Updated: 2013-09-02

You can use the nspepi tool to convert a single classic expression to the default syntax. The nspepi tool must be run from the shell prompt on the NetScaler appliance.

To convert a classic expression to the default syntax by using the command line interface

At the shell prompt, type:

nspepi -e "<classic expression>"
Example

```
root@NS# nspepi -e "REQ.HTTP.URL == /*.htm"
 "HTTP.REQ.URL.REGEX_MATCH(re#/(.*)\.htm#)"
```

Updated: 2013-09-02

You can use the nspepi tool to convert all the classic expressions in a NetScaler configuration file to the default syntax (except for those commands that do not support the default syntax). The nspepi tool must be run from the shell prompt on the NetScaler appliance.

To convert all the classic expressions in a NetScaler configuration file to the default syntax by using the command line interface

At the shell prompt, type:

nspepi -f "<ns config file>" -v
Example

```
root@NS# nspepi -f ns.conf
OUTPUT: New configuration file created: new_ns.conf
OUTPUT: New warning file created: warn_ns.conf
WARNINGS: Total number of warnings due to bind commands: 18
WARNINGS: Line numbers which has bind command issues: 305, 306, 706, 707, 708, 709, 710, 711, 712, 713,
714, 715, 767, 768, 774, 775, 776, 777
root@NS#
```

When classic expressions that are included in CLI commands are upgraded to the default syntax, the number of characters in the expression might exceed the 1499-character limit. The commands that include expressions longer than 1499 characters fail when the configuration is being applied. You must manually update these commands.

In addition, multiple classic policies can be bound to a given bind point with priority 0 or with equal priority, but the default syntax policy infrastructure does not support a priority value of 0 or policies with the same priority at a given bind point. These commands fail when the configuration is being applied. The commands must be updated manually with the correct priority values.

The line numbers of lines that threw a warning during conversion are listed at the end of the output in a warning line. In addition, a warning file is created in the same directory as the one in which the old and new configuration files reside. The name of the warning file is the same as the name of the input configuration file except that the string **warn_** is added as a prefix.

Before You Proceed

May 25, 2015

Before configuring expressions and policies, be sure you understand the relevant NetScaler feature and the structure of your data, as follows:

- Read the documentation on the relevant feature.
- Look at the data stream for the type of data that you want to configure.

You may want to run a trace on the type of traffic or content that you want to configure. This will give you an idea of the parameters and values, and operations on these parameters and values, that you need to specify in an expression.

Note: The NetScaler supports either classic or default syntax policies within a feature. You cannot have both types in the same feature. Over the past few releases, some NetScaler features have migrated from using classic policies and expressions to default syntax policies and expressions. If a feature of interest to you has changed to the default syntax format, you may have to manually migrate the older information. Following are guidelines for deciding if you need to migrate your policies:

- If you configured classic policies in a version of the Integrated Caching feature prior to release 9.0 and then upgrade to version 9.0 or later, there is no impact. All legacy policies are migrated to the default syntax policy format.
- For other features, you need to manually migrate classic policies and expressions to the default syntax if the feature has migrated to the default syntax.

Configuring Default Syntax Policies

Sep 30, 2013

You can create default syntax policies for various NetScaler features, including DNS, Rewrite, Responder, and Integrated Caching, and the clientless access function in the NetScaler Gateway. Policies control the behavior of these features.

When you create a policy, you assign it a name, a rule (an expression), feature-specific attributes, and an action that is taken when data matches the policy. After creating the policy, you determine when it is invoked by binding it globally or to either request-time or response-time processing for a virtual server.

Policies that share the same bind point are known as a *policy bank*. For example, all policies that are bound to a virtual server constitute the policy bank for the virtual server. When binding the policy, you assign it a priority level to specify when it is invoked relative to other policies in the bank. In addition to assigning a priority level, you can configure an arbitrary evaluation order for policies in a bank by specifying Goto expressions.

In addition to policy banks that are associated with a built-in bind point or a virtual server, you can configure *policy labels*. A policy label is a policy bank that is identified by an arbitrary name. You invoke a policy label, and the policies in it, from a global or virtual-server-specific policy bank. A policy label or a virtual-server policy bank can be invoked from multiple policy banks.

For some features, you can use the policy manager to configure and bind policies.

Rules for Names in Identifiers Used in Policies

Mar 20, 2012

The names of identifiers in the named expression, HTTP callout, pattern set, and rate limiting features must begin with an ASCII alphabet or an underscore (_). The remaining characters can be ASCII alphanumeric characters or underscores (_).

The names of these identifiers must not begin with the following reserved words:

- The words ALT, TRUE, or FALSE or the Q or S one-character identifier.
- The special-syntax indicator RE (for regular expressions) or XP (for XPath expressions).
- Expression prefixes, which currently are the following:
  - CLIENT
  - EXTEND
  - HTTP
  - SERVER
  - SYS
  - TARGET
  - TEXT
  - URL
  - MYSQL
  - MSSQL

Additionally, the names of these identifiers cannot be the same as the names of enumeration constants used in the policy infrastructure. For example, the name of an identifier cannot be IGNORECASE, YEAR, or LATIN2_CZECH_CS (a MySQL character set).

Note: The NetScaler appliance performs a case-insensitive comparison of identifiers with these words and enumeration constants. For example, names of the identifiers cannot begin with TRUE, True, or true.

Creating or Modifying a Policy

Nov 14, 2013

All policies have some common elements. Creating a policy consists, at minimum, of naming the policy and configuring a rule. The policy configuration tools for the various features have areas of overlap, but also differences. For the details of configuring a policy for a particular feature, including associating an action with the policy, see the documentation for the feature.

To create a policy, begin by determining the purpose of the policy. For example, you may want to define a policy that identifies HTTP requests for image files, or client requests that contain an SSL certificate. In addition to knowing the type of information that you want the policy to work with, you need to know the format of the data that the policy is analyzing.

Next, determine whether the policy is globally applicable, or if it pertains to a particular virtual server. Also consider the effect that the order in which your policies are evaluated (which will be determined by how you bind the policies) will have on the policy that you are about to configure.

At the command prompt, type the following commands to create a policy and verify the configuration:

- add responder|dns|cs|rewrite|cache policy <policyName> -rule <expression> [<feature-specific information>]
- show rewrite policy <name>

Example 1:

```
add rewrite policy "pol_remove-ae" true "act_remove-ae"
 Done
> show rewrite policy pol_remove-ae
      Name: pol_remove-ae
      Rule: true
      RewriteAction: act_remove-ae
      UndefAction: Use Global
      Hits: 0
      Undef Hits: 0
      Bound to: GLOBAL RES_OVERRIDE
      Priority: 90
      GotoPriorityExpression: END
 Done
>
```

Example 2:

```
add cache policy BranchReportsCachePolicy -rule q{http.req.url.query.value("actionoverride").contains("branchReport s")} -action cache
Done
 show cache policy BranchReportsCachePolicy
      Name: BranchReportsCachePolicy
      Rule: http.req.url.query.value("actionoverride").contains("branchReports")
      CacheAction: CACHE
      Stored in group: DEFAULT
      UndefAction: Use Global
      Hits: 0
      Undef Hits: 0
 Done
```

Note: At the command line, quote marks within a policy rule (the expression) must be escaped or delimited with the q delimiter. For more information, see "Configuring Default Syntax Expressions in a Policy."

1. In the navigation pane, expand the name of the feature for which you want to configure a policy, and then click Policies. For example, you can select Content Switching, Integrated Caching, DNS, Rewrite, or Responder.
2. In the details pane, click Add, or select an existing policy and click Open. A policy configuration dialog box appears.
3. Specify values for the following parameters. (An asterisk indicates a required parameter. For a term in parentheses, see the corresponding parameter in "Parameters for creating or modifying a policy.")
4. Click Create, and then click Close.
5. Click Save. A policy is added.
   Note: After you create a policy, you can view the policy's details by clicking the policy entry in the configuration pane. Details that are highlighted and underlined are links to the corresponding entity (for example, a named expression).

Policy Configuration Examples

Sep 02, 2013

These examples show how policies and their associated actions are entered at the command line interface. In the configuration utility, the expressions would appear in the Expression window of the feature-configuration dialog box for the integrated caching or rewrite feature.

Following is an example of creating a caching policy. Note that actions for caching policies are built in, so you do not need to configure them separately from the policy.

```
add cache policy BranchReportsCachePolicy -rule q{http.req.url.query.value("actionoverride").contains("branchReports")} -action cache
```

Following is an example of a Rewrite policy and action:

```
add rewrite action myAction1 INSERT_HTTP_HEADER "myHeader" "valueForMyHeader"
add rewrite policy myPolicy1 "http.req.url.contains(\"myURLstring\")" myAction1
```

Note: At the command line, quote marks within a policy rule (the expression) must be escaped or delimited with the q delimiter. For more information, see "Configuring Default Syntax Expressions in a Policy."

Binding Policies That Use the Default Syntax

Sep 30, 2013

After defining a policy, you indicate when the policy is to be invoked by binding the policy to a bind point and specifying a priority level. You can bind a policy to only one bind point. A bind point can be global, that is, it can apply to all virtual servers that you have configured. Or, a bind point can be specific to a particular virtual server, which can be either a load balancing or a content switching virtual server. Not all bind points are available for all features.

The order in which policies are evaluated determines the order in which they are applied, and features typically evaluate the various policy banks in a particular order. Sometimes, however, other features can affect the order of evaluation. Within a policy bank, the order of evaluation depends on the values of parameters configured in the policies. Most features apply all of the actions associated with policies whose evaluation results in a match with the data that is being processed. The integrated caching feature is an exception.

Feature-Specific Differences in Policy Bindings

You can bind policies to built-in, global bind points (or banks), to virtual servers, or to policy labels.

However, the NetScaler features differ in terms of the types of bindings that are available. The following table summarizes how you use policy bindings in various NetScaler features that use policies.

Table 1. Feature-Specific Bindings for Policies

Feature Name	Virtual Servers Configured in the Feature	Policies Configured in the Feature	Bind Points Configured for the Policies	Use of Policies in the Feature
DNS	none	DNS policies	Global	To determine how to perform DNS resolution for requests.
Content Switching Note: This feature can support either or classic policies or policies that use the default syntax, but not both.	Content Switching (CS)	Content Switching policies	• Content switching or cache redirection virtual server • Policy label	To determine what server or group of servers is responsible for serving responses, based on characteristics of an incoming request. Request characteristics include device type, language, cookies, HTTP method, content type, and associated cache server.
Integrated Caching	none	Caching policies	• Global override • Global default	To determine whether HTTP responses can be stored in, and served from, the NetScaler appliance's integrated cache.

Feature Name	Virtual Servers Configured in the Feature	Policies Configured in the Feature	Bind Points Configured for the Policies	Use of Policies in the Feature
			• Policy label • Load balancing, content switching, or SSL offload virtual server	
Responder	none	Responder policies	• Global override • Global default • Policy label • Load balancing, content switching, or SSL offload virtual server	To configure the behavior of the Responder function.
Rewrite	none	Rewrite policies	• Global override • Global default • Policy label • Load balancing, content switching, or SSL offload virtual server	To identify HTTP data that you want to modify before serving. The policies provide rules for modifying the data. For example, you can modify HTTP data to redirect a request to a selected server based on the address of the incoming request, or to mask server information in a response for security purposes.
URL Transform function in the Rewrite feature	none	Transformation policies	• Global override • Global default	To identify URLs in HTTP transactions and text files for the purpose of evaluating whether a URL should be altered.

Feature Name	Virtual Servers Configured in the Feature	Policies Configured in the Feature	Bind Points Configured for the Policies	Use of Policies in the Feature
NetScaler Gateway (clientless VPN functions only)	VPN server	Clientless Access policies	• Policy label • VPN Global • VPN server	To determine how the NetScaler Gateway performs authentication, authorization, auditing, and other functions, and to define rewrite rules for general Web access using the NetScaler Gateway.

Bind Points and Order of Evaluation

For a policy to take effect, you must ensure that the policy is invoked at some point during processing. To do so, you associate the policy with a bind point. The collection of policies that is bound to a bind point is known as a policy bank.

Following are the bind points that the NetScaler evaluates, listed in the typical order of evaluation within a policy bank

1. **Request-time override.** When a request flows through a feature, the NetScaler first evaluates request-time override policies for the feature.
2. **Request-time Load Balancing virtual server.** If policy evaluation cannot be completed after all the request-time override policies have been evaluated, the NetScaler processes request-time policies for load balancing virtual servers.
3. **Request-time Content Switching virtual server.** If policy evaluation cannot be completed after all the request-time policies for load balancing virtual servers have been evaluated, the NetScaler processes request-time policies for content switching virtual servers.
4. **Request-time default.** If policy evaluation cannot be completed after all request-time, virtual server-specific policies have been evaluated, the NetScaler processes request-time default policies.
5. **Response-time override.** At response time, the NetScaler starts with policies that are bound to the response-time override bind point.
6. **Response-time Load Balancing virtual server.** If policy evaluation cannot be completed after all response-time override policies have been evaluated, the NetScaler process the response-time policies for load balancing virtual servers.
7. **Response-time Content Switching virtual server.** If policy evaluation cannot be completed after all policies have been evaluated for load balancing virtual servers, the NetScaler process the response-time policies for content switching virtual servers.
8. **Response-time default.** If policy evaluation cannot be completed after all response-time, virtual-server-specific policies have been evaluated, the NetScaler processes response-time default policies.

Policy Evaluation across Features

In addition to attending to evaluation of policies within a feature, if you have bound policies to a content switching virtual server, note that these policies are evaluated before other policies. Binding a policy to a content switching vserver produces a different result in NetScaler versions 9.0.x and later than in 8.x versions. In NetScaler 9.0 and later versions, evaluation occurs as follows:

- Content switching policies are evaluated before other policies. If a content switching policy evaluates to TRUE, the target load balancing vserver is selected.
- If all content switching policies evaluate to FALSE, the default load balancing vserver under the content switching VIP is selected.

After a target load balancing vserver is selected by the content switching process, policies are evaluated in the following

order:

1. Policies that are bound to the global override bind point.
2. Policies that are bound to the default load balancing vserver.
3. Policies that are bound to the target content switching vserver.
4. Policies that are bound to the global default bind point.

To be sure that the policies are evaluated in the intended order, follow these guidelines:

- Make sure that the default load balancing vserver is not directly reachable from the outside; for example, the vserver IP address can be 0.0.0.0.
- To prevent exposing internal data on the load balancing default vserver, configure a policy to respond with a "503 Service Unavailable" status and bind it to the default load balancing vserver.

Entries in a Policy Bank

Each entry in a policy bank has, at minimum, a policy and a priority level. You can also configure entries that change the priority-based evaluation order, and you can configure entries that invoke external policy banks.

The following table summarizes each entry in a policy bank.

Table 2. Format of Each Entry in a Policy Bank

Policy Name	Priority	Goto Expression	Invocation Type	Policy Bank to Be Invoked
The policy name, or a "dummy" policy named NOPOLICY. The NOPOLICY entry controls evaluation flow without processing a rule.	An integer.	Optional. Identifies the next policy in the bank to evaluate, or ends any further evaluation	Optional. Indicates that an external policy bank will be invoked. This field restricts the choices to a global policy label or a virtual server.	Optional. Used with Invocation Type. This is the label for a policy bank or a virtual server name. The NetScaler returns to the current bank after processing the external bank.

If the policy evaluates to TRUE, the NetScaler stores the action that is associated with the policy. If the policy evaluates to FALSE, the NetScaler evaluates the next policy. If the policy is neither TRUE nor FALSE, the NetScaler uses the associated Undef (undefined) action.

Evaluation Order within a Policy Bank

Within a policy bank, the evaluation order depends on the following items:

A priority.

The most minimal amount of information about evaluation order is a numeric priority level. The lower the number, the higher the priority.

A Goto expression.

If supplied, the Goto expression indicates the next policy to be evaluated, typically within the same policy bank.. Goto expressions can only proceed forward in a bank. To prevent looping, a policy bank configuration is not valid if a Goto statement points backwards in the bank.

Invocation of other policy banks.

Any entry can invoke an external policy bank. The NetScaler provides a built-in entity named NOPOLICY that does not have a rule. You can add a NOPOLICY entry in a policy bank when you want to invoke another policy bank, but do not want to process any other rules prior to the invocation. You can have multiple NOPOLICY entries in multiple policy banks.

Values for a Goto expression are as follows:

NEXT.

This keyword selects the policy with the next higher priority level in the current policy bank.

An integer.

If you supply an integer, it must match the priority level of another policy in the current policy bank.

END.

This keyword stops evaluation after processing the current policy, and no additional policies in this bank are processed.

Blank.

If the Goto expression is empty, it is the same as specifying END.

A numeric expression.

This is a default syntax expression that resolves to a priority number for another policy in the current bank.

USE_INVOCATION_RESULT.

This phrase can be used only if you are invoking an external policy bank. Entering this phrase causes the NetScaler to perform one of the following actions:

- If the final Goto in the invoked policy bank has a value of END or is empty, the invocation result is END, and evaluation stops.
- If the final Goto expression in the invoked policy bank is anything other than END, the NetScaler performs a NEXT.

The following table illustrates a policy bank that uses Goto statements and policy bank invocations.

Table 3. Example of a Policy Bank That Uses Gotos and External Bank Invocations

Policy Name	Priority	Goto	Invocation	Policy Bank to Be Invoked
ClientCertificatePolicy (rule: does the request contain a client certificate?)	100	300	None	None
SubnetPolicy (rule: is the client from a private subnet?)	200	NEXT	None	None
NOPOLICY	300	USE INVOCATION RESULT	Request vserver	My_Request_VServer

Policy Name	Priority	Goto INVOCATION RESULT	Policy Invocation Label	Policy Bank to Be Invoked
NOPOLICY	350	USE	Policy	My_Policy_Label
WorkingHoursPolicy (rule: is it working hours?)	400	END	None	None

How Policy Evaluation Ends

Evaluation of a policy bank ends when one of the following takes place:

- A policy evaluates to TRUE and its Goto statement value is END.
  No further policies or policy banks in this feature are evaluated.
- An external policy bank is invoked, its evaluation returns an END, and the Goto statement uses a value of USE_INVOCATION_RESULT or END.
  Evaluation continues with the next policy bank for this feature. For example, if the current bank is the request-time override bank, the NetScaler next evaluates request-time policy banks for the virtual servers.
- The NetScaler has walked through all the policy banks in this feature, but has not encountered an END.
  If this is the last entry to be evaluated in this policy bank, the NetScaler proceeds to the next feature.

How Features Use Actions after Policy Evaluation

After evaluating all relevant policies for a particular data point (for example, an HTTP request), the NetScaler stores all the actions that are associated with any policy that matched the data.

For most features, all the actions from matching policies are applied to a traffic packet as it leaves the NetScaler. The Integrated Caching feature only applies one action: CACHE or NOCACHE. This action is associated with the policy with the lowest priority value in the “highest priority” policy bank (for example, request-time override policies are applied before virtual server-specific policies).

Binding a Policy Globally

Nov 14, 2013

The following binding procedures are typical. However, refer to the documentation for the feature of interest to you for complete instructions.

To bind an Integrated Caching policy globally by using the command line interface

At the command prompt, type the following commands to bind an Integrated Caching policy and verify the configuration:

- bind cache global <policy> -priority <positiveInteger> [-type REQ_OVERRIDE | REQ_DEFAULT | RES_OVERRIDE | RES_DEFAULT]
- show cache global

  Example

```
bind cache global _nonPostReq -priority 100 -type req_default
 Done
> show cache global
1)     Global bindpoint: REQ_DEFAULT
       Number of bound policies: 2

2)     Global bindpoint: RES_DEFAULT
       Number of bound policies: 1
 Done
```

  The type argument is optional to maintain backward compatibility. If you omit the type, the policy is bound to REQ_DEFAULT or RES_DEFAULT, depending on whether the policy rule is a response-time or a request-time expression.

To bind a Rewrite policy globally by using the command line interface

At the command prompt, type the following commands to bind a Rewrite policy and verify the configuration:

- bind rewrite global <policyName> <priority> [-type REQ_OVERRIDE | REQ_DEFAULT | RES_OVERRIDE | RES_DEFAULT]
- show rewrite global

  Example

```
bind rewrite global pol_remove-pdf 100
 Done
> show rewrite global
1)     Global bindpoint: REQ_DEFAULT
       Number of bound policies: 1

2)     Global bindpoint: REQ_OVERRIDE
       Number of bound policies: 1

 Done
```

  The type argument is optional for globally bound policies, to maintain backward compatibility. If you omit the type, the policy is bound to REQ_DEFAULT or RES_DEFAULT, depending on whether the policy rule is a response-time or a request-time expression.

To bind a compression policy globally by using the command line interface

At the command prompt, type the following commands to bind a compression policy and verify the configuration:

- bind cmp global <policyName> -priority <positiveInteger> [-type REQ_OVERRIDE | REQ_DEFAULT | RES_OVERRIDE | RES_DEFAULT]
- show cmp global

Example

```
> bind cmp global cmp_pol_1 -priority 100
 Done
> show cmp policy cmp_pol_1
        Name: cmp_pol_1
        Rule: HTTP.REQ.URL.SUFFIX.EQ("BMP")
        Response Action: COMPRESS
        Hits: 0

        Policy is bound to following entities
        1) GLOBAL REQ_DEFAULT
        Priority: 100
        GotoPriorityExpression: END
 Done
>
```

To bind a Responder policy globally by using the command line interface

At the command prompt, type the following commands to bind a Responder policy and verify the configuration:

- bind responder global <policyName> <priority> [-type OVERRIDE | DEFAULT]
- show responder global

Example

```
 bind responder global pol404Error1 200
 Done
> show responder global
1)     Global bindpoint: REQ_DEFAULT
        Number of bound policies: 1

 Done
```

To bind a DNS policy globally by using the command line interface

At the command prompt, type the following commands to bind a DNS policy and verify the configuration:

- bind dns global <policyName> <priority>
- show dns global

Example

```
> bind dns global pol_ddos_drop1 150
 Done
> show dns global
Policy name : pol_ddos_drop
        Priority : 100
```

```
        Goto expression : END
    Policy name : pol_ddos_drop1
        Priority : 150
     Done
    >
```

To bind an Integrated Caching, Responder, Rewrite, or Compression policy globally by using the configuration utility

1. In the navigation pane, click the name of the feature for which you want to bind the policy.
2. In the details pane, click <Feature Name> policy manager.
3. In the Policy Manager dialog box, select the bind point to which you want to bind the policy (for example, for Integrated Caching, Rewrite, or Compression, you could select Request and Default Global). The Responder does not differentiate between request-time and response-time policies.
4. Click Insert Policy and, from the Policy Name pop-up menu, select the policy name. A priority is assigned automatically to the policy, but you can click the cell in the Priority column and drag it anywhere within the dialog box if you want the policy to be evaluated after other policies in this bank. The priority is automatically reset. Note that priority values within a policy bank must be unique.
5. Click Apply Changes.
6. Click Close. A message in the status bar indicates that the policy is bound successfully.

To bind a DNS policy globally by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.
3. In the global bindings dialog box, click Insert Policy, and select the policy that you want to bind globally.
4. Click in the Priority field and enter the priority level.
5. Click OK. A message in the status bar indicates that the policy is bound successfully.

Binding a Policy to a Virtual Server

Nov 14, 2013

A globally bound policy applies to all load balancing and content switching virtual servers.

Note that when binding a policy to a virtual server, you must identify it as a request-time or a response-time policy.

To bind a policy to a load balancing or content switching virtual server by using the command line interface

At the command prompt, type the following commands to bind a policy to a load balancing or content switching virtual server and verify the configuration:

- bind lb|cs vserver <virtualServerName> -policyName <policyName> -priority <positiveInteger> -type REQUEST|RESPONSE
- show lb vserver <name>

Example

```
> bind lb vserver lbvip -policyName ns_cmp_msapp -priority 50
 Done
> show lb vserver lbvip
        lbvip (8.7.6.6:80) - HTTP       Type: ADDRESS
        State: DOWN
        Last state change was at Wed Jul 15 05:54:24 2009 (+226 ms)
        Time since last state change: 28 days, 01:57:26.350
        Effective State: DOWN
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        No. of Bound Services :  0 (Total)      0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE
        Vserver IP and Port insertion: OFF
        Push: DISABLED  Push VServer:
        Push Multi Clients: NO
        Push Label Rule: none

    1)      Policy : ns_cmp_msapp Priority:50
    2)      Policy : cf-pol Priority:1      Inherited
     Done
```

To bind a policy to an SSL offload virtual server by using the command line interface

At the command prompt, type the following commands to bind a policy to an SSL offload virtual server and verify the configuration:

bind ssl vserver <vServerName>@ -policyName <policyName> -priority <positiveInteger>

To bind a policy to a virtual server by using the configuration utility

1. In the navigation pane, expand Traffic Management > Load Balancing, Traffic Management > Content Switching, Traffic Management > SSL Offload, Security > AAA- Application Traffic, or NetScaler Gateway, and then click Virtual Servers.
2. In the details pane, double-click the virtual server to which you want to bind the policy, and then click Open.
3. On the Policies tab, click the icon for the type of policy that you want to bind (the choices are feature-specific), and then click the name of the policy. Note that for some features, you can bind both classic policies and policies that use the default syntax to the virtual server.
4. If you are binding a policy to a Content Switching virtual server, in the Target field select a load balancing virtual server to which traffic that matches the policy is sent.
5. Click OK. A message in the status bar indicates that the policy is bound successfully.

Displaying Policy Bindings

Oct 29, 2013

You can display policy bindings to verify that they are correct.

To display policy bindings by using the command line interface

At the command prompt, type the following commands to display policy bindings and verify the configuration:
show rewrite policy <name>

Example

```
> show rewrite policy pol_remove-pdf
      Name: pol_remove-pdf
      Rule: http.req.url.contains(".pdf")
      RewriteAction: act_remove-ae
      UndefAction: Use Global
      Hits: 0
      Undef Hits: 0
      Bound to: GLOBAL REQ_DEFAULT
      Priority: 100
      GotoPriorityExpression: END
 Done
>
```

To display global policy bindings for Integrated Caching, Rewrite, or Responder by using the configuration utility

1. In the navigation pane, expand the feature that contains the policy that you want to view, and then click Policies.
2. In the details pane, click the policy. Bound policies have a check mark next to them.
3. At the bottom of the page, under Details, next to Bound to, view the entity to which the policy is bound.

To display global policy bindings for DNS or Clientless Access in the NetScaler Gateway by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.

To display global policy bindings for Content Switching by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. In detailed pane, select policy.
3. In the details pane, click Show Bindings.

Unbinding a Policy

Nov 14, 2013

If you want to re-assign a policy or delete it, you must first remove its binding.

To unbind an integrated caching, rewrite, or compression default syntax policy globally by using the command line interface

At the command prompt, type the following commands to unbind an integrated caching, rewrite, or compression default syntax policy globally and verify the configuration:

- unbind cache | rewrite | cmp global <policyName> [-type req_override | req_default | res_override | res_default] [-priority <positiveInteger>]
- show cache | rewrite | cmp global

Example

```
> unbind cache global_nonPostReq
 Done
> show cache global
1)     Global bindpoint: REQ_DEFAULT
       Number of bound policies: 1

2)     Global bindpoint: RES_DEFAULT
       Number of bound policies: 1

 Done
```

The priority is required only for the “dummy” policy named NOPOLICY.

To unbind a responder policy globally by using the command line interface

At the command prompt, type the following commands to unbind a responder policy globally and verify the configuration:

- unbind responder global <policyName> [-type override | default] [-priority <positiveInteger>]
- show responder global

Example

```
> unbind responder global pol404Error
 Done
> show responder global
1)     Global bindpoint: REQ_DEFAULT
       Number of bound policies: 1

 Done
```

The priority is required only for the “dummy” policy named NOPOLICY.

To unbind a DNS policy globally by using the command line interface

At the command prompt, type the following commands to unbind a DNS policy globally and verify the configuration:

- unbind responder global <policyName>
- unbind responder global

Example

```
unbind dns global dfgdfg
Done
show dns global
Policy name : dfgdfggfhg
      Priority : 100
      Goto expression : END
Done
```

To unbind a default syntax policy from a virtual server by using the command line interface

At the command prompt, type the following commands to unbind a default syntax policy from a virtual server and verify the configuration:

- unbind cs vserver <name> -policyName <policyName> [-priority <positiveInteger>] [-type REQUEST | RESPONSE]
- show lb vserver <name>

Example

```
unbind cs vserver vs-cont-switch  -policyName pol1
Done
> show cs vserver vs-cont-switch
      vs-cont-switch (10.102.29.10:80) - HTTP Type: CONTENT
      State: UP
      Last state change was at Wed Aug 19 08:56:55 2009 (+18 ms)
      Time since last state change: 0 days, 02:47:55.750
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Port Rewrite : DISABLED
      State Update: DISABLED
      Default:       Content Precedence: RULE
      Vserver IP and Port insertion: OFF
      Case Sensitivity: ON
      Push: DISABLED  Push VServer:
      Push Label Rule: none
Done
```

The priority is required only for the “dummy” policy named NOPOLICY.

To unbind an integrated caching, responder, rewrite, or compression default syntax policy globally by using the configuration utility

1. In the navigation pane, click the feature with the policy that you want to unbind (for example, Integrated Caching).
2. In the details pane, click <Feature Name> policy manager.
3. In the Policy Manager dialog box, select the bind point with the policy that you want to unbind, for example, Default Global.
4. Click the policy name that you want to unbind, and then click Unbind Policy.
5. Click Apply Changes.
6. Click Close. A message in the status bar indicates that the policy is unbound successfully.

To unbind a DNS policy globally by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.
3. In the Global Bindings dialog box, select policy and click unbind policy.
4. Click OK. A message in the status bar indicates that the policy is unbinded successfully.

To unbind a default syntax policy from a load balancing or content switching virtual server by using the configuration utility

1. Navigate to Traffic Management, and expand Load Balancing or Content Switching, and then click Virtual Servers.
2. In the details pane, double-click the virtual server from which you want to unbind the policy.
3. On the Policies tab, in the Active column, clear the check box next to the policy that you want to unbind.
4. Click OK. A message in the status bar indicates that the policy is unbinded successfully.

Creating Policy Labels

May 25, 2015

In addition to the built-in bind points where you set up policy banks, you can also configure user-defined policy labels and associate policies with them.

Within a policy label, you bind policies and specify the order of evaluation of each policy relative to others in the bank of policies for the policy label. The NetScaler also permits you to define an arbitrary evaluation order as follows:

- You can use “goto” expressions to point to the next entry in the bank to be evaluated after the current one.
- You can use an entry in a policy bank to invoke another bank.

This document includes the following details:

Creating Policy Labels

Updated: 2013-11-14

Each feature determines the type of policy that you can bind to a policy label, the type of load balancing virtual server that you can bind the label to, and the type of content switching virtual server from which the label can be invoked. For example, a TCP policy label can only be bound to a TCP load balancing virtual server. You cannot bind HTTP policies to a policy label of this type. And you can invoke a TCP policy label only from a TCP content switching virtual server.

After configuring a new policy label, you can invoke it from one or more banks for the built-in bind points.

To create a caching policy label by using the command line interface

At the command prompt, type the following commands to create a Caching policy label and verify the configuration:

- add cache policylabel <labelName> -evaluates req|res
- show cache policylabel<labelName>

Example

```
> add cache policylabel lbl-cache-pol -evaluates req
 Done

> show cache policylabel lbl-cache-pol
      Label Name: lbl-cache-pol
      Evaluates: REQ
      Number of bound policies: 0
      Number of times invoked: 0
 Done
>
```

To create a Content Switching policy label by using the command line interface

At the command prompt, type the following commands to create a Content Switching policy label and verify the configuration:

- add cs policylabel <labelName> http|tcp|rtsp|ssl

- show cs policylabel <labelName>

  Example

```
> add cs policylabel lbl-cs-pol http
 Done
> show cs policylabel lbl-cs-pol
      Label Name: lbl-cs-pol
      Label Type: HTTP
      Number of bound policies: 0
      Number of times invoked: 0
 Done
```

To create a Rewrite policy label by using the command line interface

At the command prompt, type the following commands to create a Rewrite policy label and verify the configuration:

- add rewrite policylabel <labelName> http_req|http_res|url|text|clientless_vpn_req|clientless_vpn_res
- show rewrite policylabel <labelName>

  Example

```
> add rewrite policylabel lbl-rewrt-pol http_req
 Done

> show rewrite policylabel lbl-rewrt-pol
      Label Name: lbl-rewrt-pol
      Transform Name: http_req
      Number of bound policies: 0
      Number of times invoked: 0
 Done
```

To create a Responder policy label by using the command line interface

At the command prompt, type the following commands to create a Responder policy label and verify the configuration:

- add responder policylabel <labelName>
- show responder policylabel <labelName>

  Example

```
> add responder policylabel lbl-respndr-pol
 Done

> show responder policylabel lbl-respndr-pol
      Label Name: lbl-respndr-pol
      Number of bound policies: 0
      Number of times invoked: 0
 Done
```

Note: Invoke this policy label from a policy bank. For more information, see "Binding a Policy to a Policy Label."

To create a policy label by using the configuration utility

1. In the navigation pane, expand the feature for which you want to create a policy label, and then click Policy Labels. The choices are Integrated Caching, Rewrite, Content Switching, or Responder.
2. In the details pane, click Add.
3. In the Name box, enter a unique name for this policy label.
4. Enter feature-specific information for the policy label. For example, for Integrated Caching, in the Evaluates drop-down menu, you would select REQ if you want this policy label to contain request-time policies, or select RES if you want this policy label to contain response-time policies. For Rewrite, you would select a Transform name.
5. Click Create.
6. Configure one of the built-in policy banks to invoke this policy label. For more information, see "Binding a Policy to a Policy Label." A message in the status bar indicates that the policy label is created successfully.

Binding a Policy to a Policy Label

As with policy banks that are bound to the built-in bind points, each entry in a policy label is a policy that is bound to the policy label. As with policies that are bound globally or to a vserver, each policy that is bound to the policy label can also invoke a policy bank or a policy label that is evaluated after the current entry has been processed. The following table summarizes the entries in a policy label.

Name

The name of a policy, or, to invoke another policy bank without evaluating a policy, the “dummy” policy name NOPOLICY. You can specify NOPOLICY more than once in a policy bank, but you can specify a named policy only once.

Priority

An integer. This setting can work with the Goto expression.

Goto Expression

Determines the next policy to evaluate in this bank. You can provide one of the following values:

NEXT:

Go to the policy with the next higher priority.

END:

Stop evaluation.

USE_INVOCATION_RESULT:

Applicable if this entry invokes another policy bank. If the final Goto in the invoked bank has a value of END, evaluation stops. If the final Goto is anything other than END, the current policy bank performs a NEXT.

Positive number:

The priority number of the next policy to be evaluated.

Numeric expression:

An expression that produces the priority number of the next policy to be evaluated.

The Goto can only proceed forward in a policy bank.

If you omit the Goto expression, it is the same as specifying END.

Invocation Type

Designates a policy bank type. The value can be one of the following:

Request Vserver:

Invokes request-time policies that are associated with a virtual server.

Response Vserver:

Invokes response-time policies that are associated with a virtual server.

Policy label:

Invokes another policy bank, as identified by the policy label for the bank.

Invocation Name

The name of a virtual server or a policy label, depending on the value that you specified for the Invocation Type.

Configuring a Policy Label or Virtual Server Policy Bank

May 25, 2015

After you have created policies, and created policy banks by binding the policies, you can perform additional configuration of polices within a label or policy bank. For example, before you configure invocation of an external policy bank, you might want to wait until you have configured that policy bank.

This document includes the following details:

- Configuring a Policy Label
- Configuring a Policy Bank for a Virtual Server

Configuring a Policy Label

Updated: 2013-11-14

A policy label consists of a set of policies and invocations of other policy labels and virtual server-specific policy banks. An Invoke parameter enables you to invoke a policy label or a virtual server-specific policy bank from any other policy bank. A special-purpose NoPolicy entry enables you to invoke an external bank without processing an expression (a rule). The NoPolicy entry is a "dummy" policy that does not contain a rule.

For configuring policy labels from the NetScaler command line, note the following elaborations of the command syntax:

- gotoPriorityExpression is configured as described in "Entries in a Policy Bank."
- The type argument is required. This is unlike binding a conventional policy, where this argument is optional.
- You can invoke the bank of policies that are bound to a virtual server by using the same method as you use for invoking a policy label.

To configure a policy label by using the command line interface

At the command prompt, type the following commands to configure a policy label and verify the configuration:

- bind cache | rewrite | responder policylabel <policylabelName> -policyName <policyName> -priority <priority> [-gotoPriorityExpression <gotopriorityExpression>] [-invoke reqvserver | resvserver | policylabel <policyLabelName> | <vserverName>]
- show cache | rewrite | responder policylabel <policylabelName>

Example

```
bind cache policylabel _reqBuiltinDefaults -policyName  _nonGetReq -priority 100
Done
show cache policylabel _reqBuiltinDefaults
      Label Name: _reqBuiltinDefaults
      Evaluates: REQ
      Number of bound policies: 3
      Number of times invoked: 0
1)     Policy Name: _nonGetReq
       Priority: 100
       GotoPriorityExpression: END
2)     Policy Name: _advancedConditionalReq
      Priority: 200
      GotoPriorityExpression: END

3)     Policy Name: _personalizedReq
      Priority: 300
      GotoPriorityExpression: END
Done
```

To invoke a policy label from a Rewrite policy bank with a NOPOLICY entry by using the command line interface

At the command prompt, type the following commands to invoke a policy label from a Rewrite policy bank with a NOPOLICY entry and verify the configuration:

- bind rewrite global <policyName> <priority> <gotoPriorityExpression> -type REQ_OVERRIDE | REQ_DEFAULT | RES_OVERRIDE | RES_DEFAULT -invoke reqvserver | resvserver | policylabel <policyLabelName> | <vserverName>
- show rewrite global

Example

```
> bind rewrite global NOPOLICY 100 -type REQ_DEFAULT -invoke policylabel lbl-rewrt-pol
Done
> show rewrite global
1)     Global bindpoint: REQ_DEFAULT
      Number of bound policies: 1

2)     Global bindpoint: REQ_OVERRIDE
      Number of bound policies: 1
Done
```

To invoke a policy label from an Integrated Caching policy bank by using the command line interface

At the command prompt, type the following commands to invoke a policy label from an Integrated Caching policy bank and verify the configuration:

- bind cache global NOPOLICY -priority <priority> -gotoPriorityExpression <gotopriorityExpression> -type REQ_OVERRIDE | REQ_DEFAULT | RES_OVERRIDE | RES_DEFAULT -invoke reqvserver | resvserver | policylabel <policyLabelName> | <vserverName>
- show cache global

Example

```
bind cache global NOPOLICY -priority 100 -gotoPriorityExpression END -type REQ_DEFAULT -invoke policylabel lbl-cache-pol
Done
> show cache global
1)    Global bindpoint: REQ_DEFAULT
      Number of bound policies: 2

2)    Global bindpoint: RES_DEFAULT
      Number of bound policies: 1

Done
```

To invoke a policy label from a Responder policy bank by using the command line interface

At the command prompt, type the following commands to invoke a policy label from a Responder policy bank and verify the configuration:

- bind responder global NOPOLICY <priority> <gotopriorityExpression> -type OVERRIDE | DEFAULT -invoke vserver | policylabel <policyLabelName> | <vserverName>
- show responder global

Example

```
> bind responder global NOPOLICY 100 NEXT -type DEFAULT -invoke policylabel lbl-respndr-pol
Done
> show responder global
1)    Global bindpoint: REQ_DEFAULT
      Number of bound policies: 2

Done
```

To configure a policy label by using the configuration utility

1. In the navigation pane, expand the feature for which you want to configure a policy label, and then click Policy Labels. The choices are Integrated Caching, Rewrite, or Responder.
2. In the details pane, double-click the label that you want to configure.
3. If you are adding a new policy to this policy label, click Insert Policy, and in the Policy Name field, select New Policy. For more information about adding a policy, see "Creating or Modifying a Policy." Note that if you are invoking a policy bank, and do not want a rule to be evaluated prior to the invocation, click Insert Policy, and in the Policy Name field select NOPOLICY.
4. For each entry in this policy label, configure the following:
   Policy Name:
   This is already determined by the Policy Name, new policy, or NOPOLICY entry that you inserted in this bank.
   Priority:
   A numeric value that determines either an absolute order of evaluation within the bank, or is used in conjunction with a Goto expression.
   Expression:
   The policy rule. Policy expressions are described in detail in the following chapters. For an introduction, see "Configuring Default Syntax Expressions: Getting Started."
   Action:
   The action to be taken if this policy evaluates to TRUE.
   Goto Expression:
   Optional. Used to augment the Priority level to determine the next policy or policy bank to evaluate. For more information on possible values for a Goto expression, see the table "Entries in a Policy Bank."
   Invoke:
   Optional. Invokes another policy bank.
5. Click Ok. A message in the status bar indicates that the policy label is configured successfully.

Configuring a Policy Bank for a Virtual Server

Updated: 2013-09-02

You can configure a bank of policies for a virtual server. The policy bank can contain individual policies, and each entry in the policy bank can optionally invoke a policy label or a bank of policies that you configured for another virtual server. If you invoke a policy label or policy bank, you can do so without triggering an expression (a rule) by selecting a NOPOLICY "dummy" entry instead of a policy name.

To add policies to a virtual server policy bank by using the command line interface

At the command prompt, type the following commands to add policies to a virtual server policy bank and verify the configuration:

- bind lb | cs vserver <virtualServerName> <serviceType> [-policyName <policyName>] [-priority <positiveInteger>] [-gotoPriorityExpression <expression>] [-type REQUEST | RESPONSE]
- show lb | cs vserver <virtualServerName>

Example

```
add lb vserver vs-cont-sw TCP
```

```
Done
show lb vserver vs-cont-sw
    vs-cont-sw (0.0.0.0:0) - TCP    Type: ADDRESS
    State: DOWN
    Last state change was at Wed Aug 19 10:04:02 2009 (+279 ms)
    Time since last state change: 0 days, 00:02:14.420
    Effective State: DOWN
    Client Idle Timeout: 9000 sec
    Down state flush: ENABLED
    Disable Primary Vserver On Down : DISABLED
    No. of Bound Services :  0 (Total)      0 (Active)
    Configured Method: LEASTCONNECTION
    Mode: IP
    Persistence: NONE
    Connection Failover: DISABLED
Done
```

To invoke a policy label from a virtual server policy bank with a NOPOLICY entry by using the command line interface

At the command prompt, type the following commands to invoke a policy label from a virtual server policy bank with a NOPOLICY entry and verify the configuration:

- bind lb|cs vserver <virtualServerName> -policyName NOPOLICY_REWRITE|NOPOLICY_CACHE|NOPOLICY_RESPONDER -priority <integer> -type REQUEST|RESPONSE -gotoPriorityExpression <gotopriorityExpression> -invoke reqVserver|resVserver|policyLabel <vserverName>|<labelName>
- show lb vserver

Example

```
> bind lb vserver vs-cont-sw -policyname NOPOLICY-REWRITE -priority 200 -type REQUEST -gotoPriorityExpression NEXT -invoke policyLabel lbl-rewrt-pol
 Done
```

To configure a virtual server policy bank by using the configuration utility

1. In the left navigation pane, expand Traffic Management > Load Balancing, Traffic Management > Content Switching, Traffic Management > SSL Offload, Security > AAA - Application Traffic, or NetScaler Gateway, as appropriate, and then click Virtual Servers.
2. In the details pane, select the virtual server that you want to configure, and then click Open.
3. In the Configure Virtual Server dialog box click the Policies tab.
4. To create a new policy in this bank, click the icon for the type of policy or policy label that you want to add to the virtual server's bank of policies, click Insert Policy. Note that if you want to invoke a policy label without evaluating a policy rule, select the NOPOLICY "dummy" policy.
5. To configure an existing entry in this policy bank, enter the following:
   Priority:
   A numeric value that determines either an absolute order of evaluation within the bank or is used in conjunction with a Goto expression.
   Expression:
   The policy rule. Policy expressions are described in detail in the following chapters. For an introduction, see "Configuring Default Syntax Expressions: Getting Started."
   Action: on:
   The action to be taken if this policy evaluates to TRUE.
   Goto Expression:
   Optional. Determines the next policy or policy bank to evaluate. For more information on possible values for a Goto expression, see "Entries in a Policy Bank."
   Invoke:
   Optional. To invoke another policy bank, select the name of the policy label or virtual server policy bank that you want to invoke.
6. When you are done, click OK. A message in the status bar indicates that the policy is configured successfully.

Invoking or Removing a Policy Label or Virtual Server Policy Bank

Nov 14, 2013

Unlike a policy, which can only be bound once, you can use a policy label or a virtual server's policy bank any number of times by invoking it. Invocation can be performed from two places:

- From the binding for a named policy in a policy bank.
- From the binding for a NOPOLICY "dummy" entry in a policy bank.

Typically, the policy label must be of the same type as the policy from which it is invoked. For example, you would invoke a responder policy label from a responder policy.

Note: When binding or unbinding a global NOPOLICY entry in a policy bank at the command line, you specify a priority to distinguish one NOPOLICY entry from another.

To invoke a rewrite or integrated caching policy label by using the command line interface

At the command prompt, type the one of the following commands to invoke a rewrite or integrated caching policy label and verify the configuration:

- bind cache global <policy> -priority <positive_integer> [**-gotoPriorityExpression** <expression>] **-type REQ_OVERRIDE**|**REQ_DEFAULT**|**RES_OVERRIDE**|**RES_DEFAULT**] **-invoke reqvserver**|**resvserver**|**policylabel** <label_name>
- bind rewrite global<policy> -priority <positive_integer> [**-gotoPriorityExpression** <expression>] **-type REQ_OVERRIDE**|**REQ_DEFAULT**|**RES_OVERRIDE**|**RES_DEFAULT**] **-invoke reqvserver**|**resvserver**|**policylabel** <label_name>
- show cache global|show rewrite global

Example

```
> bind cache global _nonPostReq2 -priority 100 -type req_override -invoke
policylabel lbl-cache-pol
 Done
> show cache global
1)    Global bindpoint: REQ_DEFAULT
      Number of bound policies: 2

2)    Global bindpoint: RES_DEFAULT
      Number of bound policies: 1

3)    Global bindpoint: REQ_OVERRIDE
      Number of bound policies: 1

 Done
```

To invoke a responder policy label by using the command line interface

At the command prompt, type the following commands to invoke a responder policy label and verify the configuration:

- **bind responder global** <policy_Name> <priority_as_positive_integer> [<gotoPriorityExpression>] **-type REQ_OVERRIDE**|**REQ_DEFAULT**|**OVERRIDE**|**DEFAULT -invoke vserver**|**policylabel** <label_name>
- **show responder global**

Example

```
> bind responder global pol404Error1 300 -invoke policylabel lbl-respndr-pol
 Done
> show responder global
1)     Global bindpoint: REQ_DEFAULT
       Number of bound policies: 2

 Done
>
```

To invoke a Virtual Server Policy Bank by using the command line interface

At the command prompt, type the following commands to invoke a Virtual Server Policy Bank and verify the configuration:

- **bind lb vserver** <vserver_name> **-policyName** <policy_Name> **-priority** <positive_integer> [**-gotoPriorityExpression** <expression>] **-type REQUEST**|**RESPONSE -invoke reqvserver**|**resvserver**|**policylabel** <policy_Label_Name>
- **bind lb vserver** <vserver_name>

Example

```
> bind lb vserver lbvip -policyName ns_cmp_msapp -priority 100
 Done

> show lb vserver lbvip
       lbvip (8.7.6.6:80) - HTTP       Type: ADDRESS
       State: DOWN
       Last state change was at Wed Jul 15 05:54:24 2009 (+166 ms)
       Time since last state change: 28 days, 06:37:49.250
       Effective State: DOWN
       Client Idle Timeout: 180 sec
       Down state flush: ENABLED
       Disable Primary Vserver On Down : DISABLED
       Port Rewrite : DISABLED
       No. of Bound Services :  0 (Total)      0 (Active)
       Configured Method: LEASTCONNECTION
       Mode: IP
       Persistence: NONE
       Vserver IP and Port insertion: OFF
       Push: DISABLED  Push VServer:
       Push Multi Clients: NO
       Push Label Rule: none

1)     CSPolicy: pol-cont-sw   CSVserver: vs-cont-sw   Priority: 100   Hits: 0

1)     Policy : pol-ssl Priority:0
2)     Policy : ns_cmp_msapp Priority:100
3)     Policy : cf-pol Priority:1      Inherited
 Done
```

>

To remove a rewrite or integrated caching policy label by using the command line interface

At the command prompt, type one of the following commands to remove a rewrite or integrated caching policy label and verify the configuration:

- unbind rewrite global <policyName> -priority <positiveInteger> -type **REQ_OVERRIDE**|**REQ_DEFAULT**|**RES_OVERRIDE**|**RES_DEFAULT**
- unbind cache global <policyName> -priority <positiveInteger> -type **REQ_OVERRIDE**|**REQ_DEFAULT**|**RES_OVERRIDE**|**RES_DEFAULT**
- show rewrite global|show cache global

Example

```
> unbind rewrite global NOPOLICY -priority 100 -type REQ_OVERRIDE
 Done
> show rewrite global
1)     Global bindpoint: REQ_DEFAULT
       Number of bound policies: 1

 Done
```

To remove a responder policy label by using the command line interface

At the command prompt, type the following commands to remove a responder policy label and verify the configuration:

- unbind responder global <policyName> -priority <positiveInteger> **-type OVERRIDE**|**DEFAULT**
- **show responder global**

Example

```
> unbind responder global NOPOLICY -priority 100 -type REQ_DEFAULT
 Done
> show responder global
1)     Global bindpoint: REQ_DEFAULT
       Number of bound policies: 1

 Done
```

To remove a Virtual Server policy label by using the command line interface

At the command prompt, type one of the following commands to remove a Virtual Server policy label and verify the configuration:

- unbind lb vserver <virtualServerName> -policyName **NOPOLICY-REWRITE**|**NOPOLICY-RESPONDER**|**NOPOLICY-CACHE -type REQUEST**|**RESPONSE -priority** <positiveInteger>
- unbind cs vserver <virtualServerName> -policyName **NOPOLICY-REWRITE**|**NOPOLICY-RESPONDER**|**NOPOLICY-CACHE -type REQUEST**|**RESPONSE -priority** <positiveInteger>
- show lb vserver|show cs vserver

Example

```
> unbind lb vserver lbvip -policyName ns_cmp_msapp -priority 200
 Done
> show lb vserver lbvip
```

```
lbvip (8.7.6.6:80) - HTTP       Type: ADDRESS
State: DOWN
Last state change was at Wed Jul 15 05:54:24 2009 (+161 ms)
Time since last state change: 28 days, 06:47:54.600
Effective State: DOWN
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Port Rewrite : DISABLED
No. of Bound Services :  0 (Total)      0 (Active)
Configured Method: LEASTCONNECTION
Mode: IP
Persistence: NONE
Vserver IP and Port insertion: OFF
Push: DISABLED  Push VServer:
Push Multi Clients: NO
Push Label Rule: none

1)     CSPolicy: pol-cont-sw   CSVserver: vs-cont-sw   Priority: 100   Hits: 0

1)     Policy : pol-ssl Priority:0
2)     Policy : cf-pol Priority:1      Inherited
 Done
```

To invoke a policy label or virtual server policy bank by using the configuration utility

1. Bind a policy, as described in "Binding a Policy Globally", "Binding a Policy to a Virtual Server", or "Binding a Policy to a Policy Label." Alternatively, you can enter a NOPOLICY “dummy” entry instead of a policy name. You do this if you do not want to evaluate a policy before evaluating the policy bank.
2. In the Invoke field, select the name of the policy label or virtual server policy bank that you want to evaluate if traffic matches the bound policy. A message in the status bar indicates that the policy label or virtual server policy bank is invoked successfully.

To remove a policy label invocation by using the configuration utility

1. Open the policy and clear the Invoke field. Unbinding the policy also removes the invocation of the label. A message in the status bar indicates that the policy label is removed successfully.

Configuring and Binding Policies with the Policy Manager

Sep 02, 2013

Some applications provide a specialized Policy Manager in the NetScaler configuration utility to simplify configuring policy banks. It also lets you find and delete policies and actions that are not being used.

The Policy Manager is currently available for the Rewrite, Integrated Caching, Responder, and Compression features.

The following are keyboard equivalents for the procedures in this section:

- For editing a cell in the Policy Manager, you can tab to the cell and click F2 or press the SPACE bar on the keyboard.
- To select an entry in a drop-down menu, you can tab to the entry, press the space bar to view the drop-down menu, use the UP and DOWN ARROW keys to navigate to the entry that you want, and press the space bar again to select the entry.
- To cancel a selection in a drop-down menu, press the Escape key.
- To insert a policy, tab to the row above the insertion point and press Control + Insert, or click Insert Policy.
- To remove a policy, tab to the row that contains the policy and press Delete.

Note: Note that when you delete the policy, the NetScaler searches the Goto Expression values of other policies in the bank. If any of these Goto Expression values match the priority level of the deleted policy, they are removed.

To configure policy bindings by using the Policy Manager

1. In the navigation pane, click the feature for which you want to configure policies. The choices are Responder, Integrated Caching, Rewrite or Compression.
2. In the details pane, click Policy Manager.
3. If you are configuring classic policy bindings for compression, in the Compression Policy Manager dialog box, click **Switch to Classic Syntax**. The dialog box switches to the classic syntax view and displays the Switch to Default Syntax button. At any time before you complete configuring policy bindings, if you want to configure bindings for policies that use the default syntax, click the Switch to Default Syntax button.
4. For features other than Responder, to specify the bind point, click Request or Response, and then click one of the request-time or response-time bind points. The options are Override Global, LB Virtual Server, CS Virtual Server, Default Global, or Policy Label. If you are configuring the Responder, the Request and Response flow types are not available.
5. To bind a policy to this bind point, click Insert Policy, and select a previously configured policy, a NOPOLICY label, or the New policy option. Depending on the option that you select, you have the following choices:
   - **New policy:** Create the policy as described in "Creating or Modifying a Policy," and then configure the priority level, GoTo expression, and policy invocation as described in the table, "Format of Each Entry in a Policy Bank."
   - **Existing policy**, **NOPOLICY**, or **NOPOLICY<feature name>**: Configure the priority level, GoTo expression, and policy invocation as described in the table, "Format of Each Entry in a Policy Bank." The **NOPOLICY** or **NOPOLICY<feature name>** options are available only for policies that use default syntax expressions.
6. Repeat the preceding steps to add entries to this policy bank.
7. To modify the priority level for an entry, you can do any of the following:
   - Double-click the Priority field for an entry and edit the value.
   - Click and drag a policy to another row in the table.
   - Click Regenerate Priorities.

   In all three cases, priority levels of all other policies are modified as needed to accommodate the new value. Goto Expressions with integer values are also updated automatically. For example, if you change a priority value of 10 to 100,

all policies with a Goto Expression value of 10 are updated to the value 100.

8. To change the policy, action, or policy bank invocation for an row in the table, click the down arrow to the right of the entry and do one of the following:
   - To change the policy, select another policy name or select New Policy and follow the steps in "Creating or Modifying a Policy."
   - To change the Goto Expression, select Next, End, USE_INVOCATION_RESULT, or select more and enter an expression whose result returns the priority level of another entry in this policy bank.
   - To modify an invocation, select an existing policy bank, or click New Policy Label and follow the steps in "Binding a Policy to a Policy Label."
9. To unbind a policy or a policy label invocation from this bank, click any field in the row that contains the policy or policy label, and then click Unbind Policy.
10. When you are done, click Apply Changes. A message in the status bar indicates that the policy is bound successfully.

To remove unused policies by using the Policy Manager

1. In the navigation pane, click the feature for which you want to configure the policy bank. The choices are Responder, Integrated Caching, or Rewrite.
2. In the details pane, click <Feature Name> policy manager.
3. In the <Feature Name> Policy Manager dialog box, click Cleanup Configuration.
4. In the Cleanup Configuration dialog box, select the items that you want to delete, and then click Remove.
5. In the Remove dialog box, click Yes.
6. Click Close. A message in the status bar indicates that the policy is removed successfully.

Configuring Default Syntax Expressions: Getting Started

May 25, 2015

Default syntax policies evaluate data on the basis of information that you supply in default syntax expressions. A default syntax expression analyzes data elements (for example, HTTP headers, source IP addresses, the NetScaler system time, and POST body data). In addition to configuring a default syntax expression in a policy, in some NetScaler features you configure default syntax expressions outside of the context of a policy.

To create a default syntax expression, you select a prefix that identifies a piece of data that you want to analyze, and then you specify an operation to perform on the data. For example, an operation can match a piece of data with a text string that you specify, or it can transform a text string into an HTTP header. Other operations match a returned string with a set of strings or a string pattern. You configure compound expressions by specifying Boolean and arithmetic operators, and by using parentheses to control the order of evaluation.

Default syntax expressions can also contain classic expressions. You can assign a name to a frequently used expression to avoid having to build the expression repeatedly.

Policies and a few other entities include rules that the NetScaler uses to evaluate a packet in the traffic flowing through it, to extract data from the NetScaler system itself, to send a request (a “callout”) to an external application, or to analyze another piece of data. A rule takes the form of a logical expression that is compared against traffic and ultimately returns values of TRUE or FALSE.

The elements of the rule can themselves return TRUE or FALSE, string, or numeric values.

Before configuring a default syntax expression, you need to understand the characteristics of the data that the policy or other entity is to evaluate. For example, when working with the Integrated Caching feature, a policy determines what data can be stored in the cache. With Integrated Caching, you need to know the URLs, headers, and other data in the HTTP requests and responses that the NetScaler receives. With this knowledge, you can configure policies that match the actual data and enable the NetScaler to manage caching for HTTP traffic. This information helps you determine the type of expression that you need to configure in the policy.

Basic Elements of a Default Syntax Expression

May 25, 2015

A default syntax expression consists of, at a minimum, a prefix (or a single element used in place of a prefix). Most expressions also specify an operation to be performed on the data that the prefix identifies. You format an expression of up to 1,499 characters as follows:

```
<prefix>.<operation> [<compound-operator> <prefix>.<operation>. . .]
```

where

<prefix>

is an anchor point for starting an expression.

The prefix is a period-delimited key that identifies a unit of data. For example, the following prefix examines HTTP requests for the presence of a header named Content-Type:

```
http.req.header("Content-Type")
```

Prefixes can also be used on their own to return the value of the object that the prefix identifies.

<operation>

identifies an evaluation that is to be performed on the data identified by the prefix.

For example, consider the following expression:

```
http.req.header("Content-Type").eq("text/html")
```

In this expression, the following is the operator component:

```
eq("text/html")
```

This operator causes the NetScaler to evaluate any HTTP requests that contain a Content-Type header, and in particular, to determine if the value of this header is equal to the string “text/html.” For more information, see "Operations."

<compound-operator>

is a Boolean or arithmetic operator that forms a compound expression from multiple prefix or prefix.operation elements.

For example, consider the following expression:

```
http.req.header("Content-Type").eq("text/html") && http.req.url.contains(".html")
```

This document includes the following details:

- Prefixes
- Single-Element Expressions
- Operations
- Basic Operations on Expression Prefixes

Prefixes

Updated: 2013-09-30

An expression prefix represents a discrete piece of data. For example, an expression prefix can represent an HTTP URL, an HTTP Cookie header, or a string in the body of an HTTP POST request. An expression prefix can identify and return a wide

variety of data types, including the following:

- A client IP address in a TCP/IP packet
- NetScaler system time
- An external callout over HTTP
- A TCP or UDP record type

In most cases, an expression prefix begins with one of the following keywords:

CLIENT:

Identifies a characteristic of the client that is either sending a request or receiving a response, as in the following examples:

- The prefix `client.ip.dst` designates the destination IP address in the request or response.
- The prefix `client.ip.src` designates the source IP address.

HTTP:

Identifies an element in an HTTP request or a response, as in the following examples:

- The prefix `http.req.body(integer)` designates the body of the HTTP request as a multiline text object, up to the character position designated in integer.
- The prefix `http.req.header("header_name")` designates an HTTP header, as specified in header_name.
- The prefix `http.req.url` designates an HTTP URL in URL-encoded format.

SERVER:

Identifies an element in the server that is either processing a request or sending a response.

SYS:

Identifies a characteristic of the NetScaler that is processing the traffic.

Note: Note that DNS policies support only SYS, CLIENT, and SERVER objects.

In addition, in the NetScaler Gateway, the Clientless VPN function can use the following types of prefixes:

TEXT:

Identifies any text element in a request or a response.

TARGET:

Identifies the target of a connection.

URL:

Identifies an element in the URL portion of an HTTP request or response.

As a general rule of thumb, any expression prefix can be a self-contained expression. For example, the following prefix is a complete expression that returns the contents of the HTTP header specified in the string argument (enclosed in quotation marks):

```
http.res.header.("myheader")
```

Or you can combine prefixes with simple operations to determine TRUE and FALSE values. For example, the following returns a value of TRUE or FALSE:

```
http.res.header.("myheader").exists
```

You can also use complex operations on individual prefixes and multiple prefixes within an expression, as in the following example:

```
http.req.url.length + http.req.cookie.length <= 500
```

Which expression prefixes you can specify depends on the NetScaler feature. The following table describes the expression prefixes that are of interest on a per-feature basis

Table 1. Permitted Types of Expression Prefixes in Various NetScaler Features

Feature	Types of Expression Prefix Used in the Feature
DNS	SYS, CLIENT, SERVER
Responder in Protection Features	HTTP, SYS, CLIENT
Content Switching	HTTP, SYS, CLIENT
Rewrite	HTTP, SYS, CLIENT, SERVER, URL, TEXT, TARGET, VPN
Integrated Caching	HTTP, SYS, CLIENT, SERVER
NetScaler Gateway, Clientless Access	HTTP, SYS, CLIENT, SERVER, URL, TEXT, TARGET, VPN

Note: For details on the permitted expression prefixes in a feature, see the documentation for that feature.

Single-Element Expressions

The simplest type of default syntax expression contains a single element. This element can be one of the following:

- `true`. A default syntax expression can consist simply of the value `true`. This type of expression always returns a value of TRUE. It is useful for chaining policy actions and triggering Goto expressions.
- `false`. A default syntax expression can consist simply of the value `false`. This type of expression always returns a value of FALSE.
- A prefix for a compound expression. For example, the prefix `HTTP.REQ.HOSTNAME` is a complete expression that returns a host name and `HTTP.REQ.URL` is a complete expression that returns a URL. The prefix could also be used in conjunction with operations and additional prefixes to form a compound expression.

Operations

In most expressions, you also specify an operation on the data that the prefix identifies. For example, suppose that you specify the following prefix:

`http.req.url`

This prefix extracts URLs in HTTP requests. This expression prefix does not require any operators to be used in an expression. However, when you configure an expression that processes HTTP request URLs, you can specify operations that analyze particular characteristics of the URL. Following are a few possibilities:

- Search for a particular host name in the URL.
- Search for a particular path in the URL.
- Evaluate the length of the URL.
- Search for a string in the URL that indicates a time stamp and convert it to GMT.

The following is an example of a prefix that identifies an HTTP header named Server and an operation that searches for the string IIS in the header value:

```
http.res.header("Server").contains("IIS")
```

Following is an example of a prefix that identifies host names and an operation that searches for the string “www.mycompany.com” as the value of the name:

```
http.req.hostname.eq("www.mycompany.com")
```

Basic Operations on Expression Prefixes

The following table describes a few of the basic operations that can be performed on expression prefixes.

Table 2. Basic Operations for Expressions

Operation	Determines Whether or Not
CONTAINS(<string>)	The object matches <string>. Following is an example: `http.req.header("Cache-Control").contains("no-cache")`
EXISTS	A particular item is present in an object. Following is an example: `http.res.header("MyHdr").exists`
EQ(<text>)	A particular non-numeric value is present in an object. Following is an example: `http.req.method.eq(post)`
EQ(<integer>)	A particular numeric value is present in an object. Following is an example: `client.ip.dst.eq(10.100.10.100)`
LT(<integer>)	An object's value is less than a particular value. Following is an example: `http.req.content_length.lt(5000)`
GT(<integer>)	An object's value is greater than a particular value. Following is an example: `http.req.content_length.gt(5)`

The following table summarizes a few of the available types of operations.

Table 3. Basic Types of Operations

Operation Type	Description
Text operations	Match individual strings and sets of strings with any portion of a target. The target can be an entire string, the start of a string, or any portion of text in between the start and the end of the string. For example, you can extract the string "XYZ" from "XYZSomeText". Or, you can compare an HTTP header value with an array of different strings. You can also transform text into another type of data. Following are examples: • Transform a string into an integer value • Create a list from the query strings in a URL • Transform a string into a time value
Numeric operations	Numeric operations include applying arithmetic operators, evaluating content length, the number of items in a list, dates, times, and IP addresses.

Compound Default Syntax Expressions

May 25, 2015

You can configure a default syntax expression that contains Boolean or arithmetic operators and multiple atomic operations. The following compound expression contains a boolean AND:

```
http.req.hostname.eq("mycompany.com") && http.req.method.eq(post)
```

The following expression adds the value of two targets, and compares the result to a third value:

```
http.req.url.length + http.req.cookie.length <= 500
```

A compound expression can contain any number of logical and arithmetic operators. The following expression evaluates the length of an HTTP request on the basis of its URL and cookie, evaluates text in the header, and performs a Boolean AND on these two results:

```
http.req.url.length + http.req.cookie.length <= 500 && http.req.header.contains("some text")
```

You can use parentheses to control the order of evaluation in a compound expression.

This document includes the following details:

- Booleans in Compound Expressions
- Parentheses in Compound Expressions
- Compound Operations for Strings
- Compound Operations for Numbers

Booleans in Compound Expressions

You configure compound expressions with the following operators:

&&.

This operator is a logical AND. For the expression to evaluate to TRUE, all components that are joined by the And must evaluate to TRUE. Following is an example:

```
http.req.url.hostname.eq("myHost") && http.req.header("myHeader").exists
```

||.

This operator is a logical OR. If any component of the expression that is joined by the OR evaluates to TRUE, the entire expression is TRUE.

!.

Performs a logical NOT on the expression.

In some cases, the NetScaler configuration utility offers AND, NOT, and OR operators in the Add Expression dialog box. However, these are of limited use. Citrix recommends that you use the operators &&, ||, and ! to configure compound expressions that use Boolean logic.

Parentheses in Compound Expressions

You can use parentheses to control the order of evaluation of an expression. The following is an example:

```
http.req.url.contains("myCompany.com") || (http.req.url.hostname.eq("myHost") &&
http.req.header("myHeader").exists)
```

The following is another example:

```
(http.req.header("Content-Type").exists && http.req.header("Content-Type").eq("text/html")) ||
(http.req.header("Transfer-Encoding").exists || http.req.header("Content-Length").exists)
```

Compound Operations for Strings

The following table describes operators that you can use to configure compound operations on string data.

Table 1. String-Based Operations for Compound Default Syntax Expressions

All string operations	
Operations that produce a string value	
str + str	Concatenates the value of the expression on the left of the operator with the value on the right. Following is an example: `http.req.hostname + http.req.url.protocol`
str + num	Concatenates the value of the expression on the left of the operator with a numeric value on the right. Following is an example: `http.req.hostname + http.req.url.content_length`
num + str	Concatenates the numeric value of the expression on the left side of the operator with a string value on the right. Following is an example: `http.req.url.content_length + http.req.url.hostname`
str + ip	Concatenates the string value of the expression on the left side of the operator with an IP address value on the right. Following is an example: `http.req.hostname + 10.00.000.00`
ip + str	Concatenates the IP address value of the expression on the left of the operator with a string value on the right.Following is an example: `client.ip.dst + http.req.url.hostname`
str1 ALT str2	Uses the string1 or string2 value that is derived from the expression on either side of the operator, as long as neither of these expressions is a compound expressions. Following is an example: `http.req.hostname alt client.ip.src`
Operations on strings that produce a result of TRUE or FALSE	

All string operations	
str == str	Evaluates whether the strings on either side of the operator are the same. Following is an example: http.req.header("myheader") == http.res.header("myheader")
str <= str	Evaluates whether the string on the left side of the operator is the same as the string on the right, or precedes it alphabetically.
str >= str	Evaluates whether the string on the left side of the operator is the same as the string on the right, or follows it alphabetically.
str < str	Evaluates whether the string on the left side of the operator precedes the string on the right alphabetically.
str > str	Evaluates whether the string on the left side of the operator follows the string on the right alphabetically.
str != str	Evaluates whether the strings on either side of the operator are different.
Logical operations on strings	
bool && bool	This operator is a logical AND. When evaluating the components of the compound expression, all components that are joined by the AND must evaluate to TRUE. Following is an example: http.req.method.eq(GET) && http.req.url.query.contains("viewReport && my_pagelabel")
bool || bool	This operator is a logical OR. When evaluating the components of the compound expression, if any component of the expression that is joined by the OR evaluates to TRUE, the entire expression is TRUE. Following is an example: http.req.url.contains(".js") || http.res.header.("Content-Type").contains("javascript")
!bool	Performs a logical NOT on the expression.

Compound Operations for Numbers

Updated: 2013-09-02

You can configure compound numeric expressions. For example, the following expression returns a numeric value that is the sum of an HTTP header length and a URL length:

```
http.req.header.length + http.req.url.length
```

The following tables describes operators that you can use to configure compound expressions for numeric data.

Table 2. Arithmetic Operations on Numbers

Operator	Description
num + num	Add the value of the expression on the left of the operator to the value of the expression on the right. Following is an example: `http.req.content_length + http.req.url.length`
num – num	Subtract the value of the expression on the right of the operator from the value of the expression on the left.
num * num	Multiply the value of the expression on the left of the operator with the value of the expression on the right. Following is an example: `client.interface.rxthroughput * 9`
num / num	Divide the value of the expression on the left of the operator by the value of the expression on the right.
num % num	Calculate the modulo, or the numeric remainder on a division of the value of the expression on the left of the operator by the value of the expression on the right. For example, the values "15 mod 4" equals 3, and "12 mod 4" equals 0.
~number	Returns a number after applying a bitwise logical negation of the number. The following example assumes that numeric.expression returns 12 (binary 1100): `~numeric.expression.` The result of applying the ~ operator is -11 (a binary 1110011, 32 bits total with all ones to the left). Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.
number ^ number	Compares two bit patterns of equal length and performs an XOR operation on each pair of corresponding bits in each number argument, returning 1 if the bits are different, and 0 if they are the same. Returns a number after applying a bitwise XOR to the integer argument and the current number value. If the values in the bitwise comparison are the same, the returned value is a 0. The following example assumes that numeric.expression1 returns 12 (binary 1100) and numeric.expression2 returns 10 (binary 1010): `numeric.expression1 ^ numeric.expression2`

Operator	Description
	The result of applying the ^ operator to the entire expression is 6 (binary 0110). Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.
number | number	Returns a number after applying a bitwise OR to the number values. If either value in the bitwise comparison is a 1, the returned value is a 1. The following example assumes that numeric.expression1 returns 12 (binary 1100) and numeric.expression2 returns 10 (binary 1010): `numeric.expression1 | numeric.expression2` The result of applying the | operator to the entire expression is 14 (binary 1110). Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.
number & number	Compares two bit patterns of equal length and performs a bitwise AND operation on each pair of corresponding bits, returning 1 if both of the bits contains a value of 1, and 0 if either bits are 0. The following example assumes that numeric.expression1 returns 12 (binary 1100) and numeric.expression2 returns 10 (binary 1010): `numeric.expression1 & numeric.expression2` The whole expression evaluates to 8 (binary 1000). Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.
num << num	Returns a number after a bitwise left shift of the number value by the right-side number argument number of bits. Note that the number of bits shifted is integer modulo 32. The following example assumes that numeric.expression1 returns 12 (binary 1100) and numeric.expression2 returns 3: `numeric.expression1 << numeric.expression2` The result of applying the LSHIFT operator is 96 (a binary 1100000). Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.
num >> num	Returns a number after a bitwise right shift of the number value by the integer argument number of bits. Note that the number of bits shifted is integer modulo 32. The following example assumes that numeric.expression1 returns 12 (binary 1100) and numeric.expression2 returns 3: `numeric.expression1 >> numeric.expression2` The result of applying the RSHIFT operator is 1 (a binary 0001).

Operator	Description
	Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.

Table 3. Numeric Operators That Produce a Result of TRUE or FALSE

Operator	Description
num == num	Determine if the value of the expression on the left of the operator is equal to the value of the expression on the right.
num != num	Determine if the value of the expression on the left of the operator is not equal to the value of the expression on the right.
num > num	Determine if the value of the expression on the left of the operator is greater than the value of the expression on the right.
num < num	Determine if the value of the expression on the left of the operator is less than the value of the expression on the right.
num >= num	Determine if the value of the expression on the left of the operator is greater than or equal to the value of the expression on the right.
num <= num	Determine if the value of the expression on the left of the operator is less than or equal to the value of the expression on the right

Functions for Data Types in the Policy Infrastructure

The NetScaler policy infrastructure supports the following numeric data types:

- Integer (32 bits)
- Unsigned long (64 bits)
- Double (64 bits)

Simple expressions can return all of these data types. Therefore, you can create compound expressions that use arithmetic operators and logical operators to evaluate or return values of these data types. Additionally, you can use all of these values in policy expressions. Literal constants of type unsigned long can be specified by appending the string ul to the number. Literal constants of type double contain a period (.), an exponent, or both.

Arithmetic Operators, Logical Operators, and Type Promotion

In compound expressions, the following standard arithmetic and logical operators can be used for the double and unsigned long data types:

- +, -, *, and /

- %, ~, ^, &, |, <<, and >> (do not apply to double)
- ==, !=, >, <, >=, and <=

All of these operators have the same meaning as in the C programming language.

In all cases of mixed operations between operands of type integer, unsigned long, and double, type promotion is performed so that the operation can be performed on operands of the same type. A type of lower precedence is automatically promoted to the type of the operand with the highest precedence involved in the operation. The order of precedence (higher to lower) is as follows:

- Double
- Unsigned long
- Integer

Therefore, an operation that returns a numeric result returns a result of the highest type involved in the operation.

For example, if the operands are of type integer and unsigned long, the integer operand is automatically converted to type unsigned long. This type conversion is performed even in simple expressions in which the type of data identified by the expression prefix does not match the type of data that is passed as the argument to the function. To illustrate such an example, in the operation HTTP.REQ.CONTENT_LENGTH.DIV(3ul), the integer returned by the prefix HTTP.REQ.CONTENT_LENGTH is automatically converted to unsigned long (the type of the data passed as the argument to the DIV() function), and an unsigned long division is performed. Similarly, the argument can be promoted in an expression. For example, HTTP.REQ.HEADER("myHeader").TYPECAST_DOUBLE_AT.DIV(5) promotes the integer 5 to type double and performs double-precision division.

The following table describes the arithmetic and Boolean functions that can be used with the integer, unsigned long, and double data types. For information about expressions for casting data of one type to data of another type, see "Typecasting Data."

Specifying the Character Set in Expressions

Jul 11, 2013

The policy infrastructure on the Citrix® NetScaler® appliance supports the ASCII and UTF-8 character sets. The default character set is ASCII. If the traffic for which you are configuring an expression consists of only ASCII characters, you need not specify the character set in the expression. However, you must specify the character set in every simple expression that is meant for UTF-8 traffic. To specify the UTF-8 character set in a simple expression, you must include the SET_CHAR_SET(<charset>) function, with <charset> specified as UTF_8, as shown in the following examples:

```
HTTP.REQ.BODY(10).SET_CHAR_SET(UTF_8).CONTAINS("ß")
```

```
HTTP.RES.BODY(100).SET_CHAR_SET(UTF_8).BEFORE_STR("Bücher").AFTER_STR("Wörterbuch")
```

In an expression, the SET_CHAR_SET() function must be introduced at the point in the expression after which data processing must be carried out in the specified character set. For example, in the expression HTTP.REQ.BODY(1000).AFTER_REGEX(re/following example/).BEFORE_REGEX(re/In the preceding example/).CONTAINS_ANY("Greek_ alphabet"), if the strings stored in the pattern set "Greek_alphabet" are in UTF-8, you must include the SET_CHAR_SET(UTF_8) function immediately before the CONTAINS_ANY("<string>") function, as follows:

```
HTTP.REQ.BODY(1000).AFTER_REGEX(re/following example/).BEFORE_REGEX(re/In the preceding
example/).SET_CHAR_SET(UTF_8).CONTAINS_ANY("Greek_ alphabet")
```

The SET_CHAR_SET() function sets the character set for all further processing (that is, for all subsequent functions) in the expression unless it is overridden later in the expression by another SET_CHAR_SET() function that changes the character set. Therefore, if all the functions in a given simple expression are intended for UTF-8, you can include the SET_CHAR_SET(UTF_8) function immediately after functions that identify text (for example, the HEADER("<name>") or BODY(<int>) functions). In the second example that follows the first paragraph above, if the ASCII arguments passed to the AFTER_REGEX() and BEFORE_REGEX() functions are changed to UTF-8 strings, you can include the SET_CHAR_SET(UTF_8) function immediately after the BODY(1000) function, as follows:

```
HTTP.REQ.BODY(1000).SET_CHAR_SET(UTF_8).AFTER_REGEX(re/Bücher/).BEFORE_REGEX(re/Wörterbuch/).CONTAINS_ANY("Greek_alphabet")
```

The UTF-8 character set is a superset of the ASCII character set, so expressions configured for the ASCII character set continue to work as expected if you change the character set to UTF-8.

Compound Expressions with Different Character Sets

In a compound expression, if one subset of expressions is configured to work with data in the ASCII character set and the rest of the expressions are configured to work with data in the UTF-8 character set, the character set specified for each individual expression is considered when the expressions are evaluated individually. However, when processing the compound expression, just before processing the operators, the appliance promotes the character set of the returned ASCII values to UTF-8. For example, in the following compound expression, the first simple expression evaluates data in the ASCII character set while the second simple expression evaluates data in the UTF-8 character set:

```
HTTP.REQ.HEADER("MyHeader") == HTTP.REQ.BODY(10).SET_CHAR_SET(UTF_8)
```

However, when processing the compound expression, just before evaluating the "is equal to" Boolean operator, the NetScaler appliance promotes the character set of the value returned by HTTP.REQ.HEADER("MyHeader") to UTF-8.

The first simple expression in the following example evaluates data in the ASCII character set. However, when the NetScaler appliance processes the compound expression, just before concatenating the results of the two simple expressions, the appliance promotes the character set of the value returned by HTTP.REQ.BODY(10) to UTF-8.

```
HTTP.REQ.BODY(10) + HTTP.REQ.HEADER("MyHeader").SET_CHAR_SET(UTF_8)
```

Consequently, the compound expression returns data in the UTF-8 character set.

Specifying the Character Set Based on the Character Set of Traffic

You can set the character set to UTF-8 on the basis of traffic characteristics. If you are not sure whether the character set of the traffic being evaluated is UTF-8, you can configure a compound expression in which the first expression checks for UTF-8 traffic and subsequent expressions set the character set to UTF-8. Following is an example of a compound expression that first checks the value of "charset" in the request's Content-Type header for "UTF-8" before checking whether the first 1000 bytes in the request contain the UTF-8 string Bücher:

```
HTTP.REQ.HEADER("Content-Type").SET_TEXT_MODE(IGNORECASE).TYPECAST_NVLIST_T('=', '; ', '"').VALUE("charset").EQ("UTF-8") &&
HTTP.REQ.BODY(1000).SET_CHAR_SET(UTF_8).CONTAINS("Bücher")
```

If you are sure that the character set of the traffic being evaluated is UTF-8, the second expression in the example is sufficient.

Character and String Literals in Expressions

During expression evaluation, even if the current character set is ASCII, character literals and string literals, which are enclosed in single quotation marks (') and quotation marks (""), respectively, are considered to be literals in the UTF-8 character set. In a given expression, if a function is operating on character or string literals in the ASCII character set and you include a non-ASCII character in the literal, an error is returned.

Values in Hexadecimal and Octal Formats

When configuring an expression, you can enter values in octal and hexadecimal formats. However, each hexadecimal or octal byte is considered a UTF-8 byte. Invalid UTF-8 bytes result in errors regardless of whether the value is entered manually or pasted from the clipboard. For example, "\xce\x20" is an invalid UTF-8 character because "c8" cannot be followed by "20" (each byte in a multi-byte UTF-8 string must have the high bit set). Another example of an invalid UTF-8 character is "\xce \xa9," since the hexadecimal characters are separated by a white-space character.

Functions That Return UTF-8 Strings

Only the <text>.XPATH and <text>.XPATH_JSON functions always return UTF-8 strings. The following MYSQL routines determine at runtime which character set to return, depending on the data in the protocol:

- MYSQL_CLIENT_T.USER
- MYSQL_CLIENT_T.DATABASE
- MYSQL_REQ_QUERY_T.COMMAND
- MYSQL_REQ_QUERY_T.TEXT
- MYSQL_REQ_QUERY_T.TEXT(<unsigned int>)
- MYSQL_RES_ERROR_T.SQLSTATE
- MYSQL_RES_ERROR_T.MESSAGE
- MYSQL_RES_FIELD_T.CATALOG
- MYSQL_RES_FIELD_T.DB
- MYSQL_RES_FIELD_T.TABLE
- MYSQL_RES_FIELD_T.ORIGINAL_TABLE
- MYSQL_RES_FIELD_T.NAME
- MYSQL_RES_FIELD_T.ORIGINAL_NAME
- MYSQL_RES_OK_T.MESSAGE
- MYSQL_RES_ROW_T.TEXT_ELEM(<unsigned int>)

Terminal Connection Settings for UTF-8

When you set up a connection to the NetScaler appliance by using a terminal connection (by using PuTTY, for example), you must set the character set for transmission of data to UTF-8.

Classic Expressions in Default Syntax Expressions

Mar 20, 2012

Classic expressions describe basic characteristics of traffic. In some cases, you may want to use a classic expression in a default syntax expression. You can do so with the default syntax expression configuration tool. This can be helpful when manually migrating the older classic expressions to the default syntax.

Note that when you upgrade the NetScaler to version 9.0 or higher, Integrated Caching policies are automatically upgraded to default syntax policies, and the expressions in these policies are upgraded to the default syntax.

The following is the syntax for all default syntax expressions that use a classic expression:

```
SYS.EVAL_CLASSIC_EXPR("expression")
```

Following are examples of the SYS.EVAL_CLASSIC_EXPR("expression") expression:

```
sys.eval_classic_expr("req.ssl.client.cipher.bits > 1000")
sys.eval_classic_expr("url contains abc")
sys.eval_classic_expr("req.ip.sourceip == 10.102.1.61 -netmask 255.255.255.255")
sys.eval_classic_expr("time >= *:30:00GMT")
sys.eval_classic_expr("e1 || e2")
sys.eval_classic_expr("req.http.urllen > 50")
sys.eval_classic_expr("dayofweek == wedGMT")
```

Configuring Default Syntax Expressions in a Policy

Sep 02, 2013

You can configure a default syntax expression of up to 1,499 characters in a policy. The user interface for default syntax expressions depends to some extent on the feature for which you are configuring the expression, and on whether you are configuring an expression for a policy or for another use.

When configuring expressions on the command line, you delimit the expression by using quotation marks (“. . .” or '. . .'). Within an expression, you escape additional quotation marks by using a back-slash (\). For example, the following are standard methods for escaping quotation marks in an expression:

"\"abc\""

‘\"abc\"’

You must also use a backslash to escape question marks and other backslashes on the command line. For example, the expression http.req.url.contains(“\?”) requires a backslash so that the question mark is parsed. Note that the backslash character will not appear on the command line after you type the question mark. On the other hand, if you escape a backslash (for example, in the expression 'http.req.url.contains("\\\\http")'), the escape characters are echoed on the command line.

To make an entry more readable, you can escape the quotation marks for an entire expression. At the start of the expression you enter the escape sequence “q” plus one of the following special characters: /{<|~$^+=&%@`?.

You enter only the special character at the end of the expression, as follows:

q@http.req.url.contains("sometext") && http.req.cookie.exists@

q~http.req.url.contains("sometext") && http.req.cookie.exists~

Note that an expression that uses the { delimiter is closed with }.

For some features (for example, Integrated Caching and Responder), the policy configuration dialog box provides a secondary dialog box for configuring expressions. This dialog enables you to choose from drop-down lists that show the available choices at each point during expression configuration. You cannot use arithmetic operators when using these configuration dialogs, but most other default syntax expression features are available. To use arithmetic operators , write your expressions in free-form format.

To configure a default syntax rule by using the command line interface

At the command prompt, type the following commands to configure a default syntax rule and verify the configuration:

1. add cache|dns|rewrite|cs policy policyName **-rule** expression featureSpecificParameters **-action**
2. show cache|dns|rewrite|cs policy policyName

   Following is an example of configuring a caching policy:

   Example

```
> add cache policy pol-cache -rule http.req.content_length.le(5) -action INVAL
 Done

> show cache policy pol-cache
```

```
    Name: pol-cache
    Rule: http.req.content_length.le(5)
    CacheAction: INVAL
    Invalidate groups: DEFAULT
    UndefAction: Use Global
    Hits: 0
    Undef Hits: 0

Done
```

To configure a default syntax policy expression by using the configuration utility

1. In the navigation pane, click the name of the feature where you want to configure a policy, for example, you can select Integrated Caching, Responder, DNS, Rewrite, or Content Switching, and then click Policies.
2. Click Add.
3. For most features, click in the Expression field. For Content Switching, click Configure.
4. Click the Prefix icon (the house) and select the first expression prefix from the drop-down list. For example, in Responder, the options are HTTP, SYS, and CLIENT. The next set of applicable options appear in a drop-down list.
5. Double-click the next option to select it, and then type a period (.). Again, a set of applicable options appears in another drop-down list.
6. Continue selecting options until an entry field (signalled by parentheses) appears. When you see an entry field, enter an appropriate value in the parentheses. For example, if you select GT(int) (greater-than, integer format), you specify an integer in the parentheses. Text strings are delimited by quotation marks. Following is an example:
   `HTTP.REQ.BODY(1000).BETWEEN("this","that")`
7. To insert an operator between two parts of a compound expression, click the Operators icon (the sigma), and select the operator type. Following is an example of a configured expression with a Boolean OR (signalled by double vertical bars, ||):
   `HTTP.REQ.URL.EQ("www.mycompany.com")||HTTP.REQ.BODY(1000).BETWEEN("this","that")`
8. To insert a named expression, click the down arrow next to the Add icon (the plus sign) and select a named expression.
9. To configure an expression using drop-down menus, and to insert built-in expressions, click the Add icon (the plus sign). The Add Expression dialog box works in a similar way to the main dialog box, but it provides drop-down lists for selecting options, and it provides text fields for data entry instead of parentheses. This dialog box also provides a Frequently Used Expressions drop-down list that inserts commonly used expressions. When you are done adding the expression, click OK.
10. When finished, click Create. A message in the status bar indicates that the policy expression is configured successfully.

To test a default syntax expression by using the configuration utility

1. In the navigation pane, click the name of the feature for which you want to configure a policy (for example, you can select Integrated Caching, Responder, DNS, Rewrite, or Content Switching), and then click Policies.
2. Select a policy and click Open.
3. To test the expression, click the Evaluate icon (the check mark).
4. In the expression evaluator dialog box, select the Flow Type that matches the expression.
5. In the HTTP Request Data or HTTP Response Data field, paste the HTTP request or response that you want to parse with the expression, and click Evaluate. Note that you must supply a complete HTTP request or response, and the header and body should be separated by blank line. Some programs that trap HTTP headers do not also trap the response. If you are copying and pasting only the header, insert a blank line at the end of the header to form a complete HTTP request or response.

6. Click Close to close this dialog box.

Configuring Named Default Syntax Expressions

Oct 29, 2013

Instead of retyping the same expression multiple times in multiple policies, you can configure a named expression and refer to the name any time you want to use the expression in a policy. For example, you could create the following named expressions:

ThisExpression:

```
http.req.body(100).contains("this")
```

ThatExpression:

```
http.req.body(100).contains("that")
```

You can then use these named expressions in a policy expression. For example, the following is a legal expression based on the preceding examples:

```
ThisExpression || ThatExpression
```

You can use the name of a default syntax expression as the prefix to a function. The named expression can be either a simple expression or a compound expression. The function must be one that can operate on the type of data that is returned by the named expression.

Example 1: Simple Named Expression as a Prefix

The following simple named expression, which identifies a text string, can be used as a prefix to the AFTER_STR("<string>")function, which works with text data:

```
HTTP.REQ.BODY(1000)
```

If the name of the expression is top1KB, you can use top1KB.AFTER_STR("username") instead of HTTP.REQ.BODY(1000).AFTER_STR("username").

Example 2: Compound Named Expression as a Prefix

You can create a compound named expression called basic_header_value to concatenate the user name in a request, a colon (:), and the user's password, as follows:

```
add policy expression basic_header_value "HTTP.REQ.USER.NAME + \":\" + HTTP.REQ.USER.PASSWD"
```

You can then use the name of the expression in a rewrite action, as shown in the following example:

```
add rewrite action insert_b64encoded_authorization insert_http_header authorization '"Basic " + basic_header_value.b64encode' -bypassSafetyCheck YES
```

In the example, in the expression that is used to construct the value of the custom header, the B64 encoding algorithm is applied to the string returned by the compound named expression.

You can also use a named expression (either by itself or as a prefix to a function) to create the text expression for the replacement target in a rewrite.

To configure a named default syntax expression by using the command line interface

At the command prompt, type the following commands to configure a named expression and verify the configuration:

- add policy expression <name><value>

- show policy expression <name>
  Example

  ```
  > add policy expression myExp "http.req.body(100).contains(\"the other\")"
   Done

  > show policy expression myExp
  1)     Name: myExp  Expr: "http.req.body(100).contains("the other")"  Hits: 0 Type : ADVANCED
   Done
  ```

  The expression can be up to 1,499 characters.

To configure a named expression by using the configuration utility

1. In the navigation pane, expand AppExpert, and then click Expressions.
2. Click Advanced Expressions.
3. Click Add.
4. Enter a name and a description for the expression.
5. Configure the expression by using the process described in "To configure a default syntax policy expression by using the configuration utility." A message in the status bar indicates that the policy expression is configured successfully.

Configuring Default Syntax Expressions Outside the Context of a Policy

Oct 29, 2013

A number of functions, including the following, can require a default syntax expression that is not part of a policy:

Integrated Caching selectors:

You define multiple non-compound expressions (selectlets) in the definition of the selector. Each selectlet is in an implicit logical AND relationship with the others.

Load Balancing:

You configure an expression for the TOKEN method of load balancing for a load balancing virtual server.

Rewrite actions:

Expressions define the location of the rewrite action and the type of rewriting to be performed, depending on the type of rewrite action that you are configuring. For example, a DELETE action only uses a target expression. A REPLACE action uses a target expression and an expression to configure the replacement text.

Rate-based policies:

You use default syntax expressions to configure Limit Selectors. You can use these selectors when configuring policies to throttle the rate of traffic to various servers. You define up to five non-compound expressions (selectlets) in the definition of the selector. Each selectlet is in an implicit logical AND with the others.

To configure a default syntax expression outside a policy by using the command line interface (cache selector example)

At the command prompt, type the following commands to configure a default syntax expression outside a policy and verify the configuration:

- add cache selector <selectorName> <rule>
- show cache selector <selectorName>

Example

```
> add cache selector mainpageSelector "http.req.cookie.value(\"ABC_def\")"
"http.req.url.query.value(\"_ghi\")"selector "mainpageSelector" added
 Done
> show cache selector mainpageSelector
      Name: mainpageSelector
      Expressions:
            1) http.req.cookie.value("ABC_def")
            2) http.req.url.query.value("_ghi")
 Done
```

Following is an equivalent command that uses the more readable q delimiter, as described in "Configuring Default Syntax Expressions in a Policy":

```
> add cache selector mainpageSelector2 q~http.req.cookie.value("ABC_def")~
q~http.req.url.query.value("_ghi")~selector "mainpageSelector2" added
 Done
> show cache selector mainpageSelector2
      Name: mainpageSelector2
      Expressions:
```

```
        1) http.req.cookie.value("ABC_def")
        2) http.req.url.query.value("_ghi")
Done
```

Default Syntax Expressions: Evaluating Text

Sep 02, 2013

You can configure a policy with a default syntax expression that evaluates text in a request or response. Default syntax text expressions can range from simple expressions that perform string matching in HTTP headers to complex expressions that encode and decode text. You can configure text expressions to be case sensitive or case insensitive and to use or ignore spaces. You can also configure complex text expressions by combining text expressions with Boolean operators

You can use expression prefixes and operators for evaluating HTTP requests, HTTP responses, and VPN and Clientless VPN data. However, text expression prefixes are not restricted to evaluating these elements of your traffic. For information about additional default syntax text expression prefixes and operators, see the following topics:

- "Pattern Sets"
- "Regular Expressions"
- "Typecasting Data"
- "Default Syntax Expressions: Parsing HTTP, TCP, and UDP Data"
- "Default Syntax Expressions: Parsing SSL Certificates"
- "Expressions for SSL Certificate Dates"

About Text Expressions

Sep 02, 2013

You can configure various expressions for working with text that flows through the NetScaler appliance. Following are some examples of how you can parse text by using a default syntax expression:

- Determine that a particular HTTP header exists.
  For example, you may want to identify HTTP requests that contains a particular Accept-Language header for the purpose of directing the request to a particular server.
- Determine that a particular HTTP URL contains a particular string.
  For example, you may want to block requests for particular URLs. Note that the string can occur at the beginning, middle, or end of another string.
- Identify a POST request that is directed to a particular application.
  For example, you may want to identify all POST requests that are directed to a database application for the purpose of refreshing cached application data.

Note that there are specialized tools for viewing the data stream for HTTP requests and responses. For example, from the following URL, you can download a Firefox Web browser plug-in that displays HTTP request and response headers:

"https://addons.mozilla.org/en-US/firefox/addon/3829"

The following plug-in displays headers, query strings, POST data, and other information:

"https://addons.mozilla.org/en-US/firefox/addon/6647"

After you download these plug-ins, they are accessible from the Firefox Tools menu.

About Operations on Text

A text-based expression consists of at least one prefix to identify an element of data and usually (although not always) an operation on that prefix. Text-based operations can apply to any part of a request or a response. Basic operations on text include various types of string matches.

For example, the following expression compares a header value with a string:

```
http.req.header("myHeader").contains("some-text")
```

Following expressions are examples of matching a file type in a request:

```
http.req.url.suffix.contains("jpeg")
```

```
http.req.url.suffix.eq("jpeg")
```

In the preceding examples, the contains operator permits a partial match and the eq operator looks for an exact match.

Other operations are available to format the string before evaluating it. For example, you can use text operations to strip out quotes and white spaces, to convert the string to all lowercase, or to concatenate strings.

Note: Complex operations are available to perform matching based on patterns or to convert one type of text format to another type.

For more information, see the following topics:

- "Pattern Sets and Data Sets."
- "Regular Expressions."
- "Typecasting Data."

Compounding and Precedence in Text Expressions

You can apply various operators to combine text prefixes or expressions. For example, the following expression concatenates the returned values of each prefix:

```
http.req.hostname + http.req.url
```

Following is an example of a compound text expression that uses a logical AND. Both components of this expression must be TRUE for a request to match the expression:

```
http.req.method.eq(post) && http.req.body(1024).startswith("destination=")
```

Note: For more information on operators for compounding, see "Compound Default Syntax Expressions."

Categories of Text Expressions

The primary categories of text expressions that you can configure are:

- Information in HTTP headers, HTTP URLs, and the POST body in HTTP requests.
  For more information, see "Expression Prefixes for Text in HTTP Requests and Responses."
- Information regarding a VPN or a clientless VPN.
  For more information, see "Expression Prefixes for VPNs and Clientless VPNs."
- TCP payload information.
  For more information about TCP payload expressions, see "Default Syntax Expressions: Parsing HTTP, TCP, and UDP Data."
- Text in a Secure Sockets Layer (SSL) certificate.
  For information about text expressions for SSL and SSL certificate data, see "Default Syntax Expressions: Parsing SSL Certificates" and "Expressions for SSL Certificate Dates."

Note: Parsing a document body, such as the body of a POST request, can affect performance. You may want to test the performance impact of policies that evaluate a document body.

Guidelines for Text Expressions

From a performance standpoint, it typically is best to use protocol-aware functions in an expression. For example, the following expression makes use of a protocol-aware function:

```
HTTP.REQ.URL.QUERY
```

The previous expression performs better than the following equivalent expression, which is based on string parsing:

```
HTTP.REQ.URL.AFTER_STR("?")
```

In the first case, the expression looks specifically at the URL query. In the second case, the expression scans the data for the first occurrence of a question mark.

There is also a performance benefit from structured parsing of text, as in the following expression:

```
HTTP.REQ.HEADER("Example").TYPECAST_LIST_T(',').GET(1)
```

(For more information on typecasting, see "Typecasting Data.") The typecasting expression, which collects comma-delimited data and structures it into a list, typically would perform better than the following unstructured equivalent:

```
HTTP.REQ.HEADER("Example").AFTER_STR(",").BEFORE_STR(",")
```

Finally, unstructured text expressions typically have better performance than regular expressions. For example, the following is an unstructured text expression:

```
HTTP.REQ.HEADER("Example").AFTER_STR("more")
```

The previous expression would generally provide better performance than the following equivalent, which uses a regular expression:

```
HTTP.REQ.HEADER("Example").AFTER_REGEX(re/more/)
```

For more information on regular expressions, see "Regular Expressions."

Expression Prefixes for Text in HTTP Requests and Responses

Oct 07, 2016

An HTTP request or response typically contains text, such as in the form of headers, header values, URLs, and POST body text. You can configure expressions to operate on one or more of these text-based items in an HTTP request or response.

The following table describes the expression prefixes that you can configure to extract text from different parts of an HTTP request or response.

Table 1. HTTP Expression Prefixes That Return Text

Prefix	Description
HTTP.REQ.BODY(<integer>)	Example: HTTP.REQ.BODY(100) It will return first 100 characters of HTTP Request body. If the length of body is less than 100 then whole body will result as output.
HTTP.REQ.HOSTNAME	Example: HTTP.REQ.HOSTNAME.EQ("abc.com") The above example returns true if hostname is abc.com. It returns HTTP Host Name object from this request. If the target hostname is present in the first line of the request then that is selected. Otherwise the value in the last occurrence of the HOST header is selected. The format of output is abc.foo.com:8080. For more information on typecasting, see "Typecasting Data."
HTTP.REQ.HOSTNAME. DOMAIN	Example: HTTP.REQ.URL.HOSTNAME.DOMAIN.EQ("foobar.com") The above example returns true if domain name is foobar.com. It returns Domain name part of the hostname. If the hostname is www.foobar.com or www.foobar.com:8080, then domain is foobar.com.
HTTP.REQ.HOSTNAME. SERVER	Example: HTTP.REQ.URL.HOSTNAME.SERVER.EQ("www.foobar.com") The above example returns true if server name is www.foobar.com. It returns Domain name part of the hostname. If the hostname is www.foobar.com or www.foobar.com:8080, then domain is www.foobar.com.
HTTP.REQ.METHOD	Example: HTTP.REQ.HOSTNAME.SERVER("www.foobar.com") The above example returns true if domain name is www.foobar.com. Correct one is HTTP.REQ.HOSTNAME.SERVER. It returns Domain name part of the hostname.
HTTP.REQ.URL	Example: HTTP.REQ.URL.EQ("http://www.google.com") The above example returns true if domain name is http://www.google.com. It returns the HTTP URL object from request.
HTTP.REQ.URL.HOSTNAME	Example: HTTP.REQ.URL.HOSTNAME.EQ("abc.foo.com:8080") The above example returns true if hostname in URL is abc.foo.com:8080. It returns HTTP Host Name present in the URL. For more information on typecasting, see "Typecasting Data."
HTTP.REQ.URL.HOSTNAME.DOMAIN	Example: HTTP.REQ.URL.HOSTNAME.DOMAIN.EQ("foobar.com") The above example returns true if domain name is foobar.com. It returns Domain

	name part of the hostname. If the hostname is www.foobar.com or www.foobar.com:8080, then domain is foobar.com.
HTTP.REQ.URL.HOSTNAME.SERVER	Example: The above example returns true if server name is www.foobar.com. It returns Domain name part of the hostname. If the hostname is www.foobar.com or www.foobar.com:8080, then domain is www.foobar.com.
HTTP.REQ.URL.HOSTNAME.PORT	Example: HTTP.REQ.URL.HOSTNAME.PORT.EQ(80) The above example returns true if port is 80. It returns number on the port part of the hostname.
HTTP.REQ.URL.PATH	Example:HTTP.REQ.URL.PATH.GET(1) If the URL is http://www.foo.com/a/b/c/bar.html?a=1 then operation will select /a/b/c/bar.html, then the above example will result in “a”. It returns / separated List on the path component of the URL.
HTTP.REQ.URL.PATH_AND_QUERY	Example: HTTP.REQ.URL.PATH_AND_QUERY If the URL is http://www.foo.com/a/b/c/bar.html?a=1 then it will return /a/b/c/bar.html?a=1. It returns the portion of the URL following the hostname
HTTP.REQ.URL.PROTOCOL	Example: HTTP.REQ.URL.PROTOCOL If the URL is http://www.foo.com/a/b/c/bar.html?a=1 then operation will result in HTTP. It results in the protocol present in the URL.
HTTP.REQ.URL.QUERY	Example: HTTP.REQ.URL.QUERY If the URL is http://www.foo.com?abc=1&def=2 will result in abc=1&def=2. It results as Name-Value List (with delimiters = and &) on the query component of the URL.
HTTP.REQ.URL.QUERY.VALUE	Example: -NA- It returns the value component of the specified name-value component in the list.
HTTP.REQ.URL.SUFFIX	Example: HTTP.REQ.URL.SUFFIX If the path is /a/b/c.html then this operation will result html. It returns filename suffice of the URL.
HTTP.REQ.USER	Example: HTTP.REQ.USER.GROUPS('grp1:grp2') The above example will return list on the Group which is separated by given delimiter I.e. “:" It returns the AAA User associated with the current HTTP transaction.
HTTP.REQ.USER.EXTERNAL_GROUPS	Example: HTTP.REQ.USER.EXTERNAL_GROUPS The above example will list external groups which are separated by “,". IT returns list of external groups which is separated by “,".
HTTP.REQ.USER.EXTERNAL_GROUPS.IGNORE_EMPTY_ELEMENTS	Example: HTTP.REQ.USER.EXTERNAL_GROUPS. IGNORE_EMPTY_ELEMENTS.COUNT If AAA User associated with the current HTTP transaction is part of some external groups : 123,,24, ,15 then HTTP.REQ.USER.EXTERNAL_GROUPS. IGNORE_EMPTY_ELEMENTS.COUNT gives 4,

	whereas HTTP.REQ.USER.EXTERNAL_GROUPS.COUNT gives 5. It ignores empty elements in the list.
HTTP.REQ.USER.EXTERNAL_GROUPS(sep)	Example: HTTP.REQ.USER.EXTERNAL_GROUPS(":") The above example will list external groups which are separated by ":" It returns list of external groups which is separated by given delimiter.
HTTP.REQ.USER.GROUPS	Example: HTTP.REQ.USER.GROUPS The above example will list groups which are separated by ",". IT returns list of groups which is separated by ",".
HTTP.REQ.USER.GROUPS.IGNORE_EMPTY_ELEMENTS	Example: HTTP.REQ.USER.GROUPS. IGNORE_EMPTY_ELEMENTS.COUNT If AAA User associated with the current HTTP transaction is part of some groups : 123,,24, ,15 then HTTP.REQ.USER.GROUPS. IGNORE_EMPTY_ELEMENTS.COUNT gives 4, whereas HTTP.REQ.USER.GROUPS.COUNT gives 5. It ignores empty elements in the list.
HTTP.REQ.USER.GROUPS(sep)	Example: HTTP.REQ.USER.GROUPS(":") The above example will list groups which are separated by ":" IT returns list of groups which is separated by given delimiter.
HTTP.REQ.USER.INTERNAL_GROUPS	Example: HTTP.REQ.USER.INTERNAL_GROUPS The above example will list internal groups which are separated by ",". IT returns list of internal groups which is separated by ",".
HTTP.REQ.USER.INTERNAL_GROUPS.IGNORE_EMPTY_ELEMENTS	Example: HTTP.REQ.USER.INTERNAL_GROUPS. IGNORE_EMPTY_ELEMENTS.COUNT If AAA User associated with the current HTTP transaction is part of some internal groups : 123,,24, ,15 then HTTP.REQ.USER.INTERNAL_GROUPS.IGNORE_EMPTY_ELEMENTS.COUNT gives 4, whereas HTTP.REQ.USER.INTERNAL_GROUPS.COUNT gives 5. It ignores empty elements in the list.
HTTP.REQ.USER.INTERNAL_GROUPS(sep)	Example: HTTP.REQ.USER.INTERNAL_GROUPS(":") The above example will list internal groups which are separated by ":" IT returns list of internal groups which is separated by given delimiter.
HTTP.REQ.USER.IS_MEMBER_OF(group_name)	Example: HTTP.REQ.USER.IS_MEMBER_OF(grp1) The above example returns true is the current AAA user is member of group grp1. It returns TRUE if the user is a member of the group group_name.
HTTP.REQ.USER.NAME	Example: HTTP.REQ.USER.NAME The above example will return name of the user. It returns the name of user. This is the name used by user for login unless it is overridden by name from external authentication server.
HTTP.REQ.USER.PASSWD	Example: HTTP.REQ.USER.PASSWD The above example will return password of the user. It returns the password of user.

HTTP.REQ.VERSION	Example: HTTP.REQ.VERSION The above example returns HTTP version information.
HTTP.RES.BODY(<integer>)	Example: HTTP.RES.BODY(100) It will return first 100 characters of HTTP Response body. If the length of body is less than 100 then whole body will result as output.
HTTP.RES.STATUS_MSG	Example: HTTP.RES.STATUS_MSG The above example results status message of response. It can be “Done”, some error etc.
HTTP.RES.VERSION	Example: HTTP.RES.VERSION The above example returns HTTP version information.
HTTP.REQ.URL.HOSTNAME.EQ(<hostname>)	Example: HTTP.REQ.URL.HOSTNAME.EQ("abc.foo.com:8080") The above example returns true if hostname in URL is abc.foo.com:8080. It returns HTTP Host Name present in the URL.
HTTP.REQ.IS_NTLM_OR_NEGOTIATE	Example: HTTP.REQ.IS_NTLM_OR_NEGOTIATE The above example returns TRUE if request is part of NTLM or NEGOTIATE connection.
HTTP.REQ.URL.PATH.IGNORE_EMPTY_ELEMENTS	Example: HTTP.REQ.URL.PATH. IGNORE_EMPTY_ELEMENTS.COUNT If request URL has path (/123//24//15) elements as : 123,,24, ,15 then HTTP.REQ.URL.PATH.IGNORE_EMPTY_ELEMENTS.COUNT gives 4, whereas HTTP.REQ.URL.PATHS.COUNT gives 5. It ignores empty elements in the list.
HTTP.REQ.URL.QUERY.IGNORE_EMPTY_ELEMENTS	Example: HTTP.REQ.URL.QUERY.IGNORE_EMPTY_ELEMENTS.COUNT If request URL has path as : abc=1&&def=2&g=3&h=6 then HTTP.REQ.URL.QUERY.IGNORE_EMPTY_ELEMENTS.COUNT gives 4, whereas HTTP.REQ.URL.QUERY.COUNT gives 5. It ignores empty elements in the list.

Expression Prefixes for VPNs and Clientless VPNs

Aug 30, 2013

The default syntax expression engine provides prefixes that are specific to parsing VPN or Clientless VPN data. This data includes the following:

- Host names, domains, and URLs in VPN traffic.
- Protocols in the VPN traffic.
- Queries in the VPN traffic.

These text elements are often URLs and components of URLs. In addition to applying the text-based operations on these elements, you can parse these elements by using operations that are specific to parsing URLs. For more information, see "Expressions for Extracting Segments of URLs."

The following table describes the expression prefixes for this type of data.

Table 1. VPN and Clientless VPN Expression Prefixes That Return Text

VPN and Clientless VPN Expression	Description
VPN.BASEURL.CVPN_DECODE	Extracts the original URL from a clientless VPN URL.
VPN.BASEURL.CVPN_ENCODE	Converts a URL to clientless VPN format.
VPN.BASEURL.HOSTNAME	Extracts the HTTP host name from the host name in the URL. This prefix cannot be used in bidirectional policies.
VPN.BASEURL.HOSTNAME.DOMAIN	Extracts the domain name from the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, this prefix extracts mycompany.com. This prefix returns incorrect results if the host name is an IP address. For information on expressions for IP addresses, see "Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs." All text operations after this prefix are case insensitive.
VPN.BASEURL.HOSTNAME.EQ (<hostname>)	Returns a Boolean TRUE if the host name matches <hostname>. The comparison is case insensitive. For example, if the host name is www.mycompany.com, the following returns TRUE: vpn.baseurl.hostname.eq("www.mycompany.com") If the text mode is URLENCODED, the host name is decoded before comparison. For more information, see "Operations for HTTP, HTML, and XML Encoding and "Safe" Characters."
VPN.BASEURL.HOSTNAME.SERVER	Evaluates the server portion of the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the server is www.mycompany.com. All text operations after this prefix are case insensitive.
VPN.BASEURL.PATH	Extracts a slash- (/) separated list from the path component of the URL. For example, this prefix extracts /a/b/c/mypage.html from the following URL: http://www.mycompany.com/a/b/c/mypage.html?a=1 The following expression selects just the "a": http.req.url.path.get(1) For more information on the GET operation, see "Expressions for Extracting Segments of URLs."
VPN.BASEURL.PATH.IGNORE_EMPTY_ELEMENTS	This prefix ignores the elements in a list. For example, the following comma-separated list has an empty element after "a=10": a=10,,b=11, ,c=89 The element following b=11 contains a space, and by default, is not considered an empty element.

VPN and Clientless VPN Expression	Description
	Consider the following HTTP header: Cust_Header : 123,,24, ,15 The following expression returns a count of 4 when evaluating this header: http.req.header("Cust_Header").typecase_list_t(',').ignore_empty_elements.count The following expression returns a count of 5 when evaluating this header: http.req.header("Cust_Header").typecase_list_t(','). count
VPN.BASEURL.PATH_AND_QUERY	Evaluates the text in the URL that follows the host name. For example, if the URL is http://www.mycompany.com/a/b/c/mypage.html?a=1, this prefix evaluates /a/b/c/mypage.html?a=1.
VPN.BASEURL.PROTOCOL	Evaluates the protocol in the URL. Do not use this prefix in bidirectional policies.
VPN.BASEURL.QUERY	Extracts a name-value list, using the "=" and "&" delimiters from the query string in a URL.
VPN.BASEURL.QUERY.IGNORE_EMPTY_ELEMENTS	This method ignores the empty elements in a name-value list. For example, in the following name-value list, there is an empty element following "a=10": a=10;;b=11; ;c=89 The element following b=11 contains a space and is not considered an empty element. Consider the following HTTP header: Cust_Header : a=1;;b=2; ;c=3 The following expression produces a count of 4 after evaluating this header: http.req.header("Cust_Header").typecast_nvlist_t('=',';').ignore_empty_elements.count The following expression produces a count of 5 after evaluating the header: http.req.header("Cust_Header").typecast_nvlist_t('=',';').
VPN.BASEURL.SUFFIX	Evaluates the file name suffix in a URL. For example, if the path is /a/b/c/my.page.html, this operation selects "html."
VPN.CLIENTLESS_BASEURL	Evaluates the clientless VPN base URL.
VPN.CLIENTLESS_BASEURL.CVPN_DECODE	Extracts the original URL from the clientless VPN formatted URL.
VPN.CLIENTLESS_BASEURL.CVPN_ENCODE	Converts a URL to the clientless VPN format.
VPN.CLIENTLESS_BASEURL.HOSTNAME	Evaluates the host name in the URL. Do not use this prefix in bidirectional policies.
VPN.CLIENTLESS_BASEURL.HOSTNAME.DOMAIN	Evaluates the domain name part of the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the domain is mycompany.com. This operation returns incorrect results if the host name is an IP address. For information on expressions for IP addresses, see "Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs." All text operations after this prefix are case insensitive.
VPN.CLIENTLESS_BASEURL.HOSTNAME.EQ(<hostname>)	Returns a Boolean TRUE if the host name matches <hostname>. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the following

VPN and Clientless VPN Expression	Description
	is true: vpn.clientless_baseurl. hostname.eq("www.mycompany.com") The comparison is case insensitive. If the textmode is URLENCODED, the host name is decoded before comparison. For more information, see "Operations for HTTP, HTML, and XML Encoding and "Safe" Characters."
VPN.CLIENTLESS_BASEURL.HOSTNAME.SERVER	Evaluates the server part of a host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the server is www.mycompany.com. All text operations after this prefix are case insensitive.
VPN.CLIENTLESS_BASEURL.PATH	Evaluates a slash- (/) separated list in the URL path. For example, this prefix selects /a/b/c/mypage.html from the following URL: http://www.mycompany.com/a/b/c/mypage.html?a=1 The following expression selects "a" from the preceding URL: http.req.url.path.get(1) For more information on the GET operation, see "Expressions for Extracting Segments of URLs."
VPN.CLIENTLESS_BASEURL.PATH.IGNORE_EMPTY_ELEMENTS	Ignores empty elements in a list. For example, if the list delimiter is a comma (,) the following list has an empty element following "a=10": a=10,b=11, ,c=89 The element following b=11 contains a space and is not considered an empty element. Consider the following HTTP header: Cust_Header : 123,,24, ,15 The following expression returns a value of 4 after evaluating this header: http.req.header("Cust_Header").typecast_list_t(',').ignore_empty_elements.count The following expression returns a value of 5 after evaluating this header: http.req.header("Cust_Header").typecast_list_t(',').
VPN.CLIENTLESS_BASEURL.PATH_AND_QUERY	Evaluates the text following the host name in a URL. For example, this prefix selects /a/b/c/mypage.html?a=1 from the following URL: http://www.mycompany.com/a/b/c/mypage.html?a=1
VPN.CLIENTLESS_BASEURL.PROTOCOL	Evaluates the protocol in the URL. Do not use this prefix in bidirectional policies.
VPN.CLIENTLESS_BASEURL.QUERY	Extracts a name-value list that uses the delimiters "=" and "&" from a URL query string.
VPN.CLIENTLESS_BASEURL.QUERY.IGNORE_EMPTY_ELEMENTS	Ignores empty elements in a name-value list. For example, the following list contains an empty element after "a=10": a=10;;b=11; ;c=89 The element following b=11 contains a space and is not considered an empty element. As another example, consider the following http header: Cust_Header : a=1;;b=2; ;c=3 The following expression returns a value of 4 after evaluating the preceding header: http.req.header("Cust_Header").typecast_nvlist_t('=',';').ignore_empty_elements.count The following expression returns a value of 5 after evaluating the preceding header:

VPN and Clientless VPN Expression	Description
	http.req.header("Cust_Header").typecast_nvlist_t('=',';')
VPN.CLIENTLESS_BASEURL.SUFFIX	Evaluates the file suffix in a URL. For example, if the URL path is /a/b/c/mypage.html then this operation selects html.
VPN.CLIENTLESS_HOSTURL	Selects the clientless VPN host URL.
VPN.CLIENTLESS_HOSTURL.CVPN_DECODE	Selects the original URL from the clientless VPN formatted URL.
VPN.CLIENTLESS_HOSTURL.CVPN_ENCODE	Converts a URL to clientless VPN format.
VPN.CLIENTLESS_HOSTURL.HOSTNAME	Extracts the host name in the URL. Do not use this prefix in bidirectional policies.
VPN.CLIENTLESS_HOSTURL.HOSTNAME.DOMAIN	Extracts the domain name from the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the domain is mycompany.com. This operation returns incorrect results if the host name contains an IP address. For information on expressions for IP addresses, see "Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs." All text operations after this prefix are case insensitive.
VPN.CLIENTLESS_HOSTURL.HOSTNAME.EQ(<hostname>)	Results in Boolean TRUE if the host name matches the <hostname> argument. The comparison is case insensitive. For example, if the host name is www.mycompany.com or www.mycompany.com., the following expression returns TRUE: vpn.clilentless_hosturl. hostname.eq("www.mycompany.com") If the text mode is URLENCODED, the host name is decoded before comparison. For more information, see "Operations for HTTP, HTML, and XML Encoding and “Safe” Characters."
VPN.CLIENTLESS_HOSTURL.HOSTNAME.SERVER	Evaluates the server part of the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the server is www.mycompany.com. The comparison is case insensitive, and all text operations after this method are case insensitive.
VPN.CLIENTLESS_HOSTURL.PATH	Evaluates a slash- (/) separated list on the path component of the URL. For example, consider the following URL: http://www.mycompany.com/a/b/c/mypage.html?a=1 This prefix selects /a/b/c/mypage.html from the preceding URL.
VPN.CLIENTLESS_HOSTURL.PATH.IGNORE_EMPTY_ELEMENTS	This method ignores the empty elements in a list. For example, if the delimiter in a list is “,” the following list contains an empty element after the entry “a=10”: a=10,b=11, ,c=89 The element following b=11 contains a space and is not considered an empty element. Consider the following header: Cust_Header : 123,,24, ,15 The following expression returns a value of 4 for this header: http.req.header("Cust_Header").typecast_list_t(','). ignore_empty_elements.count The following expression returns a value of 5 for the same header: http.req.header("Cust_Header").typecast_list_t(',').

VPN and Clientless VPN Expression	Description
VPN.CLIENTLESS_HOSTURL.PATH_AND_QUERY	Evaluates the portion of the URL that follows the host name. For example, consider the following URL: http://www.mycompany.com/a/b/c/mypage.html?a=1 This prefix returns /a/b/c/mypage.html?a=1 from the preceding URL.
VPN.CLIENTLESS_HOSTURL.PROTOCOL	Evaluates the protocol in the URL. Do not use this prefix in bidirectional policies.
VPN.CLIENTLESS_HOSTURL.QUERY	Extracts a name-value list, using the "=" and "&" delimiters from a URL query string.
VPN.CLIENTLESS_HOSTURL.QUERY.IGNORE_EMPTY_ELEMENTS	Ignores empty elements in a name-value list. For example, the following list uses a semicolon (;) delimiter. This list contains an empty element after "a=10": a=10;;b=11; ;c=89 In the preceding example, the element following b=11 is not considered an empty element. Consider the following header: Cust_Header : a=1;;b=2; ;c=3 The following expression returns a value of 4 after evaluating this header: http.req.header("Cust_Header").typecast_nvlist_t('=',';').ignore_empty_elements.count The following expression returns a value of 5 after evaluating the same header: http.req.header("Cust_Header").typecast_nvlist_t('=',';')
VPN.CLIENTLESS_HOSTURL.SUFFIX	Extracts a file name suffix in a URL. For example, if the path is /a/b/c/my.page.html, this prefix selects html.
VPN.HOST.DOMAIN	Extracts the domain name part of the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the domain is mycompany.com. This prefix returns incorrect results if the host name contains an IP address. For information on expressions for IP addresses, see "Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs." All text operations after this prefix case insensitive.
VPN.HOST.EQ(<hostname>)	Returns a Boolean TRUE value if the host name matches the <hostname>. The comparison is case insensitive. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the following returns TRUE: vpn.host.eq("www.mycompany.com") If the text mode is URLENCODED the host name is decoded before comparison. For more information, see "Operations for HTTP, HTML, and XML Encoding and "Safe" Characters."
VPN.HOST.SERVER	Extracts the server name part of the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the server is www.mycompany.com. All text operations after this prefix are case insensitive.

Basic Operations on Text

Aug 30, 2013

Basic operations on text include operations for string matching, calculating the length of a string, and controlling case sensitivity. You can include white space in a string that is passed as an argument to an expression, but the string cannot exceed 255 characters.

The following table lists basic string matching operations in which the functions return a Boolean TRUE or FALSE.

Table 1. String Comparison Functions

Function	Description
<text>.CONTAINS(<string>)	Returns a Boolean TRUE value if the target contains <string>. Following is an example: `http.req.url.contains(".jpeg")`
<text>.EQ(<string>)	Returns a Boolean TRUE value if the target is an exact match with <string>. For example, the following expression returns a Boolean TRUE for a URL with a host name of “myhostabc”: `http.req.url.hostname.eq("myhostabc")`
<text>.STARTSWITH(<string>)	Returns a Boolean TRUE value if the target begins with <string>. For example, the following expression returns a Boolean TRUE for a URL with a host name of “myhostabc”: `http.req.url.hostname.startswith("myhost")`
<text>.ENDSWITH(<string>)	Returns a Boolean TRUE value if the target ends with <string>. For example, the following expression returns a Boolean TRUE for a URL with a host name of “myhostabc”: `http.req.url.hostname.endswith("abc")`
<text>.NE(<string>)	Returns a Boolean TRUE value if the prefix is not equal to the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with SET_TEXT_MODE(IGNORECASE) or

Function	Description
	SET_TEXT_MODE(NOIGNORECASE), and with both ASCII and UTF-8 character sets.
<text>.GT(<string>)	Returns a Boolean TRUE value if the prefix is alphabetically greater than the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with SET_TEXT_MODE(IGNORECASE) or SET_TEXT_MODE(NOIGNORECASE), and with both ASCII and UTF-8 character sets.
<text>.GE(<string>)	Returns a Boolean TRUE value if the prefix is alphabetically greater than or equal to the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with SET_TEXT_MODE(IGNORECASE) or SET_TEXT_MODE(NOIGNORECASE), and with both ASCII and UTF-8 character sets.
<text>.LT(<string>)	Returns a Boolean TRUE value if the prefix is alphabetically lesser than the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with SET_TEXT_MODE(IGNORECASE) or SET_TEXT_MODE(NOIGNORECASE), and with both ASCII and UTF-8 character sets.
<text>.LE(<string>)	Returns a Boolean TRUE value if the prefix is alphabetically lesser than or equal to the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with SET_TEXT_MODE(IGNORECASE) or SET_TEXT_MODE(NOIGNORECASE), and with both ASCII and UTF-8 character sets.

The <text>.LENGTH operation returns a numeric value that is equal to the number of characters (not bytes) in a string:

<text>.LENGTH

For example, you may want to identify request URLs that exceed a particular length. Following is an expression that

implements this example:

HTTP.REQ.URL.LENGTH < 500

After taking a count of the characters or elements in a string, you can apply numeric operations to them. For more information, see "Default Syntax Expressions: Working with Dates, Times, and Numbers."

The following functions operate on the case (upper-case or lower-case) of the characters in the string.

Table 2. Functions for Considering, Ignoring, and Changing Text Case

Function	Description
<text>.SET_TEXT_MODE(IGNORECASE|NOIGNORECASE)	This function turns case sensitivity on or off for all text operations.
<text>.TO_LOWER	Converts the target to lowercase for a text block of up to 2 kilobyte (KB). Returns UNDEF if the target exceeds 2 KB. For example, the string “ABCd:” is converted to “abcd:”.
<text>.TO_UPPER	Converts the target to uppercase. Returns UNDEF if the target exceeds 2 KB. For example, the string “abcD:” is converted to “ABCD:”.

You can use the STRIP_CHARS(<string>) function to remove specific characters from the text that is returned by a default syntax expression prefix (the input string). All instances of the characters that you specify in the argument are stripped from the input string. You can use any text method on the resulting string, including the methods used for matching the string with a pattern set.

For example, in the expression CLIENT.UDP.DNS.DOMAIN.STRIP_CHARS(".-_"), the STRIP_CHARS(<string>) function strips all periods (.), hyphens (-), and underscores (_) from the domain name returned by the prefix CLIENT.UDP.DNS.DOMAIN. If the domain name that is returned is "a.dom_ai_n-name", the function returns the string "adomainname".

In the following example, the resulting string is compared with a pattern set called "listofdomains":

CLIENT.UDP.DNS.DOMAIN.STRIP_CHARS(".-_").CONTAINS_ANY("listofdomains")

Note: You cannot perform a rewrite on the string that is returned by the STRIP_CHARS(<string>) function.
The following functions strip matching characters from the beginning and end of a given string input.

Table 3. Functions for Stripping Characters From the Beginning or End of a String

Function	Description
<text>.STRIP_START_CHARS(s)	Strips matching characters from the beginning of the input string until the first non-matching character is found and returns the remainder of the string. You must specify the characters that you want to strip as a single string within quotation marks. For example, if the name of a header is TestLang and ://_en_us: is its value, HTTP.RES.HEADER("TestLang").STRIP_START_CHARS(":/_") strips the specified characters from the beginning of the value of the header until the first non-matching character e is found and returns en_us: as a string.
<text>.STRIP_END_CHARS(s)	Strips matching characters from the end of the input string to the first non-matching character is found and returns the remainder of the string. You must specify the characters that you want to strip as a single string within quotation marks. For example, if the name of a header is TestLang and ://_en_us: is its value, HTTP.RES.HEADER("TestLang").STRIP_START_CHARS(":/_") strips the specified characters from the end of the value of the header until the first non-matching character s is found and returns ://_en_us as a string.

You can use the APPEND() function to append the string representation of the argument to the string representation of the value returned by the preceding function. The preceding function can be one that returns a number, unsigned long, double, time value, IPv4 address, or IPv6 address. The argument can be a text string, number, unsigned long, double, time value, IPv4 address, or IPv6 address. The resulting string value is the same string value that is obtained by using the + operator.

Complex Operations on Text

May 25, 2015

In addition to performing simple string matching, you can configure expressions that examine more complex aspects of text, including examining the length of a string and looking within a text block for patterns rather than specific strings.

Be aware of the following for any text-based operation:

- For any operation that takes a string argument, the string cannot exceed 255 characters.
- You can include white space when you specify a string in an expression.

This document includes the following details:

The following operations extract strings on the basis of a character count.

Table 1. String Operations Based on a Character Count

Character Count Operation	Description
<text>.TRUNCATE(<count>)	Returns a string after truncating the end of the target by the number of characters in <count>. If the entire string is shorter than <count>, nothing is returned.
<text>.TRUNCATE(<character>, <count>)	Returns a string after truncating the text after <character> by the number of characters specified in <count>.
<text>.PREFIX(<character>, <count>)	Selects the longest prefix in the target that has at most <count> occurrences of <character>.
	<text>.SUFFIX(<character>, <count>) Selects the longest suffix in the target that has at most <count> occurrences of <character>. For example, consider the following response body: JLEwx The following expression returns a value of “JLEwx”: http.res.body(100).suffix('L',1) The following expression returns “LLEwx”: http.res.body(100).suffix('L',2)
<text>.SUBSTR(<starting_offset>,	Select a string with <length> number of characters from the target object. Begin extracting the

Character Count Operation	Description
<text>.SKIP(<character>, <count>)	Select a string from the target after skipping over the longest prefix that has at most <count> occurrences of <character>.

You can extract a subset of a larger string by using one of the operations in the following table.

Table 2. Basic Operations on a Portion of a String

Basic Text Operation	Description
<text>.BEFORE_STR(<string>)	Returns the text that precedes the first occurrence of <string>. If there is no match for <string>, the expression returns a text object of 0 length. Following is an example: http.res.body(1024).after_str("start_string").before_str("end_string").contains("https")
<text>.AFTER_STR(<string>)	Returns the text that follows the first occurrence of <string>. If there is no match for <string>, the expression returns a text object of 0 length. Following is an example: http.res.body(1024).after_str("start_string").before_str("end_string").contains("https")
<text>.BETWEEN(<starting string>, <ending string>)	Returns a Boolean TRUE value if the length of the text object is greater than or equal to the sum <starting string>, <ending string> argument lengths, and if a prefix of the target matches <starting string>, and if the suffix of the target matches <ending string>.
<text>.PREFIX(<prefix length>)	Returns the starting string from a target block of text that contains the number of characters in the <prefix length> argument. If the <prefix length> argument exceeds the number of characters in the target, the entire string is selected.
<text>.SUFFIX(<suffix length>)	Returns the ending string from a target block of text that contains the number of characters in the <suffix length> argument. If the <suffix length> argument exceeds the number characters in the target, the entire string is selected.
<text>.SUBSTR(<string>)	Select the first block of text in the target that matches the <string>.
<text>.SKIP(<prefix length>)	Selects the text in the target after skipping over a <prefix length> number of characters. If the entire target has fewer characters than <prefix length>, the entire target is skipped.
<text>.STRIP_END_WS	Selects the text after removing white space from the end of the target.
<text>.STRIP_START_WS	Selects the text after removing white space from the beginning of the target.

Basic Text Operation	Description
<text>.UNQUOTE(<character>)	Selects the <character>, removes white space that immediately precedes and follows the <character>, and if the remaining text is quoted by <character>, this prefix also removes the quotes. For example, the operation UNQUOTE("") changes the following text: " abc xyz def " To the following: abc xyz def

The COMPARE operation examines the first nonmatching character of two different strings. This operation is based on lexicographic order, which is the method used when ordering terms in dictionaries.

This operation returns the arithmetic difference between the ASCII values of the first nonmatching characters in the compared strings. The following differences are examples:

- The difference between “abc” and “abd” is -1 (based on the third pair-wise character comparison).
- The difference between “@” and “abc” is -33.
- The difference between “1” and “abc” is -47.

Following is the syntax for the COMPARE operation.

<text>.COMPARE(<string>)

You can use the following functions to treat a string of bytes that represent text as a sequence of bytes, extract 8, 16, or 32 bits from the sequence, and then convert the extracted bits to an integer.

Table 3. Operations for Extracting an Integer from a String of Bytes That Represent Text

Function	Description
<text>.GET_SIGNED8(<n>)	Treats the string of bytes represented by text as a sequence of 8-bit signed integers and returns the integer at byte offset n. If the offset makes all or part of the value outside of the current text, an UNDEF condition is raised.
<text>.GET_UNSIGNED8(<n>)	Treats the string of bytes represented by text as a sequence of 8-bit unsigned integers and returns the integer at byte offset n. If the offset makes all or part of the value outside of the current text, an UNDEF condition is raised.
<text>.GET_SIGNED16(<n>, <endianness>)	Treats the text string returned by the prefix as a string of bytes, extracts 16 bits starting at byte offset n, and converts the extracted bit sequence to a 16-bit signed integer. If the offset makes all or part of the value outside of the current text, an UNDEF condition is raised. The first parameter n is the byte offset from the current position in the text string. Providing a byte offset enables the function to handle items that are not aligned on the boundaries that are required by indexes. The second parameter, endianness, takes a mnemonic value of LITTLE_ENDIAN or BIG_ENDIAN. Note: In NetScaler 9.2, the parameter n was an index into an array of 16-bit items. In NetScaler 9.3, the parameter is a byte offset. Therefore, if you used this function in NetScaler 9.2, after you upgrade to NetScaler 9.3, you must change n to 2*n to obtain the same results as you did earlier. For example, if the value of n before the upgrade was 4, you must change the value of n to 8. The

Function	Description
	parameter endianness also no longer takes the values that it did in NetScaler 9.2, which were 0 and 1. Instead, endianness accepts the mnemonic values mentioned earlier. **Example** HTTP.REQ.BODY(100).GET_SIGNED16(8, BIG_ENDIAN)
<text>.GET_UNSIGNED16(<n>, <endianness>)	Treats the text string returned by the prefix as a string of bytes, extracts 16 bits starting at byte offset n, and converts the extracted bit sequence to a 16-bit unsigned integer. If the offset makes all or part of the value outside of the current text, an UNDEF condition is raised. The first parameter n is the byte offset from the current position in the text string. Providing a byte offset enables the function to handle items that are not aligned on the boundaries that are required by indexes. The second parameter, endianness, takes a mnemonic value of LITTLE_ENDIAN or BIG_ENDIAN. Note: In NetScaler 9.2, the parameter n was an index into an array of 16-bit items. In NetScaler 9.3, the parameter is a byte offset. Therefore, if you used this function in NetScaler 9.2, after you upgrade to NetScaler 9.3, you must change n to 2*n to obtain the same results as you did earlier. For example, if the value of n before the upgrade was 4, you must change the value of n to 8. The parameter endianness also no longer takes the values that it did in NetScaler 9.2, which were 0 and 1. Instead, endianness accepts the mnemonic values mentioned earlier. **Example** HTTP.REQ.BODY(100).GET_UNSIGNED16(8, LITTLE_ENDIAN)
<text>.GET_SIGNED32(<n>, <endianness>)	Treats the text string returned by the prefix as a string of bytes, extracts 32 bits starting at byte offset n, and converts the extracted bit sequence to a 32-bit signed integer. If the offset makes all or part of the value outside of the current text, an UNDEF condition is raised. The first parameter n is the byte offset from the current position in the text string. Providing a byte offset enables the function to handle items that are not aligned on the boundaries that are required by indexes. The second parameter, endianness, takes a mnemonic value of LITTLE_ENDIAN or BIG_ENDIAN. Note: In NetScaler 9.2, the parameter n was an index into an array of 32-bit items. In NetScaler 9.3, the parameter is a byte offset. Therefore, if you used this function in NetScaler 9.2, after you upgrade to NetScaler 9.3, you must change n to 4*n to obtain the same results as you did earlier. For example, if the value of n before the upgrade was 4, you must change the value of n to 16. The parameter endianness also no longer takes the values that it did in NetScaler 9.2, which were 0 and 1. Instead, endianness accepts the mnemonic values mentioned earlier. **Example** HTTP.REQ.BODY(1000).GET_SIGNED32(12, BIG_ENDIAN)
<text>.GET_UNSIGNED32(<n>, <endianness>)	Treats the text string returned by the prefix as a string of bytes, extracts 32 bits starting at byte offset n, and returns the extracted bit sequence as part of a 64-bit unsigned long integer. If the offset makes all or part of the value outside of the current text, an UNDEF condition is raised. The first parameter n is the byte offset from the current position in the text string. Providing a byte offset enables the function to handle items that are not aligned on the boundaries that are required by indexes. The second parameter, endianness, takes a mnemonic value of LITTLE_ENDIAN or BIG_ENDIAN. **Example** HTTP.REQ.BODY(1000).GET_UNSIGNED32(30, LITTLE_ENDIAN)

Function	Description

You can convert a text string to a hash value by using the HASH function. This function returns a 31-bit positive integer as a result of the operation. Following is the format of the expression:

<text>.HASH

This function ignores case and white spaces. For example, after the operation, the two strings Ab c and a bc would produce the same hash value.

The following two functions encode and decode a text string by applying the Base64 encoding algorithm

Table 4. Functions for Encoding and Decoding a Text String by Using Base64 Encoding

Function	Description
text.B64ENCODE	Encodes the text string (designated by text) by applying the Base64 encoding algorithm.
text.B64DECODE	Decodes the Base64-encoded string (designated by text) by applying the Base64 decoding algorithm. The operation raises an UNDEF if text is not in B64-encoded format.

The EXTEND function is used in rewrite actions that specify patterns or pattern sets and target the bodies of HTTP packets. When a pattern match is found, the EXTEND function extends the scope of the search by a predefined number of bytes on both sides of the matching string. A regular expression can then be used to perform a rewrite on matches in this extended region. Rewrite actions that are configured with the EXTEND function perform rewrites faster than rewrite actions that evaluate entire HTTP bodies using only regular expressions.

The format of the EXTEND function is EXTEND(m,n), where m and n are the number of bytes by which the scope of the search is extended before and after the matching pattern, respectively. When a match is found, the new search scope comprises m bytes that immediately precede the matching string, the string itself, and the n bytes that follow the string. A regular expression can then be used to perform a rewrite on a portion of this new string.

The EXTEND function can be used only if the rewrite action in which it is used fulfills the following requirements:

- The search is performed by using patterns or patterns sets (not regular expressions)
- The rewrite action evaluates only the bodies of HTTP packets.

Additionally, the EXTEND function can be used only with the following types of rewrite actions:

- replace_all
- insert_after_all
- delete_all
- insert_before_all

For example, you might want to delete all instances of "http://exampleurl.com/" and "http://exampleurl.au/" in the first 1000 bytes of the body. To do this, you can configure a rewrite action to search for all instances of the string exampleurl, extend the scope of the search on both sides of the string when a match is found, and then use a regular expression to perform the rewrite in the extended region. The following example extends the scope of the search by 20 bytes to the left and 50 bytes to the right of the matching string:

```
add rewrite action delurl_example delete_all 'HTTP.REQ.BODY(1000)' -pattern exampleurl -refineSearch
'extend(20,50).regex_select(re#http://exampleurl.(com|au)#)'
```

The following function converts text to hexadecimal format and extracts the resulting string:

<text>.BLOB_TO_HEX(<string>)

For example, this function converts the byte string “abc” to “61:62:63”.

Updated: 2013-09-02

In default syntax expressions, you can use the ENCRYPT and DECRYPT functions to encrypt and decrypt text. Data encrypted by the ENCRYPT function on a given NetScaler appliance or high availability (HA) pair is intended for decryption by the DECRYPT function on the same NetScaler appliance or HA pair. The appliance supports the RC4, DES3, AES128, AES192, and AES256 encryption methods. The key value that is required for encryption is not user-specifiable. When an encryption method is set, the appliance automatically generates a random key value that is appropriate for the specified method. The default method is AES256 encryption, which is the most secure encryption method and the one that Citrix recommends.

You do not need to configure encryption unless you want to change the encryption method or you want the appliance to generate a new key value for the current encryption method.

Note: You can also encrypt and decrypt XML payloads. For information about the functions for encrypting and decrypting XML payloads, see "Encrypting and Decrypting XML Payloads."

Configuring Encryption

Updated: 2013-09-02

During startup, the appliance runs the set ns encryptionParams command with, by default, the AES256 encryption method, and uses a randomly generated key value that is appropriate for AES256 encryption. The appliance also encrypts the key value and saves the command, with the encrypted key value, to the NetScaler configuration file. Consequently, the AES256 encryption method is enabled for the ENCRYPT and DECRYPT functions by default. The key value that is saved in the configuration file persists across reboots even though the appliance runs the command each time you restart it.

You can run the set ns encryptionParams command manually, or use the configuration utility, if you want to change the encryption method or if you want the appliance to generate a new key value for the current encryption method. To use the CLI to change the encryption method, set only the method parameter, as shown in "**Example 1: Changing the Encryption Method**." If you want the appliance to generate a new key value for the current encryption method, set the method parameter to the current encryption method and the keyValue parameter to an empty string (""), as shown in "**Example 2: Generating a New Key Value for the Current Encryption Method**." After you generate a new key value, you must save the configuration. If you do not save the configuration, the appliance uses the newly generated key value only until the next restart, after which it reverts to the key value in the saved configuration.

1. Navigate to System > Settings.
2. In the Settings area, click Change Encryption parameters.
3. In the Change Encryption Parameters dialog box, do one of the following:
   - To change the encryption method, in the Method list, select the encryption method that you want.
   - To generate a new key value for the current encryption method, click Generate a new key for the selected method.
4. Click OK.

Using the ENCRYPT and DECRYPT Functions

You can use the ENCRYPT and DECRYPT functions with any expression prefix that returns text. For example, you can use the ENCRYPT and DECRYPT functions in rewrite policies for cookie encryption. In the following example, the rewrite actions encrypt a cookie named MyCookie, which is set by a back-end service, and decrypt the same cookie when it is returned by a client:

```
add rewrite action my-cookie-encrypt-action replace "HTTP.RES.SET_COOKIE.COOKIE(\"MyCookie\").VALUE(0)"
"HTTP.RES.SET_COOKIE.COOKIE(\"MyCookie\").VALUE(0).ENCRYPT" -bypassSafetyCheck YES

add rewrite action my-cookie-decrypt-action replace "HTTP.REQ.COOKIE.VALUE(\"MyCookie\")"
"HTTP.REQ.COOKIE.VALUE(\"MyCookie\").DECRYPT" -bypassSafetyCheck YES
```

After you configure policies for encryption and decryption, save the configuration to bring the policies into effect.

Default Syntax Expressions: Working with Dates, Times, and Numbers

Sep 02, 2013

Most numeric data that the NetScaler appliance processes consists of dates and times. In addition to working with dates and times, the appliance processes other numeric data, such as the lengths of HTTP requests and responses. To process this data, you can configure default syntax expressions that process numbers.

A numeric expression consists of an expression prefix that returns a number and sometimes, but not always, an operator that can perform an operation on the number. Examples of expression prefixes that return numbers are SYS.TIME.DAY, HTTP.REQ.CONTENT_LENGTH, and HTTP.RES.BODY.LENGTH. Numeric operators can work with any prefix expression that returns data in numeric format. The GT(<int>) operator, for example, can be used with any prefix expression, such as HTTP.REQ.CONTENT_LENGTH, that returns an integer. Numeric expression prefixes and operators are also covered in "Compound Operations for Numbers" and "Default Syntax Expressions: Parsing HTTP, TCP, and UDP Data."

Format of Dates and Times in an Expression

Nov 14, 2013

When configuring a default syntax expression in a policy that works with dates and times (for example, the NetScaler system time or a date in an SSL certificate), you specify a time format as follows:

GMT|LOCAL [<yyyy>] [<month>] [<d>] [<h>] [<m>] [<s>]

Where:

- <yyyy> is a four-digit year after GMT or LOCAL.
- <month> is a three-character abbreviation for the month, for example, Jan, Dec.
- <d> is a day of the week or an integer for the date.
  You cannot specify the day as Monday, Tuesday, and so on. You specify either an integer for a specific day of the month, or you specify a date as the first, second, third weekday of the month, and so on. Following are examples of specifying a day of the week:
  - Sun_1 is the first Sunday of the month.
  - Sun_3 is the third Sunday of the month.
  - Wed_3 is the third Wednesday of the month.
  - 30 is an example of an exact date in a month.
- <h> is the hour, for example, 10h.
- <s> is the number of seconds, for example, 30s.

The following example expression is true if the date is between 2008 Jan and 2009 Jan, based on GMT.

```
http.req.date.between(GMT 2008 Jan, GMT 2009 Jan)
```

The following example expression is true for March and all months that follow March in the calendar year, based on GMT:

```
sys.time.ge(GMT 2008 Mar)
```

When you specify a date and time, note that the format is case sensitive and must preserve the exact number of blank spaces between entries.

Note: In an expression that requires two time values, both must use GMT or both must use LOCAL. You cannot mix the two in an expression.
Note: Unlike when you use the SYS.TIME prefix in a default syntax expression, if you specify SYS.TIME in a rewrite action, the NetScaler returns a string in conventional date format (for example, Sun, 06 Nov 1994 08:49:37 GMT). For example, the following rewrite action replaces the http.res.date header with the NetScaler system time in a conventional date format: add rewrite action `sync_date replace http.res.date sys.time`

Expressions for the NetScaler System Time

Mar 20, 2012

The SYS.TIME expression prefix extracts the NetScaler system time. You can configure expressions that establish whether a particular event occurred at a particular time or within a particular time range according to the NetScaler system time.

The following table describes the expressions that you can create by using the SYS.TIME prefix.

Table 1. Expressions That Return NetScaler System Dates and Times

NetScaler Time Operation	Description
SYS.TIME.BETWEEN(<time1>, <time2>)	Returns a Boolean TRUE if the returned value is later than <time1> and earlier than <time2>. You format the <time1>, <time2> arguments as follows: • They must both be GMT or both LOCAL. • <time2> must be later than <time1>. For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following: • sys.time.between(GMT 2004, GMT 2006) • sys.time.between(GMT 2004 Jan, GMT 2006 Nov) • sys.time.between(GMT 2004 Jan, GMT 2006) • sys.time.between(GMT 2005 May Sun_1, GMT 2005 May Sun_3) • sys.time.between(GMT 2005 May 1, GMT May 2005 1) • sys.time.between(LOCAL 2005 May 1, LOCAL May 2005 1)
SYS.TIME.DAY	Returns the current day of the month as a number from 1 through 31.
SYS.TIME.EQ(<time>)	Returns a Boolean TRUE if the current time is equal to the <time> argument. For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses): • sys.time.eq(GMT 2005) (TRUE in this example.) • sys.time.eq(GMT 2005 Dec) (FALSE in this example.) • sys.time.eq(LOCAL 2005 May) (Evaluates to TRUE or FALSE in this example, depending on the current time zone.) • sys.time.eq(GMT 10h) (TRUE in this example.) • sys.time.eq(GMT 10h 30s) (TRUE in this example.) • sys.time.eq(GMT May 10h) (TRUE in this example.) • sys.time.eq(GMT Sun) (TRUE in this example.) • sys.time.eq(GMT May Sun_1) (TRUE in this example.)

NetScaler Time Operation	Description
SYS.TIME.NE(<time>)	Returns a Boolean TRUE if the current time is not equal to the <time> argument.
SYS.TIME.GE(<time>)	Returns a Boolean TRUE if the current time is later than or equal to <time>. For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses): • sys.time.ge(GMT 2004) (TRUE in this example.) • sys.time.ge(GMT 2005 Jan) (TRUE in this example.) • sys.time.ge(LOCAL 2005 May) (TRUE or FALSE in this example, depending on the current time zone.) • sys.time.ge(GMT 8h) (TRUE in this example.) • sys.time.ge(GMT 30m) (FALSE in this example.) • sys.time.ge(GMT May 10h) (TRUE in this example.) • sys.time.ge(GMT May 10h 0m) (TRUE in this example.) • sys.time.ge(GMT Sun) (TRUE in this example.) • sys.time.ge(GMT May Sun_1) (TRUE in this example.)
SYS.TIME.GT(<time>)	Returns a Boolean TRUE if the time value is later than the <time> argument. For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses): • sys.time.gt(GMT 2004) (TRUE in this example.) • sys.time.gt(GMT 2005 Jan) (TRUE in this example.) • sys.time.gt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • sys.time.gt(GMT 8h) (TRUE in this example.) • sys.time.gt(GMT 30m) (FALSE in this example.) • sys.time.gt(GMT May 10h) (FALSE in this example.) • sys.time.gt(GMT May 10h 0m) (TRUE in this example.) • sys.time.gt(GMT Sun) (FALSE in this example.) • sys.time.gt(GMT May Sun_1) (FALSE in this example.)
SYS.TIME.HOURS	Returns the current hour as an integer from 0 to 23.
SYS.TIME.LE(<time>)	Returns a Boolean TRUE if the current time value precedes or is equal to the <time> argument. For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):

NetScaler Time Operation	Description
	• sys.time.le(GMT 2006) (TRUE in this example.) • sys.time.le(GMT 2005 Dec) (TRUE in this example.) • sys.time.le(LOCAL 2005 May) (TRUE or FALSE depending on the current timezone.) • sys.time.le(GMT 8h) (FALSE in this example.) • sys.time.le(GMT 30m) (TRUE in this example.) • sys.time.le(GMT May 10h) (TRUE in this example.) • sys.time.le(GMT Jun 11h) (TRUE in this example.) • sys.time.le(GMT Wed) (TRUE in this example.) • sys.time.le(GMT May Sun_1) (TRUE in this example.)
SYS.TIME.LT(<time>)	Returns a Boolean TRUE if the current time value precedes the <time> argument. For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses): • sys.time.lt(GMT 2006) (TRUE in this example.) • sys.time.lt.time.lt(GMT 2005 Dec) (TRUE in this example.) • sys.time.lt(LOCAL 2005 May) (TRUE or FALSE depending on the current time zone.) • sys.time.lt(GMT 8h) (FALSE in this example.) • sys.time.lt(GMT 30m) (TRUE in this example.) • sys.time.lt(GMT May 10h) (FALSE in this example.) • sys.time.lt(GMT Jun 11h) (TRUE in this example.) • sys.time.lt(GMT Wed) (TRUE in this example.) • sys.time.lt(GMT May Sun_1) (FALSE in this example.)
SYS.TIME.MINUTES	Returns the current minute as an integer from 0 to 59.
SYS.TIME.MONTH	Extracts the current month and returns an integer from 1 (January) to 12 (December).
SYS.TIME.RELATIVE_BOOT	Calculates the number of seconds to the closest previous or scheduled reboot, and returns an integer. If the closest boot time is in the past, the integer is negative. If it is in the future, the integer is positive.
SYS.TIME.RELATIVE_NOW	Calculates the number of seconds between the current NetScaler system time and the specified time, and returns an integer showing the difference. If the designated time is in the past, the integer is negative; if it is in the future, the integer is positive.

NetScaler Time Operation	Description
SYS.TIME.SECONDS	Extracts the seconds from the current NetScaler system time, and returns that value as an integer from 0 to 59.
SYS.TIME.WEEKDAY	Returns the current weekday as a value from 0 (Sunday) to 6 (Saturday).
SYS.TIME.WITHIN (<time1>, <time2>)	If you omit an element of time in <time1>, for example, the day or hour, it is assumed to have the lowest value in its range. If you omit an element in <time2>, it is assumed to have the highest value of its range. The ranges for the elements of time are as follows: month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds 0-59. If you specify the year, you must do so in both <time1> and <time2>. For example, if the time is GMT 2005 May 10 10h 15m 30s, and it is the second Tuesday of the month, you can specify the following (evaluation results are shown in parentheses): • sys.time.within(GMT 2004, GMT 2006) (TRUE in this example.) • sys.time.within(GMT 2004 Jan, GMT 2006 Mar) (FALSE, May is not in the range of January to March.) • sys.time.within(GMT Feb, GMT) (TRUE, May is in the range of February to December.) • sys.time.within(GMT Sun_1, GMT Sun_3) (TRUE, the second Tuesday is between the first Sunday and the third Sunday.) • sys.time.within(GMT 2005 May 1 10h, GMT May 2005 1 17h) (TRUE in this example.) • sys.time.within(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone.)
SYS.TIME.YEAR	Extracts the year from the current system time and returns that value as a four-digit integer.

Expressions for SSL Certificate Dates

May 11, 2012

You can determine the validity period for SSL certificates by configuring an expression that contains the following prefix:

CLIENT.SSL.CLIENT_CERT

The following example expression matches a particular time for expiration with the information in the certificate:

client.ssl.client_cert.valid_not_after.eq(GMT 2009)

The following table describes time-based operations on SSL certificates. To obtain the expression you want, replace *certificate* in the expression in the first column with the prefix expression, "CLIENT.SSL.CLIENT_CERT".

Table 1. Operations on Certificate (client.ssl.client_cert) Dates and Times

SSL Certificate Operation	Description
<certificate>.VALID_NOT_AFTER	Returns the last day before certificate expiration. The return format is the number of seconds since GMT January 1, 1970 (0 hours, 0 minutes, 0 seconds).
<certificate>.VALID_NOT_AFTER.BETWEEN(<time1>, <time2>)	Returns a Boolean TRUE value if the certificate validity is between the <time1> and <time2> arguments. Both <time1> and <time2> must be fully specified. Following are examples: GMT 1995 Jan is fully specified. GMT Jan is not fully specified GMT 1995 20 is not fully specified. GMT Jan Mon_2 is not fully specified. The <time1> and <time2> arguments must be both GMT or both LOCAL, and <time2> must be greater than <time1>. For example, if it is GMT 2005 May 1 10h 15m 30s, and the first Sunday of the month, you can specify the following (evaluation results are in parentheses). • . . .between(GMT 2004, GMT 2006) (TRUE) • . . .between(GMT 2004 Jan, GMT 2006 Nov) (TRUE) • . . .between(GMT 2004 Jan, GMT 2006) (TRUE) • . . .between(GMT 2005 May Sun_1, GMT

SSL Certificate Operation	Description
	2005 May Sun_3) (TRUE) • . . .between(GMT 2005 May 1, GMT May 2005 1) (TRUE) • . . .between(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone.)
<certificate>.VALID_NOT_AFTER.DAY	Extracts the last day of the month that the certificate is valid, and returns a number from 1 through 31, as appropriate for the date.
<certificate>.VALID_NOT_AFTER.EQ(<time>)	Returns a Boolean TRUE if the time is equal to the <time> argument. For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results for this example are in parentheses): • . . .eq(GMT 2005) (TRUE) • . . .eq(GMT 2005 Dec) (FALSE) • . . .eq(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone) • . . .eq(GMT 10h) (TRUE) • . . .eq(GMT 10h 30s) (TRUE) • . . .eq(GMT May 10h) (TRUE) • . . .eq(GMT Sun) (TRUE) • . . .eq(GMT May Sun_1) (TRUE)
<certificate>.VALID_NOT_AFTER.GE(<time>)	Returns a Boolean TRUE if the time value is greater than or equal to the argument <time>. For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses): • . . .ge(GMT 2004) (TRUE) • . . .ge(GMT 2005 Jan) (TRUE) • . . .ge(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • . . .ge(GMT 8h) (TRUE) • . . .ge(GMT 30m) (FALSE) • . . .ge(GMT May 10h) (TRUE) • . . .ge(GMT May 10h 0m) (TRUE)

SSL Certificate Operation	Description
	• . . .ge(GMT Sun) (TRUE) • . . .ge(GMT May Sun_1) (TRUE)
<certificate>.VALID_NOT_AFTER.GT(<time>)	Returns a Boolean TRUE if the time value is greater than the argument <time>. For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses): • . . .gt(GMT 2004) (TRUE) • . . .gt(GMT 2005 Jan) (TRUE) • . . .gt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • . . .gt(GMT 8h) (TRUE) • . . .gt(GMT 30m) (FALSE) • . . .gt(GMT May 10h) (FALSE) • . . .gt(GMT Sun) (FALSE) • . . .gt(GMT May Sun_1) (FALSE)
<certificate>.VALID_NOT_AFTER.HOURS	Extracts the last hour that the certificate is valid and returns that value as an integer from 0 to 23.
<certificate>.VALID_NOT_AFTER.LE(<time>)	Returns a Boolean TRUE if the time precedes or is equal to the <time> argument. For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses): • . . .le(GMT 2006) (TRUE) • . . .le(GMT 2005 Dec) (TRUE) • . . .le(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • . . .le(GMT 8h) (FALSE) • . . .le(GMT 30m) (TRUE) • . . .le(GMT May 10h) (TRUE) • . . .le(GMT Jun 11h) (TRUE) • . . .le(GMT Wed) (TRUE) • . . .le(GMT May Sun_1) (TRUE)
<certificate>.VALID_NOT_AFTER.LT(<time>)	Returns a Boolean TRUE if the time precedes the

SSL Certificate Operation	Description
	<time> argument. For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following: • . . .lt(GMT 2006) (TRUE) • . . .lt(GMT 2005 Dec) (TRUE) • . . .lt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • . . .lt(GMT 8h) (FALSE) • . . .lt(GMT 30m) (TRUE) • . . .lt(GMT May 10h) (FALSE) • . . .lt(GMT Jun 11h) (TRUE) • . . .lt(GMT Wed) (TRUE) • . . .lt(GMT May Sun_1) (FALSE)
<certificate>.VALID_NOT_AFTER.MINUTES	Extracts the last minute that the certificate is valid and returns that value as an integer from 0 to 59.
<certificate>.VALID_NOT_AFTER.MONTH	Extracts the last month that the certificate is valid and returns that value as an integer from 1 (January) to 12 (December).
<certificate>.VALID_NOT_AFTER.RELATIVE_BOOT	Calculates the number of seconds to the closest previous or scheduled reboot and returns an integer. If the closest boot time is in the past, the integer is negative. If it is in the future, the integer is positive.
<certificate>.VALID_NOT_AFTER.RELATIVE_NOW	Calculates the number of seconds between the current system time and the specified time and returns an integer. If the time is in the past, the integer is negative; if it is in the future, the integer is positive.
<certificate>.VALID_NOT_AFTER.SECONDS	Extracts the last second that the certificate is valid and returns that value as an integer from 0 to 59.
<certificate>.VALID_NOT_AFTER.WEEKDAY	Extracts the last weekday that the certificate is valid. Returns a number between 0 (Sunday) and 6 (Saturday) to give the weekday in the time value.
<certificate>.VALID_NOT_AFTER.WITHIN(<time1>, <time2>)	Returns a Boolean TRUE if the time lies within all the ranges defined by the elements in <time1> and <time2>.

SSL Certificate Operation	Description
	If you omit an element of time from <time1>, it is assumed to have the lowest value in its range. If you omit an element from <time2>, it is assumed to have the highest value of its range. If you specify a year in <time1>, you must specify it in <time2>. The ranges for elements of time are as follows: month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds 0-59. For the result to be TRUE, each element in the time must exist in the corresponding range that you specify in <time1>, <time2>. For example, if time is GMT 2005 May 10 10h 15m 30s, and it is the second Tuesday of the month, you can specify the following (evaluation results are in parentheses): • . . .within(GMT 2004, GMT 2006) (TRUE) • . . .within(GMT 2004 Jan, GMT 2006 Mar) (FALSE, May is not in the range of January to March.) • . . .within(GMT Feb, GMT) (TRUE, May is in the range for February to December) • . . .within(GMT Sun_1, GMT Sun_3) (TRUE, the second Tuesday lies within the range of the first Sunday through the third Sunday) • . . .within(GMT 2005 May 1 10h, GMT May 2005 1 17h) (TRUE) • . . .within(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone)
<certificate>.VALID_NOT_AFTER.YEAR	Extracts the last year that the certificate is valid and returns a four-digit integer.
<certificate>.VALID_NOT_BEFORE	Returns the date that the client certificate becomes valid. The return format is the number of seconds since GMT January 1, 1970 (0 hours, 0 minutes, 0 seconds).
<certificate>.VALID_NOT_BEFORE.BETWEEN(<time1>, <time2>)	Returns a Boolean TRUE if the time value is between the two time arguments. Both <time1> and <time2> arguments must be fully specified.

SSL Certificate Operation	Description
	Following are examples: • GMT 1995 Jan is fully specified. • GMT Jan is not fully specified. • GMT 1995 20 is not fully specified. • GMT Jan Mon_2 is not fully specified. The time arguments must be both GMT or both LOCAL, and <time2> must be greater than <time1>. For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses): • . . .between(GMT 2004, GMT 2006) (TRUE) • . . .between(GMT 2004 Jan, GMT 2006 Nov) (TRUE) • . . .between(GMT 2004 Jan, GMT 2006) (TRUE) • . . .between(GMT 2005 May Sun_1, GMT 2005 May Sun_3) (TRUE) • . . .between(GMT 2005 May 1, GMT May 2005 1) (TRUE) • . . .between(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone.)
<certificate>.VALID_NOT_BEFORE.DAY	Extracts the last day of the month that the certificate is valid and returns that value as a number from 1 through 31 representing that day.
<certificate>.VALID_NOT_BEFORE.EQ(<time>)	Returns a Boolean TRUE if the time is equal to the <time> argument. For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses): • . . .eq(GMT 2005) (TRUE) • . . .eq(GMT 2005 Dec) (FALSE) • . . .eq(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • . . .eq(GMT 10h) (TRUE) • . . .eq(GMT 10h 30s) (TRUE)

SSL Certificate Operation	Description
	• . . .eq(GMT May 10h) (TRUE) • . . .eq(GMT Sun) (TRUE) • . . .eq(GMT May Sun_1) (TRUE)
<certificate>.VALID_NOT_BEFORE.GE(<time>)	Returns a Boolean TRUE if the time is greater than (after) or equal to the <time> argument. For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results are in parentheses): • . . .ge(GMT 2004) (TRUE) • . . .ge(GMT 2005 Jan) (TRUE) • . . .ge(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • . . .ge(GMT 8h) (TRUE) • . . .ge(GMT 30m) (FALSE) • . . .ge(GMT May 10h) (TRUE) • . . .ge(GMT May 10h 0m) (TRUE) • . . .ge(GMT Sun) (TRUE) • . . .ge(GMT May Sun_1) (TRUE)
<certificate>.VALID_NOT_BEFORE.GT(<time>)	Returns a Boolean TRUE if the time occurs after the <time> argument. For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results are in parentheses): • . . .gt(GMT 2004) (TRUE) • . . .gt(GMT 2005 Jan) (TRUE) • . . .gt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • . . .gt(GMT 8h) (TRUE) • . . .gt(GMT 30m) (FALSE) • . . .gt(GMT May 10h) (FALSE) • . . .gt(GMT May 10h 0m) (TRUE) • . . .gt(GMT Sun) (FALSE) • . . .gt(GMT May Sun_1) (FALSE)
<certificate>.VALID_NOT_BEFORE.HOURS	Extracts the last hour that the certificate is valid and returns that value as an integer from 0 to 23.
<certificate>.VALID_NOT_BEFORE.LE(<time>)	Returns a Boolean TRUE if the time precedes or is

SSL Certificate Operation	Description
	equal to the <time> argument. For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses): • . . .le(GMT 2006) (TRUE) • . . .le(GMT 2005 Dec) (TRUE) • . . .le(LOCAL 2005 May) (TRUE or FALSE,depending on the current time zone.) • . . .le(GMT 8h) (FALSE) • . . .le(GMT 30m) (TRUE) • . . .le(GMT May 10h) (TRUE) • . . .le(GMT Jun 11h) (TRUE) • . . .le(GMT Wed) (TRUE) • . . .le(GMT May Sun_1) (TRUE)
<certificate>.VALID_NOT_BEFORE.LT(<time>)	Returns a Boolean TRUE if the time precedes the <time> argument. For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses): • . . .lt(GMT 2006) (TRUE) • . . .lt(GMT 2005 Dec) (TRUE) • . . .lt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • . . .lt(GMT 8h) (FALSE) • . . .lt(GMT 30m) (TRUE) • . . .lt(GMT May 10h) (FALSE) • . . .lt(GMT Jun 11h) (TRUE) • . . .lt(GMT Wed) (TRUE) • . . .lt(GMT May Sun_1) (FALSE)
<certificate>.VALID_NOT_BEFORE.MINUTES	Extracts the last minute that the certificate is valid. Returns the current minute as an integer from 0 to 59.
<certificate>.VALID_NOT_BEFORE.MONTH	Extracts the last month that the certificate is valid. Returns the current month as an integer from 1

SSL Certificate Operation	Description
<certificate>.VALID_NOT_BEFORE.RELATIVE_BOOT	Calculates the number of seconds to the closest previous or scheduled NetScaler reboot and returns an integer. If the closest boot time is in the past, the integer is negative; if it is in the future, the integer is positive.
<certificate>.VALID_NOT_BEFORE.RELATIVE_NOW	Returns the number of seconds between the current NetScaler system time and the specified time as an integer. If the designated time is in the past, the integer is negative. If it is in the future, the integer is positive.
<certificate>.VALID_NOT_BEFORE.SECONDS	Extracts the last second that the certificate is valid. Returns the current second as an integer from 0 to 59.
<certificate>.VALID_NOT_BEFORE.WEEKDAY	Extracts the last weekday that the certificate is valid. Returns the weekday as a number between 0 (Sunday) and 6 (Saturday).
<certificate>.VALID_NOT_BEFORE.WITHIN(<time1>, <time2>)	Returns a Boolean TRUE if each element of time exists within the range defined in the <time1>, <time2> arguments. If you omit an element of time from <time1>, it is assumed to have the lowest value in its range. If you omit an element of time from <time2>, it is assumed to have the highest value in its range. If you specify a year in <time1>, it must be specified in <time2>. The ranges for elements of time are as follows: month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds 0-59. For example, if the time is GMT 2005 May 10 10h 15m 30s, and it is the second Tuesday of the month, you can specify the following (evaluation results are in parentheses): • . . .within(GMT 2004, GMT 2006) (TRUE) • . . .within(GMT 2004 Jan, GMT 2006 Mar) (FALSE, May is not in the range of January to March.) • . . .within(GMT Feb, GMT) (TRUE, May is in the range of February to December.)

(January) to 12 (December).

SSL Certificate Operation	Description
	. . .within(GMT Sun_1, GMT Sun_3) (TRUE, the second Tuesday is between the first Sunday and the third Sunday.) . . .within(GMT 2005 May 1 10h, GMT May 2005 1 17h) (TRUE) . . .within(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone)
<certificate>.VALID_NOT_BEFORE.YEAR	Extracts the last year that the certificate is valid. Returns the current year as a four-digit integer.

Expressions for HTTP Request and Response Dates

Sep 02, 2013

The following expression prefixes return the contents of the HTTP Date header as text or as a date object. These values can be evaluated as follows:

- As a number. The numeric value of an HTTP Date header is returned in the form of the number of seconds since Jan 1 1970.
  For example, the expression http.req.date.mod(86400) returns the number of seconds since the beginning of the day. These values can be evaluated using the same operations as other non-date-related numeric data. For more information, see "Expression Prefixes for Numeric Data Other Than Date and Time."
- As an HTTP header. Date headers can be evaluated using the same operations as other HTTP headers.
  For more information, see "Default Syntax Expressions: Parsing HTTP, TCP, and UDP Data."
- As text. Date headers can be evaluated using the same operations as other strings.

For more information, see "Default Syntax Expressions: Evaluating Text."

Table 1. Prefixes That Evaluate HTTP Date Headers

Prefix	Description
HTTP.REQ.DATE	Returns the contents of the HTTP Date header as text or as a date object. The date formats recognized are: RFC822. Sun, 06 Jan 1980 08:49:37 GMT RFC850. Sunday, 06-Jan-80 09:49:37 GMT ASCTIME. Sun Jan 6 08:49:37 1980
HTTP.RES.DATE	Returns the contents of the HTTP Date header as text or as a date object. The date formats recognized are: RFC822. Sun, 06 Jan 1980 8:49:37 GMT RFC850. Sunday, 06-Jan-80 9:49:37 GMT ASCTIME. Sun Jan 6 08:49:37 1980

Generating the Day of the Week, as a String, in Short and Long Formats

Mar 20, 2012

The functions, WEEKDAY_STRING_SHORT and WEEKDAY_STRING, generate the day of the week, as a string, in short and long formats, respectively. The strings that are returned are always in English. The prefix used with these functions must return the day of the week in integer format and the acceptable range for the value returned by the prefix is 0-6. Therefore, you can use any prefix that returns an integer in the acceptable range. An UNDEF condition is raised if the returned value is not in this range or if memory allocation fails.

Following are the descriptions of the functions:

Table 1. Functions That Generate the Day of the Week, as a String, in Short and Long Formats

Function	Description
<prefix>.WEEKDAY_STRING_SHORT	Returns the day of the week in short format. The short form is always 3 characters long with an initial capital and the remaining characters in lower case. For example, SYS.TIME.WEEKDAY.WEEKDAY_STRING_SHORT returns Sun if the value returned by the WEEKDAY function is 0 and Sat if the value returned by the prefix is 6.
<prefix>.WEEKDAY_STRING	Returns the day of the week in long format. The long form always has an initial capital, with the remaining characters in lower case. For example, SYS.TIME.WEEKDAY.WEEKDAY_STRING returns Sunday if the value returned by the WEEKDAY function is 0 and Saturday if the value returned by the prefix is 6.

Expression Prefixes for Numeric Data Other Than Date and Time

Sep 02, 2013

In addition to configuring expressions that operate on time, you can configure expressions for the following types of numeric data:

- The length of HTTP requests, the number of HTTP headers in a request, and so on.
  For more information, see "Expressions for Numeric HTTP Payload Data Other Than Dates."
- IP and MAC addresses.
  For more information, see "Expressions for IP Addresses and IP Subnets."
- Client and server data in regard to interface IDs and transaction throughput rate.
  For more information, see "Expressions for Numeric Client and Server Data."
- Numeric data in client certificates other than dates.
  For information on these prefixes, including the number of days until certificate expiration and the encryption key size, see "Prefixes for Numeric Data in SSL Certificates."

Converting Numbers to Text

Sep 02, 2013

The following functions produce binary strings from a number returned by an expression prefix. These functions are particularly useful in the TCP rewrite feature as replacement strings for binary data. For more information about the TCP rewrite feature, see "Rewrite."

All the functions return a value of type **text**. The **endianness** that some of the functions accept as a parameter is either LITTLE_ENDIAN or BIG_ENDIAN.

Table 1. Functions That Produce a Binary String From a Number

Function	Description
<number>.SIGNED8_STRING	Produces an 8-bit signed binary string representing the number. If the value is out of range, an **undef** condition is raised **Example** HTTP.REQ.BODY(100).GET_SIGNED8(16).SUB(3).SIGNED8_STRING
<number>.UNSIGNED8_STRING	Produces an 8-bit unsigned binary string representing the number. If the value is out of range, an **undef** condition is rais **Example** HTTP.REQ.BODY(100).GET_UNSIGNED8(31).ADD(3).UNSIGNED8_STRING
<number>.SIGNED16_STRING(<endianness>)	Produces a 16-bit signed binary string representing the number. If the value is out of range, an **undef** condition is raised. **Example** HTTP.REQ.BODY(100).SKIP(12).GET_SIGNED16(0, BIG_ENDIAN).SUB(4).SIGNED16_STRING(BIG_ENDIAN
<number>.UNSIGNED16_STRING(<endianness>)	Produces a 16-bit unsigned binary string representing the number. If the value is out of range, an **undef** condition is rais **Example** HTTP.REQ.BODY(100).GET_UNSIGNED16(47, LITTLE_ENDIAN).ADD(7).UNSIGNED16_STRING(LITTLE_ENDIAN)
<number>.SIGNED32_STRING(<endianness>)	Produces a 32-bit signed binary string representing the number. **Example** HTTP.REQ.BODY(100).AFTER_STR("delim").GET_SIGNED32(0, BIG_ENDIAN).SUB(1).SIGNED32_STRING(BIG_ENDIAN)
<unsigned_long_number>.UNSIGNED8_STRING	Produces an 8-bit unsigned binary string representing the number. If the value is out of range, an **undef** condition is rais **Example** HTTP.REQ.BODY(100).GET_UNSIGNED8(24).TYPECAST_UNSIGNED_LONG_AT.ADD(12).UNSIGNED8_STRI
<unsigned_long_number>.UNSIGNED16_STRING(<endianness>)	Produces a 16-bit unsigned binary string representing the number. If the value is out of range, an **undef** condition is rais **Example** HTTP.REQ.BODY(100).GET_UNSIGNED16(23, LITTLE_ENDIAN).TYPECAST_UNSIGNED_LONG_AT.ADD(10).UNSIGNED16_STRING(LITTLE_ENDIAN)
<unsigned_long_number>.UNSIGNED32_STRING(<endianness>)	Produces a 32-bit unsigned binary string representing the number. If the value is out of range, an **undef** condition is rais **Example** HTTP.REQ.BODY(100).AFTER_STR("delim2").GET_UNSIGNED32(0, BIG_ENDIAN).ADD(2).UNSIGNED32_STRING(BIG_ENDIAN)

Virtual Server Based Expressions

Apr 17, 2012

The SYS.VSERVER("<vserver-name>") expression prefix enables you to identify a virtual server. You can use the following functions with this prefix to retrieve information related to the specified virtual server:

- **THROUGHPUT**. Returns the throughput of the virtual server in Mbps (Megabits per second). The value returned is an unsigned long number.
  Usage: SYS.VSERVER("vserver").THROUGHPUT
- **CONNECTIONS**. Returns the number of connections being managed by the virtual server. The value returned is an unsigned long number.
  Usage: SYS.VSERVER("vserver").CONNECTIONS
- **STATE**. Returns the state of the virtual server. The value returned is UP, DOWN, or OUT_OF_SERVICE. One of these values can therefore be passed as an argument to the EQ() operator to perform a comparison that results in a Boolean TRUE or FALSE.
  Usage: SYS.VSERVER("vserver").STATE
- **HEALTH**. Returns the percentage of services in an UP state for the specified virtual server. The value returned is an integer.
  Usage: SYS.VSERVER("vserver").HEALTH
- **RESPTIME**. Returns the response time as an integer representing the number of microseconds. Response time is the average TTFB (Time To First Byte) from all the services bound to the virtual server.
  Usage: SYS.VSERVER("vserver").RESPTIME
- **SURGECOUNT**. Returns the number of requests in the surge queue of the virtual server. The value returned is an integer.
  Usage: SYS.VSERVER("vserver").SURGECOUNT

Example 1

The following rewrite policy aborts rewrite processing if the number of connections at the load balancing virtual server LBvserver exceeds 10000:

```
add rewrite policy norewrite_pol sys.vserver("LBvserver").connections.gt(10000) norewrite
```

Example 2

The following rewrite action inserts a custom header, TP, whose value is the throughout at the virtual server LBvserver:

```
add rewrite action tp_header insert_http_header TP SYS.VSERVER("LBvserver").THROUGHPUT
```

Example 3

The following audit log message action writes the average TTFB of the services bound to a virtual server, to the newnslog log file:

```
add audit messageaction log_vserver_resptime_act INFORMATIONAL "\"NS Response Time to Servers:\" +
sys.vserver(\"ssllb\").resptime + \" millisec\"" -logtoNewnslog YES -bypassSafetyCheck YES
```

Default Syntax Expressions: Parsing HTTP, TCP, and UDP Data

Sep 02, 2013

You can configure default syntax expressions to evaluate and process the payload in HTTP requests and responses. The payload associated with an HTTP connection includes the various HTTP headers (both standard and custom headers), the body, and other connection information such as the URL. Additionally, you can evaluate and process the payload in a TCP or UDP packet. For HTTP connections, for example, you can check whether a particular HTTP header is present or if the URL includes a particular query parameter.

You can configure expressions to transform the URL encoding and apply HTML or XML “safe” coding for subsequent evaluation. You can also use XPATH and JSON prefixes to evaluate date in XML and JSON files, respectively.

You can also use text-based and numeric default syntax expressions to evaluate HTTP request and response data. For more information, see "Default Syntax Expressions: Evaluating Text" and "Default Syntax Expressions: Working with Dates, Times, and Numbers."

About Evaluating HTTP and TCP Payload

Sep 02, 2013

The payload of an HTTP request or response consists of HTTP protocol information such as headers, a URL, body content, and version and status information. When you configure a default syntax expression to evaluate HTTP payload, you use a default syntax expression prefix and, if necessary, an operator.

For example, you use the following expression, which includes the http.req.header("<header_name>") prefix and the exists operator, if you want to determine whether an HTTP connection includes a custom header named "myHeader":

```
http.req.header("myHeader").exists
```

You can also combine multiple default syntax expressions with Boolean and arithmetic operators. For example, the following compound expression could be useful with various NetScaler features, such as Integrated Caching, Rewrite, and Responder. This expression first uses the && Boolean operator to determine whether an HTTP connection includes the Content-Type header with a value of "text/html." If that operation returns a value of FALSE, the expression determines whether the HTTP connection includes a "Transfer-Encoding" or "Content-Length" header.

```
(http.req.header("Content-Type").exists && http.req.header("Content-Type").eq("text/html")) ||
(http.req.header("Transfer-Encoding").exists) || (http.req.header("Content-Length").exists)
```

The payload of a TCP or UDP packet is the data portion of the packet. You can configure default syntax expressions to examine features of a TCP or UDP packet, including the following:

- Source and destination domains
- Source and destination ports
- The text in the payload
- Record types

The following expression prefixes extract text from the body of the payload:

- HTTP.REQ.BODY(integer). Returns the body of an HTTP request as a multiline text object, up to the character position designated in the integer argument. If there are fewer characters in the body than is specified in the argument, the entire body is returned.
- HTTP.RES.BODY(integer). Returns a portion of the HTTP response body. The length of the returned text is equal to the number in the integer argument. If there are fewer characters in the body than is specified in integer, the entire body is returned.
- CLIENT.TCP.PAYLOAD(integer). Returns TCP payload data as a string, starting with the first character in the payload and continuing for the number of characters in the integer argument.

Following is an example that evaluates to TRUE if a response body of 1024 bytes contains the string "https", and this string occurs after the string "start string" and before the string "end string":

```
http.res.body(1024).after_str("start_string").before_str("end_string").contains("https")
```

Note: You can apply any text operation to the payload body. For information on operations that you can apply to text, see "Default Syntax Expressions: Evaluating Text."

Expressions for Identifying the Protocol in an Incoming IP Packet

May 21, 2015

The following table lists the expressions that you can use to identify the protocol in an incoming packet.

Expression	Description
CLIENT.IP.PROTOCOL	Identifies the protocol in IPv4 packets sent by clients.
CLIENT.IPV6.PROTOCOL	Identifies the protocol in IPv6 packets sent by clients.
SERVER.IP.PROTOCOL	Identifies the protocol in IPv4 packets sent by servers.
SERVER.IPV6.PROTOCOL	Identifies the protocol in IPv6 packets sent by servers.

You can pass the Internet Assigned Numbers Authority (IANA) protocol number to the PROTOCOL function. For example, if you want to determine whether the protocol in an incoming packet is TCP, you can use CLIENT.IP.PROTOCOL.EQ(6), where 6 is the IANA-assigned protocol number for TCP. For some protocols, you can pass an enumeration value instead of the protocol number. For example, instead of CLIENT.IP.PROTOCOL.EQ(6), you can use CLIENT.IP.PROTOCOL.EQ(TCP). The following table lists the protocols for which you can use enumeration values, and the corresponding enumeration values for use with the PROTOCOL function.

Protocol	Enumeration value
Transmission Control Protocol (TCP)	TCP
User Datagram Protocol (UDP)	UDP
Internet Control Message Protocol (ICMP)	ICMP
IP Authentication Header (AH), for providing authentication services in IPv4 and IPv6	AH
Encapsulating Security Payload (ESP) protocol	ESP
General Routing Encapsulation (GRE)	GRE
IP-within-IP Encapsulation Protocol	IPIP

Protocol	Expression value
Internet Control Message Protocol for IPv6 (ICMPv6)	ICMPV6
Fragment Header for IPv6	FRAGMENT

The protocol expressions can be used in both request-based and response-based policies. You can use the expressions in various NetScaler features, such as load balancing, WAN optimization, content switching, rewrite, and listen policies. You can use the expressions with functions such as EQ() and NE(), to identify the protocol in a policy and perform an action.

Following are some use cases for the expressions:

- In Branch Repeater load balancing configurations, you can use the expressions in a listen policy for the wildcard virtual server. For example, you can configure the wildcard virtual server with the listen policy CLIENT.IP.PROTOCOL.EQ(TCP) so that the virtual server processes only TCP traffic and simply bridges all non-TCP traffic. Even though you can use an Access Control List instead of the listen policy, the listen policy provides better control over what traffic is processed.
- For content switching virtual servers of type ANY, you can configure content switching policies that switch requests on the basis of the protocol in incoming packets. For example, you can configure content switching policies to direct all TCP traffic to one load balancing virtual server and all non-TCP traffic to another load balancing virtual server.
- You can use the client-based expressions to configure persistence based on the protocol. For example, you can use CLIENT.IP.PROTOCOL to configure persistence on the basis of the protocols in incoming IPv4 packets.

Expressions for HTTP and Cache-Control Headers

Sep 02, 2013

One common method of evaluating HTTP traffic is to examine the headers in a request or a response. A header can perform a number of functions, including the following:

- Provide cookies that contain data about the sender.
- Identify the type of data that is being transmitted.
- Identify the route that the data has traveled (the Via header).

Note: Note that if an operation is used to evaluate both header and text data, the header-based operation always overrides the text-based operation. For example, the AFTER_STR operation, when applied to a header, overrides text-based AFTER_STR operations for all instances of the current header type.

The following table describes expression prefixes that extract HTTP headers.

Table 1. Prefixes That Extract HTTP Headers

HTTP Header Prefix	Description
HTTP.REQ.HEADER("<header_name>")	Returns the contents of the HTTP header specified by the <header_name> argument. The header name cannot exceed 32 characters. Note that this prefix returns the value from the Host header by default. To use this value as a host name you need to typecast it as follows: http.req.header("host").typecast_http_hostname_t For more information on typecasting, see "Typecasting Data."
HTTP.REQ.FULL_HEADER	Returns the contents of the complete set of HTTP header fields including the request line (for example, "GET /brochures/index.html HTTP/1.1") and the terminating \r\n\r\n sequence.
HTTP.REQ.DATE	Returns the contents of the HTTP Date header. The following date formats are recognized: RFC822. Sun, 06 Jan 1980 8:49:37 GMT RFC850. Sunday, 06-Jan-80 9:49:37 GMT ASCII TIME. Sun Jan 6 08:49:37 1980 To evaluate a Date header as a date object, see "Default Syntax Expressions: Working with Dates, Times, and Numbers."
HTTP.REQ.COOKIE	(Name/Value List) Returns the contents of the HTTP Cookie header.
HTTP.REQ.TXID	Returns the HTTP transaction ID. The value is a function of an internal transaction number, system boot time and system MAC address.
HTTP.RES.HEADER("<header_name>")	Returns the contents of the HTTP header specified by the <header_name> argument. The header name cannot exceed 32 characters.
HTTP.RES.FULL_HEADER	Returns the contents of the complete set of HTTP header fields including the status line (for example, "HTTP/1.1 200 OK") and the terminating \r\n\r\n sequence.
HTTP.RES.SET_COOKIE	Returns the HTTP Set-Cookie header object in a response.

HTTP Header Prefix	Description
or HTTP.RES.SET_COOKIE2	
HTTP.RES.SET_COOKIE("<name>") or HTTP.RES.SET_COOKIE2("<name>")	Returns the cookie of the specified name if it is present. If it is not present, returns a text object of length 0. Returns UNDEF if more than 15 Set-Cookie headers are present and the specified cookie was not found in these headers.
HTTP.RES.SET_COOKIE("<name>").DOMAIN or HTTP.RES.SET_COOKIE2("<name>").DOMAIN	Returns the value of the first Domain field in the cookie. For example, if the cookie is Set-Cookie : Customer = "ABC"; DOMAIN=".abc.com"; DOMAIN=.xyz.com, the following expression returns .abc.com: http.res.set_cookie.cookie("customer").domain A string of zero length is returned if the Domain field or its value is absent.
HTTP.RES.SET_COOKIE.EXISTS("<name>") or HTTP.RES.SET_COOKIE2.EXISTS("<name>")	Returns a Boolean TRUE if a Cookie with the name specified in the <name> argument exists in the Set-Cookie header. This prefix returns UNDEF if more than 15 Set-Cookie headers are present and the named cookie is not in the first 15 headers.
HTTP.RES.SET_COOKIE.COOKIE("<name>").EXPIRES or HTTP.RES.SET_COOKIE2.COOKIE("<name>").EXPIRES	Returns the Expires field of the cookie. This is a date string that can be evaluated as a number, as a time object, or as text. If multiple Expires fields are present, the first one is returned. If the Expires field is absent, a text object of length zero is returned. To evaluate the returned value as a time object, see "Default Syntax Expressions: Working with Dates, Times, and Numbers."
HTTP.RES.SET_COOKIE.COOKIE("<name>").PATH|PATH.GET(n) or HTTP.RES.SET_COOKIE2.COOKIE("<name>").PATH|PATH.GET(n)	Returns the value of Path field of the cookie as a slash- (“/”) separated list. Multiple instances of a slash are treated as single slash. If multiple Path fields are present, the value of the first instance is returned. For example, the following is a cookie with two path fields: Set-Cookie : Customer = "ABC"; PATH="/a//b/c"; PATH= "/x/y/z" The following expression returns /a//b/c from this cookie: http.res.set_cookie.cookie("Customer").path The following expression returns b: http.res.set_cookie.cookie("Customer").path.get(2) Quotes are stripped from the returned value. A string of zero length is returned if the Path field or its value is absent.
HTTP.RES.SET_COOKIE.COOKIE("<name>").PATH.IGNORE_EMPTY_ELEMENTS or HTTP.RES.SET_COOKIE2.COOKIE("<name>").PATH.IGNORE_EMPTY_ELEMENTS	Ignores the empty elements in the list. For example, in the list a=10,b=11, ,c=89, the element delimiter in the list is , and the list has an empty element following a=10. The element following b=11 is not considered an empty element. As another example, in the following expression, if a request contains Cust_Header : 123,,24, ,15 the following expression returns a value of 4: http.req.header("Cust_Header").typecast_list_t(',').ignore_empty_elements.count The following expression returns a value of 5:

HTTP Header Prefix	Description
	http.req.header("Cust_Header").typecast_list_t(',').count
HTTP.RES.SET_COOKIE.COOKIE("<name>").PORT or HTTP.RES.SET_COOKIE2.COOKIE("<name>").PORT	Returns the value of Port field of the cookie. Operate as a comma-separated list. For example, the following expression returns 80. 2580 from Set-Cookie : Customer = "ABC"; PATH="/a/b/c"; PORT= "80, 2580": http.res.set_cookie.cookie("ABC").port A string of zero length is returned if the Port field or value is absent.
HTTP.RES.SET_COOKIE.COOKIE("<name>").PORT.IGNORE_EMPTY_ELEMENTS or HTTP.RES.SET_COOKIE2.COOKIE("<name>").PORT.IGNORE_EMPTY_ELEMENTS	Ignores the empty elements in the list. For example, in the list a=10,b=11, ,c=89, the element delimiter in the list is , and the list has an empty element following a=10. The element following b=11 is not considered an empty element. As another example, in the following expression, if a request contains Cust_Header : 123,,24, ,15 the following expression returns a value of 4: http.req.header("Cust_Header").typecast_list_t(',').ignore_empty_elements.count The following expression returns a value of 5: http.req.header("Cust_Header").typecast_list_t(',').count
HTTP.RES.SET_COOKIE.COOKIE("<name>").VERSION or HTTP.RES.SET_COOKIE2.COOKIE("<name>").VERSION	Returns the value of the first Version field in the cookie as a decimal integer. For example, the following expression returns 1 from the cookie Set-Cookie : Customer = "ABC"; VERSION = "1"; VERSION = "0" http.res.set_cookie.cookie("CUSTOMER").version A zero is returned if the Version field or its value is absent or if the value is not a decimal number.
HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>) or HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>)	Returns the nth instance (0-based) of the cookie with the specified name. If the cookie is absent, returns a text object of length 0. Returns UNDEF if more than 15 Set-Cookie headers are present and the cookie is not found.
HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).DOMAIN or HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).DOMAIN	Returns the value of the Domain field of the first cookie with the specified name. For example, the following expression returns a value of abc.com from the cookie Set-Cookie : Customer = "ABC"; DOMAIN=".abc.com"; DOMAIN=.xyz.com http.res.set_cookie.cookie("CUSTOMER").domain A string of zero length is returned if the Domain field or its value is absent.
HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).EXPIRES or HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).EXPIRES	Returns the *n*th instance (0-based) of the Expires field of the cookie with the specified name as a date string. The value can be operated upon as a time object that supports a number of date formats. If the Expires attribute is absent a string of length zero is returned.
HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).PATH | PATH.GET(i)	Returns the value of the Path field of the nth cookie, as a '/' separated list. Multiple /s are treated as a single /.

HTTP Header Prefix	Description
or HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).PATH | PATH.GET(i)	For example, the following expression returns /a//b/c from the cookie Set-Cookie : Customer = "ABC"; PATH="/a//b/c"; PATH= "/x/y/z" http.res.set_cookie.cookie("CUSTOMER").path The following returns b: http.res.set_cookie.cookie("CUSTOMER").path.get(2) A string of zero length is returned if the Path field or its value is absent.
HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).PATH.IGNORE_EMPTY_ELEMENTS or HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).PATH.IGNORE_EMPTY_ELEMENTS	Ignores the empty elements in the list. For example, in the list a=10,b=11, ,c=89, the element delimiter in the list is , and the list has an empty element following a=10. The element following b=11 is not considered an empty element. As another example, in the following expression, if a request contains Cust_Header : 123,,24, ,15 the following expression returns a value of 4: http.req.header("Cust_Header").typecast_list_t(',').ignore_empty_elements.count The following expression returns a value of 5: http.req.header("Cust_Header").typecast_list_t(',').count
HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).PORT or HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).PORT	Returns the value or values of the Port field of the named cookie as a ',' separated list. For example, the following expression returns 80, 2580 from the cookie Set-Cookie : Customer = "ABC"; PATH="/a/b/c"; PORT= "80, 2580" http.res.set_cookie.cookie("ABC").port A string of zero length is returned if the Port field or its value is absent.
HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).PORT.IGNORE_EMPTY_ELEMENTS or HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).PORT.IGNORE_EMPTY_ELEMENTS	Ignores the empty elements in the list. For example, in the list a=10,b=11, ,c=89, the element delimiter in the list is , and the list has an empty element following a=10. The element following b=11 is not considered an empty element. As another example, in the following expression, if a request contains Cust_Header : 123,,24, ,15 the following expression returns a value of 4: http.req.header("Cust_Header").typecast_list_t(',').ignore_empty_elements.count The following expression returns a value of 5: http.req.header("Cust_Header").typecast_list_t(',').count
HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).VERSION or HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).VERSION	Returns the value of Version field of the *n*th cookie as a decimal integer. A string of zero length is returned if the Port field or its value is absent.
HTTP.RES.TXID	Returns the HTTP transaction ID. The value is a function of an internal transaction number, system boot time and system MAC address.

The following table describes operations that you can specify with the prefixes for HTTP headers.

Table 2. Operations That Evaluate HTTP Headers

HTTP Header Operation	Description
http header .EXISTS	Returns a Boolean TRUE if an instance of the specified header type exists. Following is an example: http.req.header("Cache-Control").exists
http header.CONTAINS" http header . CONTAINS(" <string>")	Returns a Boolean TRUE if the <string> argument appears in any instance of the header value. Note: This operation overrides any text-based Contains operations on all instances of the current header type. Following is an example of request with two headers: HTTP/1.1 200 OK\r\n MyHeader: abc\r\n Content-Length: 200\r\n MyHeader: def\r\n \r\n The following returns a Boolean TRUE: http.res.header("MyHeader"). contains("de") The following returns FALSE. Note that the NetScaler does not concatenate the different values. http.res.header("MyHeader"). contains("bcd")
http header .COUNT	Returns the number of headers in a request or response, to a maximum of 15 headers of the same type. The result is undefined if there are more than 15 instances of the header. Following is sample data in a request: HTTP/1.1 200 OK\r\n MyHeader: abc\r\n Content-Length: 200\r\n MyHeader: def\r\n \r\n When evaluating the preceding request, the following returns a count of 2: http.res.header("MyHeader").count
http header.AFTER_STR(" <string>")	Extracts the text that follows the first occurrence of the <string> argument. The headers are evaluated from the last instance to the first. Following is an example of a request: HTTP/1.1 200 OK\r\n MyHeader: 111abc\r\n Content-Length: 200\r\n MyHeader: 111def\r\n

	\r\n The following extracts the string "def" from the last instance of MyHeader. This is value "111def." http.res.header("MyHeader").after_str("111") The following extracts the string "c" from the first instance of MyHeader. This is the value "abc111." http.res.header("MyHeader").after_str("1ab")
http header.BEFORE_STR("<string>")	Extracts the text that appears prior to the first occurrence of the input <string> argument. The headers are evaluated from the last instance to the first. Following is an example of a request that contains headers: HTTP/1.1 200 OK\r\n MyHeader: abc111\r\n Content-Length: 200\r\n MyHeader: def111\r\n \r\n The following extracts the string "def" from the last instance of MyHeader. This is the value "def111." http.res.header("MyHeader").before_str("111") The following extracts the string "a" from the first instance of MyHeader. This is the value "abc111." http.res.header("MyHeader").before_str("bc1")
http header.INSTANCE(<instance number>)	An HTTP header can occur multiple times in a request or a response. This operation returns the header that occurs <instance number> of places before the final instance. For example, instance(0) selects the last instance of the current type, instance(1) selects the next-to-last instance, and so on. This prefix cannot be used in bidirectional policies. The <instance number> argument cannot exceed 14. Following is an example of a request with two headers: HTTP/1.1 200 OK\r\n MyHeader: abc\r\n Content-Length: 200\r\n MyHeader: def\r\n \r\n The following returns a text object that refers to "MyHeader: abc\r\n": http.res.header("MyHeader").instance(1)
http header.SUBSTR("<string>")	Extracts the text that matches the <string> argument. The headers are evaluated from the last instance to the first. Following is an example of a request with two headers that contain the string “111”: HTTP/1.1 200 OK\r\n MyHeader: abc111\r\n Content-Length: 200\r\n MyHeader: 111def\r\n \r\n

	The following returns "111" from the last instance of MyHeader. This is the header with the value "111def." http.res.header("MyHeader").substr("111")
http header.VALUE(<instance number>)	An HTTP header can occur multiple times in a request or a response. VALUE(0) selects the value in the last instance, VALUE(1) selects the value in the next-to-last instance, and so on. The <instance number> argument cannot exceed 14. Following is an example of a request with two headers: HTTP/1.1 200 OK\r\n MyHeader: abc\r\n Content-Length: 200\r\n MyHeader: def\r\n \r\n The following returns "abc\r\n": http.res.header("MyHeader").value(1)

The following prefixes apply specifically to Cache-Control headers.

Table 3. Prefixes That Extract Cache-Control Headers

HTTP Header Prefix	Description
HTTP.REQ.CACHE_CONTROL	Returns a Cache-Control header in an HTTP request.
HTTP.RES.CACHE_CONTROL	Returns a Cache-Control header in an HTTP response.

You can apply any of the operations for HTTP headers to Cache-Control headers. For more information, see "Operations for HTTP Headers."

In addition, the following operations identify specific types of Cache-Control headers. See RFC 2616 for information about these header types.

Table 4. Operations That Evaluate Cache-Control Headers

HTTP Header Operation	Description
Cache-Control header.NAME(<integer>)	Returns as a text value the name of the Cache-Control header that corresponds to the nth component in a name-value list, as specified by <integer>. The index of the name-value component is 0-based. If the <integer> that is specified by the integer argument is greater than the number of components in the list, a zero-length text object is returned. Following is an example: http.req.cache_control.name(3).contains("some_text")
Cache-Control header.IS_INVALID	Returns a Boolean TRUE if the Cache-Control header is not present in the request or response. Following is an example: http.req.cache_control.is_invalid

HTTP Header Operation	Description
Cache-Control header.IS_PRIVATE	Returns a Boolean TRUE if the Cache-Control header has the value Private. Following is an example: http.req.cache_control.is_private
Cache-Control header.IS_PUBLIC	Returns a Boolean TRUE if the Cache-Control header has the value Private. Following is an example: http.req.cache_control.is_public
Cache-Control header.IS_NO_STORE	Returns a Boolean TRUE if the Cache-Control header has the value No-Store. Following is an example: http.req.cache_control.is_no_store
Cache-Control header.IS_NO_CACHE	Returns a Boolean TRUE if the Cache-Control header has the value No-Cache. Following is an example: http.req.cache_control.is_no_cache
Cache-Control header.IS_MAX_AGE	Returns a Boolean TRUE if the Cache-Control header has the value Max-Age. Following is an example: http.req.cache_control.is_max_age
Cache-Control header.IS_MIN_FRESH	Returns a Boolean TRUE if the Cache-Control header has the value Min-Fresh. Following is an example: http.req.cache_control.is_min_fresh
Cache-Control header.IS_MAX_STALE	Returns a Boolean TRUE if the Cache-Control header has the value Max-Stale. Following is an example: http.req.cache_control.is_max_stale
Cache-Control header.IS_MUST_REVALIDATE	Returns a Boolean TRUE if the Cache-Control header has the value Must-Revalidate. Following is an example: http.req.cache_control.is_must_revalidate
Cache-Control header.IS_NO_TRANSFORM	Returns a Boolean TRUE if the Cache-Control header has the value No-Transform. Following is an example: http.req.cache_control.is_no_transform
Cache-Control header.IS_ONLY_IF_CACHED	Returns a Boolean TRUE if the Cache-Control header has the value Only-If-Cached. Following is an example: http.req.cache_control.is_only_if_cached

HTTP Header Operation	Description
Cache-Control header.IS_PROXY_REVALIDATE	Returns a Boolean TRUE if the Cache-Control header has the value Proxy-Revalidate. Following is an example: http.req.cache_control.is_proxy_revalidate
Cache-Control header.IS_S_MAXAGE	Returns a Boolean TRUE if the Cache-Control header has the value S-Maxage. Following is an example: http.req.cache_control.is_s_maxage
Cache-Control header.IS_UNKNOWN	Returns a Boolean TRUE if the Cache-Control header is of an unknown type. Following is an example: http.req.cache_control.is_unknown
Cache-Control header.MAX_AGE	Returns the value of the Cache-Control header Max-Age. If this header is absent or invalid, 0 is returned. Following is an example: http.req.cache_control.max_age.le(3)
Cache-Control header.MAX_STALE	Returns the value of the Cache-Control header Max-Stale. If this header is absent or invalid, 0 is returned. Following is an example: http.req.cache_control.max_stale.le(3)
Cache-Control header.MIN_FRESH	Returns the value of the Cache-Control header Min-Fresh. If this header is absent or invalid, 0 is returned. Following is an example: http.req.cache_control.min_fresh.le(3)
Cache-Control header.S_MAXAGE	Returns the value of the Cache-Control header S-Maxage. If this header is absent or invalid, 0 is returned. Following is an example: http.req.cache_control.s_maxage.eq(2)

Expressions for Extracting Segments of URLs

Sep 02, 2013

You can extract URLs and portions of URLs, such as the host name, or a segment of the URL path. For example, the following expression identifies HTTP requests for image files by extracting image file suffixes from the URL:

```
http.req.url.suffix.eq("jpeg") || http.req.url.suffix.eq("gif")
```

Most expressions for URLs operate on text and are described in "Expression Prefixes for Text in HTTP Requests and Responses." This section discusses the GET operation. The GET operation extracts text when used with the following prefixes:

- HTTP.REQ.URL.PATH
- VPN.BASEURL.PATH
- VPN.CLIENTLESS_BASEURL.PATH

The following table describes prefixes for HTTP URLs.

Table 1. Prefixes That Extract URLs

URL Prefix	Description
HTTP.REQ.URL.PATH.GET(<n>)	Returns a slash- (“/”) separated list from the URL path. For example, consider the following URL: http://www.mycompany.com/dir1/dir2/dir3/index.html?a=1 The following expression returns dir1 from this URL: http.req.url.path.get(1) The following expression returns dir2: http.req.url.path.get(2)
HTTP.REQ.URL.PATH.GET_REVERSE(<n>)	Returns a slash- (“/”) separated list from the URL path, starting from the end of the path. For example, consider the following URL: http://www.mycompany.com/dir1/dir2/dir3/index.html?a=1 The following expression returns index.html from this URL: http.req.url.path.get_reverse(0) The following expression returns dir3: http.req.url.path.get_reverse(1)

Expressions for HTTP Status Codes and Numeric HTTP Payload Data Other Than Dates

Mar 20, 2012

The following table describes prefixes for numeric values in HTTP data other than dates.

Table 1. Prefixes That Evaluate HTTP Request or Response Length

Prefix	Description
HTTP.REQ.CONTENT_LENGTH	Returns the length of an HTTP request as a number. Following is an example: `http.req.content_length < 500`
HTTP.RES.CONTENT_LENGTH	Returns the length of the HTTP response as a number. Following is an example: `http.res.content_length <= 1000`
HTTP.RES.STATUS	Returns the response status code

HTTP.RES.IS_REDIRECT	Returns a Boolean TRUE if the response code is associated with a redirect. Following are the redirect response codes:
	• 300 (Multiple Choices)
	• 301 (Moved Permanently)
	• 302 (Found)
	• 303 (See Other)
	• 305 (Use Proxy)
	• 307 (Temporary Redirect)
	Note: Status code 304 is not considered a redirect HTTP response status code. Status code 306 is unused.
	In the following example, the rewrite action replaces http in the Location header of an HTTP response with https if the response is associated with an HTTP redirect.
	`add rewrite action redloc replace 'http.res.header("Location").before_regex(re#://#)' '"https"'`
	`add rewrite policy pol1 HTTP.RES.IS_REDIRECT red_location`
	`bind rewrite global pol1 100`

Prefix	Description

SIP Expressions

Sep 23, 2014

The NetScaler default expressions language contains a number of expressions that operate on Session Initiation Protocol (SIP) connections. These expressions are intended to be used in policies for any supported protocol that operates on a request/response basis. (These expressions can be bound only to sip_udp virtual servers and global bind points.) These expressions can be used in content switching, rate limiting, responder, and rewrite policies.

Certain limitations apply to SIP expressions used with responder policies. The NetScaler operating system currently supports only SIP over UDP. Only the DROP, NOOP or RESPONDWITH actions are allowed on a SIP load balancing virtual server. Responder policies can be bound to a load balancing virtual server, an override global bind point, a default global bind point, or a sip_udp policy label.

The header format used by the SIP protocol is similar to that used by the HTTP protocol, so many of the new expressions look and function much like their HTTP analogs. Each SIP header consists of a line that includes the SIP method, the URL, and the version, followed by a series of name-value pairs that look like HTTP headers.

Following is a sample SIP header that is referred to in the expressions tables beneath it:

```
INVITE sip:16@www.sip.com:5060;transport=udp SIP/2.0
Record-Route: <sip:200.200.100.22;lr=on>
Via: SIP/2.0/UDP 200.200.100.22;branch=z9hG4bK444b.c8e103d1.0;rport=5060;
 received=10.102.84.18
Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;
 received=10.102.84.160
From: "12" <sip:12@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185
To: "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185
Call-ID: 00127f54-ec850017-0e46f5b9-5ec149c2@10.102.84.180
Max-Forwards: 69CSeq: 101 INVITE
User-Agent: Cisco-CP7940G/8.0
Contact: <sip:12@10.102.84.180:5060;transport=udp>
Expires: 180
Accept: application/sdp
Allow: ACK,BYE,CANCEL,INVITE,NOTIFY,OPTIONS,REFER,REGISTER,UPDATE
Supported: replaces,join,norefersub
Content-Length: 277
Content-Type: application/sdp
Content-Disposition: session;handling=optiona
```

The following tables contain lists of expressions that operate on SIP headers. The first table contains expressions that apply to request headers. Most response-based expressions are nearly the same as the corresponding request-based expressions. To create a response expression from the corresponding request expression, you change the first two sections of the expression from SIP.REQ to SIP.RES, and make other obvious adjustments. The second table contains those response expressions that are unique to responses and have no request equivalents. You can use any element in the following tables as a complete expression on its own, or you can use various operators to combine these expression elements with others to form more complex expressions.

Table 1. SIP Request Expressions

Expression	Description
SIP.REQ.METHOD	Operates on the method of the SIP request. The supported SIP request methods are ACK, BYE, CANCEL, INFO, INVITE, MESSAGE, NOTIFY, OPTIONS, PRACK, PUBLISH, REFER, REGISTER, SUBSCRIBE, and UPDATE. This expression is a derivative of the text class, so all operations that are applicable to text are applicable to this method. For example, for a SIP request of INVITE sip:16@10.102.84.181:5060;transport=udp SIP/2.0, this expression returns INVITE.
SIP.REQ.URL	Operates on the SIP request URL. This expression is a derivative of the text class, so all operations that are applicable to text are applicable to this method. For example, for a SIP request of INVITE sip:16@10.102.84.181:5060;transport=udp SIP/2.0, this expression returns sip:16@10.102.84.181:5060;transport=udp.
SIP.REQ.URL.PROTOCOL	Returns the URL protocol. For example, for a SIP URL of

Expression	Description
	sip:16@www.sip.com:5060;transport=udp, this expression returns sip.
SIP.REQ.URL.HOSTNAME	Returns the hostname portion of the SIP URL. For example, for a SIP URL of sip:16@www.sip.com:5060;transport=udp, this expression returns www.sip.com:5060.
SIP.REQ.URL.HOSTNAME.PORT	Returns the port portion of the SIP URL hostname. If no port is specified, this expression returns the default SIP port, 5060. For example, for a SIP hostname of www.sip.com:5060, this expression returns 5060.
SIP.REQ.URL.HOSTNAME.DOMAIN	Returns the domain name portion of the SIP URL hostname. If the host is an IP address, then this expression returns an incorrect result. For example, for a SIP hostname of www.sip.com:5060, this expression returns sip.com. For a SIP hostname of 192.168.43.15:5060, this expression returns an error.
SIP.REQ.URL.HOSTNAME.SERVER	Returns the server portion of the host. For example, for a SIP hostname of www.sip.com:5060, this expression returns www.
SIP.REQ.URL.USERNAME	Returns the username that precedes the @ character. For example, for a SIP URL of sip:16@www.sip.com:5060;transport=udp, this expression returns 16.
SIP.REQ.VERSION	Returns the SIP version number in the request. For example, for a SIP request of INVITE sip:16@10.102.84.181:5060;transport=udp SIP/2.0, this expression returns SIP/2.0.
SIP.REQ.VERSION.MAJOR	Returns the major version number (the number to the left of the period). For example, for a SIP version number of SIP/2.0, this expression returns 2.
SIP.REQ.VERSION.MINOR	Returns the minor version number (the number to the right of the period). For example, for a SIP version number of SIP/2.0, this expression returns 0.
SIP.REQ.CONTENT_LENGTH	Returns the contents of the Content-Length header. This expression is a derivative of the sip_header_t class, so all operations that are available for SIP headers can be used. For example, for a SIP Content-Length header of Content-Length: 277, this expression returns 277.
SIP.REQ.TO	Returns the contents of the To header. For example, for a SIP To header of To: "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185.
SIP.REQ.TO.ADDRESS	Returns the SIP URI, which is found in the sip_url object. All operations that are available for SIP URIs can be used. For example, for a SIP To header of To: "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns sip:16@sip_example.com.
SIP.REQ.TO.DISPLAY_NAME	Returns the display name portion of the To header. For example, for a SIP To header of To: "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 16.
SIP.REQ.TO.TAG	Returns the “tag” vale from the “tag” name value pair in the TO header. For example, for a SIP To header of To: "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 00127f54ec85a6d90cc14f45-53cc0185.
SIP.REQ.FROM	Returns the contents of the From header. For example, for a SIP From header of From: "12" <sip:12@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns sip:12@sip_example.com.

Expression	Description
SIP.REQ.FROM.ADDRESS	Returns the SIP URI, which is found in the sip_url object. All operations that are available for SIP URIs can be used. For example, for a SIP From header of From: "12" <sip:12@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns sip:12@sip_example.com.
SIP.REQ.FROM.DISPLAY_NAME	Returns the display name portion of the To header. For example, for a SIP From header of From: "12" <sip:12@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 12.
SIP.REQ.FROM.TAG	Returns the "tag" value from the "tag" name/value pair in the TO header. For example, for a SIP From header of From: "12" <sip:12@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 00127f54ec85a6d90cc14f45-53cc0185.
SIP.REQ.VIA	Returns the complete Via header. If there are multiple Via headers in the request, returns the last Via header. For example, for the two Via headers in the sample SIP header, this expression returns Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160.
SIP.REQ.VIA.SENTBY_ADDRESS	Returns the address that sent the request. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 10.102.84.180.
SIP.REQ.VIA.SENTBY_PORT	Returns the port that sent the request. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 5060.
SIP.REQ.VIA.RPORT	Returns the value from the rport name/value pair. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 5060.
SIP.REQ.VIA.BRANCH	Returns the value from the branch name/value pair. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns z9hG4bK03e76d0b.
SIP.REQ.VIA.RECEIVED	Returns the value from the received name/value pair. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 10.102.84.160.
SIP.REQ.CALLID	Returns the contents of the Callid header. This expression is a derivative of the sip_header_t class, so all operations that are available for SIP headers can be used. For example, for a SIP Callid header of Call-ID: 00127f54-ec850017-0e46f5b9-5ec149c2@10.102.84.180, this expression returns 00127f54-ec850017-0e46f5b9-5ec149c2@10.102.84.180.
SIP.REQ.CSEQ	Returns the CSEQ number from the CSEQ, as an integer. For example, for a SIP CSEQ header of CSeq: 101 INVITE, this expression returns 101.
SIP.REQ.HEADER("<header_name>")	Returns the specified SIP header. For <header_name>, substitute the name of the header that you want. For example, to return the SIP From header, you would type SIP.REQ.HEADER("From").
SIP.REQ.HEADER("	Returns the specified instance of the specified SIP header. Multiple instances of the same SIP

Expression	Description
<header_name>").INSTANCE(<line_number>)	header can occur. Where you want a specific instance of such a SIP header (for example, a specific Via header), you can specify that header by typing a number as the <line_number>. Header instances are matched from last (0) to first. In other words, SIP.REQ.HEADER("Via").INSTANCE(0) returns the last instance of the Via header, while SIP.REQ.HEADER("Via").INSTANCE(1) returns the last instance but one of the Via header, and so on. For example, if used on the example SIP header, SIP.REQ.HEADER("Via").INSTANCE(1) returns Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060.
SIP.REQ.HEADER("<header_name>").VALUE(<line_number>)	Returns the contents of the specified instance of the specified SIP header. The usage is nearly the same as the previous expression. For example, if used on the SIP header example in the preceding table entry, SIP.REQ.HEADER("Via").VALUE(1) returns SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060.
SIP.REQ.HEADER("<header_name>").COUNT	Returns the number of instances of a particular header as an integer. For example, if used on the SIP header example above, SIP.REQ.HEADER("Via").COUNT returns 2.
SIP.REQ.HEADER("<header_name>").EXISTS	Returns a boolean value of true or false, depending upon whether the specified header exists or not. For example, if used on the SIP header example above, SIP.REQ.HEADER("Expires").EXISTS returns true, while SIP.REQ.HEADER("Caller-ID").EXISTS returns false.
SIP.REQ.HEADER("<header_name>").LIST	Returns the comma-separated parameter list in the specified header. For example, if used on the SIP header example above, SIP.REQ.HEADER("Allow").LIST returns ACK,BYE,CANCEL,INVITE,NOTIFY,OPTIONS,REFER,REGISTER,UPDATE. You can append the string .GET(<list_item_number>) to select a specific list item. For example, to get the first item (ACK) from the above list, you would type SIP.REQ.HEADER("Allow").LIST.GET(0). To extract the second item (BYE), you would type SIP.REQ.HEADER("Allow").LIST.GET(1). Note: If the specified header contains a list of name/value pairs, the entire name/value pair is returned.
SIP.REQ.HEADER("<header_name>").TYPECAST_SIP_HEADER_T("<in_header_name>")	Typecasts <header_name> to <in_header_name>. Any text can be typecasted to the sip_header_t class, after which all header-based operations can be used. After you perform this operation, you can apply all operations that can be used with <in_header_name>. For example, the expression SIP.REQ.CONTENT_LENGTH.TYPECAST_SIP_HEADER_T typecasts all instances of the Content-Length header. After you perform this operation, you can apply all header operations to all instances of the specified header.
SIP.REQ.HEADER("<header_name>").CONTAINS("<string>").	Returns boolean true if the specified text string is present in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.
SIP.REQ.HEADER("<header_name>").EQUALS_ANY(<patset>)	Returns boolean true if any pattern associated with <patset> matches any content in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.
SIP.REQ.HEADER("<header_name>").CONTAINS_ANY(<patset>)	Returns Boolean true if any pattern associated with <patset> matches any content in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.
SIP.REQ.HEADER("<header_name>").CONTAINS_INDEX(<patset>)	Returns the index of the matching pattern associated with <patset> if that pattern matches any content in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.

Expression	Description
SIP.REQ.HEADER("<header_name>").EQUALS_INDEX(<patset>)	Returns the index of the matching pattern associated with <patset> if that pattern matches any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.
SIP.REQ.HEADER("<header_name>").SUBSTR("<string>")	If the specified string is present in any instance of the specified header, this expression returns that string. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160", SIP.REQ.HEADER("Via").SUBSTR("rport=5060") returns "rport=5060". SIP.REQ.HEADER("Via").SUBSTR("rport=5061") returns an empty string.
SIP.REQ.HEADER("<header_name>").AFTER_STR("<string>")	If the specified string is present in any instance of the specified header, this expression returns the string immediately after that string. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER("Via").AFTER_STR("rport=") returns 5060.
SIP.REQ.HEADER("<header_name>").REGEX_MATCH(<regex>)	Returns boolean true if the specified regular expression (*regex*) matches any instance of the specified header. You must specify the regular expression in the following format: re<delimiter>regular expression<same delimiter> The regular expression cannot be larger than 1499 characters in length. It must conform to the PCRE regular expression library. See http://www.pcre.org/pcre.txt for documentation on PCRE regular expression syntax. The pcrepattern man page also has useful information on specifying patterns by using PCRE regular expressions. The regular expression syntax supported in this expression has some differences from PCRE. Back references are not allowed. You should avoid recursive regular expressions; although some work, many do not. The dot (.) metacharacter matches newlines. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.
SIP.REQ.HEADER("<header_name>").REGEX_SELECT(<regex>)	If the specified regex matches any text in any instance of the specified header, this expression returns the text. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER("Via").REGEX_SELECT("received=[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}") returns received=10.102.84.160.
SIP.REQ.HEADER("<header_name>").AFTER_REGEX(<regex>)	If the specified regex matches any text in any instance of the specified header, this expression returns the string immediately after that text. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER("Via").AFTER_REGEX("received=") returns 10.102.84.160.
SIP.REQ.HEADER("<header_name>").BEFORE_REGEX(<regex>)	If the specified regex matches any text in any instance of the specified header, this expression returns the string immediately before that text. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER("Via").BEFORE_REGEX("[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}") returns received=.
SIP.REQ.FULL_HEADER	Returns the entire SIP header, including the terminating CR/LF.
SIP.REQ.IS_VALID	Returns boolean true if the request format is valid.
SIP.REQ.BODY(<length>)	Returns the request body, up to the specified length. If the specified length is greater than the length of the request body, this expression returns the entire request body.
SIP.REQ.LB_VSERVER	Returns the name of the load balancing virtual server (*LB vserver*) that is serving the current request.

Expression	Description
SIP.REQ.CS_VSERVER	Returns the name of the content switching virtual server (*CS vserver*) that is serving the current request.

Table 2. SIP Response Expressions

Expression	Description
SIP.RES.STATUS	Returns the SIP response status code. For example, if the first line of the response is SIP/2.0 100 Trying, this expression returns 100.
SIP.RES.STATUS_MSG	Returns the SIP response status message. For example, if the first line of the response is SIP/2.0 100 Trying, this expression returns Trying.
SIP.RES.IS_REDIRECT	Returns boolean true if the response code is a redirect.
SIP.RES.METHOD	Returns the response method extracted from the request method string in the CSeq header.

Operations for HTTP, HTML, and XML Encoding and “Safe” Characters

Nov 27, 2014

The following operations work with the encoding of HTML data in a request or response and XML data in a POST body.

Table 1. Operations That Evaluate HTML and XML Encoding

HTML or XML Operation	Description
<text>.HTML_XML_SAFE	Transforms special characters into XML safe format, as in the following examples: • A left-pointing angle bracket (<) is converted to < • A right-pointing angle bracket (>) is converted to > • An ampersand (&) is converted to & This operation safeguards against cross-site scripting attacks. Maximum length of the transformed text is 2048 bytes. This is a read-only operation. After applying the transformation, additional operators that you specify in the expression are applied to the selected text. Following is an example: `http.req.url.query.html_xml_safe.contains("myQueryString")`
<text>.HTTP_HEADER_SAFE	Converts all new line ('\n') characters in the input text to '%0A' to enable the input to be used safely in HTTP headers. This operation safeguards against response-splitting attacks. The maximum length of the transformed text is 2048 bytes. This is a read-only operation.
<text>.HTTP_URL_SAFE	Converts unsafe URL characters to '%xx' values, where “xx” is a hex-based representation of the input character. For example, the ampersand (&) is represented as %26 in URL-safe encoding. The maximum length of the transformed text is 2048 bytes. This is a read-only operation. Following are URL safe characters. All others are unsafe: • Alpha-numeric characters: a-z, A-Z, 0-9 • Asterix: "*" • Ampersand: "&" • At-sign: "@" • Colon: ":" • Comma: "," • Dollar: "$" • Dot: "." • Equals: "=" • Exclamation mark: "!" • Hyphen: "-" • Open and close parentheses: "(", ")" • Percent: "%" • Plus: "+" • Semicolon: ";" • Single quote: "'" • Slash: "/" • Question mark: "?" • Tilde: "~" • Underscore: "_"
<text>.MARK_SAFE	Marks the text as safe without applying any type of data transformation.

HTML or XML Operation	Description
<text>.SET_TEXT_MODE(URLENCODED|NOURLENCODED)	Transforms all %HH encoding in the byte stream. This operation works with characters (not bytes). By default, a single byte represents a character in ASCII encoding. However, if you specify URLENCODED mode, three bytes can represent a character. In the following example, a PREFIX(3) operation selects the first 3 characters in a target. http.req.url.hostname.prefix(3) In the following example, the NetScaler can select up to 9 bytes from the target: http.req.url.hostname.set_text_mode(urlencoded).prefix(3)
<text>.SET_TEXT_MODE(PLUS_AS_SPACE|NO_PLUS_AS_SPACE)	Specifies how to treat the plus character (+). The PLUS_AS_SPACE option replaces a plus character with white space. For example, the text “hello+world” becomes “hello world.” The NO_PLUS_AS_SPACE option leaves plus characters as they are.
<text>.SET_TEXT_MODE(BACKSLASH_ENCODED|NO_BACKSLASH_ENCODED)	Specifies whether or not backslash decoding is performed on the text object represented by <text>. If BACKSLASH_ENCODED is specified, the SET_TEXT_MODE operator performs the following operations on the text object: • All occurrences of “\XXX” will be replaced with the character “Y” (where XXX represents a number in the octal system and Y represents the ASCII equivalent of XXX). The valid range of octal values for this type of encoding is 0 to 377. For example, the encoded text "http\72//" and "http\072//" will both be decoded to "http://", where the colon (:) is the ASCII equivalent of the octal value “72”. • All occurrences of “\xHH” will be replaced with the character “Y” (HH represents a number in the hexadecimal system and Y denotes the ASCII equivalent of HH. For example, the encoded text "http\x3a//" will be decoded to "http://", where the colon (:) is the ASCII equivalent of the hexadecimal value “3a“. • All occurrences of “\\uWWXX” will be replaced with the character sequence “YZ” (Where WW and XX represent two distinct hexadecimal values and Y and Z represent their ASCII equivalents of WW and XX respectively. For example, the encoded text "http%u3a2f/" and "http%u003a//" will both be decoded to "http://", where “3a” and “2f” are two hexadecimal values and the colon (:) and forward slash (“/”) represent their ASCII equivalents respectively. • All occurrences of "\b", "\n", "\t", "\f", and "\r" are replaced with the corresponding ASCII characters. If NO_BACKSLASH_ENCODED is specified, backslash decoding is not performed on the text object.
<text>.SET_TEXT_MODE(BAD_ENCODE_RAISE_UNDEF|NO_BAD_ENCODE_RAISE_UNDEF)	Performs the associated undefined action if either the URLENCODED or the BACKSLASH_ENCODED mode is set and bad encoding corresponding to the specified encoding mode is encountered in the text object represented by <text>. If NO_BAD_ENCODE_RAISE_UNDEF is specified, the associated undefined action will not be performed when bad encoding is encountered in the text object represented by<text>.

Expressions for TCP, UDP, and VLAN Data

Sep 02, 2013

TCP and UDP data take the form of a string or a number. For expression prefixes that return string values for TCP and UDP data, you can apply any text-based operations. For more information, see "Default Syntax Expressions: Evaluating Text."

For expression prefixes that return numeric value, such as a source port, you can apply an arithmetic operation. For more information, see "Basic Operations on Expression Prefixes" and "Compound Operations for Numbers."

The following table describes prefixes that extract TCP and UDP data.

Table 1. Prefixes That Extract TCP and UDP Data

GET Operation	Description
CLIENT.TCP.PAYLOAD(<integer>)	Returns TCP payload data as a string, starting with the first character in the payload and continuing for the number of characters in the <integer> argument. You can apply any text-based operation to this prefix.
CLIENT.TCP.SRCPORT	Returns the ID of the current packet's source port as a number.
CLIENT.TCP.DSTPORT	Returns the ID of the current packet's destination port as a number.
CLIENT.TCP.OPTIONS	Returns the TCP options set by the client. Examples of TCP options are Maximum Segment Size (MSS), Window Scale, Selective Acknowledgements (SACK), and Time Stamp Option. The COUNT, TYPE(<type>), and TYPE_NAME(<m>) operators can be used with this prefix. For the TCP options set by the server, see the SERVER.TCP.OPTIONS prefix.
CLIENT.TCP.OPTIONS.COUNT	Returns the number of TCP options that the client has set.
CLIENT.TCP.OPTIONS.TYPE(<type>)	Returns the value of the TCP option whose type (or *option kind*) is specified as the argument. The value is returned as a string of bytes in big endian format (or *network byte order*). **Parameters:** type - Type value
CLIENT.TCP.OPTIONS.TYPE_NAME(<m>)	Returns the value of the TCP option whose enumeration constant is specified as the argument. The enumeration constants that you can

GET Operation	Description
	pass as the argument are REPEATER, TIMESTAMP, SACK_PERMITTED, WINDOW, and MAXSEG. To specify the TCP option kind instead of these enumeration constants, use CLIENT.TCP.OPTIONS.TYPE(<type>). For other TCP options, you must use CLIENT.TCP.OPTIONS.TYPE(<type>). Parameters: m - TCP option enumeration constant
CLIENT.TCP.REPEATER_OPTION.EXISTS	Returns a Boolean TRUE if Repeater TCP options exist.
CLIENT.TCP.REPEATER_OPTION.IP	Returns the branch repeater's IPv4 address from the Repeater TCP options.
CLIENT.TCP.REPEATER_OPTION.MAC	Returns the branch repeater's MAC address from the Repeater TCP options.
CLIENT.UDP.DNS.DOMAIN	Returns the DNS domain name.
CLIENT.UDP.DNS.DOMAIN.EQ("<hostname>")	Returns a Boolean TRUE if the domain name matches the <hostname> argument. The comparison is case insensitive. Following is an example: client.udp.dns.domain.eq("www.mycompany.com")
CLIENT.UDP.DNS.IS_AAAAREC	Returns a Boolean TRUE if the record type is AAAA. These types of records indicate an IPv6 address in forward lookups.
CLIENT.UDP.DNS.IS_ANYREC	Returns a Boolean TRUE if it is of any record type.
CLIENT.UDP.DNS.IS_AREC	Returns a Boolean TRUE if the record is type A. Type A records provide the host address.
CLIENT.UDP.DNS.IS_CNAMEREC	Returns a Boolean TRUE if the record is of type CNAME. In systems that use multiple names to identify a resource, there is one canonical name and a number of aliases. The CNAME provides the canonical name.
CLIENT.UDP.DNS.IS_MXREC	Returns a Boolean TRUE if the record is of type MX (mail exchanger). This DNS record describes a priority and a host name. The MX records for the same domain name specify the email servers in the

GET Operation	Description
	domain and the priority for each server.
CLIENT.UDP.DNS.IS_NSREC	Returns a Boolean TRUE if the record is of type NS. This is a name server record that includes a host name with an associated A record. This enables locating the domain name that is associated with the NS record.
CLIENT.UDP.DNS.IS_PTRREC	Returns a Boolean TRUE if the record is of type PTR. This is a domain name pointer and is often used to associate a domain name with an IPv4 address.
CLIENT.UDP.DNS.IS_SOAREC	Returns a Boolean TRUE if the record is of type SOA. This is a start of authority record.
CLIENT.UDP.DNS.IS_SRVREC	Returns a Boolean TRUE if the record is of type SRV. This is a more general version of the MX record.
CLIENT.UDP.DSTPORT	Returns the numeric ID of the current packet's UDP destination port.
CLIENT.UDP.SRCPORT	Returns the numeric ID of the current packet's UDP source port.
CLIENT.UDP.RADIUS	Returns RADIUS data for the current packet.
CLIENT.UDP.RADIUS.ATTR_TYPE(<type>)	Returns the value for the attribute type specified as the argument.
CLIENT.UDP.RADIUS.USERNAME	Returns the RADIUS user name.
CLIENT.TCP.MSS	Returns the maximum segment size (MSS) for the current connection as a number.
CLIENT.VLAN.ID	Returns the numeric ID of the VLAN through which the current packet entered the NetScaler.
SERVER.TCP.DSTPORT	Returns the numeric ID of the current packet's destination port.
SERVER.TCP.SRCPORT	Returns the numeric ID of the current packet's source port.
SERVER.TCP.OPTIONS	Returns the TCP options set by the server. Examples of TCP options are Maximum Segment Size (MSS), Window Scale, Selective Acknowledgements (SACK), and Time Stamp Option. The COUNT, TYPE(<type>), and TYPE_NAME(<m>) operators can be used

GET Operation	Description
	with this prefix. For the TCP options set by the client, see the CLIENT.TCP.OPTIONS prefix.
SERVER.TCP.OPTIONS.COUNT	Returns the number of TCP options that the server has set.
SERVER.TCP.OPTIONS.TYPE(<type>)	Returns the value of the TCP option whose type (or *option kind*) is specified as the argument. The value is returned as a string of bytes in big endian format (or *network byte order*). **Parameters:** type - Type value
SERVER.TCP.OPTIONS.TYPE_NAME(<m>)	Returns the value of the TCP option whose enumeration constant is specified as the argument. The enumeration constants that you can pass as the argument are REPEATER, TIMESTAMP, SACK_PERMITTED, WINDOW, and MAXSEG. To specify the TCP option kind instead of these enumeration constants, use CLIENT.TCP.OPTIONS.TYPE(<type>). For other TCP options, you must use CLIENT.TCP.OPTIONS.TYPE(<type>). **Parameters:** m - TCP option enumeration constant
SERVER.VLAN	Operates on the VLAN through which the current packet entered the NetScaler.
SERVER.VLAN.ID	Returns the numeric ID of the VLAN through which the current packet entered the NetScaler.

Expressions for Evaluating a DNS Message and Identifying Its Carrier Protocol

Aug 30, 2013

You can evaluate DNS requests and responses by using expressions that begin with DNS.REQ and DNS.RES, respectively. You can also identify the transport layer protocol that is being used to send the DNS messages.

The following functions return the contents of a DNS query.

Table 1. Functions that return the contents of a DNS query

Function	Description
DNS.REQ.QUESTION.DOMAIN	Return the domain name (the value of the QNAME field) in the question section of the DNS query. The domain name is returned as a text string, which can be passed to EQ(), NE(), and any other functions that work with text.
DNS.REQ.QUESTION.TYPE	Return the query type (the value of the QTYPE field) in the DNS query. The field indicates the type of resource record (for example, A, NS, or CNAME) for which the name server is being queried. The returned value can be compared to one of the following values by using the EQ() and NE() functions: • A • AAAA • NS • SRV • PTR • CNAME • SOA • MX • ANY Note: You can use only the EQ() and NE() functions with the TYPE function. **Example:** DNS.REQ.QUESTION.TYPE.EQ(MX)

The following functions return the contents of a DNS response.

Table 2. Functions that return the contents of a DNS response

Function	Description
DNS.RES.HEADER.RCODE	Return the response code (the value of the RCODE field) in the header section of the DNS response. You can use only the EQ() and NE() functions with the

Function	Description
	RCODE function. Following are the possible values: • NOERROR • FORMERR • SERVFAIL • NXDOMAIN • NOTIMP • REFUSED
DNS.RES.QUESTION.DOMAIN	Return the domain name (the value of the QNAME field) in the question section of the DNS response. The domain name is returned as a text string, which can be passed to EQ(), NE(), and any other functions that work with text.
DNS.RES.QUESTION.TYPE	Return the query type (the value of the QTYPE field) in the question section of the DNS response. The field indicates the type of resource record (for example, A, NS, or CNAME) that is contained in the response. The returned value can be compared to one of the following values by using the EQ() and NE() functions: • A • AAAA • NS • SRV • PTR • CNAME • SOA • MX • ANY You can use only the EQ() and NE() functions with the TYPE function. Example: DNS.RES.QUESTION.TYPE.EQ(SOA)

The following functions return the transport layer protocol name.

Table 3. Functions that return the transport layer protocol name

Function	Description
DNS.REQ.TRANSPORT	Return the name of the transport layer protocol that was used to send the DNS query. Possible values returned are TCP and UDP. You can use only the EQ() and NE() functions with the TRANSPORT function. Example: DNS.REQ.TRANSPORT.EQ(TCP)
DNS.RES.TRANSPORT	Return the name of the transport layer protocol that was used for the DNS response.

Function	Description
	Possible values returned are TCP and UDP. You can use only the EQ() and NE() functions with the TRANSPORT function. **Example:** DNS.RES.TRANSPORT.EQ(TCP)

XPath and HTML, XML, or JSON Expressions

Mar 20, 2012

The default syntax expression engine supports expressions for evaluating and retrieving data from HTML, XML, and JavaScript Object Notation (JSON) files. This enables you to find specific nodes in an HTML, XML, or JSON document, determine if a node exists in the file, locate nodes in XML contexts (for example, nodes that have specific parents or a specific attribute with a given value), and return the contents of such nodes. Additionally, you can use XPath expressions in rewrite expressions.

The default syntax expression implementation for XPath comprises a default syntax expression prefix (such as "HTTP.REQ.BODY") that designates HTML or XML text, and the XPATH operator that takes the XPath expression as its argument.

HTML files are a largely free-form collection of tags and text elements. You can use the XPATH_HTML operator, which takes an XPath expression as its argument, to process HTML files. JSON files are either a collection of name/value pairs or an ordered list of values. You can use the XPATH_JSON operator, which takes an XPath expression as its argument, to process JSON files.

Table 1. XPath and JSON Expression Prefixes That Return Text

XPath Prefix	Description
<text>.XPATH(xpathex)	Operate on an XML file and return a Boolean value. For example, the following expression returns a Boolean TRUE if a node called "creator" exists under the node "Book" within the first 1000 bytes of the XML file. HTTP.REQ.BODY(1000).XPATH(xp%boolean(//Book/creator)%) Parameters: xpathex - XPath Boolean expression
<text>.XPATH(xpathex)	Operate on an XML file and return a value of data type "double." For example, the following expression converts the string "36" (a price value) to a value of data type "double" if the string is in the first 1000 bytes of the XML file: HTTP.REQ.BODY(1000).XPATH(xp%number(/Book/price)%) Parameters: xpathex - XPath numeric expression
<text>.XPATH(xpathex)	Operate on an XML file and return a node-set or a string. Node-sets are converted to corresponding strings by using the standard XPath string conversion routine. For example, the following expression selects all the nodes that are enclosed by "/Book/creator" (a node-set) in the first 1000 bytes of the body: HTTP.REQ.BODY(1000).XPATH(xp%/Book/creator%) Parameters: xpathex - XPath expression
<text>.XPATH_HTML(xpathex)	Operate on an HTML file and return a text value. For example, the following expression operates on an HTML file and returns the

XPath Prefix	Description
	text enclosed in <title></title> tags if the title HTML element is found in the first 1000 bytes: HTTP.REQ.BODY(1000).XPATH_HTML(xp%/html/head/title%) Parameters: xpathex - XPath text expression
<text>.XPATH_HTML_WITH_MARKUP(xpathex)	Operate on an HTML file and return a string that contains the entire selected portion of the document, including markup such as including the enclosing element tags. The following expression operates on the HTML file and selects all content within the <title> tag, including markup. HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%/html/head/title%) The portion of the HTML body that is selected by the expression is marked for further processing. Parameters: xpathex - XPath expression
<text>.XPATH_JSON(xpathex)	Operate on a JSON file and return a Boolean value. For example, consider the following JSON file: { "Book":{ "creator":{ "person":{ "name":'<name>' } }, "title":'<title>' } } The following expression operates on the JSON file and returns a Boolean TRUE if the JSON file contains a node named “creator,” whose parent node is “Book,” in the first 1000 bytes: HTTP.REQ.BODY(1000).XPATH_JSON(xp%boolean(/Book/creator)%) Parameters: xpathex - XPath Boolean expression
<text>.XPATH_JSON(xpathex)	Operate on a JSON file and return a value of data type “double.” For example, consider the following JSON file: { "Book":{ "creator":{ "person":{ "name":'<name>' } }, "title":'<title>', "price":"36" } } The following expression operates on the JSON file and converts the string “36” to a value of data type “double” if the string is present in the first 1000 bytes of the JSON file. HTTP.REQ.BODY(1000).XPATH_JSON(xp%number(/Book/price)%) Parameters: xpathex - XPath numeric expression
<text>.XPATH_JSON(xpathex)	Operate on a JSON file and return a node-set or a string. Node-sets are converted to corresponding strings by using the standard XPath string conversion routine.

XPath Prefix	Description
	For example, consider the following JSON file: { "Book":{ "creator":{ "person":{ "name":'<name>' } }, "title":'<title>' } } The following expression selects all the nodes that are enclosed by “/Book" (a node-set) in the first 1000 bytes of the body of the JSON file and returns the corresponding string value, which is "<name><title>": HTTP.REQ.BODY(1000).XPATH_JSON(xp%/Book%) Parameters: xpathex - XPath expression
<text>.XPATH_JSON_WITH_MARKUP(xpathex)	Operate on an XML file and return a string that contains the entire portion of the document for the result node, including markup such as including the enclosing element tags. For example, consider the following JSON file: {"Book":{ "creator":{ "person":{ "name":'<name>' } }, "title":'<title>' } } The following expression operates on the JSON file and selects all the nodes that are enclosed by “/Book/creator" in the first 1000 bytes of the body, which is “creator:{ person:{ name:'<name>' } }.” HTTP.REQ.BODY(1000).XPATH_JSON_WITH_MARKUP(xp%/Book/creator%) The portion of the JSON body that is selected by the expression is marked for further processing. Parameters: xpathex - XPath expression
<text>.XPATH_WITH_MARKUP(xpathex)	Operate on an XML file and return a string that contains the entire portion of the document for the result node, including markup such as including the enclosing element tags. For example, the following expression operates on an XML file and selects all the nodes enclosed by “/Book/creator" in the first 1000 bytes of the body. HTTP.REQ.BODY(1000).XPATH_WITH_MARKUP(xp%/Book/creator%) The portion of the JSON body that is selected by the expression is marked for further processing. Parameters: xpathex - XPath expression

Encrypting and Decrypting XML Payloads

Sep 02, 2013

You can use the XML_ENCRYPT() and XML_DECRYPT() functions in default syntax expressions to encrypt and decrypt, respectively, XML data. These functions conform to the W3C XML Encryption standard defined at "http://www.w3.org/TR/2001/PR-xmldsig-core-20010820/." XML_ENCRYPT() and XML_DECRYPT() support a subset of the XML Encryption specification. In the subset, data encryption uses a bulk cipher method (RC4, DES3, AES128, AES192, or AES256), and an RSA public key is used to encrypt the bulk cipher key.

Note: If you want to encrypt and decrypt text in a payload, you must use the ENCRYPT and DECRYPT functions. For more information about these functions, see "Encrypting and Decrypting Text."

The XML_ENCRYPT() and XML_DECRYPT() functions are not dependent on the encryption/decryption service that is used by the ENCRYPT and DECRYPT commands for text. The cipher method is specified explicitly as an argument to the XML_ENCRYPT() function. The XML_DECRYPT() function obtains the information about the specified cipher method from the <xenc:EncryptedData> element. Following are synopses of the XML encryption and decryption functions:

- **XML_ENCRYPT(<certKeyName>, <method> [, <flags>])**. Returns an <xenc:EncryptedData> element that contains the encrypted input text and the encryption key, which is itself encrypted by using RSA.
- **XML_DECRYPT(<certKeyName>)**. Returns the decrypted text from the input <xenc:EncryptedData> element, which includes the cipher method and the RSA-encrypted key.

Note: The <xenc:EncryptedData> element is defined in the W3C XML Encryption specification.

Following are descriptions of the arguments:

certKeyName

Selects an X.509 certificate with an RSA public key for XML_ENCRYPT() or an RSA private key for XML_DECRYPT(). The certificate key must have been previously created by an add ssl certKey command.

method

Specifies which cipher method to use for encrypting the XML data. Possible values: RC4, DES3, AES128, AES192, AES256.

flags

A bitmask specifying the following optional key information (<ds:KeyInfo>) to be included in the <xenc:EncryptedData> element that is generated by XML_ENCRYPT():

- **1** - Include a KeyName element with the certKeyName. The element is <ds:KeyName>.
- **2** - Include a KeyValue element with the RSA public key from the certificate. The element is <ds:KeyValue>.
- **4** - Include an X509IssuerSerial element with the certificate serial number and issuer DN. The element is <ds:X509IssuserSerial>.
- **8** - Include an X509SubjectName element with the certificate subject DN. The element is <ds:X509SubjectName>.
- **16** - Include an X509Certificate element with the entire certificate. The element is <ds:X509Certificate>.

XML_ENCRYPT() XML_DECRYPT()

The XML encryption feature uses SSL certificate-key pairs to provide X.509 certificates (with RSA public keys) for key encryption and RSA private keys for key decryption. Therefore, before you use the XML_ENCRYPT() function in an expression, you must create an SSL certificate-key pair. The following command creates an SSL certificate-key pair, my-

certkey, with the X.509 certificate, my-cert.pem, and the private key file, my-key.pem.

```
add ssl certKey my-certkey -cert my-cert.pem -key my-key.pem -passcrypt kxPeMRYnitY=
```

The following CLI commands create rewrite actions and policies for encrypting and decrypting XML content.

```
add rewrite action my-xml-encrypt-action replace "HTTP.RES.BODY(10000).XPATH_WITH_MARKUP(xp%/%)"
"HTTP.RES.BODY(10000).XPATH_WITH_MARKUP(xp%/%).XML_ENCRYPT(\"my-certkey\", AES256, 31)" -
bypassSafetyCheck YES

add rewrite action my-xml-decrypt-action replace
"HTTP.REQ.BODY(10000).XPATH_WITH_MARKUP(xp%//xenc:EncryptedData%)"
"HTTP.REQ.BODY(10000).XPATH_WITH_MARKUP(xp%//xenc:EncryptedData%).XML_DECRYPT(\"my-
certkey\")" -bypassSafetyCheck YES

add rewrite policy my-xml-encrypt-policy "HTTP.REQ.URL.CONTAINS(\"xml-encrypt\")" my-xml-encrypt-
action

add rewrite policy my-xml-decrypt-policy
"HTTP.REQ.BODY(10000).XPATH(xp%boolean(//xenc:EncryptedData)%)" my-xml-decrypt-action

bind rewrite global my-xml-encrypt-policy 30

bind rewrite global my-xml-decrypt-policy 30
```

In the above example, the rewrite action my-xml-encrypt-action encrypts the entire XML document (XPATH_WITH_MARKUP(xp%/%)) in the request by using the AES-256 bulk encryption method and the RSA public key from my-certkey to encrypt the bulk encryption key. The action replaces the document with an <xenc:EncryptedData> element containing the encrypted data and an encrypted key. The flags represented by 31 include all of the optional <ds:KeyInfo> elements.

The action my-xml-decrypt-action decrypts the first <xenc:EncryptedData> element in the response (XPATH_WITH_MARKUP(xp%//xenc:EncryptedData%)). This requires the prior addition of the xenc XML namespace by use of the following CLI command:

```
add ns xmlnamespace xenc http://www.w3.org/2001/04/xmlenc#
```

The my-xml-decrypt-action action uses the RSA private key in my-certkey to decrypt the encrypted key and then uses the bulk encryption method specified in the element to decrypt the encrypted contents. Finally, the action replaces the encrypted data element with the decrypted content.

The rewrite policy my-xml-encrypt-policy applies my-xml-encrypt-action to requests for URLs containing xml-encrypt. The action encrypts the entire response from a service configured on the NetScaler appliance.

The rewrite policy my-xml-decrypt-policy applies my-xml-decrypt-action to requests that contain an <xenc:EncryptedData> element ((XPATH(xp%//xenc:EncryptedData%) returns a non-empty string). The action decrypts the encrypted data in requests that are bound for a service configured on the NetScaler appliance.

Default Syntax Expressions: Parsing SSL Certificates

May 25, 2015

You can use default syntax expressions to evaluate X.509 Secure Sockets Layer (SSL) client certificates. A client certificate is an electronic document that can be used to authenticate a user's identity. A client certificate contains (at a minimum) version information, a serial number, a signature algorithm ID, an issuer name, a validity period, a subject (user) name, a public key, and signatures.

You can examine both SSL connections and data in client certificates. For example, you may want to send SSL requests that use low-strength ciphers to a particular load balancing virtual server farm. The following command is an example of a Content Switching policy that parses the cipher strength in a request and matches cipher strengths that are less than or equal to 40:

```
add cs policy p1 -rule "client.ssl.cipher_bits.le(40)"
```

As another example, you can configure a policy that determines whether a request contains a client certificate:

```
add cs policy p2 -rule "client.ssl.client_cert EXISTS"
```

Or, you might want to configure a policy that examines particular information in a client certificate. For example, the following policy verifies that the certificate has one or more days before expiration:

```
add cs policy p2 -rule "client.ssl.client_cert exists && client.ssl.client_cert.days_to_expire.ge(1)"
```

Note: For information on parsing dates and times in a certificate, see "Format of Dates and Times in an Expression" and "Expressions for SSL Certificate Dates."
This document includes the following details:

- Prefixes for Text-Based SSL and Certificate Data
- Prefixes for Numeric Data in SSL Certificates
- Expressions for SSL Certificates

The following table describes expression prefixes that identify text-based items in SSL transactions and client certificates.

Table 1. Prefixes That Return Text or Boolean Values for SSL and Client Certificate Data

Prefix	Description
CLIENT.SSL.CLIENT_CERT	Returns the SSL client certificate in the current SSL transaction.
CLIENT.SSL.CLIENT_CERT.TO_PEM	Returns the SSL client certificate in binary format.
CLIENT.SSL.CIPHER_EXPORTABLE	Returns a Boolean TRUE if the SSL cryptographic SSL cryptographic cipher is exportable.
CLIENT.SSL.CIPHER_NAME	Returns the name of the SSL Cipher if invoked from an SSL connection, and a NULL string if invoked from a non-SSL connection.
CLIENT.SSL.IS_SSL	Returns a Boolean TRUE if the current connection is SSL-based.

Updated: 2015-06-17

The following table describes prefixes that evaluate numeric data other than dates in SSL certificates. These prefixes can be used with the operations that are described in "Basic Operations on Expression Prefixes" and "Compound Operations for Numbers."

Table 2. Prefixes That Evaluate Numeric Data Other Than Dates in SSL Certificates

Prefix	Description
CLIENT.SSL.CLIENT_CERT.DAYS_TO_EXPIRE	Returns the number of days that the certificate is valid, or returns -1 for expired certificates.
CLIENT.SSL.CLIENT_CERT.PK_SIZE	Returns the size of the public key used in the certificate.
CLIENT.SSL.CLIENT_CERT.VERSION	Returns the version number of the certificate. If the connection is not SSL-based, returns zero (0).
CLIENT.SSL.CIPHER_BITS	Returns the number of bits in the cryptograhic key. Returns 0 if the connection is not SSL-based.
CLIENT.SSL.VERSION	Returns a number that represents the SSL protocol version, as follows: • 0. The transaction is not SSL-based. • 0x002. The transaction is SSLv2. • 0x300. The transaction is SSLv3. • 0x301. The transaction is TLSv1. • 0x302. The transaction is TLSv1.1. • 0x303. The transaction is TLSv1.2.

Note: For expressions related to expiration dates in a certificate, see "Expressions for SSL Certificate Dates."

Updated: 2013-09-02

You can parse SSL certificates by configuring expressions that use the following prefix:

CLIENT.SSL.CLIENT_CERT

This section discusses the expressions that you can configure for certificates, with the exception of expressions that examine certificate expiration. Time-based operations are described in "Default Syntax Expressions: Working with Dates, Times, and Numbers."

The following table describes operations that you can specify for the CLIENT.SSL.CLIENT_CERT prefix.

Table 3. Operations That Can Be Specified with the CLIENT.SSL.CLIENT_CERT Prefix

SSL Certificate Operation	Description
<certificate>.EXISTS	Returns a Boolean TRUE if the client has an SSL certificate.
<certificate>.ISSUER	Returns the Distinguished Name (DN) of the Issuer in the certificate as a name-value list. An equals sign (“=”) is th name and the value, and the slash (“/”) is the delimiter that separates the name-value pairs. Following is an example of the returned DN: /C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuser
<certificate>.ISSUER. IGNORE_EMPTY_ELEMENTS	Returns the Issuer and ignores the empty elements in a name-value list. For example, consider the following: Cert-Issuer: /c=in/st=kar//l=bangelore //o=mycompany/ou=sales/ /emailAddress=myuserid@mycc The following Rewrite action returns a count of 6 based on the preceding Issuer definition: sh rewrite action insert_ssl_header Name: insert_ssl Operation: insert_http_header Target:Cert-Issuer Value:CLIENT.SSL.CLIENT_CERT.ISSUER.COUNT However, if you change the value to the following, the returned count is 9: CLIENT.SSL.CLIENT_CERT.ISSUER.IGNORE_EMPTY_ELEMENTS.COUNT
<certificate>.AUTH_KEYID	Returns a string that contains the Authority Key Identifier extension of the X.509 V3 certificate.
<certificate>.AUTH_KEYID.CERT_SERIALNUMBER	Returns the SerialNumber field of the Authority Key Identifier as a blob.
<certificate>.AUTH_KEYID.EXISTS	Returns a Boolean TRUE if the certificate contains an Authority Key Identifier extension.
<certificate>.AUTH_KEYID.ISSUER_NAME	Returns the Issuer Distinguished Name in the certificate as a name-value list. An equals sign (“=”) is the delimiter f value, and the slash (“/”) is the delimiter that separates the name-value pairs. Following is an example: /C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuser
<certificate>.AUTH_KEYID.ISSUER_NAME.IGNORE_EMPTY_ELEMENTS	Returns the Issuer Distinguished Name in the certificate as a name-value list and ignores the empty elements in t For example, the following name-value list has an empty element following “a=10”: a=10;;b=11; ;c=89 The element following b=11 is not considered an empty element.
<certificate>.AUTH_KEYID.KEYID	Returns the keyIdentifier field of the Authority Key Identifier as a blob.
<certificate>.CERT_POLICY	Returns a string that contains the client certificate policy. Note that this represents a sequence of certificate po
<certificate>.KEY_USAGE(string)	Returns a Boolean value to indicate whether the specified key usage extension bit value in the X.509 certificate is set. The string argument specifies which bit is checked. Following are valid arguments: • DIGITAL_SIGNATURE. Returns TRUE if the digital signature bit is set; otherwise, it returns FALSE. • NONREPUDIATION. Returns TRUE if the nonrepudiation bit is set; otherwise, it returns FALSE. • KEYENCIPHERMENT. Returns TRUE if the key encipherment bit is set; otherwise, it returns FALSE.

SSL Certificate Operation	Description
	• DATAENCIPHERMENT. Returns TRUE if the data encipherment bit is set; otherwise, it returns FALSE. • KEYAGREEMENT. Returns TRUE if the key agreement bit is set; otherwise, it returns FALSE. • KEYCERTSIGN. Returns TRUE if the key cert sign bit is set; otherwise, it returns FALSE. • CRLSIGN. Returns TRUE if the CRL bit is set; otherwise, it returns FALSE. • ENCIPHERONLY. Returns TRUE if the encipher only bit is set; otherwise, it returns FALSE. • DECIPHERONLY. Returns TRUE if the decipher only bit is set; otherwise, it returns FALSE.
<certificate>.PK_ALGORITHM	Returns the name of the public key algorithm used by the certificate.
<certificate>.PK_SIZE	Returns the size of the public key used in the certificate.
<certificate>.SERIALNUMBER	Returns the serial number of the client certificate. If this is a non-SSL transaction or there is an error in the certifi returns an empty string.
<certificate>.SIGNATURE_ALGORITHM	Returns the name of the cryptographic algorithm used by the CA to sign this certificate.
<certificate>.SUBJECT	Returns the Distinguished Name of the Subject as a name-value. An equals sign (“=”) separates names and values delimits name-value pairs. Following is an example: /C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuser
<certificate>.SUBJECT.IGNORE_EMPTY_ELEMENTS	Returns the Subject as a name-value list, but ignores the empty elements in the list. For example, consider the fol Cert-Issuer: /c=in/st=kar//l=bangelore //o=mycompany/ou=sales/ /emailAddress=myuserid@mycc The following Rewrite action returns a count of 6 based on the preceding Issuer definition: sh rewrite action insert_ssl_header Name: insert_ssl Operation: insert_http_header Target:Cert-Issuer Value:CLIENT.SSL.CLIENT_CERT.ISSUER.COUNT However, if you change the value to the following, the returned count is 9: CLIENT.SSL.CLIENT_CERT.ISSUER.IGNORE_EMPTY_ELEMENTS.COUNT
<certificate>.SUBJECT_KEYID	Returns the Subject KeyID of the client certificate. If there is no Subject KeyID, this operation returns a zero-len

Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs

May 26, 2015

You can use default syntax expression prefixes that return IPv4 and IPv6 addresses, MAC addresses, IP subnets, useful client and server data such as the throughput rates at the interface ports (Rx, Tx, and RxTx), and the IDs of the VLANs through which packets are received. You can then use various operators to evaluate the data that is returned by these expression prefixes.

This document includes the following details:

Updated: 2013-09-02

You can use default syntax expressions to evaluate addresses and subnets that are in Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) format. Expression prefixes for IPv6 addresses and subnets include IPv6 in the prefix. Expression prefixes for IPv4 addresses and subnets include IP in the prefix. Following is an example of an expression that identifies whether a request has originated from a particular IPv4 subnet.

```
client.ip.src.in_subnet(147.1.0.0/16)
```

Following are two examples of Rewrite policies that examine the subnet from which the packet is received and perform a rewrite action on the Host header. With these two policies configured, the rewrite action that is performed depends on the subnet in the request. These two policies evaluate IP addresses that are in the IPv4 address format.

```
add rewrite action URL1-rewrite-action replace "http.req.header(\"Host\")" "\"www.mycompany1.com\""
add rewrite policy URL1-rewrite-policy "http.req.header(\"Host\").contains(\"www.test1.com\") && client.ip.src.in_subnet(147.1.0.0/16)" URL1-rewrite-action
add rewrite action URL2-rewrite-action replace "http.req.header(\"Host\")" "\"www.mycompany2.com\""
add rewrite policy URL2-rewrite-policy "http.req.header(\"Host\").contains(\"www.test2.com\") && client.ip.src.in_subnet(10.202.0.0/16)" URL2-rewrite-action
```

Note: The preceding examples are commands that you type at the NetScaler command-line interface (CLI) and, therefore, each quotation mark must be preceded by a backslash (\). For more information, see "Configuring Default Syntax Expressions in a Policy."

Prefixes for IPV4 Addresses and IP Subnets

Updated: 2013-09-02

The following table describes prefixes that return IPv4 addresses and subnets, and segments of IPv4 addresses. You can use numeric operators and operators that are specific to IPv4 addresses with these prefixes. For more information about numeric operations, see "Basic Operations on Expression Prefixes" and "Compound Operations for Numbers."

Table 1. Prefixes That Evaluate IP and MAC Addresses

Prefix	Description
CLIENT.IP.SRC	Returns the source IP of the current packet as an IP address or as a number.
CLIENT.IP.DST	Returns the destination IP of the current packet as an IP address or as a number.
SERVER.IP.SRC	Returns the source IP of the current packet as an IP address or as a number.
SERVER.IP.DST	Returns the destination IP of the current packet as an IP address or as a number.

Operations for IPV4 Addresses

The following table describes the operators that can be used with prefixes that return an IPv4 address.

Table 2. Operations on IPV4 Addresses

Prefix	Description
<ip address>.EQ(<address>)	Returns a Boolean TRUE if the IP address value is same as the <address> argument. The following example checks whether the client's destination IP address is equal to 10.100.10.100: client.ip.dst.eq(10.100.10.100)
<ip address>.GET1. . .GET4	Returns a portion of an IP address as a numeric value. For example, if the IP address value is 10.100.200.1, the following is returned: client.ip.src.get1 Returns 10 client.ip.src.get2 returns 100

client.ip.src.get3 returns 200

Prefix	Description
<ip address>.IN_SUBNET(<subnet>)	Returns a Boolean TRUE if the <subnet> argument matches the subnet of the IP address value. For example, the following determines whether the client's destination IP address subnet is 10.100.10.100/18: client.ip.dst.eq(10.100.10.100/18)
<ip address>.SUBNET(<n>)	Returns the IP address after applying the subnet mask specified as the argument. The subnet mask can take values between 0 and 32. For example: CLIENT.IP.SRC.SUBNET(24) returns 192.168.1.0 if the IP address represented by the prefix is 192.168.1.[0-255].
<ip address>.IS_IPV6	Returns a Boolean TRUE if this is an Internet Protocol version 6 (IPv6) host for the client or server. Following is an example: client.ip.src.is_ipv6
<ip address>.MATCHES(<hostname>)	Returns a Boolean TRUE if the IP address for the host specified in <hostname> matches the current IP address. The <hostname> cannot exceed 255 characters.
<ip address>.MATCHES_LOCATION(<location>)	Returns a Boolean TRUE if the location of the IP address matches the <location> argument. The Location string can take the following form: qual1.qual2.qual3.qual4.qual5.qual6, for example: NorthAmeria.CA.* Following is an example: client.ip.src.matches_location(\"Europe.GB.17.London.*.*\")

About IPv6 Expressions

The IPv6 address format allows more flexibility than the older IPv4 format. IPv6 addresses are in the hexadecimal format (RFC 2373). In the following examples, Example 1 is an IPv6 address, Example 2 is a URL that includes the IPv6 address, and Example 3 includes the IPv6 address and a port number.

Example 1:
9901:0ab1:22a2:88a3:3333:4a4b:5555:6666
Example 2:
http://[9901:0ab1:22a2:88a3:3333:4a4b:5555:6666]/
Example 3:
https://[9901:0ab1:22a2:88a3:3333:4a4b:5555:6666]:8080/
In Example 3, the brackets separate the IP address from the port number (8080).

Note that you can only use the '+' operator to combine IPv6 expressions with other expressions. The output is a concatenation of the string values that are returned from the individual expressions. You cannot use any other arithmetic operator with an IPv6 expression. The following syntax is an example:

client.ipv6.src + server.ip.dst
For example, if the client source IPv6 address is ABCD:1234::ABCD, and the server destination IPv4 address is 10.100.10.100, the preceding expression returns "ABCD:1234::ABCD10.100.10.100".

Note that when the NetScaler appliance receives an IPv6 packet, it assigns a temporary IPv4 address from an unused IPv4 address range and changes the source address of the packet to this temporary address. At response time, the outgoing packet's source address is replaced with the original IPv6 address.

Note: You can combine an IPv6 expression with any other expression except an expression that produces a Boolean result.

Expression Prefixes for IPv6 Addresses

The IPv6 addresses that are returned by the expression prefixes in the following table can be treated as text data. For example, the prefix client.ipv6.dst returns the destination IPv6 address as a string that can be evaluated as text.

The following table describes expression prefixes that return an IPv6 address.

Table 3. IPv6 Expression Prefixes That Return Text

Prefix	Description
CLIENT.IPV6	Operates on the IPv6 address in with the current packet.
CLIENT.IPV6.DST	Returns the IPv6 address in the destination field of the IP header.
CLIENT.IPV6.SRC	Returns the IPv6 address in the source field of the IP header. Following are examples:

Prefix	Description
	client.ipv6.src.in_subnet(2007::2008/64) client.ipv6.src.get1.le(2008)
SERVER.IPV6	Operates on the IPv6 address in with the current packet.
SERVER.IPV6.DST	Returns the IPv6 address in the destination field of the IP header.
SERVER.IPV6.SRC	Returns the IPv6 address in the source field of the IP header. Following are examples: server.ipv6.src.in_subnet(2007::2008/64) server.ipv6.src.get1.le(2008)

Operations for IPV6 Prefixes

The following table describes the operators that can be used with prefixes that return an IPv6 address:

Table 4. Operations That Evaluate IPv6 Addresses

IPv6 Operation	Description
<ipv6>.EQ(<IPv6_address>)	Returns a Boolean TRUE if the IP address value is same as the <IPv6_address> argument. Following is an example: client.ipv6.dst.eq(ABCD:1234::ABCD)
<ipv6>.GET1. . .GET8	Returns a segment of an IPv6 address as a number. The following example expressions retrieve segments from the ipv6 address 1000:1001:CD10:0000:0000:89AB:4567:CDEF: • client.ipv6.dst.get5 extracts 0000, which is the fifth set of bits in the address. • client.ipv6.dst.get6 extracts 89AB. • client.ipv6.dst.get7 extracts 4567. You can perform numeric operations on these segments. Note that you cannot perform numeric operations when you retrieve an entire IPv6 address. This is because expressions that return an entire IPv6 address, such as CLIENT.IPV6.SRC, return the address in text format.
<ipv6>.IN_SUBNET(<subnet>)	Returns a Boolean TRUE if the IPv6 address value is in the subnet specified by the <subnet> argument. Following is an example: client.ipv6.dst.eq(1000:1001:CD10:0000:0000:89AB:4567:CDEF/60)
<ipv6>.IS_IPV4	Returns a Boolean TRUE if this is an IPv4 client, and returns a Boolean FALSE if it is not.
<ipv6>.SUBNET(<n>)	Returns the IPv6 address after applying the subnet mask specified as the argument. The subnet mask can take values between 0 and 128. For example: CLIENT.IPV6.SRC.SUBNET(24)

A MAC address consists of colon-delimited hexadecimal values in the format ##:##:##:##:##:##, where each "#" represents either a number from 0 through 9 or a letter from A through F. Default syntax expression prefixes and operators are available for evaluating source and destination MAC addresses.

Prefixes for MAC Addresses

The following table describes prefixes that return MAC addresses.

Table 5. Prefixes That Evaluate MAC Addresses

Prefix	Description
client.ether.dstmac	Returns the MAC address in the destination field of the Ethernet header.
client.ether.srcmac	Returns the MAC address in the source field of the Ethernet header.

Operations for MAC Addresses

The following table describes the operators that can be used with prefixes that return a MAC address.

Table 6. Operations on MAC Addresses

Prefix	Description
<mac address>.EQ(<address>)	Returns a Boolean TRUE if the MAC address value is same as the <address> argument.
<mac address>.GET1. . .GET4	Returns a numeric value extracted from the segment of the MAC address that is specified in the GET operation. For example, if the MAC address is 12:34:56:78:9a:bc, the following returns 34: client.ether.dstmac.get2

The following table describes prefixes for working with numeric client and server data, including throughput, port numbers, and VLAN IDs.

Table 7. Prefixes That Evaluate Numeric Client and Server Data

Prefix	Description
client.interface.rxthroughput	Returns an integer representing the raw received traffic throughput in kilobytes per second (KBps) for the previous seven seconds.
client.interface.txthroughput	Returns an integer representing the raw transmitted traffic throughput in KBps for the previous seven seconds.
client.interface.rxtxthroughput	Returns an integer representing the raw received and transmitted traffic throughput in KBps for the previous seven seconds.
server.interface.rxthroughput	Returns an integer representing the raw received traffic throughput in KBps for the previous seven seconds.
server.interface.txthroughput	Returns an integer representing the raw transmitted traffic throughput in KBps for the previous seven seconds.
server.interface.rxtxthroughput	Returns an integer representing the raw received and transmitted traffic throughput in KBps for the previous seven seconds.
server.vlan.id	Returns a numeric ID of the VLAN through which the current packet entered the NetScaler.
client.vlan.id	Returns a numeric ID for the VLAN through which the current packet entered the NetScaler.

Default Syntax Expressions: Stream Analytics Functions

May 21, 2015

Stream Analytics expressions begin with the ANALYTICS.STREAM(<identifier_name>) prefix. The following list describes the functions that can be used with this prefix.

COLLECT_STATS

Collect statistical data from the requests that are evaluated against the policy and create a record for each request.

REQUESTS

Return the number of requests that exist for the specified record grouping. The value returned is of type unsigned long.

BANDWIDTH

Return the bandwidth statistic for the specified record grouping. The value returned is of type unsigned long.

RESPTIME

Return the response time statistic for the specified record grouping. The value returned is of type unsigned long.

CONNECTIONS

Return the number of concurrent connections that exist for the specified record grouping. The value returned is of type unsigned long.

IS_TOP(n)

Return a Boolean TRUE if the statistical value for the specified record grouping is one among the top n groups. Otherwise, return a Boolean FALSE.

CHECK_LIMIT

Return a Boolean TRUE if the statistic for the specified record grouping has hit the preconfigured limit. Otherwise, return a Boolean FALSE.

Default Syntax Expressions: DataStream

May 25, 2015

The policy infrastructure on the Citrix NetScaler appliance includes expressions that you can use to evaluate and process database server traffic when the appliance is deployed between a farm of application servers and their associated database servers.

This document includes the following details:

- Expressions for the MySQL Protocol
- Expressions for Evaluating Microsoft SQL Server Connections

The following expressions evaluate traffic associated with MySQL database servers. You can use the request-based expressions (expressions that begin with MYSQL.CLIENT and MYSQL.REQ) in policies to make request switching decisions at the content switching virtual server bind point and the response-based expressions (expressions that begin with MYSQL.RES) to evaluate server responses to user-configured health monitors.

- **MYSQL.CLIENT**. Operates on the client properties of a MySQL connection.
- **MYSQL.CLIENT.CAPABILITIES**. Returns the set of flags that the client has set in the capabilities field of the handshake initialization packet during authentication. Examples of the flags that are set are CLIENT_FOUND_ROWS, CLIENT_COMPRESS, and CLIENT_SSL.
- **MYSQL.CLIENT.CHAR_SET**. Returns the enumeration constant assigned to the character set that the client uses. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix. Following are the character set enumeration constants:
  - LATIN2_CZECH_CS
  - DEC8_SWEDISH_CI
  - CP850_GENERAL_CI
  - GREEK_GENERAL_CI
  - LATIN1_GERMAN1_CI
  - HP8_ENGLISH_CI
  - KOI8R_GENERAL_CI
  - LATIN1_SWEDISH_CI
  - LATIN2_GENERAL_CI
  - SWE7_SWEDISH_CI
  - ASCII_GENERAL_CI
  - CP1251_BULGARIAN_CI
  - LATIN1_DANISH_CI
  - HEBREW_GENERAL_CI
  - LATIN7_ESTONIAN_CS
  - LATIN2_HUNGARIAN_CI
  - KOI8U_GENERAL_CI
  - CP1251_UKRAINIAN_CI
  - CP1250_GENERAL_CI
  - LATIN2_CROATIAN_CI
  - CP1257_LITHUANIAN_CI
  - LATIN5_TURKISH_CI

- LATIN1_GERMAN2_CI
- ARMSCII8_GENERAL_CI
- UTF8_GENERAL_CI
- CP1250_CZECH_CS
- CP866_GENERAL_CI
- KEYBCS2_GENERAL_CI
- MACCE_GENERAL_CI
- MACROMAN_GENERAL_CI
- CP852_GENERAL_CI
- LATIN7_GENERAL_CI
- LATIN7_GENERAL_CS
- MACCE_BIN
- CP1250_CROATIAN_CI
- LATIN1_BIN
- LATIN1_GENERAL_CI
- LATIN1_GENERAL_CS
- CP1251_BIN
- CP1251_GENERAL_CI
- CP1251_GENERAL_CS
- MACROMAN_BIN
- CP1256_GENERAL_CI
- CP1257_BIN
- CP1257_GENERAL_CI
- ARMSCII8_BIN
- ASCII_BIN
- CP1250_BIN
- CP1256_BIN
- CP866_BIN
- DEC8_BIN
- GREEK_BIN
- HEBREW_BIN
- HP8_BIN
- KEYBCS2_BIN
- KOI8R_BIN
- KOI8U_BIN
- LATIN2_BIN
- LATIN5_BIN
- LATIN7_BIN
- CP850_BIN
- CP852_BIN
- SWE7_BIN
- UTF8_BIN
- GEOSTD8_GENERAL_CI
- GEOSTD8_BIN
- LATIN1_SPANISH_CI
- UTF8_UNICODE_CI

- UTF8_ICELANDIC_CI
- UTF8_LATVIAN_CI
- UTF8_ROMANIAN_CI
- UTF8_SLOVENIAN_CI
- UTF8_POLISH_CI
- UTF8_ESTONIAN_CI
- UTF8_SPANISH_CI
- UTF8_SWEDISH_CI
- UTF8_TURKISH_CI
- UTF8_CZECH_CI
- UTF8_DANISH_CI
- UTF8_LITHUANIAN_CI
- UTF8_SLOVAK_CI
- UTF8_SPANISH2_CI
- UTF8_ROMAN_CI
- UTF8_PERSIAN_CI
- UTF8_ESPERANTO_CI
- UTF8_HUNGARIAN_CI
- INVAL_CHARSET

- **MYSQL.CLIENT.DATABASE**. Returns the name of the database specified in the authentication packet that the client sends to the database server. This is the databasename attribute.
- MYSQL.CLIENT.USER. Returns the user name (in the authentication packet) with which the client is attempting to connect to the database. This is the user attribute.
- **MYSQL.REQ**. Operates on a MySQL request.
- **MYSQL.REQ.COMMAND**. Identifies the enumeration constant assigned to the type of command in the request. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix. Following are the enumeration constant values:
  - SLEEP
  - QUIT
  - INIT_DB
  - QUERY
  - FIELD_LIST
  - CREATE_DB
  - DROP_DB
  - REFRESH
  - SHUTDOWN
  - STATISTICS
  - PROCESS_INFO
  - CONNECT
  - PROCESS_KILL
  - DEBUG
  - PING
  - TIME
  - DELAYED_INSERT
  - CHANGE_USER
  - BINLOG_DUMP

- TABLE_DUMP
- CONNECT_OUT
- REGISTER_SLAVE
- STMT_PREPARE
- STMT_EXECUTE
- STMT_SEND_LONG_DATA
- STMT_CLOSE
- STMT_RESET
- SET_OPTION
- STMT_FETCH

- **MYSQL.REQ.QUERY**. Identifies the query in the MySQL request.
- **MYSQL.REQ.QUERY.COMMAND**. Returns the first keyword in the MySQL query.
- **MYSQL.REQ.QUERY.SIZE**. Returns the size of the request query in integer format. The SIZE method is similar to the CONTENT_LENGTH method that returns the length of an HTTP request or response.
- **MYSQL.REQ.QUERY.TEXT**. Returns a string covering the entire query.
- **MYSQL.REQ.QUERY.TEXT(<n>)**. Returns the first n bytes of the MySQL query as a string. This is similar to HTTP.BODY(<n>).
  Parameters:

  n - Number of bytes to be returned

- **MYSQL.RES**. Operates on a MySQL response.
- **MYSQL.RES.ATLEAST_ROWS_COUNT(<i>)**. Checks whether the response has at least i number of rows and returns a Boolean TRUE or FALSE to indicate the result.
  Parameters:

  i - Number of rows

- **MYSQL.RES.ERROR**. Identifies the MySQL error object. The error object includes the error number and the error message.
- **MYSQL.RES.ERROR.MESSAGE**. Returns the error message that is retrieved from the server's error response.
- **MYSQL.RES.ERROR.NUM**. Returns the error number that is retrieved from the server's error response.
- **MYSQL.RES.ERROR.SQLSTATE**. Returns the value of the SQLSTATE field in the server's error response. The MySQL server translates error number values to SQLSTATE values.
- **MYSQL.RES.FIELD(<i>)**. Identifies the packet that corresponds to the i^{th} individual field in the server's response. Each field packet describes the properties of the associated column. The packet count (i) begins at 0.
  Parameters:

  i - Packet number

- **MYSQL.RES.FIELD(<i>).CATALOG**. Returns the catalog property of the field packet.
- **MYSQL.RES.FIELD(<i>).CHAR_SET**. Returns the character set of the column. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix.
- **MYSQL.RES.FIELD(<i>).DATATYPE**. Returns an enumeration constant that represents the data type of the column. This is the type (also called enum_field_type) attribute of the column. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix. The possible values for the various data types are:
  - DECIMAL

    - TINY
    - SHORT
    - LONG
    - FLOAT
    - DOUBLE
    - NULL
    - TIMESTAMP
    - LONGLONG
    - INT24
    - DATE
    - TIME
    - DATETIME
    - YEAR
    - NEWDATE
    - VARCHAR (new in MySQL 5.0)
    - BIT (new in MySQL 5.0)
    - NEWDECIMAL (new in MySQL 5.0)
    - ENUM
    - SET
    - TINY_BLOB
    - MEDIUM_BLOB
    - LONG_BLOB
    - BLOB
    - VAR_STRING
    - STRING
    - GEOMETRY
- **MYSQL.RES.FIELD(<i>).DB**. Returns the database identifier (db) attribute of the field packet.
- **MYSQL.RES.FIELD(<i>).DECIMALS**. Returns the number of positions after the decimal point if the type is DECIMAL or NUMERIC. This is the decimals attribute of the field packet.
- **MYSQL.RES.FIELD(<i>).FLAGS**. Returns the flags property of the field packet. Following are the possible hexadecimal flag values:
    - 0001: NOT_NULL_FLAG
    - 0002: PRI_KEY_FLAG
    - 0004: UNIQUE_KEY_FLAG
    - 0008: MULTIPLE_KEY_FLAG
    - 0010: BLOB_FLAG
    - 0020: UNSIGNED_FLAG
    - 0040: ZEROFILL_FLAG
    - 0080: BINARY_FLAG
    - 0100: ENUM_FLAG
    - 0200: AUTO_INCREMENT_FLAG
    - 0400: TIMESTAMP_FLAG
    - 0800: SET_FLAG
- **MYSQL.RES.FIELD(<i>).LENGTH**. Returns the length of the column. This is the value of the length attribute of the field packet. The value that is returned might be larger than the actual value. For example, an instance of a VARCHAR(2) column might return a value of 2 even when it contains only one character.

- **MYSQL.RES.FIELD(<i>).NAME**. Returns the column identifier (the name after the AS clause, if any). This is the name attribute of the field packet.
- **MYSQL.RES.FIELD(<i>).ORIGINAL_NAME**. Returns the original column identifier (before the AS clause, if any). This is the org_name attribute of the field packet.
- **MYSQL.RES.FIELD(<i>).ORIGINAL_TABLE**. Returns the original table identifier of the column (before the AS clause, if any). This is the org_table attribute of the field packet.
- **MYSQL.RES.FIELD(<i>).TABLE**. Returns the table identifier of the column (after the AS clause, if any). This is the table attribute of the field packet.
- **MYSQL.RES.FIELDS_COUNT**. Returns the number of field packets in the response (the field_count attribute of the OK packet).
- **MYSQL.RES.OK**. Identifies the OK packet sent by the database server.
- **MYSQL.RES.OK.AFFECTED_ROWS**. Returns the number of rows affected by an INSERT, UPDATE, or DELETE query. This is the value of the affected_rows attribute of the OK packet.
- **MYSQL.RES.OK.INSERT_ID**. Identifies the unique_id attribute of the OK packet. If an auto-increment identity is not generated by the current MySQL statement or query, the value of unique_id, and hence the value returned by the expression, is 0.
- **MYSQL.RES.OK.MESSAGE**. Returns the message property of the OK packet.
- **MYSQL.RES.OK.STATUS**. Identifies the bit string in the server_status attribute of the OK packet. Clients can use the server status to check whether the current command is a part of a running transaction. The bits in the server_status bit string correspond to the following fields (in the given order):
  - IN TRANSACTION
  - AUTO_COMMIT
  - MORE RESULTS
  - MULTI QUERY
  - BAD INDEX USED
  - NO INDEX USED
  - CURSOR EXISTS
  - LAST ROW SEEN
  - DATABASE DROPPED
  - NO BACKSLASH ESCAPES
- **MYSQL.RES.OK.WARNING_COUNT**. Returns the warning_count attribute of the OK packet.
- **MYSQL.RES.ROW(<i>)**. Identifies the packet that corresponds to the i^{th} individual row in the database server's response.
  Parameters:

  i - Row number

- **MYSQL.RES.ROW(<i>).DOUBLE_ELEM(<j>)**. Checks whether the j^{th} column of the i^{th} row of the table is NULL. Following C conventions, both indexes i and j start from 0. Therefore, row i and column j are actually the $(i+1)^{th}$ row and the $(j+1)^{th}$ column, respectively.
  Parameters:

  i - Row number

  j - Column number

- **MYSQL.RES.ROW(<i>).IS_NULL_ELEM(j)**. Checks whether the j^{th} column of the i^{th} row of the table is NULL. Following C conventions, both indexes i and j start from 0. Therefore, row i and column j are actually the $(i+1)^{th}$ row

and the $(j+1)^{th}$ column, respectively.
Parameters:

i - Row number

j - Column number

- **MYSQL.RES.ROW(<i>).NUM_ELEM(<j>)**. Returns an integer value from the j^{th} column of the i^{th} row of the table. Following C conventions, both indexes i and j start from 0. Therefore, row i and column j are actually the $(i+1)^{th}$ row and the $(j+1)^{th}$ column, respectively.
  Parameters:

  i - Row number

  j - Column number

- **MYSQL.RES.ROW(<i>).TEXT_ELEM(j)**. Returns a string from the j^{th} column of the i^{th} row of the table. Following C conventions, both indexes i and j start from 0. Therefore, row i and column j are actually the $(i+1)^{th}$ row and the $(j+1)^{th}$ column, respectively.
  Parameters:

  i - Row number

  j - Column number

- **MYSQL.RES.TYPE**. Returns an enumeration constant for the response type. Its values can be ERROR, OK, and RESULT_SET. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix.

The following expressions evaluate traffic associated with Microsoft SQL Server database servers. You can use the request-based expressions (expressions that begin with MSSQL.CLIENT and MSSQL.REQ) in policies to make request switching decisions at the content switching virtual server bind point and the response-based expressions (expressions that begin with MSSQL.RES) to evaluate server responses to user-configured health monitors.

Table 1. Expressions for Evaluating Microsoft SQL Server Connections

Expression	Description
MSSQL.CLIENT.CAPABILITIES	Returns the OptionFlags1, OptionFlags2, OptionFlags3, and TypeFlags fields of the LOGIN7 authentication packet, in that order, as a 4-byte integer. Each field is 1 byte long and specifies a set of client capabilities.
MSSQL.CLIENT.DATABASE	Returns the name of the client database. The value returned is of type text.
MSSQL.CLIENT.USER	Returns the user name with which the client authenticated. The value returned is of type text.

Expression	Description
MSSQL.REQ.COMMAND	Returns an enumeration constant that identifies the type of command in the request sent to a Microsoft SQL Server database server. The value returned is of type text. Examples of the values of the enumeration constant are QUERY, RESPONSE, RPC, and ATTENTION. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this expression.
MSSQL.REQ.QUERY.COMMAND	Returns the first keyword in the SQL query. The value returned is of type text.
MSSQL.REQ.QUERY.SIZE	Returns the size of the SQL query in the request. The value returned is a number.
MSSQL.REQ.QUERY.TEXT	Returns the entire SQL query as a string. The value returned is of type text.
MSSQL.REQ.QUERY.TEXT(<n>)	Returns the first n bytes of the SQL query. The value returned is of type text. **Parameters:** n - Number of bytes
MSSQL.REQ.RPC.NAME	Returns the name of the procedure that is being called in a remote procedure call (RPC) request. The name is returned as a string.
MSSQL.REQ.RPC.IS_PROCID	Returns a Boolean value that indicates whether the remote procedure call (RPC) request contains a procedure ID or an RPC name. A return value of TRUE indicates that the request contains a procedure ID and a return value of FALSE indicates that the request contains an RPC name.
MSSQL.REQ.RPC.PROCID	Returns the procedure ID of the remote procedure call (RPC) request as an integer.
MSSQL.REQ.RPC.BODY Note: Not available for releases before 10.1.	Returns the body of the SQL request as a string in the form of parameters represented as "a=b" clauses separated by commas, where "a" is the RPC parameter name and "b" is its value.

Expression	Description
MSSQL.REQ.RPC.BODY(n) Note: Not available for releases before 10.1.	Returns part of the body of the SQL request as a string in the form of parameters represented as "a=b" clauses separated by commas, where "a" is the RPC parameter name and "b" is its value. Parameters are returned from only the first "n" bytes of the request, skipping the SQL header. Only complete name-value pairs are returned.
MSSQL.RES.ATLEAST_ROWS_COUNT(i)	Checks whether the response has at least i number of rows. The value returned is a Boolean TRUE or FALSE value. **Parameters:** i - Number of rows
MSSQL.RES.DONE.ROWCOUNT	Returns a count of the number of rows affected by an INSERT, UPDATE, or DELETE query. The value returned is of type unsigned long.
MSSQL.RES.DONE.STATUS	Returns the status field from the DONE token sent by a Microsoft SQL Server database server. The value returned is a number.
MSSQL.RES.ERROR.MESSAGE	Returns the error message from the ERROR token sent by a Microsoft SQL Server database server. This is the value of the MsgText field in the ERROR token. The value returned is of type text.
MSSQL.RES.ERROR.NUM	Returns the error number from the ERROR token sent by a Microsoft SQL Server database server. This is the value of the Number field in the ERROR token. The value returned is a number.
MSSQL.RES.ERROR.STATE	Returns the error state from the ERROR token sent by a Microsoft SQL Server database server. This is the value of the State field in the ERROR token. The value returned is a number.
MSSQL.RES.FIELD(<i>).DATATYPE	Returns the data type of the i^{th} field in the server response. The EQ(<m>) and NE(<m>) functions, which return Boolean values to indicate the result of a comparison, are used with this prefix. For example, the following expression returns a Boolean TRUE if the DATATYPE function returns a value of datetime for the third field in the response:

Expression	Description
	Parameters: i - Row number
MSSQL.RES.FIELD(<i>).LENGTH	Returns the maximum possible length of the i^{th} field in the server response. The value returned is a number. **Parameters:** i - Row number
MSSQL.RES.FIELD(<i>).NAME	Returns the name of the i^{th} field in the server response. The value returned is of type **text**. **Parameters:** i - Row number
MSSQL.RES.ROW(<i>).DOUBLE_ELEM(<j>)	Returns a value of type **double** from the j^{th} column of the i^{th} row of the table. If the value is not a double value, an **UNDEF** condition is raised. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the $(i + 1)^{th}$ row and the $(j + 1)^{th}$ column, respectively. **Parameters:** i - Row number j - Column number
MSSQL.RES.ROW(<i>).NUM_ELEM(j)	Returns an integer value from the j^{th} column of i^{th} row of the table. If the value is not an integer value, an **UNDEF** condition is raised. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the $(i + 1)^{th}$ row and the $(j + 1)^{th}$ column, respectively. **Parameters:** i - Row number j - Column number
MSSQL.RES.ROW(<i>).IS_NULL_ELEM(j)	Checks whether the j^{th} column of the i^{th} row of the table is **NULL** and returns a Boolean **TRUE** or **FALSE** to indicate the result. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the $(i + 1)^{th}$

Expression	Description
	row and the (j + 1)th column, respectively. **Parameters:** i - Row number j - Column number
MSSQL.RES.ROW(<i>).TEXT_ELEM(j)	Returns a text string from the jth column of ith row of the table. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the (i + 1)th row and the (j + 1)th column, respectively. **Parameters:** i - Row number j - Column number
MSSQL.RES.TYPE	Returns an enumeration constant that identifies the response type. Following are the possible return values: • ERROR • OK • RESULT_SET The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this expression.

Typecasting Data

May 14, 2012

You can extract data of one type (for example, text or an integer) from requests and responses and transform it to data of another type. For example, you can extract a string and transform the string to time format. You can also extract a string from an HTTP request body and treat it like an HTTP header or extract a value from one type of request header and insert it in a response header of a different type.

After typecasting the data, you can apply any operation that is appropriate for the new data type. For example, if you typecast text to an HTTP header, you can apply any operation that is applicable to HTTP headers to the returned value.

The following table describes various typecasting operations.

Table 1. Typecasting Functions

Function	Description
<text>.TYPECAST_LIST_T(<separator>)	Treats the text in an HTTP request or response body as a list whose elements are delimited by the character in the <separator> argument. Index values in the list that is created start with zero (0). Text mode settings have no effect on the separator. For example, even if you set the text mode to IGNORECASE, and the separator is the letter "p," an uppercase "P" is not treated as a separator. The following example creates a Rewrite action that constructs a list from an HTTP request body and extracts the fourth item in the list: add rewrite action myreplace_action REPLACE 'http.req.body(100)' 'http.req.body(100).typecast_list_t('?').get(4)' set rewrite policy myreplace_policy -action myreplace_action This policy returns the string "fourth item" from the following request: GET?first item?second item?third item?fourth item? The following example extracts the fourth-from-last item from the list. add rewrite action myreplace_action1 REPLACE 'http.req.body(100)' 'http.req.body(100).typecast_list_t('?').get_reverse(4)' set rewrite policy myreplace_policy1 -action myreplace_action1 This policy returns the string "first item" from the following request: GET?first item?second item?third item?fourth item.
<text>.TYPECAST_ NVLIST_T(<separator>, <delimiter>) or text.TYPECAST_ NVLIST_T(<separator>, <delimiter>, <quote>)	Treats the text as a name-value list. The <separator> argument identifies the character and separates the name and the value. The <delimiter> argument identifies the character that separates each name-value pair. The <quote> character is required when typecasting text into a name-value list that supports quoted strings. Any delimiters that appear within the quoted string are ignored. The text mode has no effect on the delimiters. For example, if the current text mode is IGNORECASE and you specify "p" as the delimiter, an uppercase "P" is not treated as a delimiter. For example, the following policy counts the number of name-value pairs and inserts the result in a header named name-value-count: add rewrite action mycount_action insert_http_header name-value-count 'http.req.header("Cookie").typecast_nvlist_t('=',';').count' set rewrite policy mycount_policy -action mycount_action This policy can extract a count of arguments in Cookie headers and insert the count in a name-value-count header: Cookie: name=name1; rank=rank1

Function	Description
<text>.TYPECAST_TIME_T	Treats the designated text as a date string. The following formats are supported: • RFC822: Sun, 06 Nov 1994 08:49:37 GMT • RFC850: Sunday, 06-Nov-94 08:49:37 GMT • ASCII TIME: Sun Nov 6 08:49:37 1994 • HTTP Set-Cookie Expiry date: Sun, 06-Nov-1994 08:49:37 GMT For example, the following policy converts the string to a time value and then extracts the day. This policy matches all requests that have a day value lesser than or equal to 10. Add rewrite policy mytime_policy "http.req.body(100) .typecast_time_t.day.le(10)" mytime_action bind rewrite global mytime_policy 100
<numeric string>.TYPECAST_IP_ ADDRESS_T	Treats a numeric string as an IP address. For example, the following policy matches HTTP requests that contains Cookie headers with a value of: 12.34.56.78\r\n. set rewrite policy ip_check_policy -rule 'http.req.cookie .value("ip").typecast_ip_address_t.eq(12.34.56.78)' bind rewrite global ip_check_policy 200 -type req_default
<numeric string>.TYPECAST_IPV6_ADDRESS_T	Treats a string as an IPv6 address in the following format: 0000:0000:CD00:0000:0000:00AB:0000:CDEF
<text>.TYPECAST_HTTP_ URL_T	Treats the designated text as the URL in the first line of an HTTP request header. The supported format is [<protocol>://<hostname>]<path>?<query>, and the text mode is set to URLENCODED by default. For example, the following policy replaces a URL-encoded part of a string in an HTTP header named Test. add rewrite action replace_header_string replace "http.req.header(\"Test\").typecast_http_url_t.path .before_str(\"123\").after_str(\"ABC\")" "\"string\"" add rewrite policy rewrite_test_header_policy true replace_header_string bind rewrite global rewrite_test_header_policy 1 END -type res_override Consider the following header: Test: ABC%12123\r\n This policy would replace the preceding header with the value ABC%string123\r\n.
<text>.TYPECAST_HTTP_ HOSTNAME_T	Provides operations for parsing an HTTP host name as it appears in HTTP data. The format for a host name is abc.def.com:8080.
<text>.TYPECAST_HTTP_ METHOD_T	Converts text to an HTTP method. For example, the following policy matches any HTTP request that contains a Host header with a value equal to POST: Add rewrite policy method_policy "http.req.header(\"Host\") .typecast_http_method_t.eq(POST)" act1
<text>.TYPECAST_DNS_ DOMAIN_T	Enables the designated text to be parsed like a DNS domain name in the format ab.def.com.
<text>.TYPECAST_HTTP_ HEADER_T("<name>")	Converts the designated text to a multi-line HTTP header that you specify in a <name> argument.

Function	Description
	For example, the following expression converts “MyHeader” to “InHeader”: http.req.header("MyHeader").typecast_http_header_t("InHeader") Typically, text operations that you specify in this type of expression apply to only the last line of this header, with some exceptions. For example, the CONTAINS operation operates on values in all the lines in instances of this header type.
<text>.TYPECAST_COOKIE_T	Treats the designated text as an HTTP cookie as it appears in a Set-Cookie or Set-Cookie2 header. You can apply name-value list operations as well as text operations to the designated text. For example, you can designate equals (=) as the name-value delimiter and the semicolon (;) as the list element delimiter. If you apply name-value list operations, the list is parsed as if IGNORE_EMPTY_ELEMENTS were in effect. Each cookie begins with a cookie-name=cookie-value pair, optionally followed by attribute-value pairs that are separated by a semicolon, as follows: cookie1=value1;version=n.n;value;domain=value;path=value If the same attribute appears more than once in a cookie, the value for the first instance of the attribute is returned.
<number>.TYPECAST_DOUBLE_AT	Transforms the number to a value of data type double.
<number>.TYPECAST_IP_ADDRESS_AT	Converts the number to an IP address.
<number>.TYPECAST_TIME_AT	Converts the number to time format.
<number>.TYPECAST_TIME_AT.BETWEEN(<time1>, <time2>)	Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> is between the lower and upper time value arguments <time1> and <time2>. The following are prerequisites for this function: • Both the lower and upper time arguments must be fully specified. For example, GMT 1995 Jan is fully specified. But GMT Jan, GMT 1995 20 and GMT Jan Mon_2 are not fully specified. • Both arguments must be either GMT or Local. • The day of the week must not be present in either argument. However, the day of the month can be specified as the first, second, third, or fourth weekday of the month (example Wed_3 is the third Wednesday of the month). • The upper time argument, <time2>, must be bigger than the lower time argument, <time1>. The following examples assume that the current time value is GMT 2005 May 1 10h 15m 30s and that the day is the first Sunday of the month of May in 2005. The result of the evaluation is given after each example. BETWEEN(GMT 2004, GMT 2006): TRUE BETWEEN(GMT 2004 Jan, GMT 2006 Nov): TRUE BETWEEN(GMT 2004 Jan, GMT 2006): TRUE BETWEEN(GMT 2005 May Sun_1, GMT 2005 May Sun_3): TRUE BETWEEN(GMT 2005 May 1, GMT May 2005 1): TRUE BETWEEN(LOCAL 2005 May 1, LOCAL May 2005 1): The result depends on the NetScaler system's timezone. Parameters: <time1> - Lower time value <time2> - Upper time value
<number>.TYPECAST_TIME_AT.DAY	Extracts the day of the month from the current system time and returns the value as a number that corresponds to the day of the month. The returned value ranges from 1 to 31.

Function	Description
<number>.TYPECAST_TIME_AT.EQ(<t>)	Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> is equal to the time value argument <t>. The following examples assume that the current time value is GMT 2005 May 1 10h 15m 30s and that the day is the 1st Sunday of the month of May in 2005. The result of the evaluation is given after each example. EQ(GMT 2005): TRUE EQ(GMT 2005 Dec): FALSE EQ(Local 2005 May): TRUE or FALSE, depending on the time zone. EQ(GMT 10h): TRUE EQ(GMT 10h 30s): TRUE EQ(GMT May 10h): TRUE EQ(GMT Sun): TRUE EQ(GMT May Sun_1): TRUE Parameters: <t> - Time
<number>.TYPECAST_TIME_AT.GE(<t>)	Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> is greater than or equal to the time value argument <t>. The following examples assume that the current time value is GMT 2005 May 1 10h 15m 30s and that the day is the 1st Sunday of the month of May in 2005. The result of the evaluation is given after each example. GE(GMT 2004): TRUE GE(GMT 2005 Jan): TRUE GE(Local 2005 May): TRUE or FALSE, depending on the time zone. GE(GMT 8h): TRUE GE(GMT 30m): FALSE GE(GMT May 10h): TRUE GE(GMT May 10h 0m): TRUE GE(GMT Sun): TRUE GE(GMT May Sun_1): TRUE Parameters: <t> - Time
<number>.TYPECAST_TIME_AT.GT(<t>)	Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> is greater than the time value argument <t>. The following examples assume that the current time value is GMT 2005 May 1 10h 15m 30s and that the day is the 1st Sunday of the month of May in 2005. The result of the evaluation is given after each example. GT(GMT 2004): TRUE GT(GMT 2005 Jan): TRUE GT(Local 2005 May): TRUE or FALSE, depending on the time zone. GT(GMT 8h): TRUE GT(GMT 30m): FALSE GT(GMT May 10h): FALSE GT(GMT May 10h 0m): TRUE GT(GMT Sun): FALSE GT(GMT May Sun_1): FALSE Parameters: <t> - Time
<number>.TYPECAST_TIME_AT.HOURS	Extracts the hour from the current system time and returns the corresponding value as an integer that can range from 0 to 23.

Function	Description
<number>.TYPECAST_TIME_AT.LE(<t>)	Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> is lesser than or equal to the time value argument <t>. The following examples assume that the current time value is GMT 2005 May 1 10h 15m 30s and that the day is the 1st Sunday of the month of May in 2005. The result of the evaluation is given after each example. LE(GMT 2006): TRUE LE(GMT 2005 Dec): TRUE LE(Local 2005 May): TRUE or FALSE, depending on the time zone. LE(GMT 8h): FALSE LE(GMT 30m): TRUE LE(GMT May 10h): TRUE LE(GMT Jun 11h): TRUE LE(GMT Wed): TRUE LE(GMT May Sun_1): TRUE Parameters: <t> - Time
<number>.TYPECAST_TIME_AT.LT(<t>)	Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> is lesser than the time value argument <t>. The following examples assume that the current time value is GMT 2005 May 1 10h 15m 30s and that the day is the 1st Sunday of the month of May in 2005. The result of the evaluation is given after each example. LT(GMT 2006): TRUE LT(GMT 2005 Dec): TRUE LT(Local 2005 May): TRUE or FALSE, depending on the time zone. LT(GMT 8h): FALSE LT(GMT 30m): TRUE LT(GMT May 10h): FALSE LT(GMT Jun 11h): TRUE LT(GMT Wed): TRUE LT(GMT May Sun_1): FALSE Parameters: <t> - Time
<number>.TYPECAST_TIME_AT.MINUTES	Extracts the minute from the current system time and returns the value as an integer that can range from 0 to 59.
<number>.TYPECAST_TIME_AT.MONTH	Extracts the month from the current system time and returns the value as an integer that can range from 1 (January) to 12 (December).
<number>.TYPECAST_TIME_AT.RELATIVE_BOOT	Calculates the number of seconds that have elapsed after the most recent reboot or the number of seconds to the next scheduled reboot, depending on which is closer to the current time, and returns an integer. If the closest boot time is in the past, the integer is negative. If the closest boot time is in the future (scheduled reboot time), the integer is positive.
<number>.TYPECAST_TIME_AT.RELATIVE_NOW	Calculates the number of seconds between the current system time and the specified time, and returns the value as an integer. If the designated time is in the past, the integer is negative. If it is in the future, the integer is positive.
<number>.TYPECAST_TIME_AT.SECONDS	Extracts the seconds from the current system time and returns the value as an integer that can range from 0 to 59.
<number>.TYPECAST_TIME_AT.WEEKDAY	Returns an integer that corresponds to the day of the week; 0 for Sunday and 6 for Saturday.

Function	Description
<number>.TYPECAST_TIME_AT.WITHIN(<time1>, <time2>)	Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> lies within all the ranges defined by lower and upper time value arguments <time1> and <time2>. If an element of time such as the day or the hour is left unspecified in the lower argument, <time1>, then it is assumed to have the lowest value possible for its range. If an element is left unspecified in the upper argument , <time2>, then it is assumed to have the highest value possible for its range. If the year is specified in one of the arguments, then it must be specified in the other argument as well. Following are the ranges for different elements of time: • month: 1-12 • day: 1-31 • weekday: 0-6 • hour: 0-23 • minutes: 0-59 • seconds: 0-59. Each element of time in the lower time value argument defines a range in combination with the corresponding element in the upper time value argument. For the result to be TRUE, each element of time in the time value designated by <number> must lie in the corresponding range specified by the lower and upper arguments. The following examples assume that the current time value is GMT 2005 May 10 10h 15m 30s.and that the day is the second Tuesday of the month. The result of the evaluation is given after each example. WITHIN(GMT 2004, GMT 2006): TRUE WITHIN(GMT 2004 Jan, GMT 2006 Mar): FALSE (May doesn't fall in the Jan-Mar range.) WITHIN(GMT Feb, GMT): TRUE (May falls in the Feb-Dec range.) WITHIN(GMT Sun_1, GMT Sun_3): TRUE (2nd Tuesday lies within 1st Sunday and the 3rd Sunday.) WITHIN(GMT 2005 May 1 10h, GMT May 2005 1 17h): TRUE WITHIN(LOCAL 2005 May 1, LOCAL May 2005 1): The result depends on the NetScaler system's timezone. Parameters: <time1> - Lower time value <time2> - Upper time value
<number>.TYPECAST_TIME_AT.YEAR	Extracts the year from the current system time and returns the value as a four-digit integer.
<prefix>.TYPECAST_NUM_T(<type>)	Casts numeric string data to a signed 32-bit number. The argument <type> can be one of the following: • DECIMAL. Treat the string as a decimal number and cast to a signed 32-bit number. • HEX. Treat the string as a hexadecimal number and cast to a signed 32-bit number. • DECIMAL_PREFIX. Consider the part of the string up to the first occurrence of a character that is not a valid decimal character and cast to a signed 32-bit number. • HEX_PREFIX. Consider the part of the string up to the first occurrence of a character that is not a valid hexadecimal character and cast to a signed 32-bit number. For example, the following policy extracts a numeric portion of a query string, adds 4 to the number, and inserts an HTTP header named Company with the resulting decimal value. add rewrite action myadd_action insert_http_header Company "http.req.url.query.typecast_num_t(decimal).add(4)" add rewrite policy myadd_policy true myadd_action

Function	bind rewrite global myadd_policy 300 END -type RES_DEFAULT Description
	For example, this policy would extract “4444” from the following URL stub: /test/file.html?4444 The action that is associated with the policy would insert the following HTTP response header: Company: 4448\r\n
<prefix>.TYPECAST_NUM_AT	Casts a number of any data type to a number of data type integer.
<prefix>.TYPECAST_DOUBLE_AT	Casts a number of any data type to a number of data type double.
<prefix>.TYPECAST_UNSIGNED_LONG_AT	Casts a number of any data type to a number of data type unsigned long.
<prefix>.TYPECAST_NUM_T(<type>,<default>)	Casts string data to a signed 32-bit number. If the typecasting operation raises an undefined (UNDEF) condition, the function returns the value specified for default. The type argument takes the values specified for TYPECAST_NUM_T(<type>).
<prefix>.TYPECAST_UNSIGNED_LONG_T(<type>)	Casts string data to data of type unsigned long. The argument can be one of the following: • DECIMAL. Treat the string as a decimal number and cast to unsigned long. • HEX. Treat the string as a hexadecimal number and cast to unsigned long. • DECIMAL_PREFIX. Consider the part of the string up to the first occurrence of a character that is not a valid decimal character and cast to unsigned long. • HEX_PREFIX. Consider the part of the string up to the first occurrence of a character that is not a valid hexadecimal character and cast to unsigned long.
<prefix>.TYPECAST_UNSIGNED_LONG_T(<type>, <default>)	Casts string data to data of type unsigned long. If the typecasting operation raises an undefined (UNDEF) condition, the function returns the value specified for default. The type argument takes the values specified for TYPECAST_UNSIGNED_LONG_T(<type>).

Regular Expressions

Sep 02, 2013

When you want to perform string matching operations that are more complex than the operations that you perform with the CONTAINS("<string>") or EQ("<string>") operators, you use regular expressions. The policy infrastructure on the Citrix® NetScaler® appliance includes operators to which you can pass regular expressions as arguments for text matching. The names of the operators that work with regular expressions include the string REGEX. The regular expressions that you pass as arguments must conform to the regular expression syntax that is described in "http://www.pcre.org/pcre.txt." You can learn more about regular expressions at "http://www.regular-expressions.info/quickstart.html" and at "http://www.silverstones.com/thebat/Regex.html."

The target text for an operator that works with regular expressions can be either text or the value of an HTTP header. Following is the format of a default syntax expression that uses a regular expression operator to operate on text:

```
<text>.<regex_operator>(re<delimiter><regex_pattern><delimiter>)
```

The string <text> represents the default syntax expression prefix that identifies a text string in a packet (for example, HTTP.REQ.URL). The string <regex_operator> represents the regular expression operator. The regular expression always begins with the string re. A pair of matching delimiters, represented by <delimiter>, enclose the string <regex_pattern>, which represents the regular expression.

The following example expression checks whether the URL in an HTTP packet contains the string *.jpeg (where * is a wildcard) and returns a Boolean TRUE or FALSE to indicate the result. The regular expression is enclosed within a pair of slash marks (/), which act as delimiters.

```
http.req.url.regex_match(re/*.jpeg/)
```

Regular expression operators can be combined to define or refine the scope of a search. For example, `<text>.AFTER_REGEX(re/regex_pattern1/).BEFORE_REGEX(re/regex_pattern2/)` specifies that the target for string matching is the text between the patterns regex_pattern1 and regex_pattern2. You can use a text operator on the scope that is defined by the regular expression operators. For example, you can use the CONTAINS("<string>") operator to check whether the defined scope contains the string abc:

```
<text>.AFTER_REGEX(re/regex_pattern1/).BEFORE_REGEX(re/regex_pattern2/).CONTAINS("abc")
```

Note: The process of evaluating a regular expression inherently takes more time than that for an operator such as CONTAINS("<string>") or EQ("<string>"), which work with simple string arguments. You should use regular expressions only if your requirement is beyond the scope of other operators.

Basic Characteristics of Regular Expressions

Jul 10, 2013

Following are notable characteristics of regular expressions as defined on the NetScaler appliance:

- A regular expression always begins with the string “re” followed by a pair of delimiting characters (called delimiters) that enclose the regular expression that you want to use.
  For example, re#<regex_pattern># uses the number sign (#) as a delimiter.
- A regular expression cannot exceed 1499 characters.
- Digit matching can be done by using the string \d (a backslash followed by d).
- White space can be represented by using \s (a backslash followed by s).
- A regular expression can contain white spaces.

Following are the differences between the NetScaler syntax and the PCRE syntax:

- The NetScaler does not allow back references in regular expressions.
- You should not use recursive regular expressions.
- The dot meta-character also matches the newline character.
- Unicode is not supported.
- The operation SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option in the regular expression.

Operations for Regular Expressions

Jul 10, 2013

The following table describes the operators that work with regular expressions. The operation performed by a regular expression operator in a given default syntax expression depends on whether the expression prefix identifies text or HTTP headers. Operations that evaluate headers override any text-based operations for all instances of the specified header type. When you use an operator, replace <text> with the default syntax expression prefix that you want to configure for identifying text.

Table 1. Default Syntax Expression Operators That Work with Regular Expressions

Regular Expression Operation	Description
<text>.BEFORE_REGEX(<regular expression>)	Selects the text that precedes the string that matches the <regular expression> argument. If the regular expression does not match any data in the target, the expression returns a text object of length 0. The following expression selects the string "text" from "text/plain". http.res.header("content-type").before_regex(re#/#)
<text>.AFTER_REGEX(<regular expression>)	Selects the text that follows the string that matches the <regular expression> argument. If the regular expression does not match any text in the target, the expression returns a text object of length 0. The following expression extracts "Example" from "myExample": http.req.header("etag").after_regex(re/my/)
<text>.REGEX_SELECT(<regular expression>)	Selects a string that matches the <regular expression> argument. If the regular expression does not match the target, a text object of length 0 is returned. The following example extracts the string "NS-CACHE-9.0: 90" from a Via header: http.req.header("via").regex_select(re!NS-CACHE-\d\.\d:\s*\d{1,3}!)
<text>.REGEX_MATCH(<regular expression>)	Returns TRUE if the target matches a <regular expression> argument of up to 1499 characters. The regular expression must be of the following format: re<delimiter>regular expression< delimiter> Both delimiters must be the same. Additionally, the regular expression must conform to the Perl-compatible (PCRE) regular expression library syntax. For more information, go to http://www.pcre.org/pcre.txt. In particular, see the pcrepattern man page. However note the following:

Regular Expression Operation	Description
	pcrepattern man page. However, note the following: • Back-references are not allowed. • Recursive regular expressions are not recommended. • The dot metacharacter also matches the newline character. • The Unicode character set is not supported. • SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression. The following are examples: http.req.hostname.regex_match(re/[[:alpha:]]+(abc){2,3}/) http.req.url.set_text_mode(urlencoded).regex_match(re#(a*b+c*)#) The following example matches ab and aB: http.req.url.regex_match(re/a(?i)b/) The following example matches ab, aB, Ab and AB: http.req.url.set_text_mode(ignorecase).regex_match(re/ab/) The following example performs a case-insensitive, multiline match in which the dot meta-character also matches a newline character: http.req.body.regex_match(re/(?ixm) (^ab (.*) cd$) /)

Configuring Classic Policies and Expressions

May 25, 2015

Some NetScaler features use classic policies and classic expressions. As with default syntax policies, classic policies can be either global or specific to a virtual server. However, to a certain extent, the configuration method and bind points for classic policies are different from those of default syntax policies. As with default syntax expressions, you can configure named expressions and use a named expression in multiple classic policies.

The following table summarizes NetScaler features that can be configured by using classic policies.

Table 1. Policy Type and Bind Points for Policies in Features That Use Classic Policies

Feature	Virtual Servers	Supported Policies	Policy Bind Points	How You Use the Policies
System features, Authentication	None	Authentication policies	Global	For the Authentication feature, policies contain authentication schemes for different authentication methods. For example, you can configure LDAP and certificate-based authentication schemes.
SSL	None	SSL policies	• Global • Load Balancing virtual server	To determine when to apply an encryption function and add certificate information to clear text. To provide end-to-end security. After a message is decrypted, the SSL feature re-encrypts clear text and uses SSL to communicate with back-end Web servers.
Content Switching (Can use either classic or default syntax policies, but not both)	Content Switching virtual server	Content Switching policies	• Content Switching virtual server • Cache Redirection virtual server	To determine what server or group of servers is responsible for serving responses, based on characteristics of an incoming request. Request characteristics include device type, language, cookies, HTTP method, content type and associated cache server.
Compression	None	HTTP Compression policies	• Global • Content Switching virtual server • Load Balancing virtual server	To determine what type of HTTP traffic is compressed.

Feature	Virtual Servers	Supported Policies	Policy Bind Points	How You Use the Policies
			• SSL Offload virtual server • Service	
Protection features, Filter	None	Content Filtering policies	• Global • Content Switching virtual server • Load Balancing virtual server • SSL Offload virtual server • Service	To configure the behavior of the filter function.
Protection features, SureConnect	None	SureConnect policies	• Load Balancing virtual server • SSL Offload virtual server • Service	To configure the behavior of the SureConnect function.
Protection features, Priority Queuing	None	Priority Queuing policies	• Load Balancing virtual server • SSL Offload virtual server	To configure the behavior of the Priority Queuing function.
HTML Injection	None	HTML Injection Policies	• Global • Load Balancing virtual server • Content Switching virtual server • SSL Offload virtual server	To enable the NetScaler to insert text or scripts into an HTTP response that it serves to a client.
AAA - Traffic Management	None	Authentication, Authorization, Auditing, and Session policies	• Authentication virtual server (authentication, session, and auditing policies) • Load Balancing or Content Switching virtual server (authorization	To configure rules for user access to specific sessions and auditing of user access.

Feature	Virtual Servers	Supported Policies	Policy Bind Points	How You Use the Policies
			and auditing policies) • Global (session and audit policies) • AAA group or user (session, auditing, and authorization policies)	
Cache Redirection	Cache Redirection virtual server	Cache Redirection policies Map policies	Cache Redirection virtual server	To determine whether HTTP responses are served from a cache or an origin server.
Application firewall	None	Application firewall policies	Global	To identify characteristics of traffic and data that should or should not be admitted through the firewall.
NetScaler Gateway	VPN server	Pre-Authentication policies	• AAA Global • VPN vserver	To determine how the NetScaler Gateway performs authentication, authorization, auditing, and other functions, and to define rewrite rules for general Web access using the NetScaler Gateway.
		Authentication policies	• System Global • AAA Global • VPN vserver	
		Auditing policies	• User • User group • VPN vserver	
		Session policies	• VPN Global • User • User Group • VPN vserver	
		Authorization policies	• User • User Group	
		Traffic policies	• VPN Global • User	

Feature	Virtual Servers	Supported Policies	Policy Bind Points	How You Use the Policies
		TCP Compression policies	• User Group • VPN vserver VPN Global	

Configuring a Classic Policy

Oct 29, 2013

You can configure classic policies and classic expressions by using either the configuration utility or the command-line interface. A policy rule cannot exceed 1,499 characters. When configuring the policy rule, you can use named classic expressions. For more information about named expressions, see "Creating Named Classic Expressions." After configuring the policy, you bind it either globally or to a virtual server.

Note that there are small variations in the policy configuration methods for various NetScaler features.

Note: You can embed a classic expression in a default syntax expression by using the syntax SYS.EVAL_CLASSIC_EXPR**(classic_expression)**, specifying the classic_expression as the argument.

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add cmp policy <name> -rule <expression> -action <action>
- show cmp policy [<policyName>]

Example

The following commands first create a compression action and then create a compression policy that applies the action:

```
> add cmp action cmp-act-compress compress
 Done
> show cmp action cmp-act-compress
1)     Name: cmp-act-compress  Compression Type: compress
 Done
> add cmp pol cmp-pol-compress -rule ExpCheckIp -resAction cmp-act-compress
 Done
> show cmp pol cmp-pol-compress
1)     Name: cmp-pol-compress  Rule: ExpCheckIp
       Response action: cmp-act-compress      Hits: 0
 Done
>
```

1. In the navigation pane, expand the feature for which you want to configure a policy and, depending on the feature, do the following:
   - For Content Switching, Cache Redirection, and the application firewall, click Policies.
   - For SSL, click Policies, and then in the details pane, click the Policies tab.
   - For System Authentication, click Authentication, and then in the details pane, click the Policies tab.
   - For Filter, SureConnect, and Priority Queuing, expand Protection Features, select the desired function, and then in the details pane, click the Policies tab.
   - For the NetScaler Gateway, expand NetScaler Gateway, expand Policies, select the desired function, and then in the details pane, click the Policies tab.
2. For most features, click the Add button.
3. In the Create <feature name> Policy dialog box, in the Name* text box, enter a name for the policy.

Note: Note: You must begin a policy name with a letter or underscore. A policy name can consist of 1 to 31 characters, including letters, numbers, hyphen (-), period (.), pound sign (#), space ( ), and underscore (_).

4. For most features, you associate an action or a profile. For example, you may be required to select an action, or, in the case of an NetScaler Gateway or application firewall policy, you select a profile to associate with the policy. A profile is a set of configuration options that operate as a set of actions that are applied when the data being analyzed matches the policy rule.
5. Create an expression that describes the type of data that you want this policy to match.

   Depending on the type of policy you want to create, you can choose a predefined expression, or you can create a new expression. For instructions on how to create an expression for most types of classic policies, see "Configuring a Classic Expression."

   Named expressions are predefined expressions that you can reference by name in a policy rule. For more information about named expressions, see "Creating Named Classic Expressions." For a list of all the default named expressions and a definition of each, see "Expressions Reference."

6. Click Create to create your new policy.
7. Click Close to return to the Policies screen for the type of policy you were creating.

Configuring a Classic Expression

Oct 29, 2013

Classic expressions consist of the following expression elements, listed in hierarchical order:

- **Flow Type.** Specifies whether the connection is incoming or outgoing. The flow type is REQ for incoming connections and RES for outgoing connections.
- **Protocol.** Specifies the protocol, the choices for which are HTTP, SSL, TCP, and IP.
- **Qualifier.** The protocol attribute, which depends on the selected protocol.
- **Operator.** The type of test you want to perform on the connection data. Your choice of operator depends upon the connection information you are testing. If the connection information you are testing is text, you use text operators. If it is a number, you use standard numeric operators.
- **Value.** The string or number against which the connection data element—defined by the flow type, protocol, and qualifier—is tested. The value can be either a literal or an expression. The literal or expression must match the data type of the connection data element.

In a policy, classic expressions can be combined to create more complex expressions using Boolean and comparative operators.

Expression elements are parsed from left to right. The leftmost element is either REQ or RES and designates a request or a response, respectively. Successive terms define a specific connection type and a specific attribute for that connection type. Each term is separated from any preceding or following term by a period. Arguments appear in parentheses and follow the expression element to which they are passed.

The following classic expression fragment returns the client source IP for an incoming connection.

```
REQ.IP.SOURCEIP
```

The example identifies an IP address in a request. The expression element SOURCEIP designates the source IP address. This expression fragment may not be useful by itself. You can use an additional expression element, an operator, to determine whether the returned value meets specific criteria. The following expression tests whether the client IP is in the subnet 200.0.0.0/8 and returns a Boolean TRUE or FALSE:

```
REQ.IP.SOURCEIP == 200.0.0.0 -netmask 255.0.0.0
```

At the command prompt, type the following commands to set the parameters and verify the configuration:

- set appfw policy <name> -rule <expression> -action <action>
- show appfw policy <name>

Example

```
> set appfw policy GenericApplicationSSL_ 'HTTP.REQ.METHOD.EQ("get")' APPFW_DROP
 Done
> show appfw policy GenericApplicationSSL_
      Name: GenericApplicationSSL_   Rule: HTTP.REQ.METHOD.EQ("get")
      Profile: APPFW_DROP    Hits: 0
      Undef Hits: 0
      Policy is bound to following entities
```

```
    1) REQ VSERVER app_u_GenericApplicationSSLPortalPages   PRIORITY : 100
Done
```

This procedure documents the Add Expression dialog box. Depending on the feature for which you are configuring a policy, the route by which you arrive at this dialog box may be different.

1. Perform steps 1-4 in "To create a policy with classic expressions by using the configuration utility."
2. In the Add Expression dialog box, in Expression Type, click the type of expression you want to create.
3. Under Flow Type, click the down arrow and choose a flow type.

   The flow type is typically REQ or RES. The REQ option specifies that the policy applies to all incoming connections or requests. The RES option applies the policy to all outgoing connections or responses.

   For Application Firewall policies, you should leave the expression type set to General Expression, and the flow type set to REQ. The Application Firewall treats each request and response as a single paired entity, so all Application Firewall policies begin with REQ.
4. Under Protocol, click the down arrow and choose the protocol you want for your policy expression. Your choices are:
   - HTTP. Evaluates HTTP requests that are sent to a Web server. For classic expressions, HTTP includes HTTPS requests.
   - SSL. Evaluates SSL data associated with the current connection.
   - TCP. Evaluates the TCP data associated with the current connection.
   - IP. Evaluates the IP addresses associated with the current connection.
5. Under Qualifier, click the down arrow and choose a qualifier for your policy.

   The qualifier defines the type of data to be evaluated. The list of qualifiers that appears depends on which protocol you selected in step 4.

   The following list describes the qualifier choices for the HTTP protocol. For a complete list of protocols and qualifiers, see "Classic Expressions."

   The following choices appear for the HTTP protocol:

   - METHOD. Filters HTTP requests that use a particular HTTP method.
   - URL. Filters HTTP requests for a specific Web page.
   - URLQUERY. Filters HTTP requests that contain a particular query string.
   - VERSION. Filters HTTP requests on the basis of the specified HTTP protocol version.
   - HEADER. Filters on the basis of a particular HTTP header.
   - URLLEN. Filters on the basis of the length of the URL.
   - URLQUERY. Filters on the basis of the query portion of the URL.
   - URLQUERYLEN. Filters on the basis of the length of the query portion of the URL only.
6. Under Operator, click the down arrow and choose the operator for your policy expression. For a complete list of choices see the “Operators” table in "Classic Expressions." Some common operators are:

Operator	Description
==	Matches the specified value exactly or is exactly equal to the specified value.
!=	Does not match the specified value.

Operator	Description
>	Is greater than the specified value.
<	Is less than the specified value.
>=	Is greater than or equal to the specified value.
<=	Is less than or equal to the specified value.
CONTAINS	Contains the specified value.
CONTENTS	Returns the contents of the designated header, URL, or URL query.
EXISTS	The specified header or query exists.
NOTCONTAINS	Does not contain the specified value.
NOTEXISTS	The specified header or query does not exist.

7. If a Value text box appears, type a string or numeric value, as appropriate. For example, chose REQ as the Flow Type, HTTP as the Protocol, and HEADER as the qualifier, and then type the value of the header string in the Value field and the header type for which you want to match the string in the Header Name text box.
8. Click OK.
9. To create a compound expression, click Add. Note that the type of compounding that is done depends on the following choices in the Create Policy dialog box:
   - **Match Any Expression.** The expressions are in a logical OR relationship.
   - **Match All Expressions.** The expressions are in a logical AND relationship.
   - **Tabular Expressions.** Click the AND, OR, and parentheses buttons to control evaluation.
   - **Advanced Free-Form.** Enter the expressions components directly into the Expression field, and click the AND, OR, and parentheses buttons to control evaluation.

Binding a Classic Policy

Oct 29, 2013

Depending on the policy type, you can bind a classic policy either globally or to a virtual server. Policy bind points are described in the table, "Policy Type and Bind Points for Policies in Features That Use Classic Policies."

Note: You can bind a classic policy to multiple bind points.

At the command prompt, type the following commands to set the parameters and verify the configuration:

- bind cmp global <policyName> [-priority <positive_integer>]
- show cmp global

Example

```
> bind cmp global cmp-pol-compress -priority 2
 Done
> show cmp global
1)     Policy Name: cmp-pol-compress    Priority: 2
2)     Policy Name: ns_nocmp_xml_ie    Priority: 8700
3)     Policy Name: ns_nocmp_mozilla_47       Priority: 8800

>
```

At the command prompt, type the following commands to set the parameters and verify the configuration:

- bind lb vserver <name> [<targetVserver>] [-policyName <string> [-priority <positive_integer>]
- show lb vserver<name>

Example

```
> bind lb vserver lbtemp -policyName cmp-pol-compress -priority 1
 Done
> show lb vserver lbtemp
      lbtemp (10.102.29.101:80) - HTTP       Type: ADDRESS
      State: UP
      Last state change was at Tue Oct 27 06:40:38 2009 (+557 ms)
      Time since last state change: 0 days, 02:00:40.330
      Effective State: UP
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Port Rewrite : DISABLED
      No. of Bound Services :  1 (Total)      1 (Active)
      Configured Method: LEASTCONNECTION
      Current Method: Round Robin, Reason: Bound service's state changed to UP
      Group: vserver-grp
      Mode: IP
```

```
        Persistence: COOKIEINSERT (version 0)   Persistence Backup: SOURCEIP   Persistence Mask: 255.255.255.255
        Persistence Timeout: 2 min      Backup Persistence Timeout: 2 min
        Vserver IP and Port insertion: OFF
        Push: DISABLED  Push VServer:
        Push Multi Clients: NO
        Push Label Rule: none
1) http-one (10.102.29.252: 80) - HTTP State: UP       Weight: 1
        Persistence Cookie Value : NSC_wtfswfs-hsq=ffffffff096e03ed45525d5f4f58455e445a4a423660
1)      Policy : cmp-pol-compress Priority:1
 Done
>
```

Note: This procedure documents the Global Bindings dialog box. Depending on the feature for which you want to globally bind a policy, the route by which you arrive at this dialog box may be different.

1. In the navigation pane, expand the feature for which you want to globally bind a classic policy, and then locate the policy that you want to bind globally.

   Note: You cannot globally bind policies for Content Switching, Cache Redirection, SureConnect, Priority Queuing, or NetScaler Gateway Authorization.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind <feature name> Policy(s) to Global dialog box, click Insert Policy.
4. In the Policy Name column, click the name of an existing policy that you want to globally bind, or click New Policy to open the Create <feature name> Policy dialog box.
5. After you have selected the policy or created a new policy, in the Priority column, type the priority value.

   The lower the number, the sooner this policy is applied relative to other policies. For example, a policy assigned a priority of 10 is applied before a policy with a priority of 100. You can use the same priority for different policies. All features that use classic policies implement only the first policy that a connection matches, so policy priority is important for getting the results you intend.

   As a best practice, leave room to add policies by setting priorities with intervals of 50 (or 100) between each policy.
6. Click OK.

1. In the navigation pane, expand the feature that contains the virtual server to which you want to bind a classic policy (for example, if you want to bind a classic policy to a content switching virtual server, expand Traffic Management > Content Switching), and then click Virtual Servers.
2. In the details pane, select the virtual server, and then click Open.
3. In the Configure <Feature> Virtual Server dialog box, on the Policies tab, click the feature icon for the type policy that you want, and then click Insert Policy.
4. In the Policy Name column, click the name of an existing policy that you want to bind to a virtual server, or click A to open the Create <feature name> Policy dialog box.
5. After you have selected the policy or created a new policy, in the Priority column, set the priority.
   If you are binding a policy to a content switching virtual server, in the Target column, select a load balancing virtual server to which traffic that matches the policy should be sent.
6. Click OK.

Viewing Classic Policies

Oct 29, 2013

You can view classic policies by using either the configuration utility or the command line. You can view details such as the policy's name, expression, and bindings.

At the command prompt, type the following commands to view a classic policy and its binding information:

show <featureName> policy [policyName]

Example

```
> show appfw policy GenericApplicationSSL_
      Name: GenericApplicationSSL_   Rule: ns_only_get_adv
      Profile: GenericApplicationSSL_Prof1   Hits: 0
      Undef Hits: 0
      Policy is bound to following entities
      1) REQ VSERVER app_u_GenericApplicationSSLPortalPages   PRIORITY : 100
 Done
```

Note: If you omit the policy name, all policies are listed without the binding details.

1. In the navigation pane, expand the feature whose policies you want to view, (for example, if you want to view application firewall policies, expand Application Firewall), and then click Policies.
2. In the details pane, do one or more of the following:
   - To view details for a specific policy, click the policy. Details appear in the Details area of the configuration pane.
   - To view bindings for a specific policy, click the policy, and then click Show Bindings.
   - To view global bindings, click the policy, and then click Global Bindings. Note that you cannot bind a Content Switching, Cache Redirection, SureConnect, Priority Queuing, or NetScaler Gateway Authorization policy globally.

Creating Named Classic Expressions

Sep 30, 2013

A named classic expression is a classic expression that can be referenced through an assigned name. Often, you need to configure classic expressions that are large or complex and form a part of a larger compound expression. You might also configure classic expressions that you need to use frequently and in multiple compound expressions or classic policies. In these scenarios, you can create the classic expression you want, save it with a name of your choice, and then reference the expression from compound expressions or policies through its name. This saves configuration time and improves the readability of complex compound expressions. Additionally, any modifications to a named classic expression need to be made only once.

Some named expressions are built-in, and a subset of these are read-only. Built-in named expressions are divided into four categories: General, Anti-Virus, Personal Firewall, and Internet Security. General named expressions have a wide variety of uses. For example, from the General category, you can use the expressions ns_true and ns_false to specify a value of TRUE or FALSE, respectively, to be returned for all traffic. You can also identify data of a particular type (for example, HTM, DOC, or GIF files), determine whether caching headers are present, or determine whether the round trip time for packets between a client and the NetScaler is high (over 80 milliseconds).

Anti-Virus, Personal Firewall, and Internet Security named expressions test clients for the presence of a particular program and version and are used primarily in NetScaler Gateway policies.

For descriptions of the built-in named expressions, see "Classic Expressions."

Note: You cannot modify or delete built-in named expressions.

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add expression <name> <value> [-comment <string>] [-clientSecurityMessage <string>]
- show expression [<name> | -type CLASSIC

Example

```
> add expression classic_ne "REQ.HTTP.URL CONTAINS www.example1.com" -comment "Checking the URL for www.example1.com"
 Done
> show expression classic_ne
1)     Name: classic_ne  Expr: REQ.HTTP.URL CONTAINS www.example1.com  Hits: 0 Type : CLASSIC
       Comment: "Checking the URL for www.example1.com"
 Done
>
```

1. In the navigation pane, expand AppExpert, expand Expressions, and then click Classic Expressions.
2. In the details pane, click Add.

   Note: Some of the built-in expressions in the Expressions list are read-only.
3. In the Create Policy Expression dialog box, specify values for the following parameters:

   - Expression Name*—name
   - Client Security Message—clientSecurityMessage
   - Comments—comment

   * A required parameter
4. To create the expression, do one of the following:
   - You can choose inputs to this expression from the Named Expressions drop-down list.
   - You can create a new expression, as described in "To add an expression for a classic policy by using the configuration utility."
5. When you are done, click Close. Verify that your new expression was created by scrolling to the bottom of the Classic Expressions list to view it.

Expressions Reference-Default Syntax Expressions

May 26, 2015

The following table is a listing of default syntax expression prefixes, with cross-references to descriptions of these prefixes and the operators that you can specify for them. Note that some prefixes can work with multiple types of operators. For example, a cookie can be parsed by using operators for text or operators for HTTP headers.

You can use any element in the following tables as a complete expression on its own, or you can use various operators to combine these expression elements with others to form more complex expressions.

Note: The Description column in the following table contains cross-references to additional information about prefix usage and applicable operators for the prefix.

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
CLIENT.ETHER	"Prefixes for MAC Addresses." "Operations for MAC Addresses."
CLIENT.ETHER.[DSTMAC | SRCMAC]	"Prefixes for MAC Addresses." "Operations for MAC Addresses."
CLIENT.INTERFACE	Designates an expression that refers to the ID of the network interface through which the current packet entered the Application Switch. See the other CLIENT.INTERFACE prefix descriptions in this table.
CLIENT.INTERFACE.ID	Extracts the ID of the network interface that received the current packet of data. See the other CLIENT.INTERFACE prefix descriptions in this table.
CLIENT.INTERFACE.ID.EQ("id")	Returns Boolean TRUE if the interface's ID matches the ID that is passed as the argument. For example: CLIENT.INTERFACE.ID.EQ("1/1") See "Booleans in Compound Expressions."

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
CLIENT.INTEREACE.[RXTHROU GHPUT | RXTXTHROUGHPUT | TXTHROUGHPUT]	"Expressions for Numeric Client and Server Data." "Compound Operations for Numbers."
CLIENT.IP	Operates on the IP protocol data associated with the current packet. See the other CLIENT.IP prefixes in this table.
CLIENT.IP.DST	"Prefixes for IPV4 Addresses and IP Subnets." "Operations for IPV4 Addresses." "Compound Operations for Numbers."
CLIENT.IP.SRC	"Prefixes for IPV4 Addresses and IP Subnets." "Operations for IPV4 Addresses." "Compound Operations for Numbers."
CLIENT.IPV6	Operates on IPv6 protocol data. See the other CLIENT.IPV6 prefixes in this table.
CLIENT.IPV6.DST	"Expression Prefixes for IPv6 Addresses." "Operations for IPV6 Prefixes."
CLIENT.IPV6.SRC	"Expression Prefixes for IPv6 Addresses." "Operations for IPV6 Prefixes."
CLIENT.SSL	Operates on the SSL protocol data for the current packet. See the other CLIENT.SSL prefixes in this table.
CLIENT.SSL.CIPHER_BITS	"Prefixes for Numeric Data in SSL Certificates." "Compound Operations for Numbers."
CLIENT.SSL.CIPHER_EXPORTA BLE	"Prefixes for Text-Based SSL and Certificate Data."

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
CLIENT.SSL.CLIENT_CERT	"Booleans in Compound Expressions." "Expressions for SSL Certificates." "Expressions for SSL Certificate Dates."
CLIENT.SSL.IS_SSL	"Prefixes for Text-Based SSL and Certificate Data." "Booleans in Compound Expressions."
CLIENT.SSL.VERSION	"Prefixes for Numeric Data in SSL Certificates." "Compound Operations for Numbers."
CLIENT.TCP	Operates on TCP protocol data. See the other **CLIENT.TCP** prefixes in this table.
CLIENT.TCP.[DSTPORT | MSS | SRCPORT]	"Expressions for TCP, UDP, and VLAN Data." "Compound Operations for Numbers."
CLIENT.TCP.PAYLOAD(integer)	"Expressions for TCP, UDP, and VLAN Data." "Default Syntax Expressions: Evaluating Text."
CLIENT.UDP	Operates on the UDP protocol data associated with the current packet. See the other **CLIENT.UDP** prefixes in this table.
CLIENT.UDP.DNS.DOMAIN	"Expressions for TCP, UDP, and VLAN Data." "Default Syntax Expressions: Evaluating Text."
CLIENT.UDP.DNS.DOMAIN.EQ("hostname")	"Expressions for TCP, UDP, and VLAN Data." "Booleans in Compound Expressions."
CLIENT.UDP.DNS. [IS_AAAAREC | IS_ANYREC | IS_AREC | IS_CNAMEREC | IS_MXREC | IS_NSREC | IS_PTRREC |	"Expressions for TCP, UDP, and VLAN Data."

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
IS_SOAREC | IS_SRVREC]	"Booleans in Compound Expressions."
CLIENT.UDP.[DSTPORT | SRCPORT]	"Expressions for TCP, UDP, and VLAN Data." "Compound Operations for Numbers."
CLIENT.VLAN	Operates on the VLAN through which the current packet entered the NetScaler. See the other CLIENT.VLAN prefixes in this table.
CLIENT.VLAN.ID	"Expressions for TCP, UDP, and VLAN Data." "Compound Operations for Numbers."
HTTP.REQ	Operates on HTTP requests. See the other HTTP.REQ prefixes in this table.
HTTP.REQ.BODY(integer)	"Expression Prefixes for Text in HTTP Requests and Responses." "Basic Operations on Text."
HTTP.REQ.CACHE_CONTROL	"Prefixes for Cache-Control Headers." "Operations for Cache-Control Headers."
HTTP.REQ.CONTENT_LENGTH	"Expressions for Numeric HTTP Payload Data Other Than Dates." "Compound Operations for Numbers."
HTTP.REQ.COOKIE	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.REQ.DATE	"Format of Dates and Times in an Expression." "Expressions for HTTP Request and Response Dates." "Default Syntax Expressions: Evaluating

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
	Text." "Compound Operations for Numbers." "Operations for HTTP Headers."
HTTP.REQ.HEADER("header_name")	"Expression Prefixes for Text in HTTP Requests and Responses." "Prefixes for HTTP Headers." "Operations for HTTP Headers."
HTTP.REQ.FULL_HEADER("header_name")	"Prefixes for HTTP Headers." "Operations for HTTP Headers."
HTTP.REQ.HOSTNAME	"Expression Prefixes for Text in HTTP Requests and Responses."
HTTP.REQ.HOSTNAME.[DOMAIN | Server]	"Expression Prefixes for Text in HTTP Requests and Responses." "Basic Operations on Text."
HTTP.REQ.HOSTNAME.EQ("hostname")	"Expression Prefixes for Text in HTTP Requests and Responses." "Booleans in Compound Expressions." "“Basic Operations on Expression Prefixes”."
HTTP.REQ.HOSTNAME.PORT	"Expression Prefixes for Text in HTTP Requests and Responses." "Compound Operations for Numbers."
HTTP.REQ.IS_VALID	Returns TRUE if the HTTP request is properly formed. See "Booleans in Compound Expressions."
HTTP.REQ.METHOD	"Expression Prefixes for Text in HTTP Requests and Responses." "Basic Operations on Text." "Complex Operations on Text."

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
HTTP.REQ.TRACKING	Returns the HTTP body tracking mechanism. See the descriptions of other HTTP.REQ.TRACKING prefixes in this table.
HTTP.REQ.TRACKING.EQ("tracking_mechanism")	Returns TRUE or FALSE. See "Booleans in Compound Expressions."
HTTP.REQ.URL	Obtains the HTTP URL object from the request and sets the text mode to URLENCODED by default. See "Expression Prefixes for Text in HTTP Requests and Responses."
HTTP.REQ.URL.[CVPN_ENCODE | HOSTNAME | HOSTNAME.DOMAIN | SERVER | PATH | PATH_AND_QUERY | PROTOCOL | QUERY | SUFFIX | VERSION]	"Expression Prefixes for Text in HTTP Requests and Responses." "Basic Operations on Text." "Complex Operations on Text."
HTTP.REQ.URL.HOSTNAME.EQ("hostname")	"Expression Prefixes for Text in HTTP Requests and Responses. "Booleans in Compound Expressions."
HTTP.REQ.URL.HOSTNAME.PORT	"Expression Prefixes for Text in HTTP Requests and Responses. "Compound Operations for Numbers."
HTTP.REQ.URL.PATH.IGNORE_ EMPTY_ELEMENTS	Ignores spaces in the data. See the table "HTTP Expression Prefixes that Return Text."
HTTP.REQ.URL.QUERY.IGNORE _EMPTY_ELEMENTS	Ignores spaces in the data. See the table "HTTP Expression Prefixes that Return Text."
HTTP.REQ.USER.IS_MEMBER_OF	"HTTP Expression Prefixes that Return Text."

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
HTTP.REQ.USER.NAME	"HTTP Expression Prefixes that Return Text."
HTTP.REQ.VERSION	"Expression Prefixes for Text in HTTP Requests and Responses."
HTTP.REQ.VERSION.[MAJOR | MINOR]	Operates on the major or minor HTTP version string. See "Expression Prefixes for Text in HTTP Requests and Responses" and "Compound Operations for Numbers."
HTTP.RES	Operates on HTTP responses.
HTTP.RES.BODY(integer)	"Expression Prefixes for Text in HTTP Requests and Responses." "Basic Operations on Text." "Complex Operations on Text."
HTTP.RES.CACHE_CONTROL	"Prefixes for Cache-Control Headers." "Operations for Cache-Control Headers."
HTTP.RES.CONTENT_LENGTH	"Expression Prefixes for Text in HTTP Requests and Responses." "Operations for HTTP Headers." "Compound Operations for Numbers."
HTTP.RES.DATE	"Format of Dates and Times in an Expression." "Expressions for HTTP Request and Response Dates." "Expression Prefixes for Text in HTTP Requests and Responses." "Compound Operations for Numbers." "Operations for HTTP Headers."
HTTP.RES.HEADER("header_name")	"Expression Prefixes for Text in HTTP

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
HTTP.REQ.FULL_HEADER("header_name")	"Prefixes for HTTP Headers." "Operations for HTTP Headers."
HTTP.REQ.TXID	"Prefixes for HTTP Headers." "Operations for HTTP Headers."
HTTP.RES.IS_VALID	Returns TRUE if the HTTP response is properly formed. See "Booleans in Compound Expressions."
HTTP.RES.SET_COOKIE	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE.COOKIE("name")	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE.COOKI E.[DOMAIN | PATH | PORT]	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE.COOKIE.EXPIRES	Obtains the Expires field of the cookie as a date string. The value of the Expires attribute can be operated upon as a time object. If multiple Expires fields are present, this expression operates on the first one. If the Expires attribute is absent, a string of length zero is returned. Also see:

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text." "Compound Operations for Numbers."
HTTP.RES.SET_COOKIE.COOKIE.PATH.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table "Expression Prefixes for Text in HTTP Requests and Responses."
HTTP.RES.SET_COOKIE.COOKIE.PORT.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table "HTTP Expression Prefixes that Return Text."
HTTP.RES.SET_COOKIE.COOKIE.VERSION	"Prefixes for HTTP Headers." "Compound Operations for Numbers."
HTTP.RES.SET_COOKIE.COOKIE("name",integer)[.PORT | PATH | DOMAIN | VERSION | EXPIRES]	"Prefixes for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE.COOKIE.EXPIRES	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text." "Compound Operations for Numbers."
HTTP.RES.SET_COOKIE.EXISTS("name")	"Prefixes for HTTP Headers." "Booleans in Compound Expressions."
HTTP.RES.SET_COOKIE2	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
HTTP.RES.SET_COOKIE2.COOKIE("name")	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE2.COOKIE.[DOMAIN | PATH | PORT]	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE2.COOKIE.EXPIRES	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text." "Compound Operations for Numbers."
HTTP.RES.SET_COOKIE2.COOKIE.PATH.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table HTTP Expression Prefixes that Return Text."
HTTP.RES.SET_COOKIE2.COOKIE.PORT.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table "HTTP Expression Prefixes that Return Text." See also "Default Syntax Expressions: Evaluating Text" and "Compound Operations for Numbers."
HTTP.RES.SET_COOKIE2.COOKIE("name",integer)[.PORT | PATH | DOMAIN | VERSION | EXPIRES]	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE2.COOKIE.DOMAIN	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
HTTP.RES.SET_COOKIE2.COOKIE.EXPIRES	"Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text." "Compound Operations for Numbers."
HTTP.RES.SET_COOKIE2.COOKIE.VERSION	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text." "Compound Operations for Numbers."
HTTP.RES.SET_COOKIE2.EXISTS("name")	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Booleans in Compound Expressions."
HTTP.RES.STATUS	"Expression Prefixes for Text in HTTP Requests and Responses." "Compound Operations for Numbers."
HTTP.RES.STATUS_MSG	"Expression Prefixes for Text in HTTP Requests and Responses."
HTTP.RES.TRACKING	Returns the HTTP body tracking mechanism. See the descriptions of other HTTP.REQ.TRACKING prefixes in this table.
HTTP.RES.TRACKING.EQ("tracking_method")	Returns TRUE or FALSE. See "Booleans in Compound Expressions."
HTTP.RES.TXID	" Prefixes for HTTP Headers." "Operations for HTTP Headers."
HTTP.RES.VERSION	"Expression Prefixes for Text in HTTP Requests and Responses."

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
HTTP.RES.VERSION.[MAJOR | MINOR]	Operates on the major or minor HTTP version string. See "Expression Prefixes for Text in HTTP Requests and Responses" and "Compound Operations for Numbers."
SERVER	Designates an expression that refers to the server. This is the starting point for access into parameters such as Ether and SSL. See the other SERVER prefixes in this table.
SERVER.ETHER	Operates on the ethernet protocol data associated with the current packet. See the other SERVER prefixes in this table.
SERVER.ETHER.DSTMAC	"Prefixes for MAC Addresses." "Prefixes for MAC Addresses."
SERVER.INTERFACE	Designates an expression that refers to the ID of the network interface that received the current packet of data. See the other SERVER.INTERFACE prefixes in this table.
SERVER.INTERFACE.ID.EQ("id")	Returns Boolean TRUE if the interface's ID matches the ID that is passed as the argument. For example: SERVER.INTERFACE.ID.EQ("LA/1") See "Booleans in Compound Expressions."
SERVER.INTERFACE.[RXTHROUGHPUT | RXTXTHROUGHPUT | TXTHROUGHPUT]	"Expressions for Numeric Client and Server Data." "Compound Operations for Numbers."
SERVER.IP	Operates on the IP protocol data associated with the current packet. See the other SERVER.IP prefixes in this table.

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
SERVER.IP.[DST | SRC]	"Prefixes for IPV4 Addresses and IP Subnets." "Operations for IPV4 Addresses." "Compound Operations for Numbers."
SERVER.IPV6	Operates on IPv6 protocol data. See the other SERVER.IPV6 prefixes in this table.
SERVER.IPV6.DST	"Expression Prefixes for IPv6 Addresses." "Operations for IPV6 Prefixes."
SERVER.IPV6.SRC	"Expression Prefixes for IPv6 Addresses." "Operations for IPV6 Prefixes."
SERVER.TCP	Operates on TCP protocol data. See the other CLIENT.TCP prefixes in this table.
SERVER.TCP.[DSTPORT | MSS | SRCPORT]	"Expressions for TCP, UDP, and VLAN Data." "Compound Operations for Numbers."
SERVER.VLAN	Operates on the VLAN through which the current packet entered the NetScaler. See the other SERVER.VLAN prefixes in this table.
SERVER.VLAN.ID	"Expressions for TCP, UDP, and VLAN Data." "Compound Operations for Numbers."
SYS	Designates an expression that refers to the NetScaler itself, not to the client or server.. See the other SYS prefixes in this table.
SYS.EVAL_CLASSIC_EXPR(cla ssic_expression)	"Classic Expressions in Default Syntax Expressions." "Booleans in Compound Expressions."
SYS.HTTP_CALLOUT(http_callout)	"HTTP Callouts."

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
SYS.CHECK_LIMIT	"Rate Limiting."
SYS.TIME	"Expressions for the NetScaler System Time." "Compound Operations for Numbers."
SYS.TIME.[BETWEEN(time1, time2) | EQ(time) | GE(time) | GT(time) | LE(time) | LT(time) | WITHIN(time1, time2)]	"Expressions for the NetScaler System Time." "Booleans in Compound Expressions." "Compound Operations for Numbers."
SYS.TIME.[DAY | HOURS | MINUTES | MONTH | RELATIVE_BOOT | RELATIVE_NOW SECONDS | WEEKDAY | YEAR]	"Expressions for the NetScaler System Time." "Compound Operations for Numbers."
SYS.RANDOM	Returns a random number between 0 and 1, inclusive of 0 but exclusive of 1.
VPN.BASEURL.[CVPN_DECODE | CVPN_ENCODE | HOSTNAME | HOSTNAME.DOMAIN | HOSTNAME.SERVER | PATH | PATH_AND_QUERY | PROTOCOL | QUERY | SUFFIX]	"Expression Prefixes for VPNs and Clientless VPNs."
VPN.BASEURL.HOSTNAME.EQ("hostname")	"Expression Prefixes for VPNs and Clientless VPNs." "Booleans in Compound Expressions."
VPN.BASEURL.HOSTNAME.PORT	"Expression Prefixes for VPNs and Clientless VPNs." "Compound Operations for Numbers."
VPN.BASEURL.PATH.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table "HTTP Expression Prefixes that Return Text."
VPN.BASEURL.QUERY.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table "HTTP Expression Prefixes that Return Text."

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
VPN.CLIENTLESS_BASEURL VPN.CLIENTLESS_BASEURL. [CVPN_DECODE | CVPN_ENCODE | HOSTNAME | HOSTNAME.DOMAIN | HOSTNAME.SERVER | PATH | PATH_AND_QUERY | PROTOCOL | QUERY | SUFFIX]	"Expression Prefixes for VPNs and Clientless VPNs." "Expression Prefixes for VPNs and Clientless VPNs."
VPN.CLIENTLESS_BASEURL.HOSTNAME.EQ("hostname")	"Expression Prefixes for VPNs and Clientless VPNs." "Booleans in Compound Expressions."
VPN.CLIENTLESS_BASEURL.HOSTNAME.PORT	"Expression Prefixes for VPNs and Clientless VPNs." "Compound Operations for Numbers."
VPN.CLIENTLESS_BASEURL.PATH.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table "HTTP Expression Prefixes that Return Text."
VPN.CLIENTLESS_BASEURL.QUERY.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table "HTTP Expression Prefixes that Return Text."
VPN.CLIENTLESS_HOSTURL	" Expression Prefixes for VPNs and Clientless VPNs."
VPN.CLIENTLESS_HOSTURL.[CVPN_DECODE | CVPN_ENCODE | HOSTNAME | HOSTNAME.DOMAIN | HOSTNAME.SERVER | PATH | PATH_AND_QUERY | PROTOCOL | QUERY | SUFFIX]	"Expression Prefixes for VPNs and Clientless VPNs."
VPN.CLIENTLESS_HOSTURL.HOSTNAME.EQ("hostname")	"Expression Prefixes for VPNs and Clientless VPNs." "Booleans in Compound Expressions.
VPN.CLIENTLESS_HOSTURL.HOSTNAME.PORT	"Expression Prefixes for VPNs and Clientless VPNs." "Compound Operations for Numbers."
VPN.CLIENTLESS_HOSTURL.PATH.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example,

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
VPN.CLIENTLESS_HOSTURL.QUERY.IGNORE_EMPTY_ELEMENTS	see the table "HTTP Expression Prefixes that Return Text." Ignores spaces in the data. For an example, see the table "HTTP Expression Prefixes that Return Text."
VPN.HOST	" Expression Prefixes for VPNs and Clientless VPNs."
VPN.HOST.[DOMAIN | Server]	"Expression Prefixes for VPNs and Clientless VPNs."
VPN.HOST.EQ("hostname")	"Expression Prefixes for VPNs and Clientless VPNs." "Booleans in Compound Expressions.
VPN.HOST.PORT	"Expression Prefixes for VPNs and Clientless VPNs." "Default Syntax Expressions: Evaluating Text." "Compound Operations for Numbers."

Expressions Reference-Classic Expressions

May 25, 2015

The subtopics listed in the table of contents on the left side of your screen contain tables listing the NetScaler classic expressions.

In the table of operators, the result type of each operator is shown at the beginning of the description. In the other tables, the level of each expression is shown at the beginning of the description. For named expressions, each expression is shown as a whole.

This document includes the following details:

Expression Element	Definition
==	Boolean. Returns TRUE if the current expression equals the argument. For text operations, the items being compared must exactly match one another. For numeric operations, the items must evaluate to the same number.
!=	Boolean. Returns TRUE if the current expression does not equal the argument. For text operations, the items being compared must not exactly match one another. For numeric operations, the items must not evaluate to the same number.
CONTAINS	Boolean. Returns TRUE if the current expression contains the string that is designated in the argument.
NOTCONTAINS	Boolean. Returns TRUE if the current expression does not contain the string that is designated in the

Expression Element	Definition
	argument.
CONTENTS	Text. Returns the contents of the current expression.
EXISTS	Boolean. Returns TRUE if the item designated by the current expression exists.
NOTEXISTS	Boolean. Returns TRUE if the item designated by the current expression does not exist.
>	Boolean. Returns TRUE if the current expression evaluates to a number that is greater than the argument.
<	Boolean. Returns TRUE if the current expression evaluates to a number that is less than the argument.
>=	Boolean. Returns TRUE if the current expression evaluates to a number that is greater than or equal to the argument.
<=	Boolean. Returns TRUE if the current expression evaluates to a number that is less than or equal to the argument.

Expression Element	Definition
REQ	Flow Type. Operates on incoming (or request) packets.
REQ.HTTP	Protocol Operates on HTTP requests.

Expression Element	Definition
REQ.HTTP.METHOD	Qualifier Designates the HTTP method.
REQ.HTTP.URL	Qualifier Designates the URL.
REQ.HTTP.URLTOKENS	Qualifier Designates the URL token.
REQ.HTTP.VERSION	Qualifier Designates the HTTP version.
REQ.HTTP.HEADER	Qualifier Designates the HTTP header.
REQ.HTTP.URLLEN	Qualifier Designates the number of characters in the URL.
REQ.HTTP.URLQUERY	Qualifier Designates the query portion of the URL.
REQ.HTTP.URLQUERYLEN	Qualifier Designates the length of the query portion of the URL.
REQ.SSL	Protocol Operates on SSL requests.
REQ.SSL.CLIENT.CERT	Qualifier Designates the entire client certificate.
REQ.SSL.CLIENT.CERT.SUBJECT	Qualifier Designates the client certificate subject.
REQ.SSL.CLIENT.CERT.ISSUER	Qualifier

Expression Element	Definition
	Designates the issuer of the client certificate.
REQ.SSL.CLIENT.CERT.SIGALGO	Qualifier Designates the validation algorithm used by the client certificate.
REQ.SSL.CLIENT.CERT.VERSION	Qualifier Designates the client certificate version.
REQ.SSL.CLIENT.CERT.VALIDFROM	Qualifier Designates the date before which the client certificate is not valid.
REQ.SSL.CLIENT.CERT.VALIDTO	Qualifier Designates the date after which the client certificate is not valid.
REQ.SSL.CLIENT.CERT.SERIALNUMBER	Qualifier Designates the serial number of the client certificate.
REQ.SSL.CLIENT.CIPHER.TYPE	Qualifier Designates the encryption protocol used by the client.
REQ.SSL.CLIENT.CIPHER.BITS	Qualifier Designates the number of bits used by the client's SSL key.
REQ.SSL.CLIENT.SSL.VERSION	Qualifier Designates the SSL version that the client is using.
REQ.TCP	Protocol Operates on incoming TCP packets.
REQ.TCP.SOURCEPORT	Qualifier Designates the source port of the incoming packet.
REQ.TCP.DESTPORT	Qualifier Designates the destination port of the incoming packet.

Expression Element	Definition
REQ.IP	Protocol Operates on incoming IP packets.
REQ.IP.SOURCEIP	Qualifier Designates the source IP of the incoming packet.
REQ.IP.DESTIP	Qualifier Designates the destination IP of the incoming packet.
RES	Flow Type Operates on outgoing (or response) packets.
RES.HTTP	Protocol Operates on HTTP responses.
RES.HTTP.VERSION	Qualifier Designates the HTTP version.
RES.HTTP.HEADER	Qualifier Designates the HTTP header.
RES.HTTP.STATUSCODE	Qualifier Designates the status code of the HTTP response.
RES.TCP	Protocol Operates on incoming TCP packets.
RES.TCP.SOURCEPORT	Qualifier Designates the source port of the outgoing packet.
RES.TCP.DESTPORT	Qualifier Designates the destination port of the outgoing packet.
RES.IP	Protocol

Expression Element	Definition
	Operates on outgoing IP packets.
RES.IP.SOURCEIP	Qualifier Designates the source IP of the outgoing packet. This can be in IPv4 or IPv6 format. For example: add expr exp3 “sourceip == 10.102.32.123 –netmask 255.255.255.0 && destip == 2001::23/120”.
RES.IP.DESTIP	Qualifier Designates the destination IP of the outgoing packet.

Updated: 2013-10-21

The expressions to configure client settings on the Access Gateway with the following software:

- Antivirus
- Personal firewall
- Antispam
- Internet Security

For example usage, see http://support.citrix.com/article/CTX112599.

Actual Expression	Definition
CLIENT.APPLICATION.AV(<NAME>.VERSION == <VERSION>)	Checks whether the client is running the designated anti-virus program and version.
CLIENT.APPLICATION.AV(<NAME>.VERSION != <VERSION>)	Checks whether the client is not running the designated anti-virus program and version.
CLIENT.APPLICATION.PF(<NAME>.VERSION == <VERSION>)	Checks whether the client is running the designated personal firewall program and version.
CLIENT.APPLICATION.PF(<NAME>.VERSION != <VERSION>)	Checks whether the client is not running the designated personal firewall program and version.
CLIENT.APPLICATION.IS(<NAME>.VERSION == <VERSION>)	Checks whether the client is running the designated internet security program and version.

Actual Expression	Definition
CLIENT.APPLICATION.IS(<NAME>.VERSION != <VERSION>)	Checks whether the client is not running the designated internet security program and version.
CLIENT.APPLICATION.AS(<NAME>.VERSION == <VERSION>)	Checks whether the client is running the designated anti-spam program and version.
CLIENT.APPLICATION.AS(<NAME>.VERSION != <VERSION>)	Checks whether the client is not running the designated anti-spam program and version.

Expression	Definition
REQ	Flow Type. Operates on incoming, or request, packets.
REQ.VLANID	Qualifier. Operates on the virtual LAN (VLAN) ID.
REQ.INTERFACE.ID	Qualifier. Operates on the ID of the designated NetScaler interface.
REQ.INTERFACE.RXTHROUGHPUT	Qualifier. Operates on the raw received packet throughput of the designated NetScaler interface.
REQ.INTERFACE.TXTHROUGHPUT	Qualifier. Operates on the raw transmitted packet throughput of the designated NetScaler interface.
REQ.INTERFACE.RXTXTHROUGHPUT	Qualifier. Operates on the raw received and transmitted packet throughput of the designated NetScaler interface.
REQ.ETHER.SOURCEMAC	Qualifier. Operates on the source MAC address.

Expression	Definition
REQ.ETHER.DESTMAC	Qualifier. Operates on the destination MAC address.
RES	Flow Type. Operates on outgoing (or response) packets.
RES.VLANID	Qualifier. Operates on the virtual LAN (VLAN) ID.
RES.INTERFACE.ID	Qualifier. Operates on the ID of the designated NetScaler interface.
RES.INTERFACE.RXTHROUGHPUT	Qualifier. Operates on the raw received packet throughput of the designated NetScaler interface.
RES.INTERFACE.TXTHROUGHPUT	Qualifier. Operates on the raw transmitted packet throughput of the designated NetScaler interface.
RES.INTERFACE.RXTXTHROUGHPUT	Qualifier. Operates on the raw received and transmitted packet throughput of the designated NetScaler interface.
RES.ETHER.SOURCEMAC	Qualifier. Operates on the source MAC address.
RES.ETHER.DESTMAC	Qualifier. Operates on the destination MAC address.

Expression	Definition
TIME	Qualifier.

Expression	Definition
	Operates on the date and time of day, GMT.
DATE	Qualifier. Operates on the date, GMT.
DAYOFWEEK	Operates on the specified day in the week, GMT.

Updated: 2013-09-30

You can specify file system expressions in authorization policies for users and groups who access file sharing through the NetScaler Gateway file transfer utility (the VPN portal). These expressions work with the NetScaler Gateway file transfer authorization feature to control user access to file servers, folders, and files. For example, you can use these expressions in authorization policies to control access based on file type and size.

Expression	Definition
FS.COMMAND	Qualifier. Operates on a file system command. The user can issue multiple commands on a file transfer portal. (For example, ls to list files or mkdir to create a directory). This expression returns the current action that the user is taking. Possible values: Neighbor, login, ls, get, put, rename, mkdir, rmdir, del, logout, any. Following is an example: `Add authorization policy pol1 "fs.command eq login && (fs.user eq administrator || fs.serverip eq 10.102.88.221 –netmask 255.255.255.252)" allow`
FS.USER	Returns the user who is logged on to the file system.
FS.SERVER	Returns the host name of the target server. In the following example, the string `win2k3-88-22` is the server name: `fs.server eq win2k3-88-221`
FS.SERVERIP	Returns the IP address of the target server.
FS.SERVICE	Returns a shared root directory on the file server. If a particular folder is exposed as shared, a user can directly log on to the specified first level folder. This first level folder is called a service. For example, in the path \\hostname\SERVICEX\ETC, SERVICEX is the service. As

Expression	Definition
	another example, if a user accesses the file \\hostname\service1\dir1\file1.doc, FS.SERVICE will return service1. Following is an example: fs.service notcontains New
FS.DOMAIN	Returns the domain name of the target server.
FS.PATH	Returns the complete path of the file being accessed. For example, if a user accesses the file \\hostname\service1\dir1\file1.doc, FS.PATH will return \service\dir1\file1.doc. Following is an example: fs.path notcontains SSL
FS.FILE	Returns the name of the file being accessed. For example, if a user accesses the file \\hostname\service1\dir1\file1.doc, FS.FILE will return file1.doc.
FS.DIR	Returns the directory being accessed. For example, if a user accesses the file \\hostname\service1\dir1\file1.doc, FS.DIR will return \service\dir1.
FS.FILE.ACCESSTIME	Returns the time at which the file was last accessed. This is one of several options that provide you with granular control over actions that the user performs. (See the following entries in this table.)
FS.FILE.CREATETIME	Returns the time at which the file was created.
FS.FILE.MODIFYTIME	Returns the time at which the file was edited.
FS.FILE.WRITETIME	Returns the time of the most recent change in the status of the file.
FS.FILE.SIZE	Returns the file size.
FS.DIR.ACCESSTIME	Returns the time at which the directory was last accessed.
FS.DIR.CREATETIME	Returns the time at which the directory was created.
FS.DIR.MODIFYTIME	Returns the time at which the directory was last modified.
FS.DIR.WRITETIME	Returns the time at which the directory status last changed.

Note: File system expressions do not support regular expressions.

Expression	Definition
ns_all_apps_ncomp	Tests for connections with destination ports between 0 and 65535. In other words, tests for all applications.
ns_cachecontrol_nocache	Tests for connections with an HTTP Cache-Control header that contains the value “no-cache”.
ns_cachecontrol_nostore	Tests for connections with an HTTP Cache-Control header that contains the value “no-store”.
ns_cmpclient	Tests the client to determine if it accepts compressed content.
ns_content_type	Tests for connections with an HTTP Content-Type header that contains “text”.
ns_css	Tests for connections with an HTTP Content-Type header that contains “text/css”.
ns_ext_asp	Tests for HTTP connections to any URL that contains the string .asp—in other words, any connection to an active server page (ASP).
ns_ext_cfm	Tests for HTTP connections to any URL that contains the string .cfm
ns_ext_cgi	Tests for HTTP connections to any URL that contains the string .cgi—in other words, any connection to a common gateway interface (CGI) script.
ns_ext_ex	Tests for HTTP connections to any URL that contains the string .ex
ns_ext_exe	Tests for HTTP connections to any URL that contains the string .exe—in other words, any connection to a executable file.
ns_ext_htx	Tests for HTTP connections to any URL that contains the string .htx
ns_ext_not_gif	Tests for HTTP connections to any URL that does not contain the string .gif—in other words, any connection to a URL that is not a GIF image.
ns_ext_not_jpeg	Tests for HTTP connections to any URL that does not contain the string .jpeg—in other words, any connection to a URL that is not a JPEG image.

Expression	Definition
ns_ext_shtml	Tests for HTTP connections to any URL that contains the string .shtml—in other words, any connection to a server-parsed HTML page.
ns_false	Always returns a value of FALSE.
ns_farclient	Client is in a different geographical region from the NetScaler, as determined by the geographical region in the client's IP address. The following regions are predefined: 192.0.0.0 – 193.255.255.255: Multi-regional 194.0.0.0 – 195.255.255.255: European Union 196.0.0.0 – 197.255.255.255: Other1 198.0.0.0 – 199.255.255.255: North America 200.0.0.0 – 201.255.255.255: Central and South America 202.0.0.0 – 203.255.255.255: Pacific Rim 204.0.0.0 – 205.255.255.255: Other2 206.0.0.0 – 207.255.255.255: Other3
ns_header_cookie	Tests for HTTP connections that contain a Cookie header
ns_header_pragma	Tests for HTTP connections that contain a Pragma: no-cache header.
ns_mozilla_47	Tests for HTTP connections whose User-Agent header contains the string Mozilla/4.7—in other words, any connection from a client using the Mozilla 4.7 Web browser.
ns_msexcel	Tests for HTTP connections whose Content-Type header contains the string application/vnd.msexcel—in other words, any connection transmitting a Microsoft Excel spreadsheet.
ns_msie	Tests for HTTP connections whose User-Agent header contains the string MSIE—in other words, any connection from a client using any version of the Internet Explorer Web browser.
ns_msppt	Tests for HTTP connections whose Content-Type header contains the string application/vnd.ms-powerpoint—in other words, any connection transmitting a Microsoft PowerPoint file.
ns_msword	Tests for HTTP connections whose Content-Type header contains the string

Expression	Definition
	application/vnd.msword—in other words, any connection transmitting a Microsoft Word file.
ns_non_get	Tests for HTTP connections that use any HTTP method except for GET.
ns_slowclient	Returns TRUE if the average round trip time between the client and the NetScaler is more than 80 milliseconds.
ns_true	Returns TRUE for all traffic.
ns_url_path_bin	Tests the URL path to see if it points to the /bin/ directory.
ns_url_path_cgibin	Tests the URL path to see if it points to the CGI-BIN directory.
ns_url_path_exec	Tests the URL path to see if it points to the /exec/ directory.
ns_url_tokens	Tests for the presence of URL tokens.
ns_xmldata	Tests for the presence of XML data.

Expression	Definition
McAfee Virus Scan 11	Tests to determine whether the client is running the latest version of McAfee VirusScan.
McAfee Antivirus	Tests to determine whether the client is running any version of McAfee Antivirus.
Symantec AntiVirus 10 (with Updated Definition File)	Tests to determine whether the client is running the most current version of Symantec AntiVirus.
Symantec AntiVirus 6.0	Tests to determine whether the client is running Symantec AntiVirus 6.0.
Symantec AntiVirus 7.5	Tests to determine whether the client is running Symantec AntiVirus 7.5.

Expression	Definition
TrendMicro OfficeScan 7.3	Tests to determine whether the client is running Trend Microsystems' OfficeScan, version 7.3.
TrendMicro AntiVirus 11.25	Tests to determine whether the client is running Trend Microsystems' AntiVirus, version 11.25.
Sophos Antivirus 4	Tests to determine whether the client is running Sophos Antivirus, version 4.
Sophos Antivirus 5	Tests to determine whether the client is running Sophos Antivirus, version 5.
Sophos Antivirus 6	Tests to determine whether the client is running Sophos Antivirus, version 6.

Expression	Definition
TrendMicro OfficeScan 7.3	Tests to determine whether the client is running Trend Microsystems' OfficeScan, version 7.3.
Sygate Personal Firewall 5.6	Tests to determine whether the client is running the Sygate Personal Firewall, version 5.6.
ZoneAlarm Personal Firewall 6.5	Tests to determine whether the client is running the ZoneAlarm Personal Firewall, version 6.5.

Expression	Definition
Norton Internet Security	Tests to determine whether the client is running any version of Norton Internet Security.

Summary Examples of Default Syntax Expressions and Policies

Jul 10, 2013

The following table provides examples of default syntax expressions that you can use as the basis for your own default syntax expressions.

Table 1. Examples of Default Syntax Expressions

Expression Type	Sample Expressions
Look at the method used in the HTTP request.	http.req.method.eq(post) http.req.method.eq(get)
Check the Cache-Control or Pragma header value in an HTTP request (req) or response (res).	http.req.header("Cache-Control").contains("no-store") http.req.header("Cache-Control").contains("no-cache") http.req.header("Pragma").contains("no-cache") http.res.header("Cache-Control").contains("private") http.res.header("Cache-Control").contains("public") http.res.header("Cache-Control").contains("must-revalidate") http.res.header("Cache-Control").contains("proxy-revalidate") http.res.header("Cache-Control").contains("max-age")
Check for the presence of a header in a request (req) or response (res).	http.req.header("myHeader").exists http.res.header("myHeader").exists
Look for a particular file type in an HTTP request based on the file extension.	http.req.url.contains(".html") http.req.url.contains(".cgi")

Expression Type	Sample Expressions
	http.req.url.contains(".asp") http.req.url.contains(".exe") http.req.url.contains(".cfm") http.req.url.contains(".ex") http.req.url.contains(".shtml") http.req.url.contains(".htx") http.req.url.contains("/cgi-bin/") http.req.url.contains("/exec/") http.req.url.contains("/bin/")
Look for anything that is other than a particular file type in an HTTP request.	http.req.url.contains(".gif").not http.req.url.contains(".jpeg").not
Check the type of file that is being sent in an HTTP response based on the Content-Type header.	http.res.header("Content-Type").contains("text") http.res.header("Content-Type").contains("application/msword") http.res.header("Content-Type").contains("vnd.ms-excel") http.res.header("Content-Type").contains("application/vnd.ms-powerpoint") http.res.header("Content-Type").contains("text/css") http.res.header("Content-Type").contains("text/xml") http.res.header("Content-Type").contains("image/")
Check whether this response contains an expiration header.	http.res.header("Expires").exists
Check for a Set-Cookie header in a response.	http.res.header("Set-Cookie").exists
Check the agent that sent the response.	http.res.header("User-

Expression Type	Sample Expressions
	Agent").contains("Mozilla/4.7") http.res.header("User-Agent").contains("MSIE")
Check if the first 1024 bytes of the body of a request starts with the string “some text”.	http.req.body(1024).contains("some text")

The following table shows examples of policy configurations and bindings for commonly used functions.

Table 2. Examples of Default Syntax Expressions and Policies

Purpose	Example
Use the rewrite feature to replace occurrences of http:// with https:// in the body of an HTTP response.	add rewrite action httpRewriteAction replace_all http.res.body(50000) "\"https://\"" -pattern http:// add rewrite policy demo_rep34312 "http.res.body(50000).contains(\"http://\")" httpRewriteAction
Replace all occurrences of “abcd” with “1234” in the first 1000 bytes of the HTTP body.	add rewrite action abcdTo1234Action replace_all "http.req.body(1000)" "\"1234\"" -pattern abcd add rewrite policy abcdTo1234Policy "http.req.body(1000).contains(\"abcd\")" abcdTo1234Action bind rewrite global abcdTo1234Policy 100 END -type REQ_OVERRIDE
Downgrade the HTTP version to 1.0 to prevent the server from chunking HTTP responses.	add rewrite action downgradeTo1.0Action replace http.req.version.minor "\"0\"" add rewrite policy downgradeTo1.0Policy "http.req.version.minor.eq(1)" downgradeTo1.0Action bind lb vserver myLBVserver -policyName downgradeTo1.0Policy -priority 100 -gotoPriorityExpression NEXT -type REQUEST
Remove references to the HTTP or HTTPS protocol in all responses, so that if the user's connection is HTTP, the link is opened by using HTTP, and if the user's connection is HTTPS, the link is opened by using HTTPS.	add rewrite action remove_http_https replace_all "http.res.body(1000000).set_text_mode(ignorecase)" "\"//\"" -pattern "re~https?://|HTTPS?://~" add rewrite policy remove_http_https true remove_http_https

Purpose	Example
	bind lb vserver test_vsvr -policyName remove_http_https -priority 20 -gotoPriorityExpression NEXT -type RESPONSE
Rewrite instances of http:// to https:// in all URLs. This policy uses the responder functionality.	add responder action httpToHttpsAction redirect "\"https://\" + http.req.hostname + http.req.url" -bypassSafetyCheck YES add responder policy httpToHttpsPolicy "!CLIENT.SSL.IS_SSL" httpToHttpsAction bind responder global httpToHttpsPolicy 1 END -type OVERRIDE
Modify a URL to redirect from URL A to URL B. In this example, “file5.html” is appended to the path. This policy uses the responder functionality.	add responder action appendFile5Action redirect "\"http://\" + http.req.hostname + http.req.url + \"/file5.html\"" -bypassSafetyCheck YES add responder policy appendFile5Policy "http.req.url.eq(\"/testsite\")" appendFile5Action bind responder global appendFile5Policy 1 END -type OVERRIDE
Redirect an external URL to an internal URL.	add rewrite action act_external_to_internal REPLACE 'http.req.hostname.server' '"www.my.host.com"' add rewrite policy pol_external_to_internal 'http.req.hostname.server.eq("www.external.host.com")' act_external_to_internal bind rewrite global pol_external_to_internal 100 END -type REQ_OVERRIDE
Redirect requests to www.example.com that have a query string to www.Webn.example.com. The value n is derived from a server parameter in the query string, for example, server=5.	add rewrite action act_redirect_query REPLACE q#http.req.header("Host").before_str(".example.com")' '"Web" + http.req.url.query.value("server")# add rewrite policy pol_redirect_query q#http.req.header("Host").eq("www.example.com") && http.req.url.contains("?")' act_redirect_query#
Limit the number of requests per second from a URL.	add ns limitSelector ip_limit_selector http.req.url "client.ip.src" add ns limitIdentifier ip_limit_identifier -threshold 4 -timeSlice 3600 -mode request_rate -limitType smooth -

Purpose	Example
	selectorName ip_limit_selector add responder action my_Web_site_redirect_action redirect "\"http://www.mycompany.com/\"" add responder policy ip_limit_responder_policy "http.req.url.contains(\"myasp.asp\") && sys.check_limit(\"ip_limit_identifier\")" my_Web_site_redirect_action bind responder global ip_limit_responder_policy 100 END -type default
Check the client IP address but pass the request without modifying the request.	add rewrite policy check_client_ip_policy 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS || HTTP.REQ.HEADER("client-ip").EXISTS' NOREWRITE bind rewrite global check_client_ip_policy 100 END
Remove old headers from a request and insert an NS-Client header.	add rewrite action del_x_forwarded_for delete_http_header x-forwarded-for add rewrite action del_client_ip delete_http_header client-ip add rewrite policy check_x_forwarded_for_policy 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS' del_x_forwarded_for add rewrite policy check_client_ip_policy 'HTTP.REQ.HEADER("client-ip").EXISTS' del_client_ip add rewrite action insert_ns_client_header insert_http_header NS-Client 'CLIENT.IP.SRC' add rewrite policy insert_ns_client_policy 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS || HTTP.REQ.HEADER("client-ip").EXISTS' insert_ns_client_header bind rewrite global check_x_forwarded_for_policy 100 200 bind rewrite global check_client_ip_policy 200 300 bind rewrite global insert_ns_client_policy 300 END
Remove old headers from a request, insert an NS-Client header, and then modify the “insert header” action so that the value of the inserted header	add rewrite action del_x_forwarded_for delete_http_header x-forwarded-for add rewrite action del_client_ip delete_http_header

Purpose	Example
contains the client IP values from the old headers and the NetScaler appliance's connection IP address. Note that this example repeats the previous example, with the exception of the final set rewrite action.	client_ip add rewrite policy check_x_forwarded_for_policy 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS' del_x_forwarded_for add rewrite policy check_client_ip_policy 'HTTP.REQ.HEADER("client-ip").EXISTS' del_client_ip add rewrite action insert_ns_client_header insert_http_header NS-Client 'CLIENT.IP.SRC' add rewrite policy insert_ns_client_policy 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS || HTTP.REQ.HEADER("client-ip").EXISTS' insert_ns_client_header bind rewrite global check_x_forwarded_for_policy 100 200 bind rewrite global check_client_ip_policy 200 300 bind rewrite global insert_ns_client_policy 300 END set rewrite action insert_ns_client_header -stringBuilderExpr 'HTTP.REQ.HEADER("x-forwarded-for").VALUE(0) + " " + HTTP.REQ.HEADER("client-ip").VALUE(0) + " " + CLIENT.IP.SRC' -bypassSafetyCheck YES

Tutorial Examples of Default Syntax Policies for Rewrite

May 26, 2015

With the rewrite feature, you can modify any part of an HTTP header, and, for responses, you can modify the HTTP body. You can use this feature to accomplish a number of useful tasks, such as removing unnecessary HTTP headers, masking internal URLs, redirecting Web pages, and redirecting queries or keywords.

In the following examples, you first create a rewrite action and a rewrite policy. Then you bind the policy globally.

This document includes the following details:

Updated: 2013-10-29

This example describes how to create a rewrite action and rewrite policy that redirects an external URL to an internal URL. You create an action, called act_external_to_internal, that performs the rewrite. Then you create a policy called pol_external_to_internal.

To redirect an external URL to an internal URL by using the command line interface

- To create the rewrite action, at the command prompt, type:

  add rewrite action act_external_to_internal REPLACE 'http.req.hostname.server' '"host_name_of_internal_Web_server"'

- To create the rewrite policy, at the NetScaler command prompt, type:

  add rewrite policy pol_external_to_internal 'http.req.hostname.server.eq("host_name_of_external_Web_server")' act_external_to_internal

- Bind the policy globally.

To redirect an external URL to an internal URL by using the configuration utility

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, click Add.
3. In the Create Rewrite Action dialog box, enter the name act_external_to_internal.
4. To replace the HTTP server host name with the internal server name, choose Replace from the Type list box.
5. In the Header Name field, type Host.
6. In the String expression for replacement text field, type the internal host name of your Web server.
7. Click Create and then click Close.

8. In the navigation pane, click Policies.
9. In the details pane, click Add.
10. In the Name field, type pol_external_to_internal. This policy will detect connections to the Web server.
11. In the Action drop-down menu, choose the action act_external_to_internal.
12. In the Expression editor, construct the following expression:

    HTTP.REQ.HOSTNAME.SERVER.EQ("www.example.com")
13. Bind your new policy globally.

This example describes how to create a rewrite action and rewrite policy that redirects a query to the proper URL. The example assumes that the request contains a Host header set to **www.example.com** and a GET method with the **string /query.cgi?server=5**. The redirect extracts the domain name from the host header and the number from the query string, and redirects the user's query to the server **Web5.example.com**, where the rest of the user's query is processed.

Note: Although the following commands appears on multiple lines, you should enter them on a single line without line breaks.

To redirect a query to the appropriate URL using the command line

- To create a rewrite action named act_redirect_query that replaces the HTTP server host name with the internal server name, type:

  add rewrite action act_redirect_query REPLACE q#http.req.header("Host").before_str(".example.com")' '"Web" + http.req.url.query.value("server")#

- To create a rewrite policy named pol_redirect_query, type the following commands at the NetScaler command prompt.. This policy detects connections, to the Web server, that contain a query string. Do not apply this policy to connections that do not contain a query string:

  add rewrite policy pol_redirect_query q#http.req.header("Host").eq("www.example.com") && http.req.url.contains("?")' act_redirect_query#

- Bind your new policy globally.

Because this rewrite policy is highly specific and should be run before any other rewrite policies, it is advisable to assign it a high priority. If you assign it a priority of 1, it will be evaluated first.

Updated: 2014-09-17

This example describes how to rewrite Web server responses to find all URLs that begin with the string “http” and replace that string with “https.” You can use this to avoid having to update Web pages after moving a server from HTTP to HTTPS.

To redirect HTTP URLs to HTTPS by using the command line interface

- To create a rewrite action named act_replace_http_with_https that replaces all instances of the string “http” with the string “https,” enter the following command:
  add rewrite action act_replace_http_with_https replace_all 'http.res.body(100)' '"https"' -pattern http

- To create a rewrite policy named pol_replace_http_with_https that detects connections to the Web server, enter the following command:
  add rewrite policy pol_replace_http_with_https TRUE act_replace_http_with_https NOREWRITE
- Bind your new policy globally.

To troubleshoot this rewrite operation, see "Case Study: Rewrite Policy for Converting HTTP Links to HTTPS not Working."

Updated: 2013-09-02

This example explains how to use a Rewrite policy to remove unwanted headers. Specifically, the example shows how to remove the following headers:

- **Accept Encoding header.** Removing the Accept Encoding header from HTTP responses prevents compression of the response.
- **Content Location header.** Removing the Content Location header from HTTP responses prevents your server from providing a hacker with information that might allow a security breach.

To delete headers from HTTP responses, you create a rewrite action and a rewrite policy, and you bind the policy globally.

To create the appropriate Rewrite action by using the command line interface

At the command prompt, type one of the following commands to either remove the Accept Encoding header and prevent response compression or remove the Content Location header:

- add rewrite action "act_remove-ae" delete_http_header "Accept-Encoding"
- add rewrite action "act_remove-cl" delete_http_header "Content-Location"

To create the appropriate Rewrite policy by using the command line interface

At the command prompt, type one of the following commands to remove either the Accept Encoding header or the Content Location header:

- add rewrite policy "pol_remove-ae" true "act_remove-ae"
- add rewrite policy "pol_remove-cl" true "act_remove-cl"

To bind the policy globally by using the command line interface

At the command prompt, type one of the following commands, as appropriate, to globally bind the policy that you have created:

- bind rewrite global pol_remove_ae 100
- bind rewrite global pol_remove_cl 200

This example explains how to use a Rewrite policy to modify connections to your home page and other URLs that end with a forward slash (/) to the default index page for your server, preventing redirects and reducing load on your server.

To modify directory-level HTTP requests to include the default home page by using

the command line

- To create a Rewrite action named action-default-homepage that modifies URLs that end in a forward slash to include the default home page index.html, type:

  add rewrite action "action-default-homepage" replace q#http.req.url.path "/" "/index.html"#

- To create a Rewrite policy named policy-default-homepage that detects connections to your home page and applies your new action, type:

  add rewrite policy "policy-default-homepage" q#http.req.url.path.EQ("/") "action-default-homepage"#

- Globally bind your new policy to put it into effect.

This example explains how to use a Rewrite policy to mask the information in the Server header in HTTP responses from your Web server. That header contains information that hackers can use to compromise your Web site. While masking the header will not prevent a skilled hacker from finding out information about your server, it will make hacking your Web server more difficult and encourage hackers to choose less well protected targets.

To mask the Server header in responses from the command line

1. To create a Rewrite action named act_mask-server that replaces the contents of the Server header with an uninformative string, type:

   add rewrite action "act_mask-server" replace "http.RES.HEADER(\"Server\")" "\"Web Server 1.0\""

2. To create a Rewrite policy named pol_mask-server that detects all connections, type:

   add rewrite policy "pol_mask-server" true "act_mask-server"

3. Globally bind your new policy to put it into effect.

Tutorial Examples of Classic Policies

May 26, 2015

The following examples describe useful examples of classic policy configuration for certain NetScaler features, such as NetScaler Gateway, application firewall, and SSL.

This document includes the following details:

- NetScaler Gateway Policy to Check for a Valid Client Certificate
- Application Firewall Policy to Protect a Shopping Cart Application
- Application Firewall Policy to Protect Scripted Web Pages
- DNS Policy to Drop Packets from Specific IPs
- SSL Policy to Require Valid Client Certificates

Updated: 2014-09-25

The following policies enable the NetScaler to ensure that a client presents a valid certificate before establishing a connection to a company's SSL VPN.

To check for a valid client certificate by using the command line interface

- Add an action to perform client certificate authentication.

  add ssl action act1 -clientAuth DOCLIENTAUTH

- Create an SSL policy to evaluate the client requests.

  add ssl policy pol1 -rule "REQ.HTTP.METHOD == GET" -action act1

- Add a rewrite action to insert the certificate issuer details into the HTTP header of the requests being sent to web server.

  add rewrite action act2 insert_http_header "CertDN" CLIENT.SSL.CLIENT_CERT.SUBJECT

- Create a rewrite policy to insert the certificate issuer details, if the client certificate exists.

  add rewrite policy pol2 "CLIENT.SSL.CLIENT_CERT.EXISTS" act2

  Bind these new policies to the NetScaler VIP to put them into effect.

Updated: 2013-09-02

Shopping cart applications handle sensitive customer information, for example, credit card numbers and expiration dates, and they access back-end database servers. Many shopping cart applications also use legacy CGI scripts, which can contain security flaws that were unknown at the time they were written, but are now known to hackers and identity thieves.

A shopping cart application is particularly vulnerable to the following attacks:

- **Cookie tampering.** If a shopping cart application uses cookies, and does not perform the appropriate checks on the

cookies that users return to the application, an attacker could modify a cookie and gain access to the shopping cart application under another user's credentials. Once logged on as that user, the attacker could obtain sensitive private information about the legitimate user or place orders using the legitimate user's account.

- **SQL injection.** A shopping cart application normally accesses a back-end database server. Unless the application performs the appropriate safety checks on the data users return in the form fields of its Web forms before it passes that information on to the SQL database, an attacker can use a Web form to inject unauthorized SQL commands into the database server. Attackers normally use this type of attack to obtain sensitive private information from the database or modify information in the database.

The following configuration will protect a shopping cart application against these and other attacks.

To protect a shopping cart application by using the configuration utility

1. Navigate to Security > Application Firewall > Profiles, and then click Add.
2. In the Create Application Firewall Profile dialog box, in the Profile Name field, enter shopping_cart.
3. In the Profile Type drop-down list, select Web Application.
4. In the Configure Select Advanced defaults.
5. Click Create and then click Close.
6. In the details view, double-click the new profile.
7. In the Configure Web Application Profile dialog box, configure your new profile as described below:
   1. Click the Checks tab, double-click the Start URL check, and in the Modify Start URL Check dialog box, click the General tab and disable blocking, and enable learning, logging, statistics, and URL closure. Click OK and then click Close.

      Note that if you are using the command line, you configure these settings by typing the following at the prompt, and pressing ENTER:

      set appfw profile shopping_cart -startURLAction LEARN LOG STATS -startURLClosure ON

   2. For the Cookie Consistency check and Form Field Consistency checks, disable blocking, and enable learning, logging, statistics, using a similar method to the Modify Start URL Check configuration.

      If you are using the command line, you configure these settings by typing the following commands:

      set appfw profile shopping_cart -cookieConsistencyAction LEARN LOG STATS

      set appfw profile shopping_cart -fieldConsistencyAction LEARN LOG STATS

   3. For the SQL Injection check, disable blocking, and enable learning, logging, statistics, and transformation of special characters in the Modify SQL Injection Check dialog box, General tab, Check Actions section.

      If you are using the command line, you configure these settings by typing the following at the prompt, and pressing ENTER:

      set appfw profile shopping_cart -SQLInjectionAction LEARN LOG STATS -SQLInjectionTransformSpecialChars ON

   4. For the Credit Card check, disable blocking; enable logging, statistics, and masking of credit card numbers; and enable protection for those credit cards you accept as forms of payment.

      - If you are using the configuration utility, you configure blocking, logging, statistics, and masking (or x-out) in the Modify Credit Card Check dialog box, General tab, Check Actions section. You configure protection for specific credit cards in the Settings tab of the same dialog box.

- If you are using the command line, you configure these settings by typing the following at the prompt, and pressing ENTER:

  set appfw profile shopping_cart -creditCardAction LOG STATS -creditCardXOut ON -creditCard <name> [<name>...]

  For <name> you substitute the name of the credit card you want to protect. For Visa, you substitute VISA. For Master Card, you substitute MasterCard. For American Express, you substitute Amex. For Discover, you substitute Discover. For Diners Club, you substitute DinersClub. For JCB, you substitute JCB.

8. Create a policy named shopping_cart that detects connections to your shopping cart application and applies the shopping_cart profile to those connections.

   To detect connections to the shopping cart, you examine the URL of incoming connections. If you host your shopping cart application on a separate host (a wise measure for security and other reasons), you can simply look for the presence of that host in the URL. If you host your shopping cart in a directory on a host that handles other traffic, as well, you must determine that the connection is going to the appropriate directory and/or HTML page.

   The process for detecting either of these is the same; you create a policy based on the following expression, and substitute the proper host or URL for <string>.

   REQ.HTTP.HEADER URL CONTAINS <string>

   - If you are using the configuration utility, you navigate to the application firewall Policies page, click the Add... button to add a new policy, and follow the policy creation process described in “To create a policy with classic expressions using the configuration utility” beginning on page 201 and following.
   - If you are using the command line, you type the following command at the prompt and press Enter:
     add appfw policy shopping_cart "REQ.HTTP.HEADER URL CONTAINS <string>" shopping_cart

9. Globally bind your new policy to put it into effect.

Because you want to ensure that this policy will match all connections to the shopping cart, and not be preempted by another more general policy, you should assign a high priority to it. If you assign one (1) as the priority, no other policy can preempt this one.

Updated: 2013-11-14

Web pages with embedded scripts, especially legacy JavaScripts, often violate the “same origin rule,” which does not allow scripts to access or modify content on any server but the server where they are located. This security vulnerability is called cross-site scripting. The application firewall Cross-Site Scripting rule normally filters out requests that contain cross-site scripting.

Unfortunately, this can cause Web pages with older JavaScripts to stop functioning, even when your system administrator has checked those scripts and knows that they are safe. The example below explains how to configure the application firewall to allow cross-site scripting in Web pages from trusted sources without disabling this important filter for the rest of your Web sites.

To protect Web pages with cross-site scripting by using the command line interface

- At the command line, to create an advanced profile, type:

add appfw profile pr_xssokay -defaults advanced

- To configure the profile, type:

  set appfw profile pr_xssokay -startURLAction NONE -startURLClosure OFF -cookieConsistencyAction LEARN LOG STATS -fieldConsistencyAction LEARN LOG STATS -crossSiteScriptingAction LEARN LOG STATS$"

- Create a policy that detects connections to your scripted Web pages and applies the pr_xssokay profile, type:

  add appfw policy pol_xssokay "REQ.HTTP.HEADER URL CONTAINS ^\.pl\?$ || REQ.HTTP.HEADER URL CONTAINS ^\.js$" pr_xssokay

- Globally bind the policy.

To protect Web pages with cross-site scripting by using the configuration utility

1. Navigate to Security > Application Firewall > Profiles.
2. In the details view, click Add.
3. In the Create Application Firewall Profile dialog box, create a Web Application profile with advanced defaults and name it pr_xssokay. Click Create and then click Close.
4. In the details view, click the profile, click Open, and in the Configure Web Application Profile dialog box, configure the pr_xssokay profile as shown below.

   Start URL Check: Clear all actions.

   - Cookie Consistency Check: Disable blocking.
   - Form Field Consistency Check: Disable blocking.
   - Cross-Site Scripting Check: Disable blocking.

   This should prevent blocking of legitimate requests involving Web pages with cross-site scripting that you know are nonetheless safe.

5. Click Policies, and then click Add.
6. In the Create Application Firewall Policy dialog box, create a policy that detects connections to your scripted Web pages and applies the pr_xssokay profile:

   - Policy name: pol_xssokay
   - Associated profile: pr_xssokay

   Policy expression: "REQ.HTTP.HEADER URL CONTAINS ^\.pl\?$ || REQ.HTTP.HEADER URL CONTAINS ^\.js$"

7. Globally bind your new policy to put it into effect.

Updated: 2013-09-02

The following example describes how to create a DNS action and DNS policy that detects connections from unwanted IPs or networks, such as those used in a DDOS attack, and drops all packets from those locations. The example shows networks within the IANA reserved IP block 192.168.0.0/16. A hostile network will normally be on publicly routable IPs.

To drop packets from specific IPs by using the command line interface

- To create a DNS policy named pol_ddos_drop that detects connections from hostile networks and drops those packets, type:

  add dns policy pol_ddos_drop 'client.ip.src.in_subnet(192.168.253.128/25) || client.ip.src.in_subnet(192.168.254.32/27)' -drop YES'

  For the example networks in the 192.168.0.0/16 range, you substitute the IP and netmask in ###.###.###.###/## format of each network you want to block. You can include as many networks as you want, separating each CLIENT.IP.SRC.IN_SUBNET(###.###.###.###./##) command with the OR operator.
- Globally bind your new policy to put it into effect.

Updated: 2013-09-02

The following example shows an SSL policy that checks the user's client certificate validity before initiating an SSL connection with a client.

To block connections from users with expired client certificates

- Log on to the command line interface.
  If you are using the GUI, navigate to the SSL Policies page, then in the Data area, click the Actions tab.
- Create an SSL action named act_current_client_cert that requires that users have a current client certificate to establish an SSL connection with the NetScaler.

  add ssl action act_current_client_cert-clientAuth DOCLIENTAUTH -clientCert ENABLED -certHeader "clientCertificateHeader" -clientCertNotBefore ENABLED -certNotBeforeHeader "Mon, 01 Jan 2007 00:00:00 GMT"
- Create an SSL policy named pol_current_client_cert that detects connections to the Web server that contain a query string.

  add ssl policy pol_current_ client_cert 'REQ.SSL.CLIENT.CERT.VALIDFROM >= "Mon, 01 Jan 2007 00:00:00 GMT"' act_block_ssl
- Bind your new policy globally.

  Because this SSL policy should apply to any user's SSL connection unless a more specific SSL policy applies, you may want to assign it a low priority. If you assign it a priority of one thousand (1000), that should ensure that other SSL policies are evaluated first, meaning that this policy will apply only to connections that do not match more specific policy criteria.

Migration of Apache mod_rewrite Rules to the Default Syntax

May 26, 2015

The Apache HTTP Server provides an engine known as mod_rewrite for rewriting HTTP request URLs. If you migrate the mod_rewrite rules from Apache to the NetScaler, you boost back-end server performance. In addition, because the NetScaler typically load balances multiple (sometimes thousands of) Web servers, after migrating the rules to the NetScaler you will have a single point of control for these rules.

Following are examples of mod_rewrite functions, and translations of these functions into Rewrite and Responder policies on the NetScaler.

This document includes the following details:

On some Web servers you can have multiple URLs for a resource. Although the canonical URLs should be used and distributed, other URLs can exist as shortcuts or internal URLs. You can make sure that users see the canonical URL regardless of the URL used to make an initial request.

In the following examples, the URL /~user is converted to /u/user.

Apache mod_rewrite solution for converting a URL

```
RewriteRule   ^/~([^/]+)/?(.*)    /u/$1/$2[R]
```

NetScaler solution for converting a URL

```
add responder action act1 redirect '"/u/"+HTTP.REQ.URL.AFTER_STR("/~")' -bypassSafetyCheck yes
add responder policy pol1 'HTTP.REQ.URL.STARTSWITH("/~") && HTTP.REQ.URL.LENGTH.GT(2)' act1
bind responder global pol1 100
```

You can enforce the use of a particular host name for reaching a site. For example, you can enforce the use of www.example.com instead of example.com.

Apache mod_rewrite solution for enforcing a particular host name for sites running on a port other than 80

```
RewriteCond %{HTTP_HOST}   !^www.example.com
RewriteCond %{HTTP_HOST}   !^$
RewriteCond %{SERVER_PORT} !^80$
RewriteRule ^/(.*)         http://www.example.com:%{SERVER_PORT}/$1 [L,R]
```

Apache mod_rewrite solution for enforcing a particular host name for sites running on port 80

```
RewriteCond %{HTTP_HOST}   !^www.example.com
RewriteCond %{HTTP_HOST}   !^$
RewriteRule ^/(.*)         http://www.example.com/$1 [L,R]
```

NetScaler solution for enforcing a particular host name for sites running on a port other than 80

```
add responder action act1 redirect '"http://www.example.com:"+CLIENT.TCP.DSTPORT+HTTP.REQ.URL' -bypassSafetyCheck yes
add responder policy pol1 '!HTTP.REQ.HOSTNAME.CONTAINS("www.example.com")&&!HTTP.REQ.HOSTNAME.EQ("")&&!HTTP.REQ.HOSTNAME.PORT.EQ(80)&&HTTP.REQ.
bind responder global pol1 100 END
```

NetScaler solution for enforcing a particular host name for sites running on port 80

```
add responder action act1 redirect '"http://www.example.com"+HTTP.REQ.URL' -bypassSafetyCheck yes
add responder policy pol1  '!HTTP.REQ.HOSTNAME.CONTAINS("www.example.com")&&!HTTP.REQ.HOSTNAME.EQ("")&&HTTP.REQ.HOSTNAME.PORT.EQ(80)&&HTTP.REQ.
bind responder global  pol1 100 END
```

Usually the document root of a Web server is based on the URL "/". However, the document root can be any directory. You can redirect traffic to the document root if it changes from the top-level "/" directory to another directory.

In the following examples, you change the document root from / to /e/www. The first two examples simply replace one string with another. The third example is more universal because, along with replacing the root directory, it preserves the rest of the URL (the path and query string), for example, redirecting /example/file.html to /e/www/example/file.html.

Apache mod_rewrite solution for moving the document root

```
RewriteEngine on
RewriteRule   ^/$  /e/www/  [R]
```

NetScaler solution for moving the document root

```
add responder action act1 redirect '"/e/www/"' -bypassSafetyCheck yes
add responder policy pol1 'HTTP.REQ.URL.EQ("/")' act1
bind responder global pol1 100
```

NetScaler solution for moving the document root and appending path information to the request

```
add responder action act1 redirect '"/e/www"+HTTP.REQ.URL' -bypassSafetyCheck yes
add responder policy pol1 '!HTTP.REQ.URL.STARTSWITH("/e/www/")' act1
bind responder global pol1 100 END
```

You may want to redirect requests that are sent to home directories on a Web server to a different Web server. For example, if a new Web server is replacing an old one over time, as you migrate home directories to the new location you need to redirect requests for the migrated home directories to the new Web server.

In the following examples, the host name for the new Web server is newserver.

Apache mod_rewrite solution for redirecting to another Web server

```
RewriteRule   ^/(.+)  http://newserver/$1     [R,L]
```

NetScaler solution for redirecting to another Web server (method 1)

```
add responder  action act1 redirect '"http://newserver"+HTTP.REQ.URL' -bypassSafetyCheck yes
add responder policy pol1 'HTTP.REQ.URL.REGEX_MATCH(re#^/(.+)#)'   act1
bind responder global pol1 100 END
```

NetScaler solution for redirecting to another Web server (method 2)

```
add responder  action act1 redirect '"http://newserver"+HTTP.REQ.URL' -bypassSafetyCheck yes
add responder policy pol1 'HTTP.REQ.URL.LENGTH.GT(1)' act1
bind responder global pol1 100 END
```

Typically, a site with thousands of users has a structured home directory layout. For example, each home directory may reside under a subdirectory that is named using the first character of the user name. For example, the home directory for jsmith (/~jsmith/anypath) might be /home/j/smith/.www/anypath, and the home directory for rvalveti (/~rvalveti/anypath) might be /home/r/rvalveti/.www/anypath.

The following examples redirect requests to the home directory.

Apache mod_rewrite solution for structured home directories

```
RewriteRule   ^/~(([a-z])[a-z0-9]+)(.*)  /home/$2/$1/.www$3
```

NetScaler solution for structured home directories

NetScaler solution for structured home directories

```
add rewrite action act1 replace 'HTTP.REQ.URL'  '"/home/"+ HTTP.REQ.URL.AFTER_STR("~").PREFIX(1)+"/"+ HTTP.REQ.URL.AFTER_STR("~").BEFORE_STR("/")+"/.www"·
add rewrite policy pol1  'HTTP.REQ.URL.PATH.STARTSWITH("/~")' act1
bind rewrite global pol1 100
```

If a URL is not valid, it should be redirected to another Web server. For example, you should redirect to another Web server if a file that is named in a URL does not exist on the server that is named in the URL.

On Apache, you can perform this check using mod_rewrite. On the NetScaler, an HTTP callout can check for a file on a server by running a script on the server. In the following NetScaler examples, a script named file_check.cgi processes the URL and uses this information to check for the presence of the target file on the server. The script returns TRUE or FALSE, and the NetScaler uses the value that the script returns to validate the policy.

In addition to performing the redirection, the NetScaler can add custom headers or, as in the second NetScaler example, it can add text in the response body.

Apache mod_rewrite solution for redirection if a URL is wrong

```
RewriteCond   /your/docroot/%{REQUEST_FILENAME} !-f
RewriteRule   ^(.+)      http://webserverB.com/$1 [R]
```

NetScaler solution for redirection if a URL is wrong (method 1)

```
add HTTPCallout Call
set policy httpCallout Call -IPAddress 10.102.59.101 -port 80 -hostExpr '"10.102.59.101"' -returnType BOOL -ResultExpr 'HTTP.RES.BODY(100).CONTAINS("True")'  -urlSter
add responder action act1 redirect '"http://webserverB.com"+HTTP.REQ.URL' -bypassSafetyCheck yes
add responder policy pol1 '!HTTP.REQ.HEADER("Name").EXISTS  &&  !SYS.HTTP_CALLOUT(call)' act1
bind responder global pol1 100
```

NetScaler solution for redirection if a URL is wrong (method 2)

```
add HTTPCallout Call
set policy httpCallout Call -IPAddress 10.102.59.101 -port 80 -hostExpr '"10.102.59.101"' -returnType BOOL -ResultExpr 'HTTP.RES.BODY(100).CONTAINS("True")'  -urlSter
add responder  action act1 respondwith  '"HTTP/1.1 302 Moved Temporarily\r\nLocation: http://webserverB.com"+HTTP.REQ.URL+"\r\n\r\nHTTPCallout Used"' -bypassSafety
add responder policy pol1 '!HTTP.REQ.HEADER("Name").EXISTS  &&  !SYS.HTTP_CALLOUT(call)' act1
bind responder global pol1 100
```

You can rewrite a URL based on the time. The following examples change a request for example.html to example.day.html or example.night.html, depending on the time of day.

Apache mod_rewrite solution for rewriting a URL based on the time

```
RewriteCond   %{TIME_HOUR}%{TIME_MIN} >0700
RewriteCond   %{TIME_HOUR}%{TIME_MIN} <1900
RewriteRule   ^example\.html$ example.day.html [L]
RewriteRule   ^example\.html$ example.night.html
```

NetScaler solution for rewriting a URL based on the time

```
add rewrite action act1 insert_before 'HTTP.REQ.URL.PATH.SUFFIX(\'.\',0)' '"day."'
add rewrite action act2  insert_before 'HTTP.REQ.URL.PATH.SUFFIX(\'.\',0)' '"night."'
add rewrite  policy pol1 'SYS.TIME.WITHIN(LOCAL 07h 00m,LOCAL 18h 59m)' act1
add rewrite policy pol2 'true'  act2
bind rewrite global pol1 101
bind rewrite global pol2 102
```

If you rename a Web page, you can continue to support the old URL for backward compatibility while preventing users from recognizing that the page was renamed.

In the first two of the following examples, the base directory is /~quux/. The third example accommodates any base directory and the presence of query strings in the URL.

Apache mod_rewrite solution for managing a file name change in a fixed location

```
RewriteEngine  on
RewriteBase    /~quux/
RewriteRule    ^foo\.html$  bar.html
```

NetScaler solution for managing a file name change in a fixed location

```
add rewrite action act1 replace 'HTTP.REQ.URL.AFTER_STR("/~quux").SUBSTR("foo.html")' '"bar.html"'
add rewrite policy pol1 'HTTP.REQ.URL.ENDSWITH("/~quux/foo.html")' act1
bind rewrite global pol1 100
```

NetScaler solution for managing a file name change regardless of the base directory or query strings in the URL

```
add rewrite action act1 replace 'HTTP.REQ.URL.PATH.SUFFIX(\'/\',0)' '"bar.html"'
Add rewrite policy pol1 'HTTP.REQ.URL.PATH.CONTAINS("foo.html")' act1
Bind rewrite global pol1 100
```

If you rename a Web page, you may want to continue to support the old URL for backward compatibility and allow users to see that the page was renamed by changing the URL that is displayed in the browser.

In the first two of the following examples, redirection occurs when the base directory is /~quux/. The third example accommodates any base directory and the presence of query strings in the URL.

Apache mod_rewrite solution for changing the file name and the URL displayed in the browser

```
RewriteEngine on
RewriteBase    /~quux/
RewriteRule    ^old\.html$ new.html  [R]
```

NetScaler solution for changing the file name and the URL displayed in the browser

```
add responder action act1 redirect 'HTTP.REQ.URL.BEFORE_STR("foo.html")+"new.html"' -bypassSafetyCheck yes
add responder policy pol1 'HTTP.REQ.URL.ENDSWITH("/~quux/old.html")' act1
bind responder global pol1 100
```

NetScaler solution for changing the file name and the URL displayed in the browser regardless of the base directory or query strings in the URL

```
add responder action act1 redirect 'HTTP.REQ.URL.PATH.BEFORE_STR("old.html")+"new.html"+HTTP.REQ.URL.AFTER_STR("old.html")' -bypassSafetyCheck yes
add responder policy pol1 'HTTP.REQ.URL.PATH.CONTAINS("old.html")' act1
bind responder global pol1 100
```

To accommodate browser-specific limitations—at least for important top-level pages—it is sometimes necessary to set restrictions on the browser type and version. For example, you might want to set a maximum version for the latest Netscape variants, a minimum version for Lynx browsers, and an average feature version for all others.

The following examples act on the HTTP header "User-Agent", such that if this header begins with "Mozilla/3", the page MyPage.html is rewritten to MyPage.NS.html. If the browser is "Lynx" or "Mozilla" version 1 or 2, the URL becomes MyPage.20.html. All other browsers receive page MyPage.32.html.

Apache mod_rewrite solution for browser-specific settings

```
RewriteCond %{HTTP_USER_AGENT}  ^Mozilla/3.*
RewriteRule ^MyPage\.html$ MyPage.NS.html [L]
RewriteCond %{HTTP_USER_AGENT}  ^Lynx/.* [OR]
RewriteCond %{HTTP_USER_AGENT}  ^Mozilla/[12].*
RewriteRule ^MyPage\.html$ MyPage.20.html [L]
RewriteRule ^fMyPage\.html$ MyPage.32.html [L]
```

NetScaler solution for browser-specific settings

```
add patset pat1
bind patset pat1 Mozilla/1
bind Patset pat1 Mozilla/2
bind patset pat1 Lynx
bind Patset pat1 Mozilla/3
add rewrite action act1 insert_before 'HTTP.REQ.URL.SUFFIX' '"NS."'
add rewrite action act2 insert_before 'HTTP.REQ.URL.SUFFIX' '"20."'
add rewrite action act3 insert_before 'HTTP.REQ.URL.SUFFIX' '"32."'
add rewrite policy pol1 'HTTP.REQ.HEADER("User-Agent").STARTSWITH_INDEX("pat1").EQ(4)' act1
add rewrite policy pol2 'HTTP.REQ.HEADER("User-Agent").STARTSWITH_INDEX("pat1").BETWEEN(1,3)' act2
add rewrite policy pol3 '!HTTP.REQ.HEADER("User-Agent").STARTSWITH_ANY("pat1")' act3
bind rewrite global pol1 101 END
bind rewrite global pol2 102 END
bind rewrite global pol3 103 END
```

You can block a robot from retrieving pages from a specific directory or a set of directories to ease up the traffic to and from these directories. You can restrict access based on the specific location or you can block requests based on information in User-Agent HTTP headers.

In the following examples, the Web location to be blocked is /~quux/foo/arc/, the IP addresses to be blocked are 123.45.67.8 and 123.45.67.9, and the robot's name is NameOfBadRobot.

Apache mod_rewrite solution for blocking a path and a User-Agent header

```
RewriteCond %{HTTP_USER_AGENT}  ^NameOfBadRobot.*
RewriteCond %{REMOTE_ADDR}      ^123\.45\.67\.[8-9]$
RewriteRule ^/~quux/foo/arc/.+  -  [F]
```

NetScaler solution for blocking a path and a User-Agent header

```
add responder action act1 respondwith '"HTTP/1.1 403 Forbidden\r\n\r\n"'
add responder policy pol1 'HTTP.REQ.HEADER("User_Agent").STARTSWITH("NameOfBadRobot")&&CLIENT.IP.SRC.EQ(123.45.67.8)&&CLIENT.IP.SRC.EQ(123.45.67.9) && H
bind responder global pol1 100
```

If you find people frequently going to your server to copy inline graphics for their own use (and generating unnecessary traffic), you may want to restrict the browser's ability to send an HTTP Referer header.

In the following example, the graphics are located in http://www.quux-corp.de/~quux/.

Apache mod_rewrite solution for blocking access to an inline image

```
RewriteCond %{HTTP_REFERER} !^$
RewriteCond %{HTTP_REFERER} !^http://www.quux-corp.de/~quux/.*$
RewriteRule .*\.gif$ - [F]
```

NetScaler solution for blocking access to an inline image

```
add patset pat1
bind patset pat1 .gif
bind patset pat1 .jpeg
add responder action act1 respondwith '"HTTP/1.1 403 Forbidden\r\n\r\n"'
add responder policy pol1 '!HTTP.REQ.HEADER("Referer").EQ("") && !HTTP.REQ.HEADER("Referer").STARTSWITH("http://www.quux-corp.de/~quux/")&&HTTP.REQ.URL.EN
bind responder global pol1 100
```

To prevent users from knowing application or script details on the server side, you can hide file extensions from users. To do this, you may want to support extensionless links. You can achieve this behavior by using rewrite rules to add an extension to all requests, or to selectively add extensions to requests.

The first two of the following examples show adding an extension to all request URLs. In the last example, one of two file extensions is added. Note that in the last example, the mod_rewrite module can easily find the file extension because this module resides on the Web server. In contrast, the NetScaler must invoke an HTTP callout to check the extension of the requested file on the Web server. Based on the callout response, the NetScaler adds the .html or .php extension to the request URL.

Note: In the second NetScaler example, an HTTP callout is used to query a script named file_check.cgi hosted on the server. This script checks whether the argument that is provided in the callout is a valid file name.

Apache mod_rewrite solution for adding a .php extension to all requests

```
RewriteRule ^/?([a-z]+)$ $1.php [L]
```

NetScaler policy for adding a .php extension to all requests

```
add rewrite action act1 insert_after 'HTTP.REQ.URL' '".php"'
add rewrite policy pol1 'HTTP.REQ.URL.PATH.REGEX_MATCH(re#^/([a-z]+)$#)' act1
bind rewrite global pol1 100
```

Apache mod_rewrite solution for adding either .html or .php extensions to requests

```
RewriteCond %{REQUEST_FILENAME}.php -f
RewriteRule ^/?([a-zA-Z0-9]+)$ $1.php [L]
RewriteCond %{REQUEST_FILENAME}.html –f
RewriteRule ^/?([a-zA-Z0-9]+)$ $1.html [L]
```

NetScaler policy for adding either .html or .php extensions to requests

```
add HTTPCallout Call_html
add HTTPCallout Call_php
set policy httpCallout Call_html -IPAddress 10.102.59.101 -port 80 -hostExpr '"10.102.59.101"' -returnType BOOL -ResultExpr 'HTTP.RES.BODY(100).CONTAINS("True")'  -u
set policy httpCallout Call_php -IPAddress 10.102.59.101 -port 80 -hostExpr '"10.102.59.101"' -returnType BOOL -ResultExpr 'HTTP.RES.BODY(100).CONTAINS("True")'  -url
add patset pat1
bind patset pat1 .html
bind patset pat1 .php
bind patset pat1 .asp
bind patset pat1 .cgi
add rewrite  action act1 insert_after 'HTTP.REQ.URL.PATH'  '".html"'
add rewrite  action act2 insert_after "HTTP.REQ.URL.PATH"  '".php"'
add rewrite policy pol1 '!HTTP.REQ.URL.CONTAINS_ANY("pat1") && SYS.HTTP_CALLOUT(Call_html)' act1
add rewrite policy pol2 '!HTTP.REQ.URL.CONTAINS_ANY("pat1") && SYS.HTTP_CALLOUT(Call_php)' act2
bind rewrite global pol1 100 END
bind rewrite global pol2 101 END
```

Suppose that you have a set of working URLs that resemble the following:

/index.php?id=nnnn

To change these URLs to /nnnn and make sure that search engines update their indexes to the new URI format, you need to do the following:

- Redirect the old URIs to the new ones so that search engines update their indexes.
- Rewrite the new URI back to the old one so that the index.php script runs correctly.

To accomplish this, you can insert marker code into the query string (making sure that the marker code is not seen by visitors), and then removing the marker code for the index.php script.

The following examples redirect from an old link to a new format only if a marker is not present in the query string. The link that uses the new format is re-written back to the old format, and a marker is added to the query string.

Apache mod_rewrite solution

```
RewriteCond %{QUERY_STRING} !marker
RewriteCond %{QUERY_STRING} id=([-a-zA-Z0-9_+]+)
RewriteRule ^/?index\.php$ %1? [R,L]
RewriteRule ^/?([-a-zA-Z0-9_+]+)$  index.php?marker&id=$1 [L]
```

NetScaler solution

```
add responder action act_redirect redirect 'HTTP.REQ.URL.PATH.BEFORE_STR("index.php")+HTTP.REQ.URL.QUERY.VALUE("id")' -bypassSafetyCheck yes
add responder policy pol_redirect '!HTTP.REQ.URL.QUERY.CONTAINS("marker")&& HTTP.REQ.URL.QUERY.VALUE("id").REGEX_MATCH(re/[-a-zA-Z0-9_+]+/) && HTTP.REQ.U
bind responder global pol_redirect 100 END
add rewrite action act1 replace 'HTTP.REQ.URL.PATH.SUFFIX(\'/\',0)' '"index.phpmarker&id="+HTTP.REQ.URL.PATH.SUFFIX(\'/\',0)' -bypassSafetyCheck yes
add rewrite policy pol1 '!HTTP.REQ.URL.QUERY.CONTAINS("marker")'  act1
bind rewrite global pol1 100 END
```

To make sure that only secure servers are used for selected Web pages, you can use the following Apache mod_rewrite code or NetScaler Responder policies.

Apache mod_rewrite solution

```
RewriteCond %{SERVER_PORT} !^443$
RewriteRule ^/?(page1|page2|page3|page4|page5)$  https://www.example.com/%1 [R,L]
```

NetScaler solution using regular expressions

```
add responder action res_redirect redirect  '"https://www.example.com"+HTTP.REQ.URL' -bypassSafetyCheck yes
add responder policy pol_redirect '!CLIENT.TCP.DSTPORT.EQ(443)&&HTTP.REQ.URL.REGEX_MATCH(re/page[1-5]/)'  res_redirect
bind responder global pol_redirect 100 END
```

NetScaler solution using pattern sets

```
add patset pat1
bind patset pat1 page1
bind patset pat1 page2
bind patset pat1 page3
bind patset pat1 page4
bind patset pat1 page5
```

```
add responder action res_redirect redirect  '"https://www.example.com"+HTTP.REQ.URL' -bypassSafetyCheck yes
add responder policy pol_redirect '!CLIENT.TCP.DSTPORT.EQ(443)&&HTTP.REQ.URL.CONTAINS_ANY("pat1")'  res_redirect
bind responder global pol_redirect 100 END
```

Rate Limiting

Aug 12, 2014

The rate limiting feature enables you to define the maximum load for a given network entity or virtual entity on the Citrix NetScaler appliance. The feature enables you to configure the appliance to monitor the rate of traffic associated with the entity and take preventive action, in real time, based on the traffic rate. This feature is particularly useful when the network is under attack from a hostile client that is sending the appliance a flood of requests. You can mitigate the risks that affect the availability of resources to clients, and you can improve the reliability of the network and the resources that the appliance manages.

You can monitor and control the rate of traffic that is associated with virtual and user-defined entities, including virtual servers, URLs, domains, and combinations of URLs and domains. You can throttle the rate of traffic if it is too high, base information caching on the traffic rate, and redirect traffic to a given load balancing virtual server if the traffic rate exceeds a predefined limit. You can apply rate-based monitoring to HTTP, TCP, and DNS requests.

To monitor the rate of traffic for a given scenario, you configure a *rate limit identifier*. A rate limit identifier specifies numeric thresholds such as the maximum number of requests or connections (of a particular type) that are permitted in a specified time period called a *time slice*.

Optionally, you can configure filters, known as *stream selectors*, and associate them with rate limit identifiers when you configure the identifiers. After you configure the optional stream selector and the limit identifier, you must invoke the limit identifier from a default syntax policy. You can invoke identifiers from any feature in which the identifier may be useful, including rewrite, responder, DNS, and integrated caching.

You can globally enable and disable SNMP traps for rate limit identifiers. Each trap contains cumulative data for the rate limit identifier's configured data collection interval (time slice), unless you specified multiple traps to be generated per time slice. For more information about configuring SNMP traps and managers, see "SNMP."

Configuring a Stream Selector

Jul 30, 2014

A traffic stream selector is an optional filter for identifying an entity for which you want to throttle access. The selector is applied to a request or a response and selects data points (keys) that can be analyzed by a rate stream identifier. These data points can be based on almost any characteristic of the traffic, including IP addresses, subnets, domain names, TCP or UDP identifiers, and particular strings or extensions in URLs.

A stream selector consists of individual default syntax expressions called selectlets. Each selectlet is a non-compound default syntax expression. A traffic stream selector can contain up to five non-compound expressions called selectlets. Each selectlet is considered to be in an AND relationship with the other expressions. Following are some examples of selectlets:

```
http.req.url
http.res.body(1000>after_str(\"car_model\").before_str(\"made_in\")"
"client.ip.src.subnet(24)"
```

The order in which you specify parameters is significant. For example, if you configure an IP address and a domain (in that order) in one selector, and then specify the domain and the IP address (in the reverse order) in another selector, the NetScaler considers these values to be unique. This can lead to the same transaction being counted twice. Also, if multiple policies invoke the same selector, the NetScaler, again, can count the same transaction more than once.

Note: If you modify an expression in a stream selector, you may get an error if any policy that invokes it is bound to a new policy label or bind point. For example, suppose that you create a stream selector named myStreamSelector1, invoke it from myLimitID1, and invoke the identifier from a DNS policy named dnsRateLimit1. If you change the expression in myStreamSelector1, you might receive an error when binding dnsRateLimit1 to a new bind point. The workaround is to modify these expressions before creating the policies that invoke them.

At the command prompt, type:

add stream selector <name> <rule> ...

Example

```
> add stream selector myStreamSel HTTP.REQ.URL CLIENT.IP.SRC
```

Navigate to AppExpert > Rate Limiting > Selectors, click Add and specify the relevant details.

Configuring a Traffic Rate Limit Identifier

Sep 23, 2014

A rate limit identifier returns a Boolean TRUE if the amount of traffic exceeds a numeric limit within a particular time interval. The rate limit identifier definition can optionally include a stream selector. When you include a limit identifier in the compound default syntax expression in a policy rule, if you do not specify a stream selector, the limit identifier is applied to all the requests or responses that are identified by the compound expression.

Note: The maximum length for storing string results of selectors (for example, HTTP.REQ.URL) is 60 characters. If the string (for example, URL) is 1000 characters long, of which 50 characters are enough to uniquely identify a string, use an expression to extract only the required 50 characters.

At the command prompt, type:

add ns limitIdentifier <limitIdentifier> -threshold <positive_integer> -timeSlice <positive_integer> -mode <mode> -limitType (BURSTY | SMOOTH) -selectorName <string> -maxBandwidth <positive_integer> -trapsInTimeSlice <positive_integer>

Example

Configuring traffic rate limit identifier in BURSTY mode:

```
> add ns limitIdentifier 100_request_limit -threshold 100 -timeSlice 1000 -mode REQUEST_RATE -limitType BURSTY -selectorName limit_100_requests_selector -trapsInTime
```

Configuring traffic rate limit identifier in SMOOTH mode:

```
> add ns limitidentifier limit_req -mode request_rate -limitType smooth -timeslice 1000 -Threshold 2000 -trapsInTimeSlice 200
```

Navigate to AppExpert > Rate Limiting > Limit Identifiers, click Add and specify the relevant details.

Configuring and Binding a Traffic Rate Policy

Aug 30, 2013

You implement rate-based application behavior by configuring a policy in an appropriate NetScaler feature. The feature must support default syntax policies. The policy expression must contain the following expression prefix to enable the feature to analyze the traffic rate:

```
sys.check_limit(<limit_identifier>)
```

Where `limit_identifier` is the name of a limit identifier.

The policy expression must be a compound expression that contains at least two components:

- An expression that identifies traffic to which the rate limit identifier is applied. For example: `http.req.url.contains("my_aspx.aspx")`.
- An expression that identifies a rate limit identifier, for example, `sys.check_limit("my_limit_identifier")`. This must be the last expression in the policy expression.

At the command prompt, type the following command to configure a rate-based policy and verify the configuration:

add cache | dns | rewrite | responder policy <policy_name> -rule expression && sys.check_limit("<LimitIdentifierName>") [<feature-specific information>]
Following is a complete example of a rate-based policy rule. Note that this example assumes that you have configured the responder action, send_direct_url, that is associated with the policy. Note that the sys.check_limit parameter must be the last element of the policy expression:

```
add responder policy responder_threshold_policy "http.req.url.contains(\"myindex.html\") && sys.check_limit(\"my_limit_identifier\")" send_direct_url
```

For information about binding a policy globally or to a virtual server, see "Binding Default Syntax Policies."

1. In the navigation pane, expand the feature in which you want to configure a policy (for example, Integrated Caching, Rewrite, or Responder), and then click Policies.
2. In the details pane, click Add. In Name, enter a unique name for the policy.
3. Under Expression, enter the policy rule, and make sure that you include the `sys.check_limit` parameter as the final component of the expression. For example:

   ```
   http.req.url.contains("my_aspx.aspx") && sys.check_limit("my_limit_identifier")
   ```
4. Enter feature-specific information about the policy.

   For example, you may be required to associate the policy with an action or a profile. For more information, see the feature-specific documentation.
5. Click Create, and then click Close.
6. Click Save.

Viewing the Traffic Rate

Aug 30, 2013

If traffic through one or more virtual servers matches a rate-based policy, you can view the rate of this traffic. The rate statistics are maintained in the limit identifier that you named in the rule for the rate-based policy. If more than one policy uses the same limit identifier, you can view the traffic rate as defined by hits to all of the policies that use the particular limit identifier.

At the command prompt, type the following command to view the traffic rate:

show ns limitSessions <limitIdentifier>

Example

```
sh limitsession myLimitSession
```

1. Navigate to AppExpert > Rate Limiting > Limit Identifiers.
2. Select a limit identifier whose traffic rate you want to view.
3. Click the Show Sessions button. If traffic through one or more virtual servers has matched a rate limiting policy that uses this limit identifier (and the hits are within the configured time slice for this identifier), the Session Details dialog box appears. Otherwise, you receive a "No session exists" message.

Testing a Rate-Based Policy

Oct 29, 2013

To test a rate-based policy, you can send traffic to any virtual server to which a rate-based policy is bound.

1. Configure a stream selector (optional) and a rate limit identifier (required). For example:

   ```
   add stream selector sel_subnet Q.URL "CLIENT.IP.SRC.SUBNET(24)"
   add ns limitIdentifier k_subnet -Threshold 4 -timeSlice 3600 -mode REQUEST_RATE  -limittype smooth  -selectorName sel_subnet  -trapsInTimeSlice 8
   ```
2. Configure the action that you want to associate with the policy that uses the rate limit identifier. For example:

   ```
   add responder action resp_redirect redirect "\"http://response_site.com/\""
   ```
3. Configure a policy that uses the sys.check_limit expression prefix to call the rate limit identifier. For example, the policy can apply a rate limit identifier to all requests arriving from a particular subnet, as follows:

   ```
   add responder policy resp_subnet "SYS.CHECK_LIMIT(\"k_subnet\")" resp_redirect
   ```
4. Bind the policy globally or to a virtual server. For example:

   ```
   bind responder global resp_subnet 6 END -type DEFAULT
   ```
5. In a browser address bar, send a test HTTP query to a virtual server. For example:

   ```
   http://<IP of a vserver>/testsite/test.txt
   ```
6. At the NetScaler command prompt, type:

   ```
   show ns limitSessions <limitIdentifier>
   ```

   Example

   ```
   > sh limitsession k_subnet
   1)     Time Remaining:      98 secs  Hits: 2                  Action Taken: 0
         Total Hash:    1718618  Hash String: /test.txt
         IPs gathered:
               1) 10.217.253.0
         Active Transactions: 0
    Done
   >
   ```
7. Repeat the query and check the limit identifier statistics again to verify that the statistics are being updated correctly.

Examples of Rate-Based Policies

Apr 18, 2013

The following table shows examples of rate-based policies.

Table 1. Examples of Rate-Based Policies

Purpose	Example
Limit the number of requests per second from a URL	add stream selector ipStreamSelector http.req.url "client.ip.src" add ns limitIdentifier ipLimitIdentifier -threshold 4 -timeSlice 1000 -mode request_rate -limitType smooth -selectorName ipStreamSelector add responder action myWebSiteRedirectAction redirect "\"http://www.mycompany.com/\"" add responder policy ipLimitResponderPolicy "http.req.url.contains(\"myasp.asp\") && sys.check_limit(\"ipLimitIdentifier\")" myWebSiteRedirectAction bind responder global ipLimitResponderPolicy 100 END -type default
Cache a response if the request URL rate exceeds 5 per 20000 milliseconds	add stream selector cacheStreamSelector http.req.url add ns limitidentifier cacheRateLimitIdentifier -threshold 5 -timeSlice 2000 -selectorName cacheStreamSelector add cache policy cacheRateLimitPolicy -rule "http.req.method.eq(get) && sys.check_limit(\"cacheRateLimitIdentifier\")" -action cache bind cache global cacheRateLimitPolicy -priority 10
Drop a connection on the basis of cookies received in requests from www.yourcompany.com if the requests exceed the rate limit	add stream selector reqCookieStreamSelector "http.req.cookie .value(\"mycookie\")" "client.ip.src.subnet(24)" add ns limitIdentifier myLimitIdentifier -Threshold 2 -timeSlice 3000 -selectorName reqCookieStreamSelector add responder action sendRedirectUrl redirect '\"http://www.mycompany.com\" + http.req.url' -bypassSafetyCheck YES add responder policy rateLimitCookiePolicy "http.req.url.contains(\"www.yourcompany.com\") && sys.check_limit(\"myLimitIdentifier\")" sendRedirectUrl
Drop a DNS packet if the requests from a particular client IP address and DNS domain exceed the rate limit	add stream selector dropDNSStreamSelector client.udp.dns.domain client.ip.src add ns limitIdentifier dropDNSRateIdentifier -timeslice 20000 -mode request_rate -selectorName dropDNSStreamSelector -maxBandwidth 1 -trapsintimeslice 20 add dns policy dnsDropOnClientRatePolicy "sys.check_limit (\"dropDNSRateIdentifier\")" -drop yes

limit	
Purpose	Example
Limit the number of HTTP requests that arrive from the same subnet (with a subnet mask of 32) and that have the same destination IP address.	add stream selector ipv6_sel "CLIENT.IPv6.src.subnet(32)" CLIENT.IPv6.dst Q.URL add ns limitIdentifier ipv6_id -imeSlice 20000 -selectorName ipv6_sel add lb vserver ipv6_vip HTTP 3ffe::209 80 -persistenceType NONE -cltTimeout 180 add responder action redirect_page redirect "\"http://redirectpage.com/\"" add responder policy ipv6_resp_pol "SYS.CHECK_LIMIT(\"ipv6_id\")" redirect_page bind responder global ipv6_resp_pol 5 END -type DEFAULT

Sample Use Cases for Rate-Based Policies

Dec 10, 2013

The following scenarios describe two uses of rate-based policies in global server load balancing (GSLB):

- The first scenario describes the use of a rate-based policy that sends traffic to a new data center if the rate of DNS requests exceed 1000 per second.
- In the second scenario, if more than five DNS requests arrive for a local DNS (LDNS) client within a particular period, the additional requests are dropped.

In this scenario, you configure a proximity-based load balancing method, and a rate-limiting policy that identifies DNS requests for a particular region. In the rate-limiting policy, you specify a threshold of 1000 DNS requests per second. A DNS policy applies the rate limiting policy to DNS requests for the region "Europe.GB.17.London.UK-East.ISP-UK." In the DNS policy, DNS requests that exceed the rate limiting threshold, starting with request 1001 and continuing to the end of the one-second interval, are to be forwarded to the IP addresses that are associated with the region "North America.US.TX.Dallas.US-East.ISP-US."

The following configuration demonstrates this scenario:

```
add stream selector DNSSelector1 client.udp.dns.domain
add ns limitIdentifier DNSLimitIdentifier1 -threshold 5 -timeSlice 1000 -selectorName DNSSelector1
add dns policy DNSLimitPolicy1 "client.ip.src.matches_location(\"Europe.GB.17.London.*.*\") &&
sys.check_limit(\"DNSLimitIdentifier1\")" -preferredLocation "North America.US.TX.Dallas.*.*"
bind dns global DNSLimitPolicy1 5
```

In the following example of global server load balancing, you configure a rate limiting policy that permits a maximum of five DNS requests in a particular interval, per domain, to be directed to an LDNS client for resolution. Any requests that exceed this rate are dropped. This type of policy can help protect the NetScaler from resource exploitation. For example, in this scenario, if the time to live (TTL) for a connection is five seconds, this policy prevents the LDNS from requerying a domain. Instead, it uses data that is cached on the NetScaler.

```
add stream selector LDNSSelector1 client.udp.dns.domain client.ip.src
add ns limitIdentifier LDNSLimitIdentifier1 -threshold 5 -timeSlice 1000 -selectorName LDNSSelector1
add dns policy LDNSPolicy1 "client.udp.dns.domain.contains(\".\") && sys.check_limit(\"LDNSLimitIdentifier1\")" -drop YES
bind dns global LDNSPolicy1 6

Responder

Mar 20, 2012

Today's complex Web configurations often require different responses to HTTP requests that appear, on the surface, to be similar. When users request a Web site's home page, you may want to provide a different home page depending on where each user is located, which browser the user is using, or which language(s) the browser accepts and the order of preference. You might want to break the connection immediately if the request is coming from an IP range that has been generating DDoS attacks or initiating hacking attempts.

With the Responder feature, responses can be based on who sends the request, where it is sent from, and other criteria with security and system management implications. The feature is simple and quick to use. By avoiding the invocation of more complex features, it reduces CPU cycles and time spent in handling requests that do not require complex processing.

For handling sensitive data such as financial information, if you want to ensure that the client uses a secure connection to browse a site, you can redirect the request to secure connection by using https:// instead of http://.

To use the Responder feature, do the following;

- Enable the Responder feature on the NetScaler.
- Configure responder actions. The action can be to generate a custom response, redirect a request to a different Web page, or reset a connection.
- Configure responder policies. The policy determines the requests (traffic) on which an action has to be taken.
- Bind each policy to a bind point put it into effect. A bind point refers to an entity at which NetScaler examines the traffic to see if it matches a policy. For example, a bind point can be a load balancing virtual server.

You can specify a default action for requests that do not match any policy, and you can bypass the safety check for actions that would otherwise generate error messages.

The Rewrite feature of NetScaler helps in rewriting some information in the requests or responses handled by NetScaler. The following section shows some differences between the two features.

The main difference between the rewrite feature and the responder feature is as follows:

Responder cannot be used for response or server-based expressions. Responder can be used only for the following scenarios depending on client parameters:

- Redirecting a http request to new Web sites or Web pages
- Responding with some custom response
- Dropping or resetting a connection at request level

In case of a responder policy, the NetScaler examines the request from the client, takes action according to the applicable policies, sends the response to the client, and closes the connection with the client.

In case of a rewrite policy, the NetScaler examines the request from the client or response from the server, takes action according to the applicable policies, and forwards the traffic to the client or the server.

In general, it is recommended to use responder if you want the NetScaler to reset or drop a connection based on a client or request-based parameter. Use responder to redirect traffic, or respond with custom messages. Use rewrite for manipulating data on HTTP requests and responses.

Enabling the Responder Feature

Oct 29, 2013

To use the Responder feature, you must first enable it.

At the command prompt, type the following commands to enable the responder feature and verify the configuration:

- enable ns feature<feature>
- show ns feature

Example

```
enable ns feature Responder
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)    Web Logging              WL              ON
 2)    Surge Protection          SP              ON
 .
 .
 .
 22)    Responder                RESPONDER          ON
 23)   HTML Injection            HTMLInjection      ON
 24)   NetScaler Push            push               OFF
 Done
>
```

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change advanced features.
3. In the Configure Advanced Features dialog box, select the Responder check box, and then click OK.
4. In the Enable/Disable Feature(s)? dialog box, click YES. A message appears in the status bar, stating that the feature has been enabled.

Configuring a Responder Action

Sep 08, 2016

After enabling the responder feature, you must configure one or more actions for handling requests. The responder supports the following types of actions:

Respond with

Sends the response defined by the Target expression without forwarding the request to a web server. (The NetScaler appliance substitutes for and acts as a web server.) Use this type of action to manually define a simple HTML-based response. Normally the text for a Respond with action consists of a web server error code and brief HTML page.

Respond with SQL OK

Sends the designated SQL OK response defined by the Target expression. Use this type of action to send an SQL OK response to an SQL query.

Respond with SQL Error

Sends the designated SQL Error response defined by the Target expression. Use this type of action to send an SQL Error response to an SQL query.

Respond with HTML page

Sends the designated HTML page as the response. You can choose from a drop-down list of HTML pages that were previously uploaded, or upload a new HTML page. Use this type of action to send an imported HTML page as the response.

Redirect

Redirects the request to a different web page or web server. A Redirect action can redirect requests originally sent to a "dummy" web site that exists in DNS, but for which there is no actual web server, to an actual web site. It can also redirect search requests to an appropriate URL. Normally, the redirection target for a Redirect action consists of a complete URL.

At the command prompt, type the following commands to configure a responder action and verify the configuration:

- add responder action <name> <type> <target> [-bypassSafetyCheck (YES | NO)]
- show responder action

Example

To create a responder action that displays a “Not Found” error page for URLs that do not exist:

```
add responder action act404Error respondWith

'"HTTP/1.1 404 Not Found\r\n\r\n"+ "HTTP.REQ.URL.HTTP_URL_SAFE"

+ "does not exist on the web server."'

 Done
```

```
> show responder action

1)     Name: act404Error

       Operation: respondwith

       Target: "HTTP/1.1 404 Not Found

"+ "HTTP.REQ.URL.HTTP_URL_SAFE" + "does not exist on the web server."

       BypassSafetyCheck : NO

       Hits: 0

       Undef Hits: 0

       Action Reference Count: 0

 Done
```

To create a responder action that displays a “Not Found” error page for URLs that do not exist:

```
add responder action act404Error respondWith

'"HTTP/1.1 404 Not Found\r\n\r\n"+ "HTTP.REQ.URL.HTTP_URL_SAFE" +

 "does not exist on the web server."'

 Done

> show responder action
```

```
1)     Name: act404Error

       Operation: respondwith

       Target: "HTTP/1.1 404 Not Found

"+ "HTTP.REQ.URL.HTTP_URL_SAFE" + "does not exist on the web server."

BypassSafetyCheck : NO

Hits: 0

Undef Hits: 0

Action Reference Count: 0

Done
```

At the command prompt, type the following command to remove a responder action and verify the configuration:

- rm responder action <name>
- show responder action

Example

1. Navigate to AppExpert > Responder > Actions.
2. In the details pane, do one of the following:
   - To create a new action, click Add.
   - To modify an existing action, select the action, and then click Open.
3. Click Create or OK, depending on whether you are creating a new action or modifying an existing action.
4. Click Close. A message appears in the status bar, stating that the feature has been enabled.
5. To delete a responder action, select the action, and then click Remove. A message appears in the status bar, stating that the feature has been disabled.

1. In the Create Responder Action or Configure Responder Action dialog box, click Add.
2. In the Add Expression dialog box, in the first list box choose the first term for your expression.

   HTTP

   The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.

   SYS

   The protected web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

   CLIENT

   The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

   ANALYTICS

   The analytics data associated with the request. Choose this if you want to examine request metadata.

   SIP

   A SIP request. Choose this if you want to examine some aspect of a SIP request.

   When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.
3. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.
4. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

You can configure the global HTTP action to invoke a responder action when an HTTP request times out. To configure this feature, you must first create the responder action that you want to invoke. Then, you configure the global HTTP timeout action to respond to a timeout with that responder action.

To configure the global HTTP action by using the command line interface

At the command prompt, type the following command:

- set ns httpProfile -reqTimeoutAction <responder action name>
- save ns config

For **<responder action name>**, substitute the name of the responder action.

Configuring a Responder Policy

Oct 29, 2013

After you configure a responder action, you must next configure a responder policy to select the requests to which the NetScaler appliance should respond. A responder policy is based on a rule, which consists of one or more expressions. The rule is associated with an action, which is performed if a request matches the rule.

Note: For creating and managing responder policies, the configuration utility provides assistance that is not available at the NetScaler command prompt.

At the command prompt, type the following command to add a new responder policy and verify the configuration:

- add responder policy <name> <expression> <action> [<undefaction>]-appFlowaction<actionName>
- show responder policy <name>

Example

```
> add responder policy policyThree "CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)" RESET
 Done
> show responder policy policyThree

      Name: policyThree
      Rule: CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)
      Responder Action: RESET
      UndefAction: Use Global
      Hits: 0
      Undef Hits: 0
 Done
```

At the command prompt, type the following command to modify an existing responder policy and verify the configuration:

- set responder policy <name> [-rule <expression>] [-action <string>] [-undefAction <string>]
- show responder policy <name>

At the command prompt, type the following command to remove a responder policy and verify the configuration:

- rm responder policy <name>
- show responder policy

Example

```
>rm responder policy pol404Error
 Done

> show responder policy
 Done
```

1. Navigate to AppExpert > Responder > Policies.
2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.
3. Click Create or OK, depending on whether you are creating a new policy or modifying an existing policy.
4. Click Close. A message appears in the status bar, stating that the feature has been configured.

Binding a Responder Policy

Oct 29, 2013

To put a policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the NetScaler, or to a specific virtual server, so that the policy applies only to requests whose destination IP address is the VIP of that virtual server.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

In the NetScaler operating system, policy priorities work in reverse order—the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is performed first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000. The responder feature implements only the first policy that a request matches, not any additional policies that it might also match, so policy priority is important for getting the results you intend.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you globally bind it. You can then add additional policies at any time without having to reassign the priority of an existing policy.

For additional information about binding policies on the NetScaler, see "Policies and Expressions."
Note: Responder policies cannot be bound to TCP-based virtual servers.

At the command prompt, type the following command to globally bind a responder policy and verify the configuration:

- bind responder global <policyName> <priority> [<gotoPriorityExpression [-type <type>] [-invoke (<labelType> <labelName>)]
- show responder global

Example

```
> bind responder global poliError 100
 Done
> show responder global
1)     Global bindpoint: REQ_DEFAULT
       Number of bound policies: 1

 Done
```

At the command prompt, type the following command to bind responder policy to a specific virtual server and verify the configuration:
bind lb vserver <name> -policyname <policy_name> -priority <priority>
Example

```
> bind lb vserver vs-loadbal -policyName policyTwo -priority 100
 Done
> show lb vserver
```

```
1)    vs-loadbal (10.102.29.20:80) - HTTP    Type: ADDRESS
      State: OUT OF SERVICE
      Last state change was at Wed Aug 19 09:05:47 2009 (+211 ms)
      Time since last state change: 2 days, 00:58:03.260
      Effective State: DOWN
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Port Rewrite : DISABLED
      No. of Bound Services :  0 (Total)      0 (Active)
      Configured Method: LEASTCONNECTION
      Mode: IP
      Persistence: NONE
      Vserver IP and Port insertion: OFF
      Push: DISABLED  Push VServer:
      Push Multi Clients: NO
      Push Label Rule: none
2)    vs-cont-sw (0.0.0.0:0) - TCP    Type: ADDRESS
      State: DOWN
      Last state change was at Wed Aug 19 10:03:46 2009 (+213 ms)
      Time since last state change: 2 days, 00:00:04.260
      Effective State: DOWN
      Client Idle Timeout: 9000 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      No. of Bound Services :  0 (Total)      0 (Active)
      Configured Method: LEASTCONNECTION
      Mode: IP
      Persistence: NONE
      Connection Failover: DISABLED
 Done
```

1. Navigate to AppExpert > Responder > Policies.
2. On the Responder Policies page, select a responder policy, and then click Policy Manager.
3. In the Responder Policy Manager dialog box Bind Points menu, select Default Global.
4. Click Insert Policy to insert a new row and display a drop-down list of all unbound responder policies.
5. Click one of the policies on the list. That policy is inserted into the list of globally bound responder policies.
6. Click Apply Changes.
7. Click Close. A message appears in the status bar, stating that the configuration has been successfully completed.

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. On the Load Balancing Virtual Servers page, select the virtual server to which you want to bind the responder policy, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab, which displays a list of all policies configured on your NetScaler appliance.
4. Select the check box next to the name of the policy you want to bind to this virtual server.

5. Click OK. A message appears in the status bar, stating that the configuration has been successfully completed.

Setting the Default Action for a Responder Policy

Oct 25, 2016

The NetScaler appliance generates an undefined event (UNDEF event) when a request does not match a responder policy, and then carries out the default action assigned to undefined events. By default, that action is to forward the request to the next feature without changing it. This default behavior is normally what you want; it ensures that requests that do not require special handling by a specific responder action are sent to your Web servers and clients receive access to the content that they requested.

If the Web site(s) your NetScaler appliance protects receive a significant number of invalid or malicious requests, however, you may want to change the default action to either reset the client connection or drop the request. In this type of configuration, you would write one or more responder policies that would match any legitimate requests, and simply redirect those requests to their original destinations. Your NetScaler appliance would then block any other requests as specified by the default action you configured.

You can assign any one of the following actions to an undefined event:

NOOP

The NOOP action aborts responder processing but does not alter the packet flow. This means that the appliance continues to process requests that do not match any responder policy, and eventually forwards them to the requested URL unless another feature intervenes and blocks or redirects the request. This action is appropriate for normal requests to your Web servers and is the default setting.

RESET

If the undefined action is set to RESET, the appliance resets the client connection, informing the client that it must re-establish its session with the Web server. This action is appropriate for repeat requests for Web pages that do not exist, or for connections that might be attempts to hack or probe your protected Web site(s).

DROP

If the undefined action is set to DROP, the appliance silently drops the request without responding to the client in any way. This action is appropriate for requests that appear to be part of a DDoS attack or other sustained attack on your servers.

Note: UNDEF events are triggered only for client requests. No UNDEF events are triggered for responses.

At the command prompt, type the following command to set the undefined action and verify the configuration:

- set responder param -undefAction (RESET | DROP | NOOP)
- show responder param

Example

```
>set responder param -undefAction RESET
 Done
> show responder param
      Action Name: RESET
 Done
>
```

1. Navigate to AppExpert > Responder, and then under Settings, click the Change Responder Settings link.
2. In the Set Responder Params dialog box, under Global Undefined-Result Action, select NOOP, RESET, or DROP.
3. Click OK. A message appears in the status bar, stating that the Responder Parameters have been configured.

Responder Action and Policy Examples

Nov 24, 2014

Responder actions and policies are powerful and complex, but you can get started with relatively simple applications. For typical examples, see "Example: Blocking Access from Specified IPs" and "Example: Redirecting a Client to a new URL."

The following procedures block access to your protected Web site(s) by clients originating from the CIDR 222.222.0.0/16. The responder sends an error message stating that the client is not authorized to access the URL requested.

To block access by using the command line interface

At the command prompt, type the following commands to block access:

- add responder action act_unauthorized respondwith '"HTTP/1.1 200 OK\r\n\r\n" + "Client: " + CLIENT.IP.SRC + " is not authorized to access URL:" + "HTTP.REQ.URL.HTTP_URL_SAFE"'
- add responder policy pol_un "CLIENT.IP.SRC.IN_SUBNET (222.222.0.0/16)" act_unauthorized
- bind responder global pol_un 10

To block access by using the configuration utility

1. In the navigation pane, expand Responder, and then click Actions.
2. In the details pane, click Add.
3. In the Create Responder Action dialog box, do the following:
   1. In the Name text box, type act_unauthorized.
   2. Under Type, select Respond with.
   3. In the Target text area, type the following string: "HTTP/1.1 200 OK\r\n\r\n" + "Client: " + CLIENT.IP.SRC + " is not authorized to access URL:" + HTTP.REQ.URL.HTTP_URL_SAFE
   4. Click Create, and then click Close.

   The responder action you configured, named act_unauthorized, now appears in the Responder Actions page.
4. In the navigation pane, click Policies.
5. In the details pane, click Add.
6. In the Create Responder Policy dialog box, do the following:
   1. In the Name text box, type pol_unauthorized.
   2. Under Action, select act_unauthorized.
   3. In the Expression window, type the following rule: CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)
   4. Click Create, then click Close.

   The responder policy you configured, named pol_unauthorized, now appears in the Responder Policies page.
7. Globally bind your new policy, pol_unauthorized, as described in "Binding a Responder Policy."

The following procedures redirect clients who access your protected Web site(s) from within the CIDR 222.222.0.0/16 to a specified URL.

To redirect clients by using the command line interface

At the command prompt, type the following commands to redirect clients and verify the configuration:

- add responder action act_redirect redirect '"http://www.example.com/404.html"'
- show responder action act_redirect

- add responder policy pol_redirect "CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)" act_redirect
- show responder policy pol_redirect
- bind responder global pol_redirect 10

Example

```
> add responder action act_redirect redirect '" http ://www.example.com/404.html "'
> add responder policy pol_redirect "CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)" act_redirect
```

To redirect clients by using the configuration utility

1. Navigate to AppExpert > Responder > Actions.
2. In the details pane, click Add.
3. In the Create Responder Action dialog box, do the following:
   1. In the Name text box, type act_redirect.
   2. Under Type, select Redirect.
   3. In the Target text area, type the following string: "http://www.example.com/404.html"
   4. Click Create, then click Close.

   The responder action you configured, named act_redirect, now appears in the Responder Actions page.
4. In the navigation pane, click Policies.
5. In the details pane, click Add.
6. In the Create Responder Policy dialog box, do the following:
   1. In the Name text box, type pol_redirect.
   2. Under Action, select act_redirect.
   3. In the Expression window, type the following rule: CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)
   4. Click Create, then click Close.

   The responder policy you configured, named pol_redirect, now appears in the Responder Policies page.
7. Globally bind your new policy, pol_redirect, as described in "Binding a Responder Policy."

Diameter Support for Responder

Apr 09, 2014

The Responder feature now supports the Diameter protocol. You can configure Responder to respond to Diameter requests as it does HTTP and TCP requests. For example, you could configure Responder to respond to requests from a specific Diameter origin with a redirect to a web page enhanced for mobile devices. A number of NetScaler expressions have been added that support examination of the Diameter header and the attribute-value pairs (AVPs). These expressions support lookup of specific AVPs by index, ID or name, examine the information in each AVP, and send an appropriate response.

To configure the Responder feature to send a response to a diameter request, at the command prompt, type the following commands:

- add responder action <actname> RESPONDWITH "DIAMETER.NEW_REDIRECT(\"aaa://host.example.com\")"
  For <actname>, substitute a name for your new action. The name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For aaa://host.example.com, substitute the URL of the diameter host to which you want to redirect connections.
- add responder policy <polname> "diameter.req.avp(264).value.eq(\"host1.example.net\")" <actname>
  For <polname>, substitute a name for your new policy. As with <actname>, the name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For host1.example.net, substitute the name of the originating host of the requests that you want to redirect. For <actname>, substitute the name of the action that you just created.
- bind lb vserver <vservername> -policyName <polname> -priority <priority> -type REQUEST
  For <vservername>, substitute the name of the load balancing virtual server to which you want to bind the policy. For <polname>, substitute the name of the policy you just created. For <priority>, substitute a priority for the policy.

Example

To create a Responder action and policy to respond to Diameter requests that originate from "host1.example.net" with a redirect to "host.example.com", you could add the following action and policy, and bind the policy as shown.

```
> add responder action act_resp-dm-redirect RESPONDWITH "DIAMETER.NEW_REDIRECT(\"aaa://host.example.com\")"
> add responder pol_resp-dm-redirect "diameter.req.avp(264).value.eq(\"host1.example.net\")" act_resp-dm-redirect
> bind lb vserver vs1 -policyName pol_resp-dm-redirect -priority 10 -type REQUEST
```

Done

Troubleshooting

Jul 22, 2013

If the responder feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

Resources for Troubleshooting

Updated: 2013-07-22

For best results, use the following resources to troubleshoot an integrated cache issue on a NetScaler appliance:

- The ns.conf file
- The relevant trace files from the client and the NetScaler appliance

In addition to the above resources, the following tools expedite troubleshooting:

- The iehttpheaders or a similar utility
- The Wireshark application customized for the NetScaler trace files

Troubleshooting Responder Issues

Updated: 2013-07-29

- **Issue**
  The Responder feature is configured, but the responder action is not working.

  Resolution
  - Verify that the feature is enabled.
  - Check the hit counters of any of the policies to see if the counters are getting incremented.
  - Verify that the policies and actions are configured correctly.
  - Verify that the actions and policies are bound appropriately.
  - Record the packet traces on the client and the NetScaler appliance, and analyze the them to get some pointer to the issue.
  - Record the iehttpHeaters packet traces on the client and verify the HTTP requests and responses to get some pointer to the issue.
- **Issue**
  You need to create a maintenance page.

  Resolution
  1. Configure the services and virtual Server.
  2. Configure a backup virtual server with a service bound to it. This ensures that the status of the Web site is always displayed as UP.
  3. Configure the primary virtual server to use the backup virtual server as a backup.
  4. Create a responder action with an appropriate target. Following is an example for your reference:
     `add responder action sorry_page respondwith q{"HTTP/1.0 200 OK" +"\r\n\r\n" + "<html> <body>Sorry, this page is not available</body></html>" + "\r\n"} .`
  5. Create a responder policy and bind the action to it.
  6. Bind the responder policy to the backup virtual Server.

Rewrite

Aug 30, 2013

Rewrite refers to the rewriting of some information in the requests or responses handled by the NetScaler appliance. Rewriting can help in providing access to the requested content without exposing unnecessary details about the Web site's actual configuration. A few situations in which the rewrite feature is useful are described below:

- To improve security, the NetScaler can rewrite all the http:// links to https:// in the response body.
- In the SSL offload deployment, the insecure links in the response have to be converted into secure links. Using the rewrite option, you can rewrite all the http:// links to https:// for making sure that the outgoing responses from NetScaler to the client have the secured links.
- If a Web site has to show an error page, you can show a custom error page instead of the default 404 Error page. For example, if you show the home page or site map of the Web site instead of an error page, the visitor remains on the site instead of moving away from the Web site.
- If you want to launch a new Web site, but use the old URL, you can use the Rewrite option.
- When a topic in a site has a complicated URL, you can rewrite it with a simple, easy-to-remember URL (also referred to as 'cool URL').
- You can append the default page name to the URL of a Web site. For example, if the default page of a company's Web site is 'http://www.abc.com/index.php', when the user types 'abc.com' in the address bar of the browser, you can rewrite the URL to 'abc.com/index.php'.

When you enable the rewrite feature, NetScaler can modify the headers and body of HTTP requests and responses.

To rewrite HTTP requests and responses, you can use protocol-aware NetScaler policy expressions in the rewrite policies you configure. The virtual servers that manage the HTTP requests and responses must be of type HTTP or SSL. In HTTP traffic, you can take the following actions:

- Modify the URL of a request
- Add, modify or delete headers
- Add, replace, or delete any specific string within the body or headers.

To rewrite TCP payloads, consider the payload as a raw stream of bytes. Each of the virtual servers that managing the TCP connections must be of type TCP or SSL_TCP. The term TCP rewrite is used to refer to the rewrite of TCP payloads that are not HTTP data. In TCP traffic, you can add, modify, or delete any part of the TCP payload.

For examples to use the rewrite feature, see "Rewrite Action and Policy Examples."

Comparison between Rewrite and Responder options

The main difference between the rewrite feature and the responder feature is as follows:

Responder cannot be used for response or server-based expressions. Responder can be used only for the following scenarios depending on client parameters:

- Redirecting a http request to new Web sites or Web pages
- Responding with some custom response
- Dropping or resetting a connection at request level

In case of a responder policy, the NetScaler examines the request from the client, takes action according to the applicable policies, sends the response to the client, and closes the connection with the client.

In case of a rewrite policy, the NetScaler examines the request from the client or response from the server, takes action according to the applicable policies, and forwards the traffic to the client or the server.

In general, it is recommended to use responder if you want the NetScaler to reset or drop a connection based on a client or request-based parameter. Use responder to redirect traffic, or respond with custom messages. Use rewrite for manipulating data on HTTP requests and responses.

How Rewrite Works

Aug 30, 2013

A rewrite policy consists of a rule and action. The rule determines the traffic on which rewrite is applied and the action determines the action to be taken by the NetScaler. You can define multiple rewrite policies. For each policy, specify the bind point and priority.

A bind point refers to a point in the traffic flow at which the NetScaler examines the traffic to verify whether any rewrite policy can be applied to it. You can bind a policy to a specific load balancing or content switching virtual server, or make the policy global if you want the policy to be applied to the entire traffic handled by the NetScaler. These policies are referred to as global policies.

In addition to the user-defined policies, the NetScaler has some default policies. You cannot modify or delete a default policy.

For evaluating the policies, NetScaler follows the order mentioned below:

- Global policies
- Policies bound to specific virtual servers
- Default policies

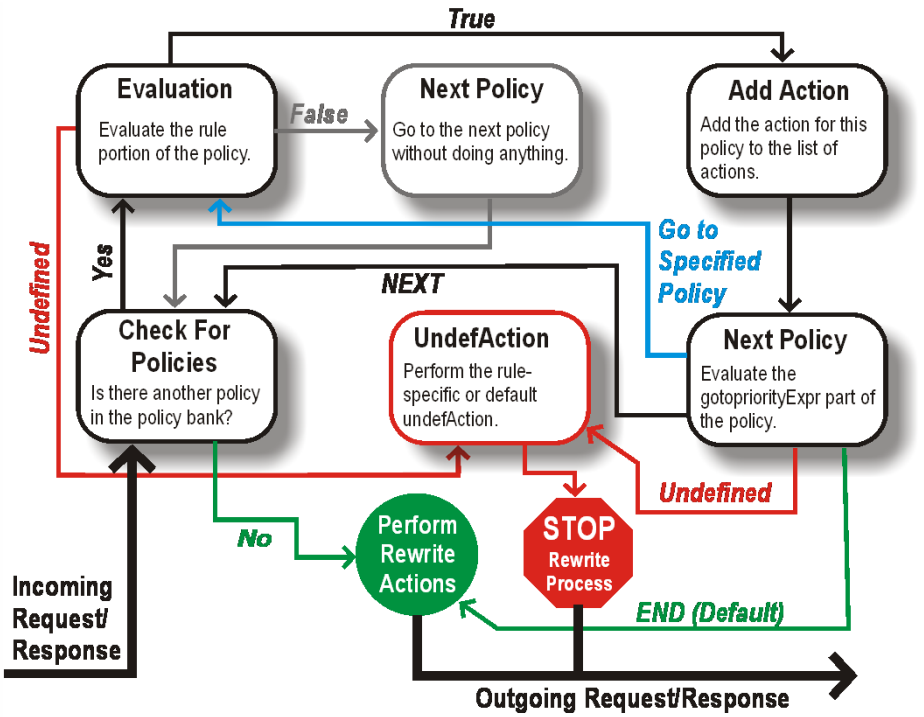
Note: NetScaler can apply a rewrite policy only when it is bound to a point.
NetScaler implements the rewrite feature in the following steps:

- The NetScaler appliance checks for global policies and then checks for policies at individual bind points.
- If multiple policies are bound to a bind point, the NetScaler evaluates the policies in the order of their priority. The policy with the highest priority is evaluated first. After evaluating each policy, if the policy is evaluated to TRUE (the traffic matches the rule), it adds the action associated with the policy to a list of actions to be performed. A match occurs when the characteristics specified in the policy rule match the characteristics of the request or response being evaluated.
- For any policy, in addition to the action, you can specify the policy that should be evaluated after the current policy is evaluated. This policy is referred to as the 'Go to Expression'. For any policy, if a Go to Expression (gotoPriorityExpr) is specified, the NetScaler evaluates the Go to Expression policy; it ignores policy with the next highest priority.
  You can specify the priority of the policy to indicate the Go to Expression policy; you cannot use the name of the policy.
  If you want the NetScaler to stop evaluating other policies after evaluating a particular policy, you can set the Go to Expression to 'END'.
- After all the policies are evaluated or when a policy has the Go to Expression set as END, the NetScaler starts performing the actions according to the list of actions.

For more information about configuring rewrite policies, see "Configuring a Rewrite Policy" and about binding rewrite policies, see "Binding a Rewrite Policy."

The following figure illustrates how NetScaler processes a request or response when the rewrite feature is used.

Figure 1. The Rewrite Process



Policy Evaluation

The policy with the highest priority is evaluated first. NetScaler does not stop the evaluation of rewrite policies when it finds a match; it evaluates all the rewrite policies configured on the NetScaler.

- If a policy evaluates to TRUE, the NetScaler follows the procedure below:
  - If the policy has the Go to Expression set to END, the NetScaler stops evaluating all the other policies and starts performing the rewrite.
  - The gotoPriorityExpression can be set to 'NEXT', 'END', some integer or 'INVOCATION_LIST'. The value determines the policy with the next priority. The following table shows the action taken by NetScaler for each value of the expression.

Value of the expression	Action
NEXT	Policy with the next priority gets evaluated.
END	Evaluation of policies stops.
<an integer>	Policy with specified priority gets evaluated.
INVOCATION_LIST	Goto NEXT or END is applied based on the result of the invocation list.

- If a policy evaluates to FALSE, the NetScaler continues the evaluation in the order of priority.
- If a policy evaluates to UNDEFINED (cannot be evaluated on the received traffic due to an error), the NetScaler performs the action assigned to the UNDEFINED condition (referred to as undefAction) and stops further evaluation of polices.

The NetScaler starts the actual rewriting only after the evaluation is complete. It refers to the list of actions identified by

policies that are evaluated to TRUE, and starts the rewriting. After implementing all the actions in the list, the NetScaler forwards the traffic as required.

Note: Ensure that the policies do not specify conflicting or overlapping actions on the same part of the HTTP header or body, or TCP payload. When such a conflict occurs, the NetScaler encounters an undefined situation and aborts the rewrite.

Rewrite Actions

On the NetScaler appliance, specify the actions to be taken such as adding, replacing, or deleting text within the body, or adding, modifying or deleting headers, or any changes in the TCP payload as rewrite actions. For more information about rewrite actions, see "Configuring a Rewrite Action."

The following table describes the steps the NetScaler can take when a policy evaluates to TRUE.

Action	Result
Insert	The rewrite action specified for the policy is carried out.
NOREWRITE	The request or response is not rewritten. NetScaler forwards the traffic without rewriting any part of the message.
RESET	The connection is aborted at the TCP level.
DROP	The message is dropped.

Note: For any policy, you can configure the undefaction (action to be taken when the policy evaluates to UNDEFINED) as NOREWRITE, RESET, or DROP.

To use the Rewrite feature, take the following steps:

- Enable the feature on the NetScaler.
- Define rewrite actions.
- Define rewrite policies.
- Bind the policies to a bind point to bring a policy into effect.

Enabling the Rewrite Feature

Aug 30, 2013

Enable the rewrite feature on the NetScaler appliance if you want to rewrite the HTTP or TCP requests or responses. If the feature is enabled, NetScaler takes rewrite action according to the specified policies. For more information, see "How Rewrite Works."

To enable the rewrite feature by using the command line interface

At the command prompt, type the following commands to enable the rewrite feature and verify the configuration:

- enable ns feature REWRITE
- show ns feature

Example

```
> enable ns feature REWRITE
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)    Web Logging              WL              OFF
 2)    Surge Protection         SP              ON
 .
 .
 .
 19)   Rewrite                  REWRITE         ON
 .
 .
 24)   NetScaler Push           push            OFF
 Done
```

To enable the rewrite feature by using the configuration utility

1. In the navigation pane, click System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure basic features.
3. In the Configure Basic Features dialog box, select the Rewrite check box, and then click OK.
4. In the Enable/Disable Feature(s) dialog box, click Yes. A message appears in the status bar, stating that the selected feature was enabled.

Configuring a Rewrite Action

Nov 24, 2014

After enabling the rewrite feature, you need to configure one or more actions unless a built-in rewrite action is sufficient. All of the built-in actions have names beginning with the string ns_cvpn, followed by a string of letters and underscore characters. Built-in actions perform useful and complex tasks such as decoding parts of a clientless VPN request or response or modifying JavaScript or XML data. The built-in actions can be viewed, enabled, and disabled, but cannot be modified or deleted.

Target expressions in actions for TCP rewrite must begin with one of the following expression prefixes:

- **CLIENT.TCP.PAYLOAD.** For rewriting TCP payloads in client requests. For example, CLIENT.TCP.PAYLOAD(10000).AFTER_STR("string1").
- **SERVER.TCP.PAYLOAD.** For rewriting TCP payloads in server responses. For example, SERVER.TCP.PAYLOAD(1000).B64DECODE.BETWEEN("string1","string2").

You can use all types of existing string manipulation functions with these prefixes to identify the strings that you want to rewrite. To configure a rewrite action, you assign it a name, specify an action type, and add one or more arguments specifying additional data. The following table describes the action types and the arguments you use with them.
Note: Action types that can be used only for HTTP rewrite are identified in the **Rewrite Action Type** column.

Table 1. Rewrite Action Types and Their Arguments

Rewrite Action Type	Argument 1	Argument 2
INSERT_HTTP_HEADER: Inserts the HTTP header you specify into the HTTP request or response. This is the default choice. This action type can be used only with HTTP requests and responses.	The HTTP header you want to insert. For example, if you want to insert the client IP from which a request is sent, type Client-IP.	A string expression that describes the contents of the header you want to insert. For example, if you want to insert the Client IP from which a request is sent, type CLIENT.IP.SRC.
INSERT_BEFORE: Inserts a new string before the designated string.	A string expression that describes the string before which you want to insert a new string. For example, if you want to find the hostname www.example.com and insert a string before the example.com portion, type the following: HTTP.REQ.HOSTNAME.BEFORE_STR ("example.com")	A string expression that describes the new string you want to insert. For example, if you want to insert the new string en. before the string example in the hostname, type en followed by a period.
INSERT_AFTER: Inserts a new string after the designated string.	A string expression that describes the string after which you want to insert a	A string expression that describes the new string

Rewrite Action Type	Argument 1	Argument 2
	new string. For example, if you want to find the hostname www.example.com, and insert a string after the www. portion, type the following: HTTP.REQ.HOSTNAME.AFTER_STR ("www.")	you want to insert. For example, if you want to insert the new string en. after the string www. in the hostname, type en followed by a period.
REPLACE: Replaces the designated string with a different string.	A string expression that describes the string you want to replace with a new string. For example, if you want to replace the entire hostname in the Host header, type HTTP.REQ.HOSTNAME.SERVER.	A string expression that describes the new string you want to insert. For example, if you want to replace the current host header with the string web01.example.net, type web01.example.net.
DELETE: Deletes the designated string.	A string expression that describes the string you want to delete. For example, if you want to find and delete the string .en in the hostname of HTTP response headers, type the following: HTTP.RES.HEADER("Host").SUBSTR("en.")	
DELETE_HTTP_HEADER: Deletes the designated HTTP header, including all header contents. This action type can be used only with HTTP requests and responses.	The name of the HTTP header you want to delete. For example, if you want to delete the cache-control header from HTTP responses, type HTTP.RES.HEADER ("Cache-Control").	
CORRUPT_HTTP_HEADER: Replaces the name of the given HTTP header with a corrupted name so that it will not be recognized by the receiver. This action type can be used only with HTTP requests and responses.	The name of the HTTP header that you want to corrupt. If the specified header occurs more than once in a request, all the occurrences are corrupted. For example, if you want to corrupt the Host header in an HTTP request, you can use the following rewrite action command: add rewrite action corrupt_header_act	

Rewrite Action Type	Argument 1	Argument 2
	CORRUPT_HTTP_HEADER Host.	
REPLACE_HTTP_RES: Replace the http response with the value specified in the target field. This action type can be used only with HTTP requests and responses.	A string expression that describes the string you want to replace the HTTP response with. For example, type HTTP 200 OK You are not authorized to view this page to replace the entire HTTP response with this warning.	
REPLACE_ALL: Will replace all occurrences of a pattern in the target text reference with the value specified in the string builder expression.	The part of either the HTTP request or response where you want to carry out the replacement.	A string expression that describes the new string you want to insert.
DELETE_ALL: Delete every occurrence of the pattern specified in the target text reference.	The part of either the HTTP request or response where you want the deletion to occur.	A string pattern after which the deletion should occur.
INSERT_AFTER_ALL: Inserts the value specified by string builder expression after each occurrence of a specified pattern in the target text reference.	The part of either the HTTP request or response where you want the insertion to occur.	A string expression that describes the new string you want to insert.
INSERT_BEFORE_ALL: Inserts the value you specify before each occurrence of the pattern you specify.	The part of either the HTTP request or response that you want to delete.	A string expression that describes the new string you want to insert.
CLIENTLESS_VPN_ENCODE: Encodes the URL you specify in clientless VPN format.	The URL you want to encode.	
CLIENTLESS_VPN_ENCODE_ALL: Encodes all of the URLs you specify in clientless VPN format.	A pattern that matches the URLs you want to encode.	
CLIENTLESS_VPN_DECODE: Decodes the URL you specify from clientless VPN format and returns it as unencoded text.	The URL you want to decode.	
CLIENTLESS_VPN_DECODE_ALL: Decodes all of the URLs you specify from clientless VPN format and returns them as unencoded text.	A pattern that matches all of the URLs you want to decode.	

To create a new rewrite action by using the command line interface

At the command prompt, type the following commands to create a new rewrite action and verify the configuration:

- add rewrite action <name> <type> <target> [<stringBuilderExpr>] [(-pattern <expression> | -patset <string>)] [-bypassSafetyCheck (YES | NO)]
- show rewrite action <name>

Example 1: Inserting an HTTP Header With the Client IP

```
> add rewrite action insertact INSERT_HTTP_HEADER "client-IP" CLIENT.IP.SRC
Done

> show rewrite action insertact

      Name: insertact
      Operation: insert_http_header   Target:Client-IP
      Value:CLIENT.IP.SRC
      BypassSafetyCheck : NO
      Hits: 0
      Undef Hits: 0
      Action Reference Count: 0
 Done
```

Example 2: Replacing Strings in a TCP Payload (TCP Rewrite)

```
> add rewrite action client_tcp_payload_replace_all REPLACE_ALL
  'client.tcp.payload(1000)' '"new-string"' -search text("old-string")
 Done
> show rewrite action client_tcp_payload_replace_all

      Name: client_tcp_payload_replace_all
      Operation: replace_all
      Target:client.tcp.payload(1000)
      Value:"new-string"
      Search: text("old-string")
      BypassSafetyCheck : NO
      Hits: 0
      Undef Hits: 0
      Action Reference Count: 0
 Done
>
```

To modify an existing rewrite action by using the command line interface

At the command prompt, type the following commands to modify an existing rewrite action and verify the configuration:

- set rewrite action <name> [-target <string>] [-stringBuilderExpr <string>] [(-pattern <expression> | -patset <string>)] [-bypassSafetyCheck (YES | NO)]
- show rewrite action <name>

Example

```
> set rewrite action insertact -target "Client-IP"
 Done
```

```
> show rewrite action insertact

      Name: insertact
      Operation: insert_http_header   Target:Client-IP
      Value:CLIENT.IP.SRC
      BypassSafetyCheck : NO
      Hits: 0
      Undef Hits: 0
      Action Reference Count: 0
 Done
```

To remove a rewrite action by using the command line interface

At the command prompt, type the following commands to remove a rewrite action :
rm rewrite action <name>
Example

```
> rm rewrite action insertact
Done
```

To configure a rewrite action by using the configuration utility

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, do one of the following:
   - To create a new action, click Add.
   - To modify an existing action, select the action, and then click Open.
3. Click Create or OK. A message appears in the status bar, stating that the Action has been configured successfully.
4. Repeat steps 2 through 4 to create or modify as many rewrite actions as you wish.
5. Click Close.

To add an expression by using the Add Expression dialog box

1. In the Create Rewrite Action or Configure Rewrite Action dialog box, under the text area for the type argument you want to enter, click Add.
2. In the Add Expression dialog box, in the first list box choose the first term for your expression.
   HTTP
   The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
   SYS
   The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   CLIENT
   The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

   When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.
3. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.
4. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

For more information about the PI expressions language and creating expressions for responder policies, see "Policies and Expressions."

If you want to test the effect of a rewrite action when used on sample HTTP data, you can use the Rewrite Expression Evaluator.
Note: The Rewrite Expression Evaluator is only available in the configuration utility. There is no NetScaler command line version.

To evaluate a rewrite action by using the Rewrite Action Evaluator dialog box

1. In the Rewrite Actions details pane, select the rewrite action that you want to evaluate, and then click Evaluate.
2. In the Rewrite Expression Evaluator dialog box, specify values for the following parameters. (An asterisk indicates a required parameter.)
   - Rewrite Action*—If the rewrite action you want to evaluate is not already selected, select it from the drop-down list. After you select a Rewrite action, the Details section displays the details of the selected Rewrite action.
   - New*—Select New to open the Create Rewrite Action dialog box and create a new rewrite action.
   - Modify*—Select Modify to open the Configure Rewrite Action dialog box and modify the selected rewrite action.
   - Flow Type*—Specifies whether to test the selected rewrite action with HTTP Request data or HTTP Response data. The default is Request. If you want to test with Response data, select Response.
   - HTTP Request/Response Data*—Provides a space for you to provide the HTTP data that the Rewrite Action Evaluator will use for testing. You can paste the data directly into the window, or click Sample to insert some sample HTTP headers.
   - Show end-of-line—Specifies whether to show UNIX-style end-of-line characters (\n) at the end of each line of sample HTTP data.
   - Sample—Inserts sample HTTP data into the HTTP Request/Response Data window. You can choose either GET or POST data.
   - Browse—Opens a local browse window so that you can choose a file containing sample HTTP data from a local or network location.
   - Clear—Clears the current sample HTTP data from the HTTP Request/Response Data window.
3. Click Evaluate. The Rewrite Action Evaluator evaluates the effect of the Rewrite action on the sample data that you chose, and displays the results as modified by the selected Rewrite action in the Results window. Additions and deletions are highlighted as indicated in the legend in the lower left-hand corner of the dialog box.
4. Continue evaluating Rewrite actions until you have determined that all of your actions have the effect that you wanted.
   - You can modify the selected rewrite action and test the modified version by clicking Modify to open the Configure Rewrite Action dialog box, making and saving your changes, and then clicking Evaluate again.
   - You can evaluate a different rewrite action using the same request or response data by selecting it from the Rewrite Action drop-down list, and then clicking Evaluate again.
5. Click Close to close the Rewrite Expression Evaluator and return to the Rewrite Actions pane.

To delete a rewrite action, select the rewrite action you want to delete, then click Remove and, when prompted, confirm your choice by clicking OK.

Configuring a Rewrite Policy

Aug 30, 2013

After you create any needed rewrite action(s), you must create at least one rewrite policy to select the requests that you want the NetScaler appliance to rewrite.

A rewrite policy consists of a rule, which itself consists of one or more expressions, and an associated action that is performed if a request or response matches the rule. Policy rules for evaluating HTTP requests and responses can be based on almost any part of a request or response.

Even though you cannot use TCP rewrite actions to rewrite data other than the TCP payload, you can base the policy rules for TCP rewrite policies on the information in the transport layer and the layers below the transport layer.

If a configured rule matches a request or response, the corresponding policy is triggered and the action associated with it is carried out.

Note: You can use either the command line interface or the configuration utility to create and configure rewrite policies. Users who are not thoroughly familiar with the command line interface and the NetScaler Policy expression language will usually find using the configuration utility much easier.

To add a new rewrite policy by using the command line interface

At the command prompt, type the following commands to add a new rewrite policy and verify the configuration:

- add rewrite policy <name> <expression> <action> [<undefaction>]
- show rewrite policy <name>

Example 1: Rewriting HTTP Content

```
> add rewrite policy policyNew "HTTP.RES.IS_VALID" insertact NOREWRITE
 Done
> show rewrite policy policyNew
      Name: policyNew
      Rule: HTTP.RES.IS_VALID
      RewriteAction: insertact
      UndefAction: NOREWRITE
      Hits: 0
      Undef Hits: 0

 Done
```

Example 2: Rewriting a TCP Payload (TCP Rewrite)

```
> add rewrite policy client_tcp_payload_policy CLIENT.IP.SRC.EQ(172.168.12.232) client_tcp_payload_replace_all
 Done
> show rewrite policy client_tcp_payload_policy
      Name: client_tcp_payload_policy
      Rule: CLIENT.IP.SRC.EQ(172.168.12.232)
      RewriteAction: client_tcp_payload_replace_all
      UndefAction: Use Global
      LogAction: Use Global
      Hits: 0
      Undef Hits: 0

 Done
>
```

To modify an existing rewrite policy by using the command line interface

At the command prompt, type the following commands to modify an existing rewrite policy and verify the configuration:

- set rewrite policy <name> -rule <expression> -action <action> [<undefaction>]
- show rewrite policy <name>

Example

```
> set rewrite policy policyNew -rule "HTTP.RES.IS_VALID" -action insertaction
 Done

> show rewrite policy policyNew
      Name: policyNew
      Rule: HTTP.RES.IS_VALID
      RewriteAction: insertaction
      UndefAction: NOREWRITE
      Hits: 0
      Undef Hits: 0

 Done
```

To remove a rewrite policy by using the command line interface

At the command prompt, type the following command to remove a rewrite policy:
rm rewrite policy <name>

Example

```
> rm rewrite policy policyNew
Done
```

To configure a rewrite policy by using the configuration utility

1. Navigate to AppExpert > Rewrite > Policies.
2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.
3. Click Create or OK. A message appears in the status bar, stating that the Policy has been configured successfully.
4. Repeat steps 2 through 4 to create or modify as many rewrite actions as you wish.
5. Click Close. To delete a rewrite policy, select the rewrite policy you want to delete, then click Remove and, when prompted, confirm your choice by clicking OK.

Binding a Rewrite Policy

Oct 29, 2013

After creating a rewrite policy, you must bind it to put it into effect. You can bind your policy to Global if you want to apply it to all traffic that passes through your NetScaler, or you can bind your policy to a specific virtual server or bind point to direct only that virtual server or bind point's incoming traffic to that policy. If an incoming request matches a rewrite policy, the action associated with that policy is carried out.

Rewrite policies for evaluating HTTP requests and responses can be bound to virtual servers of type HTTP or SSL, or they can be bound to the REQ_OVERRIDE, REQ_DEFAULT, RES_OVERRIDE, and RES_DEFAULT bind points. Rewrite policies for TCP rewrite can be bound only to virtual servers of type TCP or SSL_TCP, or to the OTHERTCP_REQ_OVERRIDE, OTHERTCP_REQ_DEFAULT, OTHERTCP_RES_OVERRIDE, and OTHERTCP_RES_DEFAULT bind points.
Note: The term OTHERTCP is used in the context of the NetScaler appliance to refer to all TCP or SSL_TCP requests and responses that you want to treat as a raw stream of bytes regardless of the protocols that the TCP packets encapsulate.
When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

In the NetScaler operating system, policy priorities work in reverse order - the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is applied first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000.

Unlike most other features in the NetScaler operating system, the rewrite feature continues to evaluate and implement policies after a request matches a policy. However, the effect of a particular action policy on a request or response will often be different depending on whether it is performed before or after another action. Priority is important to get the results you intended.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you bind it. If you do this, you can add additional policies at any time without having to reassign the priority of an existing policy.

When binding a rewrite policy, you also have the option of assigning a goto expression (gotoPriorityExpression) to the policy. A goto expression can be any positive integer that matches the priority assigned to a different policy that has a higher priority than the policy that contains the goto expression. If you assign a goto expression to a policy, and a request or response matches the policy, the NetScaler will immediately go to the policy whose priority matches the goto expression. It will skip over any policies with priority numbers that are lower than that of the current policy, but higher than the priority number of the goto expression, and not evaluate those policies.

For more information about binding policies on the NetScaler, see "Binding a Rewrite Policy."

To globally bind a rewrite policy by using the command line interface

At the command prompt, type the following commands to globally bind a rewrite policy and verify the configuration:

- bind rewrite global <policyName> <priority> [<gotoPriorityExpression>] [-type <type>] [-invoke (<labelType> <labelName>)]
- show rewrite global

Example

```
>bind rewrite global policyNew 10
 Done

> show rewrite global
1)     Global bindpoint: RES_DEFAULT
       Number of bound policies: 1

2)     Global bindpoint: REQ_OVERRIDE
       Number of bound policies: 1

 Done
```

To bind rewrite policy to a specific virtual server by using the command line interface

At the command prompt, type the following commands to bind rewrite policy to a specific virtual server and verify the configuration:

- bind lb vserver <name>@ (<serviceName>@ [-weight <positive_integer>]) | <serviceGroupName>@ | (-policyName <string>@ [-priority <positive_integer>] [-gotoPriorityExpression <expression>] [-type (REQUEST | RESPONSE)] [-invoke (<labelType> <labelName>)])
- show lb vserver <name>

Example

```
> bind lb vserver lbvip -policyName ns_cmp_msapp -priority 50
 Done
>
> show lb vserver lbvip
       lbvip (8.7.6.6:80) - HTTP       Type: ADDRESS
       State: DOWN
       Last state change was at Wed Jul 15 05:54:24 2009 (+226 ms)
       Time since last state change: 28 days, 01:57:26.350
       Effective State: DOWN
       Client Idle Timeout: 180 sec
       Down state flush: ENABLED
       Disable Primary Vserver On Down : DISABLED
       Port Rewrite : DISABLED
       No. of Bound Services :  0 (Total)      0 (Active)
       Configured Method: LEASTCONNECTION
       Mode: IP
       Persistence: NONE
       Vserver IP and Port insertion: OFF
       Push: DISABLED  Push VServer:
       Push Multi Clients: NO
       Push Label Rule: none

1)     Policy : ns_cmp_msapp Priority:50
2)     Policy : cf-pol Priority:1      Inherited
 Done
```

To bind a rewrite policy to a bind point by using the configuration utility

1. Navigate to AppExpert > Rewrite > Policies.
2. In the details pane, select the rewrite policy you want to globally bind, and then click Policy Manager.
3. In the Rewrite Policy Manager dialog box, in the Bind Points menu, do one of the following:
    1. If you want to configure bindings for HTTP rewrite policies, click HTTP, and then click either Request or Response, depending on whether you want to configure request-based rewrite policies or response-based rewrite policies.
    2. If you want to configure bindings for TCP rewrite policies, click TCP, and then click either Client or Server, depending on whether you want to configure client-side TCP rewrite policies or server-side TCP rewrite policies.
4. Click the bind point to which you want to bind the rewrite policy. The Rewrite Policy Manager dialog box displays all the rewrite policies that are bound to the selected bind point.
5. Click Insert Policy to insert a new row and display a drop-down list with all available, unbound rewrite policies.
6. Click the policy you want to bind to the bind point. The policy is inserted into the list of rewrite policies bound to the bind point.
7. In the Priority column, you can change the priority to any positive integer. For more information about this parameter, see priority in "Parameters for binding a rewrite policy."
8. If you want to skip over policies and go directly to a specific policy in the event that the current policy is matched, change the value in the Goto Expression column to equal the priority of the next policy to be applied.. For more information about this parameter, see gotoPriorityExpression in "Parameters for binding a rewrite policy."
9. To modify a policy, click the policy, and then click Modify Policy.
10. To unbind a policy, click the policy, and then click Unbind Policy.
11. To modify an action, in the Action column, click the action you want to modify, and then click Modify Action.
12. To modify an invoke label, in the Invoke column, click the invoke label you want to modify, and then click Modify Invoke Label.
13. To regenerate the priorities of all the policies that are bound to the bind point you are currently configuring, click Regenerate Priorities. The policies retain their existing priorities relative to the other policies, but the priorities are renumbered in multiples of ten.
14. Click Apply Changes.
15. Click Close. A message appears in the status bar, stating that the Policy has been configured successfully.

To bind a rewrite policy to a specific virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane list of virtual servers, select the virtual server to which you want to bind the rewrite policy, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab. All policies configured on your NetScaler appear on the list.
4. Select the check box next to the name of the policy you want to bind to this virtual server.
5. Click OK. A message appears in the status bar, stating that the Policy has been configured successfully.

Configuring Rewrite Policy Labels

Aug 30, 2013

If you want to build a more complex policy structure than is supported by single policies, you can create policy labels and then bind them as you would policies. A policy label is a user-defined point to which policies are bound. When a policy label is invoked, all the policies bound to it are evaluated in the order of the priority you configured. A policy label can include one or multiple policies, each of which can be assigned its own result. A match on one policy in the policy label can result in proceeding to the next policy, invoking a different policy label or appropriate resource, or an immediate end to policy evaluation and return of control to the policy that invoked the policy label.

A rewrite policy label consists of a name, a transform name that describes the type of policy included in the policy label, and a list of policies bound to the policy label. Each policy that is bound to the policy label contains all of the elements described in "Configuring a Rewrite Policy."

Note: You can use either the command line interface or the configuration utility to create and configure rewrite policy labels. Users who are not thoroughly familiar with the command line interface and the NetScaler Policy Infrastructure (PI) language will usually find using the configuration utility much easier.

To configure a rewrite policy label by using the command line interface

To add a new rewrite policy label, at the command prompt, type the following command:

```
add rewrite policylabel <labelName> <transform>
```

For example, to add a rewrite policy label named **polLabelHTTPResponses** to group all policies that work on HTTP responses, you would type the following:

```
add rewrite policylabel polLabelHTTPResponses http_res
```

To modify an existing rewrite policy label, at the NetScaler command prompt, type the following command:

```
set rewrite policy <name> <transform>
```

Note: The set rewrite policy command takes the same options as the add rewrite policy command.
To remove a rewrite policy label, at the NetScaler command prompt, type the following command:

```
rm rewrite policy<name>
```

For example, to remove a rewrite policy label named **polLabelHTTPResponses**, you would type the following:

```
rm rewrite policy polLabelHTTPResponses
```

To configure a rewrite policy label by using the configuration utility

1. Navigate to AppExpert > Rewrite > Policy Labels.
2. In the details pane, do one of the following:
   - To create a new policy label, click Add.
   - To modify an existing policy label, select the policy, and then click Open.
3. Add or remove policies from the list that is bound to the policy label.
   - To add a policy to the list, click Insert Policy, and choose a policy from the drop-down list. You can create a new policy and add it to the list by choosing New Policy in the list, and following the instructions in "Configuring a Rewrite Policy."

- To remove a policy from the list, select that policy, and then click Unbind Policy.

4. Modify the priority of each policy by editing the number in the Priority column.

   You can also automatically renumber policies by clicking Regenerate Priorities.

5. Click Create or OK, and then click Close.

   To remove a policy label, select it, and then click Remove. To rename a policy label, select it and then click Rename. Edit the name of the policy, and then click OK to save your changes.

Configuring the Default Rewrite Action

Aug 30, 2013

An undefined event is triggered when the NetScaler cannot evaluate a policy, usually because it detects a logical or other error in the policy or an error condition on the NetScaler. When the rewrite policy evaluation results in an error, the specified undefined action is carried out. Undefined actions configured at the rewrite policy level are carried out before a globally configured undefined action.

The NetScaler supports following three types of undefined actions:

undefAction NOREWRITE

Aborts rewrite processing, but does not alter the packet flow. This means that the NetScaler continues to process requests and responses that do not match any rewrite policy, and eventually forwards them to the requested URL unless another feature intervenes and blocks or redirects the request. This action is appropriate for normal requests to your Web servers, and is the default setting.

undefAction RESET

Resets the client connection. This means that the NetScaler tells the client that it must re-establish its session with the Web server. This action is appropriate for repeat requests for Web pages that do not exist, or for connections that might be attempts to hack or probe your protected Web site(s).

undefAction DROP

Silently drops the request without responding to the client in any way. This means that the NetScaler simply discards the connection without responding to the client. This action is appropriate for requests that appear to be part of a DDoS attack or another sustained attack on your servers.

Note: Undefined events can be triggered for both request and response flow specific policies.

To configure the default action by using the command line interface

At the command prompt, type the following commands to configure the default action and verify the configuration:

- set rewrite param -undefAction (NOREWRITE | RESET | DROP)
- show rewrite param

Example

```
> set rewrite param -undefAction NOREWRITE
 Done
> show rewrite param
      Action Name: NOREWRITE
 Done
```

To configure the default action by using the configuration utility

1. Navigate to AppExpert > Rewrite.
2. In the details pane, under Rewrite Overview, click the Change Rewrite Settings link. The Set Rewrite Params dialog box appears.
3. Under Global Undefined-Result Action, select an option as follows:
   - NoRewrite—NOREWRITE
   - Reset—RESET
   - Drop—DROP

4. Click OK. The global undefined action is set to the value you chose.

Bypassing the Safety Check

Oct 29, 2013

When you create a rewrite action, the NetScaler verifies that the expression you used to create the action is safe. Expressions created by the NetScaler from run-time data, such as URLs contained in HTTP requests, can cause unexpected errors. The NetScaler reports expressions that cause such errors as unsafe expressions.

In some cases, the expressions may be safe. For example, the NetScaler cannot validate an expression that contains a URL that does not resolve, even if the URL does not resolve because the Web server is temporarily unavailable. You can manually bypass the Safety Check to allow these expressions.

To bypass the safety check by using the command line interface

At the command prompt, type the following commands to bypass the safety check and verify the configuration:

- set rewrite action <name> -bypassSafetyCheck YES
- show rewrite action <name>

Example

```
> set rewrite action insertact -bypassSafetyCheck YES
 Done
> show rewrite action insertact

      Name: insertact
      Operation: insert_http_header   Target:Client-IP
      Value:CLIENT.IP.SRC
      BypassSafetyCheck : YES
      Hits: 0
      Undef Hits: 0
      Action Reference Count: 2
 Done
```

To bypass safety check by using the configuration utility

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, select the rewrite action to be exempted from the safety check, and then click Open.
3. In the Configure Rewrite Action dialog box, select the Bypass Safety Check check box.
4. Click OK.

Rewrite Action and Policy Examples

Mar 20, 2012

The examples in this section demonstrate how to configure rewrite to perform various useful tasks. The examples occur in the server room of Example Manufacturing Inc., a mid-sized manufacturing company that uses its Web site to manage a considerable portion of its sales, deliveries, and customer support.

Example Manufacturing has two domains: example.com for its Web site and email to customers, and example.net for its intranet. Customers use the Example Web site to place orders, request quotes, research products, and contact customer service and technical support.

As an important part of Example's revenue stream, the Web site must respond quickly and keep customer data confidential. Example therefore has several Web servers and uses Citrix NetScaler appliances to balance the Web site load and manage traffic to and from its Web servers.

The Example system administrators use the rewrite features to perform the following tasks:

Example 1: Delete old X-Forwarded-For and Client-IP Headers.

Example Inc. removes old X-Forwarded-For and Client-IP HTTP headers from incoming requests.

Example 2: Adding a Local Client-IP Header.

Example Inc. adds a new, local Client-IP header to incoming requests.

Example 3: Tagging Secure and Insecure Connections.

Example Inc. tags incoming requests with a header that indicates whether the connection is a secure connection.

Example 4: Mask the HTTP Server Type.

Example Inc. modifies the HTTP Server: header so that unauthorized users and malicious code cannot use that header to determine the HTTP server software it uses.

Example 5: Redirect an External URL to an Internal URL.

Example Inc. hides information about the actual names of its Web servers and the configuration of its server room from users, to make URLs on its Web site shorter and easier to remember, and to improve security on its site.

Example 6: Migrating Apache Rewrite Module Rules.

Example Inc. moved its Apache rewrite rules to a NetScaler appliance, translating the Apache PERL-based script syntax to the NetScaler rewrite rule syntax.

Example 7: Marketing Keyword Redirection.

The marketing department at Example Inc. sets up simplified URLs for certain predefined keyword searches on the company's Web site.

Example 8: Redirect Queries to the Queried Server.

Example Inc. redirects certain query requests to the appropriate server.

Example 9: Home Page Redirection.

Example Inc. recently acquired a smaller competitor, and it now redirects requests for the acquired company's home page to a page on its own Web site.

Each of these tasks requires that the system administrators create rewrite actions and policies and bind them to a valid bind point on the NetScaler.

Example 1: Delete Old X-Forwarded-For and Client-IP Headers

Aug 30, 2013

Example Inc. wants to remove old X-Forwarded-For and Client-IP HTTP headers from incoming requests, so that the only X-Forwarded-For headers that appear are the ones added by the local server. This configuration can be done through the NetScaler command line or the configuration utility. The Example Inc. system administrator is an old-school networking engineer and prefers to use a CLI where possible, but wants to be sure he understands the configuration utility interface so that he can show new system administrators on the team how to use it.

The examples below demonstrate how to perform each configuration with both the CLI and the configuration utility. The procedures are abbreviated on the assumption that users will already know the basics of creating rewrite actions, creating rewrite policies, and binding policies.

- For more detailed information about creating rewrite actions, see "Configuring a Rewrite Action."
- For more detailed information about creating rewrite policies, see "Configuring a Rewrite Policy."
- For more detailed information about binding rewrite policies, see "Binding a Rewrite Policy."

To delete old X-Forwarded and Client-IP headers from a request by using the command line interface

At the command prompt, type the following commands in the order shown:

```
add rewrite action act_del_xfor delete_http_header x-forwarded-for
add rewrite action act_del_cip delete_http_header client-ip
add rewrite policy pol_check_xfor 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS' act_del_xfor
add rewrite policy pol_check_cip 'HTTP.REQ.HEADER("client-ip").EXISTS' act_del_cip
bind rewrite global pol_check_xfor 100 200
bind rewrite global pol_check_cip 200 300
```

To delete old X-Forwarded and Client-IP headers from a request by using the configuration utility

In the Create Rewrite Action dialog box, create two rewrite actions with the following descriptions.

Name	Type	Argument(s)
act_del_xfor	delete_http_header	x-forwarded-for
act_del_cip	delete_http_header	client-ip

In the Create Rewrite Policy dialog box, create two rewrite policies with the following descriptions.

Name	Expression	Action
pol_check_xfor	'HTTP.REQ.HEADER("x-forwarded-for").EXISTS'	act_del_xfor
pol_check_cip	'HTTP.REQ.HEADER("client-ip").EXISTS'	act_del_cip

Bind both policies to global, assigning the priorities and goto expression values shown below.

Name	Priority	Goto Expression
pol_check_xfor	100	200
pol_check_xfor	200	300

All old X-Forwarded-For and Client-IP HTTP headers are now deleted from incoming requests.

Example 2: Adding a Local Client-IP Header

Aug 30, 2013

Example Inc. wants to add a local Client-IP HTTP header to incoming requests. This example contains two slightly different versions of the same basic task.

To add a local Client-IP header by using the command line interface

At the command prompt, type the following commands in the order shown:

```
add rewrite action act_ins_client insert_http_header NS-Client 'CLIENT.IP.SRC'
add rewrite policy pol_ins_client 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS || HTTP.REQ.HEADER("client-ip").EXISTS' act_ins_client
bind rewrite global pol_ins_client 300 END
```

To add a local Client-IP header by using the configuration utility

In the Create Rewrite Action dialog box, create a rewrite action with the following description.

Name	Type	Argument(s)
act_ins_client	insert_http_header	NS-Client 'CLIENT.IP.SRC'

In the Create Rewrite Policy dialog box, create a rewrite policy with the following description.

Name	Expression	Action
pol_ins_client	'HTTP.REQ.HEADER("x-forwarded-for").EXISTS || HTTP.REQ.HEADER("client-ip").EXISTS'	act_ins_client

Bind both policies to global, assigning the priorities and goto expression values shown below.

Name	Priority	Goto Expression
pol_check_xfor	100	200
pol_check_xfor	200	300

A local Client-IP HTTP header is now added to incoming requests. You can also modify the configuration above to append all IPs from X-Forwarded-For headers to the new Client-IP header, as shown below.

Example 3: Tagging Secure and Insecure Connections

Mar 20, 2012

Example Inc. wants to tag incoming requests with a header that indicates whether or not the connection is a secure connection. This helps the server keep track of secure connections after the NetScaler has decrypted the connections.

To implement this configuration, you would begin by creating rewrite actions with the values shown in the following tables. These actions label connections to port 80 as insecure connections, and connections to port 443 as secure connections.

Action Name	Type of Rewrite Action	Header Name	Value
Action-Rewrite-SSL_YES	INSERT_HTTP_HEADER	SSL	YES

Action Name	Type of Rewrite Action	Header Name	Value
Action-Rewrite-SSL_NO	INSERT_HTTP_HEADER	SSL	NO

You would then create a rewrite policy with the values shown in the following tables. These policies check incoming requests to determine which requests are directed to port 80 and which are directed to port 443. The policies then add the correct SSL header.

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-SSL_YES	Action-Rewrite-SSL_YES	NOREWRITE	CLIENT.TCP.DSTPORT.EQ(443)
Policy-Rewrite-SSL_NO	Action-Rewrite-SSL_NO	NOREWRITE	CLIENT.TCP.DSTPORT.EQ(80)

Finally, you would bind the rewrite policies to NetScaler, assigning the first policy a priority of 200, and the second a priority of 300, and setting the goto expression of both policies to END.

Each incoming connection to port 80 now has an SSL:NO HTTP header added to it and each incoming connection to port 443 has an SSL:YES HTTP header added to it.

Example 4: Mask the HTTP Server Type

Mar 20, 2012

Example Inc. wants to modify the HTTP Server: header so that unauthorized users and malicious code cannot use the header to identify the software that the HTTP server uses.

To modify the HTTP Server: header, you would create a rewrite action and a rewrite policy with the values in the following tables.

Action Name	Type of Rewrite Action	Expression to choose target reference	String expression for replacement text
Action-Rewrite-Server_Mask	REPLACE	HTTP.RES.HEADER("Server")	"Web Server 1.0"

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-Server_Mask	Action-Rewrite-Server_Mask	NOREWRITE	HTTP.RES.IS_VALID

You would then globally bind the rewrite policy, assigning a priority of 100 and setting the Goto Priority Expression of the policy to END.

The HTTP Server: header is now modified to read “Web Server 1.0,” masking the actual HTTP server software used by the Example Inc. Web site.

Example 5: Redirect an External URL to an Internal URL

Mar 20, 2012

Example Inc. wants to hide its actual server room configuration from users to improve security on its Web servers.

To do this, you would create a rewrite action with the values as shown in the following tables. For request headers, the action in the table modifies www.example.com to web.hq.example.net. For response headers, the action does the opposite, translating web.hq.example.net to www.example.com.

Action Name	Type of Rewrite Action	Expression to choose target reference	String expression for replacement text
Action-Rewrite-Request_Server_Replace	REPLACE	HTTP.REQ.HOSTNAME.SERVER	"Web.hq.example.net"
Action-Rewrite-Response_Server_Replace	REPLACE	HTTP.RES.HEADER("Server")	"www.example.com"

Next, you would create rewrite policies using the values shown in the following tables. The first policy checks incoming requests to see if they are valid, and if they are, it performs the Action-Rewrite-Request_Server_Replace action. The second policy checks responses to see if they originate at the server web.hq.example.net. If they do, it performs the Action-Rewrite-Response_Server_Replace action.

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-Request_Server_Replace	Action-Rewrite-Request_Server_Replace	NOREWRITE	HTTP.REQ.HOSTNAME.SERVER.EQ("www.example.com")
Policy-Rewrite-Response_Server_Replace	Action-Rewrite-Response_Server_Replace	NOREWRITE	HTTP.RES.HEADER("Server").EQ("web.hq.example.net")

Finally, you would bind the rewrite policies, assigning each a priority of 500 because they are in different policy banks and therefore will not conflict. You should set the goto expression to NEXT for both bindings.

All instances of www.example.com in the request headers are now changed to web.hq.example.net, and all instances of web.hq.example.net in response headers are now changed to www.example.com.

Example 6: Migrating Apache Rewrite Module Rules

Mar 20, 2012

Example Inc., is currently using the Apache rewrite module to process search requests sent to its Web servers and redirect those requests to the appropriate server on the basis of information in the request URL. Example Inc. wants to simplify its setup by migrating these rules onto the NetScaler platform.

Several Apache rewrite rules that Example currently uses are shown below. These rules redirect search requests to a special results page if they do not have a SiteID string or if they have a SiteID string equal to zero (0), or to the standard results page if these conditions do not apply.

The following are the current Apache rewrite rules:

- RewriteCond %{REQUEST_FILENAME} ^/search$ [NC]
- RewriteCond %{QUERY_STRING} !SiteId= [OR]
- RewriteCond %{QUERY_STRING} SiteId=0
- RewriteCond %{QUERY_STRING} CallName=DisplayResults [NC]
- RewriteRule ^.*$ /results2.html [P,L]
- RewriteCond %{REQUEST_FILENAME} ^/search$ [NC]
- RewriteCond %{QUERY_STRING} CallName=DisplayResults [NC]
- RewriteRule ^.*$ /results.html [P,L]

To implement these Apache rewrite rules on the NetScaler, you would create rewrite actions with the values in the following tables.

Action Name	Type of Rewrite Action	Expression to choose target reference	String expression for replacement text
Action-Rewrite-Display_Results_NulSiteID	REPLACE	HTTP.REQ.URL	"/results2.html"
Action-Rewrite-Display_Results	REPLACE	HTTP.REQ.URL	"/results2.html"

You would then create rewrite policies with the values as shown in the tables below.

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-Display_Results_NulSiteID	Action-Rewrite-Display_Results_NulSiteID	NOREWRITE	HTTP.REQ.URL.PATH.SET_TEXT_MODE(IGNORECASE).EQ("/search") && (!HTTP.REQ.URL.QUERY.CONTAINS("SiteId=") || HTTP.REQ.URL.QUERY.CONTAINS("SiteId=0") || HTTP.REQ.URL.QUERY.SET_TEXT_MODE(IGNORECASE).CONTAINS("CallName=DisplayResults"))
Policy-Rewrite-Display_Results	Action-Rewrite-Display_Results	NOREWRITE	HTTP.REQ.URL.PATH.SET_TEXT_MODE(IGNORECASE).EQ("/search") || HTTP.REQ.URL.QUERY.SET_TEXT_MODE(IGNORECASE).CONTAINS("CallName=DisplayResults"))

Finally, you would bind the rewrite policies, assigning the first a priority of 600 and the second a priority of 700, and then set the goto expression to NEXT for both bindings.

The NetScaler now handles these search requests exactly as the Web server did before the Apache rewrite module rules were migrated.

Example 7: Marketing Keyword Redirection

Mar 20, 2012

The marketing department at Example Inc. wants to set up simplified URLs for certain predefined keyword searches on the company's Web site. For these keywords, it wants to redefine the URL as shown below.

- External URL: http://www.example.com/<marketingkeyword>
- Internal URL: http://www.example.com/go/kwsearch.asp?keyword=<marketingkeyword>

To set up redirection for marketing keywords, you would create a rewrite action with the values in the following table.

Action Name	Type of Rewrite Action	Expression to choose target location	String expression for replacement text
Action-Rewrite-Modify_URL	INSERT_BEFORE	HTTP.REQ.URL.PATH.GET(1)	""go/kwsearch.aspkeyword="|"

You would then create a rewrite policy with the values in the following table.

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-Modify_URL	Action-Rewrite-Modify_URL	NOREWRITE	HTTP.REQ.HOSTNAME.SERVER.EQ("www.example.com")

Finally, you would bind the rewrite policy, assigning it a priority of 800. Unlike the previous rewrite policies, this policy should be the last to be applied to a request that matches its criteria. For this reason, NetScaler administrator sets its Goto Priority Expression to END.

Any request using a marketing keyword is redirected to the keyword search CGI page, whereupon a search is performed and all remaining policies are skipped.

Example 8: Redirect Queries to the Queried Server

Mar 20, 2012

Example Inc. wants to redirect query requests to the appropriate server, as shown here.

- Request: GET /query.cgi?server=5HOST: www.example.com
- Redirect URL: http://web-5.example.com/

To implement this redirection, you would first create a rewrite action with the values in the following table.

Action Name	Type of Rewrite Action	Expression to choose target reference	String expression for replacement text
Action-Rewrite-Replace_Hostheader	REPLACE	HTTP.REQ.HEADER("Host").BEFORE_STR(".example.com")	"server-" + HTTP.REQ.URL.QUERY.VALUE("web")

You would then create a rewrite policy with the values in the following table.

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-Replace_Hostheader	Action-Rewrite-Replace_Hostheader	NOREWRITE	HTTP.REQ.HEADER("Host").EQ("www.example.com")

Finally, you would bind the rewrite policy, assigning it a priority of 900. Because this policy should be the last policy applied to a request that matches its criteria, you set the goto expression to END.

Incoming requests to any URL that begins with http://www.example.com/query.cgi?server= are redirected to the server number in the query.

Example 9: Home Page Redirection

Mar 20, 2012

New Company, Inc. recently acquired a smaller competitor, Purchased Company, and wants to redirect the home page for Purchased Company to a new page on its own Web site, as shown here.

- Old URL: http://www.purchasedcompany.com/*
- New URL: http://www.newcompany.com/products/page.htm

To redirect requests to the Purchased Company home page, you would create rewrite actions with the values in the following table.

Action Name	Type of Rewrite Action	Expression to choose target reference	String expression for replacement text
Action-Rewrite-Replace_URLr	REPLACE	HTTP.REQ.URL.PATH_AND_QUERY	"/products/page.htm"
Action-Rewrite-Replace_Host	REPLACE	HTTP.REQ.HOSTNAME	"www.newcompany.com"

You would then create rewrite policies with the values in the following table.

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-Replace-None	Action-Rewrite-Replace-None	NOREWRITE	!HTTP.REQ.HOSTNAME.SERVER.EQ("www.purchasedcompany.com")
Policy-Rewrite-Replace-Host	Action-Rewrite-Replace_Host	NOREWRITE	HTTP.REQ.HOSTNAME.SERVER.EQ("www.purchasedcompany.com")
Policy-Rewrite-Replace-URL	Action-Rewrite-Replace_URL	NOREWRITE	HTTP.REQ.IS_VALID

Finally, you would bind the rewrite policies globally, assigning the first a priority of 100, the second a priority of 200, and the third a priority of 300. These policies should be the last policies applied to a request that matches the criteria. For this reason, set the goto expression to END for the first and third policies, and to 300 for the second policy. This ensures that all remaining requests are processed correctly.

Requests to the acquired company's old Web site are now redirected to the correct page on the New Company home page.

URL Transformation

Mar 21, 2012

The URL transformation feature provides a method for modifying all URLs in designated requests from an external version seen by outside users to an internal URL seen only by your Web servers and IT staff. You can redirect user requests seamlessly, without exposing your network structure to users. You can also modify complex internal URLs that users may find difficult to remember into simpler, more easily remembered external URLs.

Note: Before you can use the URL transformation feature, you must enable the Rewrite feature. To enable the Rewrite feature, see Enabling the Rewrite Feature.

To begin configuring URL transformation, you create profiles, each describing a specific transformation. Within each profile, you create one or more actions that describe the transformation in detail. Next, you create policies, each of which identifies a type of HTTP request to transform, and you associate each policy with an appropriate profile. Finally, you globally bind each policy to put it into effect.

Configuring URL Transformation Profiles

Oct 29, 2013

A profile describes a specific URL transformation as a series of actions. The profile functions primarily as a container for the actions, determining the order in which the actions are performed. Most transformations transform an external hostname and optional path into a different, internal hostname and path. Most useful transformations are simple and require only a single action, but you can use multiple actions to perform complex transformations.

You cannot create actions and then add them to a profile. You must create the profile first, and then add actions to it. In the CLI, creating an action and configuring the action are separate steps. Creating a profile and configuring the profile are separate steps in both the CLI and the configuration utility.

At the NetScaler command prompt, type the following commands, in the order shown, to create a URL transformation profile and verify the configuration. You can then repeat the second and third commands to configure additional actions:

- add transform profile <profileName> -type URL [-onlyTransformAbsURLinBody (ON | OFF)] [-comment <comment>]
- add transform action <name> <profileName> <priority>
- set transform action <name> [-priority <priority>] [-reqUrlFrom <expression>] [-reqUrlInto <expression>] [-resUrlFrom <expression>] [-resUrlInto <expression>] [-cookieDomainFrom <expression>] [-cookieDomainInto <expression>] [-state (ENABLED | DISABLED)] [-comment "<string>"]
- show transform profile <name>

Example

```
> add transform profile shoppingcart -type URL
 Done
> add transform action actshopping shoppingcart 1000
 Done
> set transform action actshopping -priority 1000 -reqUrlFrom 'shopping.example.com' -reqUrlInto 'www.example.net/shopping' -resUrlFrom 'www.example.net/shopping' -re
 Done
> show transform profile shoppingcart
      Name: shoppingcart
           Type: URL      onlyTransformAbsURLinBody: OFF
      Comment:
      Actions:

1)          Priority 1000   Name: actshopping      ENABLED
 Done
```

At the NetScaler command prompt, type the following commands to modify an existing URL transformation profile or action and verify the configuration:

Note: Use a set transform profile or set transform action command, respectively. The set transform profile command takes the same arguments as does the add transform profile command, and set transform action is the same command that was used for initial configuration.

- set transform action <name> [-priority <priority>] [-reqUrlFrom <expression>] [-reqUrlInto <expression>] [-resUrlFrom <expression>] [-resUrlInto <expression>] [-cookieDomainInto <expression>] [-state (ENABLED | DISABLED)] [-comment "<string>"]
- show transform profile <name>

Example

```
> set transform action actshopping -priority 1000 -reqUrlFrom 'searching.example.net' -reqUrlInto 'www.example.net/searching' -resUrlFrom 'www.example.net/searching' -
 Done
> show transform profile shoppingcart
      Name: shoppingcart
           Type: URL      onlyTransformAbsURLinBody: OFF
      Comment:
      Actions:

1)          Priority 1000   Name: actshopping      ENABLED
 Done
```

First remove all actions associated with that profile by typing the following command once for each action:

- rm transform action <name> After you have removed all actions associated with a profile, remove the profile as shown below.
- rm transform profile <name>

1. In the navigation pane, expand Rewrite, expand URL Transformation, and then click Profiles.
2. In the details pane, click Add.
3. In the Create URL Transformation Profile dialog box, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring URL transformation profiles" as follows (asterisk indicates a required parameter):
   - Name*—name
   - Comment—comment
   - Only transform absolute URLs in response body—onlyTransformAbsURLinBody
4. Click Create, and then click Close. A message appears in the status bar, stating that the Profile has been configured successfully.

1. In the navigation pane, expand Rewrite, expand URL Transformation, and then click Profiles.
2. In the details pane, select the profile you want to configure, and then click Open.
3. In the Configure URL Transformation Profile dialog box, do one of the following.

- To create a new action, click Add.
- To modify an existing action, select the action, and then click Open.

4. Fill in the Create URL Transformation Action or Modify URL Transformation Action dialog box by typing or selecting values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring URL transformation profiles" as follows (asterisk indicates a required parameter):
   - Action Name*—name
   - Comments—comment
   - Priority*—priority
   - Request URL from—reqUrlFrom
   - Request URL into—reqUrlInto
   - Response URL from—resUrlFrom
   - Response URL into—resUrlInto
   - Cookie Domain from—cookieDomainFrom
   - Cookie Domain into—cookieDomainInto
   - Enabled—state
5. Save your changes.
   - If you are creating a new action, click Create, and then Close.
   - If you are modifying an existing action, click OK.

   A message appears in the status bar, stating that the Profile has been configured successfully.
6. Repeat step 3 through step 5 to create or modify any additional actions.
7. To delete an action, select the action, and then click Remove. When prompted, click OK to confirm the deletion.
8. Click OK to save your changes and close the Modify URL Transformation Profile dialog box.
9. To delete a profile, in the details pane select the profile, and then click Remove. When prompted, click OK to confirm the deletion.

Configuring URL Transformation Policies

Oct 29, 2013

After you create a URL transformation profile, you next create a URL transformation policy to select the requests and responses that the NetScaler should transform by using the profile. URL transformation considers each request and the response to it as a single unit, so URL transformation policies are evaluated only when a request is received. If a policy matches, the NetScaler transforms both the request and the response.

Note: The URL transformation and rewrite features cannot both operate on the same HTTP header during request processing. Because of this, if you want to apply a URL transformation to a request, you must make sure that none of the HTTP headers it will modify are manipulated by any rewrite action.

You must create a new policy. On the command line, an existing policy can only be removed. At the NetScaler command prompt, type the following commands to configure a URL transformation policy and verify the configuration:

- add transform policy <name> <rule> <profileName>
- show transform policy <name>

Example

```
> add transform policy polsearch  HTTP.REQ.URL.SUFFIX.EQ("Searching") prosearching
 Done
> show transform policy polsearch
1)     Name: polsearch
       Rule: HTTP.REQ.URL.SUFFIX.EQ("Searching")
       Profile: prosearching
       Priority: 0
       Hits: 0
 Done
```

At the NetScaler command prompt, type the following command to remove a URL transformation policy:

rm transform policy <name>

Example

```
> rm transform policy polsearch
Done
```

1. In the navigation pane, expand Rewrite, expand URL Transformation, and then click Policies.
2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.
3. In the Create URL Transformation Policy or Configure URL Transformation Policy dialog box, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring URL transformation policies" as follows (asterisk indicates a required parameter):
   - Name*—name (Cannot be changed for a previously configured policy.)
   - Profile*—profileName
   - Expression—rule

If you want help with creating an expression for a new policy, you can either hold down the Control key and press the space bar while your cursor is in the Expression text box. To create the expression, you can type it directly as described below, or you can use the Add Expression dialog box as described in To add an expression by using the Add Expression dialog box.

1. Click Prefix, and choose the prefix for your expression.
   Your choices are:

   - HTTP—The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
   - SYS—The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   - CLIENT—The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
   - SERVER—The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.
   - URL—The URL of the request. Choose this if you want to examine some aspect of the URL to which the request was sent.
   - TEXT—Any text string in the request. Choose this if you want to examine a text string in the request.
   - TARGET—The target of the request. Choose this if you want to examine some aspect of the request target.
     After you choose a prefix, the NetScaler displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom. The choices depend on which prefix you chose.

2. Select your next term.
   If you chose HTTP as your prefix, your choices are REQ, which specifies HTTP requests, and RES, which specifies HTTP responses. If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

   When you are certain which choice you want, double-click it to insert it into the Expression window.

3. Type a period, and then continue selecting terms from the list boxes that appear to the right of the previous list box. You type the appropriate text strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

4. Click Create or OK, depending on whether you are creating a new policy or modifying an existing policy.
5. Click Close. A message appears in the status bar, stating that the Policy has been configured successfully.

1. In the Create Responder Action or Configure Responder Action dialog box, click Add.
2. In the Add Expression dialog box, in the first list box choose the first term for your expression.
   HTTP

   The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
   SYS

   The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   CLIENT

The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

SERVER

The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

URL

The URL of the request. Choose this if you want to examine some aspect of the URL to which the request was sent.

TEXT

Any text string in the request. Choose this if you want to examine a text string in the request.

TARGET

The target of the request. Choose this if you want to examine some aspect of the request target.

When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.

3. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.
4. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

Globally Binding URL Transformation Policies

Oct 29, 2013

After you have configured your URL transformation policies, you bind them to Global or a bind point to put them into effect. After binding, any a request or response that matches a URL transformation policy is transformed by the profile associated with that policy.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the NetScaler OS, policy priorities work in reverse order - the higher the number, the lower the priority.

Because the URL transformation feature implements only the first policy that a request matches, not any additional policies that it might also match, policy priority is important for achieving the results that you intend. If you give your first policy a low priority (such as 1000), you tell the NetScaler to perform it only if other policies with a higher priority do not match a request. If you give your first policy a high priority (such as 1), you tell the NetScaler to perform it first, and skip any other policies that might also match. You can leave yourself plenty of room to add other policies in any order, without having to reassign priorities, by setting priorities with intervals of 50 or 100 between each policy when you globally bind your policies.

Note: URL transformation policies cannot be bound to TCP-based virtual servers.

At the NetScaler command prompt, type the following commands to globally bind a URL transformation policy and verify the configuration:

- bind transform global <policyName> <priority>
- show transform global

Example

```
> bind transform global polisearching 100
 Done
> show transform global
1)    Policy Name: polisearching
      Priority: 100

 Done
```

1. In the navigation pane, expand Rewrite, then expand URL Transformation, and then click Policies.
2. In the details pane, click Policy Manager.
3. In the Transform Policy Manager dialog box, choose the bind point to which you want to bind the policy. The choices are:
   - **Override Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance, and are applied before any other policies.
   - **LB Virtual Server.** Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.

- **CS Virtual Server.** Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.
- **Default Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance.
- **Policy Label.** Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.

4. Select Insert Policy to insert a new row and display a drop-down list with all available, unbound URL transformation policies.
5. Select the policy you want to bind, or select New Policy to create a new policy. The policy that you selected or created is inserted into the list of globally bound URL transformation policies.
6. Make any additional adjustments to the binding.
   - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
   - To modify the policy expression, double click that field to open the Configure Transform Policy dialog box, where you can edit the policy expression.
   - To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
   - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression
7. Repeat steps 3 through 6 to add any additional URL transformation policies you want to globally bind.
8. Click OK to save your changes. A message appears in the status bar, stating that the Policy has been configured successfully.

Diameter Support for Rewrite

Apr 09, 2014

The Rewrite feature now supports the Diameter protocol. You can configure Rewrite to modify Diameter requests and response as you would HTTP or TCP requests and responses, allowing you to use Rewrite to manage the flow of Diameter requests and make necessary modifications. For example, if the "Origin-Host" value in a Diameter request is inappropriate, you can use Rewrite to replace it with a value that is acceptable to the Diameter server.

To configure the Rewrite feature to replace the Origin-Host in a diameter request with a different value, at the command prompt, type the following commands:

- add rewrite action <actname> replace "DIAMETER.REQ.AVP(264,\"netscaler.example.net\")"
  For <actname>, substitute a name for your new action. The name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For netscaler.example.net, substitute the Host-Origin that you want to use instead of the original Host-Name.
- add rewrite policy <polname> "diameter.req.avp(264).value.eq(\"host.example.com\")" <actname>
  For <polname>, substitute a name for your new policy. As with <actname>, the name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For host.example.com, substitute the name of the Host-Origin that you want to change. For <actname>, substitute the name of the action that you just created.
- bind lb vserver <vservername> -policyName <polname> -priority <priority> -type REQUEST
  For <vservername>, substitute the name of the load balancing virtual server to which you want to bind the policy. For <polname>, substitute the name of the policy you just created. For <priority>, substitute a priority for the policy.

Example

To create a Rewrite action and policy to modify all Diameter Host-Origins of "host.example.com" to "netscaler.example.net", you could add the following action and policy, and bind the policy as shown.

```
> add rewrite action rw_act_replace_avp replace "diameter.req.avp(264)" "diameter.new.avp(264,\"netscaler.example.net\")"
> add rewrite policy rw_diam_pol "diameter.req.avp(264).value.eq(\"client.realm2.net\")" rw_act_replace_avp
> bind lb vserver vs1 -policyName rw_diam_pol -priority 10 -type REQUEST

Done
```

String Maps

Apr 20, 2015

You can use string maps to perform pattern matching in all NetScaler features that use the default policy syntax. A string map is a NetScaler entity that consists of key-value pairs. The keys and values are strings in either ASCII or UTF-8 format. String comparison uses two new functions, MAP_STRING(<string_map_name>) and IS_STRINGMAP_KEY(<string_map_name>).

A policy configuration that uses string maps performs better than one that does string matching through policy expressions, and you need fewer policies to perform string matching with a large number of key-value pairs. String maps are also intuitive, simple to configure, and result in a smaller configuration.

String maps are similar in structure to pattern sets (a pattern set defines a mapping of index values to strings; a string map defines a mapping of strings to strings) and the configuration commands for string maps (commands such as add, bind, unbind, remove, and show) are syntactically similar to configuration commands for pattern sets. Also, as with index values in a pattern set, each key in a string map must be unique across the map. The following table illustrates a string map called url_string_map, which contains URLs as keys and values.

Table 1. String Map "url_string_map"

Key	Value
/url_1.html	http://www.redirect_url_1.com/url_1.html
/url_2.html	http://www.redirect_url_2.com/url_2.html
/url_3.html	http://www.redirect_url_1.com/url_1.html

The following table describes the two functions that have been introduced to enable string matching with keys in a string map. String matching is always performed with the keys. Additionally, the following functions perform a comparison between the keys in the string map and the complete string that is returned by the expression prefix. The examples in the descriptions refer to the preceding example.

Table 2. String Map Functions

Function	Description
<TEXT>.MAP_STRING(<string_map_name>)	Checks whether the value returned by the expression prefix TEXT matches any of the keys in the string map, and returns the value that corresponds to the key. If no key in the string map matches the value returned by the expression prefix, the function returns a null string. The IGNORECASE and NOIGNORECASE functions can be used for case-insensitive and case-sensitive comparison, respectively. Example 1: HTTP.REQ.URL.MAP_STRING("url_string_map") checks whether the string returned by HTTP.REQ.URL is a key in the string map url_string_map. If the value of HTTP.REQ.URL is /url_1.html, the function returns http://www.redirect_url_1.com/url_1.html. Example 2: HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).MAP_STRING("url_string_map") checks whether the string returned by HTTP.REQ.URL is a key in the string map url_string_map. The comparison does not consider case. If the string returned by HTTP.REQ.URL is /URL_1.html, the function returns http://www.redirect_url_1.com/url_1.html. Parameters: string_map_name - The string map.
<TEXT>.IS_STRINGMAP_KEY(<string_map_name>)	Returns TRUE if the string returned by the expression prefix TEXT is a key in the string

Function	Description
	map. The IGNORECASE and NOIGNORECASE functions can be used for case-insensitive and case-sensitive string matching, respectively. **Example 1:** HTTP.REQ.URL.IS_STRINGMAP_KEY("url_string_map") returns TRUE if the value of HTTP.REQ.URL is one of the keys in url_string_map. **Example 2:** HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_string_map") returns TRUE if the value of HTTP.REQ.URL is one of the keys in url_string_map. In this case, key lookup does not consider case. Therefore, the function returns TRUE even if the value of HTTP.REQ.URL is /URL_3.html. **Parameters:** string_map_name - The string map.

You first create a string map and then bind key-value pairs to it. You can create a string map from the command line interface (CLI) or the configuration utility.

To configure a string map by using the command line interface

At the command prompt, do the following:

1. Create a string map.
   add policy stringmap <name> -comment <string>
2. Bind a key-value pair to the string map.
   bind policy stringmap <name> <key> <value>

   Example:

   > bind policy stringmap url_string_map1 "/url_1.html" "http://www.redirect_url_1.com/url_1.html"

To configure a string map by using the configuration utility

Create a string map and bind the key-value pair to the created entity.

Navigate to **AppExpert** > **String Maps**, click **Add** and specify the relevant details.

The following use case involves a responder policy with a redirect action. In the example below, the first four commands create the string map url_string_map and bind the three key-value pairs used in the earlier example. After creating the map and binding the key-value pairs, you create a responder action (act_url_redirects) that redirects the client to the corresponding URL in the string map or to www.default.com. You also configure a responder policy (pol_url_redirects) that checks whether requested URLs match any of the keys in url_string_map and then performs the configured action. Finally, you bind the responder policy to the content switching virtual server that receives the client requests that are to be evaluated.

```
add stringmap url_string_map

bind stringmap url_string_map /url_1.html http://www.redirect_url_1.com/url_1.html

bind stringmap url_string_map /url_2.html http://www.redirect_url_2.com/url_2.html

bind stringmap url_string_map /url_3.html http://www.redirect_url_1.com/url_1.html

add responder action act_url_redirects redirect 'HTTP.REQ.URL.MAP_STRING("url_string_map") ALT "www.default.com"' -bypassSafetyCheck yes

add responder policy pol_url_redirects TRUE act_url_redirects

bind cs vserver csw_redirect -policyname pol_url_redirects -priority 1 -type request
```

String maps are similar in structure to pattern sets (a pattern set defines a mapping of index values to strings; a string map defines a mapping of strings to strings) and the configuration commands for string maps (commands such as add, bind, unbind, remove, and show) are syntactically similar to configuration

commands for pattern sets. Also, as with index values in a pattern set, each key in a string map must be unique across the map. The following table illustrates a string map called url_string_map, which contains URLs as keys and values.

Table 3. String Map "url_string_map"

Key	Value
/url_1.html	http://www.redirect_url_1.com/url_1.html
/url_2.html	http://www.redirect_url_2.com/url_2.html
/url_3.html	http://www.redirect_url_1.com/url_1.html

The following table describes the two functions that have been introduced to enable string matching with keys in a string map. String matching is always performed with the keys. Additionally, the following functions perform a comparison between the keys in the string map and the complete string that is returned by the expression prefix. The examples in the descriptions refer to the preceding example.

Table 4. String Map Functions

Function	Description
<TEXT>.MAP_STRING(<string_map_name>)	Checks whether the value returned by the expression prefix TEXT matches any of the keys in the string map, and returns the value that corresponds to the key. If no key in the string map matches the value returned by the expression prefix, the function returns a null string. The IGNORECASE and NOIGNORECASE functions can be used for case-insensitive and case-sensitive comparison, respectively. Example 1: HTTP.REQ.URL.MAP_STRING("url_string_map") checks whether the string returned by HTTP.REQ.URL is a key in the string map url_string_map. If the value of HTTP.REQ.URL is /url_1.html, the function returns http://www.redirect_url_1.com/url_1.html. Example 2: HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).MAP_STRING("url_string_map") checks whether the string returned by HTTP.REQ.URL is a key in the string map url_string_map. The comparison does not consider case. If the string returned by HTTP.REQ.URL is /URL_1.html, the function returns http://www.redirect_url_1.com/url_1.html. Parameters: string_map_name - The string map.
<TEXT>.IS_STRINGMAP_KEY(<string_map_name>)	Returns TRUE if the string returned by the expression prefix TEXT is a key in the string map. The IGNORECASE and NOIGNORECASE functions can be used for case-insensitive and case-sensitive string matching, respectively. Example 1: HTTP.REQ.URL.IS_STRINGMAP_KEY("url_string_map") returns TRUE if the value of HTTP.REQ.URL is one of the keys in url_string_map. Example 2: HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_string_map") returns TRUE if the value of HTTP.REQ.URL is one of the keys in url_string_map. In this case, key lookup does not consider case. Therefore, the function returns TRUE even if the value of HTTP.REQ.URL is /URL_3.html. Parameters: string_map_name - The string map.

Function	Description

Updated: 2014-07-30

You first create a string map and then bind key-value pairs to it. You can create a string map from the command line interface (CLI) or the configuration utility.

To configure a string map by using the command line interface

At the command prompt, do the following:

1. Create a string map.
   add policy stringmap <name> -comment <string>
2. Bind a key-value pair to the string map.
   bind policy stringmap <name> <key> <value>

   Example:
   > bind policy stringmap url_string_map1 "/url_1.html" "http://www.redirect_url_1.com/url_1.html"

To configure a string map by using the configuration utility

Create a string map and bind the key-value pair to the created entity.

Navigate to AppExpert > String Maps,click Add and specify the relevant details.

You can use string maps in all features that support the newer default policy syntax. For example, string maps can be used in responder redirects and rewrite actions. You can also reuse a given string map in multiple features.

Example: Responder Policy With a Redirect Action

Updated: 2015-04-20

The following use case involves a responder policy with a redirect action. In the example below, the first four commands create the string map url_string_map and bind the three key-value pairs used in the earlier example. After creating the map and binding the key-value pairs, you create a responder action (act_url_redirects) that redirects the client to the corresponding URL in the string map or to www.default.com. You also configure a responder policy (pol_url_redirects) that checks whether requested URLs match any of the keys in url_string_map and then performs the configured action. Finally, you bind the responder policy to the content switching virtual server that receives the client requests that are to be evaluated.

```
add stringmap url_string_map

bind stringmap url_string_map /url_1.html http://www.redirect_url_1.com/url_1.html

bind stringmap url_string_map /url_2.html http://www.redirect_url_2.com/url_2.html

bind stringmap url_string_map /url_3.html http://www.redirect_url_1.com/url_1.html

add responder action act_url_redirects redirect 'HTTP.REQ.URL.MAP_STRING("url_string_map") ALT "www.default.com"' -bypassSafetyCheck yes

add responder policy pol_url_redirects TRUE act_url_redirects

bind cs vserver csw_redirect -policyname pol_url_redirects -priority 1 -type request
```

Traffic Management

Jun 09, 2014

The following topics cover configuration and installation information for NetScaler traffic management features.

Cache Redirection	Analyzes incoming requests and forwards the requests for already cached data to cache servers. Dynamic HTTP requests and non-cacheable requests are forwarded to the origin servers. Cache redirection is a policy-based feature.
Content Switching	Analyzes client requests and redirects the requests to specific servers on the basis of geographical area, authorization credentials, and device from which the request was initiated.
DataStream	Ensures optimal distribution of traffic from the application and web servers to the database servers. Enables you to segment traffic according to information in the SQL query and on the basis of database names, user names, character sets, and packet size.
Domain Name System	Provides authoritative domain name server (ADNS server) functionality for a domain. The NetScaler appliance functions as a DNS end resolver and forwarder, and also helps in name resolution when fully qualified domain names are not configured.
Firewall Load Balancing	Distributes the traffic across multiple firewalls, providing fault tolerance, increased throughput, and high availability.
Global Server Load Balancing	Enables disaster recovery and ensures continuous availability of applications by protecting against points of failure in a wide area network (WAN).
Link Load Balancing	Load balances outbound traffic across multiple Internet connections to transmit packets seamlessly over the best possible link.
Load Balancing	Distributes user requests for web pages and other protected applications across multiple servers to prevent server overloading and failure. Load balancing also provides fault tolerance.
SSL Offload and Acceleration	Offloads SSL processing from a server to the NetScaler appliance to accelerate SSL transactions.
Web 2.0 Push	Offloads connection management from Web 2.0 servers. Instead of having to maintain a long-lived connection to each client, a Web 2.0 server can maintain a single connection to the NetScaler appliance. The appliance relays the server's data to waiting clients over the connections that it maintains with them.

Cache Redirection

Mar 30, 2012

In a typical deployment, different clients ask web servers for the same content repeatedly. To relieve the origin web server of processing each request, a NetScaler® appliance with cache redirection enabled can serve this content from a cache server instead of from the origin server.

The NetScaler analyzes incoming requests, sends requests for cacheable data to cache servers, and sends non-cacheable requests and dynamic HTTP requests to origin servers.

Cache redirection is a policy-based feature. By default, requests that match a policy are sent to the origin server, and all other requests are sent to a cache server. For testing or maintenance, you might want to skip policy evaluation and direct all requests to the cache or to the origin server.

You can combine content switching with cache redirection to cache selective content and serve content from specific cache servers for specific types of requested content.

A NetScaler configured for cache redirection can be deployed at the edge of a network, in front of the origin server, or anywhere along the network backbone. In an edge deployment, commonly used by Internet Service Providers (ISPs), cable companies, content delivery distribution networks, and enterprise networks, the NetScaler resides directly in front of the clients. In a server-side deployment, the NetScaler is closer to the origin servers.

Cache redirection is used most commonly with the HTTP service type, but it also supports the secure HTTPS protocol.

Cache Redirection Policies

Mar 30, 2012

A cache redirection virtual server applies cache redirection policies to each incoming request. By default, if a request matches one of the configured policies, it is considered non-cacheable, and the NetScaler appliance sends it to the origin server. Other requests are sent to a cache server. This behavior can be reversed, so that requests that match configured cache redirection policies are sent to cache servers.

The NetScaler provides a set of policies for cache redirection. If these built-in policies are not adequate for your deployment, you can configure user-defined cache redirection policies.

Note: Once you have determined which built-in cache redirection policies to use, or have created user-defined policies, proceed with configuring cache redirection. To use this feature, you must configure at least one cache redirection virtual server, and, for normal operation, you must bind at least one cache redirection policy to that virtual server.

Built-in Cache Redirection Policies

May 14, 2015

The NetScaler appliance provides built-in cache redirection policies that handle typical cache requests. These policies are based on HTTP methods, the URL or URL tokens of the incoming request, the HTTP version, or the HTTP headers and their values in the request.

Built-in cache redirection policies can be directly bound to a virtual server and do not need further configuration.

Cache redirection policies use the simpler of two NetScaler expressions languages, called *classic expressions*. For a complete description of classic expressions and how to configure them, see

The NetScaler provides the following built-in cache redirection policies

built in Policy Name	Description
bypass-non-get	Bypass the cache if the request uses an HTTP method other than GET.
bypass-cache-control	Bypass the cache if the request header contains a Cache-Control: no-cache or Cache-Control: no-store header, of if the HTTP request contains a pragma header.
bypass-dynamic-url	Bypass the cache if the URL suggests that the content is dynamic, as indicated by the presence of any of the following extensions: • cgi • asp • exe • cfm • ex • shtml • htx Also bypass the cache if the URL starts with any of the following: • /cgi-bin/ • /bin/ • /exec/
bypass-urltokens	Bypass the cache because the request is dynamic, as indicated by one of the following tokens in the URL: ?, !, or =.
bypass-cookie	Bypass the cache for any URL that has a cookie header and an extension other than .gif or .jpg.

Updated: 2013-08-23

You can display the available cache redirection polices by using the command line interface or the configuration utility.

To display the built-in cache redirection policies by using the command line interface

At the command prompt, type:

show cr policy [<policyName>]
Example

```
> show cr policy
1)      Cache-By-Pass RULE: NS_NON_GET        Policy:bypass-non-get
2)      Cache-By-Pass RULE: (NS_CACHECONTROL_NOSTORE || NS_CACHECONTROL_NOCACHE || NS_HEADER_PRAGMA)    Policy:bypass-cache-control
3)      Cache-By-Pass RULE: (NS_EXT_CGI || NS_EXT_ASP || NS_EXT_EXE || NS_EXT_CFM || NS_EXT_EX || NS_EXT_SHTML || NS_EXT_HTX) || (NS_URL_PATH_CGIBIN || NS_URL_I
4)      Cache-By-Pass RULE: NS_URL_TOKENS      Policy:bypass-urltokens
5)      Cache-By-Pass RULE: (NS_HEADER_COOKIE && NS_EXT_NOT_GIF && NS_EXT_NOT_JPEG)    Policy:bypass-cookie
 Done
>
```

To display the built-in cache redirection policies by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Policies. The configured cache redirection policies appear in the details pane.
2. Select one of the configured policies to view details.

Configuring a Cache Redirection Policy

May 14, 2015

A cache redirection policy includes one or more expressions (also called *rules*). Each expression represents a condition that is evaluated when the client request is compared to the policy.

You do not explicitly configure actions for cache redirection policies. By default, the NetScaler appliance considers any request that matches a policy to be non-cacheable and directs the request to the origin server instead of the cache.

Cache redirection uses the *classic policy* format. Each policy has a name and includes an expression or a set of expressions that are combined by using logical operators.

At the command prompt, type the following commands to add a cache redirection policy and verify the configuration:

- add cr policy <policyName> **-rule** <expression>
- show cr policy [<policyName>]

Examples

Policy with a simple expression:

```
> add cr policy Policy-CRD-1 -rule "REQ.HTTP.URL != /*.jpeg"
 Done
> show cr policy Policy-CRD-1
        Cache-By-Pass RULE: REQ.HTTP.URL != '/*.jpeg'   Policy:Policy-CRD-1
 Done
>
```

Policy with a compound expression:

```
> add cr policy Policy-CRD-2 -rule "REQ.HTTP.METHOD == POST && (REQ.HTTP.URL == /*.cgi || REQ.HTTP.URL != /*.gif)"
 Done
> show cr policy Policy-CRD-2
        Cache-By-Pass RULE: REQ.HTTP.METHOD == POST && (REQ.HTTP.URL == '/*.cgi' || REQ.HTTP.URL != '/*.gif')   Policy:Policy-CRD-2
 Done
>
```

Policy that evaluates a header:

```
> add cr policy Policy-CRD-3 -rule "REQ.HTTP.HEADER If-Modified-Since EXISTS"
 Done
> show cr policy Policy-CRD-3
        Cache-By-Pass RULE: REQ.HTTP.HEADER If-Modified-Since EXISTS    Policy:Policy-CRD-3
 Done
>
```

- To modify a cache redirection policy, use the set cr policy command, which is just like add cr policy command, except that you enter the name of an existing policy.
- To remove a policy, use the rm cr policy command, which accepts only the <name> argument. If the policy is bound to a virtual server, you have to unbind the policy, before you can remove it.

For the details of unbinding a cache redirection policy, see "Unbinding a Policy from a Cache Redirection Virtual Server."

1. Navigate to Traffic Management > Cache Redirection > Policies.
2. In the details pane, click Add.
3. In the Create Cache Redirection Policy dialog box, in the Name* text box, type the name of the policy, and then in the Expression area, click Add.
4. To configure a simple expression, enter the expression. Following is an example of an expression that checks for a .jpeg extension in a URL:

- Expression Type-General
- Flow Type -REQ
- Protocol -HTTP
- Qualifier -URL
- Operator - !=
- Value* - /*.jpeg

The simple expression in the following example checks for an If-Modified-Since header in a request:

- Expression Type -General
- Flow Type -REQ
- Protocol -HTTP
- Qualifier -HEADER
- Operator -EXISTS
- Header Name -If-Modified-Since

5. When you are finished entering the expression, click OK or Create, and then click Close.

1. Navigate to Traffic Management > Cache Redirection > Policies.
2. In the details pane, click Add.
3. In the Name text box, enter a name for the policy.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), and underscore (_) symbols. You should choose a name that will make it easy for others to tell what type of content this policy was created to detect.

4. Choose the type of compound expression that you want to create. Your choices are:
   - **Match Any Expression**. The policy matches the traffic if one or more individual expressions match the traffic.
   - **Match All Expressions**. The policy matches the traffic only if every individual expression matches the traffic.
   - **Tabular Expressions**. Switches the Expressions list to a tabular format with three columns. In the rightmost column, you place one of the following operators:
     - The AND [&&] operator, to require that, to match the policy, a request must match both the current expression and the following expression.
     - The OR [||] operator, to require that, to match the policy, a request must match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.

     You can also group expressions in nested subgroups by selecting an existing expression and clicking one of the following operators:

     - The BEGIN SUBGROUP [+ ( ] operator, which tells the NetScaler appliance to begin a nested subgroup with the selected expression. (To remove this operator from the expression, click -(.)
     - The END SUBGROUP [+)] operator, which tells the NetScaler appliance to end the current nested subgroup with the selected expression. (To remove this operator from the expression, click -) .)
   - **Advanced Free-Form**. Switches off the Expressions Editor entirely and turns the Expressions list into a text area in which you can type a compound expression. This is both the most powerful and the most difficult method of creating a policy expression, and is recommended only for those thoroughly familiar with the NetScaler classic expressions language.
     For more information about creating classic expressions in the Advanced Free-Form text area, see "Configuring Classic Policies and Expressions".

     Caution: If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression editing mode unless you are sure that you want to use it.
5. If you chose Match Any Expression, Match All Expressions, or Tabular Expressions, click **Add** to display the Add Expression dialog box.

   You should leave the expression type set to **General** for cache redirection policies.

6. In the Flow Type drop-down list, choose a flow type for your expression.

   The flow type determines whether the policy examines incoming or outgoing connections. You have two choices:

   - **REQ**. Configures the NetScaler appliance to examine incoming connections, or requests.
   - **RES**. Configures the appliance to examine outgoing connections, or responses.
7. In the Protocol drop-down list, choose a protocol for your expression.

   The protocol determines the type of information that the policy examines in the request or response. Depending upon whether you chose REQ or RES in the previous drop-down list, either all four or only three of the following choices are available:

   - **HTTP**. Configures the appliance to examine the HTTP header.
   - **SSL**. Configures the appliance to examine the SSL client certificate. Available only if you chose REQ (requests) in the previous drop-down list.
   - **TCP**. Configures the appliance to examine the TCP header.

- **IP**. Configures the appliance to examine the source or destination IP address.

8. Choose a qualifier for your expression from the Qualifier drop-down list.

The contents of the Qualifier drop-down list depend on which protocol you chose. The following table describes the choices available for each protocol.

Table 1. Cache Redirection Policy Qualifiers Available for Each Protocol

Protocol	Qualifier	Definition
HTTP	METHOD	HTTP method used in the request.
	URL	Contents of the URL header.
	URLTOKENS	URL tokens in the HTTP header.
	VERSION	HTTP version of the connection.
	HEADER	Header portion of the HTTP request.
	URLLEN	Length of the contents of the URL header.
	URLQUERY	Query portion of the contents of the URL header.
	URLQUERYLEN	Length of the query portion of the URL header.
SSL	CLIENT.CERT	SSL client certificate as a whole.
	CLIENT.CERT.SUBJECT	Contents of the client certificate subject field.
	CLIENT.CERT.ISSUER	Client certificate issuer.
	CLIENT.CERT.SIGALGO	Signature algorithm used in the client certificate.
	CLIENT.CERT.VERSION	Client certificate version.
	CLIENT.CERT.VALIDFROM	Date from which the client certificate is valid. (The start date.)
	CLIENT.CERT.VALIDTO	Date after which the client certificate is no longer valid. (The end date.)
	CLIENT.CERT.SERIALNUMBER	Client certificate serial number.
	CLIENT.CIPHER.TYPE	Encryption method used in the client certificate.
	CLIENT.CIPHER.BITS	Number of significant bits in the encryption key.
	CLIENT.SSL.VERSION	SSL version of the client certificate.
TCP	SOURCEPORT	Source port of the TCP connection.
	DESTPORT	Destination port of the TCP connection.
	MSS	Maximum segment size (MSS) of the TCP connection.

Protocol	Qualifier	Definition
IP	SOURCEIP	Source IP address of the connection.
	DESTIP	Destination IP address of the connection.

9. Choose the operator for your expression from the Operator drop-down list.

   Your choices depend on the qualifier you chose in the previous step. The complete list of operators that can appear in this drop-down list is:

   - == . Matches the following text string exactly.
   - != . Does not match the following text string.
   - > . Is greater than the following integer.
   - CONTAINS . Contains the following text string.
   - CONTENTS . The contents of the designated header, URL, or URL query.
   - EXISTS . The specified header or query exists.
   - NOTCONTAINS . Does not contain the following text string.
   - NOTEXISTS . The specified header or query does not exist.

   If you want this policy to operate on requests sent to a specific Host, you can leave the default, the equals (==) sign.

10. If the Value text box is visible, type the appropriate string or number into the text box.
    For example, if you want this policy to select requests sent to the host shopping.example.com, you would type that string in the Value text box.

11. If you chose HEADER as the qualifier, type the header you want in the Header Name text box.
12. Click OK to add your expression to the Expression list.
13. Repeat steps 4 through 11 to create additional expressions.
14. Click Close to close the Add Expression dialog box and return to the Create Cache Redirection Policy dialog box.

Cache Redirection Configurations

Mar 30, 2012

Depending on your deployment and network topology, you can configure one of the following types of cache redirection:

- **Transparent**. A transparent cache can reside on a variety of points along a network backbone to alleviate traffic along the delivery route. In transparent mode, the cache redirection virtual server intercepts all traffic flowing to the NetScaler appliance and applies cache redirection policies to determine whether content should be served from the cache or from the origin server.
- **Forward proxy**. A forward proxy cache server resides on the edge of an enterprise LAN and faces the WAN. In the forward proxy mode, the cache redirection virtual server resolves the hostname of the incoming request by using a DNS server and forwards requests for non-cacheable content to the resolved origin servers. Cacheable requests are sent to the configured cache servers.
- **Reverse proxy**. Reverse proxy caches are configured for specific origin servers. Incoming traffic directed to the reverse proxy, can either be served from a cache server or be sent to the origin server with or without modification to the URL.

Configuring Transparent Redirection

Sep 11, 2013

When you configure transparent cache redirection, the NetScaler appliance evaluates all traffic it receives, to determine whether it is cacheable. This mode alleviates traffic along the delivery route and is often used when the cache server resides on the backbone of an ISP or carrier.

By default, cacheable requests are sent to a cache server, and non-cacheable requests to the origin server. For example, when the NetScaler appliance receives a request that is directed to a web server, it compares the HTTP headers in the request with a set of policy expressions. If the request does not match the policy, the appliance forwards the request to a cache server. If the response does match a policy, the appliance forwards the request, unchanged, to the web server.

For details on how to modify this default behavior, see "Directing Policy Hits to the Cache instead of the Origin."

To configure transparent redirection, first enable cache redirection and load balancing, and configure edge mode. Then, create a cache redirection virtual server with a wildcard IP address (*), so that this virtual server can receive traffic coming to the NetScaler on any IP address the appliance owns. To this virtual server, bind cache redirection policies that describe the types of requests that should not be cached. Then, create a load balancing virtual server that will receive traffic from the cache redirection virtual server for cacheable requests. Finally, create a service that represents a physical cache server and bind it to the load balancing virtual server.

Enabling Cache Redirection and Load Balancing

Oct 31, 2013

The NetScaler cache redirection and load balancing features are not enabled by default. They must be enabled before any cache redirection configuration can take effect.

At the command prompt, type the following command to enable cache redirection and load balancing and verify the settings:

- enable ns feature cr lb
- show ns feature

Example

```
> enable ns feature cr lb
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)    Web Logging              WL              ON
 2)    Surge Protection          SP              ON
 3)    Load Balancing           LB              ON
 4)    Content Switching         CS              ON
 5)    Cache Redirection         CR              ON
 6)    Sure Connect

         ...
         ...
         ...

 23)   HTML Injection           HTMLInjection      ON
 24)   NetScaler Push           push            OF
 Done
>
```

1. In the navigation pane, expand System, and then click Settings.
2. To enable cache redirection, in the details pane, under Modes and Features, click Configure advanced features.
   1. In Configure Advanced Features dialog box, select the check box next to the Cache Redirection, and then click OK.
   2. In Enable/Disable Feature(s)? dialog box, click Yes.
3. To enable load balancing, in the details pane, under Modes and Features, click Configure basic features.
   1. In Configure Basic Features dialog box, select the check box next to the Load Balancing, and then click OK.
   2. In Enable/Disable Feature(s)? dialog box, click Yes.

Configuring Edge Mode

Oct 31, 2013

When deployed at the edge of a network, the NetScaler appliance dynamically learns about the servers on that network. Edge mode enables the appliance to dynamically learn about up to 40,000 HTTP servers and proxy TCP connections for these servers.

This mode turns off collection of statistics for the dynamically learned services and is typically used in transparent deployments for cache redirection.

At the command prompt, type the following commands to enable edge mode and verify the setting:

- enable ns mode Edge
- show ns mode

Example

```
> enable ns mode edge
 Done

> show ns mode

      Mode                  Acronym          Status
      -------               -------          ------
        ...
        ...
        ...
 6)   MAC-based forwarding       MBF             ON
 7)   Edge configuration         Edge            ON
 8)   Use Subnet IP              USNIP           OFF
        ...
        ...
        ...
 16)  Bridge BPDUs               BridgeBPDUs     OFF
 Done
>
```

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In Configure Modes dialog box, select the check box next to the Edge Configuration, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

Configuring a Cache Redirection Virtual Server

Sep 10, 2013

By default, a cache redirection virtual server forwards cacheable requests to the load balancing virtual server for the cache, and forwards non-cacheable requests to the origin server (except in a reverse proxy configuration, in which non-cacheable requests are sent to a load balancing virtual server). There are three types of cache redirection virtual servers: transparent, forward proxy, and reverse proxy.

A transparent cache redirection virtual server uses an IP address of * and a port number, usually 80, that can accept HTTP traffic sent to any IP address that the NetScaler represents. As a result, you can configure only one transparent cache redirection virtual server. Any additional cache redirection virtual servers that you configure must be forward proxy or reverse proxy redirection servers.

At the command prompt, type the following commands to add a cache redirection virtual server and verify the configuration:

- add cr vserver <name> <serviceType> [<IPAddress> <port>] [-cacheType <cacheType>] [-redirect <redirect>]
- show cr vserver [<name>]

Example

```
add cr vserver Vserver-CRD-1 HTTP * 80 -cacheType TRANSPARENT -redirect POLICY
> show cr vserver Vserver-CRD-1
      Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
      State: UP  ARP:DISABLED
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default:       Content Precedence: RULE       Cache: TRANSPARENT
      On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF
 Done
>
```

- To modify a virtual server, use the set cr vserver command, which is just like using the add cr vserver command, except that you enter the name of an existing virtual server.
- To remove a virtual server, use the rm cr vserver command, which accepts only the <name> argument.

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Cache Redirection) dialog box, specify values for the following parameters as shown:

- Name*—name
- Port*—port

* A required parameter

4. In the Protocol drop-down list, select a supported protocol (for example, **HTTP**). If the virtual server is to receive traffic on a port other than the standard port for the selected protocol, enter a new value in the Port field.
5. Click the Advanced tab.
6. Verify that Cache Type is set to TRANSPARENT and Redirect is set to POLICY.
7. Click Create, and then click Close. The Cache Redirection Virtual Servers pane displays the new virtual server.
8. Select the new cache redirection virtual server to display the details of its configuration.

Binding Policies to the Cache Redirection Virtual Server

Aug 22, 2013

Cache redirection policies are not automatically bound to the cache redirection virtual server. A policy based cache redirection virtual server cannot function unless you bind at least one policy to it.

At the command prompt, type:

- bind cr vserver <name> -policyName <string>
- show cr vserver [<name>]

Example

```
> bind cr vserver Vserver-CRD-1 -policyName bypass-cache-control
 Done
> bind cr vserver Vserver-CRD-1 -policyName bypass-dynamic-url
 Done
> bind cr vserver Vserver-CRD-1 -policyName bypass-urltokens
 Done
> bind cr vserver Vserver-CRD-1 -policyName bypass-cookie
 Done

> show cr vserver Vserver-CRD-1
      Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
      State: UP  ARP:DISABLED
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default:       Content Precedence: RULE       Cache: TRANSPARENT
      On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF

1)     Cache bypass  Policy: bypass-cache-control
2)     Cache bypass  Policy: bypass-dynamic-url
3)     Cache bypass  Policy: bypass-urltokens
4)     Cache bypass  Policy: bypass-cookie
 Done
>
```

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. Click the virtual server that you want to configure, and click Open.
3. On the Policies tab, select type of the policy and then click Insert Policy.

4. Under Policy Name column, select the policy that you want to bind.
5. Click OK.

Unbinding a Policy from a Cache Redirection Virtual Server

Aug 23, 2013

When you unbind a policy from the cache redirection virtual server, the NetScaler appliance no longer applies the policy when evaluating client requests.

At the command prompt, type:

- unbind cr vserver <name> -policyName <string>
- show cr vserver [<name>]

Example

```
unbind cr vserver Vserver-CR-1 -policyName bypass-non-get
> show cr vserver Vserver-CRD-1
      Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
      State: UP  ARP:DISABLED
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default:       Content Precedence: RULE       Cache: TRANSPARENT
      On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON      Via: ON ARP: OFF

1)     Cache bypass  Policy: bypass-cache-control
 Done
>
```

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. Click the virtual server that you want to configure, and then click Open.
3. On the Policies tab, under Policy Name, select the policy that you want to unbind.
4. Click Unbind Policy, and then click OK.

Creating a Load Balancing Virtual Server

Sep 10, 2013

The cache redirection virtual server on the NetScaler appliance can send requests to either a cache server farm, if the request is cacheable, or to the origin server farm if the request is not cacheable.

Each cache server is represented on the appliance by a service, which is bound to a load balancing virtual server that receives requests from the cache redirection virtual server and forwards those requests to the servers.

For details on configuring load balancing virtual servers and other configuration options, see "Load Balancing."

At the command prompt, type the following commands to create a load balancing virtual server and verify the configuration:

- add lb vserver <name> <serviceType> [<IPAddress>] [<port>]
- show lb vserver [<name>]

Example

```
> add lb vserver Vserver-LB-CR HTTP 10.102.20.30 80
 Done
> show lb vserver Vserver-LB-CR
        Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
        State: DOWN
        Last state change was at Fri Jul  2 08:47:52 2010
        Time since last state change: 0 days, 00:00:08.470
        Effective State: DOWN
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        No. of Bound Services :  0 (Total)      0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE
        Vserver IP and Port insertion: OFF
        Push: DISABLED  Push VServer:
        Push Multi Clients: NO
        Push Label Rule: none
 Done
>
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:

- Name*-name
- IP Address*- IPAddress
- Port*-port

* A required parameter

4. In the Protocol* drop down list, select a supported protocol (for example, **HTTP**). If the virtual server is to receive traffic on a port other than the well-known port for the selected protocol, enter a new value in the Port field.
5. Click Create, and then click Close. The Load Balancing Virtual Servers pane displays the new virtual server.

Configuring an HTTP Service

Sep 10, 2013

On the NetScaler appliance, a service represents a physical server on the network. In the transparent cache redirection configuration, the service represents the cache server. Cacheable requests are sent by the cache redirection virtual server to the load balancing virtual server, which in turn forwards each request to the correct service, which passes it on to the cache server.

At the command prompt, type the following commands to create an HTTP service and verify the configuration:

- add service <name> <IP> <serviceType> <port> -cacheType <cacheType>
- show service [<name>]

Example

```
> add service Service-HTTP-1 10.102.29.40 HTTP 80 -cacheType TRANSPARENT
 Done
> show service Service-HTTP-1
      Service-HTTP-1 (10.102.29.40:80) - HTTP
      State: DOWN
      Last state change was at Fri Jul  2 09:14:17 2010
      Time since last state change: 0 days, 00:00:13.820
      Server Name: 10.102.29.40
      Server ID : 0   Monitor Threshold : 0
      Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
      Use Source IP: NO
      Client Keepalive(CKA): NO
      Access Down Service: NO
      TCP Buffering(TCPB): NO
      HTTP Compression(CMP): YES
      Idle timeout: Client: 180 sec   Server: 360 sec
      Client IP: DISABLED
      Cache Type: TRANSPARENT Redirect Mode:
      Cacheable: NO
      SC: OFF
      SP: ON
      Down state flush: ENABLED

1)     Monitor Name: tcp-default
            State: DOWN     Weight: 1
            Probes: 3       Failed [Total: 3 Current: 3]
            Last response: Failure - Time out during TCP connection establishment stage
            Response Time: N/A
 Done
>
```

- To modify a service, use the set service command, which is just like using the add service command, except that you enter the name of an existing service.
- To remove a service, use the rm service command, which accepts only the <name> argument.

1. Navigate to Traffic Management > Load Balancing > Services
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:

   - Service Name*—name
   - Server*— IP
   - Port*—port

   * A required parameter

4. In the Protocol* drop-down list, select a supported protocol (for example, **HTTP**).
5. Click Create, and then click Close.

Binding/Unbinding a Service to/from a Load Balancing Virtual Server

Aug 22, 2013

You must bind a service to the load balancing virtual server. This enables the load balancer to forward the request to the server that the service represents. If your configuration changes, you can unbind a service from the load balancing virtual server.

To bind a service to a load balancing virtual server by using the command line interface

At the command prompt, type:

- bind lb vserver <name> <serviceName>
- show lb vserver [<name>]

Example

```
> bind lb vserver vserver-LB-CR service-HTTP-1
 Done
> show lb vserver Vserver-LB-CR
      Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
      State: DOWN
      Last state change was at Fri Jul  2 08:47:52 2010
      Time since last state change: 0 days, 00:42:25.610
      Effective State: DOWN
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Port Rewrite : DISABLED
      No. of Bound Services :  1 (Total)      0 (Active)
      Configured Method: LEASTCONNECTION
      Mode: IP
      Persistence: NONE
      Vserver IP and Port insertion: OFF
      Push: DISABLED  Push VServer:
      Push Multi Clients: NO
      Push Label Rule: none

1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
 Done
>
```

To unbind a service from a load balancing virtual server by using the command line interface

To unbind a service, use the unbind lb vserver command instead of bind lb vserver.

To bind/unbind a service from a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers
2. In the details pane, select the virtual server from which you want to bind/unbind the service, and then click Open.

3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

Disabling the Use the Proxy Port Setting for Transparent Caching

Sep 11, 2013

If the use source IP (USIP) option is disabled on a cache service configured on the NetScaler appliance, the appliance forwards client requests to the cache service by using a NetScaler-owned subnet IP (SNIP) address or mapped IP (MIP) address as the source IP address and a random port as the source port. The randomly selected port is called the proxy port.

However, if you want to configure a fully transparent cache (a cache configuration in which the cache service receives the client's IP address and port number), you must not only enable the USIP option, either globally or on the cache service, but also disable the Use Proxy Port setting, either globally or on the cache service. Disabling the Use Proxy Port setting enables the appliance to use the client's source port as the source port when it connects to the cache service, and ensures a fully transparent cache configuration.

For more information about configuring the Use Proxy Port option globally or on a service, see "Configuring the Source Port for Server-Side Connections."

Assigning a Port Range to the NetScaler

Aug 22, 2013

Sharing of the client IP address may create a conflict that makes network devices, such as routers, cache servers, origin servers, and other NetScaler appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

A method to solve this problem is to assign a source port range to the NetScaler appliance. This allotment enables network devices to unambiguously identify the NetScaler appliance that sent the request.

To assign a source port range to a NetScaler appliance by using the command line interface

At the command prompt, type:

set ns param -crPortRange <startPortNumber-endPortNumber>

To assign a source port range to a NetScaler appliance by using the NetScaler configuration utility

1. In the navigation pane, click System, and then click Settings.
2. In the Settings group, click the Change global system settings link.
3. In the Cache Redirection Port Range group, specify the port range for the NetScaler by typing a port number for Start Port and a port number for End Port.
4. Click OK.

Enabling Load Balancing Virtual Servers to Redirect Requests to Cache

Aug 23, 2013

If a load balancing virtual server is configured to listen on a particular IP address and port combination, it takes precedence over the cache redirection virtual server for any requests destined for that address-port combination. Therefore, the cache redirection virtual server does not process those requests.

If you want to override this functionality and let the cache redirection virtual server decide whether the request should be served from the cache or not, configure the particular load balancing virtual server to be cacheable.

Such a configuration is typically used when an ISP uses a NetScaler appliance at the edge of its network and all traffic flows through the appliance.

To enable load balancing virtual servers to redirect requests to the cache by using the command line interface

At the command prompt, type:

- set lb vserver <name> [-cacheable (YES | NO)]
- show lb vserver [<name>]

Example

```
set lb vserver Vserver-LB-CR –cacheable YES
> show lb vserver vserver-LB-CR
      Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
      State: DOWN
      Last state change was at Fri Jul  2 08:47:52 2010
      Time since last state change: 0 days, 01:05:51.510
      Effective State: DOWN
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Port Rewrite : DISABLED
      No. of Bound Services :  1 (Total)      0 (Active)
      Configured Method: LEASTCONNECTION
      Mode: IP

      Cacheable: YES  PQ: OFF SC: OFF
      Vserver IP and Port insertion: OFF
      Push: DISABLED  Push VServer:
      Push Multi Clients: NO
      Push Label Rule: none

1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
 Done
```

For transparent cache redirection, the NetScaler intercepts all traffic and evaluates every request to determine whether it is cacheable. Non-cacheable requests are sent unchanged to the origin server.

When using transparent cache redirection, you may want to turn off cache redirection for load balancing virtual servers that always direct traffic to origin servers.

To turn off caching for a load balancing virtual server by using the command line interface

To turn off caching for a load balancing virtual, use the unset lb vserver command instead of set lb vserver. Specify a value of NO value for the **-cacheable** parameter**.**

To enable or disable load balancing virtual servers to redirect requests to the cache by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server from which you want to enable/disable the caching, and then click Open.
3. On the Advanced tab, select/clear Cache Redirection check box.
4. Click OK.

Configuring Forward Proxy Redirection

Dec 17, 2013

A forward proxy is a single point of contact for a client or group of clients. In this configuration, the NetScaler appliance redirects non-cacheable requests to an origin server and redirects cacheable requests to either a forward proxy cache or a transparent cache.

When the NetScaler is configured as a forward proxy, users must modify their browsers so that the browser sends requests to the forward proxy instead of the destination servers.

A forward proxy cache redirection virtual server on the NetScaler compares the request with a policy for caching. If the request is not cacheable, the NetScaler queries a DNS load balancing virtual server for resolution of the destination, and then sends the request to the origin server. If the request is cacheable, the NetScaler forwards the request to a load balancing virtual server for the cache.

The NetScaler relies on a host domain name or IP address in the request's HOST header to determine the requested destination. If there is no HOST header in the request, the appliance inserts a HOST header based on the destination IP address in the request.

Typically, the NetScaler appliance acts as a forward proxy in an enterprise LAN. In such a configuration, the appliance resides at the edge of an enterprise LAN and intercepts client requests before they are fanned out to the WAN. Configuring the appliance in the forward proxy mode reduces traffic on the WAN.

To configure forward proxy cache redirection, first enable load balancing and cache redirection on the NetScaler. Then, configure a DNS load balancing virtual server and associated services. Also configure a load balancing virtual server and bind to it appropriate services for the cache. Configure a forward proxy cache redirection virtual server and bind the DNS and load balancing virtual servers to it. You must also configure caching policies and bind them to the cache redirection virtual server. To complete the setup, configure the client browsers to use the forward proxy.

For details on how to enable cache redirection and load balancing on the NetScaler, see "Enabling Cache Redirection and Load Balancing."

For details on how to create a load balancing virtual server, see "Creating a Load Balancing Virtual Server."

For details on how to configure services that represent the cache server, see "Configuring an HTTP Service."

For details on how to bind the service to a virtual server, see "Binding Services to the Virtual Server."

For details on how to create a forward proxy cache redirection server, see "Configuring a Cache Redirection Virtual Server", and create a virtual server of type TRANSPARENT or FORWARD.

For details on binding cache redirection policies to the cache redirection virtual server, see "Configuring a Cache Redirection Policy."

Creating a DNS Service

Sep 10, 2013

A DNS service is a representation, on the NetScaler appliance, of a physical DNS server in the network. A DNS load balancing virtual server sends DNS requests to the DNS server in the network through such a service.

To create a DNS service by using the command line interface

At the command line, type the following commands to create a DNS service and verify the configuration :

- add service <name> <IP> <serviceType> <port>
- show service [<name>]

Example

```
add service Service-DNS-1 10.102.29.41 DNS 53
show service Service-DNS-1
 Service-DNS-1 (10.102.29.41:53) - DNS
      State: DOWN
      Last state change was at Fri Jul  2 10:14:32 2010
      Time since last state change: 0 days, 00:00:13.550
      Server Name: 10.102.29.41
      Server ID : 0   Monitor Threshold : 0
      Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
      Use Source IP: NO
      Client Keepalive(CKA): NO
      Access Down Service: NO
      TCP Buffering(TCPB): NO
      HTTP Compression(CMP): NO
      Idle timeout: Client: 120 sec   Server: 120 sec
      Client IP: DISABLED
      Cacheable: NO
      SC: OFF
      SP: OFF
      Down state flush: ENABLED

1)     Monitor Name: ping-default
            State: DOWN     Weight: 1
            Probes: 3       Failed [Total: 3 Current: 3]
            Last response: Failure - Probe timed out.
            Response Time: 2000.0 millisec
 Done
```

To add an DNS service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:

   - Service Name*—name

- Server*—IP
- Port*—port

* A required parameter

4. In the Protocol* drop down list, select a supported protocol (for example, **DNS**).
5. Click Create, and then click Close.

Creating a DNS Load Balancing Virtual Server

Aug 23, 2013

The DNS virtual server enables the forward proxy to perform DNS resolution before forwarding a client request to an origin server. The DNS load balancing virtual server is associated with the DNS service that represents the physical DNS server on the network.

To create a DNS load balancing virtual server by using the command line interface

At the command line, type the following commands to create a DNS load balancing virtual server and verify the configuration:

- add lb vserver <name> <serviceType>
- show lb vserver [<name>]

Example

```
> add lb vserver Vserver-DNS-1 DNS
 Done
> show lb vserver Vserver-DNS-1
      Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
      State: DOWN
      Last state change was at Fri Jul  2 10:32:28 2010
      Time since last state change: 0 days, 00:00:08.10
      Effective State: DOWN  ARP:DISABLED
      Client Idle Timeout: 120 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      No. of Bound Services :  0 (Total)       0 (Active)
      Configured Method: LEASTCONNECTION
      Mode: IP
      Persistence: NONE
 Done
>
```

To create a DNS load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, in the Name box, type a name for the virtual server.
4. In the Protocol* drop down list, select a supported protocol (for example, **DNS**).
5. Click Create, and then click Close. The DNS Virtual Servers pane displays the new virtual server.

Binding the DNS Service to the Virtual Server

Aug 22, 2013

For the DNS server to respond to DNS requests, the service representing the DNS server must be bound to the DNS virtual server.

To bind the DNS service to the load balancing virtual server:

At the command prompt, type the following commands to bind the DNS service to the load balancing virtual server and verify the configuration:

- bind lb vserver <name> <serviceName>
- show lb vserver <name>

Example

```
> bind lb vserver Vserver-DNS-1 Service-DNS-1
 Done
> show lb vserver Vserver-DNS-1
      Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
      State: DOWN
      Last state change was at Fri Jul  2 10:32:28 2010
      Time since last state change: 0 days, 00:12:16.80
      Effective State: DOWN  ARP:DISABLED
      Client Idle Timeout: 120 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      No. of Bound Services :  1 (Total)      0 (Active)
      Configured Method: LEASTCONNECTION
      Mode: IP
      Persistence: NONE

1) Service-DNS-1 (10.102.29.41: 53) - DNS State: DOWN   Weight: 1
 Done
>
```

To unbind a DNS service from the load balancing virtual server:

Use the unbind lb vserver command instead of bind lb vserver.

To Bind/Unbind a DNS service to/from a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers
2. In the details pane, select the virtual server to/from which you want to bind/unbind the DNS service, and then click Open.
3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

Configuring a Client Web Browser to Use a Forward Proxy

Mar 30, 2012

When you configure the NetScaler appliance as forward proxy cache redirection virtual server in the network, you must configure the client Web browser to send requests to the forward proxy. Typically, when you use a forward proxy, the only route to the servers in the network is through the forward proxy.

Refer the documentation for your browser to configure the browser to use a forward proxy. Specify the IP address and port number of the forward proxy cache redirection virtual server for this configuration.

Configuring Reverse Proxy Redirection

Dec 17, 2013

A reverse proxy resides in front of one or more Web servers and shields the origin server from client requests. Often, a reverse proxy cache is a front-end for all client requests to a server. An administrator assigns a reverse proxy cache to a specific origin server. This is unlike transparent and forward proxy caches, which cache frequently requested content for all requests to any origin server, and the choice of a server is based on the request.

Unlike a transparent proxy cache, the reverse proxy cache has its own IP address and can replace destination domains and URLs in a non-cacheable request with new destination domains and URLs.

You can deploy reverse proxy cache redirection at the origin-server side or at the edge of a network. When deployed at the origin server, the reverse proxy cache redirection virtual server is a front-end for all requests to the origin server.

In the reverse proxy mode, when the NetScaler receives a request, a cache redirection virtual server evaluates the request and forwards it to either a load balancing virtual server for the cache or a load balancing virtual server for the origin. The incoming request can be transformed by changing the host header or the host URL before they it is sent to the backend server.

To configure reverse proxy cache redirection, first enable cache redirection and load balancing. Then, configure a load balancing virtual server and services to send cacheable requests to the cache servers. Also configure a load balancing virtual server and associated services for the origin servers. Then, configure a reverse proxy cache redirection virtual server and bind relevant cache redirection policies to it. Finally, configure mapping policies and bind them to the reverse proxy cache redirection virtual server.

The mapping policies have an associated action that enables the cache redirection virtual server to forward any non-cacheable request to the load balancing virtual server for the origin.

Be sure to create the default cache server destination.

For details on how to enable cache redirection and load balancing on the NetScaler, see "Enabling Cache Redirection and Load Balancing."

For details on how to create a load balancing virtual server, see "Creating a Load Balancing Virtual Server."

For details on how to configure services that represent the cache server, see "Configuring an HTTP Service."

For details on how to bind the service to a virtual server, see "Binding Services to the Virtual Server."

For details on how to create a reverse proxy cache redirection server, see "Configuring a Cache Redirection Virtual Server", and create a virtual server of type REVERSE.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see "Binding Policies to the Cache Redirection Virtual Server."

Configuring Mapping Policies

If an incoming request is non-cacheable, the reverse-proxy cache redirection virtual server replaces the domain and URL in the request with the domain and URL of a target origin server and forwards the request to the load balancing virtual server for the origin.

A mapping policy enables the reverse proxy cache redirection virtual server to replace the destination domain and URL and forward the request to the load balancing virtual server for the origin.

A mapping policy must first translate the domain and the URL, and then pass the request on to the origin load balancing virtual server.

A mapping policy can map a domain, a URL prefix, and a URL suffix, as follows:

- Domain mapping: You can map a domain without a prefix or suffix. The domain mapping is the default mapping for the virtual server (for example, mapping www.mycompany.com to www.myrealcompany.com).
- Prefix mapping: You can replace a specified pattern prefixed as part of the URL (for example, mapping www.mycompany.com/sports/index.html to www.mycompany.com/news/index.html).
- Suffix mapping: You can replace the file suffix in the URL (for example, mapping www.mycompany.com/sports/index.html to www.mycompany.com/sports/index.asp).

The source and the destination strings being mapped must be similar. If you specify a source domain, you must specify a destination domain, and if you specify a source suffix, you must specify a destination suffix. Similarly, if you specify an exact URL from the source, the target URL must also be an

exact URL.

Once you configure mapping policies for the reverse proxy mode, you must bind them to the cache redirection virtual server.

You can use combinations of the source URL, target URL, and source and target domains to configure all three types of domain mapping.

To configure a mapping policy for reverse proxy mode by using the command line interface

At the command prompt, type the following command to add a policy map and verify the configuration:

- add policy map <mapPolicyName> -sd <string> [-su <string>] [-td <string>] [-tu <string>]
- show policy map [<mapPolicyName>]

Example

The following command maps a domain in a client request to a target domain:

```
> add policy map myMappingPolicy -sd www.mycompany.com -td www.myrealcompany.com
 Done
> show policy map myMappingPolicy
1)     Name: myMappingPolicy
       Source Domain: www.mycompany.com       Source Url:
       Target Domain: www.myrealcompany.com    Target Url:
 Done
>
```

Following is an example of mapping a URL suffix to a different URL suffix:

```
> add policy map myOtherMappingPolicy -sd www.mycompany.com -td www.myrealcompany.com -su /news.html -tu /realnews.html
 Done
> show policy map myOtherMappingPolicy
1)     Name: myOtherMappingPolicy
       Source Domain: www.mycompany.com       Source Url: /news.html
       Target Domain: www.myrealcompany.com    Target Url: /realnews.html
 Done
>
```

To configure a mapping policy for reverse proxy mode by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Map Policies.
2. In the details pane, click Add.
3. In the Create Map Policy dialog box, specify values for the following parameters as shown:

   - Name*- mapPolicyName
   - Source Domain*-sd
   - Target Domain*-td
   - Source URL-su
   - Target URL-tu

   * A required parameter

4. Click Create, and then click Close. The Map pane displays the new mapping policy.

To bind the mapping policy to the cache redirection virtual server by using the command line interface

At the command prompt, type the following commands to bind the mapping policy to the cache redirection virtual server and verify the configuration:

- bind cr vserver <name> -policyName <string> [<targetVserver>]
- show cr vserver <name>

Example

```
> bind cr vserver Vserver-CRD-3 -policyName myMappingPolicy Vserver-LB-CR
 Done
> show cr vserver Vserver-CRD-3
        Vserver-CRD-3 (10.102.29.50:88) - HTTP  Type: CONTENT
        State: UP
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default: Vserver-LB-CR  Content Precedence: RULE        Cache: REVERSE
        On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF

1)      Policy:         Target: Vserver-LB-CR   Priority: 0     Hits: 0
1)      Map: myMappingPolicy Target: Vserver-LB-CR
 Done
>
```

To bind the mapping policy to the cache redirection virtual server by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server from which you want to bind the mapping policy, and then click Open.
3. In the Configure Virtual Server(Cache Redirection), on the Policies tab, select Map, and then click Insert Policy.
4. In the Policy Name column, select the policy from drop down list.
5. In the Target column, click the down arrow, and then select the vserver from drop down list.
6. Click OK.

Selective Cache Redirection

Sep 11, 2013

Selective cache redirection sends requests for particular types of content, for example, images, to one cache server or group of cache servers and sends other types of content to a different cache server or group of cache servers. You can configure advanced cache redirection in transparent, reverse proxy, or forward proxy modes.

In selective cache redirection, the NetScaler appliance intercepts a client request and forwards non-cacheable requests to the original destination in the client request. For cacheable requests, the appliance sends the requests to the destination cache server that can serve content of a specific content type.

Selective cache redirection involves configuring content switching policies in addition to cache redirection policies. The NetScaler first evaluates the cache redirection policies that are bound to the cache redirection virtual server. If a request matches a cache redirection policy, the cache redirection virtual server sends the request to the origin server or a load balancing virtual server for the origin. If no cache redirection policies match the request, the NetScaler evaluates the content switching policies bound to the cache redirection virtual server. If a content switching policy matches the request, the cache redirection virtual server redirects the request to a load balancing virtual server for the cache.

To configure selective cache redirection, first enable cache redirection, load balancing, and content switching on the NetScaler appliance. Then, configure a load balancing virtual server for the cache and an associated HTTP service. After this, configure a cache redirection virtual server and bind both the cache redirection and content switching policies to it. Once you have bound the policies, you can configure the virtual server to give precedence to either rule based or URL based content-switching policies.

When configured for transparent mode cache redirection in an edge deployment topology, the NetScaler sends all cacheable HTTP traffic to a transparent cache farm. Clients access the Internet through the NetScaler, which is configured as a Layer 4 switch that receives traffic on port 80.

The NetScaler can direct requests for images (for example, .gif and .jpg files) to one server in the transparent cache farm, and all other requests for static content to other servers in the farm. For this configuration, you configure content switching policies to send images to the image cache and send all other cacheable content to a default cache.

Note: The configuration described here is for transparent selective cache redirection. Therefore, it does not require a load balancing virtual server for the origin, as would a reverse proxy configuration.
To configure this type of selective cache redirection, first enable cache redirection, load balancing, and content switching. Then, configure a load balancing virtual server for the cache and configure an associated HTTP service. Then, configure a cache redirection virtual server and create and bind both cache redirection and content switching policies to this virtual server.

For details on how to enable cache redirection and load balancing on the NetScaler, see "Configuring Cache Redirection."

Enabling Content Switching

Nov 08, 2013

To configure selective cache redirection, after you enable both the load balancing and cache redirection features on the NetScaler, you must enable content switching.

To enable content switching by using the command line interface

At the command prompt, type:

- enable ns feature CS
- show ns feature

Example

```
> enable ns feature cs
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)    Web Logging              WL              ON
 2)    Surge Protection         SP              ON
 3)    Load Balancing           LB              ON
 4)    Content Switching        CS              ON
 5)    Cache Redirection        CR              ON
       ...
       ...
       ...
 23)   HTML Injection           HTMLInjection   ON
 24)   NetScaler Push           push            OFF
Done
```

To enable cache redirection and load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure basic features.
3. In Configure Basic Features dialog box, select the check box next to the Content Switching, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

Configuring a Load Balancing Virtual Server for the Cache

Dec 17, 2013

Create a load balancing virtual server and an HTTP service for each type of cache server that will be used. For example, if you want to serve JPEG files from one cache server and GIF files from another cache server, and use a third cache server for the rest of the content, create an HTTP service and virtual server for each of the three types of cache servers. Then bind each service to its respective virtual server.

For details on how to create a load balancing virtual server, see "Creating a Virtual ServerCreating a Virtual Server."

For details on how to configure services that represent the cache server, see "Configuring an HTTP Service."

For details on how to bind the service to a virtual server, see "Binding/Unbinding a Service to/from a Load Balancing Virtual Server."

For details on how to create a transparent proxy cache redirection server, see "Configuring a Cache Redirection Virtual Server", and create a virtual server of type TRANSPARENT.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see "Binding Policies to the Cache Redirection Virtual Server."

Configuring a Cache Redirection Policy for a Specific Type of Content

To identify requests that contain a .gif or .jpeg extension as cacheable, you configure a cache redirection policy and bind it to the cache redirection virtual server.

Note: If a request matches a policy, the NetScaler appliance forwards it to the origin server. As a result, in the following procedure, you configure policies to match requests that do *not* have ".gif" or ".jpeg" extensions.
To configure cache redirection for a specific type of content, configure a policy that uses a simple expression, as described in "Configuring a Cache Redirection Policy."

Configuring Policies for Content Switching

Dec 17, 2013

You must create a content switching policy to identify specific types of content to be cached in one cache server or farm and identify other types of content to serve from another cache server or farm. For example, you can configure a policy to determine the location for image files with .gif and .jpeg extensions.

After defining the content switching policy, you bind it to a cache redirection virtual server and specify a load balancing virtual server. Requests that match the policy are forwarded to the named load balancing virtual server. Requests that do not match the content switching policy are forwarded to the default load balancing virtual server for the cache.

For more details about the content switching feature and configuring content switching policies, see "Content Switching."

You must first create the content switching policy and then bind it to the cache redirection virtual server.

To create a content switching policy by using the command line interface

At the command line, type:

- add cs policy <policyName> [-url <string> | -rule <expression>]
- show cs policy [<policyName>]

Examples

```
> add cs policy Policy-CS-JPEG -rule "REQ.HTTP.URL == '/*.jpeg'"
 Done
> show cs policy Policy-CS-JPEG
       Rule: REQ.HTTP.URL == '/*.jpeg'        Policy: Policy-CS-JPEG
       Hits: 0
 Done
>

> add cs policy Policy-CS-GIF -rule "REQ.HTTP.URL == '/*.gif'"
 Done
> show cs policy Policy-CS-GIF
       Rule: REQ.HTTP.URL == '/*.gif'        Policy: Policy-CS-GIF
       Hits: 0
 Done
>

> add cs policy Policy-CS-JPEG-URL -url /*.jpg
 Done
> show cs policy Policy-CS-JPEG-URL
       URL: /*.jpg     Policy: Policy-CS-JPEG-URL
       Hits: 0
 Done
>
```

```
> add cs policy Policy-CS-GIF-URL -url /*.gif
 Done
> show cs policy Policy-CS-GIF-URL
      URL: /*.gif    Policy: Policy-CS-GIF-URL
      Hits: 0
 Done
>
```

To create a URL-based content switching policy by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.
4. Select the URL radio button.
5. In the Value text box, type the string value (for example, **/sports**).
6. Click Create and click Close. The policy you created appears in the Content Switching Policies page.

To create a rule-based content switching policy by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.
4. Select the Expression radio button, and then click Configure.
5. In the Create Expression dialog box, choose the expression syntax that you want to use.
   - If you want to use default syntax, accept the default and proceed to the next step.
   - If you want to use classic syntax, click Switch to Classic Syntax.

   The Expression portion of the dialog box changes to match your choice. The default syntax Expression view has fewer elements than does the classic syntax Expression view. In the default syntax Expression view, instead of a preview window, a button provides access to an expression evaluator. The evaluator evaluates the expression you entered, to verify that it is valid, and displays an analysis of the expression's effect.

6. Enter your policy expressions.
   - If you are using classic syntax and need further instructions, see "Configuring Classic Policies and Expressions."
   - If you are using the default syntax and need further instructions, see "Configuring Default Syntax Expressions: Getting Started."
7. Click Create and click Close. The policy you created appears in the Content Switching Policies pane.

To bind the content switching policy to a cache redirection virtual server by using the command line interface

At the command prompt, type the following commands to bind the content switching policy to a cache redirection virtual server and verify the configuration:

- bind cs vserver <name> <targetVserver> [-policyName <string>]
- show cs vserver [<name>]

Example

```
> bind cs vserver Vserver-CR-1 lbcachejpeg -policyName Policy-CS-JPEG
 Done
```

```
> bind cs vserver Vserver-CR-1 lbcachegif -policyName Policy-CS-GIF
 Done
> show cs vserver Vserver-CR-1
      Vserver-CR-1 (10.102.29.60:80) - HTTP   Type: CONTENT
      State: UP
      Last state change was at Fri Jul  2 12:53:45 2010
      Time since last state change: 0 days, 00:00:58.920
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Port Rewrite : DISABLED
      State Update: DISABLED
      Default:       Content Precedence: RULE
      Cacheable: YES
      Vserver IP and Port insertion: OFF
      Case Sensitivity: ON
      Push: DISABLED  Push VServer:
      Push Label Rule: none

1)     Policy: Policy-CS-JPEG  Target: lbcachejpeg     Priority: 0     Hits: 0
2)     Policy: Policy-CS-GIF   Target: lbcachegif      Priority: 0     Hits: 0
 Done
>
```

To bind the content switching policy to a cache redirection virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the policy (for example, **Vserver-CS-1**), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, click CSW, and then click Insert Policy.
4. In the Policy Name column, select the policy that you want to configure for the content switching virtual server.
5. In the Target column, click the green arrow, and select the target load balancing virtual server from the list.
6. Click OK.

Configuring Precedence for Policy Evaluation

Aug 23, 2013

You can configure a content switching policy based on either a rule, which is a generic configuration to accommodate various content types, or a URL, which is more specific and defines exactly the type of content that has to be sent to a particular cache server. Essentially, the same content can be defined by either a rule based policy or a URL based policy.

Once you bind content switching policies of either type to a cache redirection virtual server, you can configure the virtual server to give precedence to either rule based or URL based policies. This will, in turn, decide which servers the particular requests are directed to.

To configure precedence for policy evaluation, use the precedence parameter, which specifies the type of policy (URL or RULE) that takes precedence on the content redirection virtual server.

Possible values: RULE, URL

Default value: RULE

To configure precedence for policy evaluation by using the command line interface

At the command prompt, type the following commands to configure precedence for policy evaluation and verify the configuration:

- set cr vserver <name> [-precedence (RULE | URL)]
- show cr vserver <name>

Example

```
> set cr vserver Vserver-CRD-1 -precedence URL
 Done
> show cr vserver Vserver-CRD-1
      Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
      State: UP  ARP:DISABLED
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default:       Content Precedence: URL Cache: TRANSPARENT
      On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF

1)     Cache bypass  Policy: bypass-cache-control
2)     Cache bypass  Policy: Policy-CRD
 Done
>
```

To configure precedence for policy evaluation by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure precedence, (for example, **Vserver-CS-1**), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, next to Precedence, click Rule or URL, and then click OK.

Administering a Cache Redirection Virtual Server

Mar 30, 2012

To administer a cache redirection virtual server, you need to view cache redirection statistics. You might need to enable or disable cache redirection servers, or direct policy hits to the cache instead of the origin. Administrative tasks also include backing up a cache redirection virtual server and managing client connections.

Viewing Cache Redirection Virtual Server Statistics

Aug 23, 2013

You can view properties of a cache redirection virtual server and statistics on the traffic that has passed through a cache redirection virtual server. You can also view the cache redirection virtual servers and policies that you have bound to load balancing virtual servers.

To view statistics for a specific cache redirection virtual servers, use the name parameter to specify the name of the virtual server for which statistics will be displayed. Otherwise, statistics for all cache redirection virtual servers are displayed.
Maximum Length: 127

To view statistics for a cache redirection virtual server by using the command line interface

At the command prompt, type:

stat cr vserver [<name>]

Example

```
> stat cr vserver Vserver-CRD-1

Vserver Summary
                 IP  port    Protocol      State
Vser...CRD-1      0.0.0.0   80       HTTP         UP

VServer Stats:
                           Rate (/s)          Total
Requests                          0                0
Responses                         0                0
Request bytes                     0                0
Response bytes                    0                0

 Done
>
```

To view statistics for a cache redirection virtual server by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers
2. In the details pane, select the virtual server for which you want to view statistics, (for example, **Vserver-CRD-1**), and then click Statistics.

Omit the server name to display basic statistics for all cache redirection virtual servers. Include the server name to display detailed statistics for that virtual server, including number and size of requests and responses that pass through the virtual server

To view the statistics of a cache redirection virtual server by using the monitoring and dashboard utilities

1. To view the statistics by using the monitoring utilities, click the Monitoring tab.
2. In the Select Group drop-down menu, choose CR Virtual Servers. A list of cache redirection virtual servers appears.
3. To view the statistics by using the dashboard utilities, click the Dashboard tab.

4. Click Applet Client or Web Start Client next to Statistical Utility.
5. In the Select Group drop-down menu, choose CR Virtual Servers. The dashboard displays summary statistics for the cache redirection virtual servers.
6. To see a chart of virtual server activity, click Chart. A graphical representation of the virtual server statistics appears.

Enabling or Disabling a Cache Redirection Virtual Server

Aug 23, 2013

When you create a cache redirection virtual server, it is enabled by default. If you disable a cache redirection virtual server, its state changes to OUT OF SERVICE and it stops redirecting cacheable client requests. However, the NetScaler appliance continues to respond to ARP and ping requests for the IP address of this virtual server.

To Enable or Disable a cache redirection virtual servers by using the command line interface

At the command line, type one of the following commands:

- enable cr vserver <name>
- show cr vserver <name>
- disable cr vserver <name>
- show cr vserver <name>

Examples

```
> enable cr vserver Vserver-CRD-1
 Done
> show cr vserver Vserver-CRD-1
      Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
      State: UP  ARP:DISABLED
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default:       Content Precedence: URL Cache: TRANSPARENT
      On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF

1)     Cache bypass  Policy: bypass-cache-control
2)     Cache bypass  Policy: Policy-CRD
 Done
>
```

```
> disable cr vserver Vserver-CRD-1
 Done
> show cr vserver Vserver-CRD-1
      Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
      State: OUT OF SERVICE  ARP:DISABLED
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default:       Content Precedence: URL Cache: TRANSPARENT
      On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF
```

1) Cache bypass Policy: bypass-cache-control
2) Cache bypass Policy: Policy-CRD
Done
>

To Enable or Disable a cache redirection virtual servers by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.
3. In the details pane, select the virtual server that you want to enable or disable, (for example, **Vserver-CRD-1**), and then click Statistics.
4. In the Proceed dialog box, click Yes.

Directing Policy Hits to the Cache Instead of the Origin

Aug 23, 2013

By default, when a request matches a policy, the NetScaler appliance forwards the request either to the origin server directly, or to a load balancing virtual server for the origin, depending on how you have configured cache redirection.

You can change the default behavior so that when a request matches a policy, the request is forwarded to a load balancing virtual server for the cache.

To change the destination for a policy hit to the origin or the cache, use the onPolicyMatch parameter, which specifies where to send requests that match the cache redirection policy.

The valid options are:

1. CACHE - Directs all matching requests to the cache.
2. ORIGIN - Directs all matching requests to the origin server.

Note: For this option to work, you must select the cacheredirection type as POLICY.
Possible values: CACHE, ORIGIN

Default value: ORIGIN

To change the destination for a policy hit to the origin or the cache by using the command line interface

At the command prompt, type the following commands to change the destination for a policy hit and verify the configuration:

- set cr vserver <name> [-onPolicyMatch (ORIGIN | CACHE)]
- show cr vserver <name>

Example

```
> set cr vserver Vserver-CRD-1 -onPolicyMatch CACHE
 Done
> show cr vserver Vserver-CRD-1
      Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
      State: UP  ARP:DISABLED
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default:       Content Precedence: URL Cache: TRANSPARENT
      On Policy Match: CACHE  L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF

1)     Cache bypass  Policy: bypass-cache-control
2)     Cache bypass  Policy: Policy-CRD
 Done
```

To change the destination for a policy hit to the origin or the cache by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to change the destination for a policy hit, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, click Advanced tab.
4. Select CACHE or ORIGIN from the Redirect To drop-down list.
5. Click OK.

Backing Up a Cache Redirection Virtual Server

Aug 22, 2013

Cache redirection can fail if the primary virtual server fails, or if it is unable to handle excessive traffic. You can specify a backup virtual server to take over the processing of traffic when the primary virtual server fails.

To specify a backup cache redirection virtual server, use the backupVServer parameter, which specifies Backup Virtual Server. Maximum Length: 127

To specify a backup cache redirection virtual server by using the command line interface

At the command prompt, type the following commands to specify a backup cache redirection virtual server and verify the configuration:

- set cr vserver <name> [-backupVServer <string>]
- show cr vserver <name>

Example

```
> set cr vserver Vserver-CRD-1 -backupVServer Vserver-CRD-2
 Done
> show cr vserver Vserver-CRD-1
      Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
      State: UP  ARP:DISABLED
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default:       Content Precedence: URL Cache: TRANSPARENT
      On Policy Match: CACHE  L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF
      Backup: Vserver-CRD-2

1)     Cache bypass  Policy: bypass-cache-control
2)     Cache bypass  Policy: Policy-CRD
 Done
```

To specify a backup cache redirection virtual server by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > irtual Servers.
2. In the details pane, select the virtual server for which you want to change the destination for a policy hit, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. In the Backup Virtual Server drop-down list, select the virtual server.
5. Click OK.

Managing Client Connections for a Virtual Server

Jun 04, 2015

You can configure timeouts on a cache redirection virtual server so that client connections are not kept open indefinitely. You can also insert Via headers in requests. To possibly reduce network congestion, you can reuse open TCP connections. You can enable or disable delayed cleanup of cache redirection virtual server connections.

You can configure the NetScaler to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, NetScaler responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds even if one virtual server set to ACTIVE is UP.

This document includes the following information:

- Configuring Client Timeout
- Inserting Via Headers in the Requests
- Reusing TCP Connections
- Configuring Delayed Connection Cleanup

Updated: 2013-08-22

You can specify expiration of client requests by setting a timeout value for the cache redirection virtual server. The timeout value is the number of seconds for which the cache redirection virtual server waits to receive a response for the client request.

To configure a time-out value, use the cltTimeout parameter, which specifies the time, in seconds, after which the NetScaler appliance closes any idle client connections. The default value is 180sec for HTTP/SSL-based services and 9000sec for TCP-based services.

To configure client timeout by using the command line interface

At the command prompt, type the following commands to configure client timeout and verify the configuration:

- set cr vserver <name> [-cltTimeout <secs>]
- show cr vserver <name>

Example

```
> set cr vserver Vserver-CRD-1 -cltTimeout 6000
 Done
```

```
> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: UP  ARP:DISABLED
        Client Idle Timeout: 6000 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default:        Content Precedence: URL Cache: TRANSPARENT
        On Policy Match: CACHE  L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF
        Backup: Vserver-CRD-2

1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: Policy-CRD
 Done
```

To configure client timeout by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. In the Client Time-out(secs) text box, enter the time-out value in seconds.
5. Click OK.

Updated: 2013-08-23

A Via header lists the protocols and recipients between the start and end points for a request or a response and informs the server of proxies through which the request was sent. You can configure the cache redirection virtual server to insert a Via header in each HTTP request. The via parameter is enabled by default when you create a cache redirection virtual server.

To enable or disable Via-header insertion in client requests, use the via parameter, which specifies the state of the system in inserting a Via header in the HTTP requests.

Possible values: ON, OFF

Default value: ON

To enable or disable Via-header insertion in client requests by using the command line interface

At the command prompt, type:

- set cr vserver <name> [-via (ON | OFF)]
- show cr vserver <name>

Example

```
> set cr vserver Vserver-CRD-1 -via ON
```

```
 Done
> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: UP  ARP:DISABLED
        Client Idle Timeout: 6000 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default:        Content Precedence: URL Cache: TRANSPARENT
        On Policy Match: CACHE  L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF
        Backup: Vserver-CRD-2

1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: Policy-CRD
 Done
>
```

To enable or disable Via-header insertion in client requests by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. Select the Via check box.
5. Click OK.

Updated: 2013-11-08

You can configure the NetScaler appliance to reuse TCP connections to the cache and origin servers across client connections. This can improve performance by saving the time required to establish a session between the server and the NetScaler. The reuse option is enabled by default when you create a cache redirection virtual server.

To enable or disable the reuse of TCP connections, use the reuse parameter, which specifies the state of reuse of TCP connections to the cache or origin servers across client connections.

Possible values: ON, OFF

Default value: ON

To enable or disable the reuse of TCP connections by using the command line interface

At the command prompt, type:

- set cr vserver <name> [-reuse (ON|OFF)]
- show cr vserver <name>

Example

```
> set cr vserver Vserver-CRD-1 -reuse ON
 Done
> show cr vserver Vserver-CRD-1
      Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
      State: UP  ARP:DISABLED
      Client Idle Timeout: 6000 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default:       Content Precedence: URL Cache: TRANSPARENT
      On Policy Match: CACHE  L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF
      Backup: Vserver-CRD-2

1)     Cache bypass  Policy: bypass-cache-control
2)     Cache bypass  Policy: Policy-CRD
 Done
```

To enable or disable the reuse of TCP connections by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. Select the Reuse check box.
5. Click OK.

Updated: 2013-08-22

The down state flush option performs delayed cleanup of connections on a cache redirection virtual server. The down state flush option is enabled by default when you create a cache redirection virtual server.

To enable or disable the down state flush option, set the downStateFlush parameter.

Possible values: ENABLED, DISABLED

Default value: ENABLED

To enable of disable the down state flush option by using the command line interface

At the command prompt, type the following commands to configure delayed connection clean up and verify the configuration:

- set cr vserver <name> [-downStateFlush (ENABLED | DISABLED)]
- show cr vserver <name>

Example

```
> set cr vserver Vserver-CRD-1 -downStateFlush ENABLED
 Done
> show cr vserver Vserver-CRD-1
      Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
      State: UP  ARP:DISABLED
      Client Idle Timeout: 6000 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default:       Content Precedence: URL Cache: TRANSPARENT
      On Policy Match: CACHE  L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF
      Backup: Vserver-CRD-2

1)     Cache bypass  Policy: bypass-cache-control
2)     Cache bypass  Policy: Policy-CRD
 Done
```

To enable or disable the reuse of TCP connections by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, click Advanced tab.
4. Select the Down state flush check box.
5. Click OK.

N-Tier Cache Redirection

Mar 30, 2012

To efficiently handle large amounts of cached data, typically several gigabytes per second, an Internet Service Provider (ISP) deploys several dedicated cache servers. The cache redirection feature of the NetScaler appliance can help load balance the cache servers, but a single appliance or a couple of appliances might not efficiently handle the large volume of traffic.

You can solve the problem by deploying the NetScaler appliances in two tiers (layers), where the appliances in the upper tier load balance those in the lower tier and the appliances in the lower tier load balance the cache servers. This arrangement is called *n-tier cache redirection*.

For purposes such as auditing and security, an ISP has to track client details such as the IP address, information provided, and the time of the interaction. Therefore, client connections through a NetScaler appliance have to be fully transparent. However, if you configure transparent cache redirection, with the NetScaler appliances deployed in parallel, the IP address of the client has to be shared among all the appliances. Sharing of the client IP address creates a conflict that makes network devices, such as routers, cache servers, origin servers, and other NetScaler appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

To solve the problem, NetScaler n-tier cache redirection splits the source port range among the appliances in the lower tier and includes the client IP address in the request sent to the cache servers. The upper-tier NetScaler appliances are configured to do sessionless load balancing in order to avoid unnecessary load on the appliances.

When the lower-tier NetScaler appliance communicates with a cache server, it uses a mapped IP address (MIP) to represent the source IP address. Therefore, the cache server can identify the NetScaler from which it received the request and send the response to the same NetScaler.

The lower-tier NetScaler appliance inserts the client IP address into the header of the request sent to the cache server. The client IP in the header helps the NetScaler to determine the client to which the packet should be forwarded when it receives the response from a cache server, or the origin server in case of a cache miss. The origin server determines the response to be sent according to the client IP inserted in the request header.

The origin server sends the response to an upper-tier NetScaler, including the source port number from which the origin server received the request. The entire source port range, 1024 to 65535, is distributed among the lower-tier NetScaler appliances. Each lower-tier appliance is exclusively assigned a group of addresses within the range. This allotment enables the upper-tier appliance to unambiguously identify the lower-tier NetScaler appliance that sent the request to the origin server. The upper-tier appliance can therefore forward the response to the correct lower-tier appliance.

The upper-tier NetScaler appliances are configured to do policy-based routing, and the routing policies are defined to determine the IP address of the destination NetScaler from the source port range.

The following setup is necessary for the functioning of n-tier cache redirection:

For each upper-tier NetScaler appliance:

- Enable Layer 3 mode.
- Define policies for policy-based routes (PBRs) so that traffic is forwarded according to the range of the destination

port.

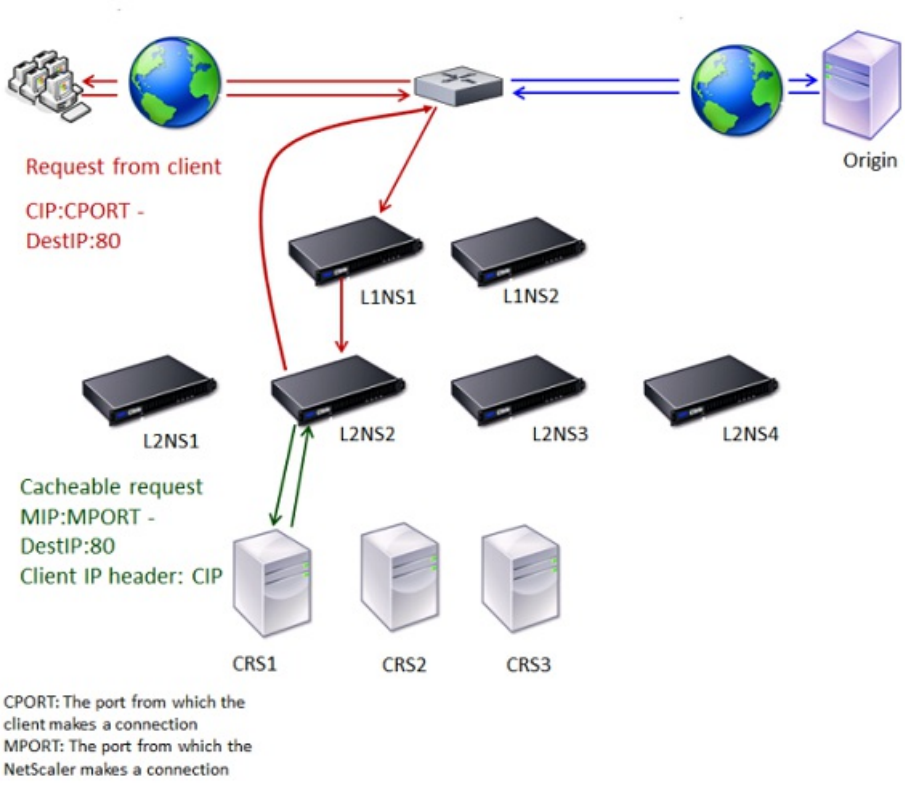
- Configure a load balancing virtual server.
- Configure the virtual server to listen to all the traffic coming from the client. Set the Service Type/Protocol to be ANY and IP Address as asterisk (*).
- Enable sessionless load balancing with MAC-based redirection mode to avoid unnecessary load on the upper-tier NetScaler appliances.
- Make sure that the Use Proxy Port option is enabled.
- Create a service for each lower-tier NetScaler and bind all the services to the virtual server.

For each lower-tier NetScaler appliance,

- Configure the cache redirection port range on the NetScaler. Assign an exclusive range to each lower-tier NetScaler.
- Configure a load balancing virtual server and enable MAC-based redirection.
- Create a service for each cache server that is to be load balanced by this NetScaler. When creating the service, enable insertion of client IP in the header. Then, bind all the services to the load balancing virtual server.
- Configure a transparent mode cache redirection virtual server with the following settings:
  - Enable the Origin USIP option.
  - Add a source IP expression to include the client IP in the header.
  - Enable the Use Port Range option.

The following figure shows how cache redirection works when a client request is cacheable and the response is sent from a cache server.

Figure 1. Cache Redirection in Case of a Cache Hit



Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2,

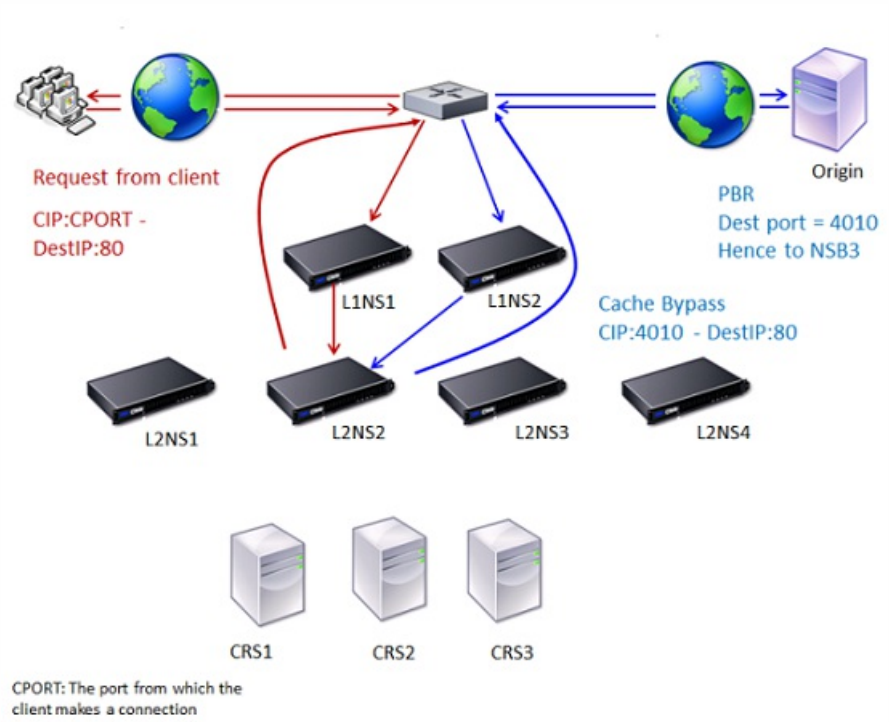
L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

Traffic Flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. L2NS2 load balances the request to the cache server CRS1, and the request is cacheable. L2NS2 includes the client IP in the request header.
4. CRS1 sends the response to L2NS2 because L2NS2 used its MIP as the source IP address when connecting to CRS1.
5. With the help of the client IP address in the request header, L2NS2 identifies the client from which the request came. L2NS2 directly sends the response to the router, avoiding unnecessary load on the NetScaler in the upper tier.
6. The router forwards the response to Client A.

The following figure shows how cache redirection works when a client request is sent to an origin server for a response.

Figure 2. Cache Redirection in Case of a Cache Bypass



Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

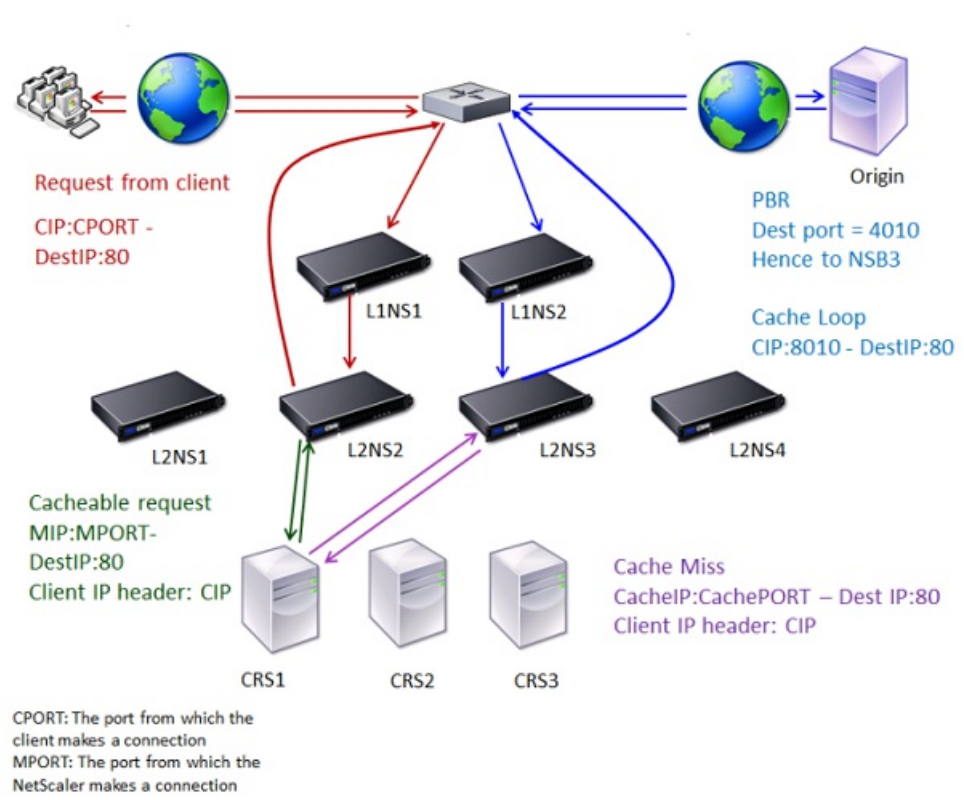
Traffic Flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. The request is uncacheable (cache bypass). Therefore, L2NS2 sends the request to the origin server through the router.
4. The origin server sends the response to an upper-tier NetScaler, L1NS2.

5. According to the PBR policies, L1NS2 forwards the traffic to the appropriate NetScaler in the lower tier, L2NS2.
6. L2NS2 uses the client IP address in the request header to identify the client from which the request came and sends the response directly to the router, avoiding unnecessary load on the NetScaler in the upper tier.
7. The router forwards the response to Client A.

The following figure shows how cache redirection works when a client request is not cached.

Figure 3. Cache Redirection in Case of a Cache Miss



Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

Traffic Flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. L2NS2 load balances the request to the cache server CRS1 because the request is cacheable.
4. CRS1 does not have the response (cache miss). CRS1 forwards the request to the origin server through the NetScaler in the lower tier. L2NS3 intercepts the traffic.
5. L2NS3 takes the client IP from the header and forwards the request to the origin server. The source port included in the packet is the L2NS3 port from which the request is sent to the origin server.
6. The origin server sends the response to an upper-tier NetScaler, L1NS2.
7. According to the PBR policies, L1NS2 forwards the traffic to the appropriate NetScaler in the lower tier, L2NS3.
8. L2NS3 forwards the response to the router.
9. The router forwards the response to Client A.

Configuring the Upper-Tier NetScaler Appliances

Oct 31, 2013

Configure each of the upper-tier NetScaler appliances as follows.

At the command prompt, type the following commands:

- add service <name>@ <serviceIP> <serviceType> <port>
  Run this command for each service to be added.
- add lb vserver <name>@ ANY * <port> -persistenceType <persistenceMethod> -lbMethod <lbMethod> -m MAC -sessionless ENABLED -cltTimeout <client_Timeout_Value>
- bind lb vserver <name>@ <serviceName>
  Run this command for each service to be bound.
- enable ns mode l3
- add ns pbr <name> <action> -srcPort <sourcePortNumber> -destPort <startPortNumber-endPortNumber> -nexthop <serviceIpAddress> -protocol TCP
- apply ns pbrs

  Run this command after adding all the necessary PBRs.

1. Enable L3 mode:
   1. In the navigation pane, click System, and then click Settings.
   2. In the Settings group, click the Configure modes link.
   3. Select the Layer 3 Mode (IP Forwarding) check box.
   4. Click OK.
2. Configure policy-based routing (PBR):
   1. Navigate to System > Network > PBRs.
   1. In the Policy-Based Routing (PBRs) pane, click Add.
   2. Type a name for the PBR.
   3. Select the action as Allow.
   4. In the Next Hop box, type the IP address of the service, which represents a lower-tier NetScaler.
   5. Select TCP from the Protocol drop-down list.
   6. Type the source port and the range of the destination port corresponding to the lower-tier NetScaler being added.
   7. Click Create.
   8. In the details pane, select the PBR and click Apply.
   9. Repeat Step (i) to Step (vii) for each lower-tier NetScaler.
3. Create a service for each lower-tier NetScaler:
   1. Navigate to Traffic Management > Load Balancing > Services.
   1. In the details pane, click Add.
   2. Specify the name, protocol, IP address, and port. The protocol should be ANY.
   3. Click Create.

4. Configure a load balancing virtual server:
    1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
    1. In the details pane, click Add.
    2. Specify the name, protocol, IP address, and port. The protocol should be ANY and the IP address should be *.
    3. In the Services tab, select the services that represent the lower-tier NetScaler appliances.
    4. In the Advanced tab, select the Redirection Mode as MAC Based and select the Sessionless check box.
    5. Click Create.

Configuring the Lower-Tier NetScaler Appliances

Oct 31, 2013

Configure each of the lower-tier NetScaler appliances as follows.

At the command prompt, type the following commands:

- add service <name>@ <cacheServiceIP> <serviceType> <port> -cip ENABLED "ClientIP" – cachetype transparent
  Repeat for each cache server.
- add lb vserver <name>@ <serviceType> -m MAC
- bind lb vserver <name>@ <cacheServiceName>
  Repeat for each cache server.
- add cr vserver <name> <serviceType> * <port> -srcIPExpr "HTTP.REQ.HEADER(\"ClientIP\")" -originusip ON – usePortRange ON
- set ns param-crPortRange <startPortNumber-endPortNumber>

1. Create a service for each cache server. To create a service:
   1. Navigate to Traffic Management > Load Balancing > Services.
   1. In the details pane, click Add, and specify the name and protocol. Clear the Directly Addressable check box.
   2. In the Advanced tab, select the Override Global check box and the Client IP check box, and then in the Header box, type ClientIP.
   3. In the Cache Type box, select Transparent Cache.
   4. Click Create.
2. Configure a load balancing virtual server:
   1. Navigate to Traffic Management > Load Balancing > Virtual Services.
   1. In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be an asterisk (*).
   2. In the Services tab, select the services that represent the cache servers.
   3. In the Advanced tab, for Redirection Mode, select MAC Based.
   4. Click Create.
3. Configure a cache redirection virtual server:
   1. Navigate to Traffic Management > Load Balancing > Virtual Services.
   1. In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be *.
   2. For Cache Type, select Transparent.
   3. On the Advanced tab, in the Cache Server box, select the new load balancing virtual server and check the Origin USIP and Use Port Range check boxes. In the Source IP Expression box, type HTTP.REQ.HEADER("ClientIP").
   4. Click Create.
4. Assign a source port range for the NetScaler:
   1. In the navigation pane, click System, and then click Settings.
   2. In the Settings group, click the Change global system settings link.

3. In the Cache Redirection Port Range group, specify the port range for the NetScaler by typing a port number for Start Port and a port number for End Port.
4. Click OK.

Content Switching

May 25, 2015

In today's complex Web sites, you may want to present different content to different users. For example, you may want to allow users from the IP range of a customer or partner to have access to a special Web portal. You may want to present content relevant to a specific geographical area to users from that area. You may want to present content in different languages to the speakers of those languages. You may want to present content tailored to specific devices, such as smartphones, to those who use the devices. The Citrix NetScaler content switching feature enables the NetScaler appliance to distribute client requests across multiple servers on the basis of specific content that you wish to present to those users.

To configure content switching, first create a basic content switching setup, and then customize it to meet your needs. This entails enabling the content switching feature, setting up load balancing for the server or servers that host each version of the content that is being switched, creating a content switching virtual server, creating policies to choose which requests are directed to which load balancing virtual server, and binding the policies to the content switching virtual server. You can then customize the setup to meet your needs by setting precedence for your policies, protecting your setup by configuring a backup virtual server, and improving the performance of your setup by redirecting requests to a cache.

Updated: 2013-08-22

Content Switching enables the NetScaler appliance to direct requests sent to the same Web host to different servers with different content. For example, you can configure the appliance to direct requests for dynamic content (such as URLs with a suffix of .asp, .dll, or .exe) to one server and requests for static content to another server. You can configure the appliance to perform content switching based on TCP/IP headers and payload.

You can also use content switching to configure the appliance to redirect requests to different servers with different content on the basis of various client attributes. Some of those client attributes are:

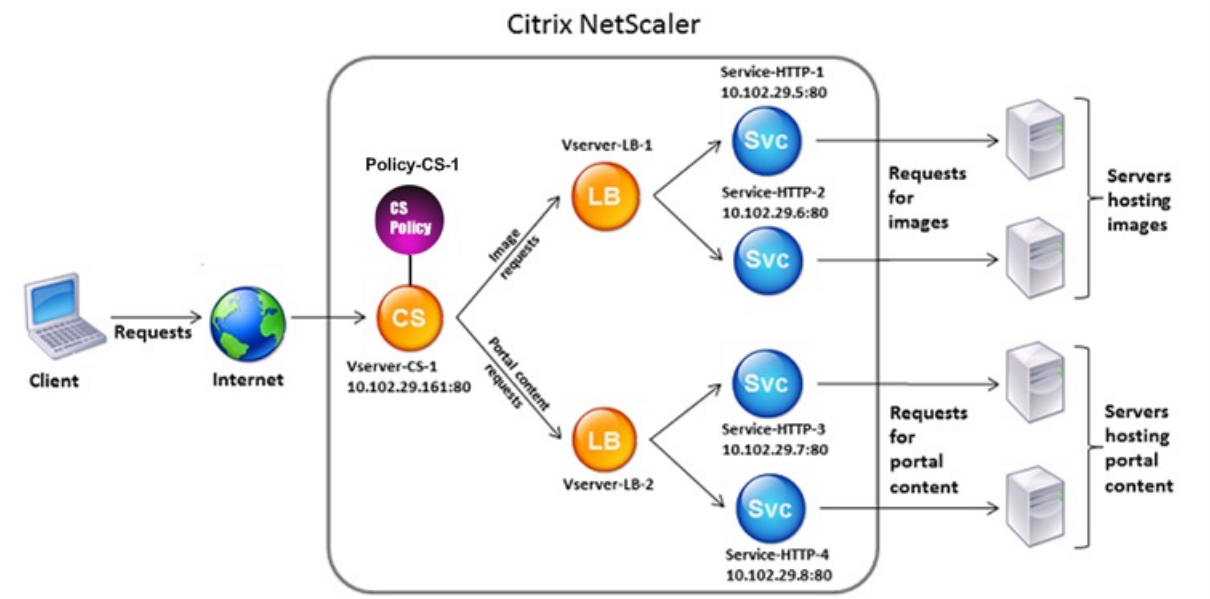
- **Device Type.** The appliance examines the user agent or custom HTTP header in the client request for the type of device from which the request originated. Based on the device type, it directs the request to a specific Web server. For example, if the request came from a cell phone, the request is directed to a server that is capable of serving content that the user can view on his or her cell phone. A request from a computer is directed to a different server that is capable of serving content designed for a computer screen.
- **Language.** The appliance examines the Accept-Language HTTP header in the client request and determines the language used by the client's browser. The appliance then sends the request to a server that serves content in that language. For example, using content switching based on language, the appliance can send someone whose browser is configured to request content in French to a server with the French version of a newspaper. It can send someone else whose browser is configured to request content in English to a server with the English version.
- **Cookie.** The appliance examines the HTTP request headers for a cookie that the server set previously. If it finds the cookie, it directs requests to the appropriate server, which hosts custom content. For example, if a cookie is found that indicates that the client is a member of a customer loyalty program, the request is directed to a faster server or one with special content. If it does not find a cookie, or if the cookie indicates that the user is not a member, the request is directed to a server for the general public.
- **HTTP Method.** The appliance examines the HTTP header for the method used, and sends the client request to the right server. For example, GET requests for images can be directed to an image server, while POST requests can be directed to

a faster server that handles dynamic content.

- **Layer 3/4 Data.** The appliance examines requests for the source or destination IP, source or destination port, or any other information present in the TCP or UDP headers, and directs the client request to the right server. For example, requests from source IPs that belong to customers can be directed to a custom web portal on a faster server, or one with special content.

A typical content switching deployment consists of the entities described in the following diagram.

Figure 1. Content Switching Architecture



A content switching configuration consists of a content switching virtual server, a load balancing setup consisting of load balancing virtual servers and services, and content switching policies. To configure content switching, you must configure a content switching virtual server and associate it with policies and load balancing virtual servers. This process creates a *content group*—a group of all virtual servers and policies involved in a particular content switching configuration.

Content switching can be used with HTTP, HTTPS, TCP, and UDP connections. For HTTPS, you must enable SSL Offload.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. The priority of the policy defines the order in which the policies bound to the content switching virtual server are evaluated. If you are using default syntax policies, when you bind a policy to the content switching virtual server, you must assign a priority to that policy. If you are using NetScaler classic policies, you can assign a priority to your policies, but are not required to do so. If you assign priorities, the policies are evaluated in the order that you set. If you do not, the NetScaler appliance evaluates your policies in the order in which they were created.

In addition to configuring policy priorities, you can manipulate the order of policy evaluation by using Goto expressions and policy bank invocations. For more details about default syntax policy configuration, see "Configuring Default Syntax Policies."

After it evaluates the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

Content switching virtual servers can only send requests to other virtual servers. If you are using an external load balancer,

you must create a load balancing virtual server for it and bind its virtual server as a service to the content switching virtual server.

Configuring Basic Content Switching

Jun 09, 2015

Before you configure content switching, you must understand how content switching is set up and how the services and virtual servers are connected.

To configure a basic, functional content switching setup, first enable the content switching feature. Then, create at least one content group. For each content group, create a content switching virtual server to accept requests to a group of web sites that use content switching. Also create a load balancing setup, which includes a group of load balancing virtual servers to which the content switching virtual server directs requests. To specify which requests to direct to which load balancing virtual server, create at least two content switching policies, one for each type of request that is to be redirected. When you have created the virtual servers and policies, bind the policies to the content switching virtual server. You can also bind a policy to multiple content switching virtual servers. When you bind a policy, you specify the load balancing virtual server to which requests that match the policy are to be directed.

In addition to binding individual policies to a content switching virtual server, you can bind policy labels. If you create additional content groups, you can bind a policy or policy label to more than one of the content switching virtual servers.

Note: After creating a content group, you can modify its content switching virtual serve to customize the configuration. For information on modifying the configuration of an existing content switching virtual server, see "Customizing the Basic Content Switching Configuration." For information on disabling and re-enabling entities, unbinding policies, and removing entities, see "Managing a Content Switching Setup."

This section includes the following details:

- Enabling Content Switching
- Creating Content Switching Virtual Servers
- Configuring a Load Balancing Setup for Content Switching
- Configuring a Content Switching Action
- Configuring Content Switching Policies
- Configuring Content Switching Policy Labels
- Binding Policies to a Content Switching Virtual Server
- Configuring Policy Based Logging for Content Switching
- Verifying the Configuration

Enabling Content Switching

Oct 31, 2013

To use the content switching feature, you must enable content switching. You can configure content switching entities even though the content switching feature is disabled. However, the entities will not work.

At the command prompt, type the following commands to enable content switching and verify the configuration:

- enable ns feature CS
- show ns feature

Example

```
> enable  feature ContentSwitch
 Done
> show feature

      Feature                Acronym          Status
      -------                -------          ------
 1)    Web Logging              WL              OFF
 2)    Surge Protection          SP              ON
 3)    Load Balancing           LB              ON
 4)    Content Switching        CS              ON
 .
 .
 .
 22)   Responder              RESPONDER         ON
 23)   HTML Injection           HTMLInjection     ON
 24)   NetScaler Push           push            OFF
Done
```

1. Navigate to System > Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Content Switching check box, and then click OK.
4. In the Enable/Disable Features(?) dialog box, click Yes.

Creating Content Switching Virtual Servers

Apr 07, 2014

You can add, modify, and remove content switching virtual servers. The state of a virtual server is DOWN when you create it, because the load balancing virtual server is not yet bound to it.

At the command prompt, type:

add cs vserver <name> <protocol> <IPAddress> <port>

Example

```
add cs vserver Vserver-CS-1 HTTP 10.102.29.161 80
```

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Content Switching) dialog box, in the Name, IP Address, and Port text boxes, type the name, IP address, and port of the virtual server, (for example, Vserver-CS-1, 10.102.29.161, and 80).
   Note: If you need to enter an IPv6 address, select the IPv6 check box before you enter the address.
4. In the Protocol list, select the type of the virtual server (for example, HTTP).
5. Click Create, and then click Close.

Configuring a Load Balancing Setup for Content Switching

Dec 17, 2013

The content switching virtual server redirects all requests to a load balancing virtual server. You must create one load balancing virtual server for each version of the content that is being switched. This is true even when your setup has only one server for each version of the content, and you are therefore not doing any load balancing with those servers. You can also configure actual load balancing with multiple load-balanced servers that mirror each version of the content. In either scenario, the content switching virtual server needs to have a specific load balancing virtual server assigned to each version of the content that is being switched.

The load balancing virtual server then forwards the request to a service. If it has only one service bound to it, it selects that service. If it has multiple services bound to it, it uses its configured load balancing method to select a service for the request, and forwards that request to the service that it selected.

To configure a basic load balancing setup, you need to perform the following tasks:

- Create load balancing virtual servers
- Create services
- Bind services to the load balancing virtual server

For more information on load balancing, see "Load Balancing." For detailed instructions on setting up a basic load balancing configuration, see "Setting Up Basic Load Balancing."

Configuring a Content Switching Action

Sep 30, 2013

You specify the target load balancing virtual server for a content switching policy when binding the policy to the content switching virtual server. Consequently, you have to configure one policy for each load balancing virtual server to which to direct traffic.

However, if your content switching policy uses a default syntax rule, you can configure an action for the policy. In the action, you can specify the name of the target load balancing virtual server, or you can configure a request-based expression that, at run time, computes the name of the load balancing virtual server to which to send the request. The action expression must be specified in the default syntax.

The expression option can drastically reduce the size of your content switching configuration, because you need only one policy per content switching virtual server. Content switching policies that use an action can also be bound to multiple content switching virtual servers, because the target load balancing virtual server is no longer specified in the content switching policy. The ability to bind a single policy to multiple content switching virtual servers helps to further reduce the size of your content switching configuration.

After you create an action, you create a content switching policy and specify the action in the policy, so that the action is performed when that policy matches a request.

Note: You can also, for a content switching policy that uses a default syntax rule, specify the target load balancing virtual server when binding the policy to a content switching virtual server, instead of using a separate action. For domain-based policies, URL-based policies, and rule based policies that use classic expressions, an action is not available. So, for these types of policies, you specify the name of the target load balancing virtual server when binding the policy to a content switching virtual server. For more information, see "Binding Policies to a Content Switching Virtual Server."

Updated: 2013-08-22

If you choose to specify the name of the target load balancing virtual server in a content switching action, you need as many content switching policies as you have target load balancing virtual servers. Content switching decisions, in this case, are based on the rule in the content switching policy, and the action merely specifies the target load balancing virtual server. When a request matches the policy, the request is forwarded to the specified load balancing virtual server.

To create and verify a content switching action that specifies the name of the target load balancing virtual server, by using the command line interface

At the command prompt, type:

- add cs action <name> -targetLBVserver <string> [-comment <string>]
- show cs action <name>

```
> add cs action mycsaction -targetLBVserver mylbvserver -comment "Forwards requests to mylbvserver."
 Done
> show cs action mycsaction
 Name: mycsaction
 Target LB Vserver: mylbvserver
```

```
Hits: 0
Undef Hits: 0
Action Reference Count: 0
Comment: "Forwards requests to mylbvserver."

Done
>
```

To configure a content switching action that specifies the name of the target load balancing virtual server, by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Actions.
2. In the details pane, do one of the following:
   - To create a content switching action, click Add.
   - To modify a content switching action, select the content switching action, and then click Open.
3. In the Create Content Switching Action or Configure Content Switching Action dialog box, set the following parameters:
   - Name*
   - Target LB Virtual Server* (Under Target LB Virtual Server, click Name.)
   - Comment

   * A required parameter
4. Click Create.

Updated: 2013-08-22

If you choose to configure a request-based expression that can dynamically compute the name of the target load balancing virtual server, you need to configure only one content switching policy to select the appropriate virtual server. The rule for the policy can be a simple TRUE (the policy matches all requests) because, in this case, content switching decisions are based on the expression in the action. By configuring an expression in an action, you can drastically reduce the size of your content switching configuration.

If you choose to configure a request-based expression for computing the name of the target load balancing virtual server at run time, you must carefully consider how to name the load balancing virtual servers in the configuration. You must be able to derive their names by using the request-based policy expression in the action.

For example, if you are switching requests on the basis of the URL suffix (file extension of the requested resource), when naming the load balancing virtual servers, you can follow the convention of appending the URL suffix to a predetermined string, such as mylb_. For example, load balancing virtual servers for HTML pages and PDF files could be named mylb_html and mylb_pdf, respectively. In that case, the rule that you can use in the content switching action, to select the appropriate load balancing virtual server, is "mylb_"+HTTP.REQ.URL.SUFFIX. If the content switching virtual server receives a request for an HTML page, the expression returns mylb_html, and the request is switched to virtual server mylb_html.

To create a content switching action that specifies an expression, by using the command line interface

At the command line, type the following commands to create a content switching action that specifies an expression and verify the configuration:

- add cs action <name> -targetVserverExpr <expression>) [-comment <string>]
- show cs action <name>

```
> add cs action mycsaction1 -targetvserverExpr '"mylb_" + HTTP.REQ.URL.SUFFIX'
 Done
> show cs action mycsaction1
 Name: mycsaction1
 Target Vserver Expression: "mylb_" + HTTP.REQ.URL.SUFFIX
 Target LB Vserver: No_Target
          ...
 Done
>
```

To configure a content switching action that specifies an expression by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Actions.
2. In the details pane, do one of the following:
   - To create a content switching action, click Add.
   - To modify a content switching action, select the content switching action, and then click Open.
3. In the Create Content Switching Action or Configure Content Switching Action dialog box, set the following parameters:
   - Name*
   - Target LB Expression* (Under Target LB Virtual Server, click Expression.)
   - Comment

   * A required parameter
4. Click Create.

Configuring Content Switching Policies

Aug 22, 2013

A content switching policy defines a type of request that is to be directed to a load balancing virtual server. These policies are applied in the order of the priorities assigned to them or (if you are using NetScaler classic policies and do not assign priorities when binding them) in the order in which the policies were created.

The policies can be:

- **Domain-based policies.** The NetScaler appliance compares the domain of an incoming URL with the domains specified in the policies. The appliance then returns the most appropriate content. Domain-based policies must be classic policies; default syntax policies are not supported for this type of content switching policy.
- **URL-based policies.** The appliance compares an incoming URL with the URLs specified in the policies. The appliance then returns the most appropriate URL-based content, which is usually the longest matching configured URL. URL-based policies must be classic policies; default syntax policies are not supported for this type of content switching policy.
- **Rule-based policies.** The appliance compares incoming data to expressions specified in the policies. You create rule-based policies by using either a classic expression or a default syntax expression. Both classic and default syntax policies are supported for rule-based content switching policies.

  Note: A rule based policy can be configured with an optional action. A policy with an action can be bound to multiple virtual servers or policy labels.

  If you set a priority when binding your policies to the content switching virtual server, the policies are evaluated in order of priority. If you do not set specific priorities when binding your policies, the policies are evaluated in the order in which they were created.

For information about NetScaler classic policies and expressions, see "Configuring Classic Policies and Expressions." For information about Default Syntax policies, see "Configuring Default Syntax Expressions."

At the command prompt, type one of the following commands:

- add cs policy <policyName> -domain <domain>
- add cs policy <policyName> -url <URLValue>
- add cs policy <policyName> -rule <RULEValue>
- add cs policy <policyName> -rule <RULEValue> -action <actionName>

Example

```
add cs policy Policy-CS-1 -url "/sports/*"

add cs policy Policy-CS-1 -domain "example.com"

add cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(24).EQ(10.217.84.0)"

add cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2009 Nov,GMT 2009 Dec)"
```

```
add cs policy Policy-CS-3 -rule "http.req.method.eq(GET)" -action act1
```

At the command prompt, type:

rename cs policy <policyName> <newName>

Example

```
rename cs policy myCSPolicy myCSPolicy1
```

1. In the navigation pane, expand Traffic Management, expand Content Switching, and then click Policies.
2. In the details pane, select the policy you want to rename, and then, in the Action list, click Rename.
3. In the Rename CSW Policy dialog box, in the Name text box, specify a new name for the policy.
4. Click OK.

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type the name of the policy (for example, Policy-CS-1).
4. Choose the type of policy that you want to create, and configure the policy.
   - To create a domain-based policy, in the Domain text box, type the domain (for example, example.com).
   - To create a URL-based policy, click URL, and in the Value text box, type an absolute or relative URL (for example, http://www.example.com/sports, or just /sports).
   - To create a rule-based policy, click Configure, and do the following:
     1. In the Create Expression dialog box, choose the expression syntax you want to use.
        - If you want to use default syntax, accept the default and proceed to the next step.
        - If you want to use classic syntax, click Switch to Classic Syntax.

        The Expression portion of the dialog box changes to match your choice. The default syntax Expression view has fewer elements than does the classic syntax Expression view. In the default syntax Expression view, instead of a preview window, a button provides access to an expression evaluator. The evaluator evaluates the expression you entered, to verify that it is valid, and displays an analysis of the expression's effect.
     2. Enter your policy expressions.
        - If you are using classic syntax and need further instructions, see Configuring Classic Policies and Expressions.
        - If you are using the default syntax and need further instructions, see Configuring Default Syntax Expressions.
5. Click Create, and then click Close. The policy you created appears in the Content Switching Policies pane.

Configuring Content Switching Policy Labels

Oct 31, 2013

A policy label is a user-defined bind point to which policies are bound. When a policy label is invoked, all the policies bound to it are evaluated in the order of the priority that you assigned to them. A policy label can include one or more policies, each of which can be assigned its own result. A match on one policy in the policy label can result in proceeding to the next policy, invoking a different policy label or appropriate resource, or an immediate end to policy evaluation and return of control to the policy that invoked the policy label. You can create policy labels for default syntax policies only.

For information about policy labels, see the "Creating Policy Labels."

A content switching policy label consists of a name, a label type, and a list of policies bound to the policy label. The policy label type specifies the protocol that was assigned to the policies bound to the label. It must match the service type of the content switching virtual server to which the policy that invokes the policy label is bound. For example, you can bind TCP Payload policies to a policy label of type TCP only. Binding TCP Payload policies to a policy label of type HTTP is not supported.

Each policy in a content switching policy label is associated with either a target (which is equivalent to the action that is associated with other types of policies, such as rewrite and responder policies) or a gotoPriorityExpression option and/or an invoke option. That is, for a given policy in a content switching policy label, you can specify a target, or you can set the gotoPriorityExpression option and/or the invoke option. Additionally, if multiple policies evaluate to true, only the target of the last policy that evaluates to true is considered.

You can use either the NetScaler command line or the configuration utility to configure content switching policy labels. In the NetScaler command-line interface (CLI), you first create a policy label by using the add cs policylabel command. Then, you bind policies to the policy label, one policy at a time, by using the bind cs policylabel command. In the NetScaler configuration utility, you perform both tasks in a single dialog box.

At the command prompt, type:

add cs policylabel <labelName> <cspolicylabelTypetype>
Example

```
add cs policylabel testpollab http
```

At the command prompt, type:

rename cs policylabel <labelName> <newName>
Example

```
rename cs policylabel oldPolicyLabelName newPolicyLabelName
```

1. In the navigation pane, expand Traffic Management, expand Content Switching, and then click Policy Labels.
2. In the details pane, select the policy label that you want to rename, and then, in the Action list, click Rename.

3. In the Rename CSW Policy Label dialog box, in the Name text box, specify a new name for the policy label.
4. Click OK.

At the command prompt, type the following commands to bind a policy to a policy label and verify the configuration:

- bind cs policylabel <labelName> <policyName> <priority>[[-targetVserver <string>] | [-gotoPriorityExpression <expression>] | [-invoke <labeltype> <labelName>]]
- show cs policylabel <labelName>

Example

```
bind cs policylabel testpollab test_Pol 100 -targetVserver LBVIP
show cs policylabel testpollab
        Label Name: testpollab
        Label Type: HTTP
        Number of bound policies: 1
        Number of times invoked: 0
1)      Policy Name: test_Pol
        Priority: 100
        Target Virtual Server: LBVIP
```

Note: If a policy is configure with an action, the target virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke (invoke) parameters are not required. If a policy is not configure with an action, you need to configure at least one of the following parameters: targetVserver, gotoPriorityExpression, and invoke.

At the command prompt, type the following commands to unbind a policy from a policy label and verify the configuration:

- unbind cs policylabel <labelName> <policyName>
- show cs policylabel <labelName>

Example

```
unbind cs policylabel testpollab test_Pol
show cs policylabel testpollab
        Label Name: testpollab
        Label Type: HTTP
        Number of bound policies: 0
        Number of times invoked: 0
```

At the command prompt, type:

rm cs policylabel <labelName>

1. Navigate to Traffic Management > Content Switching > Policy Labels.
2. In the details pane, do one of the following:
   - To create a new policy label, click Add.

- To modify an existing policy label, select the policy label, and then click Open.

3. In the Create Content Switching Policy Label dialog box, set the following parameters:

   - Name*
   - Label Type*

   * A required parameter

4. To add a policy to a list, click Insert Policy, and then click one of the policies in the drop-down list. If you click New Policy, create a new policy as described in "Creating Content Switching Policies."
5. For the policy that you added to the list, set the following parameters:

   - Priority* (The default value is 100. To modify the value, double-click in the Priority column.)
   - Target
   - Goto Expression
   - Invoke

   * A required parameter

6. To automatically renumber the policies, click Regenerate Priorities.
7. Click Create or OK.

Binding Policies to a Content Switching Virtual Server

Sep 03, 2014

After you create your content switching virtual server and policies, you bind each policy to the content switching virtual server. When binding the policy to the content switching virtual server, you specify the target load balancing virtual server.

Note: If your content switching policy uses a default syntax rule, you can configure a content switching action for the policy. If you configure an action, you must specify the target load balancing virtual server when you are configuring the action, not when you are binding the policy to the content switching virtual server. For more information about configuring a content switching action, see Configuring a Content Switching Action.

At the command prompt, type:

bind cs vserver <name>[-lbvserver<string> -targetLBVServer<string> -policyname <string> -priority <positive_integer>] [-gotoPriorityExpression <expression>] [-type (REQUEST | RESPONSE)] [-invoke (<labelType> <labelName>)]

Example

```
bind cs vserver csw-vip2 -policyname csw-ape-policy2 -priority 14 -gotoPriorityExpression NEXT

bind cs vserver csw-vip3 -policyname rewrite-policy1 -priority 17 -gotoPriorityExpression
'q.header("a").count' -flowtype REQUEST -invoke policylabel label1

bind cs vserver Vserver-CS-1 Vserver-LB-1 -policyname Policy-CS-1 -priority 20
```

Note: The parameters, target load balancing virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke method (invoke) cannot be used if a policy has an action.

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, double-click the virtual server for which you want to bind the policy (for example, Vserver-CS-1).
3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, click Insert Policy. A list of existing policies appears in the Policy Name drop-down list, You can either select an existing policy or create a new policy:
   - Select an existing policy that you previously created to bind to the virtual server.
   - Select New Policy from the Policy Name drop-down list to create a new content switching policy. After you create a new policy, it is automatically bound to the virtual server.
4. Click OK.

Configuring Policy Based Logging for Content Switching

Aug 22, 2013

You can configure policy based logging for a content switching policy. Policy based logging enables you to specify a format for log messages. The contents of the log message are defined by using a default syntax expression in the content switching policy. When the content switching action specified in the policy is performed, the NetScaler appliance constructs the log message from the expression and writes the message to the log file. Policy based logging is particularly useful if you want to test and troubleshoot a configuration in which content switching actions identify the target load balancing virtual server at run time.

Note: If multiple policies bound to a given virtual server evaluate to TRUE and are configured with an audit message action, the NetScaler appliance does not perform all the audit message actions. It performs only the audit message action that is configured for the policy whose content switching action is performed.
To configure policy based logging for a content switching policy, you must first configure an audit message action. For more information about configuring an audit message action, see Configuring Policy-Based Logging. After you configure the audit message action, you specify the action in a content switching policy.

At the command line, type the following commands to configure policy based logging for a content switching policy and verify the configuration:

- set cs policy <policyName> -logAction <string>
- show cs policy <policyName>

Example

```
> set cs policy cspol1 -logAction csLogAction
 Done
> show cs policy cspol1

 Policy: cspol1 Rule: TRUE Action: csact1
 LogAction: csLogAction
 Hits: 0

1) CS Vserver: csvs1
 Priority: 10
 Done
>
```

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click the policy for which you want to configure policy based logging, and then click Open.
3. In the Configure Content Switching Policy dialog box, from the Log Action list, select the log action that you want.

4. Click OK.

Verifying the Configuration

Mar 15, 2012

To verify that your content switching configuration is correct, you need to view the content switching entities. To verify proper operation after your content switching configuration has been deployed, you can view the statistics that are generated as the servers are accessed.

Updated: 2013-10-31

You can view the properties of content switching virtual servers that you have configured on the NetScaler. You can use the information to verify whether the virtual server is correctly configured and, if necessary, to troubleshoot. In addition to details such as name, IP address, and port, you can view the various policies bound to a virtual server, and its traffic-management settings.

The content switching policies are displayed in the order of their priority. If more than one policy has the same priority, they are shown in the order in which they are bound to the virtual server.

Note: If you have configured the content switching virtual server to forward traffic to a load balancing virtual server, you can also view the content switching policies by viewing the properties of the load balancing virtual server.

To view the properties of content switching virtual servers by using the command line interface

To list basic properties of all content switching virtual servers in your configuration, or detailed properties of a specific content switching virtual server, at the command prompt, type one of the following commands:

- show cs vserver
- show cs vserver <name>

Example

1.

```
show cs vserver Vserver-CS-1
Vserver-CS-1 (10.102.29.161:80) - HTTP Type: CONTENT
State: UP
Last state change was at Thu Jun 30 10:48:59 2011
Time since last state change: 6 days, 20:03:00.760
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Appflow logging: DISABLED
Port Rewrite : DISABLED
State Update: DISABLED
Default: Content Precedence: RULE
Vserver IP and Port insertion: OFF
Case Sensitivity: ON
Push: DISABLED Push VServer:
Push Label Rule: none
```

...
1) Policy : __ESNS_PREBODY_POLICY Priority:0
2) Policy : __ESNS_POSTBODY_POLICY Priority:0

1) Compression Policy Name: __ESNS_CMP_POLICY Priority: 2147483647
GotoPriority Expression: END
Flowtype: REQUEST

1) Rewrite Policy Name: __ESNS_REWRITE_POLICY Priority: 2147483647
GotoPriority Expression: END
Flowtype: REQUEST

1) Cache Policy Name: dfbx Priority: 10
GotoPriority Expression: END
Flowtype: REQUEST

1) Responder Policy Name: __ESNS_RESPONDER_POLICY Priority: 2147483647
GotoPriority Expression: END

1) Policy: wiki Target: LBVIP2 Priority: 25 Hits: 0
2) Policy: plain Target: LBVIP1 Priority: 90 Hits: 0
3) Policy: DispOrderTest2 Target: KerbAuthLBVS Priority: 91 Hits: 0
4) Policy: test_Pol Target: LBVIP1 Priority: 92 Hits: 0
5) Policy: PolicyNameTesting Target: LBVIP1 Priority: 100 Hits: 0
Done
>

2.
show cs vserver
1) Vserver-CS-1 (10.102.29.161:80) - HTTP Type: CONTENT
State: UP
...
Appflow logging: DISABLED
Port Rewrite : DISABLED
State Update: DISABLED

2) apubendpt (10.111.111.1:80) - HTTP Type: CONTENT
State: UP
...
Client Idle Timeout: 180 sec
Down state flush: DISABLED
...

3) apubendpt1 (10.111.111.2:80) - HTTP Type: CONTENT
State: UP
...
Disable Primary Vserver On Down : DISABLED

Appflow logging: DISABLED
Port Rewrite : DISABLED
State Update: DISABLED
...

To view the properties of content switching virtual servers by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, click a virtual server to display its configuration details at the bottom of the screen.
3. To display the names of the policies that are bound to the content switching virtual server, double-click the virtual server and then click the Policies tab.

Updated: 2013-08-22

You can view the properties of the content switching policies that you defined, such as the name, domain, and URL or expression, and use the information to find any mistakes in the configuration, or to troubleshoot if something is not working as it should.

To view the properties of content switching policies by using the command line interface

To list either basic properties of all content switching policies in your configuration or detailed properties of a specific content switching policy, at the command prompt, type one of the following commands:

- show cs policy
- show cs policy <PolicyName>

Example

```
show cs policy
```

```
show cs policy Policy-CS-1
```

To view the properties of content switching policies by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, double-click a policy to view the details.
3. To view the policy labels and virtual servers that this policy is bound to, on the Content Switching Policies pane, click Show Bindings.

Updated: 2013-08-22

The Content Switching Visualizer is a tool that you can use to view a content switching configuration in graphical format. You can use the visualizer to view the following configuration items:

- A summary of the load balancing virtual servers to which the content switching virtual server is bound.

- All services and service groups that are bound to the load balancing virtual server and all monitors that are bound to the services.
- The configuration details of any displayed element.
- Any policies bound to the content switching virtual server. These policies need not be content switching policies. Many types of policies, such as Rewrite policies, can be bound to a content switching virtual server.

After you configure the various elements in a content switching and load balancing setup, you can export the entire configuration to an application template file.

Note: The Visualizer requires a graphical interface, so it is available only through the configuration utility.

To view a content switching configuration by using the Visualizer in the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Content Switching Visualizer window, you can adjust the viewable area as follows:
   - Click the Zoom In and Zoom Out icons to increase or decrease the viewable area.
   - Click the Save Image icon to save the graph as an image file.
   - In the Search in text field, begin typing the name of the item you are looking for. When you have typed enough characters to identify the item, its location is highlighted. To restrict the search, click the drop-down menu and select the type of element that you want to search for.
4. To view configuration details for entities that are bound to this virtual server, you can do the following:
   - To view policies that are bound to the virtual server, in the tool bar at the top of the dialog box select one or more feature-specific policy icons. If policy labels are configured, they appear in the main view area.
   - To view the configuration details for a bound service or service group, click the icon for the service, click the Related Tasks tab, and then click Show Member Services.
   - To view the configuration details for a monitor, click the icon for the monitor, click the Related Tasks tab, and then click View Monitor.
5. To view detailed statistics for any virtual server in the content switching configuration, click the virtual server for which you want to view statistics, then click the Related Tasks tab, and then click Statistics.
6. To view a comparative list of the parameters whose values either differ or are not defined across service containers for a load balancing virtual server, click the icon for a container, click the Related Tasks tab, and then click Service Attributes Diff.
7. To view monitor binding details for the services in a container, in the Service Attributes Diff dialog box, in the Group column for the container, click Details. This comparative list helps you determine which service container has the configuration you want to apply to all the service containers.
8. To view the number of requests received per second at a given point in time by the virtual servers in the configuration, and the number of hits per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time. It has to be refreshed manually. To refresh the information, click Refresh Stats.
   Note: This option is available only on NetScaler nCore builds.
9. To copy configuration details for an element to a document or spreadsheet, click the icon for that element, click Related Tasks, click Copy Properties, and then paste the information into a document.
10. To export the entire configuration that is displayed in the Visualizer to an application template file, click the icon for the content switching virtual server, click Related Tasks, and then click Create Template. When creating the application template, you can configure variables in some policy expressions and actions. For more information about creating the application template file and configuring variables for a template, see AppExpert.

Customizing the Basic Content Switching Configuration

Jun 08, 2015

After you configure a basic content switching setup, you might need to customize it to meet your requirements. If your web servers are UNIX-based and rely on case sensitive pathnames, you can configure case sensitivity for policy evaluation. You can also set precedence for evaluation of the content switching policies that you configured. If you want to configure content switching for a specific a virtual LAN, you can configure a content switching virtual server with a listen policy.

To customize the basic content switching configuration, see the following sections:

- Configuring Case Sensitivity for Policy Evaluation
- Setting the Precedence for Policy Evaluation
- Support for Multiple Ports for HTTP and SSL Type Content Switching Virtual Servers
- Configuring per-VLAN Wildcarded Virtual Servers
- Configuring the Microsoft SQL Server Version Setting

Updated: 2013-10-31

You can configure the content switching virtual server to treat URLs as case sensitive in URL-based policies. When case sensitivity is configured, the NetScaler appliance considers case when evaluating policies. For example, if case sensitivity is off, the URLs /a/1.htm and /A/1.HTM are treated as identical. If case sensitivity is on, those URLs are treated as separate and can be switched to different targets.

To configure case sensitivity by using the command line interface

At the command prompt, type:

set cs vserver <name> -caseSensitive (ON | OFF)

Example

```
set cs vserver Vserver-CS-1 -caseSensitive ON
```

To configure case sensitivity by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure case sensitivity (for example, Vserver-CS-1), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, select Case Sensitivity check box, and then click OK.

Updated: 2013-10-31

Precedence refers to the order in which policies that are bound to a virtual server are evaluated. You do not normally have to configure precedence: the default precedence works correctly in many cases. If you want to make sure that one policy or set of policies is applied first, however, and another policy or set of policies is applied only if the first set does not match

a request, you can configure either URL-based precedence or rule-based precedence.

Precedence with URL-Based Policies

If there are multiple matching URLs for the incoming request, the precedence (priority) for URL-based policies is:

1. Domain and exact URL
2. Domain, prefix, and suffix
3. Domain and suffix
4. Domain and prefix
5. Domain only
6. Exact URL
7. Prefix and suffix
8. Suffix only
9. Prefix only
10. Default

If you configure precedence based on URL, the request URL is compared to the configured URLs. If none of the configured URLs match the request URL, then rule-based policies are checked. If the request URL does not match any rule-based policies, or if the content group selected for the request is down, then the request is processed as follows:

- If you configure a default group for the content switching virtual server, then the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, then an "HTTP 404 Not Found" error message is sent to the client.

Note: You should configure URL-based precedence if the content type (for example, images) is the same for all clients. However, if different types of content must be served based on client attributes (such as Accept-Language), you must use rule-based precedence.

Precedence with Rule-Based Policies

If you configure precedence based on rules, which is the default setting, the request is tested on the basis of the rule-based policies you have configured. If the request does not match any rule-based policies, or if the content group selected for the incoming request is down, the request is processed in the following manner:

- If a default group is configured for the content switching virtual server, the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, an "HTTP 404 Not Found" error message is sent to the client.

At the command prompt, type:

set cs vserver <name> -precedence (RULE | URL)

Example

```
set cs vserver Vserver-CS-1 -precedence RULE
```

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure precedence, (for example, Vserver-CS-1), and

then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, under Precedence, click Rule or URL, and then click OK.

Updated: 2013-10-31

If you want to configure content switching for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

To configure a wildcarded virtual server that listens to a specific VLAN by using the command line interface

At the command prompt, type:

add cs vserver <name> <serviceType> IPAddress * Port * -listenpolicy <expression> [-listenpriority <positive_integer>]
Example

```
add cs vserver Vserver-CS-vlan1 ANY * *
    -listenpolicy "CLIENT.VLAN.ID.EQ(2)"  -listenpriority 10
```

To configure a wildcarded virtual server that listens to a specific VLAN by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, do one of the following:
   - To create a new virtual server, click Add.
   - To modify an existing virtual server, select the virtual server, and then click Open.
3. In the Create Virtual Server or Configure Virtual Server dialog box, on the Services tab, type or select values for the following parameters:
   - Name*—name
   - Protocol*—type
   - IP address*—IPAddress
   - Port—port

   * A required parameter

4. In the Advanced tab, expand Listen Policy, and then type or select values for the following parameters:
   - Listen Priority*—priority
   - Listen Policy Rule*—rule

   * A required parameter

5. Click Create or OK, depending on whether you are creating a new virtual server or modifying an existing virtual server.
6. Click Close. The virtual server that you created now appears in the Virtual Servers page.
7. To remove a virtual server, in the Virtual Servers pane select the virtual server, and then click Remove.

After you have created this virtual server, you bind it to one or more services as described in Binding Services to the Virtual Server.

Updated: 2013-08-22

You can specify the version of Microsoft® SQL Server® for a content switching virtual server that is of type MSSQL. The version setting is recommended if you expect some clients to not be running the same version as your Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

To set the Microsoft SQL Server version parameter by using the command line interface

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a content switching virtual server and verify the configuration:

- set cs vserver <name> -mssqlServerVersion <mssqlServerVersion>
- show cs vserver <name>

```
> set cs vserver myMSSQLcsvip -mssqlServerVersion 2008R2
 Done
> show cs vserver myMSSQLcsvip
 myMSSQLcsvip (192.0.2.13:1433) - MSSQL Type: CONTENT
 State: UP
 . . .
 . . .
 MSsql Server Version: 2008R2
 . . .
 . . .
 Done
>
```

To set the Microsoft SQL Server version parameter by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the navigation pane, expand Content Switching, and then click Virtual Servers.
3. In the details pane, select the virtual server for which you want to configure the setting, and then click Open.
4. In the Configure Virtual Server dialog box, do the following:
    1. In the advanced tab, click MsSql.
    2. In the Server Version list, select the version of your Microsoft SQL Server product.
    3. Click Create or OK, and then click Close.

Protecting the Content Switching Setup against Failure

Jun 08, 2015

Content switching may fail when the content switching virtual server goes DOWN or fails to handle excessive traffic, or for other reasons. To reduce the chances of failure, you can take the following measures to protect the content switching setup against failure:

- Configure a backup content switching virtual server
- Configure spillover for preventing the overloading of the primary and diverting excess traffic to the backup virtual server
- Specify a redirect URL, the URL to which the content is switched if both the primary and backup content switching virtual servers are DOWN
- Enable the State Update option for marking a content switching virtual server as DOWN when the load balancing virtual server is DOWN
- Flush the surge queues when the queues become too long

Updated: 2013-11-08

If the primary content switching virtual server is marked DOWN or DISABLED, the NetScaler appliance can direct requests to a backup content switching virtual server. It can also send a notification message to the client regarding the site outage or maintenance. The backup content switching virtual server is a proxy and is transparent to the client.

When configuring the backup virtual server, you can specify the configuration parameter Disable Primary When Down to ensure that, when the primary virtual server comes back up, it remains the secondary until you manually force it to take over as the primary. This is useful if you want to ensure that any updates to the database on the server for the backup are preserved, enabling you to synchronize the databases before restoring the primary virtual server.

You can configure a backup content switching virtual server when you create a content switching virtual server or when you change the optional parameters of an existing content switching virtual server. You can also configure a backup content switching virtual server for an existing backup content switching virtual server, thus creating cascaded backup content switching virtual servers. The maximum depth of cascaded backup content switching virtual servers is 10. The appliance searches for a backup content switching virtual server that is up and accesses that content switching virtual server to deliver the content.

Note: If a content switching virtual server is configured with both a backup content switching virtual server and a redirect URL, the backup content switching virtual server takes precedence over the redirect URL. The redirect is used when the primary and backup virtual servers are down.

To set up a backup content switching virtual server by using the command line interface

At the command prompt, type:

set cs vserver <name> -backupVserver <string> -disablePrimaryOnDown (ON | OFF)

Example

```
set cs vserver Vserver-CS-1 -backupVserver Vserver-CS-2 -disablePrimaryOnDown ON
```

To set up a backup content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to set up a backup content switching virtual server (for example, Vserver-CS-1), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, click the Advanced tab.
4. In the Backup Virtual Server list, select the backup virtual server (for example, Vserver-CS-2).
5. If you want to configure the backup server to remain as the primary server after the primary virtual server is brought back up, select the Disable Primary When Down check box.
6. Click OK.

Updated: 2013-11-04

The spillover option diverts new connections arriving at a content switching virtual server to a backup content switching virtual server when the number of connections to the content switching virtual server exceeds the configured threshold value. The threshold value is dynamically calculated, or you can set the value. The number of established connections (in case of TCP) at the virtual server is compared with the threshold value. When the number of connections reaches the threshold, new connections are diverted to the backup content switching virtual server.

If the backup content switching virtual servers reach the configured threshold and are unable to take the load, the primary content switching virtual server diverts all requests to the redirect URL. If a redirect URL is not configured on the primary content switching virtual server, subsequent requests are dropped.

To configure a content switching virtual server to divert new connections to a backup virtual server by using the command line interface

At the command prompt, type:

set cs vserver <name> -soMethod <methodType> -soThreshold <thresholdValue> -soPersistence <persistenceValue> -soPersistenceTimeout <timeoutValue>

Example

```
set cs vserver Vserver-CS-1 -soMethod Connection -soThreshold 1000 -soPersistence enabled -soPersistenceTimeout 2
```

To set a content switching virtual server to divert new connections to a backup virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure spillover (for example, Vserver-CS-1), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, under Spillover, in the Method list, select the type of spillover, and in Threshold text box, type the threshold value (for example, Connection and 1000).
4. Select the Persistence check box and, in Persistence Time-out (min) text box, type the timeout value (for example, 2).
5. Click OK.

Updated: 2015-03-19

You can configure a redirect URL to communicate the status of the NetScaler appliance in the event that a content switching virtual server of type HTTP or HTTPS is DOWN or DISABLED. This URL can be local or remote.

Redirect URLs can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL), the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Citrix recommends using an absolute URL. That is, a URL ending in /, for example www.example.com/ instead of a relative URL. A relative URL redirection might result in the vulnerability scanner reporting a false positive.

Note: If a content switching virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect URL is used when the primary and backup virtual servers are down.
When redirection is configured and the content switching virtual server is unavailable, the appliance issues an HTTP 302 redirect to the user's browser.

To configure a redirect URL for when the content switching virtual server is unavailable by using the command line interface

At the command prompt, type:

set cs vserver <name> -redirectURL <URLValue>

Example

```
set cs vserver Vserver-CS-1 -redirectURL http://www.newdomain.com/mysite/maintenance
```

To configure a redirect URL for when the content switching virtual server is unavailable by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure a redirect URL (for example, Vserver-CS-1), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, in the Redirect URL text box, type the redirect URL (for example, http://www.newdomain.com/mysite/maintenance).
4. Click OK.

Updated: 2014-12-12

The content switching feature enables the distribution of client requests across multiple servers on the basis of the specific content presented to the users. For efficient content switching, the content switching virtual server distributes the traffic to the load balancing virtual servers according to the

content type, and the load balancing virtual servers distribute the traffic to the physical servers according to the specified load balancing method.

For smooth traffic management, it is important for the content switching virtual server to know the status of the load balancing virtual servers. The state update option helps to mark the content switching virtual server DOWN if the load balancing virtual server bound to it is marked DOWN. A load balancing virtual server is marked DOWN if all the physical servers bound to it are marked DOWN.

When State Update is disabled:

The status of the content switching virtual server is marked as UP. It remains UP even if there is no bound load balancing virtual server that is UP.

When State Update is enabled:

When you add a new content switching virtual server, initially, its status is shown as DOWN. When you bind a load balancing virtual server whose status is UP, the status of the content switching virtual server becomes UP.

If more than one load balancing virtual server is bound and if one of them is specified as the default, the status of the content switching virtual server reflects the status of the default load balancing virtual server.

If more than one load balancing virtual server is bound without any of them being specified as the default, the status of the content switching virtual server is marked UP only if all the bound load balancing virtual servers are UP.

To configure the state update option by using the command line interface

At the command prompt, type:

add cs vserver <name> <protocol> <ipAddress> <port> -stateUpdate ENABLED

add cs vserver csw_vserver HTTP 10.18.250.154 80 -stateupdate ENABLED -cltTimeout 180

To configure the state update option by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, do one of the following:
   - To add a virtual server, click Add.
   - To modify a virtual server, select the server, and click Open.
3. In the Create Virtual Server (Content Switching) dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for configuring content switching" as shown:
   - Name-vServerName
   - IP Address-ipAddress
     Note: If you need to enter an IPv6 address, select the IPv6 check box before you enter the address.
   - Port-port
   - Protocol-protocol
4. On the Advanced tab, select the State Update check box.
5. Click Create.
6. Select the new virtual server, click Open, and verify the settings.

Updated: 2013-12-04

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the NetScaler appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.
The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases

whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.
Note: Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

To flush a surge queue by using the command line interface

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]

1.
flush ns surgeQ –name SVC1ANZGB –serverName 10.10.10.1 80
The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10
2.
flush ns surgeQ
The above command flushes all the surge queues on the appliance.

To flush a surge queue by using the configuration utility

1. Navigate to Traffic Management > Load Balancing.
2. To select an entity, do one of the following:
   - To flush the surge queue of a virtual server, click Virtual Servers, and then select the virtual server.
   - To flush the surge queue of a service, click Services, and then select the service.
   - To flush the surge queue of all the members in a service group, click Service Groups, and then select the service group.
   - To flush the surge queue of a specific member in a service group, click Service Groups, and in the action pane, click Manage Members. In the Manage Members of a Service Group dialog box, select the service group member.

   Note: You can select multiple entities in any window.
   Note: To flush the surge queue of a content switching virtual server, in Steps 1 and 2, expand Content Switching, and then select a virtual server.
3. In the action pane, click Flush Surge Queue.
4. Click OK.
   Note: On the appliance, if there are other entities with the same name as you selected, you are alerted that the surge queues of those entities would also be flushed. Take an appropriate action.

Managing a Content Switching Setup

Jun 08, 2015

After a content switching setup is configured, it may require periodic changes. When operating systems or software are updated, or hardware wears out and is replaced, you may need to take down your setup. Load on your setup may increase, requiring additional resources. You may also modify the configuration to improve performance.

These tasks may require unbinding policies from the content switching virtual server, or disabling or removing content switching virtual servers. After you have made changes to your setup, you may need to re-enable servers and rebind policies. You might also want to rename your virtual servers.

To manage a content switching setup, see the following sections:

- Unbinding Policies from the Content Switching Virtual Server
- Removing Content Switching Virtual Servers
- Disabling and Re-Enabling Content Switching Virtual Servers
- Renaming Content Switching Virtual Servers
- Managing Content Switching Policies
- Modifying a Content Switching Configuration by Using the Visualizer

Updated: 2014-09-03

When you unbind a content switching policy from its virtual server, the virtual server no longer includes that policy when determining where to direct requests.

To unbind a policy from a content switching virtual server by using the command line interface

At the command prompt, type:

unbind cs vserver <name> -policyname <string>

Example

```
unbind cs vserver Vserver-CS-1 -policyname Policy-CS-1
```

To unbind a policy from a content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server form which you want to unbind the policy (for example, Vserver-CS-1), and click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, in the Active column, clear the check box next to the policy that you want to unbind from the virtual server (for example, Policy-CS-1).
4. Click OK.

Updated: 2013-10-31

You normally remove a content switching virtual server only when you no longer require the virtual server. When you remove a content switching virtual server, the NetScaler appliance first unbinds all policies from the content switching virtual server, and then removes it.

To remove a content switching virtual server by using the command line interface

At the command prompt, type:

rm cs vserver <name>@
Example

```
rm cs vserver Vserver-CS-1
```

To remove a content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server that you want to remove (for example, Vserver-CS-1), and then click Remove.
3. In the Remove dialog box, click Yes.

Updated: 2013-10-31

Content switching virtual servers are enabled by default when you create them. You can disable a content switching virtual server for maintenance. If you disable the content switching virtual server, the state of the content switching virtual server changes to Out of Service. While out of service, the content switching virtual server does not respond to requests.

To disable or re-enable a virtual server by using the command line interface

At the command prompt, type one of the following commands:

- disable cs vserver <name>@
- enable cs vserver <name>@

Example

```
disable cs vserver Vserver-CS-1
```

```
enable cs vserver Vserver-CS-1
```

To disable or re-enable a virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server that you want to disable (for example, Vserver-CS-1).
3. Disable or re-enable the virtual server by clicking Disable or Enable, and then clicking Yes to confirm your choice.

Updated: 2013-10-31

You can rename a content switching virtual server without unbinding it. The new name is propagated automatically to all affected parts of the NetScaler configuration.

To rename a virtual server by using the command line interface

At the command prompt, type:

rename cs vserver <name>@ <newName>@
Example

rename cs vserver Vserver-CS-1 Vserver-CS-2

To rename a virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server that you want to rename (for example, Vserver-CS-1).
3. Click Rename.
4. In the Name text box, type a new name for the virtual server.
5. Click OK to save your changes.

Updated: 2013-08-22

You can modify an existing policy by configuring rules or changing the URL of the policy, or you can remove a policy. You can also rename an existing advanced content switching policy. You can create different policies based on the URL. URL-based policies can be of different types, as described in the following table.

Table 1. Examples of URL-Based Policies

Type of URL-Based Policy	Specifies
Domain and Exact URL	Requests must match the configured domain name and configured URL (an exact prefix match if only the prefix is configured; or an exact match of the prefix and suffix if both the prefix and suffix are configured). **Example:** **add cs policy Policy-CS-1 -url /sports/tennis/index.html -domain "www.domainxyz.com"**
Domain and Wild Card URL	Requests must match the exact domain name and a partial prefix of the configured URL. **Example:** **add cs policy Policy-CS-1 -url /*.jsp -domain "www.domainxyz.com"**
Domain Only	Requests need match only the configured domain name. **Example:** **add cs policy Policy-CS-1 -domain "www.domainxyz.com"**

Type of URL-Based Policy	Specifies
The Exact URL	The incoming URL must exactly match the URL specified by the policy. If only a URL prefix rule is configured, there must be an exact prefix match with the incoming URL. If a URL prefix and suffix-based rule is configured, there should be an exact match of the prefix and suffix with the incoming URL. **Example:** **add cs policy Policy-CS-1 -url /sports/tennis/index.html**
Prefix Only (Wild Card URL)	All the incoming URLs must start with the configured prefix. **Example:** **add cs policy Policy-CS-1 -url /sports*** sports/*" matches all URLs under /sports "/sports*" matches all URLs whose prefix match "/sports" starting from the beginning of a URL
Suffix Only (Wild Card URL)	All incoming URLs must end with the configured URL suffix. **Example:** **add cs policy Policy-CS-1 -url /*.jsp** "/*.jsp" matches all URLs whose file extension is "jsp"
Prefix and Suffix (Wild Card URL)	All incoming URLs must start with the configured prefix and end with the configured suffix. **Example:** **add cs policy Policy-CS-1 -url /sports/*.jsp**

Note: You can configure rule-based content switching using classical policy expressions or advanced policy expressions.

To modify, remove, or rename a policy by using the command line interface

At the command prompt, type one of the following commands:

- set cs policy <policyName> [-domain <domainValue>] [-rule <ruleValue>] [-url <URLValue>]
- rm cs policy <policyName>
- rename cs policy <policyName> <newPolicyName>

Example

```
set cs policy Policy-CS-1 -domain "www.domainxyz.com"

set cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(22).EQ(10.100.148.0)"

set cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2010 Jun,GMT 2010 Jul)"
```

```
set cs policy Policy-CS-1 -url /sports/*

rename cs policy Policy-CS-1 Policy-CS-11

rm cs policy Policy-CS-1
```

To modify, remove, or rename a policy by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, select the policy that you want to modify (for example, Policy-CS-1).
3. Modify, remove, or rename the policy.
   - To modify the policy, click Open and then make the changes that you want. For example, you can type a new domain name in the Domain text box. Then, click Yes to confirm your changes.
   - To remove the policy, click Remove, and then click Yes to confirm your choice.
   - To rename the policy, click Rename, and specify the new name in the Name text field in the Rename CSW Policy dialog box, and then click OK.
4. In the Configure Content Switching Policies dialog box, in the Domain text box, type the domain name (for example, www.domainxyz.com).
5. Click OK.

Updated: 2013-08-22

You can use the Visualizer to modify a load balancing virtual server to which the content switching virtual server is bound. You can also modify a service or group of similar services, or a monitor. For more information, see "The Load Balancing Visualizer."

Managing Client Connections

May 21, 2015

To ensure efficient management of client connections, you can configure the content switching virtual servers on the NetScaler appliance to use the following features:

- Redirecting client requests to a cache
- Enabling delayed cleanup of virtual server connections
- Rewriting ports and protocols for redirection
- Inserting the IP address and port of a virtual server in the request header
- Setting a time-out value for idle client connections
- Identifying Connections with the 4-tuple and Layer 2 Connection Parameters
- Configuring the ICMP Response. You can configure the NetScaler to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.
  The following settings can be made on a virtual server:
  - When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.
  - When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, NetScaler responds even if one virtual server is UP.
  - When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds even if one virtual server set to ACTIVE is UP.

Updated: 2013-10-31

The NetScaler cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the burden of responding to HTTP requests and improve your Web site performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the NetScaler appliance sends cacheable HTTP requests to the cache and non-cacheable HTTP requests to the origin Web server. For more information on cache redirection, see "Cache Redirection."

To configure cache redirection on a virtual server by using the command line interface

At the command prompt, type:

set cs vserver <name> -cacheable <Value>

Example

```
set cs vserver Vserver-CS-1 -cacheable yes
```

To configure cache redirection on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure cache redirection (for example, Vserver-CS-1), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, select the Cache Redirection check box.
4. Click OK.

Updated: 2013-10-31

Under certain conditions, you can configure the down state flush setting to terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources and in certain cases speeds recovery of overloaded load balancing setups.

To configure the down state flush setting on a virtual server by using the command line interface

At the command prompt, type:

set cs vserver <name> -downStateFlush <Value>
Example

```
set cs vserver Vserver-CS-1 -downStateFlush enabled
```

To configure the down state flush setting on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure down state flush (for example, Vserver-CS-1), and click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, click the Advanced tab.
4. Select the Down state flush check box, and then click OK.

Updated: 2013-10-31

Virtual servers and the services that are bound to them may use different ports. When a service responds to an HTTP connection with a redirect, you may need to configure the NetScaler appliance to modify the port and the protocol to ensure that the redirection goes through successfully. You do this by enabling and configuring the redirectPortRewrite setting.

To configure HTTP redirection on a virtual server by using the command line interface

At the command prompt, type:

set cs vserver <name> -redirectPortRewrite <Value>
Example

```
set cs vserver Vserver-CS-1 -redirectPortRewrite enabled
```

To configure HTTP redirection on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure HTTP redirection (for example, Vserver-CS-1), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, click the Advanced tab.
4. Select the Redirect Port Rewrite check box, and then click OK.

Updated: 2013-10-31

If you have multiple virtual servers that communicate with different applications on the same service, you must configure the NetScaler appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, you must configure the required header tag on both virtual servers.

Note: This option is not supported for wildcarded virtual servers or dummy virtual servers.

To insert the IP address and port of the virtual server in the client requests by using the command line interface

At the command prompt, type:

set cs vserver <name> -insertVserverIPPort <vServerIPPORT>
Example

```
set cs vserver Vserver-CS-1 -insertVserverIPPort 10.201.25.136:80
```

To insert the IP address and port of the virtual server in the client requests by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure virtual server port insertion (for example, Vserver-CS-1), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, click the Advanced tab.
4. In the Vserver IP Port Insertion list, select the VIPADDR or V6TOV4MAPPING, and then type the port header in a text box next to Vserver IP Port Insertion box.
5. Click OK.

Updated: 2013-10-31

You can configure a virtual server to terminate any idle client connections after a configured time-out period elapses. When you configure this setting, the NetScaler appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection.

To set a time-out value for idle client connections by using the command line

interface

At the command prompt, type:

set cs vserver <name> -cltTimeout <Value>
Example

set cs vserver Vserver-CS-1 -cltTimeout 100

To set a time-out value for idle client connections by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to set a time-out value (for example, Vserver-CS-1), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, click the Advanced tab.
4. In the Client Time-out (secs) text box, type the time-out value (for example, 100).
5. Click OK.

Updated: 2013-08-22

You can now set the L2Conn option for a content switching virtual server. With the L2Conn option set, connections to the content switching virtual server are identified by the combination of the 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) and Layer 2 connection parameters. The Layer 2 connection parameters are the MAC address, VLAN ID, and channel ID.

To set the L2Conn option for a content switching virtual server by using the command line interface

At the command line, type the following commands to configure the L2Conn parameter for a content switching virtual server and verify the configuration:

- set cs vserver <name> -l2Conn (**ON** | **OFF**)
- show cs vserver <name>

```
> set cs vserver mycsvserver -l2Conn ON
Done
> show cs vserver mycsvserver
    mycsvserver (192.0.2.56:80) - HTTP   Type: CONTENT
    State: UP
       . . .
       . . .
    L2Conn: ON Case Sensitivity: ON
       . . .
       . . .
Done
>
```

To set the L2Conn option for a content switching virtual server by using the

configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, click the content switching virtual server for which you want to set the L2Conn option, and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, select L2 Connection.
4. Click OK.

Troubleshooting

Jul 22, 2013

If the content switching feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

Updated: 2013-07-22

For best results, use the following resources to troubleshoot a content switching issue on a NetScaler appliance:

- Configuration file
- Relevant newnslog file
- Trace files
- Network topology diagram for the network setup of the customer
- Citrix documentation, such as release notes, Knowledge Center articles, and eDocs

In addition to the above resources, the following tools expedite troubleshooting:

- The iehttpheaders or a similar utility
- The Wireshark application customized for the NetScaler trace files
- An SSH utility for command line access
- A HyperTerminal utility to access the console

Updated: 2013-08-02

The most common content switching issues involve the content switching feature not working at all, or working only intermittently, and Service Unavailable responses.

- **Issue**
  The content switching feature is not functioning.

  Resolution

  Check the configuration as follows:
  - Verify that the appliance is licensed for content switching.
  - Verify that the feature is enabled.
  - From the configuration file, verify that valid content switching policies are correctly bound to the load balancing virtual servers.
- **Issue**
  Client receives a 503 - Service Unavailable response.

  Resolution
  - Verify the URL and policy bindings. The client receives the 503 response when none of the policies you have configured is evaluated and no default load balancing virtual server is defined and bound to the content switching virtual server.
  - From the configuration, verify the policies and URL being accessed by the client.
  - Verify that for every type of request the respective policy is evaluated. If the policy is not evaluated, check the policy

expression and update it if necessary.
- Verify the URL and HTTP request and response headers. To do so, record an HTTPHeader trace and, if necessary, record the packet traces on the appliance and the client.

- **Issue**
  Intermittently, the content switching feature is not working as expected.

  Resolution
  - Study the network topology diagram, if available, of the setup to understand the various devices installed between the client and the server(s).
  - Verify the configuration and policy bindings. Make sure that the URL in the policy expression matches to the one in the client request.
  - Verify that appropriate priorities are assigned to the policies. An incorrect precedence or priority assigned to a policy can cause a problem.
  - Run the following commands to verify the bindings and the values of the policy hit counters in the output of the commands:
    ```
    show cs vserver <CS VServer>

    show cs policy <CS Policy>

    stat cs vserver <CS VServer>
    ```
  - Using iehttpheaders or a similar utility, determine whether the HTTP headers for the requests or responses provide any pointers to the issue.
  - Check the release notes and Knowledge Center articles.
  - If the issue is still not resolved, contact Citrix Technical Support with appropriate data for further investigation.

DataStream

May 25, 2015

The NetScaler DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests based on the SQL query being sent.

When deployed in front of database servers, a NetScaler ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and on the basis of database names, usernames, character sets, and packet size.

You can either configure load balancing to switch requests based on load balancing algorithms or elaborate the switching criteria by configuring content switching to make a decision based on an SQL query parameters. You can further configure monitors to track the state of database servers.

Note: NetScaler DataStream is supported only for MySQL and MS SQL databases. For information about the supported protocol version, character sets, special queries, and transactions, see DataStream Reference.

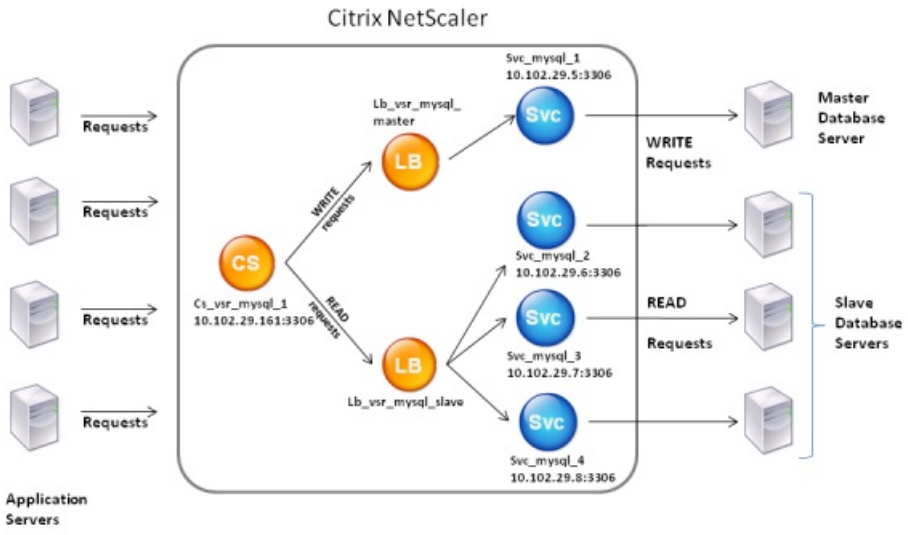
How NetScaler DataStream Works

Updated: 2013-09-18

In DataStream, the NetScaler is placed in-line between the application and/or Web servers and the database servers. On the NetScaler appliance, the database servers are represented by services.

A typical DataStream deployment consists of the entities described in the following diagram.

Figure 1. *DataStream Entity Model*



As shown in this figure, a DataStream configuration can consist of an optional content switching virtual server (CS), a load balancing setup consisting of load balancing virtual servers (LB1 and LB2) and services (Svc1, Svc2, Svc3, and Svc4), and content switching policies (optional).

The clients (application or Web servers) send requests to the IP address of a content switching virtual server (CS) configured on the NetScaler appliance. The NetScaler, then, authenticates the clients using the database user credentials configured on the NetScaler appliance. The content switching virtual server (CS) applies the associated content switching policies to the requests. After evaluating the policies, the content switching virtual server (CS) routes the requests to the appropriate load balancing virtual server (LB1 or LB2), which, then, distributes the requests to the appropriate database servers (represented by services on the NetScaler) based on the load balancing algorithm. The NetScaler uses the same database user credentials to authenticate the connection with the database server.

If a content switching virtual server is not configured on the NetScaler, the clients (application or Web servers) send their requests to the IP address of a load balancing virtual server configured on the NetScaler appliance. The NetScaler authenticates the client by using the database user credentials configured on the NetScaler appliance, and then uses the same credentials to authenticate the connection with the database server. The load balancing virtual server distributes the requests to the database servers according to the load balancing algorithm. The most effective load balancing algorithm for database switching is the least connection method.

DataStream uses connection multiplexing to enable multiple client-side requests to be made over the same server-side connection. The following connection properties are considered:

- User name
- Database name
- Packet size
- Character set

Configuring Database Users

Oct 21, 2014

In databases, a connection is always stateful, which means that as soon as a connection is established, it must be authenticated.

You need to configure your database user name and password on the NetScaler ADC. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. When you add the database user names and passwords on the ADC, these are added to the nsconfig file.
Note: Names are case sensitive.
The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

To add a database user by using the command line interface

At the command prompt, type

add db user <username> - password <password>
Example

```
> add db user nsdbuser -password dd260427edf
```

To add a database user by using the configuration utility

1. In the details pane, click Add.
2. In the Create Database User dialog box, specify values for the following parameters.
   - User Name
   - Password
   - Confirm Password
3. Click Create, and then click Close. The user you created appears in the Database Users pane.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the NetScaler.

To add a database user by using the configuration utility

1. Navigate to System > User Administration > Database Users, and then click Add.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the NetScaler.

To reset the password of a database user by using the command line interface

At the command prompt, type

set db user <username> -password <password>
Example

```
> set db user nsdbuser -password dd260538abs
```

To reset the password of database users by using the configuration utility

1. Navigate to System > User Administration > Database Users.
2. In the details pane, select the database user for which you want to reset the password, and then click Open.
3. In the Configure Database User dialog box, modify the values for the following parameters.
   - Password
   - Confirm Password
4. Click OK.

If a database user no longer exists on the database server, you can remove the user from the NetScaler. However, if the user continues to exist on the database server and you remove the user from the NetScaler, any request from the client with this user name does not get authenticated, and therefore, does not get routed to the database server.

To remove a database user by using the command line interface

At the command prompt, type

rm db user <username>
Example

```
>  rm db user nsdbuser
```

To remove a database user by using the configuration utility

1. Navigate to System > User Administration > Database Users.
2. In the details pane, select the database user that you want to remove, and then click Open.
3. In the Proceed message box, click Yes.

Configuring a Database Profile

Sep 03, 2014

A database profile is a named collection of parameters that is configured once but applied to multiple virtual servers that require those particular parameter settings. After creating a database profile, you bind it to load balancing or content switching virtual servers. You can create as many profiles as you need.

To create a database profile by using the command line interface

At the command line, type the following commands to create a database profile and verify the configuration:

- add db dbProfile <name> [-interpretQuery (YES | NO)] [-stickiness (YES | NO)] [-kcdAccount <string>]
- show db dbProfile

Example

```
> add dbProfile myDBProfile -interpretQuery YES -stickiness YES -kcdAccount mykcdaccnt
 Done
> show dbProfile myDBProfile
 Name: myDBProfile
 Interpret Query: YES
 Stickyness: YES
 KCD Account: mykcdaccnt
 Reference count: 0

 Done
>
```

To create a database profile by using the configuration utility

1. Navigate to System > Profiles.
2. In the details pane, on the Database Profiles tab, do one of the following:
   - To create a database profile, click Add.
   - To modify a database profile, click the profile, and then click Open.
3. In the Create Database Profile or Configure Database Profile dialog box, set the following parameters:
   - Name*
   - KCD Account
   - Interpret Query
   - Stickiness

   * Required parameter
4. Click Create or OK, and then click Close.

To bind a database profile to a load balancing or content switching virtual server by using the command line interface

At the command line, type:

set (lb | cs) vserver <name> -dbProfileName <string>

To bind a database profile to a load balancing or content switching virtual server by using the configuration utility

1. In the navigation pane, expand Traffic Management, and then expand Load Balancing or Content Switching, depending on the type of virtual server to which you want to bind the database profile.
2. Click Virtual Servers.
3. In the details pane, select the virtual server, and then click Open.
4. In the Configure Virtual Server (Load Balancing) or Configure Virtual Server (Content Switching) dialog box, on the Profiles tab, in the Database Profile list, select the database profile.
5. Click OK.

Configuring Load Balancing for DataStream

May 15, 2015

Before configuring a load balancing setup, you must enable the load balancing feature. Then, begin by creating at least one service for each database server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server and bind the services to the virtual server.

Parameter values specific to DataStream

Protocol

Use the MYSQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see http://dev.mysql.com/doc/internals/en/client-server-protocol.html. For information about the TDS protocol, see http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx.

Port

Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

Method

It is recommended that you use the Least Connection method for better load balancing and lower server load. However, other methods, such as Round Robin, Least Response Time, Source IP Hash, Source IP Destination IP Hash, Least Bandwidth, Least Packets, and Source IP Source Port Hash, are also supported.

Note: URL Hash method is not supported for DataStream.

MS SQL Server Version

If you are using the Microsoft SQL Server, and you expect some clients to not be running the same version as your Microsoft SQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see Configuring the MySQL and Microsoft SQL Server Version Setting.

MySQL Server Version

If you are using the MySQL Server, and you expect some clients to not be running the same version as your MySQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see Configuring the MySQL and Microsoft SQL Server Version Setting.

Configuring Content Switching for DataStream

May 15, 2015

You can segment traffic according to information in the SQL query, on the basis of database names, user names, character sets, and packet size.

You can configure content switching policies with default syntax expressions to switch content based on connection properties, such as user name and database name, command parameters, and the SQL query to select the server.

The default syntax expressions evaluate traffic associated with MYSQL and MS SQL database servers. You can use request-based expressions in default syntax policies to make request switching decisions at the content switching virtual server bind point and response-based expressions (expressions that begin with MYSQL.RES) to evaluate server responses to user-configured health monitors.

Note: For information about default syntax expressions, see Default Syntax Expressions: DataStream.

Parameter values specific to DataStream

Protocol

Use the MYSQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see http://dev.mysql.com/doc/internals/en/client-server-protocol.html. For information about the TDS protocol, see http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx.

Port

Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

MS SQL Server Version

If you are using Microsoft SQL Server, and you expect some clients to not be running the same version as your Microsoft SQL Server product, set the Server Version parameter for the content switching virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see Configuring the Microsoft SQL Server Version Setting.

Configuring Monitors for DataStream

Oct 01, 2013

To track the state of each load balanced database server in real time, you need to bind a monitor to each service. The monitor is configured to test the service by sending periodic probes to the service. (This is sometimes referred to as performing a health check.) If the monitor receives a timely response to its probes, it marks the service as UP. If it does not receive a timely response to the designated number of probes, it marks the service as DOWN.

For DataStream, you need to use the built-in monitors, MYSQL-ECV and MSSQL-ECV. This monitor provides the ability to send an SQL request and parse the response for a string.

Before configuring monitors for DataStream, you must add database user credentials to your NetScaler. For information about configuring monitors, see Monitors.

When you create a monitor, a TCP connection is established with the database server, and the connection is authenticated by using the user name provided while creating the monitor. You can then run an SQL query to the database server and evaluate the server response to check whether it matches the configured rule.

Examples

In the following example, the value of the error message is evaluated to determine the state of the server.

```
add lb monitor lb_mon1 MYSQL_ECV -sqlQuery "select * from
table2;" -evalrule "mysql.res.error.message.contains(\"Invalid
User\")"-database "NS" -userName "user1"
```

In the following example, the number of rows in the response is evaluated to determine the state of the server.

```
add lb monitor lb_mon4 MYSQL_ECV -sqlQuery "select * from
table4;" -evalrule "mysql.res.atleast_rows_count(7)" -database "NS" -userName "user2"
```

In the following example, the value of a particular column is evaluated to determine the state of the server.

```
add lb monitor lb_mon3 MYSQL_ECV
-sqlQuery "select * from ABC;" -evalrule "mysql.res.row(1).double_elem(2) == 345.12"
-database "NS" -userName "user3"
```

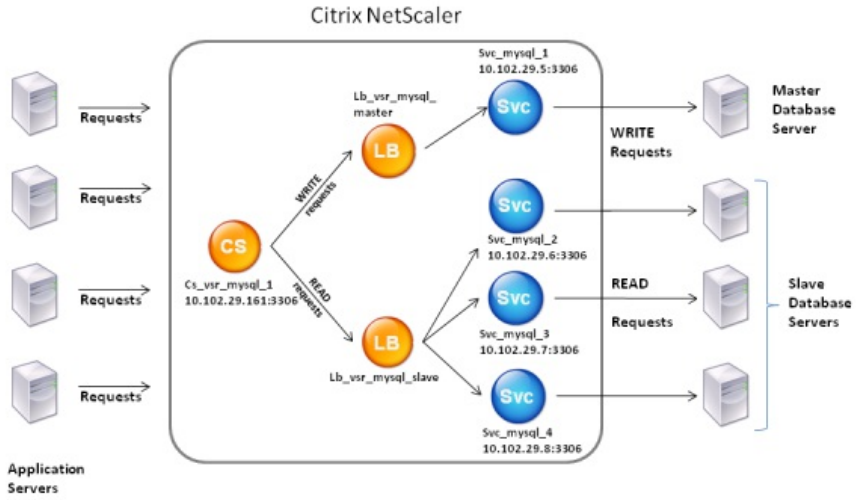
Use Case 1: Configuring DataStream for a Master/Slave Database Architecture

May 15, 2015

A commonly used deployment scenario is the master/slave database architecture where the master database replicates all information to the slave databases.
For master/slave database architecture, you may want all WRITE requests to be sent to the master database and all READ requests to the slave databases.

The following figure shows the entities and the values of the parameters you need to configure on the appliance.

Figure 1. *DataStream Entity Model for Master/Slave Database Setup*



In this example scenario, a service (Svc_mysql_1) is created to represent the master database and is bound to a load balancing virtual server (Lb_vsr_mysql_master). Three more services (Svc_mysql_2, Svc_mysql_3, and Svc_mysql_4) are created to represent the three slave databases, and they are bound to another load balancing virtual server (Lb_vsr_mysql_slave).

A content switching virtual server (Cs_vsr_mysql_1) is configured with associated policies to send all WRITE requests to the load balancing virtual server, Lb_vsr_mysql_master, and all READ requests to the load balancing virtual server, Lb_vsr_mysql_slave.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

The following table lists the names and values of the entities and the policy configured on the NetScaler.

Table 1. ***Entity and Policy Names and Values***

Entity Type	Name	IP Address	Protocol	Port	Expression

Entity Type	Name	IP Address	Protocol	Port	Expression
Services	Svc_mysql_1	10.102.29.5	MYSQL	3306	NA
	Svc_mysql_2	10.102.29.6	MYSQL	3306	NA
	Svc_mysql_3	10.102.29.7	MYSQL	3306	NA
	Svc_mysql_4	10.102.29.8	MYSQL	3306	NA
Load balancing virtual servers	Lb_vsr_mysql_master	10.102.29.201	MYSQL	3306	NA
	Lb_vsr_mysql_slave	10.102.29.202	MYSQL	3306	NA
Content switching virtual server	Cs_vsr_mysql_1	10.102.29.161	MYSQL	3306	NA
Content switching policy	Cs_select	NA	NA	NA	"MYSQL.REQ.QUERY.COMMAND.contains(\"select\")"

To configure DataStream for a master/slave database setup by using the command line interface

At the command prompt, type

- add service Svc_mysql_1 10.102.29.5 mysql 3306
- add service Svc_mysql_2 10.102.29.6 mysql 3306
- add service Svc_mysql_3 10.102.29.7 mysql 3306
- add service Svc_mysql_4 10.102.29.8 mysql 3306
- add lb vserver Lb_vsr_mysql_master mysql 10.102.29.201 3306
- add lb vserver Lb_vsr_mysql_slave mysql 10.102.29.202 3306
- bind lb vserver Lb_vsr_mysql_master svc_mysql_1
- bind lb vserver Lb_vsr_mysql_slave svc_mysql_2
- bind lb vserver Lb_vsr_mysql_slave svc_mysql_3
- bind lb vserver Lb_vsr_mysql_slave svc_mysql_4
- add cs vserver Cs_vsr_mysql_1 mysql 10.102.29.161 3306
- add cs policy Cs_select –rule "MYSQL.REQ.QUERY.COMMAND.contains(\"select\")"
- bind cs vserver Cs_vsr_mysql_1 Lb_vsr_mysql_master
- bind cs vserver Cs_vsr_mysql_1 Lb_vsr_mysql_slave –policy Cs_select –priority 10

To configure DataStream for a master/slave database setup by using the configuration utility

Add four services, one to represent the master database server and three to represent the slave database servers.

To add a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters.
   - Service Name
   - IP Address
   - Protocol
   - Port
4. Click Create, and then click Close. The service you created appears in the Services pane.

Add two load balancing virtual servers.

To create a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters.
   - Name
   - IP Address
   - Protocol
   - Port
4. Click Create, and then click Close.

Bind the service Svc_mysql_1 to the load balancing virtual server Lb_vsr_mysql_master, and bind the three services (Svc_mysql_2, Svc_mysql_3, and Svc_mysql_4) to the load balancing virtual server Lb_vsr_mysql_slave.

To bind a service to a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server to which you want to bind the service (for example, Lb_vsr_mysql_master).
3. Click Open.
4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server (for example, Svc_mysql_1).
5. Click OK.

Create a content switching virtual server.

To add a content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Content Switching) dialog box, specify values for the following parameters.-
   - Name
   - IP Address
   - Protocol
   - Port
4. Click Create, and then click Close.

Create a content switching policy to evaluate all READ requests.

To create a content switching policy by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type the name of the policy (for example, Cs_select).
4. Choose the type of policy that you want to create, and configure the policy. To create a rule-based policy, click **Configure**, and do the following:

- In the Create Expression dialog box, choose the expression syntax you want to use and enter your policy expressions.

5. Click Create, and then click Close.

Bind the content switching policy to the content switching virtual server. You should also select a load balancing virtual server as the target for the policy so that, after the content switching virtual server evaluates the policy, it routes requests that match the policy to the load balancing virtual server to forward them to the appropriate database server.

To bind the policy to the content switching virtual server and select a load balancing virtual server target by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, double-click the virtual server to which you want to bind the policy (for example, Cs_vsr_mysql_1).
3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, click Insert Policy, and in the Policy Name column, select the policy that you want to bind to the virtual server (for example, Cs_select).
4. In the Target column next to the policy, select the load balancing virtual server that you want to assign as the target for the policy (for example, Lb_vsr_mysql_slave).
5. Click OK.

Set the load balancing virtual server, Lb_vsr_mysql_master, as the default virtual server for the content switching virtual server by binding the content switching virtual server to this load balancing virtual server. This ensures that the content switching virtual server routes requests that do not match the Cs_select policy to the load balancing virtual server to forward them to the appropriate database server.

To bind the content switching virtual server to a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, double-click the virtual server to which you want to bind the policy (for example, Cs_vsr_mysql_1).
3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, click Insert Policy, and in the Policy Name column, select (Default).
4. In the Target column next to the policy, select the load balancing virtual server that you want to assign as the target for the policy (for example, Lb_vsr_mysql_master).
5. Click OK.

Use Case 2: Configuring the Token Method of Load Balancing for DataStream

May 15, 2015

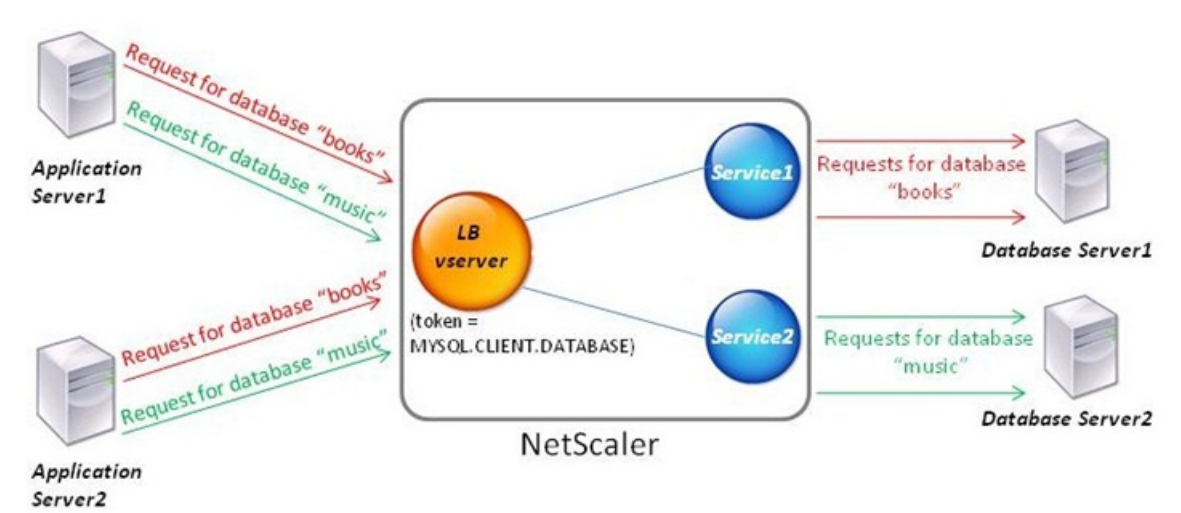
You can configure the token method of load balancing for DataStream to base the selection of database servers on the value of the token extracted from the client (application or web server) requests. These tokens are defined by using SQL expressions. For subsequent requests with the same token, the NetScaler sends the requests to the same database server that handled the initial request. Requests with the same token are sent to the same database server until the maximum connection limit is reached or the session entry has aged out.

You can use the following sample SQL expressions to define tokens:

MySQL	**MS SQL**
MYSQL.REQ.QUERY.TEXT	MSSQL.REQ.QUERY.TEXT
MYSQL.REQ.QUERY.TEXT(n)	MSSQL. REQ.QUERY.TEXT(n)
MYSQL.REQ.QUERY.COMMAND	MSSQL.REQ.QUERY.COMMAND
MYSQL.CLIENT.USER	MSSQL.CLIENT.USER
MYSQL.CLIENT.DATABASE	MSSQL.CLIENT.DATABASE
MYSQL.CLIENT.CAPABILITIES	

The following example shows how the NetScaler DataStream feature works when you configure the token method of load balancing.

Figure 1. How DataStream Works with the Token Method of Load Balancing



In this example, the token is the name of the database. A request with token **books** is sent to **Database Server1** and a request with token **music** is sent to **Database Server2**. All subsequent requests with token **books** are sent to **Database Server1** and requests with token **music** are sent to **Database Server2**. This configuration provides pseudo persistence with the database servers.

To configure this example by using the command line interface

At the command prompt, type:

- add service Service1 192.0.2.9 MYSQL 3306
- add service Service2 192.0.2.11 MYSQL 3306
- add lb vserver token_lb_vserver MYSQL 192.0.2.15 3306 -lbmethod token -rule MYSQL.CLIENT.DATABASE
- bind lb vserver token_lb_vserver Service1
- bind lb vserver token_lb_vserver Service2

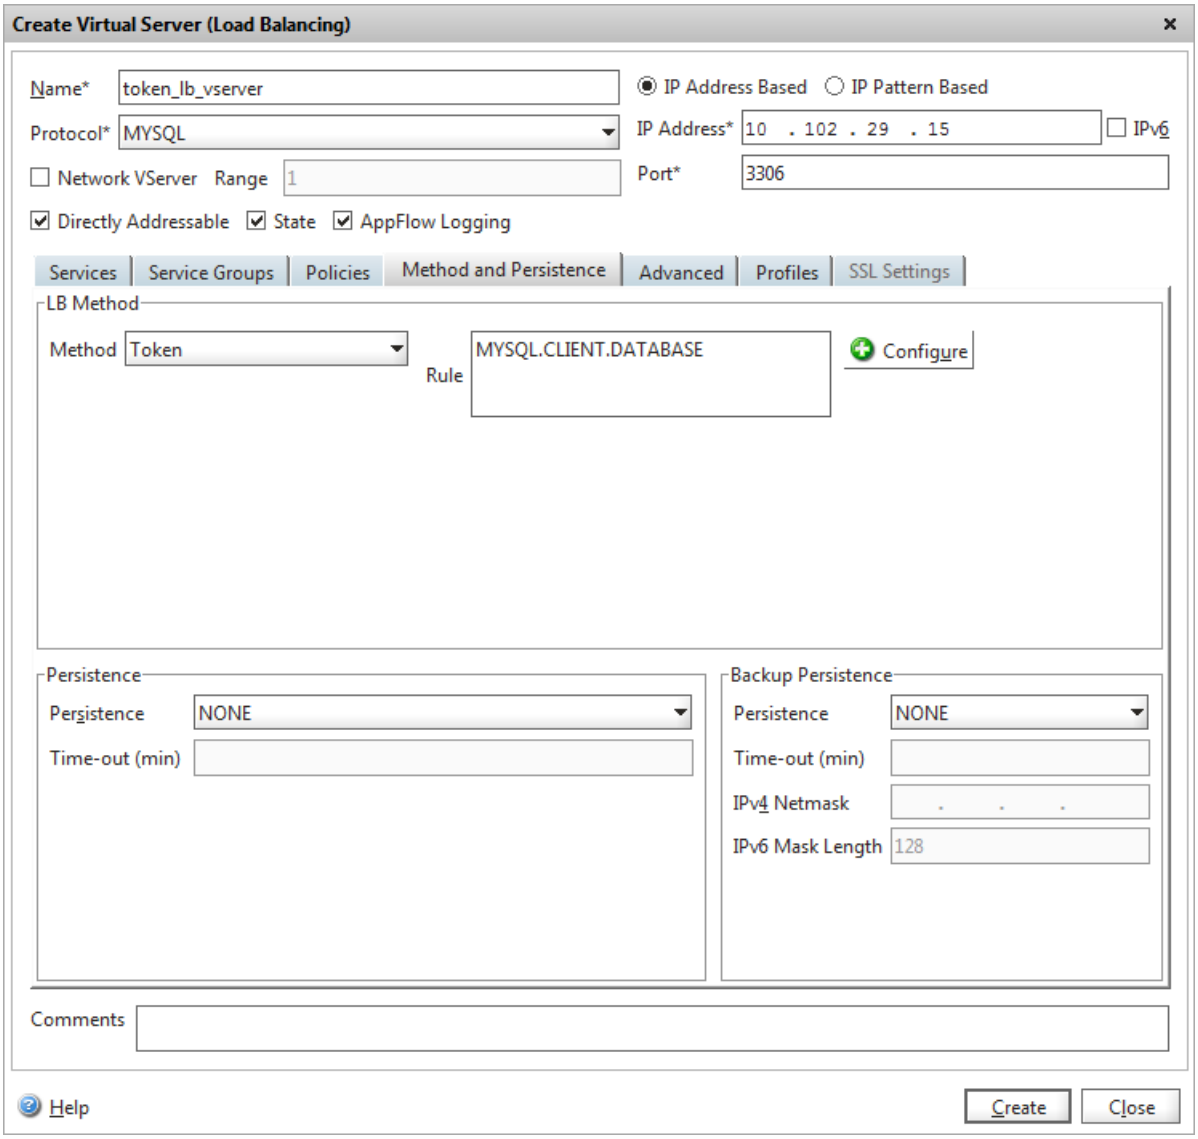
To configure this example by using the configuration utility

1. Add two services to represent the two database servers.
   1. Navigate to Traffic Management > Load Balancing > Services.
   1. In the navigation pane, expand Load Balancing, and then click Services.
   2. In the details pane, click Add.
   3. In the Create Service dialog box, set the following parameters.
      - Service Name
      - IP Address
      - Protocol
      - Port
   4. Click Create, and then click Close.
2. Add one load balancing virtual server and set the token load balancing method.
   1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
   1. In the details pane, click Add.
   2. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters.
      - Name
      - IP Address
      - Protocol

- Port

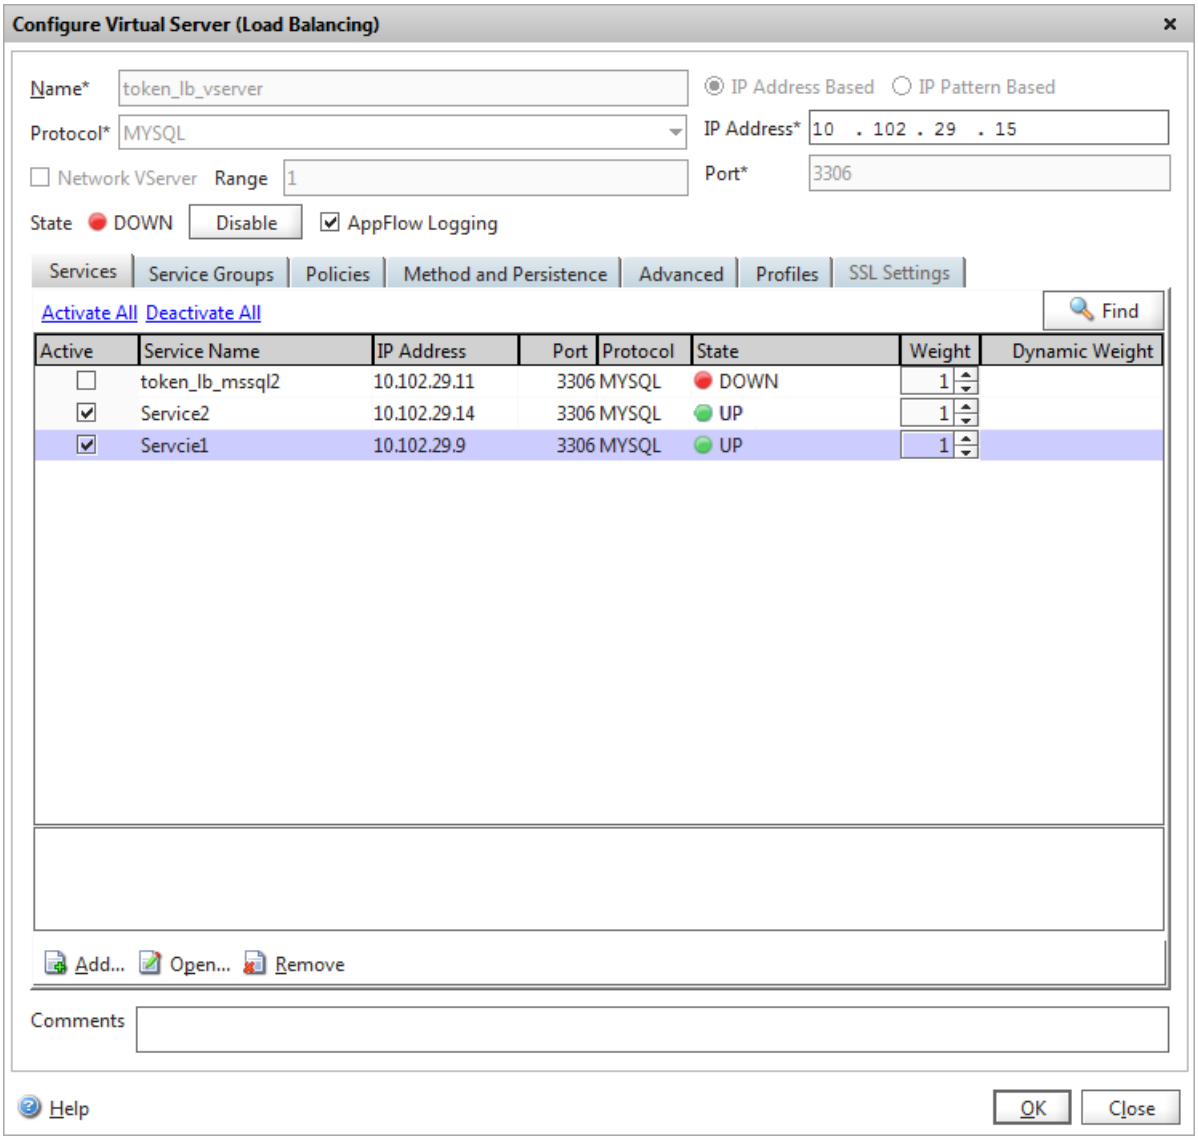
3. On the Method and Persistence tab, under LB Method, in the Method drop list, select Token.
4. In the Rule box, type MYSQL.CLIENT.DATABASE.
5. Click Create, and then click Close.

Figure 2. Configuring a Load Balancing Virtual Server by Using the Configuration Utility



3. Bind the two services to the load balancing virtual server.
   1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
   1. In the details pane, select the virtual server to which you want to bind the service (for example, token_lb_vserver).
   2. Click Open.
   3. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server (for example, Service1).
   4. Click OK.

   Figure 3. Binding Services to a Virtual Server by Using the Configuration Utility



Use Case 3: Logging MSSQL Transactions in Transparent Mode

Jun 09, 2015

You can configure the NetScaler appliance to operate transparently between MSSQL clients and servers, and to only log or analyze details of all client-server transactions. Transparent mode is designed so that the NetScaler appliance only forwards MSSQL requests to the server, and then relays the server's responses to the clients. As the requests and responses pass through the appliance, the appliance logs information gathered from them, as specified by the audit logging or AppFlow configuration, or collects statistics, as specified by the Action Analytics configuration. You do not have to add database users to the appliance.

When operating in transparent mode, the NetScaler appliance does not perform load balancing, content switching, or connection multiplexing for the requests. However, it responds to a client's pre-login packet on behalf of the server so that it can prevent encryption from being agreed upon during the pre-login handshake. The login packet and subsequent packets are forwarded to the server.

This section includes the following details:

- Summary of Configuration Tasks
- Configuring Transparent Mode by Using a Wildcard Virtual Server
- Configuring Transparent Mode by Using MSSQL Services

Summary of Configuration Tasks

Updated: 2015-05-25

For logging or analyzing MSSQL requests in transparent mode, you have to do the following:

- Configure the NetScaler appliance as the default gateway for both clients and servers.
- Do one of the following on the NetScaler appliance:
  - **If you can configure the use source IP address (USIP) option globally,** create a load balancing virtual server with a wildcard IP address and the port number on which the MSSQL servers listen for requests (a port-specific wildcard virtual server). Then, enable the USIP option globally. If you configure a port-specific wildcard virtual server, you do not have to create MSSQL services on the appliance. The appliance discovers the services on the basis of the destination IP address in the client requests. For instructions, see Configuring Transparent Mode by Using a Wildcard Virtual Server.
  - **If you do not want to configure the USIP option globally,** create MSSQL services with the USIP option enabled on each of them. If you configure services, you do not have to create a port-specific wildcard virtual server. For instructions, see Configuring Transparent Mode by Using MSSQL Services.
- Configure audit logging, AppFlow, or Action Analytics to log or collect statistics about the requests. If you configure a virtual server, you can bind your policies either to the virtual server or to the global bind point. If you do not configure a virtual server, you can bind your policies to only the global bind point.

Configuring Transparent Mode by Using a Wildcard Virtual Server

Updated: 2013-11-04

You can configure transparent mode by configuring a port-specific wildcard virtual server and enabling Use Source IP (USIP) mode globally. When a client sends its default gateway (the NetScaler appliance) a request with the IP address of an MSSQL server in the destination IP address header, the appliance checks whether the destination IP address is available. If

the IP address is available, the virtual server forwards the request to the server. Otherwise, it drops the request.

To create a wildcard virtual server by using the command line

At the command prompt, type the following commands to create a wildcard virtual server and verify the configuration:

1. add lb vserver <name> <serviceType> <IPAddress> <port>
2. show lb vserver <name>

Example

```
> add lb vserver wildcardLbVs MSSQL * 1433
 Done
> show lb vserver wildcardLbVs
 wildcardLbVs (*:1433) - MSSQL Type: ADDRESS
 State: UP
 . . .

 Done
>
```

To create a wildcard virtual server by using the NetScaler configuration utility

1. In the navigation pane, expand Traffic Management, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters:
   - Name*
   - Protocol*
   - IP Address*
   - Port*
4. Click OK.

To enable Use Source IP (USIP) mode globally by using the command line

At the command prompt, type the following commands to enable USIP mode globally and verify the configuration:

- enable ns mode USIP
- show ns mode

Example

```
> enable ns mode USIP
 Done
> show ns mode

 Mode                    Acronym                 Status
 -------                 -------                 ------
          . . .
 3) Use Source IP            USIP                    ON
          . . .
 Done
>
```

To enable USIP mode globally by using the NetScaler configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. Under Modes and Features, click Configure modes.
3. In the Configure Modes dialog box, select the Use Source IP check box.
4. Click OK.

Configuring Transparent Mode by Using MSSQL Services

Updated: 2013-08-23

You can configure transparent mode by configuring MSSQL services and enabling USIP on each service. When a client sends its default gateway (the NetScaler appliance) a request with the IP address of an MSSQL server in the destination IP address header, the appliance forwards the request to the destination server.

To create an MSSQL service and enable USIP mode on the service by using the command line interface

At the command prompt, type the following commands to create an MSSQL service, with USIP enabled, and verify the configuration:

- add service <name> (<IP> | <serverName>) <serviceType> <port> -usip YES
- show service <name>

Example

```
> add service myDBservice 192.0.2.0 MSSQL 1433 -usip YES
 Done
> show service myDBservice
 myDBservice (192.0.2.0:1433) - MSSQL
 State: UP
          . . .
 Use Source IP: YES  Use Proxy Port: YES
          . . .
 Done
>
```

To create an MSSQL service, with USIP enabled, by using the NetScaler configuration utility

1. In the navigation pane, expand Traffic Management, expand Load Balancing, and then click Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters:
   - Service Name*
   - Server*
   - Protocol*
   - Port*

   * A required parameter
4. On the Advanced tab, in the Settings area, select the Override Global check box, and then select the Use Source IP check box.

Use Case 4: Database Specific Load Balancing

Jun 09, 2015

A database server farm should be load balanced not only on the basis of the states of the servers, but also on the basis of the availability of the database on each server. A service might be up, and a load balancing device might show it as being in the UP state, but the requested database might be unavailable on that service. If a query is forwarded to a service on which the database is unavailable, the request is not served. Therefore, a load balancing device must be aware of the availability of a database on each service and, when making a load balancing decision, it must consider only those services on which the database is available.

As an example, consider that database servers server1, server2, and server3 host databases mydatabase1 and mydatabase2. If mydatabase1 becomes unavailable on server2, the load balancing device must be aware of that change in state, and it must load balance requests for mydatabase1 across only server1 and server3. After mydatabase1 becomes available on server2, the load balancing device must include server2 in load balancing decisions. Similarly, if mydatabase2 becomes unavailable on server3, the device must load balance requests for mydatabase2 across only server1 and server2, and it must include server3 in its load balancing decisions only when mydatabase2 becomes available. This load balancing behavior must be consistent across all the databases that are hosted on the server farm.

The Citrix NetScaler appliance implements this behavior by retrieving a list of all the databases that are active on a service. To retrieve the list of active databases, the appliance uses a monitor that is configured with an appropriate SQL query. If the requested database is unavailable on a service, the appliance excludes the service from load balancing decisions until it becomes available. This behavior ensures uninterrupted service to clients.

Note: Database specific load balancing is currently supported for only MSSQL and MySQL service types. This support is also available for Microsoft SQL Server 2012 high availability deployment.
To set up database specific load balancing, you must enable the load balancing feature, configure a load balancing virtual server of type MSSQL or MySQL, configure the services that host the database, and bind the services to the virtual server. The monitor needs valid user credentials to log on to the database server, so you must configure a database user account on each of the servers and then add the user account to the NetScaler appliance. Then, you configure an MSSQL-ECV or MYSQL-ECV monitor and bind the monitor to each service. Finally, you must test the configuration to ensure that it is working as intended. Before you perform these configuration tasks, make sure you understand how database specific load balancing works.

This section includes the following details:

- How Database Specific Load Balancing Works
- Enabling Load Balancing
- Configuring a Load Balancing Virtual Server for Database Specific Load Balancing
- Configuring Services
- Configuring Database Users
- Configuring a Monitor to Retrieve the Names of Active Databases
- HA Group Deployment Support for MSSQL

How Database Specific Load Balancing Works

For database specific load balancing, you configure a monitor that periodically queries each database server for the names of all the active databases on it. The Citrix NetScaler appliance stores the results, and regularly updates the records on the basis of the information retrieved through monitoring. When a client queries a particular database, the appliance uses the configured load balancing method to select a service, and then checks its records to determine whether the database is

available on that service. If the records indicate that the database is not available, it uses the configured load balancing method to select the next available service, and then repeats the check. The appliance forwards the query to the first available service on which the database is active.

Enabling Load Balancing

Updated: 2013-08-08

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

Example

```
> enable ns feature LoadBalancing
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)    Web Logging              WL              OFF
 2)    Surge Protection         SP              ON
 3)    Load Balancing           LB              ON
 .
 .
 .
 24)   NetScaler Push           push            OFF
 Done
```

To enable load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click OK.
4. In the Enable/Disable Feature(s)? message box, click Yes.

Configuring a Load Balancing Virtual Server for Database Specific Load Balancing

Updated: 2014-05-30

To configure a virtual server to load balance databases on the basis of availability, you enable the database specific load balancing parameter on the virtual server. Enabling the parameter modifies the load balancing logic so that the NetScaler appliance refers the results of the monitoring probe sent to the selected service, before forwarding the query to that service.

To configure a load balancing virtual server for database specific load balancing

At the command prompt, type the following command to configure a load balancing virtual server for database specific load balancing and verify the configuration:

- add lb vserver <name> <serviceType> <ipAddress> <port> -dbsLb ENABLED
- show lb vserver <name>

Example

In the following example, we create a Microsoft SQL virtual server.

```
> add lb vserver DBSpecificLB1 MSSQL 192.0.2.10 1433 -dbsLb ENABLED
 Done
> show lb vserver DBSpecificLB1
 DBSpecificLB1 (192.0.2.10:1433) - MSSQL Type: ADDRESS
          . . .
 DBS_LB: ENABLED
 Done
>
```

Configuring Services

Updated: 2014-06-03

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the NetScaler appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server's name instead of its IP address when you create a service.

Example

In the following example, we create a service of type MSSQL

```
add service msservice1 5.5.5.5 MSSQL 1433
```

Configuring Database Users

Updated: 2014-10-21

In databases, a connection is always stateful, which means that as soon as a connection is established, it must be authenticated.

You need to configure your database user name and password on the NetScaler ADC. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. When you add the database user names and passwords on the ADC, these are added to the nsconfig file.
Note: Names are case sensitive.
The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

To add a database user by using the command line interface

At the command prompt, type

add db user <username> - password <password>
Example

```
> add db user nsdbuser -password dd260427edf
```

To add a database user by using the configuration utility

1. In the details pane, click Add.
2. In the Create Database User dialog box, specify values for the following parameters.
   - User Name
   - Password
   - Confirm Password
3. Click Create, and then click Close. The user you created appears in the Database Users pane.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the NetScaler.

To add a database user by using the configuration utility

1. Navigate to System > User Administration > Database Users, and then click Add.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the NetScaler.

To reset the password of a database user by using the command line interface

At the command prompt, type

set db user <username> -password <password>
Example

```
> set db user nsdbuser -password dd260538abs
```

To reset the password of database users by using the configuration utility

1. Navigate to System > User Administration > Database Users.
2. In the details pane, select the database user for which you want to reset the password, and then click Open.
3. In the Configure Database User dialog box, modify the values for the following parameters.
   - Password
   - Confirm Password
4. Click OK.

If a database user no longer exists on the database server, you can remove the user from the NetScaler. However, if the user continues to exist on the database server and you remove the user from the NetScaler, any request from the client with this user name does not get authenticated, and therefore, does not get routed to the database server.

To remove a database user by using the command line interface

At the command prompt, type

rm db user <username>
Example

```
>  rm db user nsdbuser
```

To remove a database user by using the configuration utility

1. Navigate to System > User Administration > Database Users.
2. In the details pane, select the database user that you want to remove, and then click Open.
3. In the Proceed message box, click Yes.

Configuring a Monitor to Retrieve the Names of Active Databases

Updated: 2014-05-30

To retrieve a list of all the active databases on a database instance, you create a monitor that logs on to the database server by using a valid user credentials and runs an appropriate SQL query. The SQL query you need to use depends on your SQL server deployment. For example, in a database mirroring setup, you can use the following query to retrieve a list of active databases available on a server instance.

```
select name from sys.databases where state=0
```
You also configure the monitor to evaluate the response for an error condition, and to store the results if there is no error. If the response contains an error, the monitor marks the service as DOWN, and the appliance excludes the service from load balancing decisions until an error is no longer returned.

Note: The database specific load balancing feature is supported only for the MSSQL and MySQL service types. Therefore, the monitor type must be MSSQL-ECV or MYSQL-ECV.

To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line

At the command prompt, type the following commands to retrieve the names of all the active databases hosted on a service and verify the configuration:

- add lb monitor <monitorName> <type> -userName <string> -sqlQuery <text> -evalRule <expression> -storedb ENABLED
- show lb monitor <monitorName>

Example

In the following example, we create an MSSQL-ECV type monitor.

```
> add lb monitor mssql-monitor1 MSSQL-ECV -userName user1 -sqlQuery "select name
from sys.databases where state=0" -evalRule "MSSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED
 Done
> show lb monitor mssql-monitor1
1)  Name.....: mssql-monitor1  Type.....: MSSQL-ECV       State....:  ENABLED
...
```

```
Special parameters:
  Database.....:""
  User name.....:"user1"
  Query..:select name from sys.databases where state=0
  EvalRule...:MSSQL.RES.TYPE.NE(ERROR)
  Version...:70
  STORE_DB...:ENABLED
 Done
>
```

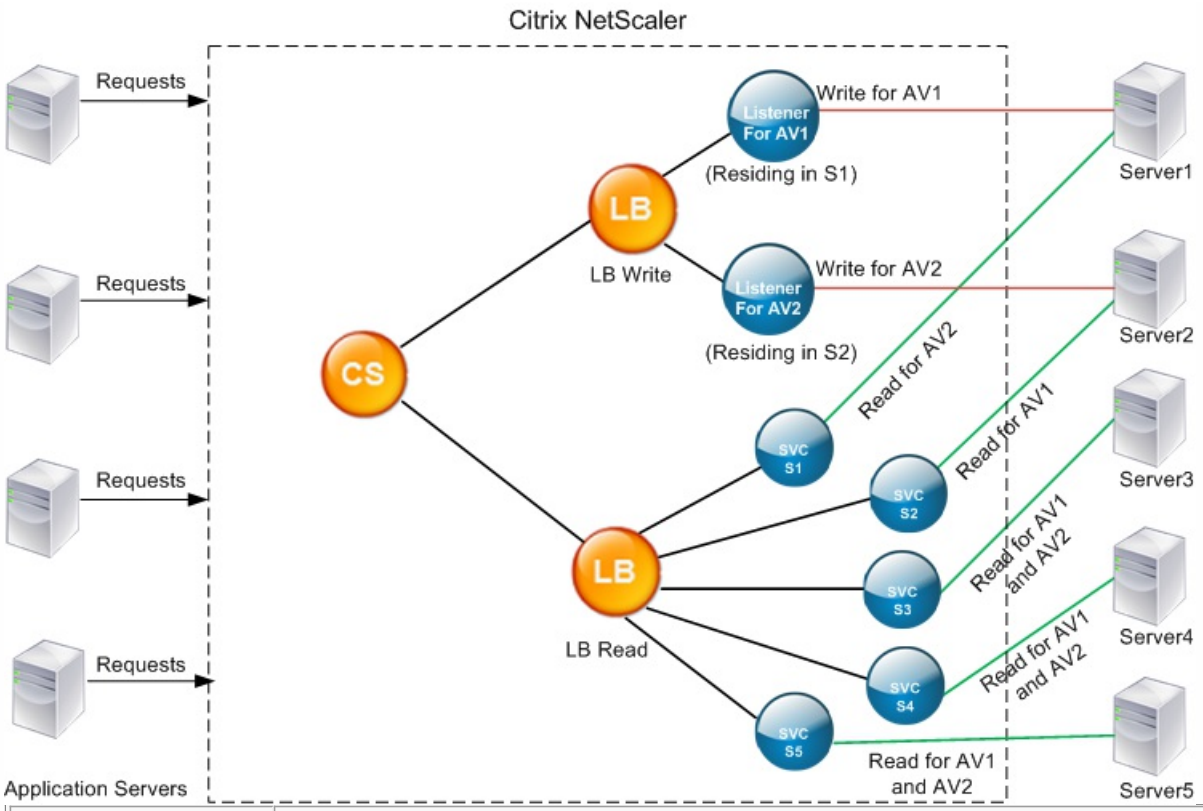
To configure a monitor to retrieve the names of all the active databases hosted on a service by using the configuration utility

1. In the navigation pane, expand Traffic Management, expand Load Balancing, and then click Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, set the following parameters:
   - Name
   - Type
4. On the Special Parameters tab, set the following parameters:
   - Query
   - User Name
   - Rule
   - Store DB
5. Click OK.

HA Group Deployment Support for MSSQL

Updated: 2014-06-17

Consider the following scenario in which database specific load balancing is configured in a high availability group deployment. S1 through S5 are the services on the NetScaler. DB1 through DB4 are the databases on the servers represented by the services S1 through S5. AV1 and AV2 are the availability groups. Each availability group contains up to one primary database server instance and up to four secondary database server instances. A service, representing the servers in the availability group, can be primary for one availability group and secondary for another availability group. Each availability group contains different databases and one listener, which is a service. All requests arrive on the listener service that resides on the primary database. AVI contains databases DB1 and DB2. AV2 contains databases DB3 and DB4. L1 and L2 are the listeners on AV1 and AV2 respectively. S1 is the primary service for AV1 and S2 is the primary service for AV2.



Service	List of Active Databases on the Service
S1	DB1, DB2, DB3, DB4
S2	DB3, DB4
S3	DB3, DB4
S4	DB1, DB2
S5	DB1, DB2

Availability Group	Databases	Services representing the Servers in Availability Group
AV1	DB1, DB2	S1, S4, S5
AV2	DB3, DB4	S1, S2, S3

Queries flow as follows:

1. A READ query for AV1 is load balanced between S4 and S5. S1 is the primary for AV1.
2. A WRITE query for AV1 is directed to L1.
3. A READ query for AV2 is load balanced between S1 and S3. S2 is the primary for AV2.
4. A WRITE query for AV1 is directed to L2.

Sample Configuration

1. Configure load balancing and content switching virtual servers.
   - add lb vserver lbwrite -dbslb enabled
   - add lbvserver lbread MSSQL -dbslb enabled
   - add csvserver csv MSSQL 1.1.1.10 1433
2. Configure two listener services, one for each availability group, and five services S1 through S5 representing databases DB1 through DB4.
   - add service L1 1.1.1.11 MSSQL 1433
   - add service L2 1.1.1.12 MSSQL 1433
   - add service s1 1.1.1.13 MSSQL 1433
   - add service s2 1.1.1.14 MSSQL 1433
   - add service s3 1.1.1.15 MSSQL 1433
   - add service s4 1.1.1.16 MSSQL 1433
   - add service s5 1.1.1.17 MSSQL 1433
3. Bind the services to the load balancing virtual servers.
   - bind lbvserver lbwrite L1
   - bind lbvserver lbwrite L2
   - bind lbvserver lbread s1
   - bind lbvserver lbread s2
   - bind lbvserver lbread s3
   - bind lbvserver lbread s4
   - bind lbvserver lbread s5
4. Configure database users.
   - add db user nsdbuser1 -password dd260427edf
   - add db user nsdbuser2 -password ccd1234xyzw
5. Configure two monitors, monitor_L1 and monitor_L2 for each listener service, to retrieve the list of active databases in that availability group. Add a monitor, monitor1 to retrieve the list of databases for the secondary database server instance.
   - add lb monitor monitor_L1 MSSQL-ECV -userName user1 -sqlQuery "SELECT name FROM sys.databases a INNER JOIN sys.dm_hadr_availability_replica_states b ON a.replica_id=b.replica_id INNER JOIN sys.availability_group_listeners c on b.group_id = c.group_id INNER JOIN sys.availability_group_listener_ip_addresses d on c.listener_id = d.listener_id WHERE b.role = 1 and d.ip_address like '1.1.1.11'" -evalRule "MSSQL.RES.TYPE.NE(ERROR)" –storedb ENABLED
   - add lb monitor monitor_L2 MSSQL-ECV -userNameuser1 -sqlQuery "SELECT name FROM sys.databases a INNER JOIN sys.dm_hadr_availability_replicca_states b ON a.replica_id=b.replica_id INNER JOIN sys.availability_group_listeners c on b.group_id = c.group_id INNER JOIN sys.availability_group_listener_ip_addresses d on c.listener_id = d.listener_id WHERE b.role = 1 and d.ip_address like '1.1.1.12'" -evalRule "MSSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED
   - add lb monitor monitor1 MSSQL-ECV -userNameuser1 -sqlQuery "SELECT name FROM sys.databases a INNER JOIN sys.dm_hadr_availability_replica_states b ON a.replica_id=b.replica_id WHERE b.role = 2" -evalRule "MSSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED
6. Configure read and write policies.
   - add cs policy pol_write -rule "MSSQL.REQ.QUERY.TEXT.CONTAINS(\"insert\")"
   - add cs policy pol_read -rule "MSSQL.REQ.QUERY.TEXT.CONTAINS(\"select\")"
7. Bind the policies to the content switching virtual server.
   - bind csvserver csv -targetLBVserver lbwrite -policyName pol_write -priority 11
   - bind csvserver csv -targetLBVserver lbread -policyName pol_read -priority 12

8. Bind monitors to the services. Bind monitors to services L1 and L2 to get the list of active databases for the availability group for which it is the listener. Bind monitors to all the services that are bound to the read-only virtual server.
   - bind service L1 -monitorName monitor_L1
   - bind service L2 -monitorName monitor_L2
   - bind service s1 -monitorName monitor1
   - bind service s2 -monitorName monitor1
   - bind service s3 -monitorName monitor1
   - bind service s4 -monitorName monitor1
   - bind service s5 -monitorName monitor1

DataStream Reference

Mar 30, 2012

This reference describes the MySQL and TDS protocols, the database versions, the authentication methods, and the character sets supported by the DataStream feature. It also describes how NetScaler handles transaction requests and special queries that modify the state of a connection.

You can also configure the NetScaler appliance to generate audit log messages for the DataStream feature.

Supported Database Versions, Protocols, and Authentication Methods

Updated: 2014-08-28

	MySQL Database	**MS SQL Database**
Database Versions	MySQL database versions 4.1, 5.0, 5.1, 5.4, 5.5, and 5.6.	MS SQL database versions 2000, 2000SP1, 2005, 2008, 2008R2, and 2012.
Protocols	MySQL protocol version 10. For information about the MySQL protocol, see http://dev.mysql.com/doc/internals/en/client-server-protocol.html	TDS protocol version 7.1 and higher. For information about the TDS protocol, see http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx
Authentication Methods	MySQL native authentication is supported.	SQL server authentication and Windows Authentication (Kerberos) are supported.

Character Sets

The DataStream feature supports only the UTF-8 charset.

The character set used by the client while sending a request may be different from the character set used in the database server responses. Although the charset parameter is set during the connection establishment, it can be changed at any time by sending an SQL query. The character set is associated with a connection, and therefore, requests on connections with one character set cannot be multiplexed onto a connection with a different character set.

NetScaler parses the queries sent by the client and the responses sent by the database server.

The character set associated with a connection can be changed after the initial handshake by using the following two queries:

- SET NAMES <charset> COLLATION <collation>
- SET CHARACTER SET <charset>

Transactions

In MySQL, transactions are identified by using the connection parameter AUTOCOMMIT or the BEGIN:COMMIT queries. The AUTOCOMMIT parameter can be set during the initial handshake, or after the connection is established by using the

query SET AUTOCOMMIT.

NetScaler explicitly parses each and every query to determine the beginning and end of a transaction.

In MySQL protocol, the response contains two flags to indicate whether the connection is a transaction, the TRANSACTION and AUTOCOMMIT flags.

If the connection is a transaction, the TRANSACTION flag is set. Or, if the AutoCommit mode is OFF, the AUTOCOMMIT flag is not set. NetScaler parses the response, and if either the TRANSACTION flag is set or the AUTOCOMMIT flag is not set, it does not do connection multiplexing. When these conditions are no longer true, the NetScaler begins connection multiplexing.

Special Queries

Updated: 2014-05-21

There are special queries, such as SET and PREPARE, that modify the state of the connection and may break request switching, and therefore, these need to be handled differently.

On receiving a request with special queries, NetScaler sends an OK response to the client and additionally, stores the request in the connection.

When a non-special query, such as INSERT and SELECT, is received along with a stored query, the NetScaler first, looks for the server-side connection on which the stored query has already been sent to the database server. If no such connections exist, NetScaler creates a new connection, and sends the stored query first, and then, sends the request with the non-special query.

In case of SET, USE db, and INIT_DB special queries, the appliance modifies a field in the server side connection corresponding to the special query. This results in better reuse of the server side connection.

Only 16 queries are stored in each connection.

The following is a list of the special queries for which NetScaler has a modified behavior.

SET query

The SET SQL queries define variables that are associated with the connection. These queries are also used to define global variables, but as of now, NetScaler is unable to differentiate between local and global variables. For this query, the NetScaler uses the 'store and forward' mechanism described earlier .

USE <db> query

Using this query, the user can change the database associated with a connection. In this case, NetScaler parses the <db> value sent and modifies a field in the server side connection to reflect the new database to be used.

INIT_DB command

Using this query, the user can change the database associated with a connection. In this case, NetScaler parses the <init_db> value sent and modifies a field in the server side connection to reflect the new database to be used.

COM_PREPARE

NetScaler stops request switching on receiving this command.

PREPARE query

This query is used to create prepared statements that are associated with a connection. For this query, the NetScaler uses the 'store and forward' mechanism described earlier in this section.

Audit Log Message Support

Updated: 2013-09-30

You can now configure the NetScaler appliance to generate audit log messages for the DataStream feature. Audit log messages are generated when client-side and server-side connections are established, closed, or dropped. The categories of messages that you can log and view are ERROR and INFO. Error messages for client-side connections begin with "CS" and error messages for server-side connections begin with "SS." Additional information is provided where necessary. For example, log messages for closed connections (CS_CONN_CLOSED) include only the connection ID. However, log messages for established connections (CS_CONN_ESTD) include information such as the user name, database name, and the client IP address in addition to the connection ID.

Domain Name System

May 26, 2015

You can configure the Citrix NetScaler appliance to function as an authoritative domain name server (ADNS server) for a domain. You can add the DNS resource records that belong to the domain for which the appliance is authoritative and configure resource record parameters. You can also configure the NetScaler appliance as a proxy DNS server that load balances a farm of DNS name servers that are either within your network or outside your network. You can configure the appliance as an end resolver and forwarder. You can configure DNS suffixes that enable name resolution when fully qualified domain names are not configured. The appliance also supports the DNS ANY query that retrieves all the records that belong to a domain.

You can configure the NetScaler appliance to concurrently function as an authoritative DNS server for one domain and a DNS proxy server for another domain. When you configure the NetScaler as the authoritative DNS server or DNS proxy server for a zone, you can enable the appliance to use the Transmission Control Protocol (TCP) for response sizes that exceed the size limit specified for the User Datagram Protocol (UDP).

How DNS Works on the NetScaler

You can configure the NetScaler appliance to function as an ADNS server, DNS proxy server, end resolver, and forwarder. You can add DNS resource records on the NetScaler, including service (SRV) records, IPv6 (AAAA) records, address (A) records, mail exchange (MX) records, canonical name (CNAME) records, pointer (PTR) records, start of authority (SOA) records, and text (TXT) records. Also, you can configure the NetScaler to load balance external DNS name servers.

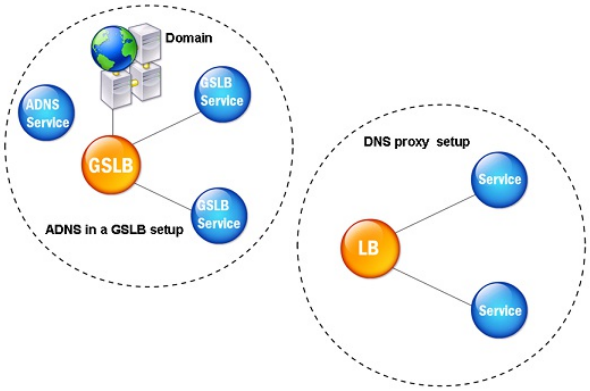
The NetScaler can be configured as the authority for a domain. To do this, you add valid SOA and NS records for the domain.

An ADNS server is a DNS server that contains complete information about a zone.

To configure the NetScaler as an ADNS server for a zone, you must add an ADNS service, and then configure the zone. To do so, you add valid SOA and NS records for the domain. When a client sends a DNS request, the NetScaler appliance searches the configured resource records for the domain name. You can configure the ADNS service to be used with the NetScaler Global Server Load Balancing (GSLB) feature.

You can delegate a subdomain, by adding NS records for the subdomain to the zone of the parent domain. You can then make the NetScaler authoritative for the subdomain, by adding a "glue record" for each of the subdomain name servers. If GSLB is configured, the NetScaler makes a GSLB load balancing decision based on its configuration and replies with the IP address of the selected virtual server. The following figure shows the entities in an ADNS GSLB setup and a DNS proxy setup.

Figure 1. DNS Proxy Entity Model



The NetScaler appliance can function as a DNS proxy. Caching of DNS records, which is an important function of a DNS proxy, is enabled by default on the NetScaler appliance. This enables the NetScaler to provide quick responses for repeated translations. You must also create a load balancing DNS virtual server, and DNS services, and then bind these services to the virtual server.

The NetScaler provides two options, minimum time to live (TTL) and maximum TTL for configuring the lifetime of the cached data. The cached data times out as specified by your settings for these two options. The NetScaler checks the TTL of the DNS record coming from the server. If the TTL is less than the configured minimum TTL, it is replaced with the configured minimum TTL. If the TTL is greater than the configured maximum TTL, it is replaced with the configured maximum TTL.

The NetScaler also allows caching of negative responses for a domain. A negative response indicates that information about a requested domain does not exist, or that the server cannot provide an answer for the query. The storage of this information is called *negative caching*. Negative caching helps speed up responses to queries on a domain, and can optionally provide the record type.

A negative response can be one of the following:

- NXDOMAIN error message - If a negative response is present in the local cache, the NetScaler returns an error message (NXDOMAIN). If the response is not in the local cache, the query is forwarded to the server, and the server returns an NXDOMAIN error to the NetScaler. The NetScaler caches the response locally, then returns the error message to the client.
- NODATA error message - The NetScaler sends a NODATA error message, if the domain name in query is valid but records of the given type are not available.

The NetScaler supports recursive resolution of DNS requests. In recursive resolution, the resolver (DNS client) sends a recursive query to a name server for a domain name. If the queried name server is authoritative for the domain, it responds with the requested domain name. Otherwise, the NetScaler queries the name servers recursively until the requested domain name is found.

Before you can apply the recursive query option, you must first enable it. You can also set the number of times the DNS resolver must send a resolution request (DNS retries) if a DNS lookup fails.

You can configure the NetScaler as a DNS forwarder. A forwarder passes DNS requests to external name servers. The NetScaler allows you to add external name servers and provides name resolution for domains outside the network. The NetScaler also allows you to set the name lookup priority to DNS or Windows Internet Name Service (WINS).

Round Robin DNS

When a client sends a DNS request to find the DNS resource record, it receives a list of IP addresses resolving to the name in the DNS request. The client then uses one of the IP addresses in the list, generally, the first record or IP address. Hence, a single server is used for the total TTL of the cache and is overloaded when a large number of requests arrive.

When the NetScaler receives a DNS request, it responds by changing the order of the list of DNS resource records in a round robin method. This feature is called *round robin DNS*. Round robin distributes the traffic equally between data centers. The NetScaler performs this function automatically. You do not have to configure this behavior.

Functional Overview

If the NetScaler is configured as an ADNS server, it returns the DNS records in the order in which the records are configured. If the NetScaler is configured as a DNS proxy, it returns the DNS records in the order in which it receives the records from the server. The order of the records present in the cache matches the order in which records are received from the server.

The NetScaler then changes the order in which records are sent in the DNS response in a round robin method. The first response contains the first record in sequence, the second response contains the second record in sequence, the third response contains the third record in sequence, and the order continues in the same sequence. Thus, clients requesting the same name can connect to different IP addresses.

Round Robin DNS Example

As an example of round robin DNS, consider DNS records that have been added as follows:

```
add dns addRec ns1 1.1.1.1  add dns addRec ns1 1.1.1.2  add dns addRec ns1 1.1.1.3  add dns addRec ns1 1.1.1.4
```

The domain, abc.com is linked to an NS record as follows:

```
add dns nsrec abc.com. ns1
```

When the NetScaler receives a query for the A record of ns1, the Address records are served in a round robin method as follows. In the first DNS response, 1.1.1.1 is served as the first record:

```
ns1.            1H IN A     1.1.1.1  ns1.            1H IN A     1.1.1.2  ns1.            1H IN A     1.1.1.3  ns1.            1H IN A     1.1.1.4
```

In the second DNS response, the second IP address, 1.1.1.2 is served as the first record:

```
ns1.            1H IN A     1.1.1.2  ns1.            1H IN A     1.1.1.3  ns1.            1H IN A     1.1.1.4  ns1.            1H IN A     1.1.1.1
```

In the third DNS response, the third IP address, 1.1.1.2 is served as the first record:

```
ns1.            1H IN A     1.1.1.3  ns1.            1H IN A     1.1.1.4  ns1.            1H IN A     1.1.1.1  ns1.            1H IN A     1.1.1.2
```

Configuring DNS Resource Records

Jun 19, 2014

You configure resource records on the Citrix® NetScaler® appliance when you configure the appliance as an ADNS server for a zone. You can also configure resource records on the appliance if the resource records belong to a zone for which the appliance is a DNS proxy server. On the appliance, you can configure the following record types:

- Service records
- AAAA records
- Address records
- Mail Exchange records
- Name Server records
- Canonical records
- Pointer records
- NAPTR records
- Start of Authority records
- Text records

The following table lists the record types and the number of records (per record type) that you can configure for a domain on the NetScaler.

Table 1. Record Type and Number Configurable

Record Type	Number of Records
Address (A)	25
IPv6 (AAAA)	5
Mail exchange (MX)	12
Name server (NS)	16
Service (SRV)	8
Pointer (PTR)	20
Canonical name (CNAME)	1
Start of Authority (SOA)	1
Text (TXT)	20

Record Type	Number of Records
Naming Authority Pointer (NAPTR)	20

Creating SRV Records for a Service

Nov 21, 2014

The SRV record provides information about the services available on the NetScaler appliance. An SRV record contains the following information: name of the service and the protocol, domain name, TTL, DNS class, priority of the target, weight of records with the same priority, port of the service, and host name of the service. The NetScaler chooses the SRV record that has the lowest priority setting first. If a service has multiple SRV records with the same priority, clients use the weight field to determine which host to use.

To add an SRV record by using the command line interface

At the command prompt, type the following commands to add an SRV record and verify the configuration:

- add dns srvRec <domain> <target> -priority <positive_integer> -weight <positive_integer> -port <positive_integer> [-TTL <secs>]
- sh dns srvRec <domain>

Example

```
> add dns srvRec _http._tcp.example.com nameserver1.com -priority 1 -weight 1 -port 80
 Done
> show dns srvRec _http._tcp.example.com
1)     Domain Name : _http._tcp.example.com
       Target Host : nameserver1.com
       Priority : 1    Weight : 1
       Port : 80       TTL : 3600 secs
 Done
>
```

To modify or remove an SRV record by using the command line interface

- To modify an SRV record, type the set dns srvRec command, the name of the domain for which the SRV record is configured, the name of the target host that hosts the associated service, and the parameters to be changed, with their new values.
- To remove an SRV record, type the rm dns srvRec command, the name of the domain for which the SRV record is configured, and the name of the target host that hosts the associated service.

To configure an SRV record by using the configuration utility

1. Navigate to Traffic Management > DNS > Records > SRV Records.
2. In the details pane, do one of the following:
   - To create a new SRV record, click Add.
   - To modify an existing SRV record, select the SRV record, and then click Open.
3. In the Create SRV Record or Configure SRV Record dialog box, specify values for the following parameters as shown:

   - Domain Name*—domain (cannot be changed for an existing SRV record)
   - Target*—target (cannot be changed for an existing SRV record)
   - Priority*—priority
   - Weight*—weight

- Port*—port
- TTL—TTL

* A required parameter

4. Click Create or OK.

Creating AAAA Records for a Domain Name

Nov 21, 2014

An AAAA resource record stores a single IPv6 address.

To add an AAAA record by using the command line interface

At the command prompt, type the following commands to add an AAAA record and verify the configuration:

- add dns aaaaRec <hostName> <IPv6Address> ... [-TTL <secs>]
- show dns aaaaRec <hostName>

Example

```
> add dns aaaaRec www.example.com 2001:0db8:0000:0000:0000:0000:1428:57ab
 Done
> show dns aaaaRec www.example.com
1)     Host Name : www.example.com
       Record Type : ADNS            TTL : 5 secs
       IPV6 Address : 2001:db8::1428:57ab
 Done
>
```

To remove an AAAA record and all of the IPv6 addresses associated with the domain name, type the rm dns aaaaRec command and the domain name for which the AAAA record is configured. To remove only a subset of the IPv6 addresses associated with the domain name in an AAAA record, type the rm dns aaaaRec command, the domain name for which the AAAA record is configured, and the IPv6 addresses that you want to remove.

To add an AAAA record by using the configuration utility

1. Navigate to Traffic Management > DNS > Records > AAAA Records.
2. In the details pane, click Add.
3. In the Create AAAA Record dialog box, specify values for the following parameters as shown:

   - Host Name*—hostName
   - IPv6 Address*—IPv6Address
   - TTL-TTL

   * A required parameter

4. Click Add. The IPv6 address appears in the IP box.
5. Click Create, and then click Close.

Creating Address Records for a Domain Name

Nov 21, 2014

Address (A) records are DNS records that map a domain name to an IPv4 address.

You cannot delete Address records for a host participating in global server load balancing (GSLB). However, the NetScaler deletes Address records added for GSLB domains when you unbind the domain from a GSLB virtual server. Only user-configured records can be deleted manually. You cannot delete a record for a host referenced by records such as NS, MX, or CNAME.

To add an Address record by using the command line interface

At the command prompt, type the following commands to add an Address record and verify the configuration:

- add dns addRec <hostName> <IPAddress> [-TTL <secs>]
- show dns addRec <hostName>

Example

```
> add dns addRec ns.example.com 192.0.2.0
 Done
> show dns addRec ns.example.com
1)     Host Name : ns.example.com
       Record Type : ADNS                TTL : 5 secs
       IP Address : 192.0.2.0
 Done
>
```

To remove an Address record and all of the IP addresses associated with the domain name, type the rm dns addRec command and the domain name for which the Address record is configured. To remove only a subset of the IP addresses associated with the domain name in an Address record, type the rm dns addRec command, the domain name for which the Address record is configured, and the IP addresses that you want to remove.

To add an Address record by using the configuration utility

1. Navigate to Traffic Management > DNS > Records > Address Records
2. In the details pane, click Add.
3. Click Add. The IP address appears in the IP Address box.
4. Click Create, and then click Close.

Creating MX Records for a Mail Exchange Server

Nov 21, 2014

Mail Exchange (MX) records are used to direct email messages across the Internet. An MX record contains an MX preference that specifies the MX server to be used. The MX preference values range from 0 through 65536. An MX record contains a unique MX preference number. You can set the MX preference and the TTL values for an MX record.

When an email message is sent through the Internet, a mail transfer agent sends a DNS query requesting the MX record for the domain name. This query returns a list of host names of mail exchange servers for the domain, along with a preference number. If there are no MX records, the request is made for the Address record of that domain. A single domain can have multiple mail exchange servers.

To add an MX record by using the command line interface

At the command prompt, type the following commands to add an MX record and verify the configuration:

- add dns mxRec <domain> -mx <string> -pref <positive_integer> [-TTL <secs>]
- show dns mxRec <domain>

Example

```
> add dns mxRec example.com -mx mail.example.com -pref 1
 Done
> show dns mxRec example.com
1)     Domain : example.com    MX Name : mail.example.com
       Preference :   1       TTL : 5 secs
 Done
>
```

To modify or remove an MX record by using the command line interface

- To modify an MX record, type the set dns mxRec command, the name of the domain for which the MX record is configured, the name of the MX record, and the parameters to be changed, with their new values.
- To set the TTL parameter to its default value, type the unset dns mxRec command, the name of the domain for which the MX record is configured, the name of the MX record, and -TTL without any TTL value. You can use the unset dns mxRec command to unset only the TTL parameter.
- To remove an MX record, type the rm dns mxRec command, the name of the domain for which the MX record is configured, and the name of the MX record.

To add an MX record by using the configuration utility

1. Navigate to Traffic Management > DNS > Records > Mail Exchange Records
2. In the details pane, do one of the following:
   - To create a new MX record, click Add.
   - To modify an existing MX record, select the MX record, and then click Open.
3. In the Create Mail Exchange Record or Configure Mail Exchange Record dialog box, specify values for the following parameters as shown:

   - Domain Name*—domain (cannot be changed for an existing MX record)

- Mail Exchange*—mx (cannot be changed for an existing MX record)
- Preference No.*—pref
- TTL—TTL

* A required parameter

4. Click Create or OK.

Creating NS Records for an Authoritative Server

Nov 21, 2014

Name Server (NS) records specify the authoritative server for a domain. You can configure a maximum of 16 NS records. You can use an NS record to delegate the control of a subdomain to a DNS server.

To create an NS record by using the command line interface

At the command prompt, type the following commands to create an NS record and verify the configuration:

- add dns nsRec <domain> <nameServer> [-TTL <secs>]
- show dns nsRec <domain>

Example

```
> add dns nsRec example.com nameserver1.example.com
 Done
> show dns nsRec example.com
1)     Domain : example.com    NameServer : nameserver1.example.com
       TTL : 5 sec
 Done
>
```

To remove an NS record, type the rm dns nsRec command, the name of the domain to which the NS record belongs, and the name of the name server.

To create an NS record by using the configuration utility

1. Navigate to Traffic Management > DNS > Records > Name Server Records
2. In the details pane, click Add.
3. In the Create Name Server Record dialog box, specify values for the following parameters as shown:

   - Domain Name*—domain
   - Name Server*—nameServer
   - TTL—TTL

   * A required parameter

4. Click Create, and then click Close.

Creating CNAME Records for a Subdomain

May 26, 2015

A canonical name record (CNAME record) is an alias for a DNS name. These records are useful when multiple services query the DNS server. The host that has an address (A) record cannot have a CNAME record.

In some cases, a NetScaler appliance in proxy mode requests an address record from the cache instead of the server.

To add a CNAME record by using the command line interface

At the command prompt, type the following commands to create a CNAME record and verify the configuration:

- add dns cnameRec <aliasName> <canonicalName> [-TTL <secs>]
- show dns cnameRec <aliasName>

Example

```
> add dns cnameRec www.example.com www.examplenw.com
 Done
> show dns cnameRec www.example.com
      Alias Name     Canonical Name  TTL
1)    www.example.com       www.examplenw.com      5 secs
 Done
>
```

To remove a CNAME record for a given domain, type the rm dns cnameRec command and the alias of the domain name.

To add a CNAME record by using the configuration utility

1. Navigate to Traffic Management > DNS > Records > Canonical Records
2. In the details pane, click Add.
3. In the Create Canonical Name Record dialog box, specify values for the following parameters as shown:

   - Alias Name*—aliasName
   - Canonical Name*—canonicalName
   - TTL—TTL

   * A required parameter

4. Click Create, and then click Close.

Caching of CNAME Records

Updated: 2015-05-26

NetScaler ADC when deployed in a proxy mode does not always send the query for an address record to the back-end server. This happens when for a answer to a query for an address record, a partial CNAME chain is present in the cache. There are few conditions in which the ADC caches the partial CNAME record and serves the query from the cache. Following are the conditions:

- NetScaler should be deployed in a proxy mode
- The response from the back-end server should have a CNAME chain, for which the record type of last entry in the answer section must be a CNAME and the question type not a CNAME

- The response from the back-end server cannot be a No-data or NX-Domain
- The response from the back-end server has to be a authoritative response

Creating NAPTR Records for Telecommunications Domain

Oct 29, 2014

NAPTR (Naming Address Pointer) is one of the most commonly used DNS record in telecommunications domain. NAPTR records map the Internet telephony address space to the Internet address space. They therefore enable a mobile device to send a request to the correct server. The combination of NAPTR records with Service Records (SRV) allows the chaining of multiple records to form complex rewrite rules that produce new domain labels or uniform resource identifiers (URIs). The DNS code for NAPTR is 35.

NetScaler ADCs support NAPTR in two modes: ADNS mode and proxy mode. In proxy mode, the ADC caches the response from the servers and uses the cached records to server future queries. A maximum of 20 NAPTR records can be added for a particular domain in NetScaler. NetScaler caches the reply to a DNS NAPTR record query. Any subsequent requests for the NAPTR record is served from the cache.

To create a NAPTR record by using command line interface

At the command prompt, type the following commands to add a NAPTR record and verify the configuration:

add dns naptrRec <order> <preference>[flags<string>][services<string>](regexp<expressions>|-replacement<string>) [-TTL<secs>]

To remove a NAPTR record by using command line interface

rm dns naptrRec<domain> (<order> <preference> [-flags <string>] [-services <string>] (-regexp <expression> | -replacement <string>)) | -recordId <positive_integer>@)

To configure a NAPTR record using configuration utility

1. In the navigation pane, expand DNS, expand Records, and then click NAPTR Records.
2. In the Create NAPTR Record dialog box, set the following parameters:
   - Domain—Name of the domain for the NAPTR record. Maximum length: 255 characters.
   - Order—Integer specifying the order in which the NAPTR records must be processed in order to accurately represent the ordered list of rules. The ordering is from lowest to highest. Maximum value: 65535.
   - Preference— Integer specifying the preference of this NAPTR among NAPTR records. Maximum value: 65535.
   - Flags— Flags for this NAPTR record. Maximum length: 255 characters.
   - Regular Expression—Regular expression that specifies the substitution expression for this NAPTR. Maximum length: 255 characters.
   - Replacement—The replacement domain name for this NAPTR record. Maximum length: 255 characters.
   - TTL— Time to Live (TTL), in seconds, for the record.
3. Click Create, and then click Close.

Offloading DNSSEC Operations to the NetScaler ADC

Nov 21, 2014

For DNS zones for which your DNS servers are authoritative, you can offload DNSSEC operations to the NetScaler ADC. In a DNSSEC offloading deployment, a DNS server sends unsigned responses. The ADC signs the response on the fly before relaying it to the client. The ADC also caches the signed response. Apart from reducing the load on the DNS servers, offloading DNSSEC operations to the ADC gives you the following benefits:

- You can sign records that the DNS servers generate programmatically. Such records cannot be signed by routine zone signing operations performed on the DNS servers.
- You can serve signed responses to clients even if you have not implemented DNSSEC on your servers.

For setting up DNSSEC offloading, you must configure a DNS load balancing virtual server, configure services that represent the DNS servers, and then bind the services to the virtual server. For information about configuring a DNS load balancing virtual server, configuring services, and binding the services to the virtual server, see Configuring a DNS Zone.

You must create a zone entity on the ADC for each DNS zone whose DNSSEC operations you want to offload. For each DNS zone, you must enable the Proxy Mode and DNSSEC Offload parameters. You can optionally configure NSEC record generation for an offloaded zone. To create a DNS zone entity for DNSSEC offloading, follow the instructions in this topic.

To complete the configuration, you must generate DNS keys for the zone, add the keys to the zone, and then sign the zone with the keys. This process is the same as for normal DNSSEC. For information about creating keys, adding keys to a zone, and signing the zone, see Domain Name System Security Extensions.

After you configure DNS offloading, you must flush the DNS cache on the ADC. Flushing the DNS cache ensures that any unsigned records in the cache are removed and subsequently replaced by signed records. For information about flushing the DNS cache, see Enabling Caching of DNS Records.

Note: DNSSEC offloading is supported on all NetScaler MPX platforms, except the NetScaler MPX 9700/10500/12500/15500 FIPS platform. The feature is also supported on NetScaler virtual appliances hosted on NetScaler SDX platforms.

At the command line, type the following commands to enable DNSSEC offloading for a zone and verify the configuration:

- add dns zone <zoneName> -proxyMode YES -dnssecOffload ENABLED [-nsec (ENABLED | DISABLED)
- show dns zone

Example

```
> add dns zone example.com -proxyMode YES -dnssecOffload ENABLED nsec ENABLED
 Done
> show dns zone example.com
  Zone Name : example.com
  Proxy Mode : YES
  DNSSEC Offload: ENABLED NSEC: ENABLED
 Done
>
```

1. Navigate to Traffic Management > DNS > Zones.
2. In the details pane, do one of the following:
   - To create a zone on the ADC, click Add.
   - To configure DNSSEC offloading for an existing zone, click the zone, and then click Open.
3. In the Create DNS Zone or Configure DNS Zone dialog box, select the Proxy Mode and DNSSEC Offload check boxes.
4. Optionally, if you want the ADC to generate NSEC records for the zone, select the NSEC check box.
5. Click OK.

Firewall Load Balancing

Jun 29, 2012

Firewall load balancing distributes traffic across multiple firewalls, providing fault tolerance and increased throughput. Firewall load balancing protects your network by:

- Dividing the load between the firewalls, which eliminates a single point of failure and allows the network to scale.
- Increasing high availability.

Configuring a NetScaler appliance for firewall load balancing is similar to configuring load balancing, with the exception that the recommended service type is ANY, recommended monitor type is PING, and the load balancing virtual server mode is set to MAC.

You can set up firewall load balancing in a sandwich, an enterprise, or multiple-firewall environment configuration. The sandwich environment is used for load balancing traffic entering the network from outside and traffic leaving the network to the internet and involves configuring two NetScaler appliances, one on each side of a set of firewalls. You configure an enterprise environment for load balancing traffic leaving the network to the internet. The enterprise environment involves configuring a single NetScaler appliance between the internal network and the firewalls that provide access to the Internet. The multiple-firewall environment is used for load balance traffic coming from another firewall. Having firewall load balancing enabled on both the sides of NetScaler improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic. The multiple-firewall environment involves configuring a NetScaler appliance sandwiched between two firewalls.

Important: If you configure static routes on the NetScaler for the destination IP address and enable L3 mode, the NetScaler uses its routing table to route the traffic instead of sending the traffic to the load balancing vserver.
Note: For FTP to work, an additional virtual server or service should be configured on the NetScaler with IP address and port as * and 21 respectively, and the service type specified as FTP. In this case, the NetScaler manages the FTP protocol by accepting the FTP control connection, modifying the payload, and managing the data connection, all through the same firewall.
Firewall Load Balancing supports only some of the load balancing methods supported on the NetScaler. Also, you can configure only a few types of persistence and monitors.

The following load balancing methods are supported for firewall load balancing.

- Least Connections
- Round Robin
- Least Packets
- Least Bandwidth
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port hash
- Least Response Time Method (LRTM)
- Custom Load

Only SOURCEIP, DESTIP, and SOURCEIPDESTIP based persistence are supported for firewall load balancing.

Only PING and transparent monitors are supported in firewall load balancing. You can bind a PING monitor (default) to the backend service that represents the firewall. If a firewall is configured not to respond to ping packets, you can configure transparent monitors to monitor hosts on the trusted side through individual firewalls.

Sandwich Environment

Apr 08, 2013

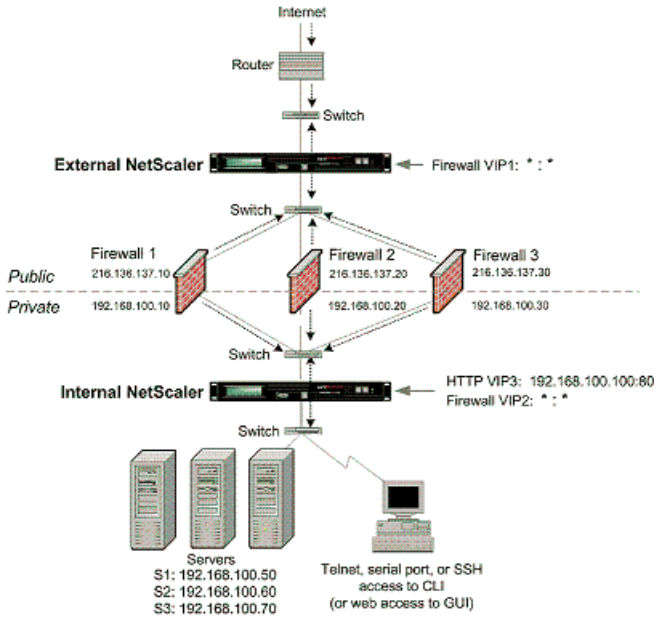
A NetScaler deployment in a sandwich mode is capable of load balancing network traffic through firewalls in both directions: ingress (traffic entering the network from the outside, such as the internet) and egress (traffic leaving the network to the internet).

In this setup, a NetScaler is located on each side of a set of firewalls. The NetScaler placed between the firewalls and the Internet, called the external NetScaler that handles ingress traffic selects the best firewall, based on the configured method. The NetScaler between the firewalls and the private network, called the internal NetScaler tracks the firewall from which the initial packet for a session is received. It then makes sure that all subsequent packets for that session are sent to the same firewall.

The internal NetScaler can be configured as a regular traffic manager to load balance traffic across the private network servers. This configuration also allows traffic originating from the private network (egress) to be load balanced across the firewalls.

The following diagram shows the sandwich firewall load balancing environment.

Figure 1. Firewall Load Balancing (Sandwich)



The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.

Updated: 2015-05-22

Perform the following tasks to configure the external NetScaler in a sandwich environment

- Enable the load balancing feature.

- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server for traffic coming from the Internet.
- Configure the virtual server in MAC rewrite mode.
- Bind services to the wildcard virtual server.
- Save and Verify the Configuration.

Enable the load balancing feature

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

Example

```
> enable ns feature LoadBalancing
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)    Web Logging              WL              OFF
 2)    Surge Protection         SP              ON
 3)    Load Balancing           LB              ON
 .
 .
 .
 24)   NetScaler Push           push            OFF
 Done
```

Configure a wildcard service for each firewall

At the command prompt, type:

add service <name> <serverName> ANY *

Example

```
add service Service-HTTP-1 10.102.29.5 ANY *
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName
4. In Protocol, select ANY, and in Port, select *.

5. Click Create, and then click Close. The service you created appears in the Services pane.

Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO)]
- bind lb monitor <monitorName> <serviceName>

Example

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
bind monitor monitor-HTTP-1 fw-svc1
To bind a PING monitor, type the following command:
bind monitor PING fw-svc1
```

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify values for the following parameters as shown:
   - Name*
   - Type*
   - Destination IP
   - Transparent

   * A required parameter
4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configure a wildcard virtual server for traffic coming from the Internet

At the command prompt, type:

add lb vserver <name> ANY * *

Example

```
add lb vserver Vserver-LB-1 ANY * *
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name—name
4. In Protocol, select ANY, and in IP Address and Port, select *.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configure the virtual server in MAC rewrite mode

At the command prompt, type:

set lb vserver <name>@ -m <RedirectionMode>

Example

```
set lb vserver Vserver-LB-1 -m MAC
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.
3. On the Advanced tab, under Redirection Mode, click MAC-Based.
4. Click OK.

Bind services to the wildcard virtual server

At the command prompt, type:

bind lb vserver <name> <serviceName>

Example

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the service.
3. Click Open.
4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server.
5. Click OK.

Note: You can bind a service to multiple virtual servers.

Save and Verify the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

Example

```
save config
sh lb vserver FWLBVIP1
FWLBVIP1 (*:*) - ANY    Type: ADDRESS
        State: UP
        Last state change was at Mon Jun 14 06:40:14 2010
        Time since last state change: 0 days, 00:00:11.240
        Effective State: UP  ARP:DISABLED
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  2 (Total)       2 (Active)
        Configured Method: SRCIPDESTIPHASH
        Mode: MAC
        Persistence: NONE
        Connection Failover: DISABLED

1) fw_svc_1 (10.102.29.251: *) - ANY State: UP   Weight: 1
2) fw_svc_2 (10.102.29.18: *) - ANY State: UP    Weight: 1
 Done
show service fw-svc1
        fw-svc1 (10.102.29.251:*) - ANY
        State: DOWN
        Last state change was at Thu Jul  8 10:04:50 2010
        Time since last state change: 0 days, 00:00:38.120
        Server Name: 10.102.29.251
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): YES
        HTTP Compression(CMP): NO
        Idle timeout: Client: 120 sec   Server: 120 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED
```

```
1)    Monitor Name: monitor-HTTP-1
          State: DOWN    Weight: 1
          Probes: 5      Failed [Total: 5 Current: 5]
          Last response: Failure - Time out during TCP connection establishment stage
          Response Time: 2000.0 millisec
2)    Monitor Name: ping
          State: UP      Weight: 1
          Probes: 3      Failed [Total: 0 Current: 0]
          Last response: Success - ICMP echo reply received.
          Response Time: 1.415 millisec
 Done
```

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
5. Navigate to Traffic Management > Load Balancing > Virtual Servers.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.

Updated: 2015-06-04

Perform the following tasks to configure the internal NetScaler in a sandwich environment

For traffic from the server (egress)

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server to load balance the traffic sent to the firewalls.
- Configure the virtual server in MAC rewrite mode.
- Bind firewall services to the wildcard virtual server.

For traffic across private network servers

- Configure a service for each virtual server .
- Configure a monitor for each service.
- Configure an HTTP virtual server to balance traffic sent to the servers.
- Bind HTTP services to the HTTP virtual server .
- Save and Verify the Configuration.

Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

Example

```
> enable ns feature LoadBalancing
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)    Web Logging              WL              OFF
 2)    Surge Protection          SP              ON
 3)    Load Balancing            LB              ON
 .
 .
 .
 24)   NetScaler Push            push            OFF
Done
```

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click OK.
4. In the Enable/Disable Feature(s)? message box, click Yes.

Configure a wildcard service for each firewall

At the command prompt, type:

add service <name> <serverName> ANY *

Example

```
add service Service-HTTP-1 10.102.29.5 ANY *
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName
4. In Protocol, select ANY, and in Port, select *.
5. Click Create, and then click Close. The service you created appears in the Services pane.

Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO)]
- bind lb monitor <monitorName> <serviceName>

Example

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
bind monitor monitor-HTTP-1 fw-svc1
```

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify values for the following parameters as shown:
   - Name*
   - Type*
   - Destination IP
   - Transparent

   * A required parameter
4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configure a wildcard virtual server to load balance the traffic sent to the firewalls

At the command prompt, type:

add lb vserver <name> ANY * *

Example

```
add lb vserver Vserver-LB-1 ANY * *
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name—name
4. In Protocol, select ANY, and in IP Address and Port, select *.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configure the virtual server in MAC rewrite mode

At the command prompt, type:

set lb vserver <name>@ -m <RedirectionMode>

Example

```
set lb vserver Vserver-LB-1 -m MAC
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.
3. On the Advanced tab, under Redirection Mode, click MAC-Based.
4. Click OK.

Bind firewall services to the wildcard virtual server

At the command prompt, type:

bind lb vserver <name> <serviceName>

Example

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the service.
3. Click Open.
4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server.
5. Click OK.

Note: You can bind a service to multiple virtual servers.

Configure a service for each virtual server

At the command prompt, type:

add service <name> <serverName> HTTP <port>

Example

```
add service Service-HTTP-1 10.102.29.5 HTTP 80
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName
   - Port—port
4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.
5. Click Create, and then click Close. The service you created appears in the Services pane.

Configure a monitor for each service

At the command prompt, type:

bind lb monitor <monitorName> <ServiceName>

Example

```
bind mon monitor-HTTP-1 Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to bind the monitor (for example, Service-HTTP-1), and then click Open.
3. On the Monitors tab, in the Available list box, select the monitor you want to bind the service (for example, monitor-HTTP-1), and then click Add.
4. In the Configured box, click OK.

Configure an HTTP virtual server to balance traffic sent to the servers

At the command prompt, type:

add lb vserver <name> HTTP <ip> <port>

Example

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:

- Name—name
- IP Address—IPAddress
  Note: If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, 1000:0000:0000:0000:0005:0600:700a:888b).
- Port—port

4. Under Protocol, select HTTP.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Bind HTTP services to the HTTP virtual server

At the command prompt, type:

bind lb vserver <name> <serviceName>

Example

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the service.
3. Click Open.
4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server.
5. Click OK.

Note: You can bind a service to multiple virtual servers.

Save and Verify the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

Example

```
save config
show lb vserver FWLBVIP2
    FWLBVIP2 (*:*) - ANY    Type: ADDRESS
    State: UP
    Last state change was at Mon Jun 14 07:22:54 2010
    Time since last state change: 0 days, 00:00:32.760
    Effective State: UP
    Client Idle Timeout: 120 sec
    Down state flush: ENABLED
```

```
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  2 (Total)       2 (Active)
        Configured Method: LEASTCONNECTION
        Current Method: Round Robin, Reason: A new service is bound
        Mode: MAC
        Persistence: NONE
        Connection Failover: DISABLED

1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
2) fw-int-svc2 (10.102.29.9: *) - ANY State: UP Weight: 1
 Done
show service fw-int-svc1
        fw-int-svc1 (10.102.29.5:*) - ANY
        State: DOWN
        Last state change was at Thu Jul  8 14:44:51 2010
        Time since last state change: 0 days, 00:01:50.240
        Server Name: 10.102.29.5
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): NO
        HTTP Compression(CMP): NO
        Idle timeout: Client: 120 sec   Server: 120 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED

1)      Monitor Name: monitor-HTTP-1
              State: DOWN     Weight: 1
              Probes: 9       Failed [Total: 9 Current: 9]
              Last response: Failure - Time out during TCP connection establishment stage
              Response Time: 2000.0 millisec
2)      Monitor Name: ping
              State: UP       Weight: 1
              Probes: 3       Failed [Total: 0 Current: 0]
              Last response: Success - ICMP echo reply received.
              Response Time: 1.275 millisec
 Done
```

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.

5. Navigate to Traffic Management > Load Balancing > Services.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

Viewing the Statistics of a Virtual Server

Updated: 2013-09-05

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

stat lb vserver [-detail] [<name>]

Example

```
>stat lb vserver -detail
Virtual Server(s) Summary
                vsvrIP  port    Protocol      State   Req/s   Hits/s
One                  *    80        HTTP         UP      5/s      0/s
Two                  *     0         TCP       DOWN      0/s      0/s
Three                *  2598         TCP       DOWN      0/s      0/s
dnsVirtualNS    10.102.29.90    53         DNS       DOWN      0/s      0/s
BRVSERV          10.10.1.1    80        HTTP       DOWN      0/s      0/s
LBVIP         10.102.29.66    80        HTTP         UP      0/s      0/s
 Done
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.
3. In the details pane, click Statistics.

Viewing the Statistics of a Service

Updated: 2013-08-28

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

At the command prompt, type:

stat service <name>

Example

```
stat service Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).
3. Click Statistics. The statistics appear in a new window.

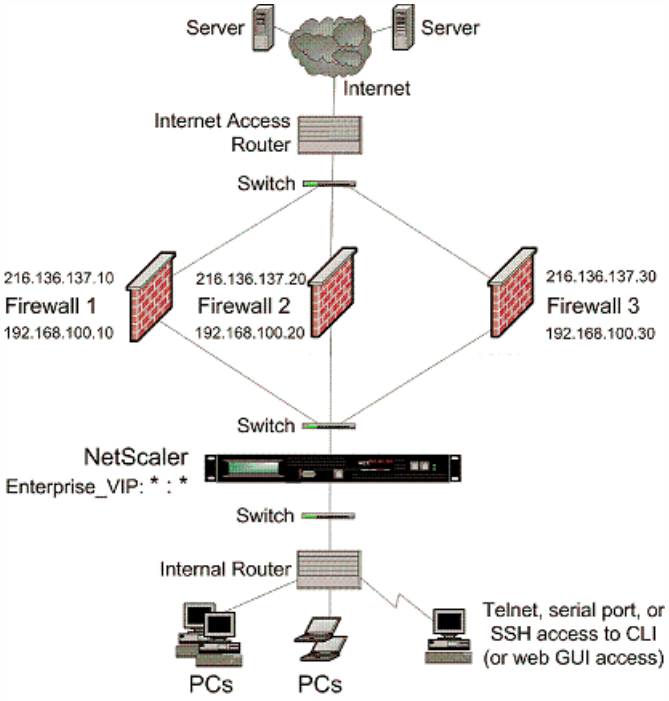
Enterprise Environment

Mar 22, 2012

In the enterprise setup, the NetScaler is placed between the firewalls connecting to the public Internet and the internal private network and handles egress traffic. The NetScaler selects the best firewall based on the configured load balancing policy.

The following diagram shows the enterprise firewall load balancing environment

Figure 1. Firewall Load Balancing (Enterprise)



The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and vserver with type HTTP or TCP. For FTP to work, configure the service with type FTP.

Updated: 2013-11-08

Perform the following tasks to configure a NetScaler in an enterprise environment.

For traffic from the server (egress)

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server to load balance the traffic sent to the firewalls .
- Configure the virtual server in MAC rewrite mode.
- Bind firewall services to the wildcard virtual server.

For traffic across private network servers

- Configure a service for each virtual server .
- Configure a monitor for each service.
- Configure an HTTP virtual server to balance traffic sent to the servers.
- Bind HTTP services to the HTTP virtual server .
- Save and Verify the Configuration.

Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

Example

```
> enable ns feature LoadBalancing
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)    Web Logging              WL              OFF
 2)    Surge Protection          SP              ON
 3)    Load Balancing            LB              ON
 .
 .
 .
 24)   NetScaler Push            push            OFF
Done
```

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click OK.
4. In the Enable/Disable Feature(s)? message box, click Yes.

Configure a wildcard service for each firewall

At the command prompt, type:

add service <name> <serverName> ANY *

Example

```
add service Service-HTTP-1 10.102.29.5 ANY *
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName
4. In Protocol, select ANY, and in Port, select *.
5. Click Create, and then click Close. The service you created appears in the Services pane.

Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO)]
- bind lb monitor <monitorName> <serviceName>

Example

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
bind monitor monitor-HTTP-1 fw-svc1
```

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify values as shown:

   - Name*
   - Type*—type
   - Destination IP
   - Transparent

   * A required parameter

4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configure a wildcard virtual server to load balance the traffic sent to the firewalls

At the command prompt, type:

add lb vserver <name> ANY * *

Example

```
add lb vserver Vserver-LB-1 ANY * *
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name—name
4. In Protocol, select ANY, and in IP Address and Port, select *.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configure the virtual server in MAC rewrite mode

At the command prompt, type:

set lb vserver <name>@ -m <RedirectionMode>

Example

```
set lb vserver Vserver-LB-1 -m MAC
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.
3. On the Advanced tab, under Redirection Mode, click MAC-Based.
4. Click OK.

Bind firewall services to the wildcard virtual server

At the command prompt, type:

bind lb vserver <name> <serviceName>

Example

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the service.
3. Click Open.
4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server.
5. Click OK.

Note: You can bind a service to multiple virtual servers.

Configure a service for each virtual server

At the command prompt, type:

add service <name> <serverName> HTTP <port>

Example

```
add service Service-HTTP-1 10.102.29.5 HTTP 80
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName
   - Port—port
4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.
5. Click Create, and then click Close. The service you created appears in the Services pane.

Configure a monitor for each service

At the command prompt, type:

bind lb monitor <monitorName> <ServiceName>

Example

```
bind mon monitor-HTTP-1 Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to bind the monitor (for example, Service-HTTP-1), and then click Open.
3. On the Monitors tab, in the Available list box, select the monitor you want to bind the service (for example, monitor-HTTP-1), and then click Add.
4. In the Configured box, click OK.

Configure an HTTP virtual server to balance traffic sent to the servers

At the command prompt, type:

add lb vserver <name> HTTP <ip> <port>
Example

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name—name
   - IP Address—IPAddress
     Note: If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, **1000:0000:0000:0000:0005:0600:700a:888b**).
   - Port—port
4. Under Protocol, select HTTP.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Bind HTTP services to the HTTP virtual server

At the command prompt, type:

bind lb vserver <name> <serviceName>
Example

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the service.
3. Click Open.
4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server.
5. Click OK.

Note: You can bind a service to multiple virtual servers.

Save and Verify the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

Example

```
save config
show lb vserver FWLBVIP2
        FWLBVIP2 (*:*) - ANY    Type: ADDRESS
        State: UP
        Last state change was at Mon Jun 14 07:22:54 2010
        Time since last state change: 0 days, 00:00:32.760
        Effective State: UP
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  2 (Total)       2 (Active)
        Configured Method: LEASTCONNECTION
        Current Method: Round Robin, Reason: A new service is bound
        Mode: MAC
        Persistence: NONE
        Connection Failover: DISABLED

1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
2) fw-int-svc2 (10.102.29.9: *) - ANY State: UP Weight: 1
 Done
show service fw-int-svc1
        fw-int-svc1 (10.102.29.5:*) - ANY
        State: DOWN
        Last state change was at Thu Jul  8 14:44:51 2010
        Time since last state change: 0 days, 00:01:50.240
        Server Name: 10.102.29.5
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): NO
        HTTP Compression(CMP): NO
        Idle timeout: Client: 120 sec   Server: 120 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED

1)      Monitor Name: monitor-HTTP-1
                State: DOWN     Weight: 1
                Probes: 9       Failed [Total: 9 Current: 9]
                Last response: Failure - Time out during TCP connection establishment stage
                Response Time: 2000.0 millisec
2)      Monitor Name: ping
                State: UP       Weight: 1
```

```
        Probes: 3      Failed [Total: 0 Current: 0]
        Last response: Success - ICMP echo reply received.
        Response Time: 1.275 millisec
Done
```

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
5. Navigate to Traffic Management > Load Balancing > Services.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

Viewing the Statistics of a Virtual Server

Updated: 2013-09-05

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

stat lb vserver [-detail] [<name>]

Example

```
>stat lb vserver -detail
Virtual Server(s) Summary
                vsvrIP  port    Protocol      State   Req/s   Hits/s
One                  *    80        HTTP         UP      5/s      0/s
Two                  *     0         TCP       DOWN      0/s      0/s
Three                *  2598         TCP       DOWN      0/s      0/s
dnsVirtualNS    10.102.29.90    53         DNS       DOWN      0/s      0/s
```

```
BRVSERV          10.10.1.1    80       HTTP        DOWN      0/s      0/s
LBVIP         10.102.29.66    80       HTTP          UP      0/s      0/s
 Done
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.
3. In the details pane, click Statistics.

Viewing the Statistics of a Service

Updated: 2013-08-28

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

At the command prompt, type:

stat service <name>
Example

stat service Service-HTTP-1

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).
3. Click Statistics. The statistics appear in a new window.

Multiple-Firewall Environment

Sep 06, 2012

Note: This feature is available in NetScaler release 9.3.e and 10.

In a multiple-firewall environment, the NetScaler appliance is placed between two sets of firewalls, the external set connecting to the public Internet, and the internal set connecting to the internal private network. The external set typically handles the egress traffic. These firewalls mainly implement access control lists to allow or deny access to external resources. The internal set typically handles the ingress traffic. These firewalls implement security to safeguard the intranet from malicious attacks apart from load-balancing the ingress traffic. The multiple-firewall environment allows you to load-balance traffic coming from another firewall. By default, the traffic coming from a firewall is not load balanced on the other firewall across a NetScaler. Having firewall load balancing enabled on both the sides of NetScaler improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic.

Figure 1 shows a multiple-firewall load balancing environment

Figure 1. Firewall Load Balancing (multiple-firewall)

With a configuration like the one shown in Figure 1, you can configure the NetScaler to load balance the traffic through the an internal firewall even if it is load balanced by an external firewall. For example, with this feature configured, the traffic coming from the external firewalls (firewalls 1, 2, and 3) is load balanced on the internal firewalls (firewalls 4, 5, and 6) and vice versa.

Firewall load balancing is supported only for MAC mode LB virtual server.

The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.

Updated: 2015-05-18

To configure a NetScaler appliance in a multiple-firewall environment, you have to enable the load balancing feature, configure a virtual server to load balance the egress traffic across the external firewalls, configure a virtual server to load balance the ingress traffic across the internal firewalls, and enable firewall load balancing on the NetScaler. To configure a virtual server to load balance traffic across a firewall in the multiple-firewall environment, you need to:

1. Configure a wildcard service for each firewall
2. Configure a monitor for each wildcard service
3. Configure a wildcard virtual server to load balance the traffic sent to the firewalls
4. Configure the virtual server in MAC rewrite mode
5. Bind firewall services to the wildcard virtual server

Enabling the load balancing feature

To configure and implement load balancing entities such as services and virtual servers, you need to enable the load balancing feature on the NetScaler device.

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature <featureName>
- show ns feature

Example

```
enable ns feature LoadBalancing
Done
show ns feature
Feature Acronym Status
------- ------- ------
1) Web Logging WL OFF
2) Surge Protection SP ON
3) Load Balancing LB ON
.
.
.
24) NetScaler Push push OFF
Done
```

1. In the navigation pane, expand System, and then click Settings.
2. In the Settings pane, under Modes and Features, click Change basic features.

3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click Ok.

Configuring a wildcard service for each firewall

To accept traffic from all the protocols, you need to configure wildcard service for each firewall by specifying support for all the protocols and ports.

At the command prompt, type the following command to configure support for all the protocols and ports:

add service <name>@ <serverName> <serviceType> <port_number>

Example

```
add service fw-svc1 10.102.29.5 ANY *
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Services dialog box, specify values for the following parameters as shown:

   - Service Name—name
   - Server—serverName

   * A required parameter

4. In Protocol, select Any and in Port, select *.
5. Click Create, and then click Close. The service you created appears in the Services pane.

Configuring a monitor for each service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO)]
- bind lb monitor <monitorName> <serviceName>

Example

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
```

bind monitor monitor-HTTP-1 fw-svc1

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify values for the following parameters as shown:

   - Name*
   - Type*—type
   - Destination IP
   - Transparent

   * A required parameter

4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configuring a virtual server to load balance the traffic sent to the firewalls

To load balance any kind of traffic, you need to configure a wildcard virtual server specifying the protocol and port as any value.

At the command prompt, type the following command:

add lb vserver <name>@ <serviceType> <IPAddress> <port_number>
Example

add lb vserver Vserver-LB-1 ANY * *

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In Protocol, select Any, and in IP Address and Port, select *.
4. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configuring the virtual server to MAC rewrite mode

To configure the virtual server to use MAC address for forwarding the incoming traffic, you need to enable the MAC rewrite mode.

At the command prompt, type the following command:

set lb vserver <name>@ -m <RedirectionMode>
Example

set lb vserver Vserver-LB-1 -m MAC

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-

LB1), and then click Open.
3. On the Advanced tab, under the Redirection Mode mode, click Open.
4. Click Ok.

Binding firewall services to the virtual server

To access a service on NetScaler, you need to bind it to a wildcard virtual server.

At the command prompt, type the following command:

bind lb vserver <name>@ <serviceName>
Example

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server(for example, Service-HTTP-1).
4. Click Ok.

Configuring the multiple-firewall load balancing on the NetScaler Appliance

To load balance traffic on both the sides of a NetScaler using firewall load balancing, you need to enable mulitpl-firewall load balancing by using the vServerSpecificMac parameter.

At the command prompt, type the following command:

set lb parameter -vServerSpecificMac <status>
Example

```
set lb parameter -vServerSpecificMac ENABLED
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Configure Load Balancing parameters).
3. In the Set Load Balancing Parameters dialog box, select the Virtual Server Specific MAC check box.
4. Click Ok.

Saving and Verifying the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

Example

```
save config
show lb vserver FWLBVIP2
        FWLBVIP2 (*:*) - ANY    Type: ADDRESS
        State: UP
        Last state change was at Mon Jun 14 07:22:54 2010
        Time since last state change: 0 days, 00:00:32.760
        Effective State: UP
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  2 (Total)      2 (Active)
        Configured Method: LEASTCONNECTION
        Current Method: Round Robin, Reason: A new service is bound
        Mode: MAC
        Persistence: NONE
        Connection Failover: DISABLED

1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
2) fw-int-svc2 (10.102.29.9: *) - ANY State: UP Weight: 1
 Done
show service fw-int-svc1
        fw-int-svc1 (10.102.29.5:*) - ANY
        State: DOWN
        Last state change was at Thu Jul  8 14:44:51 2010
        Time since last state change: 0 days, 00:01:50.240
        Server Name: 10.102.29.5
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): NO
        HTTP Compression(CMP): NO
        Idle timeout: Client: 120 sec   Server: 120 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED

1)      Monitor Name: monitor-HTTP-1
              State: DOWN     Weight: 1
              Probes: 9       Failed [Total: 9 Current: 9]
              Last response: Failure - Time out during TCP connection establishment stage
```

```
        Response Time: 2000.0 millisec
2)      Monitor Name: ping
        State: UP       Weight: 1
        Probes: 3       Failed [Total: 0 Current: 0]
        Last response: Success - ICMP echo reply received.
        Response Time: 1.275 millisec
 Done
```

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
5. Navigate to Traffic Management > Load Balancing > Services.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

Viewing the Statistics of a Virtual Server

Updated: 2013-09-05

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

stat lb vserver [-detail] [<name>]

Example

```
>stat lb vserver -detail
Virtual Server(s) Summary
                vsvrIP  port    Protocol      State   Req/s   Hits/s
One                 *   80        HTTP         UP      5/s     0/s
```

```
Two                 *     0        TCP        DOWN      0/s      0/s
Three               *  2598        TCP        DOWN      0/s      0/s
dnsVirtualNS    10.102.29.90    53        DNS        DOWN      0/s      0/s
BRVSERV          10.10.1.1    80        HTTP        DOWN      0/s      0/s
LBVIP         10.102.29.66    80        HTTP          UP      0/s      0/s
 Done
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.
3. In the details pane, click Statistics.

Viewing the Statistics of a Service

Updated: 2013-08-28

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

At the command prompt, type:

stat service <name>
Example

```
stat service Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).
3. Click Statistics. The statistics appear in a new window.

Global Server Load Balancing

Mar 22, 2012

NetScaler appliances configured for global server load balancing (GSLB) provide for disaster recovery and ensure continuous availability of applications by protecting against points of failure in a wide area network (WAN). GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers in case of an outage.

Following are some typical GSLB configurations:

- **Active-active data center setup**. Consists of multiple active data centers. Client requests are load balanced across active data centers.
- **Active-standby data center setup**. Consists of an active and a standby data center. When a failover occurs as a result of a disaster event, the standby data center becomes operational.
- **Proximity setup**. Directs client requests to the data center that is closest in geographical distance or network distance.

In a typical configuration, a local DNS server sends client requests to a GSLB virtual server, to which are bound GSLB services. A GSLB service identifies a load balancing or content switching virtual server, which can be at the local site or a remote site. If the GSLB virtual server selects a load balancing or content switching virtual server at a remote site, it sends the virtual server's IP address to the DNS server, which sends it to the client. The client then resends the request to the new virtual server at the new IP.

The GSLB entities that you must configure are the GSLB sites, the GSLB services, the GSLB virtual servers, load balancing or content switching virtual servers, and authoritative DNS (ADNS) services. You must also configure MEP. You can also configure DNS views to expose different parts of your network to clients accessing the network from different locations.

Note: To take full advantage of the NetScaler GSLB features, you should use NetScaler appliances for load balancing or content switching at each data center, so that your GSLB configuration can use the proprietary Metric Exchange Protocol (MEP) to exchange site metrics.

How GSLB Works

May 20, 2015

With ordinary DNS, when a client sends a domain name system (DNS) request, it receives a list of IP addresses of the domain or service. Generally, the client chooses the first IP address in the list and initiates a connection with that server. The DNS server uses a technique called DNS round robin to rotate through the IPs on the list, sending the first IP address to the end of the list and promoting the others after it responds to each DNS request. This technique ensures equal distribution of the load, but it does not support disaster recovery, load balancing based on load or proximity of servers, or persistence.

When you configure GSLB on NetScaler appliances and enable Metric Exchange Protocol (MEP), the appliances use the DNS infrastructure to connect the client to the data center that best meets the criteria that you set. The criteria can designate the least loaded data center, the closest data center, the data center that responds most quickly to requests from the client's location, a combination of those metrics, and SNMP metrics. An appliance keeps track of the location, performance, load, and availability of each data center and uses these factors to select the data center to which to send a client request.

A GSLB configuration consists of a group of GSLB entities on each appliance in the configuration. These entities include GSLB sites, GSLB services, GSLB virtual servers, load balancing and/or content switching servers, and ADNS services.

This document includes the following information:

- GSLB Sites
- GSLB Services
- GSLB Virtual Servers
- Load Balancing or Content Switching Virtual Servers
- ADNS Services
- DNS VIPs

A typical GSLB setup consists of data centers, each of which has various network appliances that may or may not be NetScaler appliances. The data centers are called GSLB sites. Each GSLB site is managed by a NetScaler appliance that is local to that site. Each of these appliances treats its own site as the local site and all other sites, managed by other appliances, as remote sites.

If the appliance that manages a site is the only NetScaler appliance in that data center, the GSLB site hosted on that appliance acts as a bookkeeping placeholder for auditing purposes, because no metrics can be collected. Typically, this happens when the appliance is used only for GSLB, and other products in the data center are used for load balancing or content switching.

A GSLB service is usually a representation of a load balancing or content switching virtual server, although it can represent any type of virtual server. The GSLB service identifies the virtual server's IP address, port number, and service type. GSLB services are bound to GSLB virtual servers on the NetScaler appliances managing the GSLB sites. A GSLB service bound to a GSLB virtual server in the same data center is local to the GSLB virtual server. A GSLB service bound to a GSLB virtual server in

a different data center is remote from that GSLB virtual server.

A GSLB virtual server has one or more GSLB services bound to it, and load balances traffic among those services. It evaluates the configured GSLB methods (algorithms) to select the appropriate service to which to send a client request. Because the GSLB services can represent either local or remote servers, selecting the optimal GSLB service for a request has the effect of selecting the data center that should serve the client request.

The domain for which global server load balancing is configured must be bound to the GSLB virtual server, because one or more services bound to the virtual server will serve requests made for that domain.

Unlike other virtual servers configured on a NetScaler appliance, a GSLB virtual server does not have its own virtual IP address (VIP).

Updated: 2013-09-13

A load balancing or content switching virtual server represents one or many physical servers on the local network. Clients send their requests to the load balancing or content switching virtual server's virtual IP (VIP) address, and the virtual server balances the load across the physical servers. After a GSLB virtual server selects a GSLB service representing either a local or a remote load balancing or content switching virtual server, the client sends the request to that virtual server's VIP address.

For more information about load balancing or content switching virtual servers and services, see Load Balancing, or Content Switching .

An ADNS service is a special kind of service that responds only to DNS requests for domains for which the NetScaler appliance is authoritative. When an ADNS service is configured, the appliance owns that IP address and advertises it. Upon reception of a DNS request by an ADNS service, the appliance checks for a GSLB virtual server bound to that domain. If a GSLB virtual server is bound to the domain, it is queried for the best IP address to which to send the DNS response.

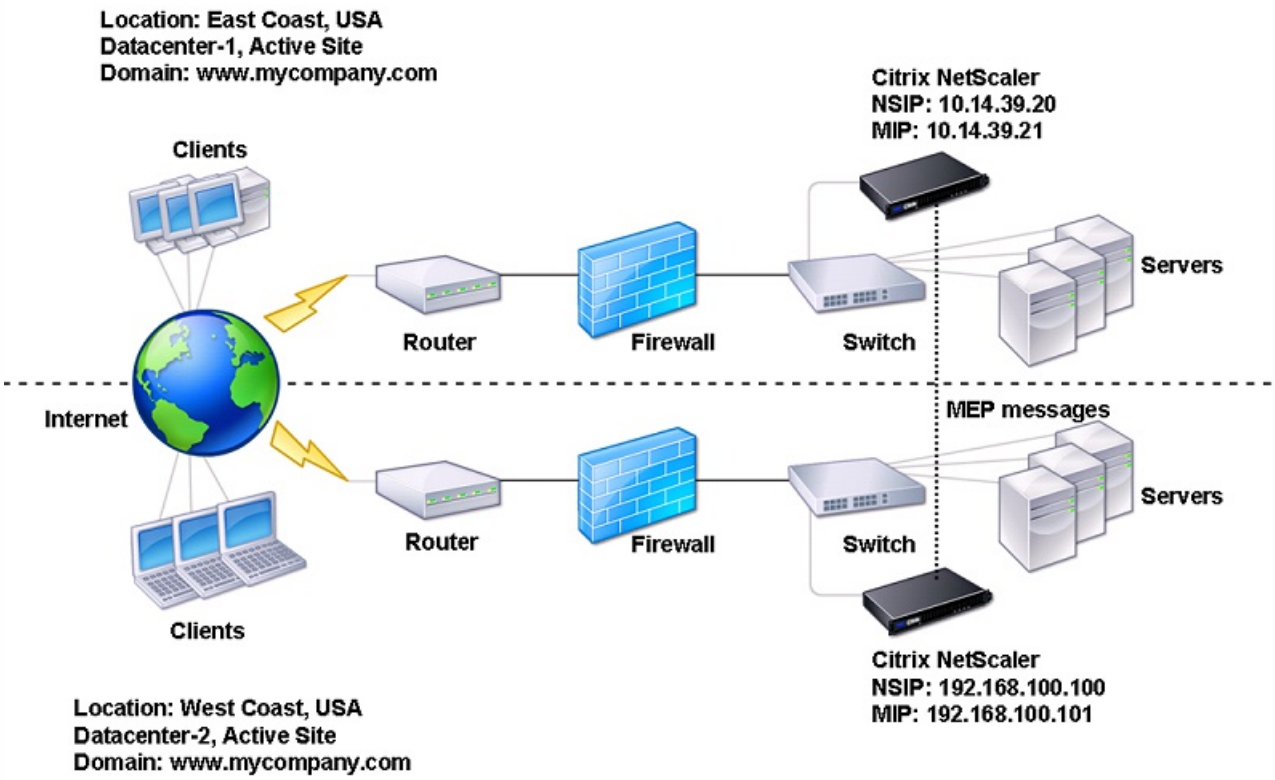
A DNS virtual IP is a virtual IP (VIP) address that represents a load balancing DNS virtual server on the NetScaler appliance. DNS requests for domains for which the NetScaler appliance is authoritative can be sent to a DNS VIP.

Configuring Global Server Load Balancing (GSLB)

May 22, 2015

Global server load balancing is used to manage traffic flow to a web site hosted on two separate server farms that ideally are in different geographic locations. For example, consider a Web site, www.mycompany.com, which is hosted on two geographically separated server farms or data centers. Both server farms use NetScaler appliances. The NetScaler appliances in these server farms are set up in one-arm mode and function as authoritative DNS servers for the www.mycompany.com domain. The following figure illustrates this configuration.

Figure 1. Basic GSLB Topology



To configure such a GSLB setup, you must first configure a standard load balancing setup for each server farm or data center. This enables you to balance load across the different servers in each server farm. Then, configure both NetScaler appliances as authoritative DNS (ADNS) servers. Next, create a GSLB site for each server farm, configure GSLB virtual servers for each site, create GLSB services, and bind the GSLB services to the GSLB virtual servers. Finally, bind the domain to the GSLB virtual servers. The GSLB configurations on the two appliances at the two different sites are identical, although the load-balancing configurations for each site is specific to that site.

Note: To configure a GSLB site in a NetScaler cluster setup, see Setting Up GSLB in a Cluster.

Updated: 2013-08-30

A load balancing virtual server balances the load across different physical servers in the data center. These servers are

represented as services on the NetScaler appliance, and the services are bound to the load balancing virtual server.

For details on configuring a basic load balancing setup, see Load Balancing.

Configuring an Authoritative DNS Service

Nov 24, 2014

When you configure the NetScaler appliance as an authoritative DNS server, it accepts DNS requests from the client and responds with the IP address of the data center to which the client should send requests.

Note: For the NetScaler to be authoritative, you must also create SOA and NS records. For more information about SOA and NS records, see "Domain Name System".

At the command prompt, type the following commands to create an ADNS service and verify the configuration:

- add service <name> <IP>@ ADNS <port>
- show service <name>

Example

```
add service Service-ADNS-1 10.14.39.21 ADNS 53
show service Service-ADNS-1
```

At the command prompt, type the following command:

set service <name> <IPAddress> ADNS <port>

Example

```
set service Service-ADNS-1 10.14.39.21 ADNS 53
```

At the command prompt, type the following command:

rm service <name>

Example

```
rm service Service-ADNS-1
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, do one of the following:
   - To create a new service, click Add.
   - To modify an existing service, select the service, and then click Open.
3. In the Create Service or Configure Service dialog box, specify values for the following parameters as shown:
   - Service Name*—name
   - Service Name*—name
   - Protocol*—(Select ADNS as the protocol.)
   - Port*—port
4. Click Create or OK, and then click Close. The server that you created appears in the GSLB Services pane.

Configuring a Basic GSLB Site

Nov 24, 2014

A GSLB site is a representation of a data center in your network and is a logical grouping of GSLB virtual servers, services, and other network entities. Typically, in a GSLB set up, there are many GSLB sites that are equipped to serve the same content to a client. These are usually geographically separated to ensure that the domain is active even if one site goes down completely. All of the sites in the GSLB configuration must be configured on every NetScaler appliance hosting a GSLB site. In other words, at each site, you configure the local GSLB site and each remote GSLB site.

Once GSLB sites are created for a domain, the NetScaler appliance sends client requests to the appropriate GSLB site as determined by the GSLB algorithms configured.

At the command prompt, type the following commands to create a GSLB site and verify the configuration:

- add gslb site <siteName> <siteIPAddress>
- show gslb site <siteName>

Example

```
add gslb site Site-GSLB-East-Coast 10.14.39.21
show glsb site Site-GSLB-East-Coast
```

- To modify a GSLB site, use the set gslb site command, which is just like using the add gslb site command, except that you enter the name of an existing GSLB Site.
- To unset a site parameter, use the unset gslb site command, followed by the siteName value and the name of the parameter to be reset to its default value.
- To remove a GSLB site, use the rm gslb site command, which accepts only the <name> argument.

1. Navigate to Traffic Management > GSLB > Sites.
2. In the details pane, do one of the following:
   - To create a new site, click Add.
   - To modify an existing site, select the site, and then click Open.
3. In the Create GSLB Site or Configure GSLB Site dialog box, specify values for the following parameters as shown:
   - Name*—siteName
   - Site IP Address*—siteIPAddress

   * A required parameter
4. Click Create or OK, and then click Close. The GSLB site you created appears in the GSLB Sites pane.

At the command prompt, type:

stat gslb site <siteName>

Example

```
stat gslb site Site-GSLB-East-Coast
```

1. Navigate to Traffic Management > GSLB > Sites.
2. In the GSLB Sites pane, select the GSLB site whose statistics you want to view.
3. Click Statistics.

Configuring a GSLB Service

Nov 24, 2014

A GSLB service is a representation of a load balancing or content switching virtual server. A local GSLB service represents a local load balancing or content switching virtual server. A remote GSLB service represents a load balancing or content switching virtual server configured at one of the other sites in the GSLB setup. At each site in the GSLB setup, you can create one local GSLB service and any number of remote GSLB services.

To create a GSLB service by using the command line interface

At the command prompt, type the following commands to create a GSLB service and verify the configuration:

- add gslb service <serviceName> <serverName | IP> <serviceType> <port>-siteName <string>
- show gslb service <serviceName>

Example

```
add gslb service Service-GSLB-1 10.14.39.14 HTTP 80 –siteName Site-GSLB-East-Coast
show gslb service Service-GSLB-1
```

To modify or remove a GSLB service by using the command line interface

- To modify a GSLB service, use the set gslb service <serviceName> command. For this command, specify the name of the GSLB service whose configuration you want to modify. You can change the existing values of the parameters either specified by you or set by default. You can change the value of more than one parameter in the same command. Refer to the add gslb service command for details about the parameters. Example
  ```
  > set gslb service SKP_GSLB_NOTCNAME_SVC2 -maxBandWidth 25 -maxClient 8
  Done
  > sh gslb service SKP_GSLB_NOTCNAME_SVC2
  SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80)- HTTP
  ...
  Max Conn: 8  Max Bandwidth: 25 kbits
  ```
- To reset a parameter to its default value, you can use the unset gslb service <serviceName> command and the parameters to be unset. Example
  ```
  > unset gslb service SKP_GSLB_NOTCNAME_SVC2 maxBandWidth
  Done
  > sh gslb service SKP_GSLB_NOTCNAME_SVC2
  SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80)- HTTP
  ...
  Max Conn: 8  Max Bandwidth: 0 kbits
  ```
- To remove a GSLB service, use the rm gslb service <serviceName> command.

To create a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. In the details pane, do one of the following:
   - To create a new service, click Add.

- To modify an existing service, select the service, and then click Open.

3. In the Create GSLB Service or Configure GSLB Service dialog box, set the following parameters:
   - Service Name*
   - Site Name*
   - Server Name - The servers added to the NetScaler configuration are displayed in a dropdown list. If you want to add a new server, click New..., and then in the Create Server dialog box, type the necessary details. For more information about creating servers, see "Adding a Server."
   - Service Type
   - Port

   Note: In the Site Name and Server Name lists, the most recently used value is displayed as selected. Make sure that you select the site and server you want to specify.
4. Click Create, and then click Close. The GSLB service you created appears in the GSLB Services pane.

To view the statistics of a GSLB service by using the command line interface

At the command prompt, type:

stat gslb service <serviceName>

Example

```
stat gslb service Service-GSLB-1
```

To view the statistics of a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the GSLB Services pane, select the GSLB Service whose statistics you want to view.
3. Click Statistics.

Updated: 2013-08-30

Before you use a GSLB service for load balancing, it must be enabled. If the service is disabled, it is not included in load balancing even though it exists on the NetScaler appliance.

To enable or disable a GSLB service by using the command line interface

At the command prompt, type one of the following commands:

- enable service <name>
- disable service <name>

Example

```
> enable service Service-GSLB-1
 Done
> disable service Service-GSLB-1
 Done
```

To enable or disable a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.

2. In the GSLB Services pane, select the GSLB service which you want to enable or disable.
3. Click enable or disable.

Configuring a GSLB Virtual Server

Dec 09, 2014

A GSLB virtual server is an entity that represents one or more GSLB services and balances traffic between them. It evaluates the configured GSLB methods or algorithms to select a GSLB service to which to send the client request.

To create a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to add a GSLB virtual server and verify the configuration:

- add gslb vserver <name> <serviceType> -ipType (IPv4 | IPv6)
- show gslb vserver <name>

Example

```
add gslb vserver Vserver-GSLB-1 HTTP -ipType IPv4
add gslb vserver Vserver-GSLB-2 HTTP -ipType IPv6
show gslb vserver Vserver-GSLB-1
show gslb vserver Vserver-GSLB-2
```

To modify or remove a GSLB virtual server by using the command line interface

- To modify a GSLB virtual server, use the set gslb vserver command, which is just like using the add gslb vserver command, except that you enter the name of an existing GSLB virtual server.
- To reset a parameter to is default value, you can use the unset gslb vserver command followed by the vserverName value and the name of the parameter to be unset.
- To remove a GSLB virtual server, use the rm gslb vserver command, which accepts only the <name> argument.

To configure a GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. Add a new GSLB virtual server, or select an existing GSLB virtual server and edit its settings.

To view the statistics of a GSLB virtual server by using the command line interface

At the command prompt, type:

stat gslb vserver <name>

Example

```
stat gslb vserver Vserver-GSLB-1
```

To view the statistics of a GSLB virtual server by using the configuration utility

Navigate to Traffic Management > GSLB > Virtual Servers, select the virtual server and click **Statistics**.

Statistics of a GSLB service

When you run the stat gslb service command from the command line or click on the Statistics link from the configuration utility, the following details of the service will be displayed:

- **Request bytes.** Total number of request bytes received on this service or virtual server.
- **Response bytes.** Number of response bytes received by this service or virtual server.
- **Current client established connections.** Number of client connections in ESTABLISHED state.
- **Current load on the service.** Load on the service (Calculated from the load monitor bound to the service).

The data of number of requests and responses, and the number of current client and server connections may not be displayed or may not be synchronized with the data of the corresponding load balancing virtual server.

Updated: 2014-11-21

When you create a GSLB virtual server, it is enabled by default. If you disable it, it cannot process traffic. A disabled GSLB virtual server is not included in GSLB configuration but is not removed from the NetScaler appliance.

To enable or disable a GSLB virtual server by using the command line interface

At the command prompt, type one of the following commands:

- enable gslb vserver <name>@
- disable gslb vserver <name>@

Example

```
enable gslb vserver Vserver-GSLB-1
disable gslb vserver Vserver-GSLB-1
```

To enable or disable a GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. Select a virtual server and, from the **Action** list, select **enable** or **disable**.

Binding GSLB Services to a GSLB Virtual Server

Nov 21, 2014

Once the GSLB services and virtual server are configured, relevant GSLB services must be bound to the GSLB virtual server to activate the configuration.

At the command prompt, type the following commands to bind a GSLB service to a GSLB virtual server and verify the configuration:

- bind gslb vserver <name> -serviceName <string>
- show gslb vserver <name>

Example

```
bind gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1
show gslb vserver Vserver-GSLB-1
```

At the command prompt, type:

unbind gslb vserver <name> -serviceName <string>

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the details pane, select the GSLB Virtual Server to which you want to bind the services (for example, Vserver-GSLB-1).
3. Click Open.
4. On the Services tab, in the Active column, select the check boxes next to the GSLB services that you want to bind to the GSLB virtual server.
5. Click OK.

Binding a Domain to a GSLB Virtual Server

Dec 09, 2014

To make a NetScaler appliance the authoritative DNS server for a domain, you must bind the domain to the GSLB virtual server. When you bind a domain to a GSLB virtual server, the NetScaler adds an address record for the domain, containing the name of the GSLB virtual server. The start of authority (SOA) and name server (NS) records for the GSLB domain must be added manually.

For details on configuring SOA and NS records, see "Domain Name System".

At the command prompt, type the following commands to bind a domain to a GSLB virtual server and verify the configuration:

- bind gslb vserver <name> -domainName <string>
- show gslb vserver <name>

Example

```
bind gslb vserver Vserver-GSLB-1 -domainName www.mycompany.com
show gslb vserver Vserver-GSLB-1
```

At the command prompt, type:

unbind gslb vserver <name> -domainName <string>

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server to which you want to bind the domain (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, do one of the following:
   - To create a new Domain, click Add.
   - To modify an existing Domain, select the domain, and then click Open.
4. In the Create GSLB Domain or Configure GSLB Domain dialog box, specify values for the following parameters as shown:
   - Domain Name*—domainName (for example, www.mycompany.com)

   * A required parameter
5. Click Create.
6. Click OK.

At the command prompt, type:

stat gslb domain <name>

Example

```
stat gslb domain www.mycompany.com
```

Note: To view statistics for a particular GSLB domain, enter the name of the domain exactly as it was added to the

NetScaler appliance. If you do not specify the domain name, or if you specify an incorrect domain name, statistics for all configured GSLB domains are displayed.

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, select the domain, and then click Statistics.

Synchronizing a Configuration in a GSLB Setup

Mar 24, 2015

Typically, a GSLB setup has a few data centers with a GSLB site configured for each data center. In each NetScaler, participating in GSLB, configure one GSLB site as a local site and the others as remote sites. When you add another GSLB site at a later point of time, ensure that all the GSLB sites have the same configuration. To have the same configuration on all the GSLB sites, you can use the NetScaler appliance's GSLB configuration synchronization option.

The NetScaler appliance from which you use the synchronization option is referred to as the 'master node' and the GSLB sites on which the configuration is copied as 'slave nodes'. When you synchronize a GSLB configuration, the configurations on all the GSLB sites participating in the GSLB setup are made similar to that on the master node.

Synchronization (may also be referred to as 'auto sync') is carried out in the following manner:

- The master node finds the differences between the configuration of the master node and slave node, and changes the configuration of the slave node to make it similar to the master node.
  If you force a synchronization (use the 'force sync' option), the NetScaler deletes the GSLB configuration from the slave node and then configures the slave to make it similar to the master node.
- During synchronization, if a command fails, synchronization is not aborted.
- Synchronization is done only on the parent sites. If a GSLB site is configured as a child site, its configuration is not affected by synchronization.

Note: On the remote GSLB site RPC node, configure the firewall to accept auto-sync connections by specifying the remote site IP (cluster IP address for cluster setup) and port (3010 for RPC and 3008 for secure RPC). The source IP address that will be used for auto-sync is the NSIP of the master node (NSIP of the configuration coordinator in a cluster setup).
If you use the saveconfig option, the sites that participate in the synchronization process automatically save their configuration, in the following way:

1. The master node saves its configuration immediately before it initiates the process of synchronization.
2. After the process of synchronization is complete, the slave nodes save their configuration. A slave node saves its configuration only if the configuration difference was applied successfully on it. If synchronization fails on a slave node, you must manually investigate the cause of the failure and take corrective action.

Limitations of synchronization:

- On the master node, the names of the remote GSLB sites must be identical to the names of sites configured on the NetScaler appliances hosting those sites.
- During the synchronization, traffic disruptions may occur.
- NetScaler can synchronize only up to 80000 lines of the configuration.
- Synchronization may fail:
  - If the spill over method is changed from CONNECTION to DYNAMIC CONNECTION.
  - If you interchange the site prefix of the GSLB services bound to a GSLB virtual server on the master node and then try to synchronize.
  - If the RPC node passwords are different for NetScaler IP address (NSIP) and loopback IP address.
- If you have configured the GSLB sites as High Availability (HA) pairs, the RPC node passwords of primary and secondary nodes should be same.
- If you rename any GLSB entity that are part of your GSLB configuration (use “show gslb runningConfig” command to display the GSLB configuration). You need to use the force sync option to synchronize the configuration to other GSLB sites.

Note: To overcome the limitations due to some settings in the GSLB configuration, you can use the force sync option. But, if you use the force sync option the GSLB entities are removed and re-added to the configuration and the GSLB statistics are reset to zero. Hence the traffic is disrupted during the configuration change.
Before you start the synchronization of a GSLB setup, make sure that:

- On all the GSLB sites including the master node, management access should be enabled for the IP address of the corresponding GSLB site. The IP address of a GSLB site must be an IP address owned by the NetScaler.
  For more information about adding the GSLB site IP addresses and enabling Management Access, see "Configuring a Basic GSLB Site" and "Configuring NetScaler-Owned IP Addresses".
- The GSLB configuration on the NetScaler appliance that is considered as the master node is complete and appropriate to be copied on all the sites.
- If you are synchronizing the GSLB configuration for the first time, all the sites participating in GSLB need to have the GSLB site entity of their respective local sites.
- You are not synchronizing sites that, by design, do not have the same configuration.

Important: After a GSLB configuration is synchronized, the configuration cannot be rolled back on any of the GSLB sites. Run the **sync gslb config** command only if you are sure that the synchronization process will not overwrite the configuration on the remote site. Site synchronization is undesirable when the local and remote sites have different configurations by design, and can lead to site outage. If some commands fail and some commands succeed, the successful commands cannot be rolled back.

At the command prompt, type the following commands to synchronize GSLB sites and verify the configuration:

- sync gslb config [-preview | -forceSync <string> | -nowarn | -saveconfig] [-debug]
- show gslb syncStatus

Example

```
> sync gslb config
[WARNING]: Syncing config may cause configuration loss on other site.
Please confirm whether you want to sync-config (Y/N)? [N]:y
Sync Time: Dec 9 2011 10:56:9
Retrieving local site info: ok
Retrieving all participating gslb sites info: ok
Gslb_site1[Master]:
      Getting Config: ok
Gslb_site2[Slave]:
      Getting Config: ok
      Comparing config: ok
       Applying changes: ok
Done
```

1. Navigate to Traffic Management > GSLB.
2. In the GSLB pane, under GSLB Configuration, click Synchronize configuration on remote sites.
3. In the Synchronize GSLB Configuration dialog box, select one of the following settings from the Synchronization Option list:

- Preview
- Force Sync
- Debug

4. If you select Force Sync as the synchronization option, in the GSLB Site Name text box, type the name of the remote site that you want to synchronize with the local site, or type all-sites.
5. If you want the participating sites to save their configuration automatically, select Save Configuration.
6. Click Run.
7. If you want to save the output of the Run command to your local system, click Save output text to a file.
8. Click Close.

Viewing and Configuring a GSLB Setup by Using the GSLB Visualizer

Sep 23, 2013

The configuration utility includes a GSLB Visualizer tool, which provides an alternative way to view and configure entities in a GSLB configuration. The visualizer displays all configured GSLB domains, GSLB services, GSLB sites, ADNS services, and any monitors that are bound to the services. It also displays all the load balancing, content switching, cache redirection, and NetScaler Gateway virtual servers that the GSLB services represent.

If you want to view the configurations of remote GSLB sites, you must configure the sites with public IP addresses and enable management access for each of them.

You can use the GSLB Visualizer to perform the following GSLB configuration tasks:

- Add, view, and configure GSLB domains and GSLB services.
- View and configure GSLB sites and ADNS services for each site.
- View and configure any monitors that are bound to the services.
- View and configure the content switching, load balancing, cache redirection, or NetScaler Gateway virtual server that each GSLB service represents.
- View statistics for GSLB domains, sites, ADNS services, and virtual servers.
- View configuration details of any displayed entity.
- View load balancing and content switching virtual servers.
- View bindings for GSLB services, ADNS services, monitors, and virtual servers.
- Enable and disable GSLB services, ADNS services, monitors, and virtual servers.
- Copy the properties of any displayed entity to a document or spreadsheet.
- Remove a domain from the GSLB setup.
- Save the visual representation of the GSLB setup as an image.

1. Navigate to Traffic Management > GSLB.
2. In the details pane, under Getting Started, click GSLB Visualizer, and then do the following.
   - To pan the view of the displayed image, click as blank area of the image, hold down the mouse button, and drag the image.
   - To adjust the viewable area click Zoom In to increase or Zoom Out to decrease the size of the objects. You can readjust the viewable area by clicking Best Fit.
   - To locate a specific item, begin typing the item's name in the Search field. Entities whose names match the typed characters are highlighted. Continue typing until the item is uniquely identified. To clear the Search field, click the x adjacent to the field.

1. Open the GSLB Visualizer and click Domain. Alternatively, if domains already exist in the GSLB setup, click the name of an existing domain.
2. Under Related Tasks, click Add.
3. Follow the instructions in the GSLB Wizard to add a GSLB domain and configure GSLB services and sites for the domain.

Open the GSLB Visualizer and do one of the following:

- To view a brief summary of an entity, place the pointer on the entity. A brief summary of the entity appears at the bottom of the viewable area.
- To view the detailed configuration information of the entity, click the entity. The configuration details for that entity appear in the Details area.

Open the GSLB Visualizer and do one of the following:

- Click the entity that you want to modify. Then, under Related Tasks, click Open.
- Double-click the entity that you want to modify.
- Right-click the entity that you want to modify, and then click Open. (This option is not available for GSLB sites.)

Open the GSLB Visualizer and do one of the following:

- Click the entity whose binding information you want to view, and then, under Related Tasks, click Show Bindings.
- Right-click the entity, and then click Show Bindings.

Open the GSLB Visualizer and do one of the following:

- Click the load balancing or content switching virtual server whose Visualizer you want to view, and then, under Related Tasks, click Visualizer.
- Right-click the virtual server, and then click Visualizer.

Open the GSLB Visualizer and do one of the following:

- Click the entity whose statistics you want to view, and then, under Related Tasks, click Statistics.
- Right-click the entity whose statistics you want to view, and then click Statistics. (This option is not available for GSLB sites.)

Open the GSLB Visualizer and do one of the following to enable or disable the entity:

- To enable the entity, click the entity and, under Related Tasks, click Enable. Alternatively, right-click the entity that you want to enable, and then click Enable.
- To disable the entity, click the entity and, under Related Tasks, click Disable. Alternatively, right-click the entity that you want to disable, and then click Disable.

Open the GSLB Visualizer and do one of the following:

- Click the entity whose properties you want to copy, and then, under Related Tasks, click Copy Properties.
- Right-click the entity, and then click Copy. (This option is not available for GSLB sites.)

1. Open the GSLB Visualizer.

2. If necessary, adjust the viewable area by using the Best Fit, Zoom In, and Zoom Out buttons.
3. Click Save Image.
4. In the Save Graph Image dialog box, browse to the folder in which you want to save the image.
5. In File Name text box, type the name, and then click Save.

1. Open the GSLB Visualizer and do one of the following:
   - Click the domain that you want to remove, and then, under Related Tasks, click Remove.
   - Right-click the domain, and then click Remove.
2. Under Remove?, click Yes.

Configuring the Metrics Exchange Protocol (MEP)

May 21, 2015

The data centers in a GSLB setup exchange metrics with each other through the metrics exchange protocol (MEP), which is a proprietary protocol for the Citrix NetScaler. The exchange of the metric information begins when you create a GSLB site. These metrics comprise load, network, and persistence information.

MEP is required for health checking of data centers to ensure their availability. A connection for exchanging network metrics can be initiated by either of the data centers involved in the exchange, but a connection for exchanging site metrics is always initiated by the data center with the lower IP address. By default, the data center uses a subnet IP address (SNIP) or a mapped IP address (MIP) to establish a connection to the IP address of a different data center. However, you can configure a specific SNIP, MIP, the NetScaler IP address (NSIP), or a virtual IP address (VIP) as the source IP address for metrics exchange. The communication process between GSLB sites uses TCP port 3011 or 3009, so this port must be open on firewalls that are between the NetScaler appliances.
Note: You cannot configure a GSLB site IP address as the source IP address for site metrics exchange.
If the source and target sites for a MEP connection (the site that initiates a MEP connection and the site that receives the connection request, respectively) have both private and public IP addresses configured, the sites exchange MEP information by using the public IP addresses.

You can also bind monitors to check the health of remote services. When monitors are bound, metric exchange does not control the state of the remote service. If a monitor is bound to a remote service and metrics exchange is enabled, the monitor controls the health status. Binding the monitors to the remote service allows the NetScaler to interact with a non-NetScaler load balancing device. The NetScaler can monitor non-NetScaler devices but cannot perform load balancing on them. The NetScaler can monitor non-NetScaler devices, and can perform load balancing on them if monitors are bound to all GSLB services and only static load balancing methods (such as the round robin, static proximity, or hash-based methods) are used.

This document includes the following information:

- Configuring Site Metric Exchange
- Configuring Network Metric Information Exchange
- Configuring Persistence Information Exchange

Updated: 2014-11-24

Site metrics exchanged between the GSLB sites include the status of each load balancing and content switching virtual server, the current number of connections, the current packet rate, and current bandwidth usage information.

The NetScaler appliance needs this information to perform load balancing between the sites. The site metric exchange interval is 1 second. A remote GSLB service must be bound to a local GSLB virtual server to enable the exchange of site metrics with the remote service.

To enable or disable site metric exchange by using the command line interface

At a command prompt, type the following commands to enable or disable site metric exchange and verify the configuration:

- set gslb site <siteName> -metricExchange(ENABLED | DISABLED)
- show gslb site <siteName>

Example

```
set gslb site Site-GSLB-East-Coast -metricExchange ENABLED
set gslb site Site-GSLB-East-Coast -metricExchange DISABLED
show gslb site Site-GSLB-East-Coast
```

To enable or disable site metric exchange by using the configuration utility

1. Navigate to Traffic Management > GSLB > Sites.
2. In the details pane, select the site, and then click Open.
3. In the Configure GSLB Site dialog box, select or clear the check box next to the Metric Exchange and click OK.

Updated: 2014-11-24

You can enable or disable the exchange of round trip time (RTT) information about the client's local DNS when the GSLB dynamic method (RTT) is enabled. This information is exchanged every 5 seconds.

For details about changing the GSLB method to a method based on RTT, see Changing the GSLB Method.

To enable or disable network metric information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable network metric information exchange and verify the configuration:

- set gslb site <siteName> -nwmetricExchange (ENABLED | DISABLED)
- show gslb site <<siteName>

Example

```
set gslb site Site-GSLB-East-Coast -nwmetricExchange ENABLED
set gslb site Site-GSLB-East-Coast -nwmetricExchange DISABLED
show gslb site Site-GSLB-East-Coast
```

To enable or disable network metric information exchange by using the configuration utility

1. Navigate to Traffic Management > GSLB > Sites.
2. In the details pane, select the site, and then click Open.
3. In the Configure GSLB Site dialog box, select or clear the check box next to the Network Metric Exchange and click OK.

Updated: 2014-11-24

You can enable or disable the exchange of persistence information at each site. This information is exchanged every 5

seconds between NetScaler appliances participating in GSLB.

For details about configuring persistence, see "Configuring Persistent Connections".

To enable/disable persistence information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable persistence information exchange and verify the configuration:

- set gslb site <siteName> -sessionExchange (ENABLED | DISABLED)
- show gslb site <siteName>

Example

```
set gslb site Site-GSLB-East-Coast -sessionExchange  ENABLED
set gslb site Site-GSLB-East-Coast -sessionExchange  DISABLED
show gslb site Site-GSLB-East-Coast
```

To enable/disable persistence information exchange by using the configuration utility

1. Navigate to Traffic Management > GSLB > Sites.
2. In the details pane, select the site, and then click Open.
3. In the Configure GSLB Site dialog box, select or clear the check box next to the Persistence Session Entry Exchange and click OK.

Configuring Site-to-Site Communication

Jun 02, 2015

GSLB site-to-site communication is between the remote procedure call (RPC) nodes that are associated with the communicating sites. A master GSLB site establishes connections with slave sites to synchronize GSLB configuration information and to exchange site metrics.

An RPC node is created automatically when a GSLB site is created, and is assigned an internally generated user name and password. The NetScaler appliance uses this user name and password to authenticate itself to remote GSLB sites during connection establishment. No configuration steps are necessary for an RPC node, but you can specify a password of your choice, enhance security by encrypting the information that GSLB sites exchange, and specify a source IP address for the RPC node.

The appliance needs a NetScaler-owned IP address to use as the source IP address when communicating with other GSLB sites. By default, the RPC nodes use either a subnet IP (SNIP) address or a mapped IP (MIP) address, but you might want to specify an IP address of your choice.

The following topics describe the behavior and configuration of RPC nodes on the NetScaler appliance:

- Changing the Password of an RPC Node
- Encrypting the Exchange of Site Metrics
- Configuring the Source IP Address for an RPC Node

Updated: 2014-11-21

You can secure the communication between sites in your GSLB setup by changing the password of each RPC node. After you change the password for the RPC node of the local site, you must manually propagate the change to the RPC node at each of the remote sites.

The password is stored in encrypted form. You can verify that the password has changed by using the **show rpcNode** command to compare the encrypted form of the password before and after the change.

To change the password of an RPC node by using the command line interface

At the command line, type the following commands to change the password of an RPC node:

- set ns rpcNode <IPAddress> {-password}
- show ns rpcNode

Example

```
> set rpcNode 192.0.2.4 -password mypassword
 Done
> show rpcNode
.
.
.
2) IPAddress:  192.0.2.4 Password:  d336004164d4352ce39e
 SrcIP:  *           Secure:  OFF
```

```
Done
>
```

To unset the password of an RPC node by using the command line interface

To unset the password of an RPC node by using the NetScaler command line, type the unset rpcNode command, the IP address of the RPC node, and the password parameter, without a value.

To change the password of an RPC node by using the configuration utility

1. Navigate to System > Network > RPC.
2. In the details pane, click the RPC node for which you want to change the password, and then click Open.
3. In the Configure RPC Node dialog box, in Password and Confirm Password, specify the password that you want the RPC node to use.

Updated: 2014-11-24

You can secure the information that is exchanged between GSLB sites by setting the secure option for the RPC nodes in the GSLB setup. With the secure option set, the NetScaler appliance encrypts all communication sent from the node to other RPC nodes.

To encrypt the exchange of site metrics by using the command line interface

At the command prompt, type the following commands to encrypt the exchange of site metrics and verify the configuration:

- set ns rpcNode <IPAddress> [-secure (YES | NO)]
- show rpcNode

Example

```
> set rpcNode 192.0.2.4 -secure YES
 Done
>
> show rpcNode
.
.
.
3) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP: 192.0.2.3    Secure: ON
 Done
>
```

To unset the secure parameter by using the command line interface

To unset the secure parameter by using the NetScaler command line, type the unset rpcNode command, the IP address of the RPC node, and the secure parameter, without a value.

To encrypt the exchange of site metrics by using the NetScaler configuration utility

1. Navigate to System > Network > RPC.
2. In the details pane, click the RPC node whose communication you want to encrypt, and then click Open.

3. In the Configure RPC Node dialog box, click Secure.
4. Click OK.

Updated: 2014-11-24

By default, the NetScaler appliance uses a NetScaler-owned subnet IP (SNIP) address or mapped IP (MIP) address as the source IP address for an RPC node, but you can configure the appliance to use a specific SNIP address or MIP address. If neither a SNIP address nor a MIP address is available, the GSLB site cannot communicate with other sites. In such a scenario, you must configure either the NetScaler IP (NSIP) address or a virtual IP (VIP) address as the source IP address for an RPC node. A VIP address can be used as the source IP address of an RPC node only if the RPC node is a remote node. If you configure a VIP address as the source IP address and remove the VIP address, the appliance uses a SNIP address or a MIP address.

To specify a source IP address for an RPC node by using the command line interface

At the command prompt, type the following commands to change the source IP address for an RPC node and verify the configuration:

- set ns rpcNode <IPAddress> [-srcIP <ip_addr|ipv6_addr|*>]
- show ns rpcNode

Example

```
> set rpcNode 192.0.2.4 -srcIP 192.0.2.3
 Done
> show rpcNode
.
.
.
2) IPAddress:  192.0.2.4 Password:  d336004164d4352ce39e SrcIP:  192.0.2.3      Secure:  OFF
 Done
>
```

To unset the source IP address parameter by using the command line interface

To unset the source IP address parameter by using the NetScaler command line, type the unset rpcNode command, the IP address of the RPC node, and the srcIP parameter, without a value.

To specify a source IP address for an RPC node by using the NetScaler configuration utility

1. Navigate to System > Network > RPC.
2. In the details pane, click the RPC node for which you want to assign a specific source IP address for site metrics exchange, and then click Open.
3. In the Configure RPC Node dialog box, in Source IP Address, enter the IP address that you want the RPC node to use as the source IP address.

Customizing Your GSLB Configuration

May 21, 2015

Once your basic GSLB configuration is operational, you can customize it by modifying the bandwidth of a GSLB service, configuring CNAME based GSLB services, static proximity, dynamic RTT, persistent connections, or dynamic weights for services, or changing the GSLB Method.

You can also configure monitoring for GSLB services to determine their states.

These settings depend on your network deployment and the types of clients you expect to connect to your servers.

This document includes the following information:

- Modifying Maximum Connections or Maximum Bandwidth for a GSLB Service
- Creating CNAME-Based GSLB Services
- Configuring Transition Out-Of-Service State (TROFS) in GSLB
- Configuring Dynamic Weights for Services

Updated: 2014-11-26

You can restrict the number of new clients that can simultaneously connect to a load balancing or content switching virtual server by configuring the maximum number of clients and/or the maximum bandwidth for the GSLB service that represents the virtual server.

To modify the maximum clients or bandwidth of a GSLB service by using the command line interface

At the command prompt, type the following command to modify the maximum number of client connections or the maximum bandwidth of a GSLB service and verify the configuration:

- set gslb service <serviceName> [-maxClients <positive_integer>] [-maxBandwidth <positive_integer>]
- show gslb service <serviceName>

Example

```
set glsb service Service-GSLB-1 –maxBandwidth 100 –maxClients 100
show gslb service Service-GSLB-1
```

To modify the maximum clients or bandwidth of a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. In the details pane, select the service to be modified and click Open.
3. In the Configure GSLB Service dialog box specify values for one or both of the following parameters:
   - Max Clients—maxClients
   - Max Bandwidth—maxBandwidth

4. Click OK.
5. Verify that the Details area displays the values that you entered.

Updated: 2014-11-24

To configure a GSLB service, you can use the IP address of the server or a canonical name of the server. If you want to run multiple services (like an FTP and a Web server, each running on different ports) from a single IP address or run multiple HTTP services on the same port, with different names, on the same physical host, you can use canonical names (CNAMES) for the services.

For example, you can have two entries in DNS as ftp.example.com and www.example.com for FTP services and HTTP services on the same domain, example.com. CNAME-based GSLB services are useful in a multilevel domain resolver configuration or in multilevel domain load balancing. Configuring a CNAME-based GSLB service can also help if the IP address of the physical server is likely to change.

If you configure CNAME-based GSLB services for a GSLB domain, when a query is sent for the GSLB domain, the NetScaler appliance provides a CNAME instead of an IP address. If the A record for this CNAME record is not configured, the client must query the CNAME domain for the IP address. If the A record for this CNAME record is configured, the NetScaler provides the CNAME with the corresponding A record (IP address). The NetScaler appliance handles the final resolution of the DNS query, as determined by the GSLB method. The CNAME records can be maintained on a different NetScaler appliance or on a third-party system.

In an IP-address-based GSLB service, the state of a service is determined by the state of the server that it represents. However, a CNAME-based GSLB service has its state set to UP by default; the virtual server IP (VIP) address or metric exchange protocol (MEP) are not used for determining its state. If a desktop-based monitor is bound to a CNAME-based GSLB service, the state of the service is determined according to the result of the monitor probes.

You can bind a CNAME-based GSLB service only to a GSLB virtual server that has the DNS Record Type as CNAME. Also, a NetScaler appliance can contain at most one GSLB service with a given CNAME entry.

The following are some of the features supported for a CNAME-based GSLB service:
- GSLB-policy based site affinity is supported, with the CNAME as the preferred location.
- Source IP persistence is supported. The persistency entry contains the CNAME information instead of the IP address and port of the selected service.

The following are the limitations of CNAME-based GSLB services:
- Site persistence is not supported, because the service referenced by a CNAME can be present at any third-party location.
- Multiple-IP-address response is not supported because one domain cannot have multiple CNAME entries.
- Source IP Hash and Round Robin are the only load balancing methods supported. The Static Proximity method is not supported because a CNAME is not associated with an IP address and static proximity can be maintained only according to the IP addresses.

Note: The Empty-Down-Response feature should be enabled on the GSLB virtual server to which you bind the CNAME-based GSLB service. If you enable the Empty-Down-Response feature, when a GSLB virtual server is DOWN or disabled, the response to a DNS query, for the domains bound to this virtual server, contains an empty record without any IP addresses, instead of an error code.

To create a CNAME-based GSLB service by using the command line interface

At the command prompt, type:

add gslb service <serviceName> -cnameEntry <string> -siteName <string>

Example

```
add gslb service Service-GSLB-1 -cnameEntry transport.mycompany.com -siteName Site-GSLB-East-Coast
add gslb service Service-GSLB-2 -cnameEntry finance.mycompany.com -siteName Site-GSLB-West-Coast
```

To create a CNAME-based GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. In the details pane, click Add.
3. In the Create GSLB Service dialog box, set the following parameters:
   - Service Name*
   - Site Name*
   - Type should be Canonical name based.
   - DNS Canonical name*

   * A required parameter
4. Click Create, and then click Close.

When you configure persistence on a GSLB virtual server to which a service is bound, the service continues to serve requests from the client even after it is disabled, accepting new requests or connections only to honor persistence. After a configured period of time, known as the graceful shutdown period, no new requests or connections are directed to the service, and all of the existing connections are closed.

When disabling a service, you can specify a graceful shutdown period, in seconds, by using the delay argument. During the graceful shutdown period, if the service is bound to a virtual server, its state appears as Out of Service.

Updated: 2015-06-02

In a typical network, there are servers that have a higher capacity for traffic than others. However, with a regular load balancing configuration, the load is evenly distributed across all services even though different services represent servers with different capacities.

To optimize your GSLB resources, you can configure dynamic weights on a GSLB virtual server. The dynamic weights can be based on either the total number of services bound to the virtual server or the sum of the weights of the individual services bound to the virtual server. Traffic distribution is then based on the weights configured for the services.

When dynamic weights are configured on the GSLB virtual server, requests are distributed according to the load balancing method, the weight of the GSLB service, and the dynamic weight. The product of the weight of the GSLB service and the dynamic weight is known as the cumulative weight. Therefore, when dynamic weight is configured on the GSLB virtual server, requests are distributed on the basis of the load balancing method and the cumulative weight.

When dynamic weight for a virtual server is disabled, the numerical value is set to 1. This ensures that the cumulative weight is a non-zero integer at all times.

Dynamic weight can be based on the total number of active services bound to load balancing virtual servers or on the weights assigned to the services.

Consider a configuration with two GSLB sites configured for a domain and each site has two services that can serve the client. If a service at either site goes down, the other server in that site has to handle twice as much traffic as a service at the other site. If dynamic weight is based on the number of active services, the site with both services active has twice the weight of the site with one service down and therefore receives twice as much traffic.

Alternatively, consider a configuration in which the services at the first site represent servers that are twice as powerful as servers at the second site. If dynamic weight is based on the weights assigned to the services, twice as much traffic can be sent to the first site as to the second.

Note: For details on assigning weights to load balancing services, see " Assigning Weights to Services".
As an illustration of how dynamic weight is calculated, consider a GSLB virtual server that has a GSLB service bound to it. The GSLB service represents a load balancing virtual server that in turn has two services bound to it. The weight assigned to the GSLB service is 3. The weights assigned to the two services are 1 and 2 respectively. In this example, when dynamic weight is set to:

- **Disabled**:The cumulative weight of the GSLB virtual server is the product of the dynamic weight (disabled = 1) and the weight of the GSLB service (3), so the cumulative weight is 3.
- **SERVICECOUNT**: The count is the sum of the number of services bound to the load balancing virtual servers corresponding to the GSLB service (2), and the cumulative weight is the product of the dynamic weight (2) and the weight of the GSLB service (3), which is 6.
- **SERVICEWEIGHT**: The dynamic weight is the sum of the number of services bound to the GSLB service (2), and the cumulative weight is the product of the dynamic weight (2) and the weight of the GSLB service (3), which is 6.

Note: Dynamic weights are not applicable when content switching virtual servers are configured.

To configure a GSLB virtual server to use dynamic weights by using the command line interface

At the command prompt, type:

set gslb vserver <name> -dynamicWeight SERVICECOUNT | SERVICEWEIGHT
Example

set gslb vserver vserver-GSLB-1 -dynamicWeight SERVICECOUNT

To set GSLB virtual server to use dynamic weights by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the GSLB Virtual Servers pane, select the GSLB virtual server for which you want to set dynamic weights (for example, vserver-GSLB-1).
3. Click Open.
4. On the Method and Persistence tab, under Method, select SERVICECOUNT or SERVICEWEIGHT from the Dynamic Weight list.
5. Click OK.

Changing the GSLB Method

Mar 22, 2012

Unlike traditional DNS servers that simply respond with the IP addresses of the configured servers, a NetScaler appliance configured for GSLB responds with the IP addresses of the services, as determined by the configured GSLB method. By default, the GSLB virtual server is set to the least connection method. If all GSLB services are down, the NetScaler responds with the IP addresses of all the configured GSLB services.

GSLB methods are algorithms that the GSLB virtual server uses to select the best-performing GSLB service. After the host name in the Web address is resolved, the client sends traffic directly to the resolved service IP address.

The NetScaler appliance provides the following GSLB methods:

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

For GSLB methods to work with a remote site, either MEP must be enabled or explicit monitors must be bound to the remote services. If MEP is disabled, RTT, Least Connections, Least Bandwidth, Least Packets and Least Response Time methods default to Round Robin.

The Static Proximity and RTT load balancing methods are specific to GSLB.

Updated: 2013-11-11

For information about the Round Robin, Least Connections, Least Response Time, Least Bandwidth, Least Packets, Source IP Hash, or Custom Load method, see "Load Balancing."

To change the GSLB method by using the command line interface

At the command prompt, type:

set gslb vserver <name> -lbMethod GSLBMethod

Example

set gslb vserver Vserver-GSLB-1 -lbMethod ROUNDROBIN

To change the GSLB method by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the details pane, select a GSLB virtual server and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Method and Persistence tab, under Method, select a method from the Choose Method list.

4. Click OK, and verify that the method you selected appears under Details at the bottom of the screen.

Configuring Static Proximity

May 22, 2015

The static proximity method for GSLB uses an IP-address based static proximity database to determine the proximity between the client's local DNS server and the GSLB sites. The NetScaler appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the NetScaler appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

For the static proximity method to work, you must either configure the NetScaler appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the GSLB method.

This document includes the following information:

- Adding a Location File to Create a Static Proximity Database
- Adding Custom Entries to a Static Proximity Database
- Setting the Location Qualifiers
- Specifying the Proximity Method
- Synchronizing GSLB Static Proximity Database

Adding a Location File to Create a Static Proximity Database

Dec 22, 2014

A static proximity database is a UNIX-based ASCII file. Entries added to this database from a location file are called static entries. Only one location file can be loaded on a NetScaler appliance. Adding a new location file overrides the existing file. The number of entries in the static proximity database is limited by the configured memory in the NetScaler appliance.

The static proximity database can be created in the default format or in a format derived from commercially configured third party databases (such as www.maxmind.com and www.ip2location.com).

These databases vary in the details they provide. There is no strict enforcement of the database file format, except that the default file has format tags. The database files are ASCII files that use a comma as the field delimiter. There are differences in the structure of fields and the representation of IP addresses in the locations.

The format parameter describes the structure of the file to the NetScaler appliance. Specifying an incorrect value for the format option can corrupt the internal data.

Note: The default location of the database file is /var/netscaler/locdb, and on a high availability (HA) setup, an identical copy of the file must be present in the same location on both NetScaler appliances.
The following abbreviations are used in this section:

- **CSHN**. Short name of a country based on the country code standard of ISO-3166.
- **LCN**. Long name of the country.
- **RC**. Region code based on ISO-3166-2 (for US and Canada). The region code “FIPS-10-4” is used for the other regions.

Note: Some databases provide short country names according to ISO-3166 and long country names as well. The NetScaler uses short names when storing and matching qualifiers.
To create a static proximity database, log on to the UNIX shell of the NetScaler appliance and use an editor to create a file with the location details in one of the NetScaler-supported formats.

To add a static location file by using the command line interface

At the command prompt, type:

- add locationFile <locationFile> [-format <format>]
- show locationFile

Example

```
> add locationFile /var/nsmap/locdb/nsgeo1.0 -format netscaler
 Done
> show locationFile
Location File: /var/nsmap/locdb/nsgeo1.0
Format: netscaler
 Done
>
```

To add a static location file by using the configuration utility

1. Navigate to AppExpert > Location, click the **Static Database** tab.

2. Click **Add** to add a static location file.

You can view an imported location file database by using the View Database dialog box in the configuration utility. There is no NetScaler command line equivalent.

To view a static location file by using the configuration utility

1. Navigate to AppExpert > Location, click the **Static Database** tab.
2. Select a static location file, and from the **Action** list, click **View Database**.

To convert a location file into the netscaler format

By default, when you add a location file, it is saved in the netscaler format. You can convert a location file of other formats into the netscaler format.

Note: The nsmap option can be accessed only from the command line interface. The conversion is possible only into the netscaler format.
To convert the static database format, at the NetScaler command prompt, type the following command:

nsmap -f <inputFileFormat> -o <outputFileName> <inputFileName>

Example

```
nsmap -f ip-country-region-city -o nsfile.ns ip-country-region-city.cvs
```

Adding Custom Entries to a Static Proximity Database

Jan 22, 2015

Custom entries take precedence over static entries in the proximity database. You can add a maximum of 500 custom entries. For a custom entry, denote all omitted qualifiers with an asterisk (*) and, if qualifiers have a period or space in the name, enclose the parameter in double quotation marks. The first 31 characters are evaluated for each qualifier. You can also provide the longitude and latitude of the geographical location of the IP address-range for selecting a service with the static proximity GSLB method.

To add custom entries by using the command line interface

At the command prompt, type the following commands to add a custom entry to the static proximity database and verify the configuration:

- add location < IPfrom> < IPto> <preferredLocation> [-longitude <integer>[-latitude <integer>]]
- show location

Example

```
>add location 192.168.100.1 192.168.100.100 *.us.ca.mycity
>show location
```

Parameters for adding custom entries

IPfrom

First IP address in the range, in dotted decimal notation. This is a mandatory argument.

IPto

Last IP address in the range, in dotted decimal notation. This is a mandatory argument.

preferredLocation

String of qualifiers, in dotted notation, describing the geographical location of the IP address range. Each qualifier is more specific than the one that precedes it, as in continent.country.region.city.isp.organization. For example,"NA.US.CA.San Jose.ATT.citrix".

Note: A qualifier that includes a dot (.) or space ( ) must be enclosed in double quotation marks.

This is a mandatory argument. Maximum Length: 197

longitude

Numerical value, in degrees, specifying the longitude of the geographical location of the IP address-range.

Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location.

Maximum value: 180

latitude

Numerical value, in degrees, specifying the latitude of the geographical location of the IP address-range.

Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location.

Maximum value: 180

To add custom entries by using the configuration utility

Navigate to AppExpert > Location, click the **Custom Entries** tab, and add the custom entries.

Setting the Location Qualifiers

Nov 24, 2014

The database used to implement static proximity contains the location of the GSLB sites. Each location contains an IP address range and up to six qualifiers for that range. The qualifiers are literal strings and are compared in a prescribed order at run time. Every location must have at least one qualifier. The meaning of the qualifiers (context) is defined by the qualifier labels, which are user defined. The NetScaler has two built-in contexts:
Geographic context, which has the following qualifier labels:

- Qualifier 1 – “Continent”
- Qualifier 2 – “Country”
- Qualifier 3 – “State”
- Qualifier 4 – “City”
- Qualifier 5 – “ISP”
- Qualifier 6 – “Organization”

Custom entries, which have the following qualifier labels:

- Qualifier 1 – “Qualifier 1”
- Qualifier 2 – “Qualifier 2”
- Qualifier 3 – “Qualifier 3”
- Qualifier 4 – “Qualifier 4”
- Qualifier 5 – “Qualifier 5”
- Qualifier 6 – “Qualifier 6”

If the geographic context is set with no Continent qualifier, Continent is derived from Country. Even the built-in qualifier labels are based on the context, and the labels can be changed. These qualifier labels specify the locations mapped with the IP addresses used to make static proximity decisions.

To perform a static proximity-based decision, the NetScaler appliance compares the location attributes (qualifiers) derived from the IP address of the local DNS server resolver with the location attributes of the participating sites. If only one site matches, the appliance returns the IP address of that site. If there are multiple matches, the site selected is the result of a round robin on the matching GSLB sites. If there is no match, the site selected is a result of a round robin on all configured sites. A site that does not have any qualifiers is considered a match.

To set the location qualifiers by using the command line interface

At the command prompt, type:

set locationparameter -context <context> -q1label <string> [-q2label <string>] [-q3label <string>] [-q4label <string>] [-q5label <string>] [-q6label <string>]
Example

```
set locationparameter -context custom -q1label asia
```

To set the location qualifiers by using the configuration utility

1. Navigate to Traffic Management > GSLB > Location.
2. Click Location Parameters.
3. In the Context drop-down list, select the appropriate context (for example, Custom).
4. In the Qualifier Label -1 text box, type the qualifier (for example asia).

5. Click OK.

Specifying the Proximity Method

Nov 24, 2014

When you have configured the static proximity database, you are ready to specify static proximity as the GLSB method.

To specify static proximity by using the command line interface

At the command prompt, type the following commands to configure static proximity and verify the configuration:

- set gslb vserver <name> -lbMethod STATICPROXIMITY
- show gslb vserver <name>

Example

```
set gslb vserver Vserver-GSLB-1 -lbMethod STATICPROXIMITY
show gslb vserver
```

To specify static proximity by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the GSLB Virtual Servers pane, select the GSLB Virtual Server that you want to set to static proximity (for example, vserver-GSLB-1).
3. Click Open.
4. On the Method and Persistence tab, under Method, select Static Proximity from the Choose Method list.
5. Click OK.
6. Verify that the Details pane shows static proximity as the GSLB method.

Synchronizing GSLB Static Proximity Database

Apr 08, 2014

Synchronizing a global server load balancing (GSLB) static proximity database requires that one of the sites be identified as the master GSLB node. Any site in the topology can be designated as the master node. The rest of the GSLB nodes are automatically designated as slave nodes.

Synchronizing GSLB static proximity databases synchronizes the files in the /var/netscaler/locdb directory across the slave nodes. During the synchronization process, the master node fetches the running configuration from each of the slave nodes and compares it to the configuration on the master node. The master GSLB node uses the rsync program to synchronize the static proximity database across the slave nodes. To speed up the synchronization process, the rsync program makes only enough changes to eliminate the differences between the two files. The synchronization process cannot be rolled back.

The following example synchronizes Site2, which is a slave site, to master site Site1. The administrator enters the **sync gslb config** command on Site1:

```
sync gslb config -nowarn
Sync Time: Feb 24 2014 14:56:16
Retrieving local site info: ok
Retrieving all participating gslb sites info:
0 bytes in 0 blocks
ok
site1[Master]:
      Getting Config: ok
site2[Slave]:
      Syncing gslb static proximity database: ok
      Getting Config: ok
      Comparing config: ok
      Applying changes: ok
 Done
```

Configuring the Dynamic Method (RTT)

May 22, 2015

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client's local DNS server and a data resource. To measure dynamic RTT, the NetScaler appliance probes the client's local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value.

When a client's DNS request for a domain comes to the NetScaler appliance configured as the authoritative DNS for that domain, the appliance uses the RTT value to select the IP address of the best performing site to send it as a response to the DNS request.

The NetScaler appliance uses different mechanisms, such as ICMP echo request / reply (PING), UDP, and TCP to gather the RTT metrics for connections between the local DNS server and participating sites. The appliance first sends a ping probe to determine the RTT. If the ping probe fails, a DNS UDP probe is used. If that probe also fails, the appliance uses a DNS TCP probe.

These mechanisms are represented on the Netscaler appliance as Load Balancing Monitors and are easily identified due to their use of the "ldns" prefix. The three monitors, in their default order, are:

- ldns-ping
- ldns-dns
- ldns-tcp

These monitors are built in to the appliance and are set to safe defaults, but may be customized just like any other monitor on the appliance.

The default order may also be changed by setting it explicitly as a GSLB parameter. For example, to set the order to be the DNS UDP query followed by the PING and then TCP, type the following command:

set gslb parameter -ldnsprobeOrder DNS PING TCP

Unless they have been customized, the NetScaler appliance performs UDP and TCP probing on port 53, however unlike regular load balancing monitors the probes need not be successful in order to provide valid RTT information. ICMP port unavailable messages, TCP Resets and DNS error responses, which would usually constitute a failure are all acceptable for calculating the RTT value.

Once the RTT data has been compiled, the Netscaler uses the proprietary metrics exchange protocol (MEP) to exchange RTT values between participating sites. After calculating RTT metrics, the appliance sorts the RTT values to identify the data center with the best (smallest) RTT metric."

If RTT information is not available (for example, when a client's local DNS server accesses the site for the first time), the NetScaler appliance selects a site by using the round robin method and directs the client to the site.

To configure the dynamic method, you configure the site's GSLB virtual server for dynamic RTT. You can also set the interval at which local DNS servers are probed to a value other than the default.

This document includes the following information:

- Configuring a GSLB Virtual Server for Dynamic RTT

Configuring a GSLB Virtual Server for Dynamic RTT

Updated: 2014-11-24

To configure a GSLB virtual server for dynamic RTT, you specify the RTT load balancing method.

The NetScaler appliance regularly validates the timing information for a given local server. If a change in latency exceeds the configured tolerance factor, the appliance updates its database with the new timing information and sends the new value to other GSLB sites by performing a MEP exchange. The default tolerance factor is 5 milliseconds (ms).

The RTT tolerance factor must be the same throughout the GSLB domain. If you change it for a site, you must configure identical RTT tolerance factors on all NetScaler appliances deployed in the GSLB domain.

To configure a GSLB virtual server for dynamic RTT by using the command line interface

At the command prompt, type:

set gslb vserver <name> -lbMethod RTT -tolerance <value>
Example

set gslb vserver Vserver-GSLB-1 -lbMethod RTT -tolerance 10

To configure a GSLB virtual server for dynamic RTT by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the GSLB Virtual Servers pane, select the GSLB Virtual server that you want to set to dynamic RTT (for example, vserver-GSLB-1).
3. Click Open.
4. On the Method and Persistence tab, under Method, select Dynamic Method (RTT) from the Choose Method list.
5. To change the tolerance factor, type the new value in the Tolerance (ms) text box.
6. Click OK.

Setting the Probing Interval of Local DNS Servers

Updated: 2014-11-24

The NetScaler appliance uses different mechanisms, such as ICMP echo request / reply (PING), TCP, and UDP to obtain RTT metrics for connections between the local DNS server and participating GSLB sites. By default, the appliance uses a ping monitor and probes the local DNS server every 5 seconds. The appliance then waits 2 seconds for the response and, if a response is not received in that time, it uses the TCP DNS monitor for probing.

However, you can modify the time interval for probing the local DNS server to accommodate your configuration.

To modify the probing interval by using the command line interface

At the command prompt, type:

set lb monitor <monitorName> <type> -interval <integer> <units> -resptimeout <integer> <units>

Example

```
set lb monitor monitor-HTTP-1 HTTP -interval 10 sec -resptimeout 5 sec
```

To modify the probing interval by using the configuration utility

- Navigate to Traffic Management > Load Balancing > Monitors.
- Select the monitor that you want to modify (for example, ping).
- Click Open.
- Click OK.

Configuring Persistent Connections

Jun 04, 2015

Persistence ensures that a series of client requests for a particular domain name is sent to the same data center instead of being load balanced. If persistence is configured for a particular domain, it takes precedence over the configured GSLB method. Persistence is useful for deployments that deal with e-commerce, such as shopping card usage, where the server needs to maintain the state of the connection to track the transaction. To maintain the state of connection, you must configure persistence on a virtual server. With persistence configured, NetScaler selects a data center to process a client request and forwards the IP address of the selected data center for all subsequent DNS requests. If the configured persistence applies to a site that is down, the NetScaler appliance uses a GSLB method to select a new site, and the new site becomes persistent for subsequent requests from the client.

The GSLB virtual server is responsible for DNS-based site persistence, and it controls the site persistence for a remote GSLB service. The NetScaler appliance supports persistence based on the source IP address or on HTTP cookies.

When you bring a physical service DOWN with a delay time, the physical service goes into the transition out of service (TROFS) state. Site persistence is supported as long as the service is in the TROFS state. That is, if the same client sends a request for the same service within the specified delay time after a service is marked TROFS, the same GSLB site (data center) services the request.

Note: If connection proxy is specified as the site persistence method and if you also want to configure persistence of the physical servers, do not configure SOURCEIP persistence. When the connection is proxied, an IP address owned by the NetScaler is used, and not the actual IP address of the client. Configure methods such as cookie persistence or rule-based persistence on the load balancing virtual server.
This document includes the following information:

- Configuring Persistence Based on Source IP Address
- Configuring Persistence Based on HTTP Cookies

Configuring Persistence Based on Source IP Address

Updated: 2014-11-24

With source-IP persistence, when a DNS request is received at a data center, the NetScaler appliance first looks for an entry in the persistence table and, if an entry for the local DNS server exists and the server mentioned in the entry is configured, the IP address of that server is sent as the DNS response.

For the first request from a particular client, the NetScaler appliance selects the best GSLB site for the request and sends its IP address to the client. Since persistence is configured for the source IP address of the client, all subsequent requests by that client or another local DNS server in the same IP subnet are sent the IP address of the GSLB site that was selected for the first request.

For source-IP address based persistence, the same set of persistence identifiers must be configured on the GSLB virtual servers in all data centers. A persistence identifier is a number used by the data centers to identify a particular GSLB virtual server. A cookie transmits the persistence identifier, enabling the NetScaler appliance to identify the domain so that it can forward all appropriate requests to the same domain. When persistence is enabled, the persistence information is also exchanged as part of metrics exchange.

For the NetScaler appliance to support persistence across sites, persistence must be enabled on the GSLB virtual servers of all participating sites. When you use source IP address persistence on the network identifier, you must configure a subnet mask. For any domain, persistence takes precedence over any other configured GSLB method.

To configure persistence based on source IP address by using the command line interface

At the command prompt, type:

set gslb vserver <name> -persistenceType (SOURCEIP | NONE) -persistenceId <positive_integer> [-persistMask <netmask>] – [timeout <mins>]

Example

```
set gslb vserver vserver-GSLB-1 -persistenceType SOURCEIP -persistenceId 23 -persistMask 255.255.255.255 –timeout 2
```

To configure persistence based on source IP address by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the GSLB Virtual Servers pane, select the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
3. Click Open.
4. On the Method and Persistence tab, under Persistence, select SOURCEIP from the Persistence list and specify values for the following parameters as shown:
   - Time-out—timeout
   - Persistence Id—persistenceID
   - IPv4 Netmask or IPv6 Mask length—persistMask
5. Click OK.

Configuring Persistence Based on HTTP Cookies

Updated: 2014-11-26

The NetScaler appliance provides persistence at the HTTP-request level by using connection proxy and HTTP redirect. With these persistence methods, the appliance uses an HTTP cookie (known as a “site cookie”) to reconnect the client to the same server. The NetScaler inserts the site cookie in the first HTTP response.

The site cookie contains information about the selected GSLB service on which the client has a persistent connection. The cookie expiration is based on the cookie timeout configured on the NetScaler appliance. If the virtual server names are not identical on all the sites, you must use the persistence identifier. Cookies inserted are compliant with RFC 2109.

When the NetScaler appliance responds to a client DNS request by sending the IP address of the selected GSLB site, the client sends an HTTP request to that GSLB site. The physical server in that GSLB site adds a site cookie to the HTTP header, and connection persistence is in effect.

If the DNS entry in the client cache expires, and then the client sends another DNS query and is directed to a different GSLB site, the new GSLB site uses the site cookie present in the client request header to implement persistence. If the GSLB configuration at the new site uses connection-proxy persistence, the new site creates a connection to the GSLB site that inserted the site cookie, proxies the client request to the original site, receives a response from the original GSLB site, relays that response back to the client, and closes the connection. If the GSLB configuration uses HTTP redirect persistence, the new site redirects the request to the site that originally inserted the cookie.

Note: Connection proxy persistence can be configured only for local services. However, connection proxy persistence must be enabled on both local and remote GSLB services that are configured for the GSLB virtual server.
Connection proxy occurs when the following conditions are satisfied:

- Requests are sent from a domain participating in GSLB. The domain is obtained from the URL/Host header.
- Requests are sent from a local GSLB service whose public IP address matches the public IP address of an active service bound to the GSLB virtual server.
- The local GSLB service has connection proxy enabled.
- The request includes a valid cookie that contains the IP address of an active remote GSLB service.

If one of the conditions is not met, connection proxy does not occur, but a site cookie is added if the local GSLB service has connection proxy enabled AND:

- No site cookie is supplied; OR,
- The site cookie refers to an IP address that is not an active GSLB remote service; OR,
- The cookie refers to the IP address of the virtual server on which the request is received.

The following are the limitations of using connection proxy site cookies:

- Site cookies do not work for non-HTTP(S) protocols.
- If an HTTP request is sent to a back-up virtual server, the virtual server does not add a cookie.
- Site cookies do not work if SSL client authentication is required.
- At the local site, the statistics for a GSLB service on a remote site are not the same as the statistics recorded for that service at the remote site. At the local site, the statistics for a remote GSLB service are slightly higher than the statistics that the remote site records

for that same service.

Redirect persistence can be used only:

- For HTTP or HTTPS protocols.
- If the domain name is present in the request (either in the URL or in the HOST header), and the domain is a GSLB domain.
- When the request is received on a backup VIP or a GSLB local service that is in the down state.

To set persistence based on HTTP cookies by using the command line interface

At the command prompt, type:

set gslb service <serviceName> -sitePersistence (ConnectionProxy [-sitePrefix <prefix>] | HTTPredirect -sitePrefix <prefix>)

Example

```
set gslb service service-GSLB-1 -sitePersistence ConnectionProxy
set gslb service service-GSLB-1 -sitePersistence HTTPRedirect -sitePrefix vserver-GSLB-1
```

To set persistence based on cookies by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. In the GSLB Services pane, select the service that you want to configure for site persistence (for example, service-GSLB-1).
3. Click Open.
4. On the Advanced tab, under Site Persistence type, specify values for the following parameters as shown:
   - Site Persistence type—sitePersistence
   - Site Prefix—sitePrefix
5. Click OK.

Overriding Static Proximity Behavior by Configuring Preferred Locations

Mar 22, 2012

You might want to direct traffic from a local DNS (LDNS) server or network to a GSLB service other than the GSLB service that the static proximity method selects for that traffic. That is, you have a *preferred location* for that traffic. To override the static proximity method with preferred locations, you can do the following:

1. Configure a DNS action that consists of a list of preferred locations. For more information about configuring a DNS action, see Configuring a DNS Action.
2. Configure a DNS policy to identify the traffic arriving from the LDNS server or network for which you want to override static proximity, and apply the action in the policy.
3. Bind the policy to the global request bind point.

In the DNS action, you can configure a list of up to 8 preferred locations. The locations must be provided in the dotted qualifier notation, which is the notation in which you add custom locations to the static proximity database. The locations can include wildcards for qualifiers that you want to omit. For information about the dotted qualifier notation for locations, see Adding Custom Entries to a Static Proximity Database. When entering the preferred locations, you must enter them in the descending order of priority.

When a policy evaluates to TRUE, the NetScaler appliance matches the preferred locations, in priority order, with the locations of GSLB services. Matches are of the following two types:

- If all the non-wildcard qualifiers in a preferred location match the corresponding qualifiers in the location of a GSLB service, the match is considered a perfect match. For example, a GSLB service location of *.UK.*.* or Europe.UK.*.* is a perfect match for the preferred location *.UK.*.*.
- If only a subset of the non-wildcard qualifiers match, the match is considered a partial match. For example, a GSLB service location of Europe.EG is a partial match for the preferred location Europe.UK.

When a DNS policy evaluates to TRUE, the following algorithm is used to select a GSLB service:

1. The appliance evaluates the preferred location that has the highest priority and moves down the priority order until a perfect match is found between a preferred location and the location of a GSLB service.

   If a perfect match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple perfect matches are found (which can happen when one or more wildcards are used in a preferred location), the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

2. If a perfect match is not found for any of the preferred locations, the appliance returns to the preferred location that has the highest priority and moves down the priority order until a partial match is found between a preferred location and the location of a GSLB service.

   If a partial match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple partial matches are found, the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

3. If none of the perfect and partial matches are up, the appliance load balances all other available GSLB services.

In this way, the appliance implements a type of site affinity for traffic that matches the DNS policy.

Example

Consider a GSLB configuration that consists of the following eight GSLB services:

- Asia.IN
- Asia.JPN
- Asia.HK
- Europe.UK
- Europe.RU
- Europe.EG
- Africa.SD
- Africa.ZMB

Further consider the following DNS action and policy configuration:

```
> add dns action prefLoc11 GslbPrefLoc -preferredLocList "Asia.HK" "Europe.UK"
 Done
> add dns policy dnsPolPrefLoc "CLIENT.IP.SRC.MATCHES_LOCATION(\"*.ZMB.*.*\")" prefLoc11
 Done
```

When the appliance receives a request from the location *.ZMB.*.*, the preferred locations are evaluated as follows:

1. The appliance attempts to find a GSLB service whose location is a perfect match for Asia.HK, which is the preferred location that has the highest priority. It finds that the GSLB service at Asia.HK is a perfect match. If the GSLB service is up, it sends the client the IP address of the GSLB service.
2. If the GSLB service at Asia.HK is down, the appliance attempts to find a perfect match for the second preferred location, Europe.UK. It finds that the GSLB service at Europe.UK is a perfect match. If the GSLB service is up, it sends the client the IP address of the service.
3. If the GSLB service at Europe.UK is down, it returns to the preferred location that has the highest priority, Asia.HK, and looks for partial matches. For Asia.HK, it finds that Asia.IN and Asia.JPN are partial matches. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
4. If all partial matches for Asia.HK are down, the appliance looks for partial matches for Europe.UK. It finds that Europe.RU and Europe.EG are partial matches for the preferred location. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
5. If all partial matches for Europe.UK are down, the appliance load balances all other available GSLB services. In the current example, the appliance load balances Africa.SD and Africa.ZMB because the remaining six GSLB services have been found to be down.

Monitoring GSLB Services

May 22, 2015

When you bind a remote service to a GSLB virtual server, the GSLB sites exchange metric information, including network metric Information, which is the round-trip-time and persistence Information.

If a metric exchange connection is momentarily lost between any of the participating sites, the remote site is marked as DOWN and load balancing is performed on the remaining sites that are UP. When metric exchange for a site is DOWN, the remote services belonging to the site are marked DOWN as well.

The NetScaler appliance periodically evaluates the state of the remote GSLB services by using either MEP or monitors that are explicitly bound to the remote services. Binding explicit monitors to local services is not required, because the state of the local GSLB service is updated by default using the MEP. However, you can bind explicit monitors to a remote service. When monitors are explicitly bound, the state of the remote service is not controlled by the metric exchange.

By default, when you bind a monitor to a remote GSLB service, the NetScaler appliance uses the state of the service reported by the monitor. However, you can configure the NetScaler appliance to use monitors to evaluate services in the following situations:

- Always use monitors (default setting).
- Use monitors when MEP is DOWN.
- Use monitors when remote services and MEP are DOWN.

The second and third of the above settings enable the NetScaler to stop monitoring when MEP is UP. For example, in a hierarchical GSLB setup, a GSLB site provides the MEP information about its child sites to its parent site. Such an intermediate site may evaluate the state of the child site as DOWN because of network issues, though the actual state of the site is UP. In this case, you can bind monitors to the services of the parent site and disable MEP to determine the actual state of the remote service. This option enables you to control the manner in which the states of the remote services are determined.

To use monitors, first create them, and then bind them to GSLB services.

This document includes the following information:

- Adding or Removing Monitors
- Binding Monitors to a GSLB Service

Adding or Removing Monitors

Updated: 2014-11-24

To add a monitor, you specify the type and the port. You cannot remove a monitor that is bound to a service. You must first unbind the monitor from the service.

To add a monitor by using the command line interface

At the command prompt, type the following commands to create a monitor and verify the configuration:

- add lb monitor <monitorName> -type <monitorType> -destPort <portNumber>
- show lb monitor <monitorName>

Example

add lb monitor monitor-HTTP-1 -type HTTP -destPort 80
show lb monitor monitor-HTTP-1

To remove a monitor by using the command line interface

At the command prompt, type:

rm lb monitor <monitorName>

To add a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify values for the following parameters
   - Name*—name
   - Type*—type

   * A required parameter
4. On the Standard Parameters tab, in the Destination Port text box, type the destination port number (see “destPort” in the above parameter list).
5. Click Create, and then click Close.

Binding Monitors to a GSLB Service

Updated: 2014-11-24

Once you create monitors, you must bind them to GSLB services. When binding monitors to the services, you can specify a weight for the monitor. After binding one or more weighted monitors, you can configure a monitor threshold for the service. This threshold takes the service down if the sum of the bound monitor weights falls below the threshold value.

Note: In the configuration utility, you can set both the weight and the monitoring threshold at the same time that you bind the monitor. When using the command line, you must issue a separate command to set the service’s monitoring threshold.

To bind the monitor to the GSLB service by using the command line interface

At the command prompt, type:

bind monitor <name> <serviceName> [-state (**Enabled** | **Disabled**)] -weight <positiveInteger>
Example

bind monitor monitor-HTTP-1 service-GSLB-1 -state enabled -weight 2

To set the monitoring threshold for a GSLB service by using the command line interface

At the command prompt, type:

set gslb service <ServiceName> -monThreshold <PositiveInteger>
Example

set gslb service service-GSLB-1 -monThreshold 9

To bind the monitor to the GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. The details pane, select the service to which you want to bind the monitor (for example, select service-GSLB-1).
3. Click Open.
4. In the Configure GSLB Service dialog box, on the Monitors tab, select the monitor that you want to bind to the service (for example, monitor-HTTP-1).
5. Click Add.
6. In the Configured table, you can select the newly assigned monitor and enter a new weight value.
7. To enable the monitor, make sure the State check box is selected.
8. Repeat the preceding steps to add additional monitors.
9. In the Monitor Threshold text box, you can enter a threshold value.
10. Click OK.

Monitoring GSLB Sites

Nov 24, 2014

The NetScaler appliance uses MEP or monitors to determine the state of the GSLB sites. You can configure a GSLB site to always use monitors (the default), use monitors when MEP is down, or use monitors when both the remote service and MEP are down. In the latter two cases, the NetScaler appliance stops monitoring when MEP returns to the UP state.

To configure monitor triggering by using the command line interface

At the command prompt, type:

set gslb site <siteName> –triggerMonitor (ALWAYS | MEPDOWN | MEPDOWN_SVCDOWN)

Example

```
> set gslb site Site-GSLB-North-America –triggerMonitor Always
 Done
```

To configure monitor triggering by using the configuration utility

1. Navigate to Traffic Management > GSLB > Sites.
2. In the details pane, select the site, and then click Open.
3. In the Configure GSLB Site dialog box, in the Trigger Monitors drop-down list, select an option for when to trigger monitoring.
4. Click OK.

Protecting the GSLB Setup Against Failure

May 22, 2015

You can protect your GSLB setup against failure of a GSLB site or a GSLB virtual server by configuring a backup GSLB virtual server, configuring the NetScaler appliance to respond with multiple IP addresses, or configuring a Backup IP address for a GSLB domain. You can also divert excess traffic to a backup virtual server by using spillover.

This document includes the following information:

- Configuring a Backup GSLB Virtual Server
- Configuring a GSLB Setup to Respond with Multiple IP Addresses
- Configuring a GSLB Virtual Server to Respond with an Empty Address Record When DOWN
- Configuring a Backup IP Address for a GSLB Domain
- Diverting Excess Traffic to a Backup Virtual Server

Configuring a Backup GSLB Virtual Server

Updated: 2015-05-04

Configuring a backup entity for a GSLB virtual server ensures that DNS traffic to a site is not interrupted if the GSLB virtual server goes down. The backup entity can be another GSLB virtual server, or it can be a backup IP address. With a backup entity configured, if the primary GSLB virtual server goes down, the backup entity handles DNS requests. To specify what should happen when the primary GSLB virtual server comes back up again, you can configure the backup entity to continue handling traffic until you manually enable the primary virtual server to take over (using the disablePrimaryOnDown option), or you can configure a timeout period after which the primary takes over.

If you configure both the timeout and the disablePrimaryOnDown option for the backup entity, the backup session time-out takes precedence over the disablePrimaryOnDown setting.

To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server as a backup virtual server and verify the configuration:

- set gslb vserver <name> -backupVServer <name> [-backupSessionTimeout <timeoutValue>] [-disablePrimaryOnDown (ENABLED | DISABLED)]
- show gslb vserver <name>

Example

```
set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2 -backupSessionTimeout 3 -disablePrimaryOnDown ENABLED
show gslb vserver vserver-GSLB-1
```

To set GSLB virtual server as a backup virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the GSLB Virtual Servers pane, select the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
3. Click Open.
4. On the Advanced tab, specify values for the following parameters as shown:
   - Backup VServer—backupVServer
   - Backup Session Time-out (mins)—backupSessionTimeout
   - Disable Primary When Down—disablePrimaryOnDown
5. Click OK.

Configuring a GSLB Setup to Respond with Multiple IP Addresses

Updated: 2014-11-24

A typical DNS response contains the IP address of the best performing GSLB service. However, if you enable multiple IP response (MIR), the

NetScaler appliance sends the best GSLB service as the first record in the response and adds the remaining active services as additional records. If MIR is disabled (the default), the NetScaler appliance sends the best service as the only record in the response.

To configure a GSLB virtual server for multiple IP responses by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server for multiple IP responses and verify the configuration:

- set gslb vserver<name> -MIR (ENABLED | DISABLED)
- show gslb vserver <name>

Example

```
set gslb vserver vserver-GSLB-1 -MIR ENABLED
 show gslb vserver <vserverName>
```

To set a GSLB virtual server for multiple IP responses by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the GSLB Virtual Servers pane, select the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
3. Click Open.
4. On the Advanced tab, under When this VServer is “UP,” select the Send all “active” service IP in response (MIR) check box.
5. Click OK.

Configuring a GSLB Virtual Server to Respond with an Empty Address Record When DOWN

Updated: 2014-11-24

A DNS response can contain either the IP address of the requested domain or an answer stating that the IP address for the domain is not known by the DNS server, in which case the query is forwarded to another name server. These are the only possible responses to a DNS query.

When a GSLB virtual server is disabled or in a DOWN state, the response to a DNS query for the GSLB domain bound to that virtual server contains the IP addresses of all the services bound to the virtual server. However, you can configure the GSLB virtual server to in this case send an empty down response (EDR). When this option is set, a DNS response from a GSLB virtual server that is in a DOWN state does not contain IP address records, but the response code is successful. This prevents clients from attempting to connect to GSLB sites that are down.

Note: You must configure this setting for each virtual server to which you want it to apply.

To configure a GSLB virtual server for empty down responses by using the command line interface

At the command prompt, type:

set gslb vserver<name> -EDR (ENABLED | DISABLED)
Example

```
> set gslb vserver vserver-GSLB-1 -EDR ENABLED
 Done
```

To set a GSLB virtual server for empty down responses by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the GSLB Virtual Servers pane, select the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
3. Click Open.
4. On the Advanced tab, under When this VServer is “Down,” select the Do not send any service’s IP address in response (EDR) check box.
5. Click OK.

Configuring a Backup IP Address for a GSLB Domain

Updated: 2014-11-24

You can configure a backup site for your GSLB configuration. With this configuration in place, if all of the primary sites go DOWN, the IP address of the backup site is provided in the DNS response.

Typically, if a GSLB virtual server is active, that virtual server sends a DNS response with one of the active site IP addresses as selected by the configured GSLB method. If all the configured primary sites in the GSLB virtual server are inactive (in the DOWN state), the authoritative domain name system (ADNS) server or DNS server sends a DNS response with the backup site's IP address.

Note: When a backup IP address is sent, persistence is not honored.

To set a backup IP address for a domain by using the command line interface

At the command prompt, type the following commands to set a backup IP address and verify the configuration:

- set gslb vserver <name> -domainName <string> -backupIP <IPAddress>
- show gslb vserver <name>

Example

```
set gslb vserver vserver-GSLB-1 -domainName www.abc.com -backupIP 10.102.29.66
show gslb vserver vserver-GSLB-1
```

To set a backup IP address for a domain by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the GSLB Virtual Servers pane, select the GSLB virtual server to which you want to bind the backup domain (for example, vserver-GSLB-1).
3. Click Open.
4. On the Domains tab, select a domain and click Open.
5. In the Configure GSLB Domain dialog box, in the Backup IP text box, type the IP address of the backup domain.
6. Click OK.

Diverting Excess Traffic to a Backup Virtual Server

Updated: 2014-11-24

Once the number of connections to a primary GSLB virtual server exceeds the configured threshold value, you can use the spillover option to divert new connections to a backup GSLB virtual server. This threshold value can be calculated dynamically or set manually. Once the number of connections to the primary virtual server drops below the threshold, the primary GSLB virtual server resumes serving client requests.

You can configure persistence with spillover. When persistence is configured, new clients are diverted to the backup virtual server if that client is not already connected to a primary virtual server. When persistence is configured, connections that were diverted to the backup virtual server are not moved back to the primary virtual server after the number of connections to the primary virtual server drops below the threshold. Instead, the backup virtual server continues to process those connections until they are terminated by the user. Meanwhile, the primary virtual server accepts new clients.

The threshold can be measured either by the number of connections or by the bandwidth.

If the backup virtual server reaches the configured threshold and is unable to take any additional load, the primary virtual server diverts all requests to the designated redirect URL. If a redirect URL is not configured on the primary virtual server, subsequent requests are dropped.

The spillover feature prevents the remote backup GSLB service (backup GSLB site) from getting flooded with client requests when the primary GSLB virtual server fails. This occurs when a monitor is bound to a remote GSLB service, and the service experiences a failure that causes its state to go DOWN. The monitor continues to keep the state of the remote GSLB service UP, however, because of the spillover feature.

As part of the resolution to this problem, two states are maintained for a GSLB service, the primary state and effective state. The primary state is the state of the primary virtual server and the effective state is the cumulative state of the virtual servers (primary and backup chain). The effective state is set to UP if any of the virtual servers in the chain of virtual servers is UP. A flag that indicates that the primary VIP has reached the threshold is also provided. The threshold can be measured by either the number of connections or the bandwidth.

A service is considered for GSLB only if its primary state is UP. Traffic is directed to the backup GSLB service only when all the primary virtual servers are DOWN. Typically, such deployments will have only one backup GSLB service.

Adding primary and effective states to a GSLB service has the following effects:

- When source IP persistence is configured, the local DNS is directed to the previously selected site only if the primary virtual server on the selected site is UP and below threshold. Persistence can be ignored in the round robin mode.
- If cookie-based persistence is configured, client requests are redirected only when the primary virtual server on the selected site is UP.
- If the primary virtual server has reached its saturation and the backup VIP(s) is absent or down, the effective state is set to DOWN.

- If external monitors are bound to an HTTP-HTTPS virtual server, the monitor decides the primary state.
- If there is no backup virtual server to the primary virtual server and the primary virtual server has reached its threshold, the effective state is set to DOWN.

To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a backup GSLB virtual server and verify the configuration:

- set gslb vserver <name> -soMethod <method> -soThreshold <threshold> -soPersistence (**ENABLED** | **DISABLED**) -soPersistenceTimeout <timeout>
- show gslb vserver <name>

Example

```
set gslb vserver Vserver-GSLB-1 -soMethod CONNECTION -soThreshold 1000 -soPersistence ENABLED -soPersistenceTimeout 2
show gslb vserver Vserver-GSLB-1
```

To configure a backup GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the details pane, select the virtual server that you want to configure as a backup (for example, Vserver-LB-1), and then click Open.
3. On the Advanced tab, under Spillover, specify values for the following parameters:
   - Method— soMethod
   - Threshold— soThreshold
   - Persistence Time-out (min) — soPersistenceTimeout
4. Select the Persistence check box.
5. Click OK.

Managing Client Connections

May 22, 2015

To facilitate management of client connections, you can enable delayed cleanup of connections to the virtual server. You can then manage local DNS traffic by configuring DNS policies.

This document includes the following information:

- Enabling Delayed Cleanup of Virtual Server Connections
- Managing Local DNS Traffic by Using DNS Policies
- Adding DNS Views

Enabling Delayed Cleanup of Virtual Server Connections

Updated: 2014-11-24

The state of a virtual server depends on the states of the services bound to it, and the state of each service depends on the monitors bound to it. If a server is slow or down, the monitoring probes time out and the service that represents the server is marked as DOWN. A virtual server is marked as DOWN only when all services bound to it are marked as DOWN. You can configure services and virtual servers to either terminate all connections when they go down, or allow the connections to go through. The latter setting is for situations in which a service is marked as DOWN because of a slow server.

When you configure the down state flush option, the NetScaler appliance performs a delayed cleanup of connections to a GSLB service that is down.

To enable delayed cleanup of virtual server connections by using the command line interface

At the command prompt, type the following commands to configure delayed connection cleanup and verify the configuration:

- set gslb service <name> -downStateFlush (ENABLED | DISABLED)
- show gslb service <name>

Example

```
> set gslb service Service-GSLB-1 -downStateFlush ENABLED
 Done
> show gslb service Service-GSLB-1
 Done
```

To enable delayed cleanup of virtual server connections by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. In the GSLB Services pane, select the service (for example, service-GSLB-1), and then click Open.
3. On the Advanced tab, select the Down state flush check box.
4. Click OK.

Managing Local DNS Traffic by Using DNS Policies

Updated: 2015-05-22

You can use DNS policies to implement site affinity by directing traffic from the IP address of a local DNS resolver or network to a predefined target GSLB site. This is configured by creating DNS policies with DNS expressions and binding the policies globally on the NetScaler appliance.

This document includes the following information:

- DNS Expressions
- Configuring DNS Actions
- Configuring DNS Policies
- Binding DNS Policies

DNS Expressions

Updated: 2013-07-18

The NetScaler appliance provides certain predefined DNS expressions that can be used for configuring actions specific to a domain. Such actions can, for example, drop certain requests, select a specific view for a specific domain, or redirect certain requests to a specific location.

These DNS expressions (also called *rules*) are combined to create DNS policies that are then bound globally on the NetScaler appliance.

Following is the list of predefined DNS qualifiers available on the NetScaler appliance:

- CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
- CLIENT.UDP.DNS.IS_AREC
- CLIENT.UDP.DNS.IS_AAAAREC
- CLIENT.UDP.DNS.IS_SRVREC
- CLIENT.UDP.DNS.IS_MXREC
- CLIENT.UDP.DNS.IS_SOAREC
- CLIENT.UDP.DNS.IS_PTRREC
- CLIENT.UDP.DNS.IS_CNAME
- CLIENT.UDP.DNS.IS_NSREC
- CLIENT.UDP.DNS.IS_ANYREC

The CLIENT.UDP.DNS.DOMAIN DNS expression can be used with string expressions. If you are using domain names as part of the expression, they must end with a period (.). For example, CLIENT.UDP.DNS.DOMAIN.ENDSWITH("abc.com.")

To create an expression by using the configuration utility

1. Click the icon next to the Expression text box. Click Add. (Leave the Flow Type and Protocol drop-down list boxes empty.) Follow these steps to create a rule.
2. In the Qualifier box, select a qualifier (for example, LOCATION).
3. In the Operator box, select an operator (for example, ==).
4. In the Value box, type a value (for example, Asia, Japan....).
5. Click OK. Click Create and click Close. The rule is created.
6. Click OK.

Configuring DNS Actions

Updated: 2014-11-24

A DNS policy includes the name of a DNS action to be performed when the policy rule evaluates to TRUE. A DNS action can do one of the following:

- Send the client an IP address for which you have configured a DNS view. For more information about DNS views, see Adding DNS Views.
- Send the client the IP address of a GSLB service after referring to a list of preferred locations that overrides static proximity behavior. For more information about preferred locations, see Overriding Static Proximity Behavior by Configuring Preferred Locations.
- Send the client a specific IP address as determined by the evaluation of the DNS query or response (DNS response rewrite).
- Forward a request to the name server without performing a lookup in the appliance's DNS cache.
- Drop a request.

You cannot create a DNS action for dropping a DNS request or for bypassing the DNS cache on the appliance. If you want to drop a DNS request, use the built-in action, dns_default_act_Drop. If you want to bypass the DNS cache, use the built-in action, dns_default_act_Cachebypass. Both actions are available along with custom actions in the Create DNS Policy and the Configure DNS Policy dialog boxes. These built-in actions cannot be modified or removed.

To configure a DNS action by using the command line interface

At the command prompt, type the following commands to configure a DNS action and verify the configuration:

- add dns action <actionName> <actionType> (-IPAddress <ip_addr | ipv6_addr> ... | -viewName <string> | -preferredLocList <string> ...) [-TTL <secs>]
- show dns action [<actionName>]

Examples

Example 1: Configuring DNS Response Rewrite. The following DNS action sends the client a preconfigured IP address when the policy to which the action is bound evaluates to true:

```
> add dns action dns_act_response_rewrite Rewrite_Response -IPAddress 192.0.2.20 192.0.2.56 198.51.100.10
 Done
> show dns action dns_act_response_rewrite
1) ActionName:  dns_act_response_rewrite ActionType:  Rewrite_Response TTL:  3600          IPAddress:  192.0.2.20 192.0.2.56 198.51.100.10
 Done
```

Example 2: Configuring a DNS-View Based Response. The following DNS action sends the client an IP address for which you have configured a DNS view:

```
> add dns action send_ip_from_view_internal_ip ViewName -viewName view_internal_ip
 Done
> show dns action send_ip_from_view_internal_ip
1) ActionName:  send_ip_from_view_internal_ip ActionType:  ViewName   ViewName:  view_internal_ip
 Done
```

Example 3: Configuring a Response Based on a Preferred Location List. The following DNS action sends the client the IP address that corresponds to the preferred location that it selects from the specified list of locations:

```
> add dns action send_preferred_location GslbPrefLoc -preferredLocList NA.tx.ns1.*.*.* NA.tx.ns2.*.*.* NA.tx.ns3.*.*.*
 Done
```

```
> show dns action  send_preferred_location
1) ActionName:  send_preferred_location ActionType:  GslbPrefLoc PreferredLocList:  "NA.tx.ns1.*.*.*" "NA.tx.ns2.*.*.*" "NA.tx.ns3.*.*.*"
 Done
```

To configure a DNS action by using the NetScaler configuration utility

1. Navigate to Traffic Management > DNS > Actions.
2. In the details pane, do one of the following:
   - To create a DNS action, click Add.
   - To modify a DNS action, select the DNS action that you want to modify, and then click Open.
3. In the Create DNS Action or Configure DNS Action dialog box, set the following parameters:
   - Action Name (cannot be changed for an existing DNS action)
   - Type (cannot be changed for an existing DNS action)
     To set the Type parameter, do one of the following:
     - To create a DNS action that is associated with a DNS view, select View Name. Then, from the View Name list, select the DNS view that you want to use in the action.
     - To create a DNS action with a preferred location list, select Preferred Location List. In Preferred Location, enter a location, and then click Add. Add as many DNS locations as you want.
     - To configure a DNS action for rewriting a DNS response on the basis of policy evaluation, select Rewrite Response. In IP Address, enter an IP address, and then click Add. Add as many IP addresses as you want.
   - TTL (applicable only to the Rewrite Response action type)

Configuring DNS Policies

Updated: 2014-11-24

DNS policies operate on a location database that uses static and custom IP addresses. The attributes of the incoming local DNS request are defined as part of an expression, and the target site is defined as part of a DNS policy. While defining actions and expressions, you can use a pair of single quotation marks (‘’) as a wildcard qualifier to specify more than one location. When a DNS policy is configured and a GSLB request is received, the custom IP address database is first queried for an entry that defines the location attributes for the source:

- When a DNS query comes from an LDNS, the characteristics of the LDNS are evaluated against the configured policies. If they match, an appropriate action (site affinity) is executed. If the LDNS characteristics match more than one site, the request is load balanced between the sites that match the LDNS characteristics.
- If the entry is not found in the custom database, the static IP address database is queried for an entry, and if there is a match, the above policy evaluation is repeated.
- If the entry is not found in either the custom or static databases, the best site is selected and sent in the DNS response on the basis of the configured load balancing method.

The following restrictions apply to DNS policies created on the NetScaler appliance.

- A maximum of 64 policies are supported.
- DNS policies are global to the NetScaler and cannot be applied to a specific virtual server or domain.
- Domain or virtual server specific binding of policy is not supported.

You can use DNS policies to direct clients that match a certain IP address range to a specific site. For example, if you have a GSLB setup with multiple GSLB sites that are separated geographically, you can direct all clients whose IP address is within a specific range to a particular data center.

Both TCP-based and UDP-based DNS traffic can be evaluated. Policy expressions are available for UDP-based DNS traffic on the server and for both UDP-based DNS traffic and TCP-based DNS traffic on the client side. Additionally, you can configure expressions to evaluate queries and responses that involve only the following DNS question types (or QTYPE values):

- A
- AAAA
- NS
- SRV
- PTR
- CNAME
- SOA
- MX
- ANY

The following response codes (RCODE values) are also supported:

- NOERROR - No error
- FORMERR - Format error
- SERVFAIL - Server failure
- NXDOMAIN - Non-existent domain
- NOTIMP - Query type not implemented
- REFUSED - Query refused

You can configure expressions to evaluate DNS traffic. A DNS expression begins with the DNS.REQ or DNS.RES prefixes. Functions are available for evaluating the

queried domain, the query type, and the carrier protocol. For more information about DNS expressions, see "Expressions for Evaluating a DNS Message and Identifying Its Carrier Protocol" in "Policy Configuration and Reference".

To add a DNS policy by using the command line interface

At the command prompt, type the following commands to create a DNS policy and verify the configuration:

- add dns policy <name> <rule> <actionName>
- show dns policy <name>

Example

```
> add dns policy policy-GSLB-1 'CLIENT.UDP.DNS.DOMAIN.EQ(\"domainname\")' my_dns_action
 Done
> show dns policy policy-GSLB-1
 Name: policy-GSLB-1
 Rule: CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
 Action Name: my_dns_action
 Hits: 0
 Undef Hits: 0

 Done
```

To remove a configured DNS policy by using the command line interface

At the command prompt, type:

rm dns policy <name>

To configure a DNS policy by using the NetScaler configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, do one of the following:
   - To create a DNS policy, click Add.
   - To modify a DNS policy, select the DNS policy, and then click OK.
3. In the Create DNS Policy or Configure DNS Policy dialog box, set the following parameters:
   - Policy Name (cannot be changed for an existing policy)
   - Action
   - Expression

     To specify an expression, do the following:
     1. Click Add, and then, in the drop-down box that appears, select the expression element with which you want to begin the expression. A second list appears. The list contains a set of expression elements that you can use immediately after the firs expression element.
     2. In the second list, select the expression element that you want, and then enter a period.
     3. After each selection, if you enter a period, the next set of valid expression elements appear in a list. Select expression elements and fill in arguments to functions until you have the expression you want.
4. Click Create or OK, and then click Close.

Binding DNS Policies

Updated: 2013-08-29

DNS policies are bound globally on the NetScaler appliance and are available for all configured GSLB virtual servers. Even though DNS policies are globally bound, policy execution can be limited to a specific GSLB virtual server by specifying the domain in the expression.

Note: Even though the bind dns global command accepts REQ_OVERRIDE and RES_OVERRIDE as valid bind points, those bind points are redundant, because DNS policies can be bound only globally. Bind your DNS policies only to the REQ_DEFAULT and RES_DEFAULT bind points.

To bind a DNS policy globally by using the command line interface

At the command prompt, type the following commands to bind a DNS policy globally and verify the configuration:

- bind dns global <policyName> <priority> [-gotoPriorityExpression <string>] [-type <type>]
- show dns global -type <type>

Example

```
> bind dns global policy-GSLB-1 10 -gotoPriorityExpression END
 Done
> show dns global -type REQ_DEFAULT
1) Policy Name: policy-GSLB-1
 Priority: 10
```

```
GotoPriorityExpression: END

Done
```

To bind a DNS policy globally by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind DNS Policy(s) to Global dialog box, click Insert Policy.
4. In the Policy Name column, select, from the list, the policy that you want to bind. Alternatively, in the list, click New Policy, and then create a DNS policy by setting parameters in the Create DNS Policy dialog box.
5. To modify a policy that is already bound globally, click the name of the policy, and then click Modify Policy. Then, in the Configure DNS Policy dialog box, modify the policy, and then click OK.
6. To unbind a policy, click the name of the policy, and then click Unbind Policy.
7. To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
8. To regenerate assigned priorities, click Regenerate Priorities. The priority values are modified to begin at 100, with increments of 10, without affecting the order of evaluation.
9. Click OK.

To view the global bindings of a DNS policy by using the command line interface

At the command prompt, type:

show dns global

To view the global bindings of a DNS policy by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings. The global bindings of all DNS policies appear in this dialog box.

Adding DNS Views

Updated: 2014-11-24

You can configure DNS views to identify various types of clients and provide an appropriate IP address to a group of clients who query for the same GSLB domain. DNS views are configured by using DNS policies that select the IP addresses sent back to the client.

For example, if you have configured GSLB for your company's domain and have the server hosted in your company's network, clients querying for the domain from within your company's internal network can be provided with the server's internal IP address instead of the public IP address. Clients that query DNS for the domain from the Internet, on the other hand, can be provided the domain's public IP address.

To add a DNS view, you assign it a name of up to 31 characters. The leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ). After adding the view, you configure a policy to associate it with clients and a part of the network, and you bind the policy globally. To configure and bind a DNS policy, see Configuring DNS Policies and Binding DNS Policies.

To add a DNS view by using the command line interface

At the command prompt, type the following commands to create a DNS view and verify the configuration:

- add dns view <viewName>
- show dns view <viewName>

Example

```
add dns view PrivateSubnet
show dns view PrivateSubnet
```

To remove a DNS view by using the command line interface

At the command prompt, type:

rm dns view <viewName>

To add a DNS view by using the configuration utility

1. Navigate to Traffic Management > DNS > Views.
2. In the details pane, click Add.
3. In the Create DNS view dialog box, in the Name text box, enter the name of the DNS view.
4. Click Create, and then click Close. The DNS view that you created appears in the Views pane.

For details on how to create a DNS policy, see Configuring DNS Policies and for details on how to bind DNS policies globally, see Binding DNS Policies.

Configuring GSLB for Disaster Recovery

May 22, 2015

Disaster recovery capability is critical, because downtime is costly. A NetScaler appliance configured for GSLB forwards traffic to the least-loaded or the best-performing data center. This configuration, referred to as an active-active setup, not only improves performance, but also provides immediate disaster recovery by routing traffic to other data centers if a data center that is part of the setup goes down. Alternatively, you can configure an active-standby GSLB setup for disaster recovery only.

This document includes the following information:

- Configuring GSLB for Disaster Recovery in an Active-Standby Data Center Setup
- Configuring for Disaster Recovery in an Active-Active Data Center Setup
- Configuring for Disaster Recovery with Weighted Round Robin
- Configuring for Disaster Recovery with Data Center Persistence

Configuring GSLB for Disaster Recovery in an Active-Standby Data Center Setup

Updated: 2014-11-24

A conventional disaster recovery setup includes an active data center and a standby data center. The standby data center is a remote site. When a failover occurs as a result of a disaster event that causes the primary active data center to be inactive, the standby data center becomes operational.
Configuring disaster recovery in an active-standby data-center setup consists of the following tasks.

- Create the active data center.
  - Add a local GSLB site.
  - Add a GSLB vserver, which represents the active data center.
  - Bind the domain to the GSLB virtual server.
  - Add gslb services and bind the services to active GSLB virtual server.
- Create the standby data center.
  - Add a remote gslb site.
  - Add a gslb vserver, which represents standby data center.
  - Add gslb services which represents standby data center and bind the services to the standby gslb vserver.
  - Designate the standby data center by configuring the standby GSLB virtual server as the backup virtual server for the active GSLB virtual server.

Once you have configured the primary data center, replicate the configuration for the backup data center and designate it as the standby GSLB site by designating a GSLB virtual server at that site as the backup virtual server.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

To designate the standby GSLB site by using the command line interface

At both the active site and the remote site, at the command prompt, type:

set gslb vserver <name> -backupVserver <string>
Example

```
set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2
```

To configure the standby site by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. Select the GSLB virtual server for the primary site and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Advanced tab, in the Backup VServer drop-down list box, select a backup virtual server.
4. Click OK.

By default, once the primary virtual server becomes active, it starts receiving traffic. However, if you want the traffic to be directed to the backup virtual server even after the primary virtual server becomes active, use the 'disable primary on down' option.

Configuring for Disaster Recovery in an Active-Active Data Center Setup

An active-active GSLB deployment, in which both GSLB sites are active, removes any risk that may arise in having a standby data center. With such a setup, web or application content can be mirrored in geographically separate locations. This ensures that data is consistently available at each distributed data center.

To configure GSLB for disaster recovery in an active-active data center set up, you must first configure the basic GSLB setup on the first data center and then configure all other data centers.

First create at least two GSLB sites. Then, for the local site, create GSLB a virtual server and GSLB services and bind the services to the virtual servers. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server in the local site. Finally, at the local site, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Once you have configured the first data center, replicate the configuration for other data centers part of the setup.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

Configuring for Disaster Recovery with Weighted Round Robin

Updated: 2014-11-24

When you configure GSLB to use the weighted round robin method, weights are added to the GSLB services and the configured percentage of incoming traffic is sent to each GSLB site. For example, you can configure your GSLB setup to forward 80 percent of the traffic to one site and 20 percent of the traffic to another. After you do this, the NetScaler appliance will send four requests to the first site for each request that it sends to the second.

To set up the weighted round robin method, first create two GSLB sites, local and remote. Next, for the local site create a GSLB virtual server and GSLB services, and bind the services to the virtual servers. Configure the GSLB method as round robin. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Each service that represents a physical server in the network has weights associated with it. Therefore the GSLB service is assigned a dynamic weight that is the sum of weights of all services bound to it. Traffic is then split between the GSLB services based on the ratio of the dynamic weight of the particular service to the total weight. You can also configure individual weights for each GSLB service instead of the dynamic weight.

If the services do not have weights associated with them, you can configure the GSLB virtual server to use the number of

services bound to it to calculate the weight dynamically.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

Once you configure a basic GSLB setup, you must configure the weighted round robin method such that the traffic is split between the configured GSLB sites according to the weights configured for the individual services.

To configure a virtual server to assign weights to services by using the command line interface

At the command prompt, type one of the following commands, depending upon whether you want to create a new load balancing virtual server or configure an existing one:

- add lb vserver <name>@ -weight <WeightValue> <ServiceName>
- set lb vserver <name>@ -weight <WeightValue> <ServiceName>

Example

```
add lb vserver Vserver-LB-1 -weight 4 Service-HTTP-1
set lb vserver Vserver-LB-1 -weight 4 Service-HTTP-1
```

To set dynamic weight by using the command line interface

At the command prompt, type:

set gslb vserver <name> -dynamicWeight DynamicWeightType

Example

```
set gslb vserver Vserver-GSLB-1 -dynamicWeight ServiceWeight
```

To add weights to the GSLB services by using the command line interface

At the command prompt, type:

set gslb vserver <name> -serviceName GSLBServiceName -weight WeightValue

Example

```
set gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1 -weight 1
```

To configure a virtual server to assign weights to services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Select the virtual server (for example, Vserver-LB-1) and click Open.
3. On the Services tab, in the Weights spin box, type or select the weight of a service (for example, 4) next to Service-HTTP-1).
4. Click OK.

To add weights to the GSLB services by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. Select the virtual server (for example vserver-GSLB-1) and click Open.

3. On the Services tab, in the Weight spin box, type or select the weight of a service (for example, next to service-GSLB-1, type 1).
4. Click OK.

To set dynamic weight by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. Select the virtual server (for example vserver-GSLB-1) and click Open.
3. On the Method and Persistence tab, under Method, in Dynamic Weight drop-down list, select SERVICEWEIGHT.
4. Click OK.

Configuring for Disaster Recovery with Data Center Persistence

Updated: 2014-11-24

Data center persistence is required for web applications that require maintaining a connection with the same server instead of having the requests load balanced. For example, in an e-commerce portal, maintaining a connection between the client and the same server is critical. For such applications, HTTP redirect persistence can be configured in an active-active setup.

To configure GSLB for disaster recovery with data center persistence, you must first configure the basic GSLB set up and then configure HTTP redirect persistence.

First create two GSLB sites, local and remote. Next, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Next, create a load balancing virtual server with the same virtual server IP address as the GSLB service. Finally, duplicate the previous steps for the remote configuration, or configure the NetScaler appliance to autosynchronize your GSLB configuration.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

Once you have configured a basic GSLB setup, configure HTTP redirect precedence to enable data center persistence.

To configure HTTP redirect by using the command line interface

At the command prompt, type the following commands to configure HTTP redirect and verify the configuration:

- set gslb service <serviceName> -sitePersistence <sitePersistence> -sitePrefix <string>
- show gslb service <serviceName>

Example

```
set gslb service Service-GSLB-1 -sitePersistence HTTPRedirect -sitePrefix vserver-GSLB-1
show gslb service Service-GSLB-1
```

To configure HTTP redirect by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Select the GSLB service to be configured and click Open.
3. On the Advanced tab, under Site Persistence options, select the HTTPRedirect option.
4. In the Site Prefix text box, enter the site prefix (for example, vserver-GSLB-1).
5. Click OK.

Configuring GSLB for Proximity

Aug 30, 2013

When you configure GSLB for proximity, client requests are forwarded to the closest data center. The main benefit of the proximity-based GSLB method is faster response times resulting from the selection of the closest available data center. Such a deployment is critical for applications that require fast access to large volumes of data.

You can configure GSLB for proximity based on the round trip time (RTT), static proximity, or a combination of the two.

Configuring Dynamic Method (RTT)

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client's local DNS server and a data resource. To measure dynamic RTT, the NetScaler appliance probes the client's local DNS server and gathers RTT metric information. The NetScaler then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value

To configure GSLB for proximity with dynamic method, you must first configure the basic GSLB set up and then configure dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

Once you have configured a basic GSLB setup, configure the dynamic RTT method.

For details on how to configure the GSLB virtual server to use the dynamic RTT method for load balancing, see Configuring Dynamic RTT.

Configuring Static Proximity

The static proximity method for GSLB uses an IP address-based static proximity database to determine the proximity between the client's local DNS server and the GSLB sites. The NetScaler appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the NetScaler appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

To configure GSLB for proximity with static proximity, you must first configure the basic GSLB set up and then configure static proximity.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

Once you have configured a basic GSLB setup, configure static proximity.

For details on how to configure the GSLB virtual server to use static proximity for load balancing, see Configuring Static Proximity.

Configuring Static Proximity and Dynamic RTT

You can configure the GSLB virtual server to use a combination of static proximity and dynamic RTT when you have some clients coming from an internal network like a branch office. You can configure GSLB such that the clients coming from the branch office or any other internal network are directed to a particular GSLB site that is geographically close to the client network. For all other requests, you can use dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

Once you have configured a basic GSLB setup, configure the GSLB virtual server to use static proximity for all traffic originating from an internal network and then use dynamic RTT for all other traffic.

For details on how to configure static proximity, see Configuring Static Proximity and for details on how to configure dynamic RTT, see Configuring Dynamic RTT.

Configuring Parent-Child Topology

Aug 26, 2016

NetScaler appliances configured for global server load balancing (GSLB) provide for disaster recovery and ensure continuous availability of applications by protecting against points of failure in a wide area network (WAN). GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers in the event of an outage.

There are three fundamental entities that must be configured for GSLB:

- **Site**: A GSLB site represents a NetScaler or a high availability (HA) pair of NetScaler appliances that maintain GSLB state information and provide information about how the NetScaler nodes should communicate. A site can also represent a data center.
- **GSLB virtual server**: A GSLB virtual server represents a group of resources to which users can be directed, and the logic used to select one resource verses another.
- **GSLB service**: A GSLB service represents a target resource and is bound to a GSLB virtual server. The target resource might be a load balancing virtual server on a NetScaler, or it could represent a third party server.

Sites and services are inherently linked to indicate proximity between the two. That is, all services must belong to a site, and are assumed to be in the same location as the GSLB site for proximity purposes. Likewise, services and virtual servers are linked, so that the logic is linked to the resources that are available.

Relationships among GSLB Sites

The concept of sites is central to NetScaler GSLB implementations. Unless otherwise specified, sites form a peer relationship among themselves. This relationship is used first to exchange health information and then to distribute load as determined by the selected algorithm. In many situations, however, a peer relationship among all GSLB sites is not desirable. Reasons for not having an all-peer implementation could be

1. To clearly separate GSLB sites. For example, to separate sites that participate in resolving DNS queries from the traffic management sites.
2. To reduce the volume of Metric Exchange Protocol (MEP) traffic, which increases exponentially with an increasing number of peer sites.

These goals can be achieved by using parent and child GSLB sites. Parent-child relationships can be used to build a two-level hierarchical GSLB design with the following characteristics:

- At the top level are parent sites that have peer relationships with other parents.
- Each parent can have multiple children, but each child can have only one parent.
- Each parent site exchanges health information with its children and with other parent sites.
- A child communicates only with its parent.

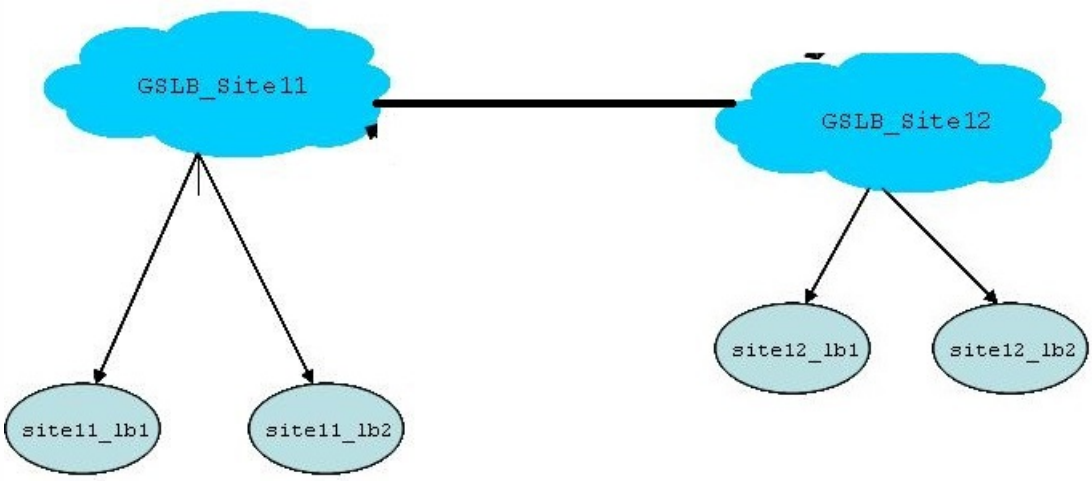
Note: In a parent-child relationship for GSLB, only the parent site does the GSLB resolution. The child sites act as normal load balancing sites.

Limitations of GSLB Parent-Child site configuration:

- You can configure 32 Parent sites and 1024 Child sites for each Parent site.
- On the Child site, by default, the nwmetricExchange and sessionExchange options are disabled.
- Round Trip Time (RTT) GSLB method is not recommended for GSLB Parent-Child site configuration.
- ADNS service or DNS load balancing virtual servers should be configured only in the Parent site.

Setting Up a Parent-Child Configuration for Global Server Load Balancing

If you have a firewall configured at a GSLB site, make sure that port 3011 is open. Follow the procedures at the following location to create services and virtual servers: Configuring Global Server Load Balancing (GSLB)
Figure 1. GSLB Parent-Child Topology



In the above figure:

- GSLB_Site11 and GSLB_Site12 are parent sites in a peer relationship.
- site11_lb1 and site11_lb2 are the child sites of GSLB_Site11, while site12_lb1 and site_lb2 are the child sites of GSLB_Site12.

The configuration of each parent site includes the information about all the child sites associated with it, but the configuration of each child site pertains only to that child and its parent. A child site is not aware about any other parent site or other child sites in the configuration. For example, in the above figure, the configuration of child site site11_lb1 would include only information about its parent site, GSLB_Site11.
Note: GSLB auto sync syncs only the GSLB configuration across the parent sites. It does not sync any configuration to the child sites.

To set up a parent-child configuration for GSLB by using the NetScaler command line

1. On each parent site, enter the following command: add gslb site<siteName><siteIPAddress> [-publicIP<ip_addr|ipv6_addr|*>] [-parentSite<string>] For example: # add gslb site gslb_site11 1.1.1.1 -publicIP 1.1.1.1
   # add gslb site site11_lb1 1.1.1.2 -publicIP 1.1.1.2 -parentSite gslb_site11

   # add gslb site site11_lb2 1.1.1.3 -publicIP 1.1.1.3 -parentSite gslb_site11

   # add gslb site gslb_site12 3.3.3.1 -publicIP 3.3.3.1

   # add gslb site site12_lb1 3.3.3.2 -publicIP 3.3.3.2 -parentSite gslb_site12

   # add gslb site site12_lb2 3.3.3.3 -publicIP 3.3.3.3 -parentSite gslb_site12

   The above command makes the parent site aware of its child sites as well as of the other parent site in the configuration.

2. On each child site, enter the following command: add gslb site<siteName><siteIPAddress> [-publicIP<ip_addr|ipv6_addr|*>] [-parentSite<string>] For example: # add gslb site site11_lb1 1 1.1.1.1 -publicIP

1.1.1.1

```
# add gslb site site11_lb2 1 1.1.1.2 -publicIP 1.1.1.2 -parentSite gslb_site11
```

The above command creates the child site and adds the parent-site information to child site's configuration.

Network metrics, such as RTT and persistence session information, are synced only across the parent sites. Therefore, parameters like nwMetric and sessionExchange are disabled by default on all the child sites.

To verify correct parent-child configuration, check the states of all the GSLB services bound to the parent sites.

Note: If you want to use different private and public IP address for GSLB services, add the corresponding GSLB-service related configuration to the child site in a separate procedure, not as part of the GSLB site configuration.

Link Load Balancing

May 19, 2015

Link load balancing (LLB) balances outbound traffic across multiple Internet connections provided by different service providers. LLB enables the Citrix® NetScaler® appliance to monitor and control traffic so that packets are transmitted seamlessly over the best possible link. Unlike with server load balancing, where a service represents a server, with LLB, a service represents a router or the next hop. A link is a connection between the NetScaler and the router.

To configure link load balancing, many users begin by configuring a basic setup with default settings. Configuring a basic setup involves configuring services, virtual servers, monitors, routes, an LLB method, and, optionally, configuring persistence. Once a basic setup is operational, you can customize it for your environment.

Load balancing methods that are applicable to LLB are round robin, destination IP hash, least bandwidth, and least packets. You can optionally configure persistence for connections to be sustained on a specific link. The available persistence types are source IP address-based, destination IP address-based, and source IP and destination IP address-based. PING is the default monitor but configuring a transparent monitor is recommended.

You can customize your setup by configuring reverse NAT (RNAT) and backup links.

This document includes the following information:

- Configuring a Basic LLB Setup
- Configuring RNAT with LLB
- Configuring a Backup Route
- Resilient LLB Deployment Scenario
- Monitoring an LLB Setup

Configuring a Basic LLB Setup

May 19, 2015

To configure LLB, you first create services representing each router to the Internet Service Providers (ISPs). A PING monitor is bound by default to each service. Binding a transparent monitor is optional but recommended. Then, you create a virtual server, bind the services to the virtual server, and configure a route for the virtual server. The route identifies the virtual server as the gateway to the physical routers represented by the services. The virtual server selects a router by using the load balancing method that you specify. Optionally, you can configure persistence to make sure that all traffic for a particular session is sent over a specific link.

To configure a basic LLB setup, do the following:

- Configure services
- Configure an LLB virtual server and binding a service
- Configure the LLB method and persistence
- Configure an LLB route
- Create and bind a transparent monitor

Configuring Services

Updated: 2014-10-27

A default monitor (PING) is automatically bound to a service type of ANY when the service is created, but you can replace the default monitor with a transparent monitor, as described in "Creating and Binding a Transparent Monitor."

To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port>
- show service <name>

Example

```
add service ISP1R_svc_any 10.10.10.254 any *
show service ISP1R_svc_any
      ISP1R_svc_any (10.10.10.254:*) - ANY
      State: DOWN
      Last state change was at Tue Aug 31 04:31:13 2010
      Time since last state change: 2 days, 05:34:18.600
      Server Name: 10.10.10.254
      Server ID : 0   Monitor Threshold : 0
      Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
      Use Source IP: NO
      Client Keepalive(CKA): NO
      Access Down Service: NO
      TCP Buffering(TCPB): YES
```

```
    HTTP Compression(CMP): NO
    Idle timeout: Client: 120 sec  Server: 120 sec
    Client IP: DISABLED
    Cacheable: NO
    SC: OFF
    SP: OFF
    Down state flush: ENABLED

1)  Monitor Name: ping
        State: UP      Weight: 1
        Probes: 244705  Failed [Total: 0 Current: 0]
        Last response: Success - ICMP echo reply received.
        Response Time: 1.322 millisec
 Done
```

To create services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters:

   - Service Name*—name
   - Server—IP
   - Protocol*—serviceType (Select ANY from the drop-down list.)
   - Port*—port

   * A required parameter

4. Click Create.
5. Repeat Steps 2-4 to create another service.
6. Click Close.
7. In the Services pane, select the services that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configuring an LLB Virtual Server and Binding a Service

Updated: 2014-10-28

After you create a service, create a virtual server and bind services to the virtual server. The default LB method of least connections is not supported in LLB. For information about changing the LB method, see "Configuring the LLB Method and Persistence."

To create a link load balancing virtual server and bind a service by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType>
- bind lb vserver < name> <serviceName>
- show lb vserver < name>

Example

```
add lb vserver Router1-vip any
bind lb vserver Router-vip ISP1R_svc_any
sh lb vserver router-vip
        Router-vip (0.0.0.0:0) - ANY    Type: ADDRESS
        State: DOWN
        Last state change was at Thu Sep  2 10:51:32 2010
        Time since last state change: 0 days, 17:51:46.770
        Effective State: DOWN
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  1 (Total)      0 (Active)
        Configured Method: ROUNDROBIN
        Mode: IP
        Persistence: NONE
        Connection Failover: DISABLED

1) ISP1R_svc_any (10.10.10.254: *) - ANY State: DOWN    Weight: 1
 Done
```

To create a link load balancing virtual server and bind a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers pane, click Add.
3. In the Create Virtual Servers (Load Balancing) dialog box, specify values for the following parameters:

   - Name*—name
   - Protocol*—serviceType (Select ANY.)

   * A required parameter

   Note: Make sure Directly Addressable is unchecked.
4. Under the Services tab, in the Active column, select the check box for the service that you want to bind to the virtual server.
5. Click Create, and then click Close.
6. In the Load Balancing Virtual Servers tab, select the virtual server that you just created, and verify that the settings displayed in the Details pane are correct.

Configuring the LLB Method and Persistence

Updated: 2014-10-28

By default, the NetScaler appliance uses the least connections method to select the service for redirecting each client request, but you should set the LLB method to one of the supported methods. You can also configure persistence, so that different transmissions from the same client are directed to the same server.

To configure the LLB method and/or persistence by using the command line interface

At the command prompt, type the following command:

- set lb vserver <name> -lbMethod <lbMethod> -persistenceType <persistenceType>
- show lb vserver <name>

Example

```
set lb vserver router-vip -lbmethod ROUNDROBIN -persistencetype SOURCEIP

show lb vserver Router-vip
        Router-vip (0.0.0.0:0) - ANY    Type: ADDRESS
        State: DOWN
        Last state change was at Fri Sep  3 04:46:48 2010
        Time since last state change: 0 days, 00:52:21.200
        Effective State: DOWN
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  0 (Total)      0 (Active)
        Configured Method: ROUNDROBIN
        Mode: IP
        Persistence: SOURCEIP
     Persistence Mask: 255.255.255.255      Persistence v6MaskLength: 128   Persistence Timeout: 2 min
        Connection Failover: DISABLED
```

To configure the link load balancing method and/or persistence by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the Load Balancing method and/or persistence settings, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, specify values for some or all of the following parameters:
   - Method—lbMethod
   - Persistence—persistenceType
4. Click OK.
5. In the Load Balancing Virtual Servers pane, select the virtual server that you just configured and verify that the settings displayed in the Details pane are correct.

Configuring an LLB Route

Updated: 2014-10-28

After configuring the IPv4 or IPv6 services, virtual servers, LLB methods, and persistence, you configure an IPv4 or IPv6 LLB route for the network specifying the virtual server as the gateway. A route is a collection of links that are load balanced. Requests are sent to the virtual server IP address that acts as the gateway for all outbound traffic and selects the router based on the LLB method configured.

To configure an IPv4 LLB route by using the command line interface

At the command prompt, type:

- add lb route <network> <netmask> <gatewayName>
- show lb route [<network> <netmask>]

Example

```
add lb route 0.0.0.0 0.0.0.0 Router-vip
show lb route 0.0.0.0 0.0.0.0
     Network         Netmask       Gateway/VIP          Flags
    -----------     -------------  --------------        --------
1)    0.0.0.0         0.0.0.0       Router-vip            UP
```

To configure an IPv6 LLB route by using the command line interface

At the command prompt, type:

- add lb route6 <network> <gatewayName>
- show lb route6

```
add lb route6 ::/0 llb6_vs
show lb route6
     Network          VIP           Flags
    -----------      ---------       --------
1)    ::/0            llb6_vs           UP
```

Example

To configure an LLB route by using the configuration utility

1. Navigate to System > Network > Routes.
2. In the details pane, select one of the following:
   - Click LLB to configure an IPv4 route.
   - Click LLBV6 to configure an IPv4 route.
3. In the Create LB Route or Create LB IPV6 Routedialog box, set the following parameters:

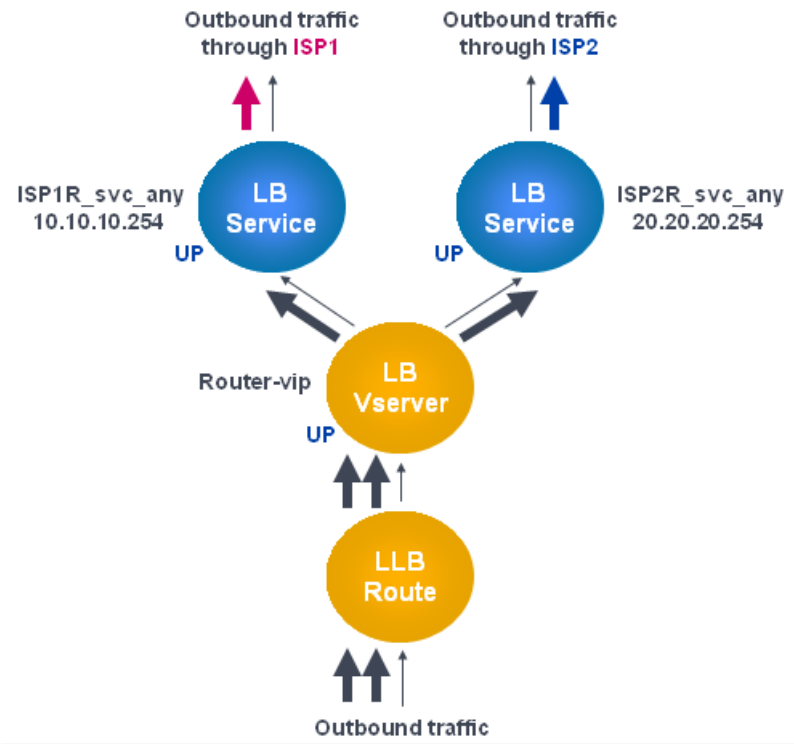
   - Network*
   - Netmask*—Required for IPV4 routes.
   - Gateway Name*—gatewayName

   * A required parameter

4. Click Create, and then click Close. The route that you just created appears on the LLB or the LLB6 tab in the Routes pane.

The following diagram shows a basic LLB setup. A service is configured for each of the two links (ISPs) and PING monitors are bound by default to these services. A link is selected based on the LLB method configured.

Figure 1. Basic LLB Setup



Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

Creating and Binding a Transparent Monitor

Updated: 2014-10-28

You create a transparent monitor to monitor the health of upstream devices, such as routers. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the router is UP but one of the next hop devices from that router is down, the appliance includes the router while performing load balancing and forwards the packet to the router. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the router) are down, the service is marked as DOWN and the router is not included when the appliance performs link load balancing.

To create a transparent monitor by using the command line interface

At the command prompt, type:

- add lb monitor <monitorName> <type> -destIP <ip_addr|*> -transparent YES
- show lb monitor [<monitorName>]

Example

```
add lb monitor monitor-1 PING -destIP 10.10.10.11 -transparent YES
> show lb monitor monitor-1
1)  Name.....: monitor-1  Type.....:    PING   State....:   ENABLED
Standard parameters:
```

```
Interval.....:          5 sec   Retries.....:            3
Response timeout.:        2 sec   Down time.....:        30 sec
Reverse.....:           NO   Transparent.....:          YES
Secure.....:            NO   LRTM.....:        ENABLED
Action.....:   Not applicable   Deviation.....:         0 sec
Destination IP...:     10.10.10.11
Destination port.:    Bound service
Iptunnel.....:          NO
TOS.....:           NO   TOS ID.....:            0
SNMP Alert Retries:           0     Success Retries..:           1
Failure Retries..:          0
```

To create a transparent monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the Monitors pane, click Add.
3. In the Create Monitor dialog box, set the following parameters:

   - Name*
   - Type*
   - Destination IP
   - Transparent

   * A required parameter

4. Click Create, and then click Close.
5. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed in the Details pane are correct.

To bind a monitor to a service by using the command line interface

At the command prompt, type:

- bind lb monitor <monitorName> <serviceName>
- show service <name>

Example

```
bind lb monitor monitor-HTTP-1 isp1R_svc_any
 Done
> show service isP1R_svc_any
      ISP1R_svc_any (10.10.10.254:*) - ANY
      State: UP
      Last state change was at Thu Sep  2 10:51:07 2010
      Time since last state change: 0 days, 18:41:55.130
      Server Name: 10.10.10.254
      Server ID : 0   Monitor Threshold : 0
      Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
      Use Source IP: NO
      Client Keepalive(CKA): NO
```

```
    Access Down Service: NO
    TCP Buffering(TCPB): YES
    HTTP Compression(CMP): NO
    Idle timeout: Client: 120 sec  Server: 120 sec
    Client IP: DISABLED
    Cacheable: NO
    SC: OFF
    SP: OFF
    Down state flush: ENABLED

1)  Monitor Name: monitor-HTTP-1
        State: UP  Weight: 1
        Probes: 1256  Failed [Total: 0 Current: 0]
        Last response: Success - ICMP echo reply received.
        Response Time: 1.322 millisec
Done
```

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select a service to which you want to bind a monitor, and then click Open.
3. In the Configure Service dialog box, on the Monitors tab, under Available, select the monitor that you want to bind to the service, and then click Add.
4. Click OK.
5. In the Services pane, select the service that you just configured and verify that the settings displayed in the Details pane are correct.

Configuring RNAT with LLB

Oct 28, 2014

You can configure an LLB setup for reverse network address translation (RNAT) for outbound traffic. This ensures that the return network traffic for a specific flow is routed through the same path. First configure basic LLB, as described in "Configuring a Basic LLB Setup", and then configure RNAT. You must then enable use subnet IP (USNIP) mode.

To configure RNAT by using the command line interface

At the command prompt, type:

- set rnat <network> <netmask>
- show rnat

Example

```
set rnat 10.102.29.0 255.255.255.0
> show rnat
1)     Network: 10.102.29.0    Netmask: 255.255.255.0
       NatIP: *
```

To configure RNAT by using the configuration utility

1. Navigate to System > Network > Routes.
2. In the detailspane, on the RNAT tab, click Configure RNAT.
3. In the Configure RNAT dialog box, specify values for the following parameters:
   - Network*—network
   - Netmask*—netmask

   * A required parameter
4. Click Create, and then click Close. The RNAT route that you just created appears in the on the RNAT tab in the Routes pane.

To enable Use Subnet IP mode by using the command line interface

At the command prompt, type:

- enable ns mode USNIP
- show ns mode

Example

```
enable ns mode USNIP
> show ns mode
      Mode                  Acronym          Status
      -------               -------          ------
 1)   Fast Ramp                FR              ON
 2)   ....
 8)   Use Subnet IP             USNIP            ON
```

9) ...

To enable Use Subnet IP mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In details pane, under Modes and Features, click Configure modes.
3. In the Configure Modes dialog box, select Use Subnet IP, and then click OK.
4. In the Enable/Disable Mode(s) message box, click Yes.

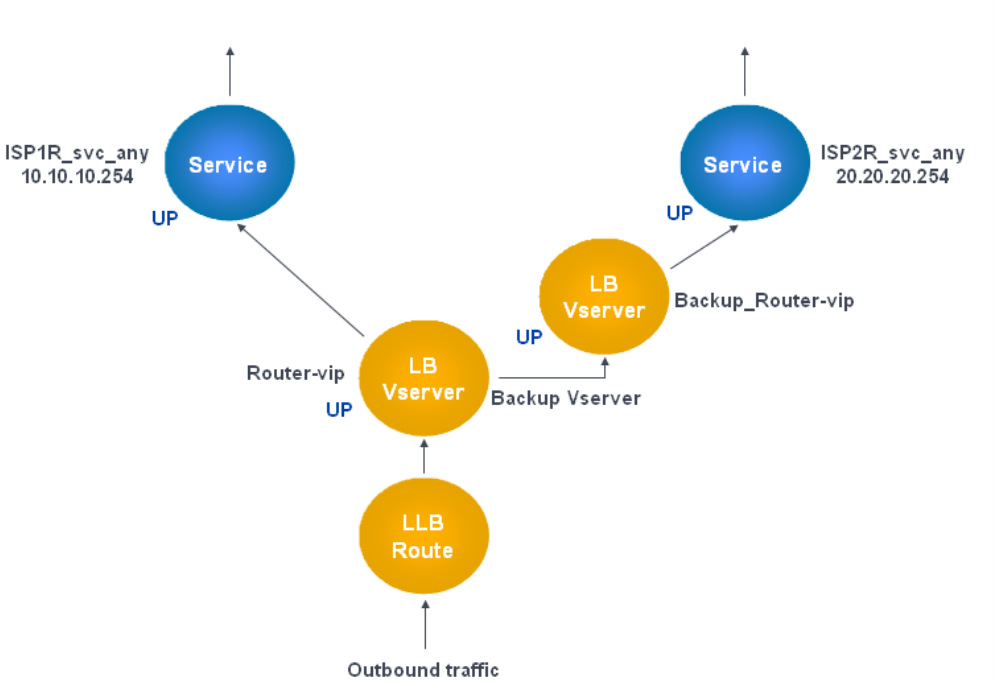
Configuring a Backup Route

Oct 28, 2014

To prevent disruption in services when the primary route is down, you can configure a backup route. Once the backup route is configured, the NetScaler appliance automatically uses it when the primary route fails. First create a primary virtual server as described in "Configuring an LLB Virtual Server and Binding a Service." To configure a backup route, create a secondary virtual server similar to a primary virtual server and then designate this virtual server as a backup virtual server (route).

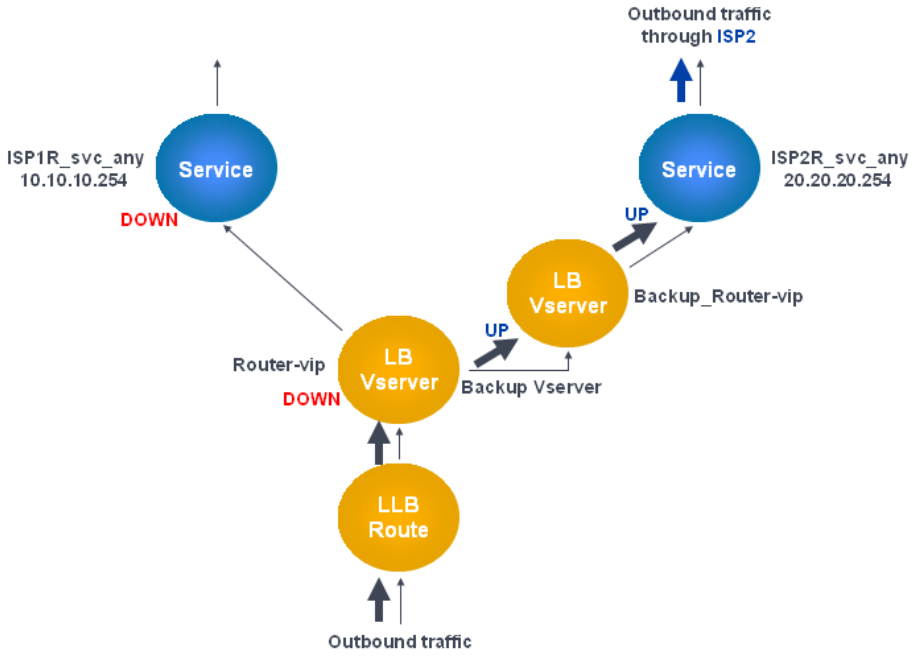
In the following diagram, **Router-vip** is the primary virtual server, and **Backup_Router-vip** is the secondary virtual server designated as the backup virtual server.

Figure 1. Backup Route Setup



Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.
By default, all traffic is sent through the primary route. However, when the primary route fails, all traffic is diverted to the backup route as shown in the following diagram.

Figure 2. Backup Routing in Operation



Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

To set the secondary virtual server as the backup virtual server by using the command line interface

At the command prompt, type:

set lb vserver <name> -backupVserver <string>

Example

```
set lb vserver Router-vip -backupVServer Backup_Router-vip
> show lb vserver Router-vip
      Router-vip (0.0.0.0:0) - ANY    Type: ADDRESS
      State: UP
      Last state change was at Fri Sep  3 04:46:48 2010
      Time since last state change: 0 days, 03:09:45.600
      Effective State: UP
      Client Idle Timeout: 120 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      No. of Bound Services :  1 (Total)      1 (Active)
      Configured Method: ROUNDROBIN
      Mode: IP
      Persistence: DESTIP     Persistence Mask: 255.255.255.255      Persistence v6MaskLength: 128   Persistence Timeout: 2 min
      Backup: Router2-vip
      Connection Failover: DISABLED
 Done
```

To set the secondary virtual server as the backup virtual server by using the configuration utility

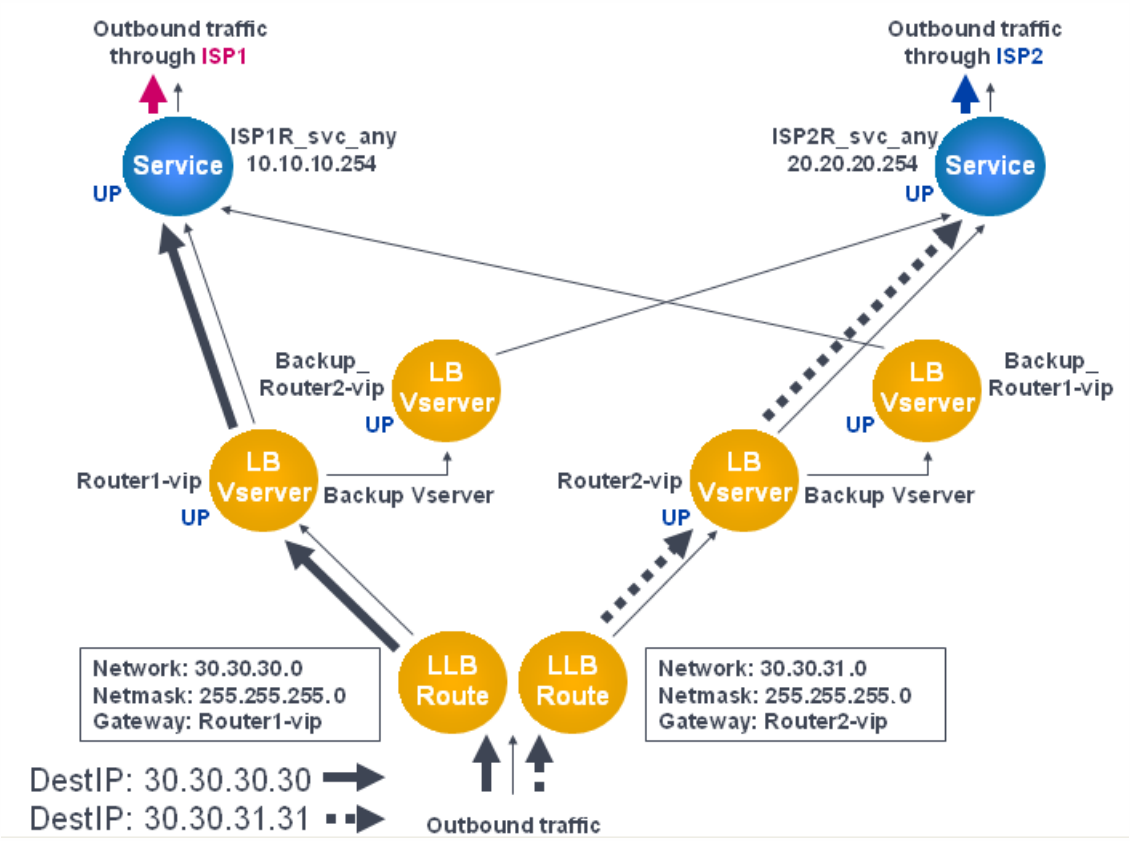
1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the secondary virtual server for which you want to configure the backup virtual server, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. In the Backup Virtual Server drop-down list, select the secondary backup virtual server, and then click OK.

Resilient LLB Deployment Scenario

Mar 22, 2012

In the following diagram, there are two networks: 30.30.30.0 and 30.30.31.0. Link load balancing is configured based on the destination IP address. Two routes are configured with gateways **Router1-vip** and **Router2-vip**, respectively. **Router1-vip** is configured as a backup to **Router2-vip** and vice versa. All traffic with the destination IP specified as 30.30.30.30 is sent through **Router1-vip** and traffic with the destination IP specified as 30.30.31.31 is sent through **Router2-vip**.

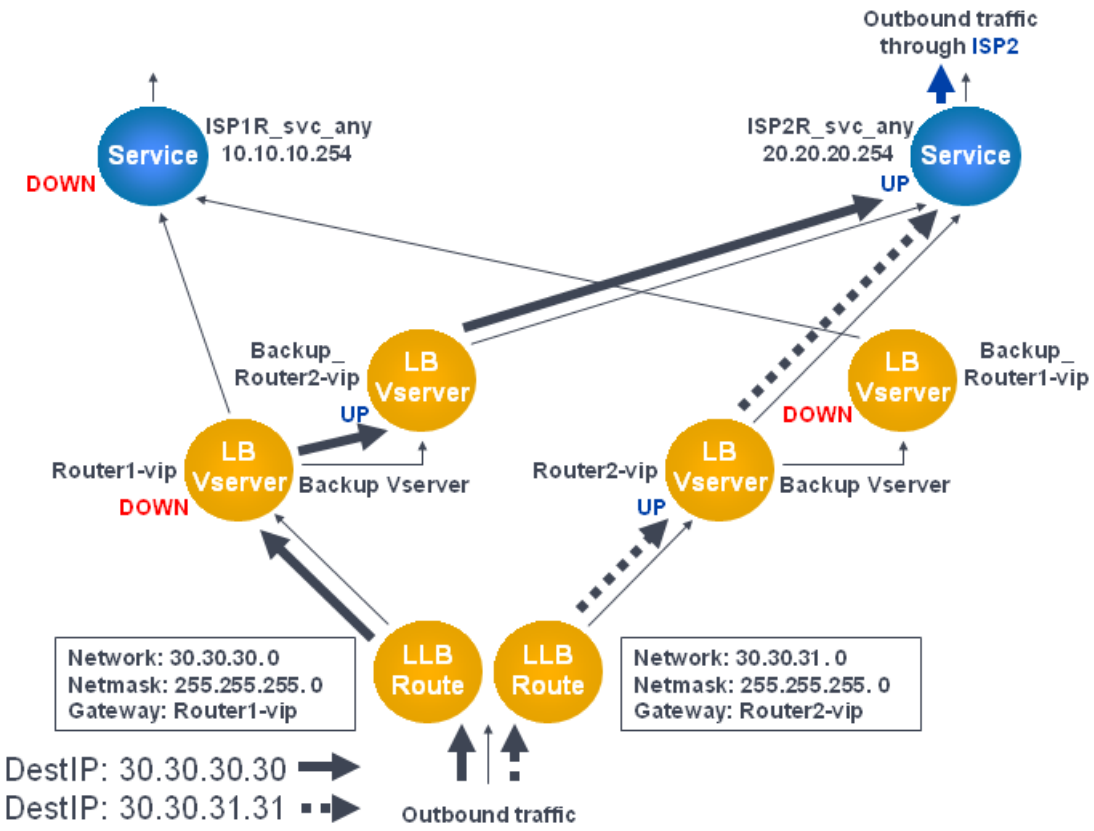
Figure 1. Resilient LLB Deployment Setup



Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

However, if any one of the gateways (**Router1-vip** or **Router2-vip**) is DOWN, traffic is routed through the backup router. In the following diagram, **Router1-vip** for ISP1 is DOWN, so all traffic with the destination IP specified as 30.30.30.30 is also sent through ISP2.

Figure 2. Resilient LLB Deployment Scenario



Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

Monitoring an LLB Setup

Sep 20, 2010

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

Viewing the Statistics of a Virtual Server

Updated: 2013-09-05

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

stat lb vserver [-detail] [<name>]

Example

```
>stat lb vserver -detail
Virtual Server(s) Summary
                vsvrIP  port    Protocol      State   Req/s   Hits/s
One                  *    80        HTTP         UP     5/s     0/s
Two                  *     0         TCP       DOWN     0/s     0/s
Three                *  2598         TCP       DOWN     0/s     0/s
dnsVirtualNS    10.102.29.90    53         DNS       DOWN     0/s     0/s
BRVSERV          10.10.1.1    80        HTTP       DOWN     0/s     0/s
LBVIP         10.102.29.66    80        HTTP         UP     0/s     0/s
 Done
```

To display virtual server statistics by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.
3. In the details pane, click Statistics.

Viewing the Statistics of a Service

Updated: 2013-08-28

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

stat service <name>
Example

stat service Service-HTTP-1

To view the statistics of a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).
3. Click Statistics. The statistics appear in a new window.

Load Balancing

Mar 24, 2015

The load balancing feature distributes user requests for web pages and other protected applications across multiple servers that all host (or mirror) the same content. You use load balancing primarily to manage user requests to heavily used applications, preventing poor performance and outages and ensuring that users can access your protected applications. Load balancing also provides fault tolerance; when one server that hosts a protected application becomes unavailable, the feature distributes user requests to the other servers that host the same application.

You can configure the load balancing feature to:

- Distribute all requests for a specific protected website, application, or resource between two or more identically configured servers.
- Use any of several different algorithms to determine which server should receive each incoming user request, basing the decision on different factors, such as which server has the fewest current user connections or which server has the lightest load.

The load balancing feature is a core feature of the NetScaler appliance. Most users first set up a working basic configuration and then customize various settings, including persistence for connections. In addition, you can configure features for protecting the configuration against failure, managing client traffic, managing and monitoring servers, and managing a large scale deployment.

How Load Balancing Works

Jun 08, 2015

In a basic load balancing setup, clients send their requests to the IP address of a virtual server configured on the NetScaler appliance. The virtual server distributes them to the load-balanced application servers according to a preset pattern, called the load balancing algorithm. In some cases, you might want to assign the load balancing virtual server a wildcard address instead of a specific IP address. For instructions about specifying a global HTTP port on the appliance, see Global HTTP Ports.

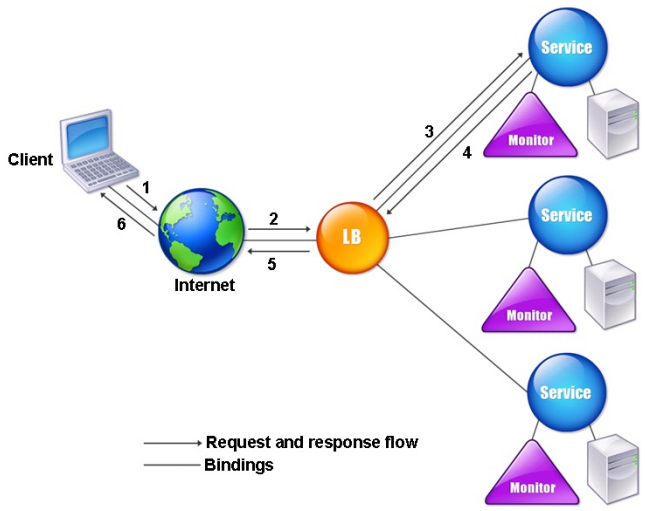
To understand how load balancing works, see the following sections:

- Load Balancing Basics
- Understanding the Topology
- Use of Wildcards Instead of IP Addresses and Ports
- Configuring Global HTTP Ports

Load Balancing Basics

A load balancing setup includes a load-balancing virtual server and multiple load-balanced application servers. The virtual server receives incoming client requests, uses the load balancing algorithm to select an application server, and forwards the requests to the selected application server. The following conceptual drawing illustrates a typical load balancing deployment. Another variation involves assigning a global HTTP port.

Figure 1. Load Balancing Architecture



The load balancing virtual server can use any of a number of algorithms (or methods) to determine how to distribute load among the load-balanced servers that it manages. The default load balancing method is the least connection method, in which the NetScaler appliance forwards each incoming client connection to whichever load-balanced application server currently has the fewest active user connections.

The entities that you configure in a typical NetScaler load balancing setup are:

- **Load balancing virtual server.** The IP address, port, and protocol combination to which a client sends connection

requests for a particular load-balanced website or application. If the application is accessible from the Internet, the virtual server IP (VIP) address is a public IP address. If the application is accessible only from the local area network (LAN) or wide area network (WAN), the VIP is usually a private (ICANN non-routable) IP address.

- **Service.** The IP address, port, and protocol combination used to route requests to a specific load-balanced application server. A service can be a logical representation of the application server itself, or of an application running on a server that hosts multiple applications. After creating a service, you bind it to a load balancing virtual server.
- **Server object.** A virtual entity that enables you to assign a name to a physical server instead of identifying the server by its IP address. If you create a server object, you can specify its name instead of the server's IP address when you create a service. Otherwise, you must specify the server's IP address when you create a service, and the IP address becomes the name of the server.
- **Monitor.** An entity on the NetScaler appliance that tracks a service and ensures that it is operating correctly. The monitor periodically probes (or performs a health check on) each service to which you assign it. If the service does not respond within the time specified by the time-out, and a specified number of health checks fail, that service is marked DOWN. The NetScaler appliance then skips that service when performing load balancing, until the issues that caused the service to quit responding are fixed.

The virtual server, services, and load balanced application servers in a load balancing setup can use either Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) IP addresses. You can mix IPv4 and IPv6 addresses in a single load balancing setup.

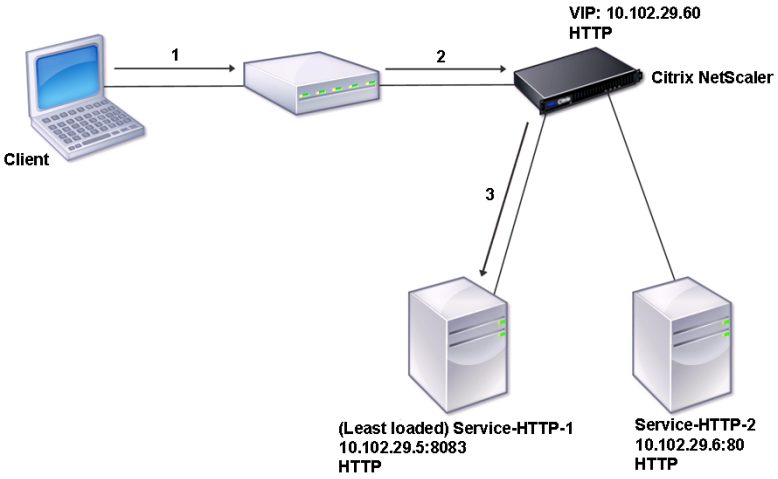
For variations in the load balancing setup, see the following use cases:

- Configuring Load Balancing in Direct Server Return Mode
- Configuring LINUX Servers in DSR Mode
- Configuring DSR Mode When Using TOS
- Configuring Load Balancing in DSR Mode by Using IP Over IP
- Configuring Load Balancing in One-arm Mode
- Configuring Load Balancing in the Inline Mode
- Load Balancing of Intrusion Detection System Servers
- Load Balancing RDP services

Understanding the Topology

In a load balancing setup, the load balancing server is logically located between the client and the server farm, and manages traffic flow to the servers in the server farm. On the NetScaler appliance, the application servers are represented by virtual entities called services. The following diagram shows the topology of a basic load balancing configuration.

Figure 2. Basic Load Balancing Topology

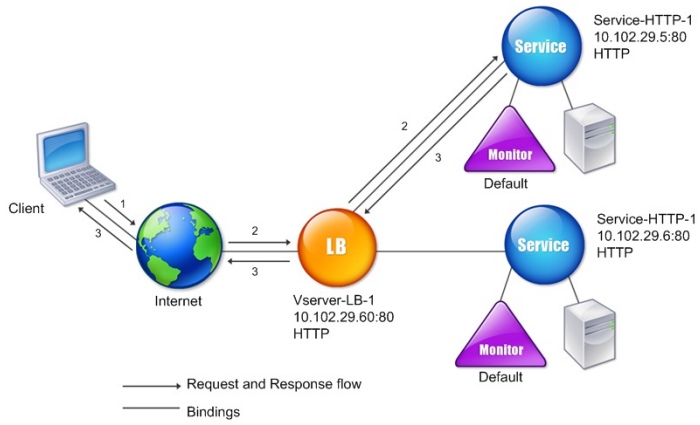


In the diagram, load balancing is used to manage traffic flow to the servers. The virtual server selects the service and assigns it to serve client requests. Consider a scenario where the services Service-HTTP-1 and Service-HTTP-2 are created and bound to the virtual server named Vserver-LB-1. Vserver-LB-1 forwards the client request to either Service-HTTP-1 or Service-HTTP-2. The NetScaler appliance uses the least connection load balancing method to select the service for each request. The following table lists the names and values of the basic entities that must be configured on the appliance.

Entity	**Mandatory Parameters and Sample Values**			
	Name	**IP Address**	**Port**	**Protocol**
Virtual server	Vserver-LB-1	10.102.29.60	80	HTTP
Services	Service-HTTP-1	10.102.29.5	8083	HTTP
	Service-HTTP-2	10.102.29.6	80	HTTP
Monitors	Default	None	None	None

The following diagram shows the load balancing sample values and mandatory parameters that are described in the preceding table.

Figure 3. Load Balancing Entity Model



Use of Wildcards Instead of IP Addresses and Ports

Updated: 2013-11-20

In some cases you might need to use a wildcard for the IP address or the port of a virtual server or for the port of a service. The following cases may require using a wildcard:

- If the NetScaler appliance is configured as a transparent pass through, which must accept all traffic that is sent to it regardless of the IP or port to which it is sent.
- If one or more services listen on ports that are not well known.
- If one or more services, over time, change the ports that they listen on.
- If you reach the limit for the number of IP addresses and ports that you can configure on a single NetScaler appliance.
- If you want to create virtual servers that listen for all traffic on a specific virtual LAN.

When a wildcard-configured virtual server or service receives traffic, the NetScaler appliance determines the actual IP address or port and creates new records for the service and associated load balanced application server. These dynamically created records are called dynamically learned server and service records.

For example, a firewall load balancing configuration can use wildcards for both the IP address and port. If you bind a wildcard TCP service to this type of load balancing virtual server, the virtual server receives and processes all TCP traffic that does not match any other service or virtual server.

The following table describes some of the different types of wildcard configurations and when each should be used.

IP	Port	Protocol	Description
*	*	TCP	A general wildcard virtual server that accepts traffic sent to any IP address and port on the NetScaler appliance. When using a wildcarded virtual server, the appliance dynamically learns the IP and port of each service and creates the necessary records as it processes traffic.
*	*	TCP	A firewall load balancing virtual server. You can bind firewall services to this virtual server,

IP	Port	Protocol	Description
IP Address	*	TCP,UDP, and ANY	A virtual server that accepts all traffic that is sent to the specified IP address, regardless of the port. You must explicitly bind to this type of virtual server the services to which it will redirect traffic. It will not dynamically learn them. Note: You do not configure services or virtual servers for a global HTTP port. In this case, you configure a specific port as a global HTTP port (for example, set ns param -httpPort 80). The appliance then accepts all traffic that matches the port number, and processes it as HTTP traffic. The appliance dynamically learns and creates services for this traffic.
*	port	SSL, SSL_TCP	A virtual server that accepts all traffic sent to any IP address on a specific port. Used for global transparent SSL offloading. All SSL, HTTP, and TCP processing that usually is performed for a service of the same protocol type is applied to traffic that is directed to this specific port. The appliance uses the port to dynamically learn the IP of the service it should use. If –cleartext is not specified, the NetScaler appliance uses end-to-end SSL.
*	port	Not applicable	All other virtual servers that can accept traffic to the port. You do not bind services to these virtual servers; the NetScaler appliance learns them dynamically.

Note: If you have configured your NetScaler appliance as a transparent pass through that makes use of global (wildcard) ports, you may want to turn on Edge mode. For more information, see "Configuring Edge Mode."
The NetScaler appliance attempts to locate virtual servers and services by first attempting an exact match. If none is found, it continues to search for a match based on wildcards, in the following order:

1. Specific IP address and specific port number
2. Specific IP address and a * (wildcard) port
3. * (wildcard) IP address and a specific port
4. * (wildcard) IP address and a * (wildcard) port

If the appliance is unable to select a virtual server by IP address or port number, it searches for a virtual server on the basis of the protocol used in the request, in the following order:

1. HTTP
2. TCP
3. ANY

Configuring Global HTTP Ports

Updated: 2013-10-23

You do not configure services or virtual servers for a global HTTP port. Instead, you configure a specific port by using the set ns param command. After configuring this port, the NetScaler appliance accepts all traffic that matches the port number, and processes it as HTTP traffic, dynamically learning and creating services for that traffic.

You can configure more than one port number as a global HTTP port. If you are specifying more than one port number in a single set ns param command, separate the port numbers by a single white space. If one or more ports have already been

specified as global HTTP ports, and you want to add one or more ports without removing the ports that are currently configured, you must specify all the port numbers, current and new, in the command. Before you add port numbers, use the **show ns param** command to view the ports that are currently configured.

To configure a global HTTP port by using the command line interface

At the command prompt, type the following commands to configure a global HTTP port and verify the configuration:

- set ns param –httpPort <port>
- show ns param

Example 1: Configuring a port as a global HTTP port

In this example, port 80 is configured as a global HTTP port.

```
> set ns param -httpPort 80
 Done
> show ns param
        Global configuration settings:
                     HTTP port(s): 80
                  Max connections: 0
          Max requests per connection: 0
                Client IP insertion: DISABLED
                   Cookie version: 0
       Persistence Cookie Secure Flag: ENABLED
       ...
       ...
```

Example 2: Adding ports when one or more global HTTP ports are already configured

In this example, port 8888 is added to the global HTTP port list. Port 80 is already configured as a global HTTP port.

```
> show ns param

       Global configuration settings:
                     HTTP port(s): 80
                  Max connections: 0
          Max requests per connection: 0
                Client IP insertion: DISABLED
                   Cookie version: 0
       Persistence Cookie Secure Flag: ENABLED
                     Min Path MTU: 576
       ...
       ...
 Done
> set ns param -httpPort 80 8888
 Done
>  show ns param

       Global configuration settings:
                     HTTP port(s): 80,8888
```

```
                Max connections: 0
          Max requests per connection: 0
                Client IP insertion: DISABLED
                   Cookie version: 0
         Persistence Cookie Secure Flag: ENABLED
                   Min Path MTU: 576

        ...
        ...
 Done
>
```

To configure a global HTTP port by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Settings, click Change HTTP parameters.
3. In the Configure HTTP Parameters dialog box, in the HTTP Port area, do the following:
   - To add a port, enter the port number, and then click Add.
   - To remove a port that has already been configured, click the port number, and then click Remove.
4. Click OK.

Setting Up Basic Load Balancing

Oct 22, 2015

Before configuring your initial load balancing setup, enable the load balancing feature. Then begin by creating at least one service for each server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server, and bind each service to the virtual server. That completes the initial setup. Before proceeding with further configuration, verify your configuration to make sure that each element was configured properly and is operating as expected.

To set up basic load balancing, see the following sections:

- Enabling Load Balancing
- Configuring Services
- Creating a Virtual Server
- Binding Services to the Virtual Server
- Verifying the Configuration

Enabling Load Balancing

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

Example

```
> enable ns feature LoadBalancing
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)    Web Logging              WL              OFF
 2)    Surge Protection         SP              ON
 3)    Load Balancing           LB              ON
 .
 .
 .
 24)   NetScaler Push           push            OFF
 Done
```

To enable load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click OK.
4. In the Enable/Disable Feature(s)? message box, click Yes.

Configuring Services

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the NetScaler appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server's name instead of its IP address when you create a service.

When you create a service that uses UDP as the transport layer protocol, a ping monitor is automatically bound to the service. A ping monitor is the most basic of the built-in monitors. When you create a service that uses TCP as the transport layer protocol, a TCP_default monitor is automatically bound to the service. When you develop a strategy for managing your load balancing setup, you might decide to bind a different type of monitor, or multiple monitors, to the service.

Creating a Service

Before you create a service, you need to understand the different service types and how each is used. The following list describes the types of services supported on the NetScaler appliance.

HTTP

Used for load-balanced servers that accept HTTP traffic, such as standard web sites and web applications. The HTTP service type enables the NetScaler appliance to provide compression, content filtering, caching, and client keep-alive support for your Layer 7 web servers. This service type also supports virtual server IP port insertion, redirect port rewriting, Web 2.0 Push, and URL redirection support.

Because HTTP is a TCP-based application protocol, you can also use the TCP service type for web servers. If you do so, however, the NetScaler appliance is able to perform only Layer 4 load balancing. It cannot provide any of the Layer 7 support described earlier.

SSL

Used for servers that accept HTTPS traffic, such as ecommerce web sites and shopping cart applications. The SSL service type enables the NetScaler appliance to encrypt and decrypt SSL traffic (perform SSL offloading) for your secure web applications. It also supports HTTP persistence, content switching, rewrite, virtual server IP port insertion, Web 2.0 Push, and URL redirection.

You can also use the SSL_BRIDGE, SSL_TCP, or TCP service types. If you do so, however, the NetScaler performs only Layer 4 load balancing. It cannot provide SSL offloading or any of the Layer 7 support described above

FTP

Used for servers that accept FTP traffic. The FTP service type enables the NetScaler appliance to support specific details of the FTP protocol.

You can also use TCP or ANY service types for FTP servers.

TCP

Used for servers that accept many different types of TCP traffic, or that accept a type of TCP traffic for which a more specific type of service is not available.

You can also use the ANY service type for these servers.

SSL_TCP

Used for servers that accept non-HTTP-based SSL traffic, to support SSL offloading.

You can also use the TCP service type for these services. If you do so, the NetScaler appliance performs both the Layer 4 load balancing and SSL offloading.

UDP

Used for servers that accept UDP traffic. You can also use the ANY service type.

SSL_BRIDGE

Used for servers that accept SSL traffic when you do not want the NetScaler appliance to perform SSL offloading. Alternatively, you can use the SSL_TCP service type.

NNTP

Used for servers that accept Network News Transfer Protocol (NNTP) traffic, typically Usenet sites.

DNS

Used for servers that accept DNS traffic, typically nameservers. With the DNS service type, the NetScaler appliance validates the packet format of each DNS request and response. It can also cache DNS responses. You can apply DNS policies to DNS services.

You can also use the UDP service type for these services. If you do, however, the NetScaler appliance can only perform Layer 4 load balancing. It cannot provide support for DNS-specific features.

ANY

Used for servers that accept any type of TCP, UDP, or ICMP traffic. The ANY parameter is used primarily with firewall load balancing and link load balancing.

SIP-UDP

Used for servers that accept UDP-based Session Initiation Protocol (SIP) traffic. SIP initiates, manages, and terminates multimedia communications sessions, and has emerged as the standard for Internet telephony (VoIP).

You can also use the UDP service type for these services. If you do, however, the NetScaler appliance performs only Layer 4 load balancing. It cannot provide support for SIP-specific features.

DNS-TCP

Used for servers that accept DNS traffic, where the NetScaler appliance acts as a proxy for TCP traffic sent to DNS servers. With services of the DNS-TCP service type, the NetScaler appliance validates the packet format of each DNS request and response and can cache DNS responses, just as with the DNS service type.

You can also use the TCP service type for these services. If you do, however, the NetScaler appliance only performs Layer 4 load balancing of external DNS name servers. It cannot provide support for any DNS-specific features.

RTSP

Used for servers that accept Real Time Streaming Protocol (RTSP) traffic. RTSP provides delivery of multimedia and other streaming data. Select this type to support audio, video, and other types of streamed media.

You can also use the TCP service type for these services. If you do, however, the NetScaler appliance performs only Layer 4 load balancing. It cannot parse the RTSP stream or provide support for RTSPID persistence or RTSP NATting.

DHCPRA

Used for servers that accept DHCP traffic. The DHCPRA service type can be used to relay DHCP requests and responses between VLANs.

DIAMETER

Used for load balancing Diameter traffic among multiple Diameter servers. Diameter uses message-based load balancing.

SSL_DIAMETER

Used for load balancing Diameter traffic over SSL.

Services are designated as DISABLED until the NetScaler appliance connects to the associated load-balanced server and verifies that it is operational. At that point, the service is designated as ENABLED. Thereafter, the NetScaler appliance periodically monitors the status of the servers, and places any that fail to respond to monitoring probes (called health checks) back in the DISABLED state until they respond.

Note: You can create a range of services from a single CLI command or the same dialog box. The names in the range vary by a number used as a suffix/prefix. For example, service1, service2, and so on. From the configuration utility, you can specify a range only in the last octet of the IP address, which is the fourth in case of an IPv4 address and the eighth in case of an IPv6 address. From the command line, you can specify the range in any octet of the IP address.

To create a service by using the command line interface

At the command prompt, type:

add service <name> <serverName> <serviceType> <port>

Example COPY

```
add service Service-HTTP-1 192.0.2.5 HTTP 80
```

To create a service by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. In the details pane, click **Add**.
3. In the **Create Service** dialog box, specify values for the following parameters:

- Service Name—name
- Server—serverName
- Protocol—serviceType
- Port—port

4. Click **Create**, and then click **Close**. The service you created appears in the **Services** pane.

Creating a Virtual Server

After you create your services, you must create a virtual server to accept traffic for the load balanced Web sites, applications, or servers. Once load balancing is configured, users connect to the load-balanced Web site, application, or server through the virtual server's IP address or FQDN.

Note: The virtual server is designated as DOWN until you bind the services that you created to it, and until the NetScaler appliance connects to those services and verifies that they are operational. Only then is the virtual server designated as UP.

To create a virtual server by using the command line interface

At the command prompt, type:

add lb vserver <name> <serviceType> <ip> <port>
Example

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

To create a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters:
   - Name—name
   - IP Address—IPAddress
     Note: If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, 1000:0000:0000:0000:0005:0600:700a:888b).
   - Protocol—serviceType
   - Port—port
4. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Binding Services to the Virtual Server

After you have created services and a virtual server, you must bind the services to the virtual server. In most cases, services are bound to virtual servers of the same type, but you can bind certain types of services to certain different types of virtual servers, as shown below.

Virtual Server Type	Service Type	Comment
HTTP	SSL	You would normally bind an SSL service to an HTTP virtual server to do encryption.
SSL	HTTP	You would normally bind an HTTP service to an SSL virtual server to do SSL offloading.

Virtual Server Type	Service Type	Comment
SSL_TCP	TCP	You would normally bind a TCP service to an SSL_TCP virtual server to do SSL offloading for other TCP (SSL decryption without content awareness).

The state of the services bound to a virtual server determines the state of the virtual server: if all of the bound services are DOWN, the virtual server is marked DOWN, and if any of the bound services is UP or OUT OF SERVICE, the state of the virtual server is UP.

To bind a service to a load balancing virtual server by using the command line interface

At the command prompt, type:

bind lb vserver <name> <serviceName>
Example

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind a service to a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the service.
3. Click Open.
4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server.
5. Click OK.

Note: You can bind a service to multiple virtual servers.

Verifying the Configuration

After finishing your basic configuration, you should view the properties of each service and load balancing virtual server in your load balancing setup to verify that each is configured correctly. After the configuration is up and running, you should view the statistics for each service and load balancing virtual server to check for possible problems.

Viewing the Properties of a Server Object

You can view properties such as the name, state, and IP address of any server object in your NetScaler appliance configuration.

To view the properties of server objects by using the command line interface

At the command prompt, type:

show server <serverName>

Example COPY

```
show server server-1
```

To view the properties of server objects by using the configuration utility

Navigate to **Traffic Management** > **Load Balancing** > **Servers**. The parameter values of the available servers appear in the details pane.

Viewing the Properties of a Virtual Server

You can view properties such as the name, state, effective state, IP address, port, protocol, method, and number of bound services for your virtual servers. If you have configured more than the basic load balancing settings, you can view the persistence settings for your virtual servers, any policies that are bound to them, and any cache redirection and content switching virtual servers that have been bound to the virtual servers.

To view the properties of a load balancing virtual server by using the command line interface

At the command prompt, type:

show lb vserver <name>

Example COPY

```
show lb vserver Vserver-LB-1
```

To view the properties of a load balancing virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.

2. In the details pane, click a virtual server to display its properties at the bottom of the

details pane.

3. To view cache redirection and content switching virtual servers that are bound to this

virtual server, click **Show CS/CR Bindings**.

Viewing the Properties of a Service

You can view the name, state, IP address, port, protocol, maximum client connection, maximum requests per connection, and server type of the configured services, and use this information to troubleshoot any mistake in the service configuration.

To view the properties of services by using the command line interface

At the command prompt, type:

show service <name>

Example COPY

```
show service Service-HTTP-1
```

To view the properties of services by using the configuration utility

Navigate to **Traffic Management** > **Load Balancing** > **Services**. The details of the available services appear on the **Services** pane.

Viewing the Bindings of a Service

You can view the list of virtual servers to which the service is bound. The binding information also provides the name, IP address, port and state of the virtual servers to which the services are bound. You can use the binding information to troubleshoot any problem with binding the services to virtual servers.

To view the bindings of a service by using the command line

At the command prompt, type:

show service bindings <name>

Example COPY

```
show service bindings Service-HTTP-1
```

To view the bindings of a service by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.

2. In the details pane, select the service whose binding information you want to view.

3. In the **Action** tab, click **Show Bindings**.

Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name

- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the appliance, or for a single virtual server, at the command prompt, type:

stat lb vserver [-detail] [<name>]

Example COPY

```
>stat lb vserver -detail

Virtual Server(s) Summary

vsvrIP port Protocol State Req/s Hits/s

One * 80 HTTP UP 5/s 0/s

Two * 0 TCP DOWN 0/s 0/s

Three * 2598 TCP DOWN 0/s 0/s

dnsVirtualNS 10.102.29.90 53 DNS DOWN 0/s 0/s

BRVSERV 10.10.1.1 80 HTTP DOWN 0/s 0/s

LBVIP 10.102.29.66 80 HTTP UP 0/s 0/s

Done
```

To display virtual server statistics by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.

2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.

3. In the details pane, click **Statistics**.

Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

stat service <name>

Example COPY

```
stat service Service-HTTP-1
```

To view the statistics of a service by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.

2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).

3. Click **Statistics**. The statistics appear in a new window.

Load Balancing Algorithms

Aug 29, 2013

The load balancing algorithm defines the criteria that the NetScaler appliance uses to select the service to which to redirect each client request. Different load balancing algorithms use different criteria. For example, the least connection algorithm selects the service with the fewest active connections, while the round robin algorithm maintains a running queue of active services, distributes each connection to the next service in the queue, and then sends that service to the end of the queue.

Some load balancing algorithms are best suited to handling traffic on websites, others to managing traffic to DNS servers, and others to handling complex web applications used in e-commerce or on company LANs or WANs. The following table lists each load balancing algorithm that the NetScaler appliance supports, with a brief description of how each operates.

Name	Server Selection Based On
LEASTCONNECTION	Which service currently has the fewest client connections. This is the default load balancing algorithm.
ROUNDROBIN	Which service is at the top of a list of services. After that service is selected for a connection, it moves to the bottom of the list.
LEASTRESPONSETIME	Which load balanced server currently has the quickest response time.
URLHASH	A hash of the destination URL.
DOMAINHASH	A hash of the destination domain.
DESTINATIONIPHASH	A hash of the destination IP address.
SOURCEIPHASH	A hash of the source IP address.
SRCIPDESTIPHASH	A hash of the source and destination IP addresses.
CALLIDHASH	A hash of the call ID in the SIP header.
SRCIPSRCPORTHASH	A hash of the client's IP address and port.
LEASTBANDWIDTH	Which service currently has the fewest bandwidth constraints.
LEASTPACKETS	Which service currently is receiving the fewest packets.

Name	Server Selection Based On
CUSTOMLOAD	Data from a load monitor.
TOKEN	The configured token.
LRTM	Fewest active connections and the lowest average response time.

Depending on the protocol of the service that it is load balancing, the NetScaler appliance sets up each connection between client and server to last for a different time interval. This is called load balancing granularity, of which are three types: request-based, connection-based, and time-based granularity. The following table describes each type of granularity and when each is used.

Granularity	Types of Load Balanced Service	Specifies
Request - based	HTTP or HTTPS	A new service is chosen for each HTTP request, independent of TCP connections. As with all HTTP requests, after the Web server fulfills the request, the connection is closed.
Connection-based	TCP and TCP-based protocols other than HTTP	A service is chosen for every new TCP connection. The connection persists until terminated by either the service or the client.
Time-based	UDP and other IP protocols	A new service is chosen for each UDP packet. Upon selection of a service, a session is created between the service and a client for a specified period of time. When the time expires, the session is deleted and a new service is chosen for any additional packets, even if those packets come from the same client.

During startup of a virtual server, or whenever the state of a virtual server changes, the virtual server can initially use the round robin method to distribute the client requests among the physical servers. This type of distribution, referred to as *startup round robin,* helps prevent unnecessary load on a single server as the initial requests are served. After using the round robin method at the startup, the virtual server switches to the load balancing method specified on the virtual server.

The Startup RR Factor works in the following manner:

- If the Startup RR Factor is set to zero, the NetScaler switches to the specified load balancing method depending on the request rate.
- If the Startup RR Factor is any number other than zero, NetScaler uses the round robin method for the specified number of requests before switching to the specified load balancing method.
- By default, the Startup RR Factor is set to zero.

Note: You cannot set the startup RR Factor for an individual virtual server. The value you specify applies to all the virtual servers on the NetScaler appliance.

To set the startup round-robin factor by using the command line interface

At the command prompt, type:

set lb parameter -startupRRFactor <positive_integer>

Example

```
set lb parameter -startupRRFactor 25000
```

To set the startup round-robin factor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing.
2. Under Settings, click Configure Load Balancing Parameters.
3. In the Configure Load Balancing Parameters dialog box, for Startup RR Factor type a value.
4. Click OK.

The Least Connection Method

Jul 10, 2013

When a virtual server is configured to use the least connection load balancing algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.

For TCP, HTTP, HTTPS, and SSL_TCP services, the NetScaler appliance includes the following connection types in its list of existing connections:

- **Active connections to a service.** Connections representing requests that a client has sent to the virtual server and that the virtual server has forwarded to a service. For HTTP and HTTPS services, active connections represent only those HTTP or HTTPS requests that have not yet received a response.
- **Waiting connections in the surge queue.** Any connections to the virtual server that are waiting in a surge queue and have not yet been forwarded to a service. Connections can build up in the surge queue at any time, for any of the following reasons:
  - Your services have connection limits, and all services in your load balancing configuration are at that limit.
  - The surge protection feature is configured and has been activated by a surge in requests to the virtual server.
  - The load-balanced server has reached an internal limit and therefore does not open any new connections. (For example, an Apache server's connection limit is reached.)

  When a virtual server uses the least connection method, it considers the waiting connections as belonging to the specific service. Therefore, it does not open new connections to those services.

For UDP services, the connections that the least connection algorithm considers include all sessions between the client and a service. These sessions are logical, time-based entities. When the first UDP packet in a session arrives, the NetScaler appliance creates a session between the source IP address and port and the destination IP address and port.

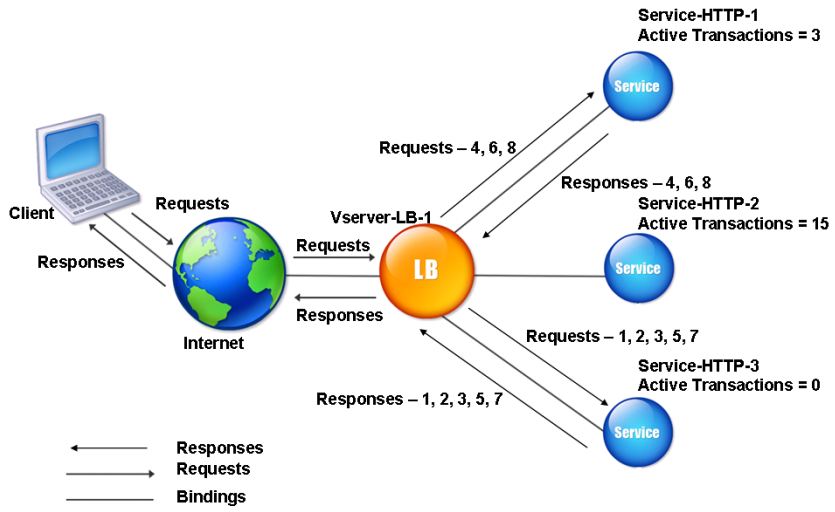
For Real-Time Streaming Protocol (RTSP) connections, the NetScaler appliance uses the number of active control connections to determine the lowest number of connections to an RTSP service.

The following example shows how a virtual server selects a service for load balancing by using the least connection method. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions.
- Service-HTTP-2 is handling 15 active transactions.
- Service-HTTP-3 is not handling any active transactions.

The following diagram illustrates how the NetScaler appliance forwards incoming requests when using the least connection method.

Figure 1. Mechanism of the Least Connections Load Balancing Method



In this diagram, the virtual server selects the service for each incoming connection by choosing the server with the fewest active transactions.

Connections are forwarded as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.

  Note: The service with no active transaction is selected first.
- Service-HTTP-3 receives the second and third requests because the service has the next least number of active transactions.
- Service-HTTP-1 receives the fourth request Because Service-HTTP-1 and Service-HTTP-3 have same number of active transactions, the virtual server uses the round robin method to choose between them.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-1 receives the sixth request, and so on, until both Service-HTTP-1 and Service-HTTP-3 are handling the same number of requests as Service-HTTP-2. At that time, the NetScaler appliance starts forwarding requests to Service-HTTP-2 when it is the least loaded service or its turn comes up in the round robin queue.

  Note: If connections to Service-HTTP-2 close, it might get new connections before each of the other two services has 15 active transactions.

The following table explains how connections are distributed in the three-service load balancing setup described above.

Incoming Connection	Service Selected	Current Number of Active Connections	Remarks
Request-1	Service-HTTP-3 (N = 0)	1	Service-HTTP-3 has the fewest active connections.
Request-2	Service-	2	

Incoming Connection	Service Selected	Current Number of Active Connections	Remarks
	HTTP-3 (N = 1)		
Request-3	Service-HTTP-3 (N = 2)	3	
Request-4	Service-HTTP-1 (N = 3)	4	Service-HTTP-1 and Service-HTTP-3 have the same number of active connections.
Request-5	Service-HTTP-3 (N = 3)	4	
Request-6	Service-HTTP-1 (N = 4)	5	
Request-7	Service-HTTP-3 (N = 4)	5	
Request-8	Service-HTTP-1 (N = 5)	6	
Service-HTTP-2 is selected for load balancing when it completes its active transactions and the current connections to it close, or when the other services (Service-HTTP-1 and Service-HTTP-3) have 15 or more connections each.			

The NetScaler appliance can also use the least connection method when weights are assigned to services. It selects a service by using the value (Nw) of the following expression:

Nw = (Number of active transactions) * (10000 / weight)

The following example shows how the NetScaler appliance selects a service for load balancing by using the least connection method when weights are assigned to services. In the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. Connections are forwarded as follows:

- Service-HTTP-3 receives the first because the service is not handling any active transactions.

  Note: If services are not handling any active transactions, the NetScaler appliance uses the round robin method regardless of the weights assigned to each of the services.
- Service-HTTP-3 receives the second, third, fourth, fifth, sixth, and seventh requests because the service has lowest Nw value.
- Service-HTTP-1 receives the eighth request. Because Service-HTTP-1 and Service-HTTP-3 now have same Nw value, the NetScaler performs load balancing in a round robin manner. Therefore, Service-HTTP-3 receives the ninth request.

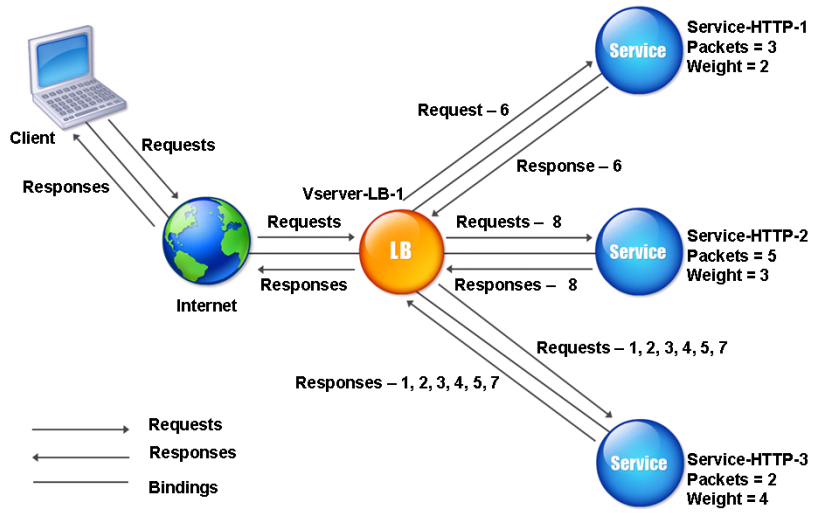
The following table explains how connections are distributed on the three-service load balancing setup that is described above.

Request Received	**Service Selected**	**Current Nw (Number of active transactions) * (10000 / weight) value**	**Remarks**
Request-1	Service-HTTP-3 (Nw = 0)	Nw = 2500	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3 (Nw = 2500)	Nw = 5000	
Request-3	Service-HTTP-3 (Nw = 5000)	Nw = 7500	
Request-4	Service-HTTP-3 (Nw = 7500)	Nw = 10000	
Request-5	Service-HTTP-3 (Nw = 10000)	Nw = 12500	
Request-6	Service-HTTP-3	Nw = 15000	

Request Received	Service Selected	Current Nw (Number of active transactions) * (10000 / weight) value	Remarks
Request-7	Service-HTTP-1 (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw values
Request-8	Service-HTTP-3 (Nw = 15000)	Nw = 17500	
Service-HTTP-2 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-1 and Service-HTTP-3) is equal to 50000.			

The following diagram illustrates how the NetScaler appliance uses the least connection method when weights are assigned to the services.

Figure 2. Mechanism of the Least Connections Load Balancing Method when Weights are Assigned



To configure the least connection method, see Configuring a Load Balancing Method that Does Not Include a Policy.

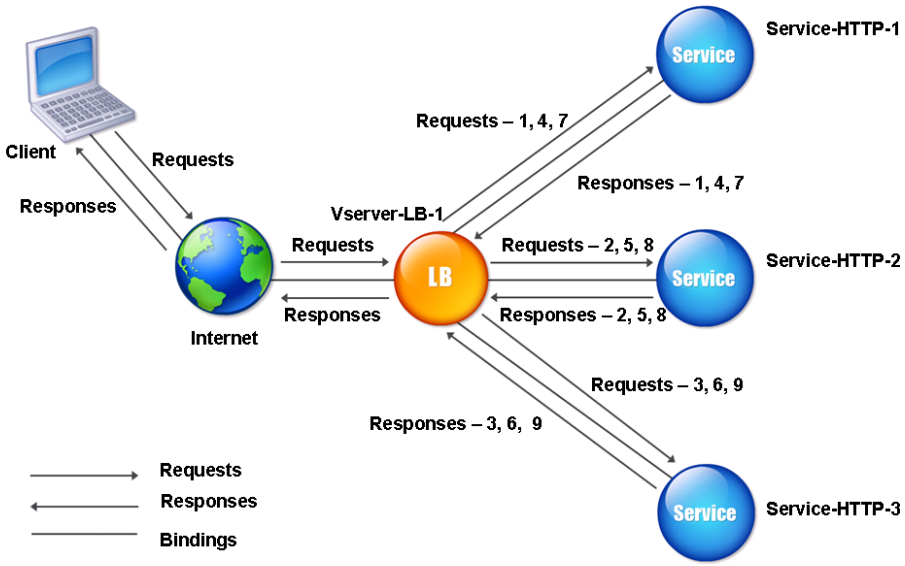
The Round Robin Method

Mar 16, 2012

When a load balancing virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.

The following diagram illustrates how the NetScaler appliance uses the round robin method with a load balancing setup that contains three load-balanced servers and their associated services.

Figure 1. How the Round Robin Load Balancing Method Works



If you assign a different weight to each service, the NetScaler appliance performs weighted round robin distribution of incoming connections. It does this by skipping the lower-weighted services at appropriate intervals.

For example, assume that you have a load balancing setup with three services. You set Service-HTTP-1 to a weight of 2, Service-HTTP-2 to a weight of 3, and Service-HTTP-3 to a weight of 4. The services are bound to Vserver-LB-1, which is configured to use the round robin method. With this setup, incoming requests are delivered as follows:

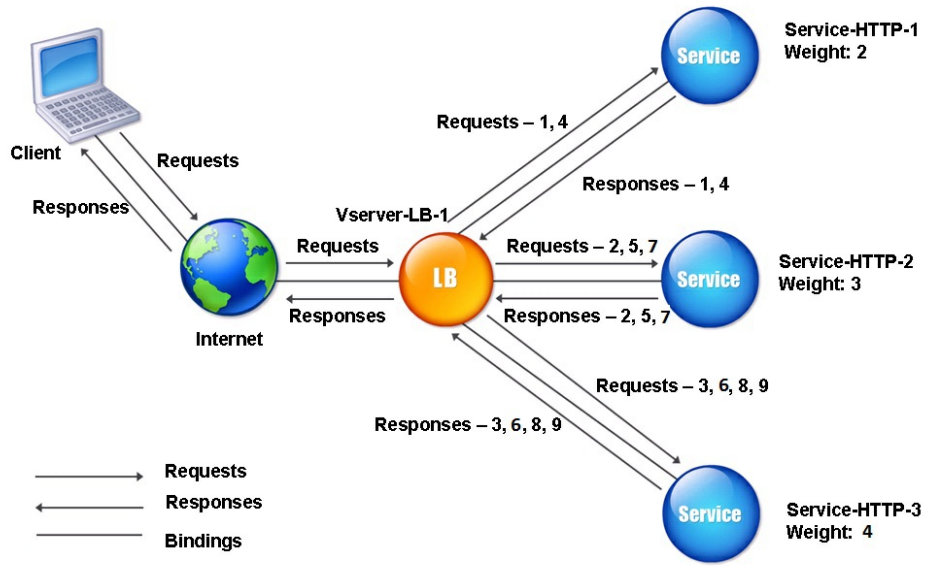
- Service-HTTP-1 receives the first request.
- Service-HTTP-2 receives the second request.
- Service-HTTP-3 receives the third request.
- Service-HTTP-1 receives the fourth request.
- Service-HTTP-2 receives the fifth request.
- Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh request.
- Service-HTTP-3 receives both the eighth and the ninth requests.

Note: You can also configure weights on services to prevent multiple services from using the same server and overloading

the server.
A new cycle then begins, using the same pattern.

The following diagram illustrates the weighted round robin method.

Figure 2. How the Round Robin Load Balancing Method Works with Weighted Services



To configure the round robin method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Least Response Time Method

Jul 10, 2013

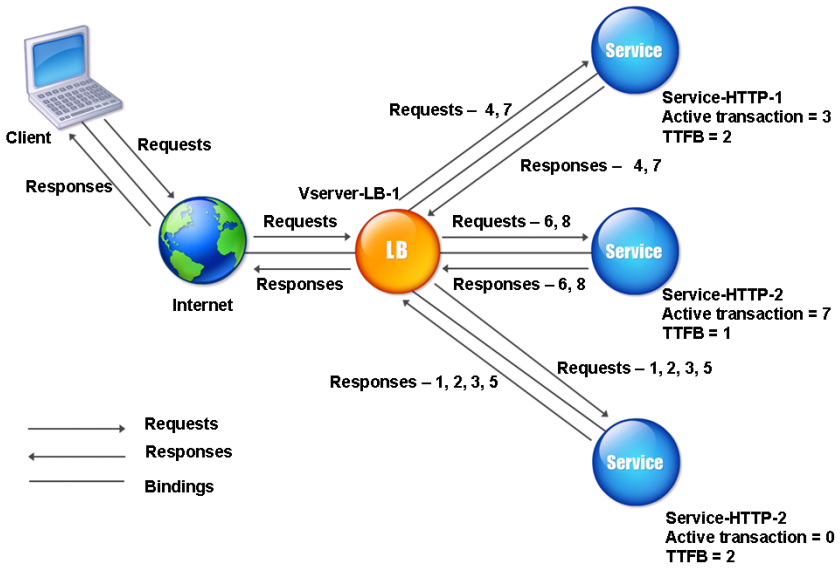
When the load balancing virtual server is configured to use the least response time method, it selects the service with the fewest active connections and the lowest average response time. You can configure this method for HTTP and Secure Sockets Layer (SSL) services only. The response time (also called Time to First Byte, or TTFB) is the time interval between sending a request packet to a service and receiving the first response packet from the service. The NetScaler appliance uses response code 200 to calculate TTFB.

The following example shows how a virtual server selects a service for load balancing by using the least response time method. Consider the following three services:

- Service-HTTP-1 is handling three active transactions and TTFB is two seconds.
- Service-HTTP-2 is handling seven active transactions and TTFB is one second.
- Service-HTTP-3 is not handling any active transactions and TTFB is two seconds.

The following diagram illustrates how the NetScaler appliance uses the least response time method to forward the connections.

Figure 1. How the Least Response Time Load Balancing Method Works



The virtual server selects a service by multiplying the number of active transactions by the TTFB for each service and then selecting the service with the lowest result. For the example shown above, the virtual server forwards requests as follows:

- Service-HTTP-3 receives the first request, because the service is not handling any active transactions.
- Service-HTTP-3 also receives the second and third requests, because the result is lowest of the three services.
- Service-HTTP-1 receives the fourth request. Since Service-HTTP-1 and Service-HTTP-3 have the same result, the NetScaler appliance chooses between them by applying the Round Robin method.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-2 receives the sixth request, because at this point it has the lowest result.
- Because Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all have the same result at this point, the NetScaler

switches to the round robin method, and continues to distribute connections using that method.

The following table explains how connections are distributed in the three-service load balancing setup described above.

Request Received	Service Selected	Current N Value (Number of Active Transactions * TTFB)	Remarks
Request-1	Service-HTTP-3 (N = 0)	N = 2	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-3 (N = 2)	N = 4	
Request-3	Service-HTTP-3 (N = 3)	N = 6	
Request-4	Service-HTTP-1 (N = 6)	N = 8	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-5	Service-HTTP-3 (N = 6)	N = 8	
Request-6	Service-HTTP-2 (N = 7)	N = 8	Service-HTTP-2 has the lowest N value.
Request-7	Service-HTTP-1 (N = 8)	N = 15	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-8	Service-HTTP-2 (N = 8)	N = 9	

Request Received	Service Selected	Current N Value (Number of Active Transactions) * TFB	Remarks

The virtual server selects a service based on the value (Nw) in the following expression:

Nw = (N) * (10000 / weight)

Suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned weight of 3, and Service-HTTP-3 is assigned weight of 4.

The NetScaler appliance distributes requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.

  If services are not handling any active transactions, the NetScaler selects them regardless of the weights assigned to them.

- Service-HTTP-3 receives the second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and therefore the highest Nw value, so the virtual server does not select it for load balancing.

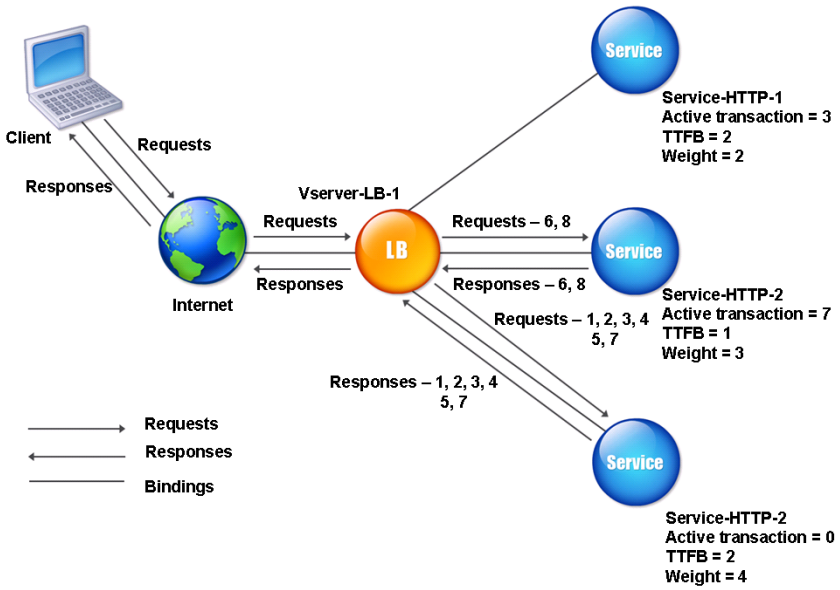
The following table explains how connections are distributed in the three-service load balancing setup described above.

Request Received	Service Selected	Current Nw Value (Number of Active Transactions) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-3 (Nw = 0)	Nw = 2500	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3 (Nw = 2500	Nw = 5000	
Request-3	Service-HTTP-3 (Nw = 5000)	Nw = 15000	
Request-4	Service-HTTP-3 (Nw = 15000)	Nw = 20000	

Request Received	Service Selected	Current Nw Value (Number of Active Transactions) * (10000 / Weight)	Remarks
Request-5	Service-HTTP-3 (Nw = 20000)	Nw = 25000	
Request-6	Service-HTTP-2 (Nw = 23333.34)	Nw = 26666.67	Service-HTTP-2 has the lowest Nw value.
Request-7	Service-HTTP-3 (Nw = 25000)	Nw= 30000	Service-HTTP-3 has the lowest Nw value.
Request-8	Service-HTTP-2 (Nw = 26666.67)	Nw = 33333.34	Service-HTTP-2 has the lowest Nw value.
Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw values of other services (Service-HTTP-2 and Service-HTTP-3) are equal to 105000.			

The following diagram illustrates how the NetScaler appliance uses the least response time method when weights are assigned.

Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned



To configure the least response time method, see Configuring a Load Balancing Method that Does Not Include a Policy.

When a load balancing virtual server is configured to use the least response time method with monitors, it uses the existing monitoring infrastructure to select the service with the smallest number of active transactions and the fastest average response time. Before you use the least response time method with monitoring, you must bind application-specific monitors to each service and enable least response time method mode on these monitors. The NetScaler appliance then makes load balancing decisions based on the response times it calculates from monitoring probes. For more information about configuring monitors, see Configuring Monitors in a Load Balancing Setup.

You can use the least response time method with monitors to select non-HTTP and non-HTTPS services. You can also use this method when several monitors are bound to a service. Each monitor determines the response time by using the protocol that it measures for the service that it is bound to. The virtual server then calculates an average response time for that service by averaging the results.

The following table summarizes how response times are calculated for various monitors.

Monitor	Response Time Calculation
PING	Time difference between the ICMP ECHO request and the ICMP ECHO response.
TCP	Time difference between the SYN request and the SYN+ACK response.
HTTP	Time difference between the HTTP request (after the TCP connection is established) and the HTTP response.
TCP-ECV	Time difference between the time the data send string is sent and the data receive string is returned. A tcp-ecv monitor without the send and receive strings is considered to have an incorrect

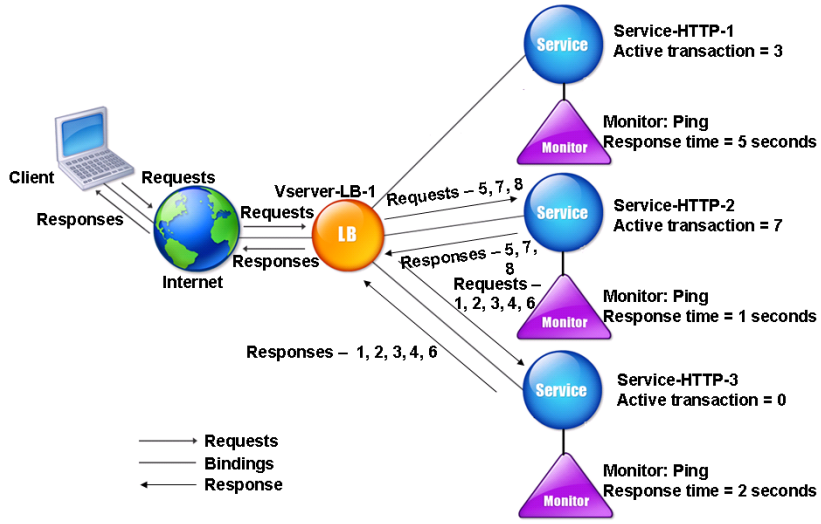
Monitor	Response Time Calculation
HTTP-ECV	Time difference between the HTTP request and the HTTP response.
UDP-ECV	Time difference between the UDP send string and the UDP receive string. A udp-ecv monitor without the receive string is considered to have an incorrect configuration.
DNS	Time difference between a DNS query and the DNS response.
TCPS	Time difference between a SYN request and the SSL handshake completion.
FTP	Time difference between the sending of the user name and the completion of user authentication.
HTTPS (monitors HTTPS requests)	Time difference is same as for the HTTP monitor.
HTTPS-ECV (monitors HTTPS requests)	Time difference is same as for the HTTP-ECV monitor
USER	Time difference between the time when a request is sent to the dispatcher and the time when the dispatcher response is received.

The following example shows how the NetScaler appliance selects a service for load balancing by using the least response time method with monitors. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions and the response time is five seconds.
- Service-HTTP-2 is handling 7 active transactions and the response time is one second.
- Service-HTTP-3 is not handling any active transactions and the response time is two seconds.

The following diagram illustrates the process that the NetScaler appliance follows when it forwards requests.

Figure 3. How the Least Response Time Load Balancing Method Works When Using Monitors



The virtual server selects a service by using the value (N) in the following expression:

N = Number of active transactions * Response time that is determined by the monitor

The virtual server delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service is not handling any active transaction.
- Service-HTTP-3 receives the second, third, and fourth requests, because this service has the lowest N value.
- Service-HTTP-2 receives the fifth request, because this service has the lowest N value.
- Since both Service-HTTP-2 and Service-HTTP-3 currently have the same N value, the NetScaler appliance switches to the round robin method Therefore, Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh and eighth requests, because this service has the lowest N value.

Service-HTTP-1 is not considered for load balancing, because it is more heavily loaded (has the highest N value) when compared to the other two services. However, if Service-HTTP-1 completes its active transactions, the NetScaler appliance again considers that service for load balancing.

The following table summarizes how N is calculated for the services.

Request Received	Service Selected	Current N Value (Number of Active Transactions)	Remarks
Request-1	Service-HTTP-3 (N = 0)	N = 2	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-3 (N = 2)	N = 4	

Request Received	Service Selected	Current N Value (Number of Active Transactions)	Remarks
Request-3	Service-HTTP-3 (N = 4)	N = 6	
Request-4	Service-HTTP-3 (N = 6)	N = 8	
Request-5	Service-HTTP-2 (N = 7)	N = 8	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-6	Service-HTTP-3 (N = 8)	N = 10	
Request-7	Service-HTTP-2 (N = 8)	N = 9	Service-HTTP-2 has the lowest N value.
Request-8	Service-HTTP-1 (N = 9)	N = 10	
Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when the N value of the other services (Service-HTTP-2 and Service-HTTP-3) is equal to 15.			

The NetScaler appliance also performs load balancing by using the number of active transactions, response time, and weights if different weights are assigned to services. The NetScaler appliance selects the service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight)

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4.

The NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.
- Service-HTTP-3 receives the second, third, and fourth requests, because this service has the lowest Nw value.

- Service-HTTP-2 receives the fifth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the seventh and the eighth requests, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and the highest Nw value, so the NetScaler appliance does not select it for load balancing.

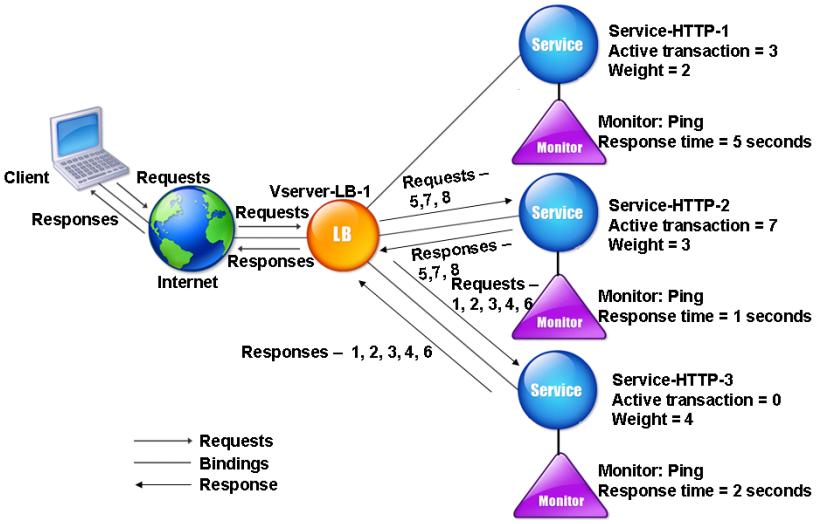
The following table summarizes how Nw is calculated for various monitors.

Request Received	**Service Selected**	**Current Nw Value (Number of Active Transactions) * (10000 / Weight)**	**Remarks**
Request-1	Service-HTTP-3 (Nw = 0)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3 (Nw = 5000	Nw = 10000	
Request-3	Service-HTTP-3 (Nw = 15000)	Nw = 20000	
Request-4	Service-HTTP-3 (Nw = 20000)	Nw = 25000	
Request-5	Service-HTTP-2 (Nw = 23333.34)	Nw = 26666.67	Service-HTTP-2 has the lowest Nw value.
Request-6	Service-HTTP-3 (Nw = 25000)	Nw = 30000	Service-HTTP-3 has the lowest Nw value.

Request Received	Service Selected	Current Nw Value (Number of Active Transactions) * (10000 / Weight)	Remarks
Request-7	Service-HTTP-2 (Nw = 23333.34)	Nw= 26666.67	Service-HTTP-2 has the lowest Nw value.
Request-8	Service-HTTP-2 (Nw =25000)	Nw = 30000	Service-HTTP-2 has the lowest Nw value.
Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw value of the other services (Service-HTTP-2 and Service-HTTP-3) is equal to 75000.			

The following diagram illustrates how the virtual server uses the least response time method when weights are assigned.

Figure 4. How the Least Response Time Load Balancing Method with Monitors Works When Weights Are Assigned



To configure the least response time method using monitors, see Configuring a Load Balancing Method that Does Not Include a Policy.

About Hashing Methods

Mar 16, 2012

Load balancing methods based on hashes of certain connection information or header information constitute the majority of the NetScaler appliance's load balancing methods. Hashes are shorter and easier to use than the information that they are based on, while retaining enough information to ensure that no two different pieces of information generate the same hash and are therefore confused with one another.

You can use the hashing load balancing methods in an environment where a cache serves a wide range of content from the Internet or specified origin servers. Caching requests reduces request and response latency, and ensures better resource (CPU) utilization, making caching popular on heavily used Web sites and application servers. Since these sites also benefit from load balancing, hashing load balancing methods are widely useful.

The NetScaler provides the following hashing methods:

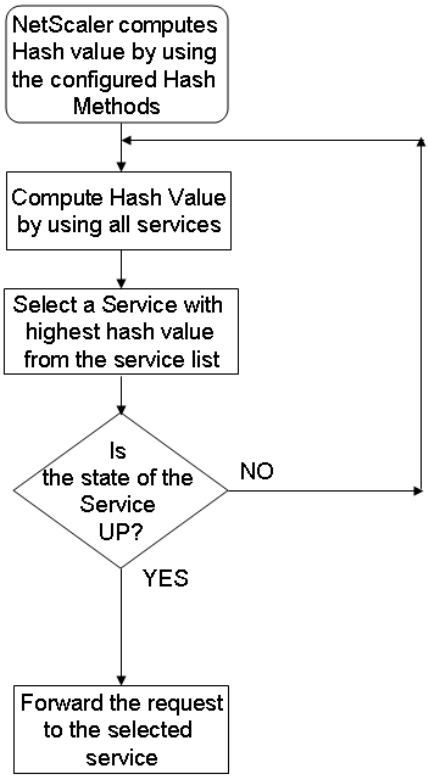
- URL hash method
- Domain hash method
- Destination IP hash method
- Source IP hash method
- Source IP Destination IP hash method
- Source IP Source Port hash method
- Call ID hash method
- Token method

These hashing algorithms ensure minimal disruption when services are added to or deleted from your load balancing setup. Most of them calculate two hash values:

- A hash of the service's IP address and port.
- A hash of the incoming URL, the domain name, the source IP address, the destination IP address, or the source and destination IP addresses, depending on the configured hash method.

The NetScaler appliance then generates a new hash value by using both of those hash values. Finally, it forwards the request to the service with highest hash value. As the appliance computes a hash value for each request and selects the service that will process the request, it populates a cache. Subsequent requests with the same hash value are sent to the same service. The following flow chart illustrates this process.

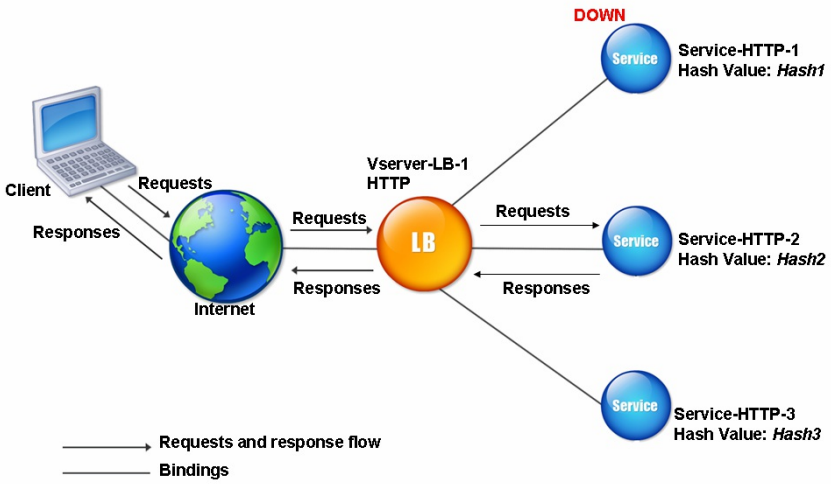
Figure 1. How the Hashing Methods Distribute Requests



Hashing methods can be applied to IPv4 and IPv6 addresses.

Consider a scenario where three services (Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3) are bound to a virtual server, any hash method is configured, and the hash value is Hash1. When the configured services are UP, the request is sent to Service-HTTP-1. If Service-HTTP-1 is down, the NetScaler appliance calculates the hash value for the last log of the number of services. The NetScaler then selects the service with the highest hash value, such as Service-HTTP-2. The following diagram illustrates this process.

Figure 2. Entity Model for Hashing Methods



Note: If the NetScaler appliance fails to select a service by using a hashing method, it defaults to the least connection method to select a service for the incoming request. You should adjust server pools by removing services during periods of low traffic to enable the caches to repopulate without affecting performance on your load balancing setup.

The URL Hash Method

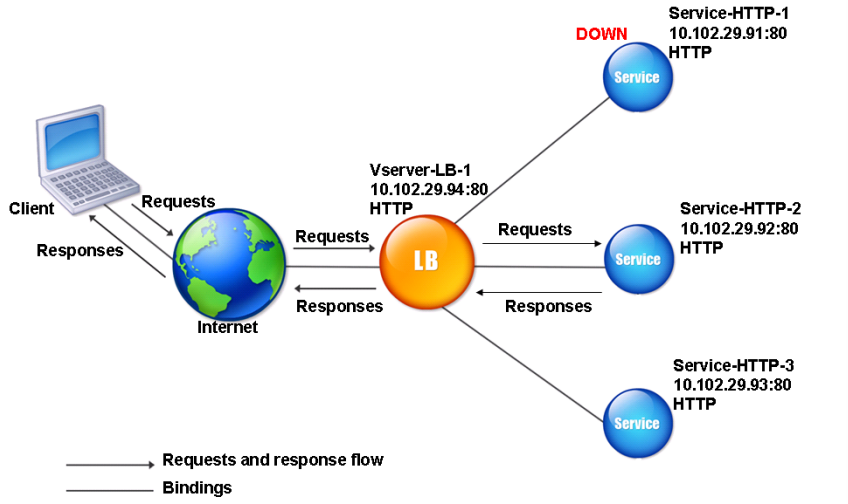
When you configure the NetScaler appliance to use the URL hash method for load balancing the services, for selecting a service, the NetScaler generates a hash value of the HTTP URL present in the incoming request. If the service selected by the hash value is DOWN, the algorithm has a method to select another service from the list of active services. The NetScaler caches the hashed value of the URL, and when it receives subsequent requests that use the same URL, it forwards them to the same service. If the NetScaler cannot parse an incoming request, it uses the round robin method for load balancing instead of the URL hash method.

For generating the hash value, NetScaler uses a specific algorithm and considers a part of the URL. By default, the NetScaler considers the first 80 bytes of the URL. If the URL is of less than 80 bytes, the complete URL is used. You can specify a different length. The hash length can be from 1 to 4096 bytes. Generally, if long URLs are used where only a small number of characters are different, it is a good idea to make the hash length as high as possible to try to ensure a more even load distribution.

Consider a scenario where three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3, are bound to a virtual server, and the load balancing method configured on the virtual server is the URL hash method. The virtual server receives a request and the hash value of the URL is U1. NetScaler selects Service-HTTP-1. If Service-HTTP-1 is DOWN, the NetScaler selects Service-HTTP-2.

The following diagram illustrates this process.

Figure 3. How URL Hashing Operates



If both Service-HTTP-1 and Service-HTTP-2 are DOWN, NetScaler sends requests with hash value U1 to Service-HTTP-3.

If Service-HTTP-1 and Service-HTTP-2 are down, requests that generate the hash URL1 are sent to Service-HTTP-3. If these services are UP, requests that generate the hash URL1 are distributed in the following manner:

- If the Service-HTTP-2 is up, the request is sent to Service-HTTP-2.
- If the Service-HTTP-1 is up, the request is sent to Service-HTTP-1.
- If Service-HTTP-1 and Service-HTTP-2 are up at the same time, the request is sent to Service-HTTP-1.

To configure the URL hash method, see Configuring a Load Balancing Method that Does Not Include a Policy. Select the load balancing method as URL Hash, and set the hash length to the number of bytes to be used for generating the hash

value.

The Domain Hash Method

A load balancing virtual server configured to use the domain hash method uses the hashed value of the domain name in the HTTP request to select a service. The domain name is taken from either the incoming URL or the Host header of the HTTP request. If the domain name appears in both the URL and the Host header, the NetScaler gives preference to the URL.

If you configure domain name hashing, and an incoming HTTP request does not contain a domain name, the NetScaler appliance defaults to the round robin method for that request.

The hash-value calculation uses the name length or hash length value, whichever is smaller. By default, the NetScaler appliance calculates the hash value from the first 80 bytes of the domain name. To specify a different number of bytes in the domain name when calculating the hash value, you can set the hashLength parameter (Hash Length in the configuration utility) to a value of from 1 to 4096 (bytes).

To configure the domain hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Destination IP Hash Method

Updated: 2013-09-03

A load balancing virtual server configured to use the destination IP hash method uses the hashed value of the destination IP address to select a server. You can mask the destination IP address to specify which part of it to use in the hash value calculation, so that requests that are from different networks but destined for the same subnet are all directed to the same server. This method supports IPv4 and IPv6-based destination servers.

This load balancing method is appropriate for use with the cache redirection feature.

To configure the destination IP hash method for an IPv4 destination server, you set the netMask parameter. To configure this method for an IPv6 destination server, you use the v6NetMaskLen parameter. In the configuration utility, text boxes for setting these parameters appear when you select the Destination IP Hash method.

To configure the destination IP hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Source IP Hash Method

A load balancing virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Source IP Destination IP Hash Method

A load balancing virtual server configured to use the source IP destination IP hash method uses the hashed value of the source and destination IP addresses (either IPv4 or IPv6) to select a service. Hashing is symmetric; the hash-value is the same regardless of the order of the source and destination IPs. This ensures that all packets flowing from a particular client to the same destination are directed to the same server.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP destination IP hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Source IP Source Port Hash Method

A load balancing virtual server configured to use the source IP source port hash method uses the hash value of the source IP (either IPv4 or IPv6) and source port to select a service. This ensures that all packets on a particular connection are directed to the same service.

This method is used in connection mirroring and firewall load balancing. For more information about connection mirroring, see Connection Failover.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP source port hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Call ID Hash Method

A load balancing virtual server configured to use the call ID hash method uses the hash value of the call ID in the SIP header to select a service. Packets for a particular SIP session are therefore always directed to the same proxy server.

This method is applicable to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

To configure the call ID hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Least Bandwidth Method

Jan 17, 2014

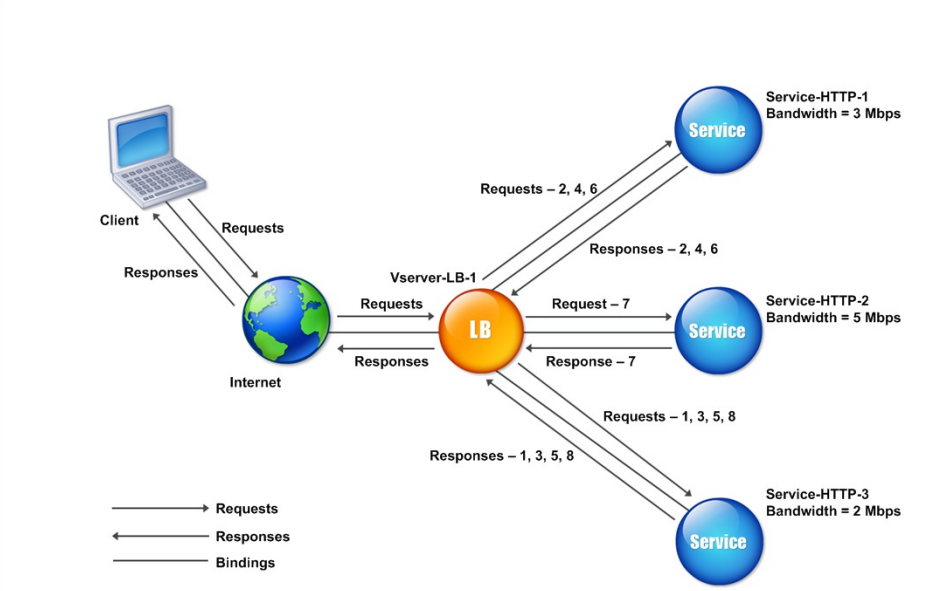
A load balancing virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps). The following example shows how the virtual server selects a service for load balancing by using the least bandwidth method.

Consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has 3 Mbps bandwidth.
- Service-HTTP-2 has 5 Mbps bandwidth.
- Service-HTTP-3 has 2 Mbps bandwidth.

The following diagram illustrates how the virtual server uses the least bandwidth method to forward requests to the three services.

Figure 1. How the Least Bandwidth Load Balancing Method Works



The virtual server selects the service by using the bandwidth value (N), which is the sum of the number of bytes transmitted and received over the previous 14 seconds. If each request requires 1 Mbps bandwidth, the NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Since Service-HTTP-1 and Service-HTTP-3 now have same N value, the virtual server switches to the round robin method for these servers, alternating between them. Service-HTTP-1 receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 now all have same N value, the virtual server includes Service-HTTP-2 in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

Request Received	Service Selected	Current N Value	Remarks
Request-1	Service-HTTP-3 (N = 2)	N = 3	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-1 (N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-3	Service-HTTP-3 (N = 3)	N = 4	
Request-4	Service-HTTP-1 (N = 4)	N = 5	
Request-5	Service-HTTP-3 (N = 4)	N = 5	
Request-6	Service-HTTP-1 (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-7	Service-HTTP-2 (N = 5)	N = 6	
Request-8	Service-HTTP-3 (N = 5)	N = 6	

Note: If you enable the RTSP NAT option on the virtual server, the NetScaler appliance uses the number of data and control bytes exchanged to determine the bandwidth usage for RTSP services. For more information about RTSP NAT

option, see Managing RTSP Connections.
The NetScaler appliance also performs load balancing by using the bandwidth and weights if different weights are assigned to the services. It selects a service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight)

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

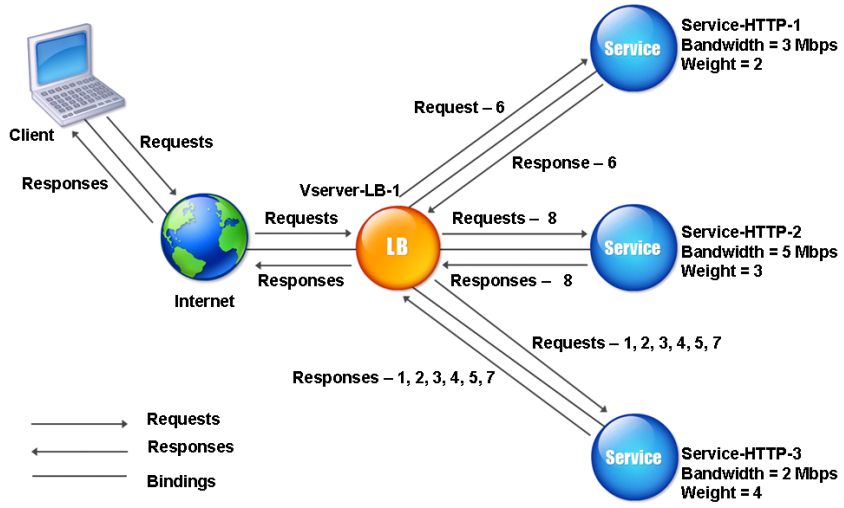
The following table summarizes how Nw is calculated.

Request Received	**Service Selected**	**Current Nw Value (Number of Active Transactions) * (10000 / Weight)**	**Remarks**
Request-1	Service-HTTP-3 (Nw = 5000)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3 (Nw = 5000)	Nw = 7500	
Request-3	Service-HTTP-3 (Nw = 7500)	Nw = 10000	
Request-4	Service-HTTP-3 (Nw = 10000)	Nw = 12500	
Request-5	Service-HTTP-3 (Nw =	Nw = 15000	

Request Received	Service Selected	Current Nw Value (Number of Active Transactions) * (10000 / Weight)	Remarks
Request-6	Service-HTTP-1 (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-7	Service-HTTP-3 (Nw = 15000)	Nw = 17500	
Request-8	Service-HTTP-2 (Nw = 16666.67)	Nw = 20000	Service-HTTP-2 has the lowest Nw value.

The following diagram illustrates how the virtual server uses the least bandwidth method when weights are assigned to the services.

Figure 2. How the Least Bandwidth Load Balancing Method Works When Weights Are Assigned



To configure the least bandwidth method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Least Packets Method

Jan 17, 2014

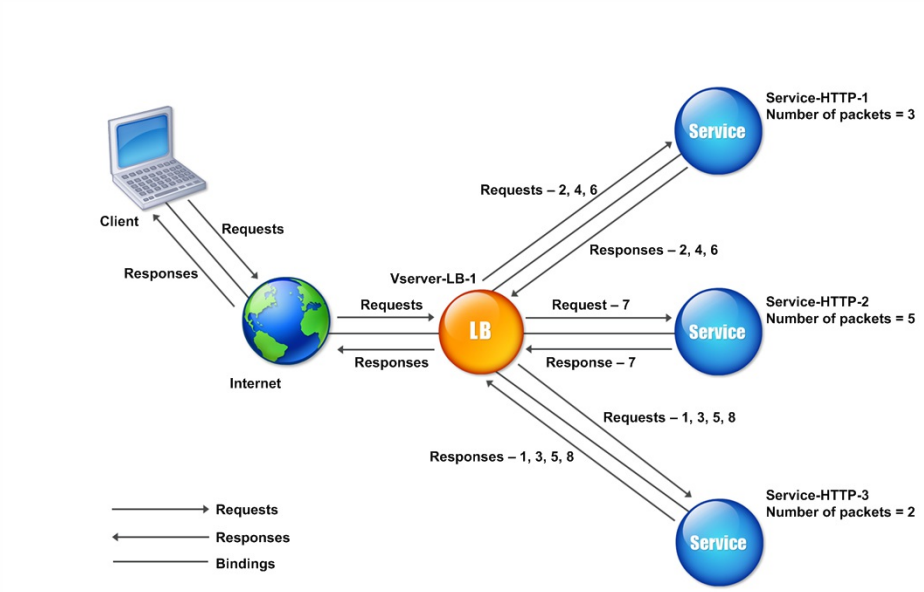
A load balancing virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has handled three packets in last 14 seconds.
- Service-HTTP-2 has handled five packets in last 14 seconds.
- Service-HTTP-3 has handled two packets in last 14 seconds.

The following diagram illustrates how the NetScaler appliance uses the least packets method to choose a service for each request that it receives.

Figure 1. How the Least Packets Load Balancing Method Works



The NetScaler appliance selects a service by using the number of packets (N) transmitted and received by each service in the last 14 seconds. Using this method, it delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Since Service-HTTP-1 and Service-HTTP-3 now have the same N value, the virtual server switches to the round robin method. Service-HTTP-1 therefore receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have same N value, the virtual server switches to the round robin method for Service-HTTP-2 as well, including it in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

Request Received	Service Selected	Current N Value	Remarks
Request-1	Service-HTTP-3 (N = 2)	N = 3	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-1 (N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-3	Service-HTTP-3 (N = 3)	N = 4	
Request-4	Service-HTTP-1 (N = 4)	N = 5	
Request-5	Service-HTTP-3 (N = 4)	N = 5	
Request-6	Service-HTTP-1 (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-7	Service-HTTP-2 (N = 5)	N = 6	
Request-8	Service-HTTP-3 (N = 5)	N = 6	

Note: If you enable the RTSP NAT option on the virtual server, the NetScaler uses the number of data and control packets to calculate the number of packets for RTSP services. For more information about RTSP NAT option, see Managing RTSP

Connections.

The NetScaler appliance also performs load balancing by using the number of packets and weights when a different weight is assigned to each service. It selects a service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight)

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

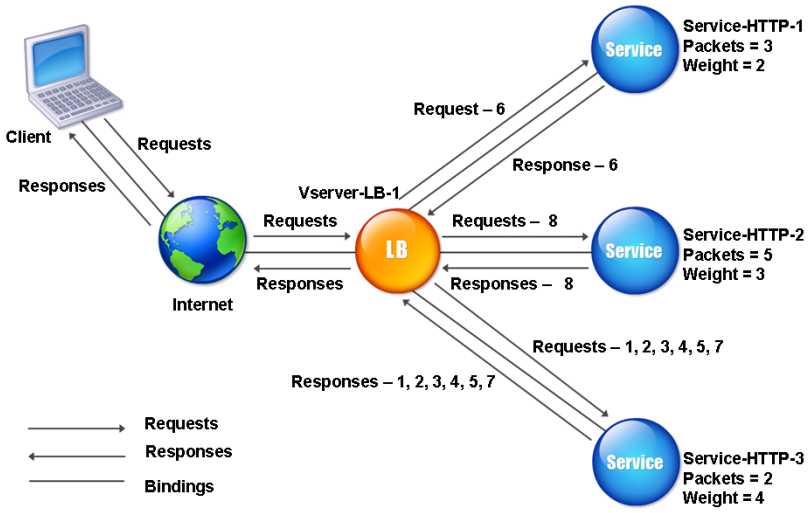
The following table summarizes how Nw is calculated.

Request Received	**Service Selected**	**Current Nw Value (Number of Active Transactions) * (10000 / weight)**	**Remarks**
Request-1	Service-HTTP-3 (Nw = 5000)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3 (Nw = 5000)	Nw = 7500	
Request-3	Service-HTTP-3 (Nw = 7500)	Nw = 10000	
Request-4	Service-HTTP-3 (Nw = 10000)	Nw = 12500	
Request-5	Service-HTTP-3 (Nw =	Nw = 15000	

Request Received	Service Selected	Current Nw Value (Number of Active Transactions) * (10000 / weight)	Remarks
Request-6	Service-HTTP-1 (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-7	Service-HTTP-3 (Nw = 15000)	Nw = 17500	
Request-8	Service-HTTP-2 (Nw = 16666.67)	Nw = 20000	Service-HTTP-2 has the lowest Nw value.

The following diagram illustrates how the virtual server uses the least packets method when weights are assigned.

Figure 2. How the Least Packets Method Works When Weights Are Assigned



To configure the least packets method, see Configuring a Load Balancing Method that Does Not Include a Policy.

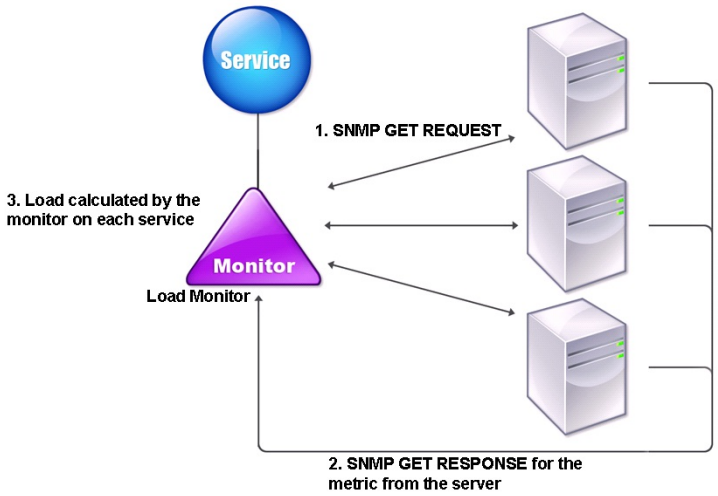
The Custom Load Method

Feb 24, 2015

Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the NetScaler appliance usually selects a service that is not handling any active transactions. If all of the services in the load balancing setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the load balancing decision when those services are not UP.

For more information about load monitors, see Understanding Load Monitors. The following diagram illustrates how a load monitor operates.

Figure 1. How Load Monitors Operate



The load monitor uses Simple Network Management Protocol (SNMP) probes to calculate load on each service by sending an SNMP GET request to the service. This request contains one or more object IDs (OIDs). The service responds with an SNMP GET response, with metrics corresponding to the SNMP OIDs. The load monitor uses the response metrics, described below, to calculate the load on the service.

The load monitor calculates the load on a service by using the following parameters:

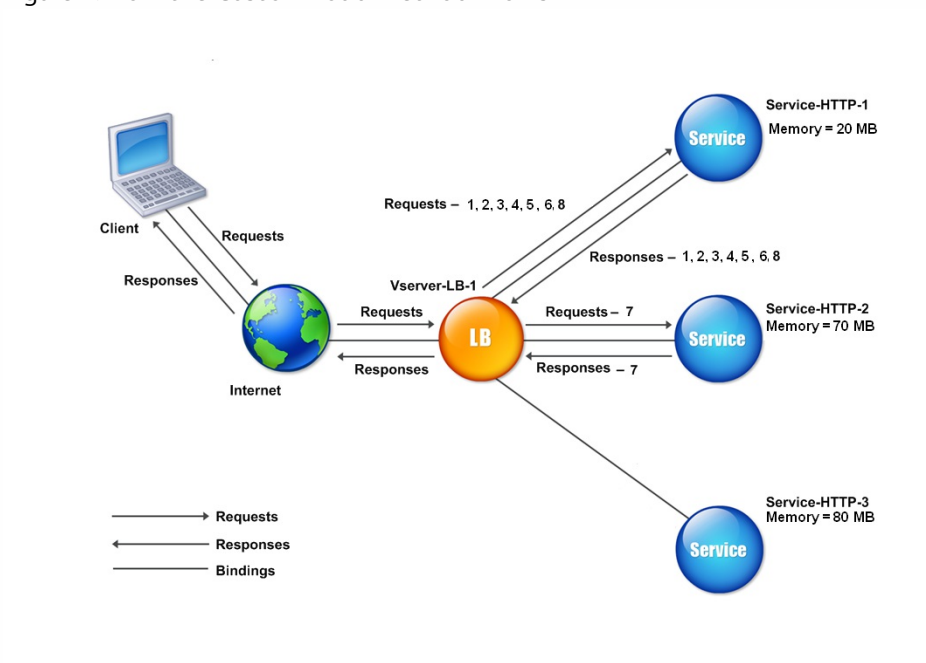
- Metrics values retrieved through SNMP probes that exist as tables in the NetScaler.
- Threshold value set for each metric.
- Weight assigned to each metric.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 is using 20 megabytes (MB) of memory.
- Service-HTTP-2 is using 70 MB of memory.
- Service-HTTP-3 is using 80 MB of memory.

The load balanced servers can export metrics such as CPU and memory usage to the services, which can in turn provide them to the load monitor. The load monitor sends an SNMP GET request containing the OIDs 1.3.6.1.4.1.5951.4.1.1.41.1.5, 1.3.6.1.4.1.5951.4.1.1.41.1.4, and 1.3.6.1.4.1.5951.4.1.1.41.1.3 to the services. SNMP OIDs of type STRING are not supported, because you cannot calculate the load by using a STRING OID. Loads can be calculated by using other data types, such as INT and gauge32. The three services respond to the request. The NetScaler appliance compares the exported metrics, and then selects Service-HTTP-1 because it has more available memory. The following diagram illustrates this process.

Figure 2. How the Custom Load Method Works



If each request uses 10 MB memory, the NetScaler appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, and fifth requests, because this service has the lowest N value.
- Service-HTTP-1 and Service-HTTP-2 now have the same load, so the virtual server reverts to the round robin method for these servers. Therefore, Service-HTTP-2 receives the sixth request, and Service-HTTP-1 receives the seventh request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have same load, the virtual server reverts to the round robin method for Service-HTTP-3 as well. Therefore, Service-HTTP-3 receives the eighth request.

The following table summarizes how N is calculated.

Request received	Service selected	Current N Value (Number of Active Transactions)	Remarks
Request-1	Service-HTTP-1 (N = 20)	N = 30	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-1 (N = 30)	N = 40	

Request received	Service selected	Current N Value (Number of Active Transactions)	Remarks
Request-3	Service-HTTP-1 (N = 40)	N = 50	
Request-4	Service-HTTP-1 (N = 50)	N = 60	
Request-5	Service-HTTP-1 (N = 60)	N = 70	
Request-6	Service-HTTP-1 (N = 70)	N = 80	Service-HTTP-2 and Service-HTTP-3 have the same N values.
Request-7	Service-HTTP-2 (N = 70)	N = 80	
Request-8	Service-HTTP-1 (N = 80)	N = 90	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.

If different weights are assigned to the services, the custom load algorithm considers both the load on each service and the weight assigned to each service. It selects a service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight)

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 4, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 2. If each request uses 10 MB memory, the NetScaler appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, fifth, sixth, seventh, and eighth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the ninth request, because this service has the lowest Nw value.

Service-HTTP-3 has the highest Nw value, and is therefore not considered for load balancing.

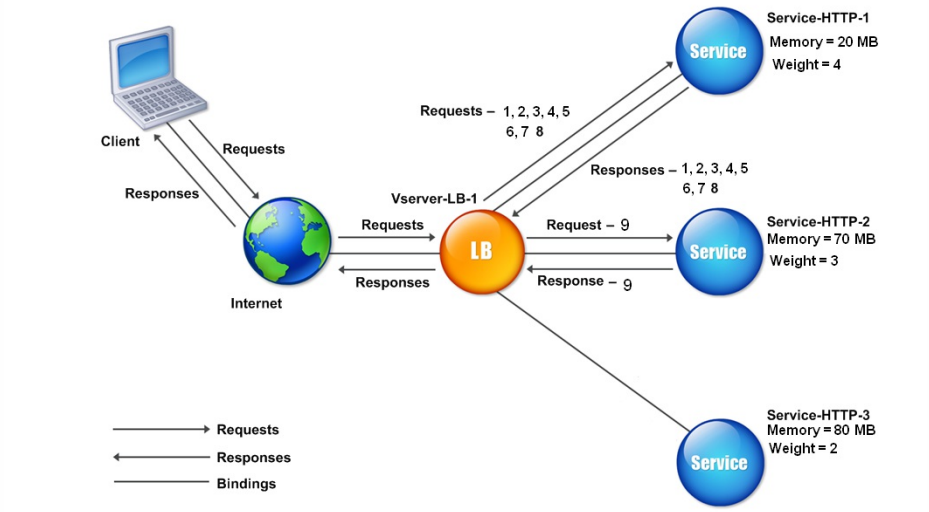
The following table summarizes how Nw is calculated.

Request received	Service selected	Current Nw Value (Number of Active Transactions) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-1 (Nw = 50000)	Nw = 75000	Service-HTTP-1 has the lowest Nw value.
Request-2	Service-HTTP-1 (Nw = 5000)	Nw = 100000	
Request-3	Service-HTTP-1 (Nw = 15000)	Nw = 125000	
Request-4	Service-HTTP-1 (Nw = 20000)	Nw = 150000	
Request-5	Service-HTTP-1 (Nw = 23333.34))	Nw = 175000	
Request-6	Service-HTTP-1 (Nw = 25000)	Nw = 200000	
Request-7	Service-HTTP-1 (Nw = 23333.34)	Nw = 225000	
Request-8	Service-	Nw = 250000	

Request received	Service selected	Current Nw Value (Number of Active Transactions) * (10000 / Weight)	Remarks
	HTTP-1 (Nw = 25000)		
Request-9	Service-HTTP-2 (Nw = 233333.34)	Nw = 266666.67	Service-HTTP-2 has the lowest Nw value.
Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-2 and Service-HTTP-3) is equal to 400,000.			

The following diagram illustrates how the NetScaler appliance uses the custom load method when weights are assigned.

Figure 3. How the Custom Load Method Works When Weights Are Assigned



To configure the custom load method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Configuring the Token Method

Jul 15, 2014

A load balancing virtual server configured to use the token method bases its selection of a service on the value of a data segment extracted from the client request. The data segment is called the token. You configure the location and size of the token. For subsequent requests with the same token, the virtual server chooses the same service that handled the initial request.

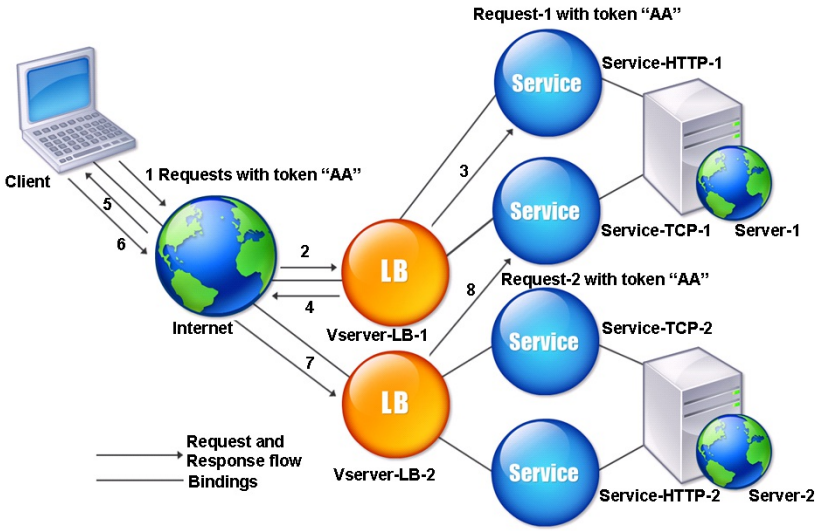
This method is content aware; it operates differently for TCP, HTTP, and HTTPS connections. For HTTP or HTTPS services, the token is found in the HTTP headers, the URL, or the BODY. To locate the token, you specify or create a classic or advanced expression. For more information on classic or advanced expressions, see Policy Configuration and Reference.

For HTTP services, the virtual server searches for the configured token in the first 24 kilobytes (KB) of the TCP payload. For non-HTTP (TCP, SSL, and SSL_TCP) services, the virtual server searches for the configured token in the first 16 packets if the total size of the 16 packets is less than 24 KB. But if the total size of the 16 packets is greater than 24 KB, the NetScaler searches for the token in the first 24 KB of payload. You can use this load balancing method across virtual servers of different types to make sure that requests presenting the same token are directed to appropriate services, regardless of the protocol used.

For example, consider a load balancing setup consisting of servers that contain Web content. You want to configure the NetScaler appliance to search for a specific string (the token) inside the URL query portion of the request. Server-1 has two services, Service-HTTP-1 and Service-TCP-1, and Server-2 has two services, Service-HTTP-2 and Service-TCP-2. The TCP services are bound to Vserver-LB-2, and the HTTP services are bound to Vserver-LB-1.

If Vserver-LB-1 receives a request with the token AA, it selects the service Service-HTTP-1 (bound to server-1) to process the request. If Vserver-LB-2 receives a different request with the same token (AA), it directs this request to the service Service-TCP-1. The following diagram illustrates this process.

Figure 1. How the Token Method Works



To configure the Token load balancing method by using the command line interface

At the command prompt, type the following commands to configure the token load balancing method and verify the configuration:

- set lb vserver <name> -lbMethod TOKEN -rule <rule> -datalength <length> -dataoffset <offset>
- show lb vserver <name>

Example

```
set lb vserver LB-VServer-1 -lbMethod TOKEN -rule 'AA' -datalength 2 -dataoffset 25

show lb vserver LB-VServer-1
```

To configure the Token load balancing method by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure a rule, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Method and Persistence tab and under LB Method, select Token.
4. Click Configure next to the Rule text box.
5. In the Create Expression dialog box, select Classic Syntax or Advanced Syntax.
6. Under Expression, click Add.
7. In the Add Expression dialog box, enter an expression. For more information about expressions, see Policy Configuration and Reference. For example, if you are configuring a classic expression, you can select an Expression Type of General, a Flow Type of REQ, a Protocol of HTTP, a Qualifier of URLQUERY, an Operator of CONTAINS, and in the Value text box, type AA.
8. Click OK, and then click Close.
9. In the Create Expression dialog box, click Create. The expression you created appears in the Rule text box.
10. Click OK.

Configuring a Load Balancing Method That Does Not Include a Policy

Jul 16, 2014

After you select a load balancing algorithm for your load balancing setup, you must configure the NetScaler appliance to use that algorithm. You can configure it by using the NetScaler command line or by using the configuration utility.

Note:
The token method is policy based and requires more configuration than is described here. To configure the token method, see Configuring the Token Method.

For some hash-based methods, you can mask an IP address to direct requests belonging to the same subnet to the same server. For more information, see The Destination IP Hash Method, The Source IP Hash Method, The Source IP Destination IP Hash Method, and The Source IP Source Port Hash Method.

To set the load balancing method by using the command line interface

At the command prompt, type:

set lb vserver <name> -lbMethod <method>

Example

```
set lb vserver Vserver-LB-1 -lbMethod LeastConnection
```

To set the load balancing method by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure an LB method, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Method and Persistence tab.
4. From the drop-down menu under LB Method, select a method, (for example, Least Response Time).
5. Click OK.

Persistence and Persistent Connections

Mar 16, 2012

Unless you configure persistence, a load balancing stateless protocol, such as HTTP, disrupts the maintenance of state information about client connections. Different transmissions from the same client might be directed to different servers even though all of the transmissions are part of the same session. You must configure persistence on a load balancing virtual server that handles certain types of Web applications, such as shopping cart applications.

Before you can configure persistence, you need to understand the different types of persistence, how they are used, and what the implications of each type is. You then need to configure the NetScaler appliance to provide persistent connections for those Web sites and Web applications that require them.

You can also configure backup persistence, which takes effect in the event that the primary type of persistence configured for a load balancing virtual server fails. You can configure persistence groups, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

For information about persistence with RADIUS load balancing, see Configuring RADIUS Load Balancing with Persistence.

About Persistence

Mar 16, 2012

You can choose from among any of several types of persistence for a given load balancing virtual server, which then routes to the same service all connections from the same user to your shopping cart application, Web-based email, or other network application. The persistence session remains in effect for a period of time, which you specify.

If a server participating in a persistence session goes DOWN, the load balancing virtual server uses the configured load balancing method to select a new service, and establishes a new persistence session with the server represented by that service. If the server goes OUT OF SERVICE, it continues to process existing persistence sessions, but the virtual server does not direct any new traffic to it. After the shutdown period elapses, the virtual server ceases to direct connections from existing clients to the service, closes existing connections, and redirects those clients to new services if necessary.

Depending on the persistence type you configure, the NetScaler appliance might examine the source IPs, destination IPs, SSL session IDs, Host or URL headers, or some combination of these things to place each connection in the proper persistence session. It might also base persistence on a cookie issued by the Web server, on an arbitrarily assigned token, or on a logical rule. Almost anything that allows the appliance to match connections with the proper persistence session and be used as the basis for persistence.

The following table summarizes the persistence types available on the NetScaler appliance.

Table 1. Types of Persistence

Persistence Type	Description
Source IP	SOURCEIP. Connections from the same client IP address are parts of the same persistence session.
HTTP Cookie	COOKIEINSERT. Connections that have the same HTTP Cookie header are parts of the same persistence session.
SSL Session ID	SSLSESSION. Connections that have the same SSL Session ID are parts of the same persistence session.
URL Passive	URLPASSIVE. Connections to the same URL are treated as parts of the same persistence session.
Custom Server ID	CUSTOMSERVERID. Connections with the same HTTP HOST header are treated as parts of the same persistence session.
Destination IP	DESTIP. Connections to the same destination IP are treated as parts of the same persistence session.
Source and	SRCIPDESTIP. Connections that are both from the same source IP and to the same destination IP

Persistence Type	Description
Destination IPs	are treated as parts of the same persistence session.
SIP Call ID	CALLID. Connections that have the same call ID in the SIP header are treated as parts of the same persistence session.
RTSP Session ID	RTSPSID. Connections that have the same RTSP Session ID are treated as parts of the same persistence session.
User-Defined Rule	RULE. Connections that match a user-defined rule are treated as parts of the same persistence session.

Depending on the type of persistence that you have configured, the virtual server can support either 250,000 simultaneous persistent connections or any number of persistent connections up to the limits imposed by the amount of RAM on your NetScaler appliance. The following table shows which types of persistence fall into each category.

Table 2. Persistence Types and Numbers of Simultaneous Connections Supported

Persistence Type	Number of Simultaneous Persistent Connections Supported
Source IP, SSL Session ID, Rule, destination IP, source IP/destination IP, SIP Call ID, RTSP Session ID	250 K
Cookie, URL Server ID, Custom Server ID	Memory limit. In case of CookieInsert, if timeout is not 0, the number of connections is limited by memory.

Some types of persistence are specific to particular types of virtual server. The following table lists each type of persistence and indicates which types of persistence are supported on which types of virtual server.

Table 3. Relationship of Persistence Type to Virtual Server Type

Persistence Type	HTTP	HTTPS	TCP	UDP/IP	SSL_Bridge	SSL_TCP	RTSP	SIP_UDP
SOURCEIP	YES	YES	YES	YES	YES	YES	NO	NO
COOKIEINSERT	YES	YES	NO	NO	NO	NO	NO	NO
SSLSESSION	NO	YES	NO	NO	YES	YES	NO	NO
URLPASSIVE	YES	YES	NO	NO	NO	NO	NO	NO

Persistence Type	HTTP	HTTPS	TCP	UDP/IP	SSL_Bridge	SSL_TCP	RTSP	SIP_UDP
CUSTOMSERVERID	YES	YES	NO	NO	NO	NO	NO	NO
RULE	YES	YES	YES	NO	NO		NO	NO
SRCIPDESTIP	YES	YES	YES	YES	YES	YES	NO	NO
DESTIP	YES	YES	YES	YES	YES	YES	NO	NO
CALLID	NO	NO	NO	NO	NO	NO	NO	YES
RTSPID	NO	NO	NO	NO	NO	NO	YES	NO

Persistence Based on Source IP Address

Mar 16, 2012

When source IP persistence is configured, the load balancing virtual server uses the configured load balancing method to select a service for the initial request, and then uses the source IP address (client IP address) to identify subsequent requests from that client and send them to the same service. You can set a time-out value, which specifies the maximum inactivity period for the session. When the time-out value expires, the session is discarded, and the configured load balancing algorithm is used to select a new server.

Caution: In some circumstances, using persistence based on source IP address can overload your servers. All requests to a single Web site or application are routed through the single gateway to the NetScaler appliance, even though they are then redirected to multiple locations. In multiple proxy environments, client requests frequently have different source IP addresses even when they are sent from the same client, resulting in rapid multiplication of persistence sessions where a single session should be created. This issue is called the "Mega Proxy problem." You can use HTTP cookie-based persistence instead of Source IP-based persistence to prevent this from happening.
To configure persistence based on Source IP Address, see Configuring Persistence Types That Do Not Require a Rule.

Note: If all incoming traffic comes from behind a Network Address Translation (NAT) device or proxy, the traffic appears to the NetScaler appliance to come from a single source IP address. This prevents Source IP persistence from functioning properly. Where this is the case, you must select a different persistence type.

Persistence Based on HTTP Cookies

Feb 11, 2015

When HTTP cookie persistence is configured, the NetScaler appliance sets a cookie in the HTTP headers of the initial client request. The cookie contains the IP address and port of the service selected by the load balancing algorithm. As with any HTTP connection, the client then includes that cookie with any subsequent requests.

When the NetScaler appliance detects the cookie, it forwards the request to the service IP and port in the cookie, maintaining persistence for the connection. You can use this type of persistence with virtual servers of type HTTP or HTTPS. This persistence type does not consume any NetScaler resources and therefore can accommodate an unlimited number of persistent clients.

Note: If the client's Web browser is configured to refuse cookies, HTTP cookie-based persistence will not work. It might be advisable to configure a cookie check on the Web site, and warn clients that do not appear to be storing cookies properly that they will need to enable cookies for the Web site if they want to use it.
The format of the cookie that the NetScaler appliance inserts is:

NSC_XXXX=<ServiceIP ><ServicePort>

where:

- NSC_XXXX is the virtual server ID that is derived from the virtual server name.
- ServiceIP and ServicePort are encoded representations of the service IP address and service port, respectively. The IP address and port are encoded separately.

You can set a time-out value for this type of persistence to specify an inactivity period for the session. When the connection has been inactive for the specified period of time, the NetScaler appliance discards the persistence session. Any subsequent connection from the same client results in a new server being selected based on the configured load balancing method, and a new persistence session being established.

Note: If you set the time-out value to 0, the NetScaler appliance does not specify an expiration time, but sets a session cookie that is not saved when the client's browser is shut down.
By default, the NetScaler appliance sets HTTP version 0 cookies for maximum compatibility with client browsers. (Only certain HTTP proxies understand version 1 cookies; most commonly used browsers do not.) You can configure the appliance to set HTTP version 1 cookies, for compliance with RFC2109. For HTTP version 0 cookies, the appliance inserts the cookie expiration date and time as an absolute Coordinated Universal Time (GMT). It calculates this value as the sum of the current GMT time on the appliance and the time-out value. For HTTP version 1 cookies, the appliance inserts a relative expiration time by setting the "Max-Age" attribute of the HTTP cookie. In this case, the client's browser calculates the actual expiration time.

To configure persistence based on a cookie inserted by the appliance, see Configuring Persistence Types That Do Not Require a Rule.

In the HTTP cookie, the appliance by default sets the httponly flag to indicate that the cookie is nonscriptable and should not be revealed to the client application. Therefore, a client-side script cannot access the cookie, and the client is not susceptible to cross-site scripting.

Certain browsers, however, do not support the httponly flag and, therefore, might not return the cookie. As a result, persistence is broken. For browsers that do not support the flag, you can omit the httponly flag in the persistence cookie.

To change the httponly flag setting by using the command line interface

At the command prompt, type:

set lb parameter -httpOnlyCookieFlag (ENABLED | DISABLED)

Example

```
>  set lb parameter -httpOnlyCookieFlag disabled
   Done
> show lb parameter
  Global LB parameters:
      Persistence Cookie HttpOnly Flag: DISABLED
      Use port for hash LB: YES
 Done
```

To change the httponly flag setting by using the configuration utility

1. Navigate to Traffic Management > Load Balancing.
2. In the Settings group, click Configure Load Balancing Parameters.
3. To not set the httponly flag in the persistence cookie, clear the Persistence Cookie HTTPOnly Flag check box.
4. Click OK.
5. Open the Configure Load Balancing Parameters dialog box and verify the setting you just configured.

Persistence Based on SSL Session IDs

Mar 16, 2012

When SSL Session ID persistence is configured, the NetScaler appliance uses the SSL Session ID, which is part of the SSL handshake process, to create a persistence session before the initial request is directed to a service. The load balancing virtual server directs subsequent requests that have the same SSL session ID to the same service. This type of persistence is used for SSL bridge services.

Note:
There are two issues that users should consider before choosing this type of persistence. First, the NetScaler appliance does not encrypt or decrypt data when it forwards requests to services in an SSL bridge configuration, because it must maintain the data structures to keep track of the sessions. This type of persistence therefore consumes resources on the NetScaler appliance, which limits the number of concurrent persistence sessions that it can support. If you expect to support a very large number of concurrent persistence sessions, you might want to choose another type of persistence.

Second, if the client and the load-balanced server should renegotiate the session ID during their transactions, persistence is not maintained, and a new persistence session is created when the client's next request is received. This may result in the client's activity on the Web site being interrupted and the client being required to reauthenticate or restart the session. It may also result in large numbers abandoned sessions if the timeout is set to too large a value.

To configure persistence based on SSL session ID, see Configuring Persistence Types That Do Not Require a Rule.

Persistence Based on Diameter AVP Number

Aug 29, 2013

You can use persistence based on the AVP number of a Diameter message to create persistent Diameter sessions. When the NetScaler appliance finds the AVP in the Diameter message, it creates a persistence session based on the value of the AVP. All subsequent messages that match the value of the AVP are directed to the previously selected server. If the value of the AVP does not match the persistence session, a new session is created for the new value.

Note: If the AVP number is not defined in Diameter base-protocol RFC 6733, and if the number is nested inside a grouped AVP, you must define a sequence of AVP numbers (maximum of 3) in parent-to-child order. For example, if persist AVP number X is nested inside AVP Y, which is nested in Z, define the list as Z Y X.

To configure Diameter-based persistence on a virtual server by using the command line interface

At the command prompt, type the following command:

set lb vserver <name> -PersistenceType <type-> persistAVPno <positive_integer>

Example

```
set lb vserver diameter_vs -persistenceType DIAMETER -persistAVPno 263
```

Custom Server ID Persistence

Sep 15, 2015

In the Custom Server ID persistence method, the Server ID specified in the client request is used to maintain persistence. For this type of persistence to work, you must first set a server ID on the services. The NetScaler appliance checks the URL of the client request and connects to the server associated with the specified server ID. The service provider should make sure that the users are aware of the server IDs to be provided in their requests for specific services.

For example, if your site provides different types of data, such as images, text, and multimedia, from different servers, you can assign each server a server ID. On the NetScaler appliance, you specify those server IDs for the corresponding services, and you configure custom server ID persistence on the corresponding load balancing virtual server. When sending a request, the client inserts the server ID into the URL indicating the required type of data.

To configure custom server ID persistence:

- In your load balancing setup, assign a server ID to each service for which you want to use the user-defined server ID to maintain persistence. Alphanumeric server IDs are allowed.
- Specify rules, in the default-syntax expression language, to examine the URL queries for the server ID and forward traffic to the corresponding server.
- Configure custom server ID persistence.

Note: The persistence time-out value does not affect the Custom Server ID persistence type. There is no limit on the maximum number of persistent clients because this persistence type does not store any client information.

Example

In a load balancing setup with two services, assign server ID 2345-photo-56789 to Service-1, and server ID 2345-drawing-abb123 to Service-2. Bind these services to a virtual server named Web11.

```
set service Service-1 10.102.29.5 -CustomServerID 2345-photo-56789
set service Service-2 10.102.29.6 -CustomServerID 2345-drawing-abb123
```

On virtual server Web11, enable Custom Server ID persistence.

Example

```
set lb vserver Web11 -persistenceType customserverID
bind lb vserver Web11 Service-[1-2]
```

Create the following expression so that all URL queries containing the string "sid=" are examined.

```
HTTP.REQ.URL.AFTER_STR("sid=")
```

When a client sends a request with the following URL to the IP address of Web11, the NetScaler directs the request to Service-2 and honors persistence.

Example

```
http://www.example.com/index.asp?&sid=2345-drawing-abb123
```

For more information about default-syntax policy expressions, see the Policy Configuration and Reference.

To configure custom server ID persistence by using the configuration utility

1. Assign a server ID to each of the services for which you want to configure custom server ID persistence.
   1. Navigate to Traffic Management > Load Balancing > Services.
   2. In the details pane, select the service for which you want to specify a server ID, and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.
4. Scroll down, and under Others, in the Server ID box, type an ID for the server.
5. Click OK.

2. Configure custom server ID persistence on the virtual server to which the services are bound.
    1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
    2. In the details pane, select the virtual server for which you want to specify persistence, and then click Open.
    3. On the Method and Persistence tab, in the Persistence group, select CUSTOMSERVERID.
    4. In the Rule box, type an expression, or click Configure, and use the options available in the Create Expression dialog box, to create the expression.
    5. Click OK.

Persistence Based on IP Addresses

Jun 03, 2015

You can base persistence on Destination IP addresses, or on both Source IP and Destination IP Addresses.

Persistence Based on Destination IP Addresses

Updated: 2013-09-24

With destination IP address-based persistence, when the NetScaler appliance receives a request from a new client, it creates a persistence session based on the IP address of the service selected by the virtual server (the destination IP address). Subsequently, it directs requests to the same destination IP to the same service. This type of persistence is used with link load balancing. For more information about link load balancing, see Link Load Balancing.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in Persistence Based on Source IP Address.

To configure persistence based on the destination IP address, see Configuring Persistence Types That Do Not Require a Rule.

Persistence Based on Source and Destination IP Addresses

With source and destination IP address-based persistence, when the NetScaler appliance receives a request, it creates a persistence session based on both the IP address of the client (the source IP address) and the IP address of the service selected by the virtual server (the destination IP address). Subsequently, it directs requests from the same source IP and to the same destination IP to the same service.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in Persistence Based on Source IP Address.

To configure persistence based on both source and destination IP addresses, see Configuring Persistence Types That Do Not Require a Rule.

Persistence Based on SIP Call ID

Mar 16, 2012

With SIP Call ID persistence, the NetScaler appliance chooses a service based on the call ID in the SIP header. This enables it to direct packets for a particular SIP session to the same service and, therefore, to the same load balanced server. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

To configure persistence based on SIP Call ID, see Configuring Persistence Types That Do Not Require a Rule.

Persistence Based on RTSP Session IDs

Aug 29, 2013

With RTSP Session ID persistence, when the NetScaler appliance receives a request from a new client, it creates a new persistence session based on the Real-Time Streaming Protocol (RTSP) session ID in the RTSP packet header, and then directs the request to the RTSP service selected by the configured load balancing method. It directs subsequent requests that contain the same session ID to the same service. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

Note: RTSP Session ID persistence is configured by default on RTSP virtual servers, and you cannot modify that setting. Sometimes different RTSP servers issue the same session IDs. When this happens, unique sessions cannot be created between the client and the RTSP server by using only the RTSP session ID. If you have multiple RTSP servers that may issue the same session IDs, you can configure the appliance to append the server IP address and port to the session ID, creating a unique token that can be used to establish persistence. This is called session ID mapping.

To configure persistence based on RTSP Session IDs, see Configuring Persistence Types That Do Not Require a Rule.

Important: If you need to use session ID mapping, you must set the following parameter when configuring each service within the load balancing setup. Also, make sure that no non-persistent connections are routed through the RTSP virtual server.

Configuring URL Passive Persistence

Nov 23, 2015

With URL Passive persistence, when the NetScaler appliance receives a request from a client, it extracts the server IP address-port information (expressed as a single hexadecimal number) from the client request.

URL passive persistence requires configuring an advanced expression that specifies the query element that contains the server IP address-port information. For more information about classic and advanced policy expressions, see Policy Configuration and Reference.

The following expression configures the appliance to examine requests for URL queries that contain the string "urlp=", extract the server IP address-port information, convert it from a hexadecimal string to an IP and port number, and forward the request to the service configured with this IP address and port number.

HTTP.REQ.URL.AFTER_STR("urlp=")

If URL passive persistence is enabled and the above expression is configured, a request with the following URL and server IP address-port string is directed to 10.102.29.10:80.

http://www.example.com/index.asp?&urlp=0A661D0A0050

The persistence time-out value does not affect this persistence type; persistence is maintained as long as the server IP address-port information can be extracted from client requests. This persistence type does not consume any NetScaler resources, so it can accommodate an unlimited number of persistent clients.

To configure URL passive persistence, you first configure persistence as described in Configuring Persistence Types That Do Not Require a Rule. You set the persistence type to URLPASSIVE. You then perform the procedures provided below.

To configure URL passive persistence by using the command line interface

At the command prompt, type:

set lb vserver <vserverName> [-persistenceType <persistenceType>] [-rule <expression>]

Example

set lb vserver LB-VServer-1 -persistenceType URLPASSIVE –rule HTTP.REQ.URL.AFTER_STR("urlp=")

To configure URL passive persistence by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in Persistence, select URLPASSIVE.
3. Click the Configure button next to the Rule field.
4. In the dialog box that appears, create the rule that you want to use. For more information about creating rules, see Policy Configuration and Reference.
5. Click OK.

Configuring Persistence Based on User-Defined Rules

Aug 29, 2013

When rule based persistence is configured, the NetScaler appliance creates a persistence session based on the contents of the matched rule before directing the request to the service selected by the configured load balancing method. Subsequently, it directs all requests that match the rule to the same service. You can configure rule based persistence for services of type HTTP, SSL, RADIUS, ANY, TCP, and SSL_TCP.

Rule based persistence requires a classic or default syntax expression. You can use a classic expression to evaluate request headers, or you can use a default syntax expression to evaluate request headers, Web form data in a request, response headers, or response bodies. For example, you could use a classic expression to configure persistence based on the contents of the HTTP Host header. You could also use a default syntax expression to configure persistence based on application session information in a response cookie or custom header. For more information on creating and using classic and default syntax expressions, see Policy Configuration and Reference.

The expressions that you can configure depends on the type of service for which you are configuring rule based persistence. For example, certain RADIUS-specific expressions are not allowed for protocols other than RADIUS, and TCP-option based expressions are not allowed for service types other than the ANY type. For TCP and SSL_TCP service types, you can use expressions that evaluate TCP/IP protocol data, Layer 2 data, TCP options, and TCP payloads.

Note: For a use case that involves configuring rule based persistence on the basis of Financial Information eXchange ("FIX") Protocol data transmitted over TCP, see Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream.
Rule based persistence can be used for maintaining persistence with entities such as Branch Repeater appliances, Branch Repeater plug-ins, cache servers, and application servers.

Note: On an ANY virtual server, you cannot configure rule-based persistence for the responses.
To configure persistence based on a user-defined rule, you first configure persistence as described in Configuring Persistence Types That Do Not Require a Rule, and set the persistence type to RULE. You then perform the procedures provided below. You can configure rule based persistence by using the configuration utility or the NetScaler command line.

To configure persistence based on user-defined rules by using the command line interface

At the command prompt, type:

set lb vserver <vserverName> [-rule <expression>][-resRule <expression>]
Example

```
set lb vserver vsvr_name –rule http.req.header("cookie").value(0).typecast_nvlist_t('=',';').value("server")

set lb vserver vsvr_name –resrule http.res.header("set-cookie").value(0).typecast_nvlist_t('=',';').value("server")
```

To configure persistence based on user-defined rules by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click **Add**.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, choose the type of rule you want to configure.
   - If you want to base the rule on the request, click the Configure button next to the Rule field.
   - If you want to base the rule on the response, click the Configure button next to the Response Rule field.
4. In the dialog box that appears, select Switch to Classic Syntax or Switch to Advanced Syntax.
5. Select or create the rule that you want to use. Some examples of rules that you might find useful are provided below. For more information, see Policy Configuration and Reference.
6. Click OK.

Example: Classic Expression for a Request Payload

The following classic expression creates a persistence session based on the presence of a User-Agent HTTP header that contains the string, “MyBrowser”, and directs any subsequent client requests that contain this header and string to the same server that was selected for the initial request.

```
http header User-Agent contains MyBrowser
```

Example: Default syntax Expression for a Request Header

The following default syntax expression does exactly the same thing as the previous classic expression.

```
HTTP.REQ.HEADER("User-Agent").CONTAINS ("MyBrowser")
```

Example: Default syntax Expression for a Response Cookie

The following expression examines responses for “server” cookies, and then directs any requests that contain that cookie to the same server that was selected for the initial request.

```
HTTP.RES.HEADER("SET-COOKIE").VALUE(0).TYPECAST_NVLIST_T('=',';').VALUE("server")
```

Configuring Persistence Types That Do Not Require a Rule

Aug 29, 2013

To configure persistence, you must first set up a load balancing virtual server, as described in Setting Up Basic Load Balancing. You then configure persistence on the virtual server.

To configure persistence on a virtual server by using the command line interface

At the command prompt, type the following commands to configure persistence and verify the configuration:

- set lb vserver <name> -PersistenceType <type> [-timeout <integer>]
- show lb vserver

Example

```
set lb vserver Vserver-LB-1 -persistenceType SOURCEIP

show lb vserver
```

Note: For IP-based persistence, you can also set the persistMask parameter.

To configure persistence on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure persistence, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in the Persistence list, select the persistence type you want to use (for example, SOURCEIP).
4. In the Time-out and Netmask text boxes type the time-out and subnet mask values (for example, 2 and 255.255.255.255).
5. Click OK.

Configuring Backup Persistence

Nov 12, 2013

The NetScaler appliance uses backup persistence to choose a new type of persistence when the primary persistence type fails. For example, if the primary persistence type is set to Cookie Insert, and backup persistence is set to Source IP, the NetScaler appliance uses Source IP-based persistence when the cookie is missing from the HTTP header or when the client browser does not support cookies.

You can set a time-out value for backup persistence only when the primary persistence type is HTTP Cookie-based or RTSP session ID-based persistence, and the backup persistence type is Source IP-based.

To set backup persistence for a virtual server by using the command line interface

At the command prompt, type:

set lb vserver <name>@ -persistenceType <PersistenceType> -persistenceBackup <BackupPersistenceType>

Example

set lb vserver Vserver-LB-1 -persistenceType CookieInsert -persistenceBackup SourceIP

To set backup persistence for a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure backup persistence (for example, Vserver-LB-1), and then click Open.
3. The Configure Virtual Server (Load Balancing) dialog box, click the Method and Persistence tab.
4. In the Persistence list, select the persistence type you want (for example, COOKIEINSERT).
5. In the Time-out text box, type the time-out value you want (for example, 20).
6. In the Backup Persistence list, select the backup persistence type that you want to configure (for example, SOURCEIP).
7. In the Backup Time-out and Netmask text boxes, type the backup time-out value and netmask (for example, 20 and 255.255.255.255).
8. Click OK.

Configuring Persistence Groups

Aug 29, 2013

When you have load-balanced servers that handle several different types of connections (such as Web servers that host multimedia), you can configure a virtual server group to handle these connections. To create a virtual server group, you bind different types of virtual servers, one for each type of connection that your load balanced servers accept, into a single group. You then configure a persistence type for the entire group.

You can configure either source IP-based persistence or HTTP cookie-based persistence for persistence groups. After you set persistence for the entire group, you cannot change it for individual virtual servers in the group. If you configure persistence on a group and then add a new virtual server to the group, the persistence of the new virtual server is changed to match the persistence setting of the group.

When persistence is configured on a group of virtual servers, persistence sessions are created for initial requests, and subsequent requests are directed to the same service as initial request, regardless of the virtual server in the group that receives each client request.

If you configure HTTP cookie-based persistence, the domain attribute of the HTTP cookie is set. This setting causes the client software to add the HTTP cookie into client requests if different virtual servers have different public host names. For more information about CookieInsert persistence type, see Persistence Based on HTTP Cookies.

To create a virtual server persistency group by using the command line interface

At the command prompt, type:

bind lb group <vServerGroupName> <vServerName> -persistenceType <PersistenceType>

Example

bind lb group Vserver-Group-1 Vserver-LB-1 -persistenceType CookieInsert

To create a virtual server persistency group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Persistency Groups.
2. On the Persistency Groups pane, click Add.
3. In the Create Persistency Group dialog box, in the Group Name text box type a name for the group (for example, Vserver-Group-1).
4. In the Persistence list, select a persistence type (for example, SOURCEIP).
5. In the Persistence Mask and Time-out text boxes, type the persistence mask and timeout values (for example, 255.255.255.255 and 2).
6. Under Virtual Server List, in the Available Virtual Server list box, select the virtual server that you want to bind to the group (for example, Vserver-LB-1), and then click Add.
7. Click Create, and then click Close. The virtual server group you created appears in the Persistence Groups pane.

You can also change the backup persistence type, backup persistence time-out, and cookie domain value on an existing persistence group.

To modify a virtual server group by using the command line interface

At the command prompt, type:

set lb group <vServerGroupName> -PersistenceBackup <BackupPersistenceType> -persistMask <SubnetMaskAddress>

Example

```
set lb group vserver-Group-1 -PersistenceBackup SourceIP -persistMask 255.255.255.255
```

To modify a virtual server group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Persistency Groups.
2. In the Persistency Groups pane, select the virtual server group that you want to modify (for example, Vserver-Group-1), and click Open.
3. The Configure Virtual Server Group dialog box appears.
4. In the Backup Persistence list, select the type of backup persistence (for example, SOURCEIP).
5. In the Persistence Mask text box, type the subnet mask (for example, 255.255.255.255).
6. Click OK.

Configuring RADIUS Load Balancing with Persistence

Jun 08, 2015

Today's complex networking environment often requires coordinating a high-volume, high-capacity load balancing configuration with robust authentication and authorization. Application users may connect to a VPN through mobile access points such as consumer-grade DSL or Cable connections, WiFi, or even dial-up nodes. Those connections usually use dynamic IPs, which can change during the connection.

If you configure RADIUS load balancing on the NetScaler appliance to support persistent client connections to RADIUS authentication servers, the appliance uses the user logon or the specified RADIUS attribute instead of the client IP as the session ID, directing all connections and records associated with that user session to the same RADIUS server. Users are therefore able to log on to your VPN from mobile access locations without experiencing disconnections when the client IP or WiFi access point changes.

To configure RADIUS load balancing with persistence, you must first configure RADIUS authentication for your VPN. For information and instructions, see the Authentication, Authorization, Auditing (AAA) chapter in AAA Application Traffic. You must also choose either the Load Balancing or Content Switching feature as the basis for your configuration, and make sure that the feature you chose is enabled. The configuration process with either feature is almost the same.

Then, you configure either two load balancing, or two content switching, virtual servers, one to handle RADIUS authentication traffic and the other to handle RADIUS accounting traffic. Next, you configure two services, one for each load balancing virtual server, and bind each load balancing virtual server to its service. Finally, you create a load balancing persistency group and set the persistency type to RULE.

To configure RADIUS load balancing with persistence, see the following sections:

- Enabling the Load Balancing or Content Switching Feature
- Configuring Virtual Servers
- Configuring Services
- Binding Virtual Servers to Services
- Configuring a Persistency Group for Radius

Enabling the Load Balancing or Content Switching Feature

Updated: 2013-08-29

To use the Load Balancing or Content Switching feature, you must first ensure that the feature is enabled. If you are configuring a new NetScaler appliance that has not previously been configured, both of these features are already enabled, so you can skip to the next section. If you are configuring a NetScaler appliance with a previous configuration on it, and you are not certain that the feature you will use is enabled, you must do that now.

- For instructions on enabling the load balancing feature, see Enabling Load Balancing.
- For instructions on enabling the content switching feature, see Enabling Content Switching.

Configuring Virtual Servers

Updated: 2013-09-13

After enabling the load balancing or content switching feature, you must next configure two virtual servers to support RADIUS authentication:

- **RADIUS authentication virtual server.** This virtual server and its associated service will handle authentication traffic to your RADIUS server. Authentication traffic consists of connections associated with users logging onto your protected application or virtual private network (VPN).
- **RADIUS accounting virtual server.** This virtual server and its associated service will handle accounting connections to your RADIUS server. Accounting traffic consists of connections that track an authenticated user's activities on your protected application or VPN.

Important: You must create either a pair of load balancing virtual servers or a pair of content switching virtual servers to use in your RADIUS persistence configuration. You cannot mix virtual server types.

To configure a load balancing virtual server by using the command line interface

At the command prompt type the following commands to create a new load balancing virtual server and verify the configuration:

- add lb vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule <rule>
- show lb vserver <name>

To configure an existing load balancing virtual server, replace the above add lb virtual server command with the set lb vserver command, which takes the same arguments.

To configure a content switching virtual server by using the command line interface

At the command prompt type the following commands to create a new content switching virtual server and verify the configuration:

- add cs vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule <rule>
- show cs vserver <name>

To configure an existing content switching virtual server, replace the above add cs vserver command with the set cs vserver command, which takes the same arguments.

Example

```
add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812
    -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813
    -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
set lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812
    -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
set lb vserver radius_auth_vs1 RADIUS 192.168.46.34 1813
    -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
```

To configure a load balancing or content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers or Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, do one of the following:

- To create a new virtual server, click Add.
- To modify an existing virtual server, select the virtual server, and then click Open.

3. In the Create Virtual Server (Load balancing) or Configure Virtual Server (Content Switching) dialog box, specify values for the following parameters:
   - Name*—name
   - Protocol*—protocol
   - IP address*—IPAddress
   - Port*—port

   * A required parameter

4. In the Method and Persistence tab, specify values for the following parameters:
   - Method*—method
   - Rule*—rule

   * A required parameter

5. Click Close. The virtual server that you created now appears in the Virtual Servers pane.

Configuring Services

Updated: 2013-09-17

After configuring your virtual servers, you must next configure two services, one for each of the virtual servers that you created. For instructions, see Configuring Services.

Note: Once configured, these services are in the DISABLED state until the NetScaler appliance can connect to your RADIUS server's authentication and accounting IPs and monitor their status.

Binding Virtual Servers to Services

After configuring your services, you must next bind each of the virtual servers that you created to the appropriate service. For instructions, see Binding Services to the Virtual Server.

Configuring a Persistency Group for Radius

Updated: 2013-09-17

After binding your load balancing virtual servers to the corresponding services, you must set up your RADIUS load balancing configuration to support persistence. To do so, you configure a load balancing persistency group that contains your RADIUS load balancing virtual servers and services, and configure that load balancing persistency group to use rule-based persistence. For instructions, see Configuring Persistence Groups.

Viewing Persistence Sessions

Sep 13, 2013

You can view the different persistence sessions that are in effect globally or for a particular virtual server.

Note: A NetScaler nCore appliance uses multiple CPU cores for packet handling. Every session on the appliance is owned by a CPU core. If the appliance receives a request for which a session does not already exist, a session is created, and one of the cores is designated as the owner of that session. Subsequent requests that belong to that session might not always arrive at and be handled by the owner core. In that case, inter-core messaging ensures that the session information on the owner core is always current. However, when a core receives a request that belongs to a persistence session owned by another core, the inter-core messaging does not refresh the timeout value for the persistence session. Consequently, in the output of successively executed show lb persistentSessions commands, which display timeout values from owner cores only, the timeout value for a persistence session might diminish to 0 (zero), even if the persistence session continues to be active.

To view a persistence session by using the command line interface

At the command prompt, to view all persistence sessions type:

show lb persistentSessions [<vServer>]

Example

show lb persistentSessions myVserver

To view persistence sessions by using the configuration utility

1. Navigate to Traffic Management > Load Balancing.
2. In the details pane, under Monitor Sessions, click Virtual Server persistence sessions.

Clearing Persistence Sessions

Nov 12, 2013

You might need to clear persistence sessions from the NetScaler if sessions fail to time out. You can do one of the following:

- Clear all sessions for all virtual servers at once.
- Clear all sessions for a given virtual server at once.
- Clear a particular session that is associated with a given virtual server.

Note: The functionality for clearing a particular session that is associated with a given virtual server is available only on NetScaler 10.e.

To clear a persistence session by using the command line interface

At the command prompt, type the following commands to clear persistence sessions and verify the configuration:

- clear lb persistentSessions [<vServer> [-persistenceParam <string>]]
- show persistentSessions <vServer>

Examples

Example 1 clears all persistence sessions for load balancing virtual server lbvip1. Example 2 first displays the persistence sessions for load balancing virtual server lbvip1, clears the session with persistence parameter xls, and then displays the persistence sessions to verify that the session was cleared.

Example

```
> clear persistentSessions lbvip1
 Done
> show persistentSessions
 Done
>
```

Example 2

```
> show persistentSessions lbvip1
Type      SRC-IP   ...   PERSISTENCE-PARAMETER
RULE      0.0.0.0  ...   xls
RULE      0.0.0.0  ...   txt
RULE      0.0.0.0  ...   html
 Done
> clear persistentSessions lbvip1 -persistenceParam xls
 Done
> show persistentSessions lbvip1
Type      SRC-IP   ...   PERSISTENCE-PARAMETER
RULE      0.0.0.0  ...   txt
RULE      0.0.0.0  ...   html
 Done
>
```

To clear persistence sessions by using the configuration utility

1. Navigate to Traffic Management > Load Balancing.
2. In the details pane, under Monitor Sessions, click Clear persistence sessions.

3. In the Clear Persistence Sessions dialog box, do one of the following:
   - If you want to clear all sessions for all virtual servers on the appliance, in Virtual Server, select All Virtual Servers.
   - If you want to clear all sessions for a given virtual server, in Virtual Server, select the virtual server.
   - If you want to clear a particular session, in Virtual Server, select the virtual server, and then, in Persistence Parameter, select the persistence parameter whose session you want to clear.
4. Click OK.

Overriding Persistence Settings for Overloaded Services

Aug 29, 2013

When a service is loaded or is otherwise unavailable, service to clients is degraded. To work around this situation, you might have to configure the NetScaler appliance to temporarily forward to other services the requests that would otherwise be included in the persistence session that is associated with the overloaded service. In other words, you might have to override the persistence setting that is configured for the load balancing virtual server. You can achieve this functionality by setting the skippersistency parameter. With the parameter set, when the virtual server receives new connections for an overloaded service, the virtual server disregards any existing persistence sessions that are associated with that service, until the service returns to a state at which it can accept requests. Persistence sessions associated with other services are not affected. The functionality is available for only virtual servers whose type is ANY or UDP.

In Branch Repeater load balancing configurations, you must also configure a load monitor and bind it to the service. The monitor takes the service out of subsequent load balancing decisions until the load on the service is brought below the configured threshold. For information about configuring a load monitor for your virtual server, see Understanding Load Monitors.

You can configure the virtual server to perform one of the following actions with the requests that would otherwise form a part of the persistence session:

- **Send each request to one of the other services.** The virtual server takes a load balancing decision and sends each request to one of the other services on the basis of the configured load balancing method. If all the services are overloaded, requests are dropped until a service becomes available.
  Both wildcard and IP address–based virtual servers support this option. This action is appropriate for all deployments, including deployments in which the virtual server is load balancing Branch Repeater appliances or firewalls.

- **Bypass the virtual server-service configuration.** The virtual server does not take a load balancing decision. Instead, it simply bridges each request through to a physical server on the basis of the destination IP address in the request.
  Only wildcard virtual servers of type ANY and UDP support the bypass option. Wildcard virtual servers have a *:* IP and port combination. This action is appropriate for deployments in which you are using the virtual server to load balance Branch Repeater appliances or firewalls. In these deployments, the NetScaler appliance first forwards a request to a Branch Repeater appliance or firewall, and then forwards the processed response to a physical server. If you configure the virtual server to bypass the virtual server–service configuration for overloaded services, if a Branch Repeater appliance or firewall gets overloaded, the virtual server bridges requests directly to their destination IP addresses until the Branch Repeater appliance or firewall can accept requests.

To override persistence settings for overloaded services by using the command line interface

At the command prompt, type the following commands to override persistence settings for overloaded services and verify the configuration:

- set lb vserver <name> -skippersistency <skippersistency>
- show lb vserver <name>

Example

```
> set lb vserver mylbvserver -skippersistency ReLb
```

```
 Done
> show lb vserver mylbvserver
 mylbvserver (*:*) - ANY Type: ADDRESS
   . . .
   . . .
 Skip Persistency: ReLb
   . . .
 Done
>
```

To override persistence settings for overloaded services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click the virtual server that you want to override persistence settings when services are overloaded, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in the Skip Persistency list, select the option that you want.
4. Click OK.

Troubleshooting

Feb 28, 2014

The statistics from the NetScaler VPX appliance indicate that the appliance has reached the session persistence limit. As a result, persistence sessions are failing. Is possible to increase the session persistence limit?

Cause: The NetScaler appliance has the system limit of 250,000 persistence session for a core.

Resolution: To resolve this issue, you can perform any of the following tasks:

- Reduce the time out value for persistence
- Increase the number of cores for the appliance

After configuring Cookie Insert persistence on the NetScaler appliance, the users report that the connections work fine for some time, but then start getting disconnected. What best practice should I follow when configuring persistence?

Cause: By default, the time-out value for Cookie Insert persistence is 120 seconds.

Resolution: When you configure persistence for applications for which idle time cannot be determined, set the Cookie Insert persistence time-out value to 0. With this setting, the connection does not time out.

After configuring an HTTP virtual server on the NetScaler appliance, I need to make sure that a user always connects to the same server for the requested content, so I configured SourceIP persistence. Now, increasing the time-out value for persistence introduces latency. How can I increase the timeout value without affecting performance?

Resolution: Consider using Cookie Insert persistence with the time-out value set to 0. This setting enables long-duration persistence settings, because the appliance does not specify a time for expiring the cookie.

After configuring Cookie Insert persistence on the NetScaler appliance, it works as expected when clients from the same time zone access the content. However, when a client from another time zone makes an attempt to connect, the connection is immediately timed out.

Cause: Time based Cookie Insert persistence works as expected when a client from the same time zone makes a connection. However, when the client machine and NetScaler appliance are in different time zones, the cookie is not valid. For example, when a client in EST time zone sends a cookie at 11:00 AM EST to a NetScaler appliance in the PST time zone, the appliance receives the cookie at 2:00 PM PST. As a result of the difference in time, the cookie is not valid, and the connection is immediately timed-out.

Resolution: Set the time-out value for Cookie Insert persistence to 0.

A NetScaler appliance is used to load balance application servers, such as Oracle Weblogic server. To make sure that clients get persistent connections to these servers, SourceIP persistence is configured. It works as expected when a connection is made from a computer. However, when thin clients attempt a connection through a terminal server and, as a result, the appliance receives requests from multiple clients from the same IP address (the terminal server IP address). Therefore, the connections from all thin clients are directed to the same application server. Is it possible to configure persistency for requests from individual thin clients based on the client IP address?

Cause: The NetScaler appliance receives requests from the terminal server and the source IP address of the request remains the same. As a result, the appliance cannot distinguish among the requests received from the thin clients and provide persistence according to the requests from thin clients.

Resolution: To avoid this problem, you can configure Rule persistence based on some unique parameter value for each thin client.

The NetScaler appliance is used to load balance Web Interface servers. When accessing the servers, the user receives the "State Error" error message. Additionally, when one of the Web Interface servers is shut down or not available, some of the users receive an error message.

Cause: Lack of persistence to the Web Interface servers can result in error messages when a user attempts to connect to the server.

Resolution: Citrix recommends that you specify the Cookie Insert persistence method on the NetScaler appliance when load balancing Web Interface servers.

Customizing a Load Balancing Configuration

Jun 09, 2015

After you configure a basic load balancing setup, you can make a number of modifications to it so that it distributes load exactly as you need. The load balancing feature is complex. You can modify the basic elements by changing the load balancing algorithm, configuring load balancing groups and using them to create your load balancing configuration, configuring persistent client-server connections, configuring the redirection mode, and assigning different weights to different services that have different capacities.

The default load balancing algorithm on the NetScaler appliance is the least connection method, which configures the appliance to send each incoming connection to the service that is currently handling the fewest connections. You can specify different load balancing algorithms, each of which is suited to different conditions.

To accommodate applications such as shopping carts, which require that all requests from the same user be directed to the same server, you can configure the appliance to maintain persistent connections between clients and servers. You can also specify persistence for a group of virtual servers, causing the appliance to direct individual client requests to the same service regardless of which virtual server in the group receives the client request.

You can enable and configure the redirection mode that the appliance uses when redirecting user requests, choosing between IP-based and MAC-based forwarding. You can assign weights to different services, specifying what percentage of incoming load should be directed to each service, so that you can include servers with different capacities in the same load balancing setup without overloading the lower-capacity servers or allowing the higher-capacity servers to sit idle.

This section includes the following details:

- Customizing the Hash Algorithm for Persistence across Virtual Servers
- Configuring the Redirection Mode
- Configuring per-VLAN Wildcarded Virtual Servers
- Assigning Weights to Services
- Configuring the MySQL and Microsoft SQL Server Version Setting

Customizing the Hash Algorithm for Persistence across Virtual Servers

Aug 29, 2013

The NetScaler appliance uses hash-based algorithms for maintaining persistence across virtual servers. By default, the hash-based load balancing method uses a hash value of the IP address and port number of the service. If a service is made available at different ports on the same server, the algorithm generates different hash values. Therefore, different load balancing virtual servers might send requests for the same application to different services, breaking the pseudo-persistence.

As an alternative to using the port number to generate the hash value, you can specify a unique hash identifier for each service. For a service, the same hash identifier value must be specified on all the virtual servers. If a physical server serves more than one type of application, each application type should have a unique hash identifier.

The algorithm for computing the hash value for a service works as follows:

- By default, a global setting specifies the use of port number in a hash calculation.
- If you configure a hash identifier for a service, it is used, and the port number is not, regardless of the global setting.
- If you do not configure a hash identifier, but change the default value of the global setting so that it does not specify use of the port number, the hash value is based only on the IP address of the service.
- If you do not configure a hash identifier or change the default value of the global setting to use the port number, the hash value is based on the IP address and the port number of the service.

You can also specify hash identifiers when using the NetScaler command line to bind services to a service group. In the configuration utility, you can open a service group and add hash identifiers on the Members tab.

To change the use-port-number global setting by using the command line interface

At the command prompt, type:

set lb parameter -usePortForHashLb (YES | NO)

Example

```
> set lb parameter -usePortForHashLb NO
 Done
>show lb parameter
Global LB parameters:
      Persistence Cookie HttpOnly Flag: DISABLED
      Use port for hash LB: NO
 Done
```

To change the use-port-number global setting by using the configuration utility

1. Navigate to Traffic Management > Load Balancing.
2. In the Settings group, click Configure Load Balancing Parameters.
3. To not use the port number to generate the hash value, clear the Use Port for Hash Based LB Methods check box.
4. Click OK.
5. Open the Configure Load Balancing Parameters dialog box and verify the setting you just configured.

To create a new service and specify a hash identifier for a service by using the command line interface

At the command prompt, type the following commands to set the hash ID and verify the setting:

add service < name > (< ip > |< serverName >) < serviceType > < port > -hashId < positive_integer >

show service <name>

Example

```
> add service flbkng 10.101.10.1 http 80 -hashId 12345
 Done
>show service flbkng
      flbkng (10.101.10.1:80) - HTTP
      State: DOWN
      Last state change was at Thu Nov  4 10:14:52 2010
      Time since last state change: 0 days, 00:00:15.990
      Server Name: 10.101.10.1
      Server ID : 0   Monitor Threshold : 0

      Down state flush: ENABLED
      Hash Id: 12345

1)     Monitor Name: tcp-default
            State: DOWN     Weight: 1

 Done
```

To specify a hash identifier for an existing service by using the command line interface

Type the set service command, the name of the service, and **-hashID** followed by the ID value.

To specify a hash identifier while adding a service group member

To specify a hash identifier for each member to be added to the group and verify the setting, at the command prompt, type the following commands (Be sure to specify a unique hashID for each member.):

bind servicegroup <serviceGroupName> <memberName> <port> -hashId <positive_integer>

show servicegroup <serviceGroupName>

Example

```
 bind servicegroup http_svc_group 10.102.27.153 80 -hashId 2222222

>show servicegroup SRV
      SRV - HTTP
      State: ENABLED  Monitor Threshold : 0
      ...

      1)       1.1.1.1:80   State: DOWN     Server Name: 1.1.1.1    Server ID: 123  Weight: 1
      Hash Id: 32211
```

```
        Monitor Name: tcp-default      State: DOWN
    ...

    2)      2.2.2.2:80   State: DOWN    Server Name: 2.2.2.2    Server ID: 123  Weight: 1
    Hash Id: 12345

        Monitor Name: tcp-default      State: DOWN
    ...
Done
```

To specify a hash identifier for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, do one of the following:
   - To create a new service, click Add.
   - To modify an existing service, select the service and then click Open.
3. In the Create Service or Configure Service dialog box:
   - ServiceName*—name
   - Server*—ip or serverName
   - Protocol*—serviceType
   - Port*—port
4. Click the Advanced tab and then scroll down in the dialog box.
5. In the Hash ID box, type a unique hash ID value.
6. Click Create.
7. Open the service and verify the settings you just configured.

To specify a hash identifier for an already configured service group member by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and then click Open.
3. On the Members tab, under Configured Members, in the row of the member for which you want to specify a hash ID value, double-click the space in the Hash ID column.
4. Type a unique hash ID value.
5. Click OK.
6. Open the service group and verify the hash IDs of the service group members you just configured.

Configuring the Redirection Mode

Aug 02, 2016

The redirection mode configures the method used by a virtual server to determine where to forward incoming traffic. The NetScaler appliance supports the following redirection modes:

- IP-Based forwarding (the default)
- MAC-Based forwarding

You can configure MAC-Based forwarding on networks that use direct server return (DSR) topology, link load balancing, or firewall load balancing. For more information on MAC-Based forwarding, see Configuring MAC-Based Forwarding.

To configure the redirection mode by using the command line interface

At the command prompt, type:

set lb vserver <name>@ -m <RedirectionMode>

Example

set lb vserver Vserver-LB-1 -m MAC

To configure the redirection mode by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode, and then click Open.
3. On the Advanced tab, under Redirection Mode, click either IP-Based or MAC-Based.
4. Click OK.

Configuring per-VLAN Wildcarded Virtual Servers

Nov 12, 2013

If you want to configure load balancing for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

To configure a wildcarded virtual server that listens to a specific VLAN by using the command line interface

At the command prompt, type the following commands to configure a wildcarded virtual server that listens to a specific VLAN and verify the configuration:

- add lb vserver <name> <serviceType> IPAddress * Port * -listenpolicy <expression> [-listenpriority <positive_integer>]
- show vserver

Example

```
add lb vserver Vserver-LB-vlan1 ANY -listenpolicy "CLIENT.VLAN.ID.EQ(2)" -listenpriority 10

show vserver Vserver-LB-vlan1
```

To configure a wildcarded virtual server that listens to a specific VLAN by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, do one of the following:
   - To create a new virtual server, click Add.
   - To modify an existing virtual server, select the virtual server, and then click Open.
3. In the Create Virtual Server or Configure Virtual Server dialog box, on the Services tab, specify values for the following parameters:
   - Name*—name
   - Protocol*—serviceType
   - IP address*—IPAddress
   - Port—port

   *A required parameter
4. In the Advanced tab, expand Listen Policy, and then specify values for the following parameters:
   - Listen Priority*—listenpriority
   - Listen Policy Rule*—rule

   *A required parameter
5. Click Create or OK, depending on whether you are creating a new virtual server or modifying an existing virtual server.
6. Click Close. The virtual server that you created now appears in the Virtual Servers page.
7. To remove a virtual server, in the Virtual Servers pane select the virtual server, and then click Remove.

After you have created this virtual server, you bind it to one or more services as described in Setting Up Basic Load Balancing.

Assigning Weights to Services

Nov 12, 2013

In a load balancing configuration, you assign weights to services to indicate the percentage of traffic that should be sent to each service. Services with higher weights can handle more requests; services with lower weights can handle fewer requests. Assigning weights to services allows the NetScaler appliance to determine how much traffic each load balanced server can handle, and therefore more effectively balance load.

Note: If you use a load balancing method that supports weighting of services (for example, the round robin method), you can assign a weight to the service.

The following table describes the load balancing methods that support weighting, and briefly describes the manner in which weighting affects how a service is selected for each one.

Load Balancing Methods	**Service Selection with Weights**
Round Robin	The virtual server prioritizes the queue of available services such that services with the highest weights come to the front of the queue more frequently than those with the lowest weights and receive proportionately more traffic. For a complete description, see The Round Robin Method.
Least Connection	The virtual server selects the service with the best combination of fewest active transactions and highest weight. For a complete description, see The Least Connection Method.
Least Response Time and Least Response Time Method using Monitors	The virtual server selects the service with the best combination of fewest active transactions and fastest average response time. For a complete description, see The Least Response Time Method.
Least Bandwidth	The virtual server selects the service with the best combination of least traffic and highest bandwidth. For a complete description, see The Least Bandwidth Method.
Least Packets	The virtual server selects the service with the best combination of fewest packets and highest weight. For a complete description, see The Least Packets Method.
Custom Load	The virtual server selects the service with the best combination of lowest load and highest weight. For a complete description, see The Custom Load Method.
Hashing methods and Token method	Weighting is not supported by these load balancing methods.

To configure a virtual server to assign weights to services by using the command line interface

At the command prompt, type:

set lb vserver <name>@ -weight <Value> <ServiceName>

Example

set lb vserver Vserver-LB-1 -weight 10 Service-HTTP-1

To configure a virtual server to assign weights to services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server, and then click Open.
3. On the Services tab, in the Weights spin box, type or select the weight to assign to the service (for example, 10).
4. Click OK.

Configuring the MySQL and Microsoft SQL Server Version Setting

Mar 24, 2015

You can specify the version of Microsoft® SQL Server® and the MySQL server for a load balancing virtual server that is of type MSSQL and MySQL respectively. The version setting is recommended if you expect some clients to not be running the same version as your MySQL or Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a load balancing virtual server and verify the configuration:

- set lb vserver <name> -mssqlServerVersion <mssqlServerVersion>
- show lb vserver <name>

Example

```
> set lb vserver myMSSQLvip -mssqlServerVersion 2008R2
 Done
> show lb vserver myMSSQLvip
 myMSSQLvip (190.0.2.12:1433) - MSSQL Type: ADDRESS
. . .
. . .
 MSsql Server Version: 2008R2
. . .
. . .
 Done
>
```

At the command prompt, type the following commands to set the MySQL Server version parameter for a load balancing virtual server and verify the configuration:

- set lb vserver <name> -mysqlServerVersion <string>
- show lb vserver <name>

Example

```
> set lb vserver mysqlsvr -mysqlserverversion 5.5.30
 Done
> sh lb vserver mysqlsvr
  mysqlsvr (2.22.2.222:3306) - MYSQL      Type: ADDRESS
. . .
. . .
 Mysql Server Version: 5.5.30
. . .
```

```
. . .
 Done
>
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the setting, and then click Open.
3. In the Configure Virtual Server dialog box, do the following:
    1. In the advanced tab, click MsSql or MySql.
    2. In the Server Version list, select the version of your Microsoft SQL Server product.
    3. Click Create or OK, and then click Close.

Configuring Diameter Load Balancing

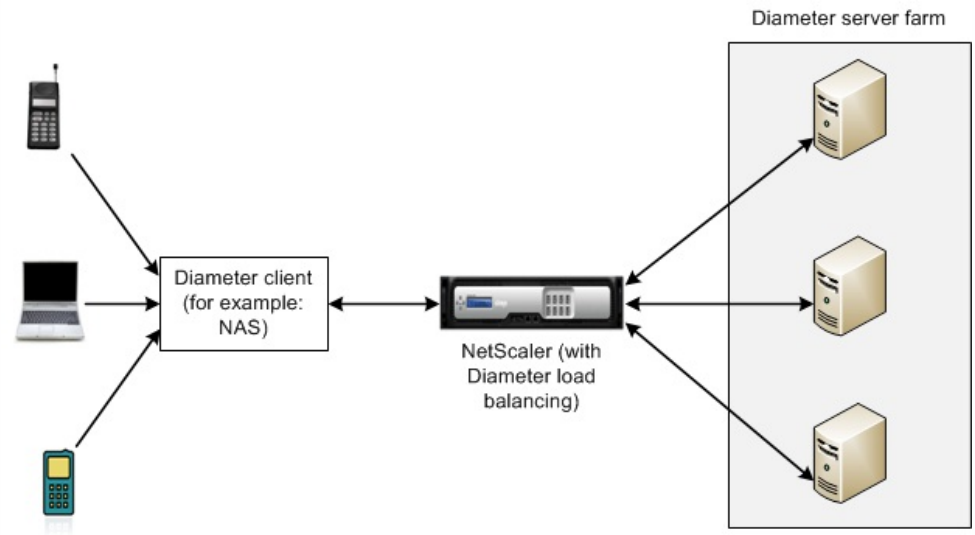
Mar 18, 2013

The Diameter protocol is a next generation Authentication, Authorization, and Accounting (AAA) signaling protocol used mainly on mobile devices such as laptops and mobile phones. It is a peer-to-peer protocol, as opposed to the traditional client-server model used by most other protocols. However, in most Diameter deployments, the clients originates the request and the server responds to the request.

When Diameter messages are exchanged, the Diameter server usually does much more processing than does the Diameter client. With the increase in control plane signaling volume, the Diameter server becomes a bottleneck. Therefore, Diameter messages must be load balanced to multiple servers. A virtual server performing load balancing of Diameter messages provides the following benefits:

- Lighter load on Diameter servers, which translates to faster response time to end users.
- Server health monitoring and better failover capabilities.
- Better scalability in terms of server addition without changing client configuration.
- High availability.
- SSL-Diameter offloading.

The following figure shows a Diameter system in a NetScaler deployment:



A Diameter system has the following components:

- **Diameter client.** Supports Diameter client applications in addition to the base protocol. Diameter clients are often implemented in devices situated at the edge of a network and provide access control services for that network. Typical examples of Diameter clients are a Network Access Server (NAS) and the Mobile IP Foreign Agent (FA).
- **Diameter agent.** Provides relay, proxy, redirect, or translation services. The NetScaler appliance (configured with a Diameter load balancing virtual server) plays the role of a Diameter agent.
- **Diameter server.** Handles the authentication, authorization, and accounting requests for a particular realm. A Diameter server must support Diameter server applications in addition to the base protocol.

In a typical Diameter topology, when an end-user device (such as a mobile phone) needs a service, it sends a request to a Diameter client. Each Diameter client establishes a single connection (TCP connection—SCTP is not yet supported) with a Diameter server as specified by the Diameter base-protocol RFC 6733. The connection is long-lived and all messages between

the two Diameter nodes (client and server) are exchanged over this connection. The NetScaler uses message based load balancing .

Example

A mobile service provider uses Diameter for its billing system. When a subscriber uses a prepaid number, the Diameter client repeatedly sends requests to the server to check the available balance. The Diameter protocol establishes a connection between the client and the server, and all requests are exchanged over that connection. Connection based load balancing would be pointless, because there is only one connection. However, with the large number of messages on the connection, message based load balancing expedites the process of billing the prepaid mobile subscriber.

A Diameter client opens a connection to the NetScaler appliance and sends a Diameter capability exchange (CER) message. Diameter messages are composed of command codes and each command has a set of Attribute-Value Pairs (AVPs), such as Origin-Host and Host-IP-Address.

The NetScaler selects a Diameter server, opens a connection to the server, and forwards the CER message to the server. The server reads the client identity and determines that it is directly connected to the client.

The Diameter server prepares the Diameter handshake reply and sends it to the NetScaler appliance. The appliance modifies the handshake and inserts its own identity. At this point, the Diameter client determines that it is directly connected to the NetScaler (the agent).

Note: Until the Diameter handshake is complete, all Diameter request messages from the client are queued on the selected server. The packets are forwarded to the server when the handshake is complete.

Load Balancing Diameter Traffic

When a client sends a request to the NetScaler appliance, the appliance parses the request and contextually load balances it to a Diameter server on the basis of a persist AVP. The NetScaler has advertised the client identity to the server, so it does not add route entries, because the server is expecting messages directly from client.

Server initiated requests are not as frequent as client requests. Server initiated requests are similar to client initiated requests, except:

- Since messages are received from multiple servers, the NetScaler maintains the transaction state by adding a unique Hop by Hop (HbyH) number to each forwarded request message. When the message response arrives (with same HbyH number), the appliance translates this HbyH number to the HbyH number that was received on the server when the request arrived.
- NetScaler adds a route entry by putting its identity, because the client sees the NetScaler as a relay agent.

Note: If a Diameter message spans more than one packet, the NetScaler accumulates the packets in an incomplete header queue and forwards them to the server when the full message is accumulated. Similarly, if a single packet contains more than one Diameter message, the NetScaler splits the packet and forwards the messages to servers as determined by the load balancing virtual server.

Disconnecting a Session

A Disconnect Peer Request (DPR) indicates the peer's intention of closing the connection, with the reason for closing the connection. The peer replies with a DPA (TCP always provides successful DPA).

- When the NetScaler receives a DPR from the client, it broadcasts the DPR to all servers and immediately replies with a DPA to the client. The servers reply with DPAs, but the NetScaler ignores them. The client sends a FIN, which the NetScaler broadcasts to all servers.
- When the NetScaler receives a DPR from the server, it replies with a DPA to that server alone, and does not remove the

server from the reuse pool. When the server sends a FIN, the NetScaler replies with FIN/ACK and removes connections from the reuse pool.

- If the NetScaler receives a FIN from the client, it sends the client a FIN/ACK, broadcasts the FIN, and immediately removes the server connection from the reuse pool.
- If the NetScaler receives a FIN from the server, it sends a FIN/ACK and removes it from reuse pool. Any new message for this server is sent on a new connection.

Updated: 2013-11-12

To configure the NetScaler appliance to load balance Diameter traffic, you must first set the Diameter parameters on the appliance, then add the Diameter monitor, add the Diameter services, bind the services to the monitor, add the Diameter load balancing virtual server, and bind the services to the virtual server.

To configure load balancing for Diameter traffic by using the command line interface

1. Configure the Diameter parameters.
   set ns diameter -identity <string> -realm <string> -serverClosePropagation <YES | NO>

   Example
   set ns diameter -identity mydomain.org -realm org -serverClosePropagation YES
2. Add a Diameter monitor.
   add lb monitor <monitorName> DIAMETER -originHost <string> -originRealm <string>

   Example
   add lb monitor diameter_mon DIAMETER -originHost mydomain.org -originRealm org
3. Create the Diameter services.
   add service <name>@ <IP>@ DIAMETER <port>

   Example
   add service diameter_svc0 10.102.82.86 DIAMETER 3868
   add service diameter_svc1 10.102.82.87 DIAMETER 3868
   add service diameter_svc2 10.102.82.88 DIAMETER 3868
   add service diameter_svc3 10.102.82.89 DIAMETER 3868
4. Bind the Diameter services to the Diameter monitor.
   bind service <name>@ monitorName <monitorName>

   -Example
   bind service diameter_svc0 -monitorName diameter_mon
   bind service diameter_svc1 -monitorName diameter_mon
   bind service diameter_svc2 -monitorName diameter_mon
   bind service diameter_svc3 -monitorName diameter_mon
5. Add a Diameter load balancing virtual server with Diameter persistence.
   add lb vserver <name>@ DIAMETER <IPAddress> <port> -persistenceType DIAMETER -persistAVPno <positive_integer>

   Example
   add lb vserver diameter_vs DIAMETER 10.102.112.152 3868 -persistenceType DIAMETER -persistAVPno 263
6. Bind the Diameter services to the Diameter load balancing virtual server.
   bind lb vserver <name>@ <serviceName>

   Example

```
bind lb vserver diameter_vs diameter_svc0
bind lb vserver diameter_vs diameter_svc1
bind lb vserver diameter_vs diameter_svc2
bind lb vserver diameter_vs diameter_svc3
```

7. Save the configuration.
   save ns config

   Note: You can also configure load balancing of Diameter traffic over SSL by using the **SSL_DIAMETER** service type.

To configure load balancing for Diameter traffic by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, click Change Diameter Parameters.
3. In the Configure Diameter Parameters dialog box, specify values for the following parameters. (Hover on a parameter's name to display its description.)
   - Host Identity
   - Realm
   - Server Close Propagation
4. Click OK to configure the Diameter parameters.
5. Navigate to Traffic Management > Load Balancing > Monitors.
6. In the details pane, click Add.
7. In the Create Monitor dialog box, create a monitor with Type as Diameter.
8. On the Special Parameters tab, enter values for Origin Host and Origin Realm.
9. Navigate to Traffic Management > Load Balancing > Services.
10. In the details pane, click Add.
11. In the Create Service dialog box, create a service with Protocol as Diameter and bind the created Diameter monitor to this service.
12. Navigate to Traffic Management > Load Balancing > Virtual Servers.
13. In the details pane, click Add.
14. In the Create Virtual Server (Load Balancing) dialog box, create a load balancing virtual server with Protocol as DIAMETER and bind the created Diameter services to this virtual server.
15. On the Method and Persistence tab, select the Persistence as DIAMETER and specify a **AVP Number**.

Protecting a Load Balancing Configuration against Failure

Jun 03, 2015

When a load balancing virtual server fails, or when the virtual server is unable to handle excessive traffic, the load balancing setup can fail. You can protect your load balancing setup against failure by configuring the NetScaler appliance to redirect excess traffic to an alternate URL, configuring a backup load balancing virtual server, and configuring stateful connection failover.

To protect a load balancing configuration against failure, see the following sections:

- Redirecting Client Requests to an Alternate URL
- Configuring a Backup Load Balancing Virtual Server
- Configuring Spillover
- Connection Failover
- Flushing the Surge Queue

Redirecting Client Requests to an Alternate URL

Sep 02, 2013

In the event that a load balancing virtual server of type HTTP or type HTTPS goes DOWN or is disabled, you can redirect requests to an alternate URL by using an HTTP 302 redirect. The alternate URL can provide information about the status of the server.

You can redirect to a page on the local server or a remote server. You can redirect to a relative URL or an absolute URL. If you configure a redirect to a relative URL consisting of a domain name with no path, the NetScaler appliance appends the path of the incoming URL to the domain. If you use an absolute URL, the HTTP redirect is sent to that URL with no modification.

Note: If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when both the primary and backup virtual servers are DOWN.

At the command prompt, type:

set lb vserver <vServerName> -redirectURL <URLValue>

Example

set lb vserver Vserver-LB-1 -redirectURL http://www.newdomain.com/mysite/maintenance

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure redirect URL, and then click Open.
3. On the Advanced tab, in the Redirect URL text box, type the URL (for example, http://www.newdomain.com/mysite/maintenance).
4. Click OK.

Configuring a Backup Load Balancing Virtual Server

Sep 02, 2013

You can configure the NetScaler appliance to direct requests to a backup virtual server in the event that the primary load balancing virtual server is DOWN or unavailable. The backup virtual server is a proxy and is transparent to the client. The appliance can also send a notification message to the client regarding the site outage.

You can configure a backup load balancing virtual server when you create it, or you can change the optional parameters of an existing virtual server. You can also configure a backup virtual server for an existing backup virtual server, thus creating cascading backup virtual servers. The maximum depth of cascading backup virtual servers is 10.

If you have multiple virtual servers that connect to two servers, you have a choice for what happens if the primary virtual server goes DOWN and then comes back up. The default behavior is for the primary virtual server to resume its role as primary. However, you may want to configure the backup virtual server to remain in control in the event that it takes over. For example, you may want to sync updates on the backup virtual server to the primary virtual server and then manually force the original primary server to resume its role. In this case, you can designate the backup virtual server to remain in control in the event that the primary virtual server goes DOWN and then comes back up.

You can configure a redirect URL on the primary load balancing virtual server as a fallback for when both the primary and the backup virtual servers are DOWN or have reached their threshold for handling requests. When services bound to virtual servers are OUT OF SERVICE, the appliance uses the redirect URL.

Note: If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when the primary and backup virtual servers are down.

At the command prompt, type:

set lb vserver <vServerName> -backupVserver <BackupVServerName> [-disablePrimaryOnDown]

Example

```
set lb vserver Vserver-LB-1 -backupVserver Vserver-LB-2 -disablePrimaryOnDown
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the backup virtual server, and then click Open.
3. On the Advanced tab, in the Backup Virtual Server list, select the backup virtual server.
4. If you want the backup virtual server to remain in control until you manually re-enable the primary virtual server even if the primary virtual server comes back up, select the Disable Primary When Down check box.
5. Click OK.

Configuring Spillover

Sep 02, 2013

A spillover configuration on the appliance consists of a primary virtual server that is configured with a spillover method, a spillover threshold, and a backup virtual server. Backup virtual servers can also be configured for spillover, creating a chain of backup virtual servers.

The spillover method specifies the operational condition on which you want to base your spillover configuration (for example, the number of established connections, bandwidth, or combined health of the server farm). When a new connection arrives, the appliance verifies that the primary virtual server is up and compares the operational condition with the configured spillover threshold. If the threshold is reached, the spillover feature diverts new connections to the first available virtual server in the backup chain. The backup virtual server manages the connections it receives until the load on the primary falls below the threshold.

If you configure spillover persistence, the backup virtual server continues to process the connections it received, even after the load on the primary falls below the threshold. If you configure spillover persistence and a spillover persistence timeout, the backup virtual server processes connections for only the specified period of time after the load on the primary falls below the threshold.

Note: In most cases, spillover is triggered if the value associated with the spillover method exceeds the threshold (for example, number of connections). Keep in mind, however, that with the server-health spillover method, spillover is triggered if the health of the server farm falls below the threshold.
You can configure spillover in one of the following ways:

- Specify a predefined spillover method. Four predefined methods are available, and they fulfill common spillover requirements.
- Configure policy based spillover. In policy based spillover, you use a NetScaler rule to specify the conditions that should be met for spillover to occur. NetScaler rules give you the flexibility to configure spillover for various operational conditions.

Use policy based spillover if a predefined method does not satisfy your requirements. If you configure both for a primary virtual server, the policy based spillover configuration takes precedence over the predefined method.

First, you create the primary virtual server and the virtual servers that you need for the backup chain. You set up the backup chain by specifying one virtual server as the backup for the primary (that is, you create a secondary virtual server), a virtual server as the backup for the secondary (that is, you create a tertiary virtual server), and so on. Then, you configure spillover by either specifying a predefined spillover method or creating and binding spillover policies.

For instructions for assigning a virtual server as the backup for another virtual server, see Configuring a Backup Load Balancing Virtual Server.

Updated: 2013-09-02

Predefined spillover methods fulfill some of the more common spillover requirements. To use one of the predefined spillover methods, you configure spillover parameters on the primary virtual server. To create a chain of backup virtual servers, you also configure spillover parameters on backup virtual servers.

If the backup virtual servers reach their own threshold values, and the service type is TCP, the NetScaler appliance sends clients a TCP reset. For service types HTTP, SSL, and RTSP , it diverts new requests to the redirect URL configured for the primary virtual server. A redirect URL can be specified for only HTTP, SSL, and RTSP virtual servers. If a redirect URL is not configured, the NetScaler appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).

Note: With RTSP virtual servers, the NetScaler appliance uses only data connections for spillover. If the backup RTSP virtual server is not available, the requests are redirected to an RTSP URL and an RTSP redirect message is sent to the client.

To configure a predefined spillover method for a virtual server by using the command line interface

At the command prompt, type:

set lb vserver <vServerName> -soMethod <spillOverType> -soThreshold <positiveInteger> -soPersistence ENABLED -soPersistenceTimeout <positiveInteger>

```
set lb vserver Vserver-LB-1 -soMethod Connection -soThreshold 1000 -soPersistence enabled -soPersistenceTimeout 2
```

To configure a predefined spillover method for a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the spillover, and then click Open.
3. On the Advanced tab, in the Method list, select the type of threshold, and in Threshold text box, type the threshold value.
4. Under Spillover, select the Persistence check box, and in Persistence Time-out (min) text box type the time-out.
5. Click OK.

Updated: 2013-09-02

Spillover policies, which are based on rules (expressions), enable you to configure the appliance for a wider range of spillover scenarios. For example, you can configure spillover on the basis of the virtual server's response time, or on the basis of number of connections in the virtual server's surge queue.

To configure policy based spillover, first create a spillover action. You then select the expression that you want to use in the spillover policy , configure the policy, and associate the action with it. Finally, you bind the spillover policy to a load balancing, content switching, or global server load balancing virtual server. You can bind multiple spillover policies to a virtual server, with priority numbers. The appliance evaluates the spillover policies in ascending order of priority numbers and performs the action associated with the last policy to evaluate to TRUE.

A virtual server can also have a backup action. The backup action is performed if the virtual server does not have one or more backup virtual servers, or if all of the backup virtual servers are DOWN, disabled, or have reached their own spillover limits.

When a spillover policy results in an UNDEF condition (an exception thrown when the result of policy evaluation is undefined), an UNDEF action is performed. The UNDEF action is always ACCEPT. You cannot specify an UNDEF action of your choice.

Configuring a Spillover Action

Updated: 2013-09-13

A spillover action is performed when the spillover policy with which it is associated evaluates to TRUE. Currently, SPILLOVER is the only supported spillover action.

At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

- add spillover action <name> -action SPILLOVER
- show spillover action <name>

Example

```
> add spillover action mySoAction -action SPILLOVER
 Done
> show spillover action mySoAction
1) Name: mySoAction Action: SPILLOVER
 Done
>
```

Selecting an Expression for the Spillover Policy

Updated: 2013-09-02

In the policy expression, you can use any virtual-server based expression that returns a Boolean value. For example, you could use one of the following expressions:

SYS.VSERVER("vserver").RESPTIME.GT(<int>), SYS.VSERVER("vserver").STATE.EQ("<string>"), and SYS.VSERVER("vserver").THROUGHPUT.LT(<int>).

In addition to the existing functions such as RESPTIME, STATE, and THROUGHPUT, you can use the following virtual server based functions that have been introduced with this feature:

Averagesurgecount

Returns the average number of requests in the surge queues of active services. Returns 0 (zero) if there are no active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

Activeservices

Returns the number of active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

Activetransactions

Returns the value of the virtual-server-level counter for current active transactions.

is_dynamic_limit_reached

Returns a Boolean TRUE if the number of connections being managed by the virtual server equals the dynamically calculated threshold. The dynamic threshold is the sum of the maximum client (Max Clients) settings of the bound services that are UP.

You can use a policy expression to implement any of the predefined spillover methods. The following table maps the predefined spillover methods to the expressions you can use to implement them:

Table 1. Converting predefined spillover methods to policy expressions

Predefined spillover method	Corresponding expression
CONNECTION	SYS.VSERVER(\"<vserver-name>\").CONNECTIONS, used with the GT(int) arithmetic function.
BANDWIDTH	SYS.VSERVER(\"<vserver-name>\").THROUGHPUT, used with the GT(int) arithmetic function.
HEALTH	SYS.VSERVER(\"<vserver-name>\").HEALTH, used with the LT(int) arithmetic function.
DYNAMICCONNECTION	SYS.VSERVER(\"<vserver-name>\").IS_DYNAMIC_LIMIT_REACHED Note: If you implement policy based spillover by using the IS_DYNAMIC_LIMIT_REACHED function, you must also configure the predefined DYNAMICCONNECTION method for the virtual server, so that statistics required for spillover to work are collected.

Configuring a Spillover Policy

Updated: 2013-09-13

A spillover policy uses a Boolean expression as a rule to specify the conditions that must be met for spillover to occur.

At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

- add spillover policy <name> -rule <expression> -action <string> [-comment <string>]
- show spillover policy <name>

Example

```
> add spillover policy mySoPolicy -rule SYS.VSERVER("v1").RESPTIME.GT(50) -action mySoAction -comment "Triggers spillover when the vserver's response time is greater
 Done
> show spillover policy mySoPolicy
1) Name: mySoPolicy Rule: "SYS.VSERVER(\"v1\").RESPTIME.GT(50)" Action: mySoAction Hits: 0 ActivePolicy: 0
 Comment: "Triggers spillover when the vserver\'s response time is greater than 50 ms."
 Done
>
```

Binding a Spillover Policy to a Virtual Server

Updated: 2013-09-13

You can bind a spillover policy to load balancing, content switching, or global server load balancing virtual servers). You can bind multiple policies to a virtual server, with Goto expressions controlling the flow of evaluation.

At the command prompt, type the following commands to bind a spillover policy to a load balancing, content switching, or global server load balancing virtual server and verify the configuration:

- bind (lb | cs | gslb) vserver <name> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>]
- show (lb | cs | gslb) vserver <name>

Example

```
> bind lb vserver vserver1 -policyName mySoPolicy -priority 5
 Done
> show lb vserver vserver1
 vserver1 (2.2.2.12:80) - HTTP Type: ADDRESS
 . . .

1) Spillover Policy Name: mySoPolicy Priority: 5
 GotoPriority Expression: END
 Flowtype: REQUEST
 Done
>
```

Configuring a Backup Action for a Spillover Event

Updated: 2013-09-02

A backup action specifies what to do in the event that the spillover threshold is reached but one or more backup virtual serves are either not configured or are down, disabled, or have reached their own thresholds.

Note: For the predefined spillover methods that are configured directly on the virtual server (as values of the Spillover Method parameter), the backup action is not configurable. By default, the appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).
The backup action is configured on the virtual server. You can configure the virtual server to accept requests (after the threshold specified by the policy is reached), redirect clients to a URL, or simply drop requests until the number of requests falls below the threshold.

At the command prompt, type the following commands to configure a backup action and verify the configuration:

- set lb vserver <name> -soBackupAction <soBackupAction>
- show lb vserver <name>

Example

```
> set lb vserver vs1 -soBackupAction REDIRECT -redirectURL http://www.mysite.com/maintenance
 Done
> show lb vserver vs1
 vs1 (10.102.29.76:80) - HTTP Type: ADDRESS
 State: UP
 . . .
 Redirect URL: http://www.mysite.com/maintenance
          . . .
Done
>
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Select the virtual server for which you want to configure a backup spillover action, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. In the Spillover area of the tab, in Backup Action, select an action.
5. Click OK.

Connection Failover

Sep 30, 2013

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. In a NetScaler High Availability (HA) setup, *connection failover* (or *connection mirroring-CM*) refers to keeping active an established TCP or UDP connection when a failover occurs. The new primary NetScaler appliance has information about the connections established before the failover and continues to serve those connections. After failover, the client remains connected to the same physical server. The new primary appliance synchronizes the information with the new secondary appliance by using the SSF framework. If the L2Conn parameter is set, Layer 2 connection parameters are also synchronized with the secondary.

You can set up connection failover in either stateless or stateful mode. In the stateless connection failover mode, the HA nodes do not exchange any information about the connections that are failed over. This method has no runtime overhead.

In the stateful connection failover mode, the primary appliance synchronizes the data of the failed-over connections with the new secondary appliance.

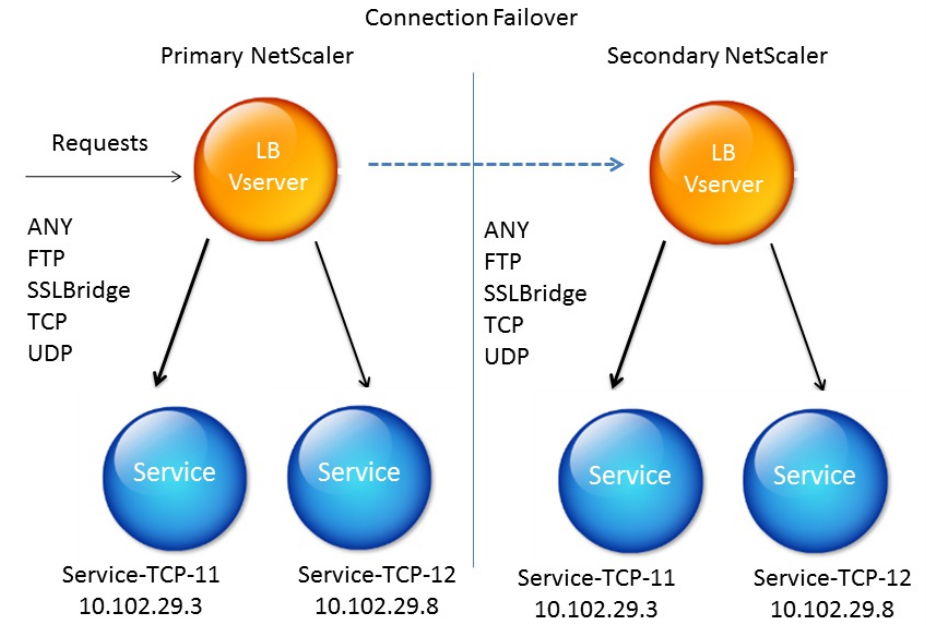
In stateless connection failover, the new primary appliance tries to re-create the packet flow according to the information contained in the packets it receives.

In stateful failover, to maintain current information about the mirrored connections, the primary appliance sends messages to the secondary appliance. The secondary appliance maintains the data related to the packets but uses it only in the event of a failover. If a failover occurs, the new primary (old secondary) appliance starts using the stored data about the mirrored connections and accepting traffic. During the transition period, the client and server may experience a brief disruption and retransmissions.

Note:
Verify that the primary appliance is able to authorize itself on the secondary appliance. To verify correct configuration of the passwords, use the show rpcnode command from command line or use the RPC option of the Network menu from the configuration utility.

A basic HA configuration with connection failover contains the entities shown in the following figure.

Figure 1. Connection Failover Entity Diagram



Connection failover can be configured only on load balancing virtual servers. It cannot be configured on content-switching virtual servers.

The following table describes the setup supported for connection failover.

Table 1. Connection Failover - Supported Setup

Setting	Stateless	Stateful
Service type	ANY.	ANY, UDP, TCP, FTP, SSL_BRIDGE.
Load balancing methods	All methods supported for the service type ANY. However, if Source IP persistence is not set, the SRCIPSRCPORTHASH method must be used.	All methods applicable to the supported service types.
Persistence types	SOURCEIP persistence.	All types applicable to the supported service types are supported.
USIP	Must be ON.	No restriction. It can be ON or OFF.
Service bindings	Service can be bound to only one virtual server.	Service can be bound to one or more virtual servers.
Internet	IPv4 and IPv6	IPV4

Setting	Stateless	Stateful
Protocol (IP) versions		
Redundancy support	Clustering and high availability	High availability

The following table lists the features affected if connection failover is configured.

Table 2. How Connection Failover Affects NetScaler Features

Feature	Impact of Connection Failover
SYN protection	For any connection, if a failover occurs after the NetScaler issues SYN-ACK but before it receives the final ACK, the connection is not supported by connection failover. The client must reissue the request to establish the connection.
Surge protection	If the failover occurs before a connection with the server is established, the new primary NetScaler tries to establish the connection with the server. It also retransmits all the packets held in the course of surge protection.
Access down	If enabled, the access-down functionality takes precedence over connection failover.
Application Firewall™	The Application Firewall feature is not supported.
INC	Independent network configuration is not supported in the high availability (HA) mode.
TCP buffering	TCP buffering is not compatible with connection mirroring.
Close on response	After failover, the NATPCBs may not be closed on response.
IPv6 virtual servers	Not yet supported.

Configuring Connection Failover

Sep 13, 2013

You can configure connection failover on a load balancing virtual server.

At the command prompt, type:

set lb vserver <vServerName> -connFailover <Value>

Example

```
set lb vserver Vserver-LB-1 -connFailover stateful
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers pane, select the virtual server for which you want to configure connection failover, and click Open.
3. On the Advanced tab, in the Connection Failover drop-down list, select Stateful.
4. Click OK.

Disabling Connection Failover

Sep 02, 2013

When connection failover is disabled on a virtual server, the resources allocated to the virtual server are freed.

At the command prompt, type:

set lb vserver <vServerName> -connFailover <Value>

Example

```
set lb vserver Vserver-LB-1 -connFailover disable
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers pane, select the virtual server for which you want to configure a connection failover and click Open.
3. On the Advanced tab, in the Connection Failover drop-down list box, select Disable.
4. Click OK.

Flushing the Surge Queue

Dec 04, 2013

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the NetScaler appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.
Note: Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]

Examples

1.
flush ns surgeQ –name SVC1ANZGB –serverName 10.10.10.1 80
The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10
2.
flush ns surgeQ
The above command flushes all the surge queues on the appliance.

1. Navigate to Traffic Management > Load Balancing.
2. To select an entity, do one of the following:
   - To flush the surge queue of a virtual server, click Virtual Servers, and then select the virtual server.
   - To flush the surge queue of a service, click Services, and then select the service.

- To flush the surge queue of all the members in a service group, click Service Groups, and then select the service group.
- To flush the surge queue of a specific member in a service group, click Service Groups, and in the action pane, click Manage Members. In the Manage Members of a Service Group dialog box, select the service group member.

Note: You can select multiple entities in any window.

Note: To flush the surge queue of a content switching virtual server, in Steps 1 and 2, expand Content Switching, and then select a virtual server.

3. In the action pane, click Flush Surge Queue.
4. Click OK.

Note: On the appliance, if there are other entities with the same name as you selected, you are alerted that the surge queues of those entities would also be flushed. Take an appropriate action.

Managing a Load Balancing Setup

Jun 09, 2015

An existing Load Balancing setup does not require a great deal of work to maintain as long as it is unchanged, but most do not remain unchanged for long. Increasing load requires new load-balanced servers and eventually new NetScaler appliances, which must be configured and added to the existing setup. Old servers wear out and need to be replaced, requiring removal of some servers and addition of others. Upgrades to your networking equipment or changes to topology may also require modifications to your load balancing setup. Therefore, you will need to perform operations on server objects, services, and virtual servers. The Visualizer can display your configuration graphically, and you can perform operations on the entities in the display. You can also take advantage of a number of other features that facilitate management of the traffic through your load balancing setup.

This section includes the following details:

- Managing Server Objects
- Managing Services
- Managing a Load Balancing Virtual Server
- The Load Balancing Visualizer

Managing Server Objects

Nov 12, 2013

During basic load balancing setup, when you create a service, a server object with the IP address of the service is created, if one does not already exist. If you prefer for your service objects named with domain names rather than IP addresses, you might also have created one or more server objects manually. You can enable, disable, or remove any server object.

When you enable or disable a server object, you enable or disable all services associated with the server object. When you refresh the NetScaler appliance after disabling a server object, the state of its service appears as OUT OF SERVICE. If you specify a wait time when disabling a server object, the server object continues to handle established connections for the specified amount of time, but rejects new connections. If you remove a server object, the service to which it is bound is also deleted.

At the command prompt, type:

enable server <name>@
Example

```
enable server 10.102.29.5
```

1. Navigate to Traffic Management > Load Balancing > Servers.
2. In the details pane, select the server that you want to enable, and then click Enable.
3. In the Enable dialog box, click Yes.

At the command prompt, type:

disable server <name>@ <delay>
Example

```
disable server 10.102.29.5 30
```

1. Navigate to Traffic Management > Load Balancing > Servers.
2. In the details pane, select the server that you want to disable, and then click Disable.
3. In the Wait Time dialog box, type the wait time after which the server is to be disabled (for example 30).
4. Click Enter.

At the command prompt, type:

rm server <name>@
Example

```
rm server 10.102.29.5
```

1. Navigate to Traffic Management > Load Balancing > Servers.
2. In the details pane, select the server that you want to remove, and then click Remove.
3. In the Remove dialog box, click Yes.

Managing Services

Nov 12, 2013

Services are enabled by default when you create them. You can disable or enable each service individually. When disabling a service, you normally specify a wait time during which the service continues to handle established connections, but rejects new ones, before shutting down. If you do not specify a wait time, the service shuts down immediately. During the wait time, the service's state is OUT OF SERVICE.

You can remove a service when it is no longer used. When you remove a service, it is unbound from its virtual server and deleted from the NetScaler configuration.

At the command prompt, type:

enable service <name>

Example

```
enable service Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service that you want to enable (for example, Service-HTTP-1), and click Enable.
3. In the Enable dialog box, click Yes.

At the command prompt, type:

disable service <name>@ <DelayInSeconds>

Example

```
disable service Service-HTTP-1 30
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service that you want to disable (for example, Service-HTTP-1), and then click Disable.
3. In the Wait Time dialog box, type the wait time after which the service is to be disabled (for example, 30).
4. Click Enter.

At the command prompt, type:

rm service <name>@

Example

```
rm service Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service that you want to remove (for example, Service-HTTP-1), and then click Remove.

3. In the Remove dialog box, click Yes.

Managing a Load Balancing Virtual Server

Feb 17, 2014

Virtual servers are enabled by default when you create them. You can disable and enable virtual servers manually. If you disable a virtual server, the virtual server's state appears as OUT OF SERVICE. When this happens, the virtual server terminates all connections, either immediately or after allowing existing connections to complete, depending on the setting of the downStateFLush parameter. If downStateFLush is ENABLED (default), all the connections are flushed. If DISABLED, the virtual server continues to serve requests on existing connections.

You remove a virtual server only when you no longer require the virtual server. Before you remove it, you must unbind all services from it.

At the command prompt, type:

enable lb vserver <name>@

Example

```
enable lb vserver Vserver-LB-1
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to enable, and click Enable.
3. In the Enable dialog box, click Yes.

At the command prompt, type:

disable vserver

Example

```
disable lb vserver Vserver-LB-1
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to disable, and then click Disable.
3. In the Disable dialog box, click Yes.

Note: In the disabled state, a virtual server continues to exist on the network. The NetScaler appliance continues to respond to address resolution protocol (ARP) and Internet control message protocol (ICMP) requests directed to the IP address of the virtual server.

At the command prompt, type:

unbind lb vserver <name>@ <serviceName>

Example

```
unbind lb vserver Vserver-LB-1 Service-HTTP-1
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server from which you want to unbind a service, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, in the Services tab, clear the Active check box next to the service that you want to unbind from the virtual server.
4. Click OK.

At the command prompt, type:

rm lb vserver <name>@

Example

rm lb vserver Vserver-LB-1

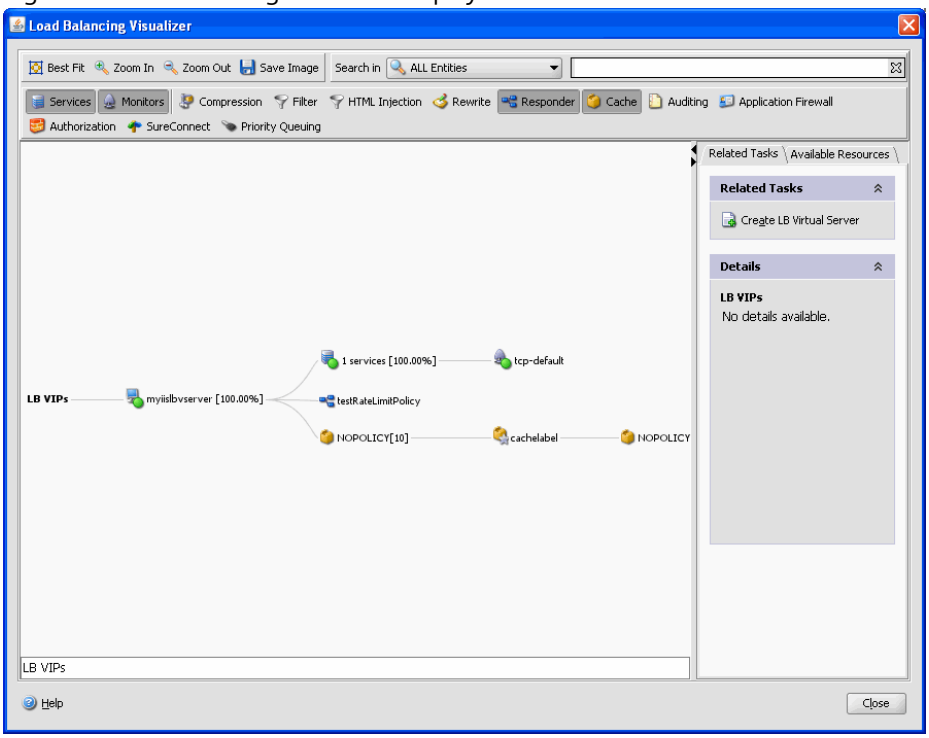
1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to remove, and then click Remove.
3. In the Remove dialog box, click Yes.

The Load Balancing Visualizer

Sep 03, 2013

The Load Balancing Visualizer is a tool that you can use to view and modify the load balancing configuration in graphical format. Following is an example of the Visualizer display

Figure 1. Load Balancing Visualizer Display



You can use the visualizer to view the following:

- The services and service groups that are bound to a virtual server.
- The monitors that are bound to each service.
- The policies that are bound to the virtual server.
- The policy labels, if configured.
- Configuration details of any displayed element.
- Load balancing virtual server statistics.
- Statistical information such as the number of requests received per second by the virtual server and the number of hits per second for rewrite, responder, and cache policies.
- A comparative list of all the parameters whose values either differ or are not defined across service containers.

You can also use the Visualizer to add and bind new objects, modify existing ones, and enable or disable objects. Most configuration elements displayed in the Visualizer appear under the same names as in other parts of the configuration utility. However, unlike the rest of the configuration utility, the Visualizer groups services that have the same configuration details and monitor bindings into an entity called a service container.

A service container is set of similar services and service groups that are bound to a single load balancing virtual server. Next to the service container is a number that shows the number of services in the group. The services in the container have the same properties, with the exception of the name, IP address, and port, and their monitor bindings should have the same weight and binding state. When you bind a new service to a virtual server, it is placed into an existing container if its configuration and monitor bindings match those of other services; otherwise, it is placed in its own container.

The service container display can help you troubleshoot your configuration if something is not functioning as you expect. More than one container for a particular virtual server is an indication that something is wrong with the configuration of that virtual server and its services. To correct the problem, you must first identify the container that has the desired configuration. You can do so by using the Service Attributes Diff feature, described below. After you identify the container, you right-click the container and click Apply Configuration.

The following procedures provide only basic steps for using the Visualizer. Because the Visualizer duplicates functionality in other areas of the Load Balancing feature, other methods of viewing or configuring all of the settings that can be configured in the Visualizer are provided throughout the Load Balancing documentation.

Note: The Visualizer requires a graphic interface, so it is available only through the configuration utility.

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, you can adjust the viewable area as follows:
   - Click the Zoom In and Zoom Out icons to increase or decrease the size of the viewed objects. You can click and drag the viewable area if an item that you want to see disappears from view after zooming in.
   - Click the Best Fit icon to optimize the viewing area.
   - Click the Save Image icon to save the graph as an image file.
   - Click the image, hold down the mouse button, and drag the image to pan the view.
   - In the Search in text field, begin typing the name of the item you are looking for. The item's location is then highlighted. To restrict the search, click the drop-down menu and select the type of element that you want to search for

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, to view configuration details for entities that are bound to this virtual server, you can do the following:
   - To view a summary of bound services, position the cursor over the virtual server icon.
   - To view services in a service container, click the icon for a service group, click the Related Tasks tab, click Show Member Services, and then click the service group name. To view additional details about the services click Open.
   - To view common properties of services in a service group, click the icon for the service group, click the Related Tasks tab, and view the Details section of the tab.
   - To view a comparative list of the parameters whose values either differ or are not defined across service containers, click the icon for a container, click the Related Tasks tab, and then click Service Attributes Diff. To view monitor binding details for the services in a container, in the Service Attributes Diff dialog box, in the Group column for the container, click Details.
   - To view the details for a monitor, position the cursor over the icon or click the icon for the monitor. For additional details, click the icon, click the Related Tasks tab, and then click View Monitor.
   - To view binding details of a monitor, click the connecting line between the monitor and its related service.

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, to view configuration details for entities that are bound to this virtual server, you can do the following:
   - To view policies that are bound to this virtual server, select one or more policy icons in the tool bar at the top of the dialog box. For example, you can select Compression, Filter, Rewrite, and Responder. If policy labels are configured, they appear in the main view area.
   - For bound policies that appear in the view pane of the Visualizer, to view a policy's expression and actions, position the cursor over the policy icon. To view binding details, position the cursor over the line that connects the policy to the virtual server. To view these details, click the policy. The details of the policy appear in the details pane.

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, to view statistical information, you can do the following:
   - To view detailed statistics for the load balancing virtual server, click the icon for the virtual server, click the Related Tasks tab, and then click Statistics.
   - To view the number of requests received per second at a given point in time by the load balancing virtual server and the number of hits per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time and has to be refreshed manually. To refresh this information, click Refresh Stats.

     Note: The Show Stats option is available only on NetScaler nCore builds.

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. To copy configuration details for an element to a document or spreadsheet, click the icon for that element, click Related Tasks.
4. In the Related Tasks tab, click Copy Properties and then paste the information into a document.

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure bindings, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, click the Available Resources tab, select a resource type in the drop-down menu, and do one or more of the following:
   - To bind a new monitor to a service, select Monitors, click a particular monitor, and then drag it to the service container icon. Use CONTROL + click to select multiple monitors and drag them to the service.
   - To bind a service or service group, select Services or Service Groups, respectively, click a particular service or service group, and then drag it to the virtual server icon. To bind multiple services or service groups at one time, press CONTROL + click to select multiple services and drag them over the virtual server.
   - To bind a policy, select one of the policy groups, click a particular policy, and then drag it to a virtual server. To bind multiple policies (classic policies only) at one time, press CONTROL + policies and drag them over the virtual server. For details on classic and advanced policies, see Policy Configuration and Reference.

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server from which you want to unbind a service, policy, or monitor, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, on the Visualizer image, click the connecting line between the resources that you want to unbind, and then click Unbind. For example, to unbind a monitor, you would click the link between the monitor and its bound service and click Unbind.
4. In the Unbind dialog box, click Yes.

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, on the Visualizer image, double-click the resource that you want to modify.
   Note: Alternatively, on the Available Resources tab, select the resource type from the drop-down menu, select the particular resource that you want to configure and then click Open.
4. In the modify dialog box, enter new settings for the resource.

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, right-click the icon for the resource that you want to add, remove, or disable, and then select the corresponding option from the menu.
   Note: Alternatively, on the Available Resources tab, click the resource type from the drop-down menu, and then click Add to add an entity, or select the particular resource that you want to configure and then click Open.
   Note: These options are not available for service groups or policies.

Managing Client Traffic

Jun 03, 2015

Managing client connections properly helps to ensure that your applications remain available to users even when your NetScaler appliance is experiencing high loads. A number of load balancing features and other features available on the appliance can be integrated into a load balancing setup to process load more efficiently, divert it when necessary, and prioritize the tasks that the appliance must perform:

- **Sessionless load balancing.** You can configure sessionless load balancing virtual servers and perform load balancing without creating sessions in configurations that use DSR or intrusion detection systems (IDS).
- **Integrated caching.** You can redirect HTTP requests to a cache.
- **Priority queuing.** You can direct requests based on priority, by integrating your configuration with the Priority Queuing feature.
- **SureConnect.** You can use load balancing with the SureConnect feature to redirect important requests to a custom Web page, insulating them from delays due to network congestion.
- **Delayed cleanup.** You can configure delayed cleanup of virtual server connections to prevent the cleanup process from using CPU cycles during periods when the NetScaler appliance is experiencing high loads.
- **Rewrite.** You can use the Rewrite feature to modify port and protocol when performing HTTP redirection, or insert the virtual server IP address and port into a custom Request header.
- **RTSP NAT.**
- **Rate-based monitoring.** You can enable rate-based monitoring to divert excess traffic.
- **Layer 2 Parameters.** You can configure a virtual server to use the L2 parameters to identify a connection.
- **ICMP Response**. You can configure the NetScaler to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.
  The following settings can be made on a virtual server:
  - When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.
  - When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, NetScaler responds even if one virtual server is UP.
  - When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds even if one virtual server set to ACTIVE is UP.

To manage client traffic, see the following sections:

- Configuring Sessionless Load Balancing Virtual Servers
- Redirecting HTTP Requests to a Cache
- Directing Requests According to Priority
- Directing Requests to a Custom Web Page
- Enabling Cleanup of Virtual Server Connections
- Graceful Shut down of Services
- Rewriting Ports and Protocols for HTTP Redirection
- Inserting the IP Address and Port of a Virtual Server in the Request Header
- Using a Specified Source IP for Backend Communication
- Setting a Timeout Value for Idle Client Connections
- Managing RTSP Connections
- Managing Client Traffic on the Basis of Traffic Rate
- Identifying a connection with Layer 2 Parameters

- Configuring the Prefer Direct Route Option

Configuring Sessionless Load Balancing Virtual Servers

Nov 11, 2013

When the NetScaler appliance performs load balancing, it creates and maintains sessions between clients and servers. The maintenance of session information places a significant load on the NetScaler resources, and sessions might not be needed in scenarios such as a direct server return (DSR) setup and the load balancing of intrusion detection systems (IDS). To avoid creating sessions when they are not necessary, you can configure a virtual server on the appliance for sessionless load balancing. In sessionless load balancing, the appliance carries out load balancing on a per-packet basis.

Sessionless load balancing can operate in MAC-based forwarding mode or IP-based forwarding mode.

For MAC-based forwarding, the IP address of the sessionless virtual server must be specified on all the physical servers to which the traffic is forwarded.

For IP-based forwarding in sessionless load balancing, the IP address and port of the virtual server need not be specified on the physical servers, because this information is included in the forwarded packets. When forwarding a packet from the client to the physical server, the appliance leaves client details such as IP address and port unchanged and adds the IP address and port of the destination.

NetScaler sessionless load balancing supports the following service types and load balancing methods:

Service Types

- ANY for MAC-based redirection
- ANY, DNS, and UDP for IP-based redirection

Load Balancing Methods

- Round Robin
- Least Bandwidth
- LRTM (Least response time method)
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port Hash
- Custom Load

Limitations

Sessionless load balancing has the following limitations:

- The NetScaler must be deployed in two-arm mode.
- A service must be bound to only one virtual server.
- Sessionless load balancing is not supported for service groups.
- Sessionless load balancing is not supported for domain based services (DBS services).
- Sessionless load balancing in the IP mode is not supported for a virtual server that is configured as a backup to a primary virtual server.
- You cannot enable spillover mode.

- For all the services bound to a sessionless load balancing virtual server, the Use Source IP (USIP) option must be enabled.
- For a wildcard virtual server or service, the destination IP address will not be changed.

Note: While configuring a virtual server for sessionless load balancing, explicitly specify a supported load balancing method. The default method, Least Connection, cannot be used for sessionless load balancing.
Note: To configure sessionless load balancing in MAC-based redirection mode on a virtual server, the MAC-based forwarding option must be enabled on the NetScaler.

At the command prompt, type the following commands to add a sessionless virtual server and verify the configuration:

- add lb vserver <name>@ <serviceType> <IPAddress>@ <port> -m <redirectionMode> -sessionless <(ENABLED | DISABLED)> -lbMethod <load_balancing_method>
- show lb vserver <name>

Example

```
add lb vserver sesslessv1 any 11.11.12.123 54 -sessionless ENABLED -lbMethod roundrobin -m ip
    Done
show lb vserver sesslessv1
    sesslessv1 (11.11.12.123:54) - ANY Type: ADDRESS
    State: DOWN
    ...
    Effective State: DOWN
    Client Idle Timeout: 120 sec
    Down state flush: ENABLED
    ...
    Persistence: NONE
    Sessionless LB: ENABLED
    Connection Failover: DISABLED
    L2Conn: OFF
    1) Policy : cmp_text Priority:8680 Inherited
    2) Policy : cmp_nocmp_ie60 Priority:8690 Inherited
```

To configure sessionless load balancing on an existing virtual server

At the command prompt, type:

set lb vserver <name>@ -m <redirectionMode> -sessionless <(ENABLED | DISABLED)> -lbMethod <load_balancing_method>

```
set lb vserver sesslessv1 -m mac -sessionless ENABLED -lbmethod lrtm
  Done
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, do one of the following:
   - To add a sessionless virtual server, click Add.
   - To specify sessionless load balancing for an existing virtual server, select it, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, specify values for the following parameters:
   - Service Name*-serviceName
   - Protocol*-serviceType
   - Server*-serverName
   - Port*-port

   *A required parameter
4. In the Configure Virtual Server (Load Balancing) dialog box, on the Methods and Persistence tab, in the LB Method group, select a supported load balancing method.
5. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, under Redirection Mode, select MAC Based or IP Based.
6. Select Sessionless.
7. Click Create or click OK.
8. In the details pane, click the arrow next to the name of the virtual server and verify the configuration.

Redirecting HTTP Requests to a Cache

Nov 11, 2013

The NetScaler cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the impact of responding to HTTP requests and improve your Web site performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the NetScaler appliance sends cacheable HTTP requests to the cache, and non-cacheable HTTP requests to the origin Web server.

At the command prompt, type:

set lb vserver <name>@ -cacheable <Value>

Example

```
set lb vserver Vserver-LB-1 -cacheable yes
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure cache redirection, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. Select the Cache Redirection check box, and then click OK.

Directing Requests According to Priority

Nov 11, 2013

The NetScaler appliance supports prioritization of client requests with its priority queuing feature. This feature allows you to designate certain requests, such as those from important clients, as priority requests and sends them to the “front of the line,” so that the appliance responds to them first. This allows you to provide uninterrupted service to those clients through demand surges or DDoS attacks on your Web site.

At the command prompt, type:

set lb vserver <name>@ -pq <Value>

Example

set lb vserver Vserver-LB-1 -pq yes

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure priority queuing, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. Select the PQ check box, and then click OK.

Note: You must configure priority queuing globally for it to function correctly.

Directing Requests to a Custom Web Page

Nov 11, 2013

The NetScaler appliance provides the SureConnect option to ensure that web applications respond despite delays caused by limited server capacity or processing speed. SureConnect does this by displaying an alternative web page of your choice when the server that hosts the primary web page is either unavailable or responding slowly.

To configure SureConnect on a virtual server, you must first configure the alternative content. For information about configuring a SureConnect website, see SureConnect. After you configure the website, enable SureConnect on the load balancing virtual server to put your SureConnect custom web page in use.

Note: For SureConnect to function correctly, you must configure it globally.

At the command prompt, type:

set lb vserver <name>@ -sc <Value>

Example

set lb vserver Vserver-LB-1 -sc yes

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure SureConnect, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. Select the SC check box, and then click OK.

Enabling Cleanup of Virtual Server Connections

Nov 11, 2013

Under certain conditions, you can configure the downStateFlush setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes and health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN.

A virtual server is marked DOWN only when all services bound to it are marked DOWN. When a virtual server goes DOWN, it terminates all connections, either immediately or after allowing existing connections to complete.

You must not enable the downStateFlush setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, Vserver-LB-1, with two services bound to it, Service-TCP-1 and Service-TCP-2. The virtual server intercepts two connections, C1 and C2, and redirects them to Service-TCP-1 and Service-TCP-2, respectively. In the table, E and D denote the state of the downStateFlush setting: E means Enabled, and D means Disabled.

Vserver-LB-1	Service-TCP-1	State of connections
E	E	Both client and server connections are terminated.
E	D	Both client and server connections are terminated. In case of HTTP services, both client and server connections are terminated only if the transaction is active. If the transaction is not active, only client connections are terminated.
D	E	Both client and server connections are terminated. In case of HTTP services, both client and server connections are terminated only if the transaction is active. If the transaction is not active, only server connections are terminated.
D	D	Neither client nor server connections are terminated.

Note: In case of HTTP services, the downStateFlush setting is effective only when the client is connected to the server. If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown of a service, see Graceful Shutdown of Services.

To configure the down state flush setting on a virtual server by using the command line interface

At the command prompt, type:

set lb vserver <name>@ -downStateFlush <Value>

Example

set lb vserver Vserver-LB-1 -downStateFlush enabled

To configure the down state flush setting on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure down state flush, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. Select the Down state flush check box, and then click OK.

Graceful Shut down of Services

Nov 03, 2016

During scheduled network outages such as system upgrades or hardware maintenance, you may have to close or disable some services. To avoid disrupting sessions that have already been established, you can specify a wait time, which places a service in the transition out of service (TROFS) state until the specified wait time expires. The service then enters the out of service (OFS) state.

Often, however, you cannot estimate the amount of time needed for all the connections to a service to complete the existing transactions. If a transaction is unfinished when the wait time expires, shutting down the service may result in data loss. In this case, you can specify graceful shutdown for the service, so that the service is disabled only when all the current active client connections are closed by either the server or the client. See the following table for behavior if you specify a wait time in addition to graceful shutdown.
Persistence is maintained according to the specified method even if you enable graceful shutdown. The system continues to serve all the persistent clients, including new connections from the clients, unless the service is marked DOWN during the graceful shutdown state as a result of the checks made by a monitor.

The following table describes graceful shut down options.

Table 1. Graceful Shut down Options

State	Results
Graceful shutdown is enabled and a wait time is specified.	Service is shut down after the last of the current active client connections is served, even if the wait time has not expired. The appliance checks the status of the connections once every second. If the wait time expires, any open sessions are closed.
Graceful shutdown is disabled and a wait time is specified.	Service is shut down only after the wait time expires, even if all established connections are served before expiration.
Graceful shutdown is enabled and no wait time is specified.	Service is shut down only after the last of the previously established connections is served, regardless of the time taken to serve the last connection.
Graceful shutdown is disabled and no wait time is specified.	No graceful shutdown. Service is shut down immediately after the disable option is chosen or the disable command is issued. (The default wait time is zero seconds.)

To terminate existing connections when a service or a virtual server is marked DOWN, you can use the Down State Flush option. For more information, see Enabling Cleanup of Virtual Server Connections.

To configure graceful shutdown for a service by using the command line interface

At the command prompt, type the following commands to shut down a service gracefully and verify the configuration:

- disable service <name>@ [<delay>] [-graceFul (YES | NO)]
- show service <name>

Example

```
> disable service svc1 6000 -graceFul YES
Done
>show service svc1
svc1 (10.102.80.41:80) - HTTP
State: GOING OUT OF SERVICE (Graceful, Out Of Service in 5998 seconds)
Last state change was at Mon Nov 15 22:44:15 2010
Time since last state change: 0 days, 00:00:01.160
...
Down state flush: ENABLED

1 bound monitor:
1) Monitor Name: tcp-default
State: UP           Weight: 1
Probes: 13898    Failed [Total: 0 Current: 0]
Last response: Probe skipped - live traffic to service.
Response Time: N/A
Done

>show service svc1
svc1 (10.102.80.41:80) - HTTP
State: OUT OF SERVICE
Last state change was at Mon Nov 15 22:44:19 2010
Time since last state change: 0 days, 00:00:03.250
Down state flush: ENABLED

1 bound monitor:
1)  Monitor Name: tcp-default
State: UNKNOWN          Weight: 1
Probes: 13898    Failed [Total: 0 Current: 0]
Last response: Probe skipped - service state OFS.
Response Time: N/A
Done
```

To configure graceful shutdown for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service, and then click Disable.
3. To delay disabling the service, in the Wait Time dialog box, type the wait time after which the service is to be disabled.
4. To disable the service only after all previously initiated transactions have been completed, check the Graceful Shutdown check box.
5. Click Enter.
6. In the Services pane, you can verify that the service is marked as UP until the wait time expires and after that, it is marked as OUT OF SERVICE.

Rewriting Ports and Protocols for HTTP Redirection

Nov 11, 2013

Virtual servers and the services that are bound to them may use different ports. When a service responds to an HTTP connection with a redirect, you might need to configure the NetScaler appliance to modify the port and the protocol to make sure that the redirection goes through successfully. You do this by enabling and configuring the redirectPortRewrite setting.

This setting affects only HTTP and HTTPS traffic. If this setting is enabled on a virtual server, the virtual server rewrites the port on redirects, replacing the port used by the service with the port used by the virtual server.

If the virtual server or service is of type SSL, you must enable SSL redirect on the virtual server or service. If both the virtual server and service are of type SSL, enable SSL redirect on the virtual server.

The redirectPortRewrite setting can be used in the following scenarios:

- The virtual server is of type HTTP and the services are of type SSL.
- The virtual server is of type SSL and the services are of type HTTP.
- The virtual server is of type HTTP and the services are of type HTTP.
- The virtual server is of type SSL and the services are of type SSL.

Scenario 1: The virtual server is of type HTTP and services are of type SSL. SSL redirect, and optionally port rewrite, is enabled on the service. If port rewrite is enabled, the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

Redirect URL from the Server	**Redirect URL sent to the Client**
Only SSL redirect is enabled. The virtual server can be configured on any port.	
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/
SSL redirect and port rewrite are enabled. The virtual server is configured on port 80.	
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/

Redirect URL from the Server https://domain.com:444/	Redirect URL sent to the Client https://domain.com/
SSL redirect and port rewrite are enabled. Virtual server is configured on port 8080.	
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	http://domain.com:8080/
https://domain.com:444/	http://domain.com:8080/

Scenario 2: The virtual server is of type SSL and services are of type HTTP. If port rewrite is enabled, only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

Redirect URL from the Server	Redirect URL sent to the Client
SSL redirect is enabled on the virtual server. The virtual server can be configured on any port.	
http://domain.com/	https://domain.com/
http://domain.com:8080/	https://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/
SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443.	
http://domain.com/	https://domain.com/
http://domain.com:8080/	https://domain.com/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/
SSL redirect and port rewrite are enabled. The virtual server is configured on port 444.	

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	https://domain.com:444/
http://domain.com:8080/	https://domain.com:444/
https://domain.com/	https://domain.com/
https://domain.com:445/	https://domain.com:445/

Scenario 3: The virtual server and service are of type HTTP. Port rewrite must be enabled on the virtual server. Only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

Redirect URL from the Server	Redirect URL sent to the Client
The virtual server is configured on port 80.	
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/
The virtual server is configured on port 8080.	
http://domain.com/	http://domain.com:8080/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:445/	https://domain.com:445/

Scenario 4: The virtual server and service are of type SSL. If port rewrite is enabled, only the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

Redirect URL from the Server	Redirect URL sent to the Client
SSL redirect is enabled on the virtual server. The virtual server can be configured on any port.	

Redirect URL from the Server http://domain.com/	Redirect URL sent to the Client http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/
SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443.	
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com/
SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 444.	
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com:444/
https://domain.com:445/	https://domain.com:444/

To configure HTTP redirection on a virtual server by using the command line interface

At the command prompt, type:

set lb vserver <name>@ -redirectPortRewrite (ENABLED | DISABLED)

Example

set lb vserver Vserver-LB-1 -redirectPortRewrite enabled

To configure HTTP redirection on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure HTTP redirection, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. Select the Redirect Port Rewrite check box, and then click OK.

To configure SSL Redirect on an SSL virtual server or service by using the command line interface

At the command prompt, type:

- set ssl vserver <vServerName> - sslRedirect (ENABLED | DISABLED)
- set ssl service <serviceName> - sslRedirect (ENABLED | DISABLED)

Example

```
set ssl vserver Vserver-SSL-1 -sslRedirect enabled
set ssl service service-SSL-1 -sslRedirect enabled
```

To configure SSL redirection and SSL port rewrite on an SSL virtual server or service by using the configuration utility

1. Navigate to Traffic Management > SSL Offload > Virtual Servers or Traffic Management > SSL Offload > Services.
2. In the details pane, select the virtual server or service for which you want to configure SSL redirection, and then click Open.
3. In the Configure Virtual Server (SSL Offload) dialog box, click the SSL Settings tab, and then click SSL Parameter.
4. In the Configure SSL Params dialog box, select SSL Redirect. Optionally, select SSL Redirect Port Rewrite.
5. Click OK.
6. In the Configure Virtual Server (SSL Offload) dialog box, click OK.

Inserting the IP Address and Port of a Virtual Server in the Request Header

Nov 11, 2013

If you have multiple virtual servers that communicate with different applications on the same service, you must configure the NetScaler appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, then you must configure the required header tag on both virtual servers.

Note: This option is not supported for wild card virtual servers or dummy virtual servers.

To insert the IP address and port of the virtual server in the client requests by using the command line interface

At the command prompt, type:

set lb vserver <name>@ -insertVserverIPPort <insertVserverIPPort> [<vipHeader>]

Example

set lb vserver Vserver-LB-1 -insertVserverIPPort VipAddr

To insert the IP address and port of the virtual server in the client requests by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to insert the IP address and port, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. In the Vserver IP Port Insertion list, select the VIPADDR or V6TOV4MAPPING, and then type the port header in a text box next to Vserver IP Port Insertion box.
5. Click OK.

Using a Specified Source IP for Backend Communication

Jun 17, 2014

For communication with the physical servers or other peer devices, the NetScaler appliance uses an IP address owned by it as the source IP address. NetScaler maintains a pool of its IP addresses, and dynamically selects an IP address while connecting with a server. Depending on the subnet in which the physical server is placed, NetScaler decides which IP address to use. This address pool is used for sending traffic as well as monitor probes.

In many situations, you may want the NetScaler to use a specific IP address or any IP address from a specific set of IP addresses for backend communications. The following are a few examples:

- A server can distinguish monitor probes from traffic if the source IP address used for monitor probes belongs to a specific set.
- To improve server security, a server may be configured to respond to requests from a specific set of IP addresses or, sometimes, from a single specific IP address. In such a case, the NetScaler can use only the IP addresses accepted by the server as the source IP address.
- The NetScaler can manage its internal connections efficiently if it can distribute its IP addresses into IP sets and use an address from a set only for connecting to a specific service.

To configure the NetScaler to use a specified source IP address, create net profiles (network profiles) and configure the NetScaler entities to use the profile. A net profile can be bound to load balancing or content switching virtual servers, services, service groups, or monitors. A net profile has NetScaler owned IP addresses (SNIPs) that can be used as the source IP address. It can be a single IP address or a set of IP addresses, referred to as an IP set. If a net profile has an IP set, NetScaler dynamically selects an IP address from the IP set at the time of connection. If a profile has a single IP address, the same IP address is used as the source IP.

If a net profile is bound to a load balancing or content switching virtual server, the profile will be used for sending traffic to all the services bound to it. If a net profile is bound to a service group, NetScaler uses the profile for all the members of the service group. If a net profile is bound to a monitor, NetScaler uses the profile for all the probes sent from the monitor.

Usage of a net profile for sending traffic:

If the Use Source IP Address (USIP) option is enabled, NetScaler uses the IP address of the client and ignores all the net profiles. If the USIP option is not enabled, NetScaler selects the source IP in the following manner:

- If there is no net profile on the virtual server or the service/service group, NetScaler uses the default method.
- If there is a net profile only on the service/service group, NetScaler uses that net profile.
- If there is a net profile only on the virtual server, NetScaler uses the net profile.
- If there is a net profile both on the virtual server and service/service group, NetScaler uses the net profile bound to the service/service group.

Usage of a net profile for sending monitor probes:

For monitor probes, NetScaler selects the source IP in the following manner:

- If there is a net profile bound to the monitor, NetScaler uses the net profile of the monitor. It ignores the net profiles bound to the virtual server or service/service group.
- If there is no net profile bound to the monitor,

- If there is a net profile on the service/service group, NetScaler uses the net profile of the service/service group.
- If there is no net profile even on the service/service group, NetScaler uses the default method of selecting a source IP.

Note: If there is no net profile bound to a service, NetScaler looks for a net profile on the service group if the service is bound to a service group.
To use a specified source IP address for communication, go through the following steps:

1. Create IP sets from the pool of SNIPs owned by the NetScaler. An IP set can consist of both SNIP addresses. For instructions, see Creating IP Sets.
2. Create net profiles. For instructions, see Creating a Net Profile.
3. Bind the net profiles to NetScaler entities. For instructions, see Binding a Net Profile to a NetScaler Entity.

Note: A net profile can have only the IP addresses specified as SNIP on the NetScaler.

Managing Net Profiles

A net profile (or network profile) contains an IP address or an IP set. During communication with physical servers or peers, the NetScaler appliance uses the addresses specified in the profile as the source IP address. For more information on the use of net profiles, see Using a User-specified Source IP Address for Backend Communication.

- For instructions on creating a network profile, see Creating a Network Profile.
- For instructions on binding a network profile to a NetScaler entity, see Binding a Network Profile.

Creating an IP Set

Updated: 2014-06-17

An IP set is a set of IP addresses, which are configured on the NetScaler appliance as Subnet IP addresses (SNIPs) . An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it. To create an IP set, add an IP set and bind NetScaler owned IP addresses to it. SNIP addresses can be present in the same IP set. For more information about the use of IP sets, see Using a User-specified Source IP Address for Backend Communication.

To create an IP set by using the command line interface

At the command prompt, type the following commands:

- add ipset <name>
- bind ipset <name> <IPAddress>@
  or
- bind ipset <name> <IPAddress>@
- show ipset [<name>]
  The above command shows the names of all the IP sets on the NetScaler if you do not pass any name. It shows the IP addresses bound to the specified IP set if you pass a name.

Examples

1.

```
> add ipset skpnwipset
 Done
> bind ipset skpnwipset 21.21.20.1
 Done
```

2.

```
 > add ipset testnwipset
 Done
> bind ipset testnwipset 21.21.21.[21-25]
 IPAddress "21.21.21.21" bound
 IPAddress "21.21.21.22" bound
 IPAddress "21.21.21.23" bound
 IPAddress "21.21.21.24" bound
 IPAddress "21.21.21.25" bound
 Done
```

3.

```
 > bind ipset skpipset 11.11.11.101
 ERROR: Invalid IP address
[This IP address could not be added because this is not an IP address owned by the NetScaler]
 > add ns ip 11.11.11.101 255.255.255.0 -type SNIP
 ip "11.11.11.101" added
 Done
 > bind ipset skpipset 11.11.11.101
 IPAddress "11.11.11.101" bound
 Done
```

4.

```
> sh ipset
1) Name: ipset-1
2) Name: ipset-2
3) Name: ipset-3
4) Name: skpnewipset
 Done
```

5.

```
> sh ipset skpnewipset
IP:21.21.21.21
IP:21.21.21.22
IP:21.21.21.23
IP:21.21.21.24
IP:21.21.21.25
 Done
```

To create an IP set by using the configuration utility

1. Navigate to System > Network > IP Sets.
2. In the details pane, do one of the following:
   - To create a new IP set, click Add.
   - To modify an existing IP set, select the IP set, and then click Open.
3. In the Create IP Set dialog box, set the following parameters:
   - Name
   - IP Address (The SNIPs specified on the NetScaler are displayed. Check the IP addresses that you want to bind to the IP set. You can select more than one.)

If you want to add an IP address to the pool, do one of the following:

- To add an IPv4 address, click Add IPv4, and then in the Create IP dialog box, type the necessary details.
- To add an IPv6 address, click Add IPv6, and then in the Create IPV6 dialog box, type the necessary details.

4. Click Create.

Creating a Net Profile

Updated: 2014-06-17

A net profile (network profile) consists of one or more SNIP addresses of the NetScaler. For more information about the usage of net profiles, see Using a User-specified Source IP Address for Backend Communication.

To create a net profile by using the command line interface

At the command prompt, type:

add netprofile <name> [-srcIp <srcIpVal>] If the srcIpVal is not provided in this command, it can be provided later by using the set netprofile command.
Examples

```
> add netprofile skpnetprofile1 -srcIp 21.21.20.1
Done

> add netprofile baksnp -srcIp bakipset
Done

> set netprofile yahnp -srcIp 12.12.23.1
Done

> set netprofile citkbnp -srcIp citkbipset
Done
```

Binding a Net Profile to a NetScaler Entity

Updated: 2013-11-12

A net profile can be bound to a load balancing virtual server, service, service group, or a monitor. For more information about the effect of binding a net profile to a NetScaler entity, see Using a User-specified Source IP Address for Backend Communication.
Note: You can bind a net profile at the time of creating a NetScaler entity or bind it to an already existing entity.

To bind a net profile to a server by using the command line interface

You can bind a net profile to load balancing virtual servers and content switching virtual servers. Specify the appropriate virtual server.

At the command prompt, type:

- set lb vserver <name>@ -netProfile <net_profile_name>
  or
- set cs vserver <name> -netProfile <net_profile_name>

Examples

```
set lb vserver skpnwvs1 -netProfile gntnp
 Done
set cs vserver mmdcsv -netProfile mmdnp
 Done
```

To bind a net profile to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers or Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server to which you want to bind a net profile, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, or Configure Virtual Server (Content Switching) click the Profiles tab.
4. In the Net Profile drop-down list, select a net profile. In this dialog box, you can click New... to add a net profile or Modify... to modify the selected net profile.
5. Click OK.

To bind a net profile to a service by using the command line interface

At the command prompt, type:

set service <name>@ -netProfile <net_profile_name>
Example

```
set service brnssvc1 -netProfile brnsnp
 Done
```

To bind a net profile to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service to which you want to bind a net profile, and then click Open.
3. In the Configure Service dialog box, click the Profiles tab.
4. In the Net Profile drop-down list, select a net profile. In this dialog box, you can click New... to add a net profile or Modify... to modify the selected net profile.
5. Click OK.

To bind a net profile to a service group by using the command line interface

At the command prompt, type:

set servicegroup <serviceGroupName>@ -netProfile <net_profile_name>
Example

```
set servicegroup ndhsvcgrp -netProfile ndhnp
 Done
```

To bind a net profile to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the details pane, select the service group to which you want to bind a net profile, and then click Open.
3. In the Configure Service Group dialog box, click the Profiles tab.
4. In the Net Profile drop-down list, select a net profile. In this dialog box, you can click New... to add a net profile or

Modify... to modify the selected net profile.

5. Click OK.

To bind a net profile to a monitor by using the command line interface

At the command prompt, type:

set monitor <monitor_name> -netProfile <net_profile_name>
Example

```
set monitor brnsecvmon1 -netProfile brnsmonnp
 Done
```

To bind a net profile to a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, select the monitor to which you want to bind a net profile, and then click Open.
3. In the Configure Monitor dialog box, in the Net Profile drop-down list, select a net profile.
4. Click OK.

Setting a Timeout Value for Idle Client Connections

Nov 11, 2013

You can configure a virtual server to terminate any idle client connections after a configured timeout period elapses. When you configure this setting, the NetScaler appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection.

To set a time-out value for idle client connections by using the command line interface

At the command prompt, type:

set lb vserver <name>@ -cltTimeout <Value>

Example

set lb vserver Vserver-LB-1 -cltTimeout 100

To set a time-out value for idle client connections by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure a time-out value, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. In the Client Time-out (secs) text box, type the timeout value (for example, 100).
5. Click OK.

Managing RTSP Connections

Nov 11, 2013

The NetScaler appliance can use either of two topologies—NAT-on mode or NAT-off mode—to load balance RTSP servers. In NAT-on mode, Network Address Translation (NAT) is enabled and configured on the appliance. RTSP requests and responses both pass through the appliance. You must therefore configure the appliance to perform network address translation (NAT) to identify the data connection.

For more information about enabling and configuring NAT, see "IP Addressing."

In NAT-off mode, NAT is not enabled and configured. The appliance receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. The load balanced RTSP servers send their responses directly to the client, bypassing the appliance. You must therefore configure the appliance to use Direct Server Return (DSR) mode, and assign publicly accessible FQDNs in DNS to your load balanced RTSP servers.

For more information about enabling and configuring DSR mode, see "Configuring Load Balancing in Direct Server Return Mode." For more information about configuring DNS, see "Domain Name System."

In either case, when you configure RTSP load balancing, you must also configure rtspNat to match the topology of your load balancing setup.

To configure RTSP NAT by using the command line interface

At the command prompt, type:

set lb vserver <name>@–RTSPNAT <ValueOfRTSPNAT>

Example

set lb vserver vserver-LB-1 –RTSPNAT ON

To configure RTSP NAT by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure RTSP NAT, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. Select the RTSP Natting check box, and then click OK.

Managing Client Traffic on the Basis of Traffic Rate

Jun 03, 2015

You can monitor the rate of traffic that flows through load balancing virtual servers and control the behavior of the NetScaler appliance based on the traffic rate. You can throttle the traffic flow if it is too high, cache information based on the traffic rate, and if the traffic rate is too high redirect excess traffic to a different load balancing virtual server. You can apply rate-based monitoring to HTTP and Domain Name System (DNS) requests.

For more information on rate-based policies, see Rate Limiting.

Identifying a connection with Layer 2 Parameters

Nov 12, 2013

Generally, to identify a connection, the NetScaler uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.

Enabling the L2Conn parameter for a load balancing virtual server allows multiple TCP and non-TCP connections with the same 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) to co-exist on the NetScaler appliance. The appliance uses both the 4-tuple and the Layer 2 parameters to identify TCP and non-TCP connections.

You can enable the L2Conn option in the following scenarios:

- Multiple VLANs are configured on the NetScaler appliance, and a firewall is set up for each VLAN.
- You want the traffic originating from the servers in one VLAN and bound for a virtual server in another VLAN to pass through the firewalls configured for both VLANs.

Therefore, when an nCore NetScaler appliance on which the l2Conn parameter is set for one or more load balancing virtual servers is downgraded to a Classic build or to an nCore build that does not support the l2Conn parameter, the load balancing configurations that use the l2Conn parameter become ineffective.

To configure the L2 connection option by using the command line interface

At the command prompt, type:

add lb vserver <name>@ <serviceType> <IPAddress>@ <port> -l2Conn ON

Example

```
add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -l2Conn ON
```

To configure the L2 connection option by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click **Add**.
3. In the CreateVirtual Server (Load Balancing) dialog box, specify values.: *A required parameter
4. On the Advanced tab, selectL2 Connection.
5. Click Create.
6. Open the virtual server you configured and verify the configuration.

Configuring the Prefer Direct Route Option

Aug 29, 2013

On a wildcard load balancing virtual server if you explicitly configure a route to a destination, by default, the NetScaler appliance forwards traffic according to the configured route. If you want the NetScaler to not look up for the configured route, you can set the Prefer Direct Route option to NO.

If a device is directly connected to a NetScaler appliance, the NetScaler directly forwards traffic to the device. For example, if the destination of a packet is a firewall, the packet need not be routed through another firewall. However, in some cases, you may want the traffic to go through the firewall even if the device is directly connected to it. In such cases, you can set the Prefer Direct Route Option to NO.

Note: The preferDirectRoute setting is applicable to all the wildcard virtual servers on the NetScaler appliance.

To set the prefer direct route option by using the command line interface

At the command prompt, type:

set lb parameter -preferDirectRoute (YES | NO)

Example

set lb parameter -preferDirectRoute YES

To set the prefer direct route option by using the configuration utility

1. Navigate to Traffic Management > Load Balancing.
2. Under Settings, click Configure Load Balancing Parameters.
3. In the Configure Load Balancing Parameters dialog box, select the Prefer Direct Route check box.
4. Click OK.

Advanced Load Balancing Settings

Jun 03, 2015

In addition to configuring virtual servers, you can configure advanced settings for services.

To configure advanced load balancing settings, see the following sections:

- Gradually Stepping Up the Load on a New Service with Virtual Server–Level Slow Start
- The No-Monitor Option for Services
- Protecting Applications on Protected Servers Against Traffic Surges
- Enabling Cleanup of Service Connections
- Directing Requests to a Custom Web Page
- Enabling Access to Services When Down
- Enabling TCP Buffering of Responses
- Enabling Compression
- Maintaining Client Connection for Multiple Client Requests
- Inserting the IP Address of the Client in the Request Header
- Using the Source IP Address of the Client When Connecting to the Server
- Configuring the Source Port for Server-Side Connections
- Setting a Limit on the Number of Client Connections
- Setting a Limit on Number of Requests Per Connection to the Server
- Setting a Threshold Value for the Monitors Bound to a Service
- Setting a Timeout Value for Idle Client Connections
- Setting a Timeout Value for Idle Server Connections
- Setting a Limit on the Bandwidth Usage by Clients
- Redirecting Client Requests to a Cache
- Retaining the VLAN Identifier for VLAN Transparency
- Configuring Automatic State Transition Based on Percentage Health of Bound Services

Gradually Stepping Up the Load on a New Service with Virtual Server–Level Slow Start

Mar 16, 2012

You can configure the NetScaler appliance to gradually increase the load on a service (the number of requests that the service receives per second) immediately after the service is either added to a load balancing configuration or has a state change from DOWN to UP (hereafter, the term "new service" is used for both situations). You can either increase the load manually with load values and intervals of your choice (manual slow start) or configure the appliance to increase the load at a specified interval (automated slow start) until the service is receiving as many requests as the other services in the configuration. During the ramp-up period for the new service, the appliance uses the configured load balancing method.

This functionality is not available globally. It has to be configured for each virtual server. The functionality is available only for virtual servers that use one of the following load balancing methods:

- Round robin
- Least connection
- Least response time
- Least bandwidth
- Least packets
- LRTM (Least Response Time Method)
- Custom load

For this functionality, you need to set the following parameters:

- The new service request rate, which is the amount by which to increase the number or percentage of requests sent to a new service each time the rate is incremented. That is, you specify the size of the increment in terms of either the number of requests per second or the percentage of the load being borne, at the time, by the existing services. If this value is set to 0 (zero), slow start is not performed on new services.
  Note: In automated slow start mode, the final increment is smaller than the specified value if the specified value would place a heavier load on the new service than on the other services.
- The increment interval, in seconds. If this value is set to 0 (zero), the load is not incremented automatically. You have to increment it manually.

With automated slow start, a service is taken out of the slow start phase when one of the following conditions applies:

- The actual request rate is less than the new service request rate.
- The service does not receive traffic for three successive increment intervals.
- The request rate has been incremented 200 times.
- The percentage of traffic that the new service must receive is greater than or equal to 100.

With manual slow start, the service remains in the slow start phase until you take it out of that phase.

Manual Slow Start

If you want to manually increase the load on a new service, do not specify an increment interval for the load balancing virtual server. Specify only the new service request rate and the units. With no interval specified, the appliance does not increment the load periodically. It maintains the load on the new service at the value specified by the combination of the new service request rate and units until you manually modify either parameter. For example, if you set the new service request rate and unit parameters to 25 and "per second," respectively, the appliance maintains the load on the new service at 25 requests per second until you change either parameter. When you want the new service to exit the slow start mode

and receive as many requests as the existing services, set the new service request rate parameter to 0.

As an example, assume that you are using a virtual server to load balance 2 services, Service1 and Service2, in round robin mode. Further assume that the virtual server is receiving 240 requests per second, and that it is distributing the load evenly across the services. When a new service, Service3, is added to the configuration, you might want to increase the load on it manually through values of 10, 20, and 40 requests per second before sending it its full share of the load. The following table shows the values to which you set the three parameters.

Table 1. Parameter Values

Parameter	Value
Interval in seconds	0
New service request rate	10, 20, 40, and 0, at intervals that you choose
Units for the new service request rate	Requests per second

When you set the new service request rate parameter to 0, Service3 is no longer considered a new service, and receives its full share of the load.

Assume that you add another service, Service4, during the ramp-up period for Service3. In this example, Service4 is added when the new service request rate parameter is set to 40. Therefore, Service4 begins receiving 40 requests per second.

The following table shows the load distribution on the services during the period described in this example.

Table 2. Load Distribution on Services when Manually Stepping Up the Load

	new service request rate = 10 req/sec (Service3added)	new service request rate = 20 req/sec	new service request rate = 40 req/sec (Service4added)	new service request rate = 0 req/sec (new services exit slow start mode)
Service1	115	110	80	60
Service2	115	110	80	60
Service3	10	20	40	60
Service4	-	-	40	60
Total req/sec (load	240	240	240	240

on the virtual server)	new service request rate = 10 req/sec	new service request rate = 20 req/sec	new service request rate = 40 req/sec	new service request rate = 0 req/sec
	(Service3added)		(Service4added)	(new services exit slow start mode)

Automated Slow Start

If you want the appliance to increase the load on a new service automatically at specified intervals until the service can be considered capable of handling its full share of the load, set the new service request rate parameter, the units parameter, and the increment interval. When all the parameters are set to values other than 0, the appliance increments the load on a new service by the value of the new service request rate, at the specified interval, until the service is receiving it's full share of the load.

As an example, assume that four services, Service1, Service2, Service3, and Service4, are bound to a load balancing virtual server, vserver1. Further assume that vserver1 receives 100 requests per second, and that it distributes the load evenly across the services (25 requests per second per service). When you add a fifth service, Service5, to the configuration, you might want the appliance to send the new service 4 requests per second for the first 10 seconds, 8 requests per second for the next 10 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters:

Table 3. Parameter Values

Parameter	Value
Interval in seconds	10
Increment value	4
Units for the new service request rate	Requests per second

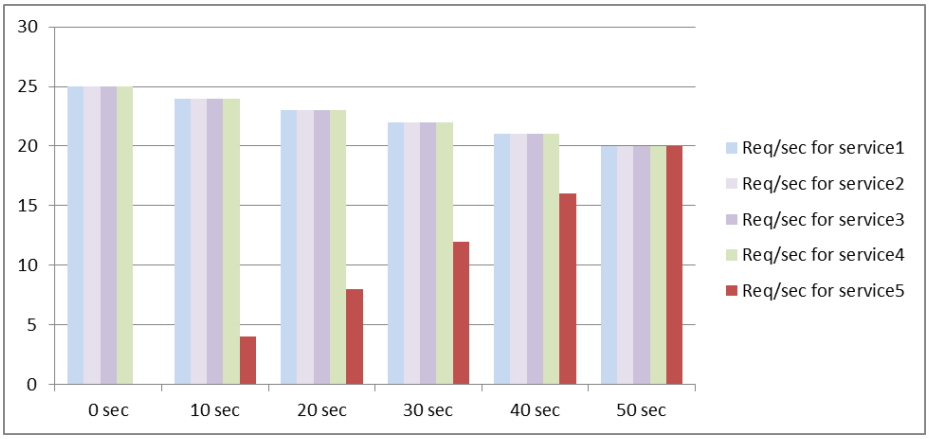
With this configuration, the new service begins receiving as many requests as the existing services 50 seconds after it is added or its state has changed from DOWN to UP. During each interval in this period, the appliance distributes to the existing servers the excess of requests that would have been sent to the new service in the absence of stepwise increments. For example, in the absence of stepwise increments, each service, including Service5, would have received 20 requests each per second. With stepwise increments, during the first 10 seconds, when Service5 receives only 4 requests per second, the appliance distributes the excess of 16 requests per second to the existing services, resulting in the distribution pattern shown in the following table and figure over the 50-second period. After the 50-second period, Service5 is no longer considered a new service, and it receives its normal share of traffic.

Table 4. Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added

	0 sec	10 sec	20 sec	30 sec	40 sec	50 sec
Req/sec forService1	25	24	23	22	21	20
Req/sec forService2	25	24	23	22	21	20
Req/sec forService3	25	24	23	22	21	20

	0 sec	10 sec	20 sec	30 sec	40 sec	50 sec
Req/sec forService4	25	24	23	22	21	20
Req/sec forService5	0	4	8	12	16	20
Total req/sec (load on the virtual server)	100	100	100	100	100	100

Figure 1. A Graph of the Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added



An alternative requirement might be for the appliance to send Service5 25% of the load on the existing services in the first 5 seconds, 50% in the next 5 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters.

Table 5. Parameter Values

Parameter	Value
Interval in seconds	5
Increment value	25
Units for the new service request rate	Percent

With this configuration, the service begins receiving as many requests as the existing services 20 seconds after it is added or its state has changed from DOWN to UP. The traffic distribution during the ramp-up period for the new service is identical to the one described earlier, where the unit for the step increments was “requests per second.”

Setting the Slow Start Parameters

Updated: 2013-12-04

You set the slow start parameters by using either the set lb vserver or the add lb vserver command. The following command is for setting slow start parameters when adding a virtual server.

To configure stepwise load increments for a new service by using the command line interface

At the command prompt, type the following commands to configure stepwise increments in the load for a service and verify the configuration:

- add lb vserver <name> <serviceType> <IPAddress> <port> [-newServiceRequest <positive_integer>] [<newServiceRequestUnit>] [-newServiceRequestIncrementInterval <positive_integer>]
- show lb vserver <name>

Example

```
> set lb vserver BR_LB -newServiceRequest 5 PER_SECOND -newServiceRequestIncrementInterval 10
 Done
> show lb vserver BR_LB
 BR_LB (192.0.2.33:80) - HTTP Type: ADDRESS
 State: UP
            ...
            ...
 New Service Startup Request Rate: 5 PER_SECOND, Increment Interval: 10
            ...
            ...
Done
>
```

To configure stepwise load increments for a new service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, do one of the following:
   - To configure stepwise increments for a new load balancing virtual server, click Add.
   - To configure stepwise increments for an existing load balancing virtual server, select the virtual server, and then click Open.
3. In the Create Virtual Server or Configure Virtual Server dialog box, on the Method and Persistence tab, set the following parameters:
   - New Service Startup Request Rate. Also, from the list next to the text box, select the unit (PER_SECOND or PERCENT).
   - Increment Interval.
4. Click Create or OK, and then click Close.

The No-Monitor Option for Services

Nov 11, 2013

If you use an external system to perform health checks on the services and do not want the NetScaler appliance to monitor the health of a service, you can set the no-monitor option for the service. If you do so, the appliance does not send probes to check the health of the service but shows the service as UP. Even if the service goes DOWN, the appliance continues to send traffic from the client to the service as specified by the load balancing method.

The monitor can be in the ENABLED or DISABLED state when you set the no-monitor option, and when you remove the no-monitor option, the earlier state of the monitor is resumed.

You can set the no-monitor option for a service when creating the service. You can also set the no-monitor option on an existing service.

The following are the consequences of setting the no-monitor option:

- If a service for which you enabled the no-monitor option goes down, the NetScaler continues to show the service as UP and continues to forward traffic to the service. A persistent connection to the service can worsen the situation. In that case, or if many services shown as UP are actually DOWN, the system may fail. To avoid such a situation, when the external mechanism that monitors the services reports that a service that is DOWN, remove the service from the NetScaler configuration.
- If you configure the no-monitor option on a service, you cannot configure load balancing in the Direct Server Return (DSR) mode. For an existing service, if you set the no-monitor option, you cannot configure the DSR mode for the service.

To set the no-monitor option for a new service by using the command line interface

At the command prompt, type the following commands to create a service with the health monitor option, and verify the configuration:

add service <serviceName> <IP | serverName> <serviceType> <port> -healthMonitor (YES|NO)

Example

```
 >add service nomonsrvc 10.102.21.21 http 80
 -healthMonitor no
 Done
 > show service nomonsrvc
nomonsrvc (10.102.21.21:80) - HTTP
State: UP
Last state change was at Mon Nov 15 22:41:29 2010
Time since last state change: 0 days, 00:00:00.970
Server Name: 10.102.21.21
 Server ID : 0 Monitor Threshold : 0
...
Access Down Service: NO
...
Down state flush: ENABLED
Health monitoring: OFF
```

1 bound monitor:
1) Monitor Name: tcp-default
State: UNKNOWN Weight: 1
Probes: 3 Failed [Total: 3 Current: 3]
Last response: Probe skipped - Health monitoring is turned off.
Response Time: N/A
Done

To set the no-monitor option for an existing service by using the command line interface

At the command prompt, type the following command to set the health monitor option:

set service <name> -healthMonitor (YES | NO)

Example

By default, the state of a service and the state of the corresponding monitor are UP.
>show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP

1) Monitor Name: http-ecv
State: UP Weight: 1
Probes: 99992 Failed [Total: 0 Current: 0]
Last response: Success - Pattern found in response.
Response Time: 3.76 millisec
Done

When the no-monitor option is set on a service, the state of the monitor changes to UNKNOWN.
> set service LB-SVC1 -healthMonitor NO
Done
> show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP
Last state change was at Fri Dec 10 10:17:37 2010.
Time since last state change: 5 days, 18:55:48.710
Health monitoring: OFF

1) Monitor Name: http-ecv
State: UNKNOWN Weight: 1
Probes: 100028 Failed [Total: 0 Current: 0]
Last response: Probe skipped - Health monitoring is turned off.
Response Time: 0.0 millisec
Done
When the no-monitor option is removed, the earlier state of the monitor is resumed.
> set service LB-SVC1 -healthMonitor YES
Done
>show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP

State: UP
Last state change was at Fri Dec 10 10:17:37 2010
Time since last state change: 5 days, 18:57:47.880
1) Monitor Name: http-ecv
State: UP Weight: 1
Probes: 100029 Failed [Total: 0 Current: 0]
Last response: Success - Pattern found in response.
Response Time: 5.690 millisec
Done

To set the no-monitor option for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, do one of the following:
   - To create a new service, click Add.
   - To modify an existing service, select the service and then click Open.
3. In the Create Service or Configure Service dialog box, specify values for the following parameters:
   - Service Name*–serviceName
   - Protocol*–serviceType
   - Server*–ipAddress
   - Port*–port
   - Health Monitor–healthMonitor

   * A required parameter
4. Click Create. The service you created appears in the Services pane.
5. From the Services pane, open the service that you added, and verify the health monitor setting.

Protecting Applications on Protected Servers Against Traffic Surges

Jun 08, 2015

The NetScaler provides the surge protection option to maintain the capacity of a server or cache. The NetScaler regulates the flow of client requests to servers and controls the number of clients that can simultaneously access the servers. The NetScaler blocks any surges passed to the server, thereby preventing overloading of the server.

For surge protection to function correctly, you must enable it globally. For more information about surge protection, see "Surge Protection."

To set surge protection on the service by using the command line interface

At the command prompt, type:

set service <name>@ -sp <Value>

Example

set service Service-HTTP-1 -sp ON

To set surge protection on the service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure surge protection, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab, scroll down, and under Others, select the Surge Protection check box.
4. Click OK.

Enabling Cleanup of Service Connections

Nov 25, 2013

When cleanup of service connections is enabled, the NetScaler performs a cleanup of the connections on a service that is down. This setting is described in Enabling Cleanup of Virtual Server Connections.

To set down state flush on the service by using the command line interface

At the command prompt, type:

set service <name> -downStateFlush <Value>

Example

```
set service Service-HTTP-1 -downStateFlush enabled
```

To set down state flush on the service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure down state flush, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Scroll down, and under Others, select the Down state flush check box.
5. Click OK.

Directing Requests to a Custom Web Page

Jun 08, 2015

For SureConnect to function correctly, you must set it globally. The NetScaler provides the SureConnect option to ensure the response from an application. For more information about the SureConnect option, see "Sure Connect."

To set SureConnect on the service by using the command line interface

At the command prompt, type:

set service <name>@ -sc <Value>

Example

set service Service-HTTP-1 -sc ON

To set SureConnect on the service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure SureConnect, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Scroll down, and under Others, select the Sure Connect check box.
5. Click OK.

Enabling Access to Services When Down

Jun 08, 2015

You can enable access to a service when it is disabled or in a DOWN state by configuring the NetScaler appliance to use Layer 2 mode to bridge the packets sent to the service. Normally, when requests are forwarded to services that are DOWN, the request packets are dropped. When you enable the Access Down setting, however, these request packets are sent directly to the load balanced servers.

For more information about Layer 2 and Layer 3 modes, see IP Addressing.

For the appliance to bridge packets sent to the DOWN services, enable Layer 2 mode with the accessDown parameter.

To enable access down on a service by using the command line interface

At the command prompt, type:

set service <name>@ -accessDown <Value>

Example

set service Service-HTTP-1 -accessDown YES

To enable access down on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure access down, click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Scroll down, and under Others, select the Access Down check box.
5. Click OK.

Enabling TCP Buffering of Responses

Jun 08, 2015

The NetScaler appliance provides a TCP buffering option that buffers only responses from the load balanced server. This enables the appliance to deliver server responses to the client at the maximum speed that the client can accept them. The appliance allocates from 0 through 4095 megabytes (MB) of memory for TCP buffering, and from 4 through 20480 kilobytes (KB) of memory per connection.

Note: TCP buffering set at the service level takes precedence over the global setting. For more information about configuring TCP buffering globally, see "TCP Buffering."

To enable TCP Buffering on a service by using the command line interface

At the command prompt, type:

set service <name>@ -TCPB <Value>

Example

set service Service-HTTP-1 -TCPB YES

To enable TCP Buffering on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure TCP buffering (for example, Service-HTTP-1), and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Scroll down, and under Settings, select the TCP Buffering check box.
5. Click OK.

Enabling Compression

Jun 08, 2015

The NetScaler appliance provides a compression option to transparently compress HTML and text files by using a set of built-in compression policies. Compression reduces bandwidth requirements and can significantly improve server responsiveness in bandwidth-constrained setups. The compression policies are associated with services bound to the virtual server. The policies determine whether a response can be compressed and send compressible content to the appliance, which compresses it and sends it to the client.

Note: For compression to function correctly, you must enable it globally. For more information about configuring compression globally, see Compression.

To enable compression on a service by using the command line interface

At the command prompt, type:

set service <name> -CMP <YES | NO>

Example

set service Service-HTTP-1 -CMP YES

To enable compression on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure compression (for example, Service-HTTP-1), and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Under Settings, select the Compression check box.
5. Click OK.

Maintaining Client Connection for Multiple Client Requests

Jun 08, 2015

You can set the client keep-alive parameter to configure an HTTP or SSL service to keep a client connection to a Web site open across multiple client requests. If client keep-alive is enabled, even when the load balanced Web server closes a connection, the NetScaler appliance keeps the connection between the client and itself open. This setting allows services to serve multiple client requests on a single client connection.

If you do not enable this setting, the client will open a new connection for every request that it sends to the Web site. The client keep-alive setting saves the packet round trip time required to establish and close connections. This setting also reduces the time to complete each transaction. Client keep-alive can be enabled only on HTTP or SSL service types.

Client keep-alive set at the service level takes precedence over the global client keep-alive setting. For more information about client keep-alive, see Client Keep-Alive.

To enable client keep-alive on a service by using the command line interface

At the command prompt, type:

set service <name>@ -CKA <Value>

Example

set service Service-HTTP-1 -CKA YES

To enable client keep-alive on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure client keep-alive, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Under Settings, select the Client Keep-Alive check box.
5. Click OK.

Inserting the IP Address of the Client in the Request Header

Nov 11, 2013

A NetScaler uses the mapped IP address (MIP) to connect to the server. The server need not be aware of the client.

However, in some situations, the server needs to be aware of the client it has to serve. When you enable the client IP setting, the NetScaler inserts the client's IPv4 or IPv6 address while forwarding the requests to the server. The server inserts this client IP in the header of the responses. The server is thus aware of the client.

At the command prompt, type:

set service <name>@ -CIP <Value> <cipHeader>

Example

```
set service Service-HTTP-1 -CIP enabled X-forwarded-for
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to add the client IP address in the request, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Under Settings, select the Client IP check box.
5. In the Header text box, type the header tag (for example, X-Forwarded-for).
6. Click OK.

Using the Source IP Address of the Client When Connecting to the Server

Jun 08, 2015

You can configure the NetScaler appliance to forward packets from the client to the server without changing the source IP address. This is useful when you cannot insert the client IP address into a header, such as when working with non-HTTP services.

For more information about configuring USIP globally, see "Enabling Use Source IP Mode."

For information about using the port of the client when connecting to the server, see Using the Client Port When Connecting to the Server.

At the command prompt, type:

set service <name>@ -usip (**YES** | **NO**)

Example

```
set service Service-HTTP-1 -usip YES
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to enable the USIP mode, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Under Settings, select the Use Source IP check box.
5. Click OK.

Configuring the Source Port for Server-Side Connections

Jun 08, 2015

When the NetScaler appliance connects to a physical server, it can use the source port from client's request, or it can use a proxy port as the source port for the connection. You can set the Use Proxy Port parameter to YES to handle situations such as the following scenario:

- The NetScaler appliance is configured with two load balancing virtual servers, LBVS1 and LBVS2.
- Both the virtual servers are bound to the same service, S-ANY.
- Use (the client's) source IP address (USIP) is enabled on the service.
- Client C1 sends two requests, Req1 and Req2, for the same service.
- Req1 is received by LBVS1 and Req2 is received by LBVS2.
- LBVS1 and LBVS2 forward the request to S-ANY, and when S-ANY sends the response, they forward the response to the client.
- Consider two cases:
  - Use the client port. When the NetScaler uses the client port, both the virtual servers use the client's IP address (because USIP is ON) and the client's port when connecting to the server. Therefore, when the service sends the response, the NetScaler cannot determine which virtual server should receive the response.
  - Use proxy port. When the NetScaler uses a proxy port, the virtual servers use the client's IP address (because USIP is ON), but different ports when connecting to the server. Therefore, when the service sends the response, the port number identifies the virtual server that should receive the response.

However, if you require a fully transparent configuration, such as a fully transparent cache redirection configuration, you must disable the Use Proxy port Setting so that the NetScaler appliance can use the source port from the client's request.

The Use Proxy Port option becomes relevant if the use source IP (USIP) option is enabled. For TCP-based service types, such as TCP, HTTP, and SSL, the option is enabled by default. For UDP-based service types, such as UDP and DNS, including ANY, the option is disabled by default. For more information about the USIP option, see "Enabling Use Source IP Mode."

You can configure the Use Proxy Port setting either globally or on a given service.

Updated: 2013-11-11

You configure the Use ProxyPort settingon the service if you want to override the global setting.

To configure the Use Proxy Port setting on a service by using the command line interface

At the command prompt, type:

set service <name>@ -useProxyPort (YES | NO)

Example

```
> set service svc1 -useproxyport YES
 Done > show service svc1
```

```
svc1 (10.102.29.30:80) - HTTP
State: UP
. . .
Use Source IP: YES  Use Proxy Port: YES
. . .
Done
>
```

To configure the Use Proxy Port setting on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to use the source IP address, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Under Others, in the Use Proxy Port drop-down list, select YES.
5. Click OK.

Updated: 2013-09-13

You configure the Use Proxy Port setting globally if you want to apply the setting to all the services on the NetScaler appliance. The global setting is overridden by service-specific Use Proxy Port settings.

To configure the Use Proxy Port setting globally by using the command line interface

At the command prompt, type the following commands to configure the Use Proxy Port setting globally and verify the configuration:

- set ns param -useproxyport (ENABLED | DISABLED)
- show ns param

```
> set ns param -useproxyport ENABLED
Done
> show ns param
Global configuration settings:
          . . .
          Use Proxy Port: ENABLED
Done
>
```

To configure the Use Proxy Port setting globally by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Settings, click Change global system settings.
3. In the Set the Global Settings Parameters dialog box, select or clear the Use Proxy Port check box.
4. Click OK.

Setting a Limit on the Number of Client Connections

Nov 11, 2013

You can specify a maximum number of client connections that each load balanced server can handle. The NetScaler appliance then opens client connections to a server only until this limit is reached. When the load balanced server reaches its limit, monitor probes are skipped, and the server is not used for load balancing until it has finished processing existing connections and frees up capacity.

For more information on the Maximum Client setting, see "Load Balancing Domain-Name Based Services."

Note: Connections that are in the process of closing are not considered for this limit.

At the command prompt, type:

set service <name> -maxclient <Value>

Example

```
set service Service-HTTP-1 -maxClient 1000
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure the maximum number of client connections (for example, Service-HTTP-1), and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Under Thresholds, in the Max Clients text box, type the maximum number of client connections (for example, 100).
5. Click OK.

Setting a Limit on Number of Requests Per Connection to the Server

Aug 29, 2013

The NetScaler appliance can be configured to reuse connections to improve performance. In some scenarios, however, load balanced Web servers may have issues when connections are reused for too many requests. For HTTP or SSL services, use the max request option to limit the number of requests sent through a single connection to a load balanced Web server.

Note: You can configure the max request option for HTTP or SSL services only.

At the command prompt, type:

set service <ServiceName> -maxReq <Value>

Example

```
set service Service-HTTP-1 -maxReq 100
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure the maximum number of client requests, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Under Thresholds, in the Max Requests text box, type the maximum number of client requests (for example, 100).
5. Click OK.

Setting a Threshold Value for the Monitors Bound to a Service

Nov 11, 2013

The NetScaler appliance designates a service as UP only when the sum of the weights of all monitors bound to it and that are UP is equal to or greater than the threshold value configured on the service. The weight for a monitor specifies how much that monitor contributes to designating the service to which it is bound as UP.

For example, assume that three monitors, named Monitor-HTTP-1, Monitor-HTTP-2, and Monitor-HTTP-3 respectively, are bound to Service-HTTP-1, and that the threshold configured on the service is three. Suppose the following weights are assigned to each monitor:

- The weight of Monitor-HTTP-1 is 1.
- The weight of Monitor-HTTP-2 is 3.
- The weight of Monitor-HTTP-3 is 1.

The service is marked UP only when one of the following is true:

- Monitor-HTTP-2 is UP.
- Monitor-HTTP-2 and Monitor-HTTP-1 or Monitor-HTTP-3 are UP
- All three monitors are UP.

At the command prompt, type:

set service <name> -monThreshold <Value>

Example

```
set service Service-HTTP-1 -monThreshold 100
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure monitor threshold (for example, Service-HTTP-1), and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. In the Monitor Threshold text box, type the monitor threshold.
5. Click OK.

Setting a Timeout Value for Idle Client Connections

Nov 11, 2013

You can configure the service with a time-out value to terminate any idle client connections when the configured time elapses. If the client is idle during the configured time, the NetScaler closes the client connection.

At the command prompt, type:

set service <name> -cltTimeout <Value>

Example

```
set service Service-HTTP-1 -cltTimeout 100
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure the time-out value for client connections, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Under Idle Time-out (secs), in the Client text box, type the timeout value.
5. Click OK.

Setting a Timeout Value for Idle Server Connections

Nov 11, 2013

You can configure a service with a timeout value to terminate any idle server connections when the configured time elapses. If the server is idle for the configured amount of time, the NetScaler appliance closes the server connection.

At the command prompt, type:

set service <name>@ -svrTimeout <Value>

Example

set service Service-HTTP-1 -svrTimeout 100

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure the timeout value for server connections (for example, Service-HTTP-1), and click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Under Idle Time-out (secs), in the Server text box, type a timeout value as a number of seconds (for example, 100).
5. Click OK.

Setting a Limit on the Bandwidth Usage by Clients

Nov 11, 2013

In some cases, servers may have limited bandwidth to handle client requests and may become overloaded. To prevent overloading a server, you can specify a maximum limit on the bandwidth processed by the server. The NetScaler appliance forwards requests to a load balanced server only until this limit is reached.

At the command prompt, type:

set service <name> -maxBandwidth <Value>

Example

```
set service Service-HTTP-1 -maxBandwidth 100
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details page, select the service for which you want to configure maximum bandwidth usage (for example, Service-HTTP-1), and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Under Thresholds, in the Max Bandwidth (kbits) text box, type the maximum bandwidth (for example, 100).
5. Click OK.

Redirecting Client Requests to a Cache

Nov 11, 2013

You can configure a service to redirect client requests to a cache, and forward only those requests that are cache misses to a service chosen by the configured load balancing method.

At the command prompt, type:

set service <name>@ -cacheable <Value>

Example

```
set service Service-HTTP-1 -cacheable YES
```

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure cache redirection, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Scroll down, and under Cache Redirection Options, in Cache Type list, select the type of cache (for example, Regular Server).
5. Click OK.

Retaining the VLAN Identifier for VLAN Transparency

Aug 29, 2013

You can configure a load balancing virtual server to retain the client's VLAN identifier in packets that are to be forwarded to servers. The virtual server must be a wildcard virtual server of type ANY, and must be functioning in MAC mode.

At the command prompt, type the following command to configure a load balancing virtual server to retain the client VLAN ID and verify the configuration:

- set lb vserver <name> -m MAC -macmodeRetainvlan ENABLED
- show lb vserver <name>

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Select the virtual server for which you want to configure VLAN transparency, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, select the Macmode Retain VLAN check box.
4. Click OK.

Configuring Automatic State Transition Based on Percentage Health of Bound Services

Nov 11, 2013

You can configure a load balancing virtual server to automatically transition from the UP state to the DOWN state if the percentage of active services falls below a configured threshold. For example, if you bind 10 services to a load balancing virtual server and configure a threshold of 50% for that virtual server, it transitions from UP to DOWN if six or more services are DOWN. When the percentage health rises above the threshold value, the virtual server returns to the UP state.

You can also enable an SNMP alarm called ENTITY-STATE if you want the NetScaler appliance to notify you when the percentage health of bound services causes a virtual server to change state.

At the command prompt, type the following commands to configure automatic state transition for a virtual server and verify the configuration:

- set lb vserver <name>@ -healthThreshold <positive_integer>
- show lb vserver <name>

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Select the load balancing virtual server that you want to configure, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. In the Health Threshold text box, type the threshold value. The threshold value is an integer ranging from 0 (the default) to 100.
5. Click OK.

At the command prompt, type the following commands to enable the ENTITY-STATE SNMP alarm and verify the configuration:

- enable snmp alarm ENTITY-STATE
- show snmp alarm

1. In the navigation pane, expand System, expand SNMP, and then click Alarms.
2. In the details pane, click the ENTITY-STATE alarm, and then, in the Action list, click Enable.

The Built-in Monitors

Jun 09, 2015

The NetScaler appliance contains a number of built-in monitors that you can use to monitor your services. These built-in monitors handle most of the common protocols. You cannot modify or remove the built-in monitors; you can only bind a built-in monitor to a service and unbind it from the service.

Note: You can create a custom monitor based on a built-in monitor. To learn how to create custom monitors, see Configuring Monitors in a Load Balancing Setup.

This section includes the following details:

- Monitoring TCP-based Applications
- Monitoring SSL Services
- Monitoring FTP Services
- Monitoring SIP Services
- Monitoring RADIUS Services
- Monitoring Accounting Information Delivery from a RADIUS Server
- Monitoring DNS and DNS-TCP Services
- Monitoring LDAP Services
- Monitoring MySQL Services
- Monitoring SNMP Services
- Monitoring NNTP Services
- Monitoring POP3 Services
- Monitoring SMTP Services
- Monitoring RTSP Servers
- Monitoring the XML Broker Services
- Monitoring ARP Requests
- Monitoring the XenDesktop Delivery Controller Services
- Monitoring Web Interface Services
- Monitoring Citrix StoreFront Stores

Monitoring TCP-based Applications

Apr 03, 2014

The NetScaler appliance has two built-in monitors that monitor TCP-based applications: tcp-default and ping-default. When you create a service, the appropriate default monitor is bound to it automatically, so that the service can be used immediately if it is UP. The tcp-default monitor is bound to all TCP services; the ping-default monitor is bound to all non-TCP services.

You cannot delete or modify default monitors. When you bind any other monitor to a TCP service, the default monitor is unbound from the service. The following table lists the monitor types, and the parameters and monitoring processes associated with each type.

Monitor type	Specific parameters	Process
tcp	Not applicable	The NetScaler appliance establishes a 3-way handshake with the monitor destination, and then closes the connection. If the appliance observes TCP traffic to the destination, it does not send TCP monitoring requests. This occurs if LRTM is disabled. By default, LRTM is disabled on this monitor.
http	httprequest [“HEAD /”] - HTTP request that is sent to the service. respcode [200] - A set of HTTP response codes are expected from the service.	The NetScaler appliance establishes a 3-way handshake with the monitor destination. After the connection is established, the appliance sends HTTP requests, and then compares the response code with the configured set of response codes.
tcp-ecv	send [""] - is the data that is sent to the service. The maximum permissible length of the string is 512 K bytes. recv [""] - expected response from the service. The maximum permissible length of the string is 128 K bytes.	The NetScaler appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send specific data to the service and expects a specific response through the receive parameter.

Monitor type	Specific parameters	Process
http-ecv	send [""] - HTTP data that is sent to the service recv [""] - the expected HTTP response data from the service	The NetScaler appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send the HTTP data to the service and expects the HTTP response that the receive parameter specifies. (HTTP body part without including HTTP headers). Empty response data matches any response. Expected data may be anywhere in the first 24K bytes of the HTTP body of the response.
ping	Not Applicable	The NetScaler appliance sends an ICMP echo request to the destination of the monitor and expects an ICMP echo response.

To configure built-in monitors for TCP-based applications, see Configuring Monitors in a Load Balancing Setup.

Monitoring SSL Services

Jun 16, 2014

The NetScaler appliance has built-in secure monitors, TCPS and HTTPS. You can use the secure monitors to monitor HTTP as well as non-HTTP traffic. To configure a secure HTTP monitor, select the monitor type as HTTP, and then set the secure flag. To configure a secure TCP monitor, select the monitor type as TCP, and then set the secure flag.The secure monitors work as described below:

- **Secure TCP monitoring.** The NetScaler appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. After the handshake is over, the appliance closes the connection.
- **Secure HTTP monitoring.** The NetScaler appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. When the SSL connection is established, the appliance sends HTTP requests over the encrypted channel and checks the response codes.

The following table describes the available built-in monitors for monitoring SSL services.

Monitor type	Probe	Success criteria (Direct condition)
TCP	TCP connection SSL handshake	Successful TCP connection established and successful SSL handshake.
HTTP	TCP connection SSL handshake Encrypted HTTP request	Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP response code in server HTTP response is encrypted.
TCP-ECV	TCP connection SSL handshake (Data sent to a server is encrypted.)	Successful TCP connection is established, successful SSL handshake is performed, and expected TCP data is received from the server.
HTTP-ECV	TCP connection SSL handshake (Encrypted HTTP request)	Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP data is received from the server.

Monitoring FTP Services

Mar 24, 2015

To monitor FTP services, the NetScaler appliance opens two connections to the FTP server. It first connects to the control port, which is used to transfer commands between a client and an FTP server. After it receives the expected response, it connects to the data port, which is used to transfer files between a client and an FTP server. Only when the FTP server responds as expected on both connections is it marked UP.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.
The NetScaler appliance has two built-in monitors for FTP services: the FTP monitor and the FTP-EXTENDED monitor. The FTP monitor checks basic functionality; the FTP-EXTENDED monitor also verifies that the FTP server is able to transmit a file correctly.

Parameter	Specifies
userName	User name used in the probe. Applies to both the FTP and FTP-EXTENDED monitor.
password	Password used in monitoring. Applies to both the FTP and FTP-EXTENDED monitor
fileName	File name to be used for FTP-EXTENDED monitor only.

To configure built-in monitors to check the state of FTP services, see Configuring Monitors in a Load Balancing Setup.

Monitoring SIP Services

Oct 14, 2014

A NetScaler ADC has two built-in monitors that you can use to monitor SIP services: the **SIP-UDP** and **SIP-TCP** monitors. A SIP monitor periodically checks the SIP service to which the SIP monitor is bound, by sending SIP request methods to the SIP service. If the SIP service replies with a response code, the monitor marks the service as UP. If the SIP service does not respond, or responds incorrectly, it is marked as DOWN.

Parameter	Specifies
sipURI	SIP addressing schema of the SIP server.
sipmethod	Type of SIP request used to probe the SIP service. Specify one of the following methods: • INVITE • OPTION (the default) • REGISTER
respcode	SIP response code with which the SIP service responds the probe request. Default: 200.

The Session Initiation Protocol (SIP) is designed to initiate, manage, and terminate multimedia communications sessions. It has emerged as the standard for Internet telephony (VoIP). SIP messages can be transmitted over TCP or UDP. SIP messages are of two types: request messages and response messages.

The following table summarizes the structure of SIP messages.

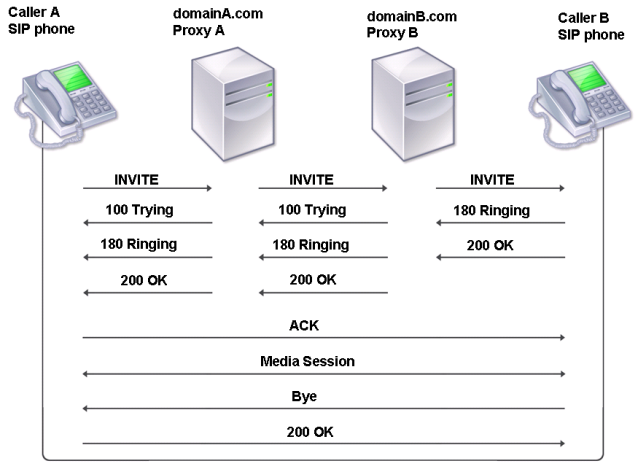
Message type	Components	Components
Request	Method	Invite, Ack, Options, Bye, Cancel, Register
	Request URI	Represents the subject, media type, or urgency of sessions initiated. The common format is: sip:user:password@host:port;uri-parameters?headers
	SIP version	The SIP version being used
Response	SIP version	The SIP version that is being used.
	Status code	A 3-digit integer result code. The possible values are: 1xx: Information Responses. For example: 180, Ringing

Message type	Components	Components
		2xx: Successful Responses. For example: 200, OK 3xx: Redirection Responses. For example: 302, Moved Temporarily 4xx: Request Failures Responses. For example: 403, Forbidden 5xx: Server Failure Responses. For example: 504, Gateway Time-out 6xx: Global Failure Responses. For example: 600, Busy Everywhere
	Reason-phrase	Textual description of the status code.

The traffic in an SIP-based communication system is routed through dedicated devices and applications (entities). In a multimedia communication session, these entities exchange messages.

One of the most common uses for SIP is VoIP, where SIP is used to set up the session. The following diagram illustrates how the messages and entities in a SIP-based communication system interoperate.

Figure 1. How SIP Works



The entity that initiates the call is referred to as the user agent (UA). The UA can be an SIP softphone (a PC-based application) or a SIP phone.

To initiate a call, the user agent sends an INVITE request to the previously configured SIP proxy server. The INVITE request contains the details of the destination, such as the destination uniform resource identifier (URI) and Call ID. In the diagram, the Caller A (user agent) sends an INVITE request to Proxy A.

When the proxy server receives the INVITE request, it sends a 100 (Trying) response to the user agent, Caller A. It also performs a DNS lookup to locate the SIP proxy server of the destination domain. After the SIP proxy server of the destination domain is located, the SIP proxy at the source domain sends the INVITE request to it. Here, Proxy A sends a 100 (Trying) response to Caller A and an INVITE request to Proxy B.

When the SIP proxy server of the destination domain receives the INVITE request from the SIP proxy server of the source domain, it responds with a 100 (Trying) response. It then sends the INVITE request to the destination user agent. In this

case, Proxy B sends a 100 (Trying) response to Proxy A and an INVITE request to Caller B.

When the destination user agent receives the INVITE request, it alerts Caller B and responds with a 180 (ringing) response. This response is routed back to the source user agent through the proxies.

When caller B accepts the call, the destination user agent responds with a 200 (OK) response. This signifies that caller B has answered the call. This response is routed back to the source user agent through the proxies. After the call is set up, the user agents communicate directly without the proxies.

The following table describes the entities of a SIP-based communication system and their roles.

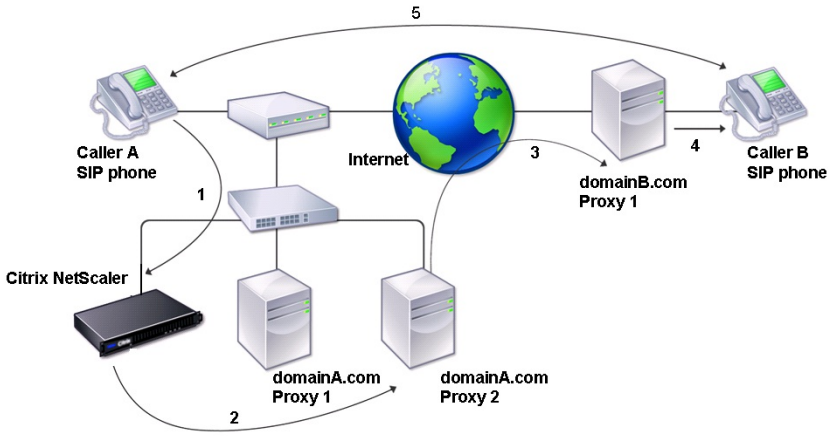
Entity	Role
User Agent (UA)	SIP user agents generate requests and respond to incoming requests. A user agent that generates requests is known as a User Agent Client (UAC). The user agent that responds to requests is known as the User Agent Server (UAS). In the preceding example, Caller A was the UAC and Caller B was the UAS.
Proxy Server	Proxies receive and route SIP requests based on the URI. They can selectively rewrite parts of the request message before forwarding it. They also handle registrations and invitations to user agents, and apply call policies.
Redirect Server	Redirect servers send routing information to the SIP proxy servers.
Registrar Server	Registrar servers provide location information to user agents and proxy servers.
Back-to-Back User Agent (B2BUA)	Back-to-Back User Agents (B2BUA) are combination of UAS and UAC.

You can configure the NetScaler appliance to load balance SIP requests to a group of SIP proxy servers. To do so, you need to create a load balancing virtual server with the load balancing method set to Call-ID hash, and then bind to it the services that are bound to the SIP proxies.

For load balancing to work, you must also configure the SIP proxies so that they do not add private IP addresses or private domains to the SIP header/payload. SIP proxies must add to the SIP header a domain name that resolves to the IP address of the SIP virtual server. Also, the SIP proxies must communicate with a common database to share registration information.

The NetScaler appliance can load balance SIP proxies in either a one-arm DSR configuration or an inline direct server return (DSR) configuration. In a one-arm DSR configuration, the appliance receives SIP requests from user agents and routes the requests to the appropriate SIP proxy by using the configured load balancing method. The SIP proxies send their responses to the destination SIP proxies, bypassing the appliance, as illustrated in the following diagram.

Figure 2. SIP in One-Arm Mode

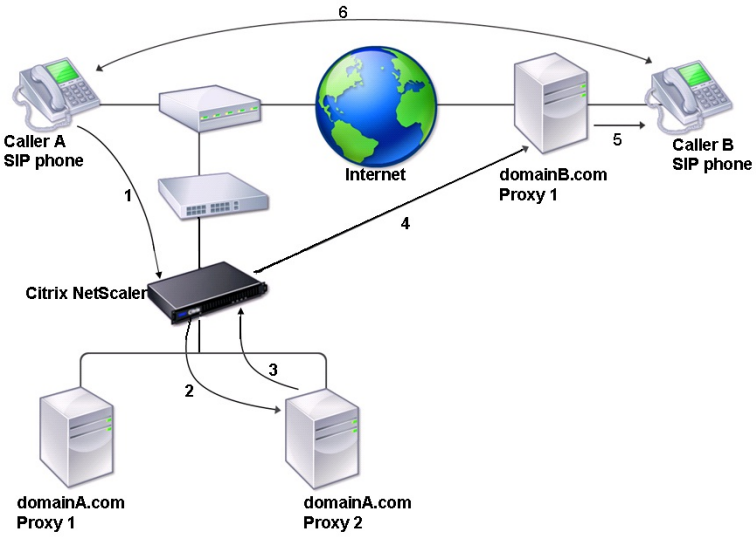


The flow of requests and responses in this configuration is as follows:

- The user agent, Caller A, sends an INVITE request to the NetScaler. The NetScaler, using a load balancing method, routes the request to Proxy 2.
- Proxy 2 receives the INVITE request from the NetScaler and responds with a 100 (Trying) message.
- Proxy 2 performs a DNS lookup to obtain the IP address of the destination SIP proxy at domainB.com. It then sends the INVITE request to the destination proxy.
- The destination proxy responds with a 100 (Trying) message and sends the INVITE request to the destination user agent, Caller B. The destination user agent, Caller B, begins to ring and responds with a 180 (Ringing) message. This message is sent to Caller A through the NetScaler and the Proxy 2. After the user accepts the call, Caller B responds with a 200 (OK) message that is propagated to Caller A through the NetScaler and the Proxy 2.
- After Caller B accepts the call, the user agents (Caller A and Caller B) communicate independently.

In an inline DSR configuration, the appliance is placed between the router and the SIP proxy, as illustrated in the following diagram.

Figure 3. SIP in Inline Mode



The flow of requests and responses is as follows:

- The user agent, Caller A, sends an INVITE request to the appliance. The NetScaler, using a load balancing method, routes the request to Proxy 2.
- Proxy 2 receives the INVITE request from the appliance and responds with a 100 (Trying) message.
- Proxy 2 performs a DNS lookup to obtain the IP address of the destination SIP proxy at domainb.com. It then propagates the INVITE request to the destination proxy through the appliance.
- The appliance performs RNAT, and replaces the source IP address in the INVITE request with the NAT IP address, and then forwards the INVITE request to the destination SIP proxy.
- The destination proxy responds with a 100 (Trying) message and sends the INVITE request to the destination user agent, Caller B. Caller B begins to ring and responds with a 180 (Ringing) message. This message is sent to Caller A through the NetScaler and the Proxy 2. After the user accepts the call, Caller B responds with a 200 (OK) message that is propagated to Caller A through the appliance and Proxy 2.
- After the user accepts the call, the user agents (Caller A and Caller B) communicate independently.

Parameter	Specifies
maxForwards	SIP packet max-forwards. Possible Values: 0-255. Default: 1.
sipMethod	SIP method to be used for the query. Possible values: OPTIONS, INVITE, REGISTER Default value: OPTIONS.
sipURI	SIP method string, sent to the server. For example “OPTIONS sip:sip.test.”
sipregURI	SIP user to be registered.

To configure built-in monitors to check the state of SIP server, see Configuring Monitors in a Load Balancing Setup.

Monitoring RADIUS Services

Aug 01, 2013

The NetScaler appliance RADIUS monitor periodically checks the state of the RADIUS service to which it is bound by sending an authentication request to the service. The RADIUS server authenticates the RADIUS monitor and sends a response. By default, the monitor expects to receive a response code of 2, the default Access-Accept response, from the RADIUS server. As long as the monitor receives the appropriate response, it marks the service UP.

Note: RADIUS monitor supports only PAP type authentication.

- If the client authenticated successfully, the RADIUS server sends an Access-Accept response. The default access-accept response code is 2, and this is the code that the appliance uses.
- If the client fails to authenticate successfully (such as when there is a mismatch in the user name, password, or secret key), the RADIUS server sends an Access-Reject response. The default access-reject response code is 3, and this is the code that the appliance uses.

Parameter	Specifies
userName	User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.
password	Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.
radKey	Shared secret key value that the RADIUS server uses during client authentication.
radNASid	NAS-ID that is encapsulated in the payload when an access request is made.
radNASip	The IP address that is encapsulated in the payload when an access-request is made. When radNASip is not configured, the NetScaler sends the mapped IP address (MIP) to the RADIUS server as the NAS IP address.

To monitor a RADIUS service, you must configure the RADIUS server to which it is bound as follows:

1. Add the user name and password of the client that the monitor will use for authentication to the RADIUS authentication database.
2. Add the IP address and secret key of the client to the appropriate RADIUS database.
3. Add the IP addresses that the appliance uses to send RADIUS packets to the RADIUS database. If the NetScaler appliance has more than one mapped IP address, or if a subnet IP address (SNIP) is used, you must add the same secret key for all of the IP addresses.

   Caution: If the IP address used by the appliance are not added to the RADIUS database, the RADIUS server will discard all packets.

To configure built-in monitors to check the state of RADIUS server, see Configuring Monitors in a Load Balancing Setup.

Monitoring Accounting Information Delivery from a RADIUS Server

Sep 13, 2013

You can configure a monitor called a *RADIUS accounting* monitor to determine whether the Radius server used for Authentication, Authorization, and Accounting (AAA) is delivering accounting information as expected. The monitor is of type RADIUS_ACCOUNTING. The probe is generated by a Perl script called nsbmradius.pl, which is located in the /nsconfig/monitors/ directory. The script sends successive accounting request probes to the RADIUS server. The probe is considered successful only if the RADIUS accounting server responds with a packet whose Code field is set to 5, which, according to RFC 2866, indicates an Accounting-Response packet.

When configuring a RADIUS accounting monitor, you must specify a secret key. You can specify optional parameters, each of which represents a RADIUS attribute, such as Acct-Status-Type and Framed-IP-Address. For information about these attributes, see RFC 2865, "Remote Authentication Dial In User Service (RADIUS)," and RFC 2866, "RADIUS Accounting."

At the command prompt, type the following commands to configure a RADIUS accounting monitor and verify the configuration:

- add lb monitor <monitorName> RADIUS_ACCOUNTING [-userName <string>] {-password } {-radKey } [-radNASip <ip_addr>] [-radAccountType <positive_integer>] [-radFramedIP <ip_addr>] [-radAPN <string>] [-radMSISDN <string>] [-radAccountSession <string>]
- show lb monitor <monitorName>

Example

```
add lb monitor radAccntMon RADIUS_ACCOUNTING -radKey "8d#>9jr4rV)L7%a2-zW13sM"
```

Monitoring DNS and DNS-TCP Services

Mar 19, 2012

The NetScaler appliance has two built-in monitors that can be used to monitor DNS services: DNS and DNS-TCP. When bound to a service, either monitor periodically checks the state of that DNS service by sending a DNS query to it. The query resolves to an IPv4 or IPv6 address. That IP address is then checked against the list of test IP addresses that you configure. The list can contain up to five IP addresses. If the resolved IP address matches at least one IP address on the list, the DNS service is marked as up. If the resolved IP does not match any IP addresses on the list, the DNS service is marked as down.

Parameter	Parameter
query	The DNS query (domain name) sent to the DNS service that is being monitored. Default value: “\007” If the DNS query succeeds, the service is marked as UP; otherwise, it is marked as DOWN. For a reverse monitor, if the DNS query succeeds, the service is marked as DOWN; otherwise, it is marked as UP. If no response is received, the service is marked as DOWN.
queryType	The type of DNS query that is sent. Possible values: Address, Zone.
IPAddress	List of IP addresses that are checked against the response to the DNS monitoring probe.
IPv6	Select this check box if the IP address uses IPv6 format.

To configure the built-in DNS or DNS-TCP monitors, see Configuring Monitors in a Load Balancing Setup.

Monitoring LDAP Services

Mar 24, 2015

The NetScaler appliance has one built-in monitor that can be used to monitor LDAP services: the LDAP monitor. It periodically checks the LDAP service to which it is bound by authenticating and sending a search query to it. If the search is successful, the service is marked UP. If the LDAP server does not locate the entry, a failure message is sent to the LDAP monitor, and the service is marked DOWN.

You configure the LDAP monitor to define the search that it should perform when sending a query. You can use the Base DN parameter to specify a location in the directory hierarchy where the LDAP server should start the test query. You can use the Attribute parameter to specify an attribute of the target entity.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

Parameter	Specifies
baseDN	Base name for the LDAP monitor from where the LDAP search must start. If the LDAP server is running locally, the default value of base is dc=netscaler, dc=com.
bindDN	BDN name for the LDAP monitor.
filter	Filter for the LDAP monitor.
password	Password used in monitoring LDAP servers.
attribute	Attribute for the LDAP monitor.

To configure the built-in LDAP monitor, see Configuring Monitors in a Load Balancing Setup.

Monitoring MySQL Services

Mar 24, 2015

The NetScaler appliance has one built-in monitor that can be used to monitor MySQL services: the MySQL monitor. It periodically checks the MySQL service to which it is bound by sending a search query to it. If the search is successful, the service is marked UP. If the MySQL server does not respond or the search fails, a failure message is sent to the MySQL monitor, and the service is marked DOWN.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

Parameter	Specifies
database	Database that is used for the MySQL monitor.
sqlQuery	SQL query that is used for the MySQL monitor.

To configure built-in MySQL monitor, see Configuring Monitors in a Load Balancing Setup.

Monitoring SNMP Services

Mar 24, 2015

The NetScaler appliance has one built-in monitor that can be used to monitor SMNP services: the SNMP monitor. It periodically checks the SNMP agent on the service to which it is bound by sending a query for the enterprise identification ID (OID) that you configure for monitoring. If the query is successful, the service is marked UP. If the SNMP service finds the OID that you specified, the query succeeds and the SNMP monitor marks the service UP. If it does not find the OID, the query fails and the SNMP monitor marks service DOWN.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

Parameter	Specifies
SNMPOID	OID that is used for the SNMP monitor.
snmpCommunity	Community that is used for the SNMP monitor.
snmpThreshold	Threshold that is used for the SNMP monitor.
snmpVersion	SNMP version that is used for load monitoring. Possible Values: V1, V2.

To configure the built-in SNMP monitor, see Configuring Monitors in a Load Balancing Setup.

Monitoring NNTP Services

Mar 24, 2015

The NetScaler appliance has one built-in monitor that can be used to monitor NNTP services: the NNTP monitor. It periodically checks the NNTP service to which it is bound by connecting to the service and checking for the existence of the newsgroup that you specify. If the newsgroup exists, the search is successful and the service is marked UP. If the NNTP service does not respond or the search fails, the service is marked DOWN.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.
The NNTP monitor can optionally be configured to post a test message to the newsgroup as well.

Parameter	Specifies
userName	User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.
password	Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.
group	Group name to be queried for NNTP monitor.

To configure the built-in NNTP monitor, see Configuring Monitors in a Load Balancing Setup.

Monitoring POP3 Services

Mar 24, 2015

The NetScaler appliance has one built-in monitor that can be used to monitor POP3 services: the POP3 monitor. It periodically checks the POP3 service to which it is bound by opening a connection with a POP3 server. If the POP3 server responds with the correct response codes within the configured time period, it marks the service UP. If the POP3 service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

Parameter	Specifies
userName	User name POP3 server. This user name is used in the probe.
password	Password used in monitoring POP3 servers.
scriptName	The path and name of the script to execute.
dispatcherIP	The IP address of the dispatcher to which the probe is sent.
dispatcherPort	The port of the dispatcher to which the probe is sent.

To configure the built-in POP3 monitor, see Configuring Monitors in a Load Balancing Setup.

Monitoring SMTP Services

Mar 24, 2015

The NetScaler appliance has one built-in monitor that can be used to monitor SMTP services: the SMTP monitor. It periodically checks the SMTP service to which it is bound by opening a connection with it and conducting a series of handshakes to ensure that the server is operating correctly. If the SMTP service completes the handshakes properly, the monitor marks the service UP. If the SMTP service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

Parameter	Specifies
userName	User name SMTP server. This user name is used in the probe.
password	Password used in monitoring SMTP servers.
scriptName	The path and name of the script to execute.
dispatcherIP	The IP Address of the dispatcher to which the probe is sent.
dispatcherPort	The port of the dispatcher to which the probe is sent.

To configure the built-in SMTP monitor, see Configuring Monitors in a Load Balancing Setup.

Monitoring RTSP Servers

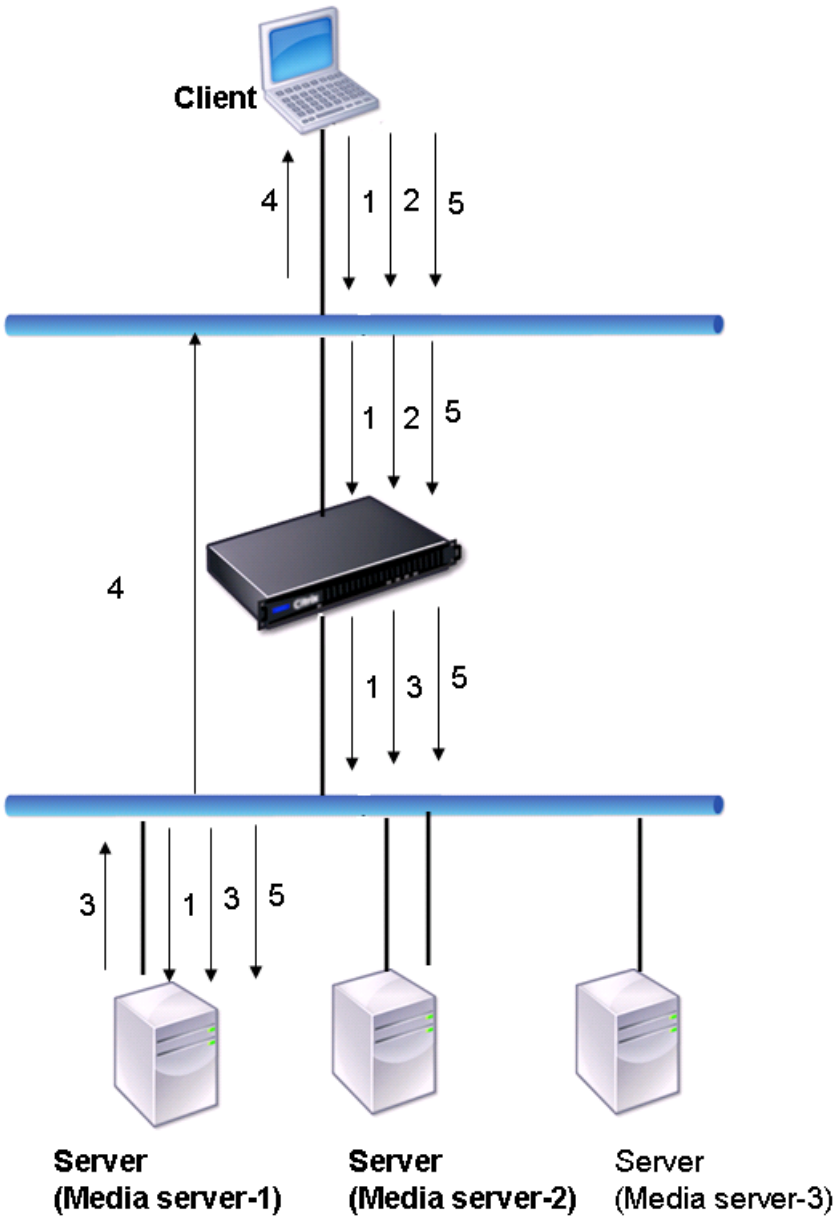
Apr 08, 2013

The NetScaler appliance has one built-in monitor that can be used to monitor RTSP services: the RTSP monitor. It periodically checks the RTSP service to which it is bound by opening a connection with the load balanced RTSP server. The type of connection that it opens, and the response that it expects, differs depending upon the network configuration. If the RTSP service responds as expected within the configured time period, it marks the service UP. If the service does not respond, or responds incorrectly, it marks the service DOWN.

The NetScaler appliance can be configured to load balance RTSP servers using two topologies: NAT-off and NAT-on. RTSP servers send their responses directly to the client, bypassing the appliance. The appliance must be configured to monitor RTSP services differently depending upon which topology your network uses. The appliance can be deployed either in inline or non-inline mode in both NAT-off and NAT-on mode.

In NAT-off mode, the appliance operates as a router: it receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. If your load balanced RTSP servers are assigned publicly accessible FQDNs in DNS, the load balanced servers send their responses directly to the client, bypassing the appliance. The following figure demonstrates this configuration.

Figure 1. RTSP in NAT-off Mode



The flow of requests and responses in this scenario is as follows:

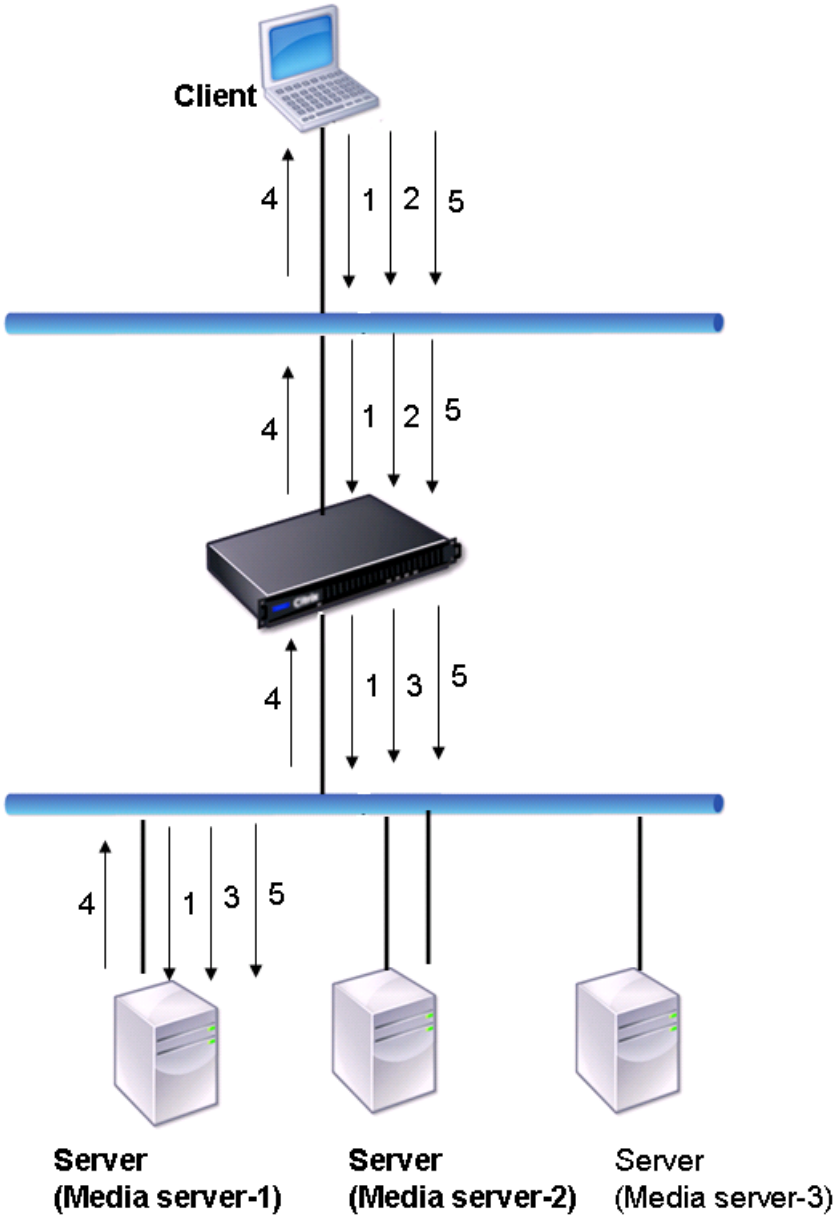
1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:
   - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
   - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request may be sent to a different service.
3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.

Note: The appliance does not perform NAT to identify the RTSP connection, because the RTSP connections bypass it.

4. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the media server. Media Server-1 performs the requested actions, such as play, forward, or rewind.

In NAT-on mode, the appliance receives RTSP requests from the client and routes those requests to the appropriate media server using the configured load balancing method. The media server then sends its responses to the client through the appliance, as illustrated in the following diagram.

Figure 2. RTSP in NAT-on Mode



The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using the RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:

- If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
- If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request may be sent to a different service.

3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.
4. The appliance performs NAT to identify the client for RTSP data connections, and the RTSP connections pass through the appliance and are routed to the correct client.
5. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the appliance. The appliance uses RTSPSID persistence to identify the appropriate service, and routes the request to Media Server-1. Media Server-1 performs the requested action, such as play, forward, or rewind.

The RTSP monitor uses the RTSP protocol to evaluate the state of the RTSP services. The RTSP monitor connects to the RTSP server and conducts a sequence of handshakes to ensure that the server is operating correctly.

Parameter	Specifies
rtspRequest	The RTSP request string that is sent to the RTSP server (for example, OPTIONS *). The default value is 07. The length of the request must not exceed 163 characters.
respCode	Set of response codes that are expected from the service.

For instructions on configuring an RTSP monitor, see Configuring Monitors in a Load Balancing Setup.

Monitoring the XML Broker Services

Sep 13, 2013

The NetScaler appliance has a built-in monitor type, CITRIX-XML-SERVICE, with which you can create monitors to monitor the XML Broker services. The XML Broker services are used by Citrix XenApp. The monitor opens a connection to the service and periodically probes the XML services to which it is bound. If the server responds as expected within the configured time period, the monitor marks the service UP. If the service does not respond, or responds incorrectly, the monitor marks the service DOWN.

To configure a CITRIX-XML-SERVICE monitor, you need to specify the application name in addition to setting the standard parameters. The application name is the name of the application that has to be run to monitor the state of the XML Broker service. The default application is Notepad.

To configure monitors for XML Broker services, see "Configuring Monitors in a Load Balancing Setup."

Monitoring ARP Requests

Mar 19, 2012

The NetScaler appliance has one built-in monitor that can be used to monitor ARP requests: the ARP monitor. This monitor periodically sends an ARP request to the service to which it is bound, and listens for the expected response. If it receives the expected response, it marks the service UP. If it receives no response or the wrong response, it marks the service DOWN.

ARP locates a hardware address for a load balanced server when only the network layer address is known. ARP works with IPv4 to translate IP addresses to Ethernet MAC addresses. ARP monitoring is not relevant to IPv6 networks, and is therefore not supported on those networks.

There are no special parameters for the ARP monitor.

For instructions on configuring an ARP monitor, see Configuring Monitors in a Load Balancing Setup.

Monitoring the NetScaler Gateway

Mar 19, 2012

The NetScaler appliance has one built-in monitor that can be used to monitor a load-balanced NetScaler Gateway: the CITRIX-AG monitor. This is in addition to two monitors for the Advanced Access Control login page and agent service page, which are described separately. The CITRIX-AG monitor periodically logs on to the NetScaler Gateway service to which it is bound, and awaits the expected responses to its requests. If it receives the expected responses, it marks the service UP. If it receives no response or the wrong responses, it marks the service DOWN.

To configure monitoring of an NetScaler Gateway, you must first create a local user and password for the monitor on the load balanced NetScaler Gateway server that the service is bound to. After you configure the NetScaler Gateway, you then configure the monitor. The monitor logs on to the NetScaler Gateway using the realm and user name. For example, if you configured a realm of LDAP and a user name of user1, the NetScaler Gateway logs on as LDAP/user1.

Note: RSA SecurID authentication is not supported for this monitor. RSA SecurID requires an RSA-generated token as a password, which is not supported on the NetScaler appliance.

Parameter	Specifies
userName	A user name.
password	A password for the username.
secondaryPassword	A secondary password for the username.

For instructions on configuring the CITRIX-AG monitor, see Configuring Monitors in a Load Balancing Setup.

Monitoring the Advanced Access Control Login Page

Jul 10, 2013

The NetScaler appliance has one built-in monitor that can be used to monitor the Advanced Access Control (AAC) login page on a load-balanced NetScaler Gateway: the CITRIX-AAC-LOGINPAGE monitor. This monitor periodically logs on to the AAC login page via the NetScaler Gateway service to which it is bound, and awaits the expected response. If it receives the expected response, it marks the service UP. If it receives no response or the wrong response, it marks the service DOWN.

Parameter	Specifies
logonpointName	The URL from which users access corporate resources using the NetScaler Gateway Advanced Edition. This setting controls access to server farms, the Access Interface configuration, and other session-specific settings. It can also be used as a filter within NetScaler Gateway policies.

For instructions on configuring the CITRIX-AAC-LOGINPAGE monitor, see Configuring Monitors in a Load Balancing Setup.

Monitoring the Advanced Access Control Logon Agent Service Page

Jul 10, 2013

The NetScaler appliance has one built-in monitor that can be used to monitor the Advanced Access Control (AAC) agent service page on a load-balanced NetScaler Gateway: the CITRIX-AAC-LAS monitor. The Logon Agent Service (LAS) is a service component of Advanced Access Control that requests authentication to the Authentication Service. This monitor periodically logs on to the AAC agent service page via the NetScaler Gateway service to which it is bound, and awaits the expected response. If it receives the expected response, it marks the service UP. If it receives no response or the wrong response, it marks the service DOWN.

Parameter	Specifies
logonpointName	The URL from which users access corporate resources using the NetScaler Gateway advanced edition. This setting controls access to server farms, the Access Interface configuration, and other session-specific settings. It can also be used as a filter within NetScaler Gateway policies.
lasVersion	The version number of the agent.

For instructions on configuring the CITRIX-AAC-LAS monitor, see Configuring Monitors in a Load Balancing Setup.

Monitoring the XenDesktop Delivery Controller Services

Nov 26, 2013

In desktop virtualization, the NetScaler appliance can be used to load balance the Web Interface (WI) servers and the XenDesktop Delivery Controller servers deployed by Citrix XenDesktop environment. The NetScaler provides a built-in monitor, CITRIX-XD-DDC monitor, which monitors the XenDesktop Delivery Controller servers. In addition to the health check, you can also verify whether the probe is sent by a valid user of the XenDesktop Delivery Controller server.

The monitor sends a probe to the XenDesktop Delivery Controller server in the form of an XML message. If the server responds to the probe with the identity of the server farm, the probe is considered to be successful and the server's status is marked as UP. If the HTTP response does not have a success code or the identity of the server farm is not present in the response, the probe is considered to be a failure and the server's status is marked as DOWN.

The Validate Credentials option determines the probe to be sent by the monitor to the XenDesktop Delivery Controller server, that is, whether to request only the server name or to also validate the login credentials.

Note: Regardless of whether or not the user credentials (user name, password and domain) are specified on the CITRIX-XD-DDC monitor, the XenDesktop Delivery Controller server validates the user credentials only if the option to validate credentials is enabled on the monitor.
If you use the wizard for configuring the load balancing of the XenDesktop servers, the CITRIX-XD-DDC monitor is automatically created and bound to the XenDesktop Delivery Controller services. If you do not use the wizard, add a monitor of the type CITRIX-XD-DDC.

- For instructions on using the wizard, see Configuring the load balancing of XenDesktop.
- For instructions on adding a monitor, see Creating Monitors.
- For instructions on binding a monitor to a service, see Binding Monitors to Services.

At the command prompt, type the following commands to add an XD-DDC monitor and verify the configuration:

- add lb monitor <monitorName> <monitorType> -userName <userName> -password <password> -ddcDomain <ddc_domain_name> -validateCred YES
- show lb monitor <monitorName>

Example

```
 > add lb monitor xdddcmon Citrix-xd-ddc -userName Administrator -password E12Dc35450a1 -ddcDomain dhop -validateCred YES
 Done
> show lb monitor xdddcmon
1) Name......:xdddcmon Type......:CITRIX-XD-DDC State......: ENABLED

Standard parameters:
Interval......:..5 sec...Retries......:..3
Response timeout......:..2 sec...Down time......:..30 sec
Reverse......:..NO...Transparent......:..NO
Secure......:..NO...LRTM......:..ENABLED
Action......:..Not applicable...Deviation......:..0 sec
Destination IP......:..Bound service
Destination port......:..Bound service
Iptunnel......:..NO
TOS.....:..NO...TOS ID.....:..0
SNMP Alert Retries.....:..0...Success Retries.....:..1
Failure Retries.....:..0

Special parameters:
User Name..........:"Administrator"
Password..........:*****
DDC Domain.........: "dhop"
Done
```

At the command prompt, type:

set lb monitor <monitorName> <monitorType> -userName -password -ddcDomain <ddc_domain_name> -validateCred YES

Example

```
 > set lb monitor XD_DDC_21.21.21.22_443_mn CITRIX-xd-ddc -userName Administrator -password D123S1R2A123 -ddcDomain dhop -validateCred YES
Done
```

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, do one of the following:
   - To add an XD-DDC monitor, click Add.
   - To modify an XD-DDC monitor, select the monitor, and click Open.
3. Type a name for the monitor.

4. Select the monitor type as CITRIX-XD-DDC.
5. On the Special Parameters tab:
   - Validate Credentials—validateCred (To specify YES, select the check box.)
   - Name*—monitorName
   - Type*—monitorType
   - User Name*—userName
   - Password*—password
   - Domain Name*—ddcDomain

   *A required parameter
6. Click Create.
7. Select the new monitor, click Open, and verify the settings.

Monitoring Web Interface Services

May 07, 2015

In desktop virtualization, the NetScaler appliance can be used to load balance the Web Interface (WI) servers and Dynamic Desktop Controller (DDC) servers deployed in the Citrix XenApp and Citrix XenDesktop and environments. The NetScaler appliance has two built-in monitor types for monitoring the WI servers used in these environments.

A CITRIX-WEB-INTERFACE monitor can monitor the Web Interface services efficiently because it monitors a dynamic page at the location specified by the site path. The monitor checks for critical failures in resource availability.

To mark a service as UP, the appliance expects the following response from the server:

1. For the first GET request, 200 OK .
2. For the POST request with credentials, 302 Found with the required WIAuthID.
3. For the last GET request with session cookie, 200 OK.

Note: If a redirect URL is configured, 302 Found is expected in the first request before 200 OK.
Note: Monitor probes originate from the NetScaler IP (NSIP) address.
When you configure a CITRIX-WEB-INTERFACE monitor, specify the site path to the location of the http page that displays the data collected by the monitor. To monitor the status of the service, in the specified site path, you can view the data updated dynamically by the monitoring script auth/nocookies.aspx.

Note: End the site path with a slash (/) to indicate that the monitored resource is dynamic.
Note: When you configure the WI-EXTENDED monitor, when specifying the site path, do not enter a slash (/) at the end of the path as the software internally adds a slash at the end of the path. For example, note the following command:

```
add monitor wi CITRIX-WI-EXTENDED -sitepath "/Citrix/DesktopWeb" -username aaa -password bbb -domain ccc
```

A CITRIX-WI-EXTENDED monitor verifies the logging process with the Web Interface service. This monitor accesses the login page and passes the user name, password, domain, and site path that were specified while configuring the monitor. It verifies the validity of the login credentials, correct configuration of the monitor (for example, the site path), and the connection with the IIS server.

Note: The CITRIX-WI-EXTENDED monitor is supported only for the .NET version of the WI servers. This monitor will not work for the JSP version of the WI servers.
If you use the wizard for configuring load balancing of the XenDesktop servers, a CITRIX-WEB-INTERFACE monitor is automatically created and bound to the WI services. The wizard adds and binds a CITRIX-WEB-INTERFACE monitor by default. If you want to add and bind a CITRIX-WI-EXTENDED monitor, select the Validate Credentials check box and type the necessary data. If you do not use the wizard, add a monitor corresponding to the WI services and bind it to each WI service that you create.

- For instructions on using the wizard, see Configuring XenDesktop for Load Balancing or Configuring XenApp for Load Balancing.
- For instructions on adding a CITRIX-WEB-INTERFACE monitor, see Creating Monitors.
- For instructions on binding a monitor to a service, see Binding Monitors to Services.

At the command prompt, type:

add lb monitor <monitorName> <monitorType> -sitePath <site_path> -dispatcherIP 127.0.0.1 -dispatcherPort 3013 -userName <username> -password <password> -domain <domain_name>

Examples

```
add lb monitor mwie CITRIX-WEB-INTERFACE -sitePath "/Citrix/XDWI/"
add lb monitor mwie CITRIX-WI-EXTENDED -sitePath "/Citrix/XDWI/"
-dispatcherIP 127.0.0.1 -dispatcherPort 3013 -userName administrator
```

```
-password d83d154575d426 -encrypted -domain wi
```

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, do one of the following:
   - To add a WI monitor, click Add.
   - To modify a WI monitor, select the monitor, and click Open.
3. Type a name for the monitor.
4. Select the monitor type as CITRIX-WEB-INTERFACE or CITRIX-WI-EXTENDED.
5. On the Special Parameters tab, type the site path. To configure the CITRIX-WI-EXTENDED monitor, specify values for the following parameters:
   - User Name*—userName
   - Password*—password
   - Domain Name*—domain
6. Click Create.
7. Select the new monitor, click Open, and verify the settings.

Monitoring Citrix StoreFront Stores

Sep 30, 2015

You can configure a user monitor for a Citrix Storefront store. The monitor determines the state of the StoreFront store by successively probing the account service, authentication service, and discovery document (in that order). If any of those services do not respond to the probe, the monitor probe fails, and the StoreFront store is marked as DOWN. The monitor sends probes to the IP address and port of the bound service.

Note: Monitor probes originate from the NetScaler IP (NSIP) address. However, if the subnet of a StoreFront server is different from that of the appliance, then the subnet IP (SNIP) address is used.
Beginning with build 120.13, you can also bind a StoreFront monitor to a service group. A monitor is bound to each member of the service group and probes are sent to the IP address and port of the bound member (service). Also, because each member of a service group is now monitored by using the member's IP address, you can now use the StoreFront monitor to monitor StoreFront cluster nodes that are added as members of the service group.

The hostname parameter for StoreFront monitors is deprecated. The secure parameter is now used to determine whether to use HTTP (the default) or HTTPS to send monitor probes.

To use HTTPS, set the secure option to Yes.

At the command prompt, type the following commands to configure a StoreFront monitor and verify the configuration:

- add lb monitor <monitorName> STOREFRONT <string> -storeName <string> [-storefrontacctservice (YES | NO)] -secure (YES | NO)
- show lb monitor <monitorName>

Example

```
add lb monitor storefront_ssl STOREFRONT -storename myStore -storefrontacctservice YES -secure YES
```

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the Create Monitor dialog box, in the details pane, click Add, and then, in the Create Monitor dialog box, in the Type list, select STOREFRONT.
3. On the Standard Parameters tab, to use HTTPS, select Secure.
4. On the Special Parameters tab, set the following parameters:
   - Store Name
   - StoreFront Account Service
5. Click OK.

Custom Monitors

Jun 09, 2015

In addition to built-in monitors, you can use custom monitors to check the state of your services. The NetScaler appliance provides several types of custom monitors based on scripts that are included with NetScaler operating system that can be used to determine the state of services based on the load on the service or network traffic sent to the service. These are the inline monitors, user monitors, and load monitors.

With any of these types of monitors, you can use the supplied functionality, or you can create your own scripts and use those scripts to determine the state of the service to which the monitor is bound.

This section includes the following details:

- Configuring HTTP-Inline Monitors
- Understanding User Monitors
- How to Use a User Monitor to Check Web Sites
- Understanding the Internal Dispatcher
- Configuring a Custom User Monitor
- Understanding Load Monitors
- Configuring Load Monitors
- Unbinding Metrics from a Metrics Table

Configuring HTTP-Inline Monitors

Apr 15, 2015

Inline monitors analyze and probe the responses from the services to which they are bound only when those services receive client requests. The inline monitor is of type HTTP-INLINE and can only be configured to work with HTTP and HTTPS services. An inline monitor determines that the service to which it is bound is UP by checking its responses to the requests that are sent to it. When no client requests are sent to the service, the inline monitor probes the service by using the configured URL.

Note: Inline monitors cannot be bound to HTTP or HTTPS Global Server Load Balancing (GSLB) remote or local services because these services represent virtual servers rather than actual load balanced Web servers.
Inline monitors have a time-out value and a retry count when probes fail. You can select any of the following action types for the NetScaler appliance to take when a failure occurs:

- **NONE.** No explicit action is taken. You can view the service and monitor, and the monitor indicates the number of current contiguous error responses and cumulative responses checked.
- **LOG.** Logs the event in ns/syslog and displays the counters.
- **DOWN.** Marks the service down and does not direct any traffic to the service. This setting breaks any persistent connections to the service. This action also logs the event and displays counters.

After the service is down, the service remains DOWN for the configured down time. After the DOWN time elapses, the inline monitor uses the configured URL to probe the service to see if it is available again. If the probe succeeds, the state of the service is changed to UP. Traffic is directed to the service, and monitoring resumes as before.

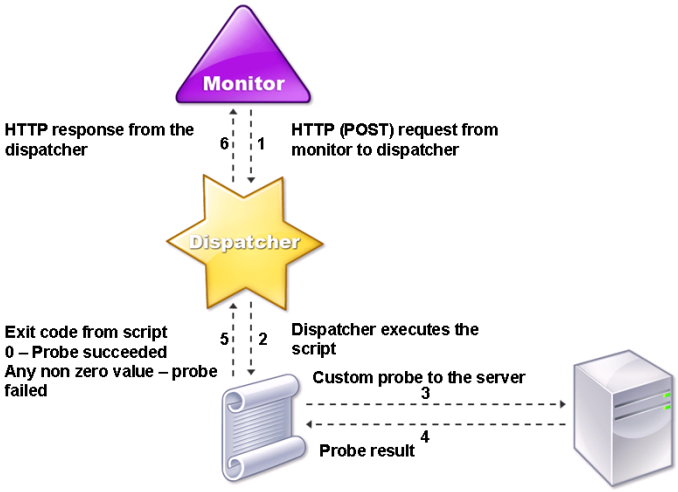
To configure inline monitors, see Configuring Monitors in a Load Balancing Setup.

Understanding User Monitors

Sep 09, 2015

User monitors extend the scope of custom monitors. You can create user monitors to track the health of customized applications and protocols that the NetScaler appliance does not support. The following diagram illustrates how a user monitor works.

Figure 1. User Monitors



A user monitor requires the following components.

- **Dispatcher**. A process, on the appliance, that listens to monitoring requests. A dispatcher can be on the loopback IP address (127.0.0.1) and port 3013. Dispatchers are also known as internal dispatchers. A dispatcher can also be a web server that supports Common Gateway Interface (CGI). Such dispatchers are also known as external dispatchers. They are used for custom scripts that do not run on the FreeBSD environment, such as .NET scripts.

  Note: You can configure the monitor and the dispatcher to use HTTPS instead of HTTP by enabling the “secure” option on the monitor and configure it as an external dispatcher. However, an internal dispatcher understands only HTTP, and cannot use HTTPS.

  In a HA setup, the dispatcher runs on both the primary and secondary NetScaler appliances. The dispatcher remains inactive on the secondary appliance.
- **Script**. The script is a program that sends custom probes to the load balanced server and returns the response code to the dispatcher. The script can return any value to the dispatcher, but if a probe succeeds, the script must return a value of zero (0). The dispatcher considers any other value as probe failure.

  The NetScaler appliance is bundled with sample scripts for commonly used protocols. The scripts exist in the /nsconfig/monitors directory. If you want to add a new script, add it there. If you want to customize an existing script, create a copy with a new name and modify it.

Important: Starting with release 10.1 build 122.17, the script files for user monitors are in a new location. If you upgrade an

MPX or VPX virtual appliance to release 10.1 build 122.17 or later, the changes are as follows:

- A new directory named conflicts is created in /nsconfig/monitors/ and all the built-in scripts of the previous builds are moved to this directory.
- All new built-in scripts are available in the /netscaler/monitors/ directory. All custom scripts are available in the /nsconfig/monitors/ directory.
- You must save a new custom script in the /nsconfig/monitors/ directory.
- After the upgrade is completed, if a custom script is created and saved in the /nsconfig/monitors/ directory, with the same name as that of a built-in script, the script in the /netscaler/monitors/ directory takes priority. That is, the custom script does not run.

If you provision a virtual appliance with release 10.1 build 122.17 or later, the changes are as follows:

- All built-in scripts are available in the /netscaler/monitors/ directory.
- The /nsconfig/monitors/ directory is empty.
- If you create a new custom script, you must save it in the /nsconfig/monitors/ directory.

For the scripts to function correctly, the name of the script file must not exceed 63 characters, and the maximum number of script arguments is 512. To debug the script, you must run it by using the nsumon-debug.pl script from the NetScaler command line. You use the script name (with its arguments), IP address, and the port as the arguments of the nsumon-debug.pl script. Users must use the script name, IP address, port, time-out, and the script arguments for the nsumon-debug.pl script.

Important: Starting with release 10.1 build 133.x, script files for user monitors support IPv6 addresses and include the following changes:

- For the following protocols, new pm files have been included for IPv6 support.
  - Radius
  - NNTP
  - POP3
  - SMTP
- The following sample scripts in /netscaler/monitors/ has been updated for IPv6 support:
  - nsbmradius.pl
  - nsldap.pl
  - nsnntp.pl
  - nspop3 nssf.pl
  - nssnmp.pl
  - nswi.pl
  - nstftp.pl
  - nssmtp.pl
  - nsrdp.pl
  - nsntlm-lwp.pl
  - nsftp.pl
  - nsappc.pl
- The following LB monitor types have been updated to support IPv6 addresses:
  - SMTP
  - NNTP
  - LDAP

- SNMP
- POP3
- FTP_EXTENDED (If you need to monitor the FTP services with IPv6 addresses, use FTP_EXTENDED monitor instead of USER monitor that uses nsftp.pl script.)

  Note: If the configured monitor is of type USER, you do not have to make any changes to your existing custom scripts.

To track the status of the server, the monitor sends an HTTP POST request to the configured dispatcher. This POST request contains the IP address and port of the server, and the script that must be executed. The dispatcher executes the script as a child process, with user-defined parameters (if any). Then, the script sends a probe to the server. The script sends the status of the probe (response code) to the dispatcher. The dispatcher converts the response code to an HTTP response and sends it to the monitor. Based on the HTTP response, the monitor marks the service as up or down.

The appliance logs the error messages to the /var/nslog/nsumond.log file when user monitor probes fail. The following table lists the user monitors and the possible reasons for failure.

User monitor type	Probe failure reasons
SMTP	Monitor fails to establish a connection to the server.
NNTP	Monitor fails to establish a connection to the server.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Monitor fails to find the NNTP group.
LDAP	Monitor fails to establish a connection to the server.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Monitor fails to bind to the LDAP server.
	Monitor fails to locate an entry for the target entity in the LDAP server.
FTP	The connection to the server times out.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.

User monitor type	Probe failure reasons
	Logon fails.
	Monitor fails to find the file on the server.
POP3	Monitor fails to establish a connection to the database.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Logon fails.
POP3	Monitor fails to establish a connection to the database.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Logon fails.
	Preparation of SQL query fails.
	Execution of SQL query fails.
SNMP	Monitor fails to establish a connection to the database.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Logon fails.
	Monitor fails to create the SNMP session.
	Monitor fails to find the object identifier.
	The monitor threshold value setting is greater than or equal to the actual threshold of the monitor.
RDP (Windows Terminal Server)	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.

User monitor type	Probe failure reasons
	Monitor fails to create a socket.
	Mismatch in versions.
	Monitor fails to confirm connection.

You can view the log file from the NetScaler command line by using the following commands, which open a BSD shell, display the log file on the screen, and then close the BSD shell and return you to the NetScaler command prompt:

```
> shell
root@ns# cat /var/nslog/nsumond.log
root@ns# exit
>
```

User monitors also have a time-out value and a retry count for probe failures. You can use user monitors with non-user monitors. During high CPU utilization, a non-user monitor enables faster detection of a server failure.

Note: If the user monitor probe times out during high CPU usage, the state of the service remains unchanged.

How to Use a User Monitor to Check Web Sites

Mar 19, 2012

You can configure a user monitor to check for specific Web site problems that are reported by HTTP servers using specific HTTP codes. The following table lists the HTTP response codes that this user monitor expects.

HTTP response code	Meaning
200 - success	Probe success.
503 - service unavailable	Probe failure.
404 - not found	Script not found or cannot execute.
500 - Internal server error	Internal error/resource constraints in dispatcher (out of memory, too many connections, unexpected system error, or too many processes). The service is not marked DOWN.
400 - bad request	Error parsing HTTP request.
502 - bad gateway	Error decoding script's response.

You configure the user monitor for HTTP by using the following parameters.

Parameter	Specifies
scriptName	The path and name of the script to execute.
scriptArgs	The strings that are added in the POST data. They are copied to the request verbatim.
dispatcherIP	The IP address of the dispatcher to which the probe is sent.
dispatcherPort	The port of the dispatcher to which the probe is sent.
localfileName	The name of a monitor script file on the local system.

Parameter	Specifies
destPath	A particular location on the NetScaler appliance where the uploaded local file is stored.

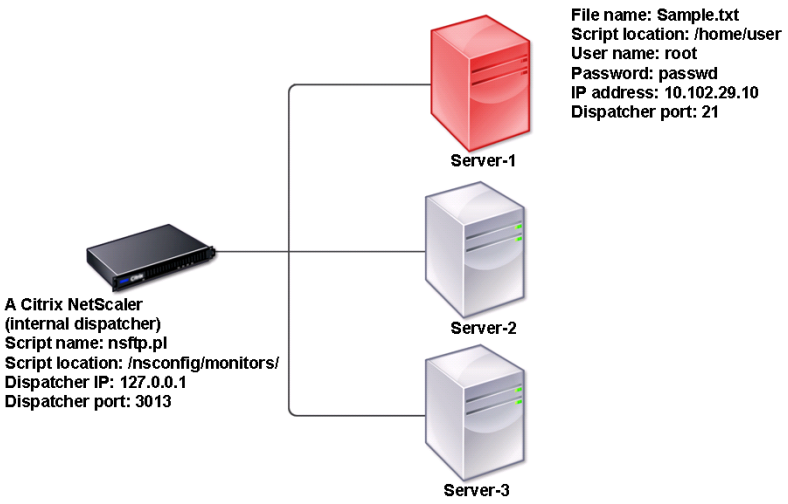
To create a user monitor to monitor HTTP, see Configuring Monitors in a Load Balancing Setup.

Understanding the Internal Dispatcher

Mar 19, 2012

You can use a custom user monitor with the internal dispatcher. Consider a case where you need to track the health of a server based on the presence of a file on the server. The following diagram illustrates this scenario.

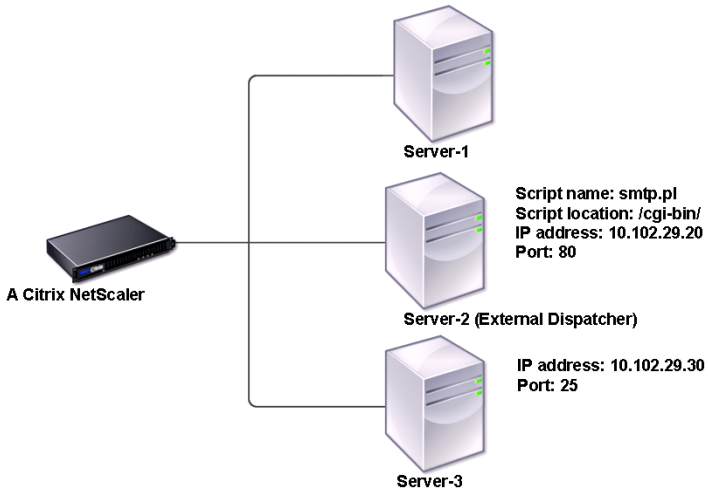
Figure 1. Using a User Monitor with the Internal Dispatcher



A possible solution is to use a Perl script that initiates an FTP session with the server and checks for the presence of the file. You can then create a user monitor that uses the Perl script. The NetScaler includes such a Perl script (nsftp.pl), in the /nsconfig/monitors/ directory.

You can use a user monitor with an external dispatcher. Consider a case where you must track the health of a server based on the state of an SMTP service on another server. This scenario is illustrated in the following diagram.

Figure 2. Using a User Monitor with an External Dispatcher



A possible solution would be to create a Perl script that checks the state of the SMTP service on the server. You can then create a user monitor that uses the Perl script.

Configuring a Custom User Monitor

Aug 24, 2016

To configure a custom user monitor, you must first write the script that performs the action that the monitor will use to check the service that is bound to it, and upload the script to the /nsconfig/monitors directory on the NetScaler appliance. Then you create the monitor on the appliance, as described below.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

To configure a user monitor by using the command line interface

At the command prompt, type:

add lb monitor <monitorName> USER -scriptname <NameOfScript> –scriptargs <Arguments>

Example

```
add monitor Monitor-User-1 USER -scriptname nsftp.pl –scriptargs "file=/home/user/
sample.txt;user=root;password=passwd"
```

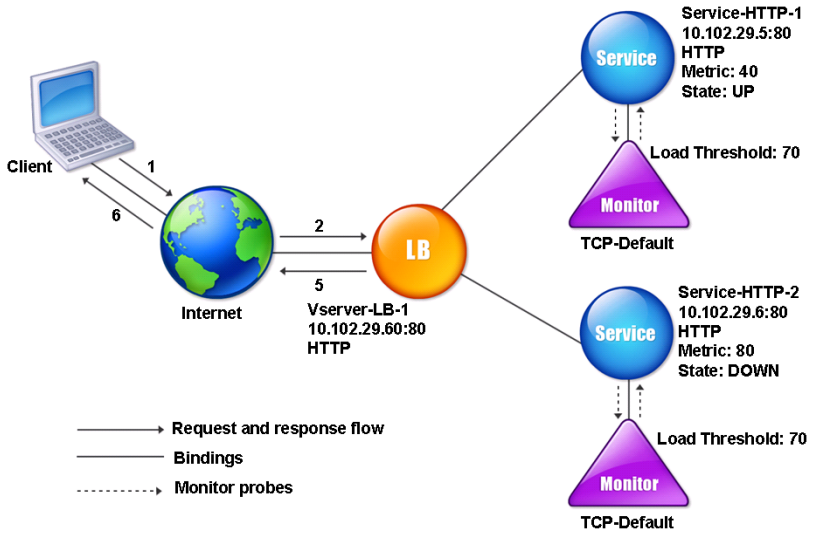
Understanding Load Monitors

Mar 19, 2012

Load monitors use SNMP polled OIDs to calculate load. The load monitor uses the IP address of the service to which it is bound (the destination IP address) for polling. It sends an SNMP query to the service, specifying the OID for a metric. The metrics can be CPU, memory, or number of server connections. The server responds to the query with a metric value. The metric value in the response is compared with the threshold value. The NetScaler appliance considers the service for load balancing only if the metric is less than the threshold value. The service with the lowest load value is considered first.

The following diagram illustrates a load monitor configured for the services described in the basic load balancing setup discussed in Setting Up Basic Load Balancing.

Figure 1. Operation of Load Monitors



Note: The load monitor does not determine the state of the service. It only enables the appliance to consider the service for load balancing.

After you configure the load monitor, you must then configure the metrics that the monitor will use. For load assessment, the load monitor considers server parameters known as metrics, which are defined within the metric tables in the appliance configuration. Metric tables can be of two types:

- **Local.** By default, this table exists in the appliance. It consists of four metrics: connections, packets, response time, and bandwidth. The appliance specifies these metrics for a service, and SNMP queries are not originated for these services. These metrics cannot be changed.
- **Custom.** A user-defined table. Each metric is associated with an OID.

By default, the appliance generates the following tables:

- NetScaler
- RADWARE
- CISCO-CSS
- LOCAL

- FOUNDRY
- ALTEON

You can either add the appliance-generated metric tables, or you can add tables of your own choosing, as shown in the following table. The values in the metric table are provided only as examples. In an actual scenario, consider the real values for the metrics.

Metric name	OIDs	Weight	Threshold
CPU	1.2.3.4	2	70
Memory	4.5.6.7	3	80
Connections	5.6.7.8	4	90

To calculate the load for one or more metrics, you assign a weight to each metric. The default weight is 1. The weight represents the priority given to each metric. If the weight is high, the priority is high. The appliance chooses a service based on the SOURCEIPDESTIP hash algorithm.

You can also set the threshold value for each metric. The threshold value enables the appliance to select a service for load balancing if the metric value for the service is less than the threshold value. The threshold value also determines the load on each service.

Configuring Load Monitors

Nov 12, 2013

To configure a load monitor, first create the load monitor. For instructions on creating a monitor, see Creating Monitors. Next, select or create the metric table to define a set of metrics that determine the state of the server, and (if you create a metric table) bind each metric to the metric table.

To create a metric table by using the command line interface

At the command prompt, type the following commands:

- add lb metricTable <metricTableName>
- bind lb metricTable <metricTableName> <metric> <SNMPOID>

Example

```
add metricTable Table-Custom-1

bind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5 11
```

To create a metric table and bind metrics to it by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Metric Tables.
2. In the details pane, click Add.
3. In the Create Metric Table dialog box, in the Metric Table Name text box, type the name of the metric table (for example, Table-Custom-1).
4. Click Create.
5. In the details pane, select the metric table that you just created (for example, Table-Custom-1), and then click Open.
6. In the Configure Metric Table dialog box, in the Metric and SNMP OID text boxes, type the metric and SNMP OID for the metric table (for example, 1.3.6.1.4.1.5951.4.1.1.41.1.5 and 11).
7. Click Add.
8. Click Close. The metric table you created appears in the Metric Tables pane.

Unbinding Metrics from a Metrics Table

Nov 12, 2013

You can unbind metrics from a metrics table if the metrics need to be changed, or if you want to remove the metrics table entirely.

To unbind metrics from a metric table by using the command line interface

At the command prompt, type:

unbind lb metricTable <metricTable> <metric>

Example

unbind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5

To unbind metrics from a metric table by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Metric Tables.
2. In the details pane, select the metric table from which you want to unbind the metrics (for example, Table-Custom-1), click Open.
3. In the Configure Metric Table dialog box, in the Bound Metrics list box, select the metric that you want to unbind from the table (for example, 1.3.6.1.4.1.5951.4.1.1.41.1.5).
4. Click Remove, and then click OK.

You can view the detail of all configured metric tables, such as name and type, to determine whether the metric table is internal or created and configured.

Removing a Load Monitoring Metric Table

Nov 12, 2013

You can remove a metric table from the NetScaler configuration.

Note: Before you can remove a metric table, you must unbind all metrics from it.

To remove a metric table by using the command line interface

At the command prompt, type:

rm lb metricTable <metricTable>

Example

rm metricTable <Table-Custom-1>

To remove a metric table by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Metric Tables.
2. In the details pane, select the metric table that you want to remove (for example, Table-Custom-1), and click Remove.
3. In the Remove dialog box, and then click Yes.

You can unbind a metric from a metric table to remove that metric from consideration.

Viewing Metrics Tables

Nov 12, 2013

You can view a metrics table and the metrics bound to it.

To view the metric tables by using the command line interface

At the command prompt, type:

show lb metricTable <metricTable>

Example

show metricTable Table-Custom-1

To view the metric tables by using the configuration utility

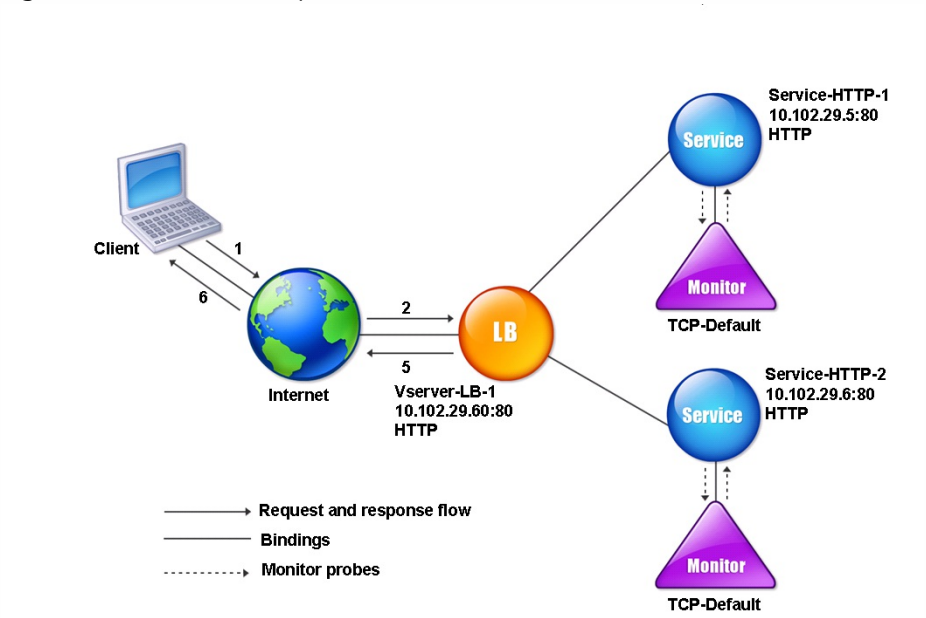
1. Navigate to Traffic Management > Load Balancing.
2. Click Metric Tables. The details of the available metric table appear on the Metric Tables pane.

Configuring Monitors in a Load Balancing Setup

Jun 09, 2015

To configure monitors on a Web site, you first decide whether to use a built-in monitor or create your own monitor. If you create a monitor, you can choose between creating a monitor based on a built-in monitor, or creating a custom monitor that uses a script that you write to monitor the service. For more information about creating custom monitors, see Custom Monitors. Once you have chosen or created a monitor, you then bind it to the appropriate service. The following conceptual diagram illustrates a basic load balancing setup with monitors.

Figure 1. How Monitors Operate



As shown above, each service has a monitor bound to it. The monitor probes the load balanced server via its service. As long as the load balanced server responds to the probes, the monitor marks it UP. If the load balanced server should fail to respond to the designated number of probes within the designated time period, the monitor marks it DOWN.

This section includes the following details:

- Creating Monitors
- Binding Monitors to Services
- Modifying Monitors
- Enabling and Disabling Monitors
- Unbinding Monitors
- Removing Monitors
- Viewing Monitors
- Closing Monitor Connections
- Ignoring the Upper Limit on Client Connections for Monitor Probes

Creating Monitors

Nov 12, 2013

The NetScaler appliance provides a set of built-in monitors. It also allows you to create custom monitors, either based on the built-in monitors or from scratch.

To create a monitor by using the command line interface

At the command prompt, type:

add lb monitor <monitorName> <monitorType> [<interval>]

Example

add lb mon monitor-HTTP-1 HTTP

add lb mon monitor-HTTP-2 TCP 2

To create a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, click Add.
3. In the Create Monitor dialog box, in the Name and Interval text boxes type the name and interval value of the monitor.
4. In the Type list, select the type of the monitor.
5. In the list next to the Interval text box, select Seconds.
6. Click Create, and then click Close. The monitor that you created appears in the Monitors pane.

Binding Monitors to Services

Nov 12, 2013

After creating a monitor, you bind it to a service. You can bind one or multiple monitors to a service. If you bind one monitor to a service, that monitor determines whether the service is marked UP or DOWN. If you bind multiple monitors to a service, the NetScaler appliance checks all monitors bound to that service using a calculation that you control, and marks the service UP or DOWN depending on the results.

Note: The destination IP address of a monitor probe can be different than the server IP address and port.

To bind a monitor to a service by using the command line interface

At the command prompt, type:

bind lb monitor <monitorName> <ServiceName>

Example

bind mon monitor-HTTP-1 Service-HTTP-1

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to bind the monitor (for example, Service-HTTP-1), and then click Open.
3. On the Monitors tab, in the Available list box, select the monitor you want to bind the service (for example, monitor-HTTP-1), and then click Add.
4. In the Configured box, click OK.

Modifying Monitors

Nov 12, 2013

You can modify the settings for any monitor that you created.

Note: Two sets of parameters apply to monitors: those that apply to all monitors, regardless of type, and those that are specific to a monitor type. For information on parameters for a specific monitor type, see the description for that type of monitor.

To modify an existing monitor by using the command line interface

At the command prompt, type:

set lb monitor <monitorName> <type> -interval <interval> -resptimeout <resptimeout>

Example

```
set mon monitor-HTTP-1 HTTP -interval 50 milli
-resptimeout 20 milli
```

To modify an existing monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, select the monitor that you want to modify (for example, monitor-HTTP-1), and then click Open.
3. On the Standard Parameters tab, in the Interval and Response Time-out text boxes, type the interval and response timeout values (for example, 50 and 20).
4. In the list next to Interval text box, select the interval (for example, Milli Seconds).
5. In the list next to Response Time-out text box, select the interval (for example, Milli Seconds).
6. Click OK.

Enabling and Disabling Monitors

Nov 12, 2013

By default, monitors bound to services and service groups are enabled. When you enable a monitor, the monitor begins probing the services to which it is bound. If you disable a monitor bound to a service, the state the service is determined using the other monitors bound to the service. If the service is bound to only one monitor, and if you disable the monitor, the state of the service is determined using the default monitor.

To enable a monitor by using the command line interface

At the command prompt, type:

enable lb monitor <monitorName>

Example

enable lb mon monitor-HTTP-1

To enable a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, select the monitor that you want to enable (for example, monitor-HTTP-1), and then click Enable.
3. In the Enable dialog box, click Yes.

To disable a monitor by using the command line interface

At the command prompt, type:

disable lb monitor <monitorName>

Example

disable lb mon monitor-HTTP-1

To disable a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, select the monitor that you want to disable (for example, monitor-HTTP-1), and then click Disable.
3. In the Disable dialog box, click Yes.

Unbinding Monitors

Nov 12, 2013

You can unbind monitors from a service and service group. When you unbind a monitor from the service group, the monitors are unbound from the individual services that constitute the service group. When you unbind a monitor from a service or a service group, the monitor does not probe the service or the service group.

Note: When you unbind all user-configured monitors from a service or a service group, the default monitor is bound to the service and the service group. The default monitors then probes the service or the service groups.

To unbind a monitor from a service by using the command line interface

At the command prompt, type:

unbind lb monitor <monitorName>

Example

unbind mon monitor-HTTP-1 Service-HTTP-1

To unbind a monitor from a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service from that you want to unbind the monitor (for example, Service-HTTP-1), click Open.
3. In the Configure Service dialog box, under Configured, select the monitor that you want to unbind from the service (for example, monitor-HTTP-1), and then click Remove.
4. Click OK.

Removing Monitors

Nov 12, 2013

After you unbind a monitor that you created from its service, you can remove that monitor from the NetScaler configuration. (If a monitor is bound to a service, it cannot be removed.)

Note: When you remove monitors bound to a service, the default monitor is bound to the service. You cannot remove default monitors.

To remove a monitor by using the command line interface

At the command prompt, type:

rm lb monitor <monitorName> <type>

Example

rm lb monitor monitor-HTTP-1 HTTP

To remove a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, select the monitor that you want to remove (for example, monitor-HTTP-1), and then click Remove.
3. In the Remove dialog box, click Yes.

Viewing Monitors

Nov 12, 2013

You can view the services and service groups that are bound to a monitor. You can verify the settings of a monitor to troubleshoot your NetScaler configuration. The following procedure describes the steps to view the bindings of a monitor to the services and service groups.

To view monitor bindings by using the command line interface

At the command prompt, type:

show lb monbindings <MonitorName>

Example

show lb monbindings monitor-HTTP-1

To view monitor bindings by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, select the monitor for which you want to view the binding information (for example, monitor-HTTP-1), and then click Show Bindings. The binding information for the monitor that you selected appears in the Binding Info for Monitor: monitor-HTTP-1 dialog box.

To view monitors by using the command line interface

At the command prompt, type:

show lb monitor <monitorName>

Example

show lb mon monitor-HTTP-1

To view monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors. The details of the available monitors appear in the Monitors pane.

Closing Monitor Connections

Aug 29, 2013

The NetScaler appliance sends probes to the services through the monitors bound to the services. By default, the monitor on the NetScaler and the physical server follow the complete handshake procedure even for monitor probes. However, this procedure adds overhead to the monitoring process and may not be always necessary.

For the TCP monitors, you can configure the NetScaler to close a monitor-probe connection after receiving SYN-ACK from the service. To do so, set the value of the monitorConnectionClose parameter to RESET. If you want the monitor-probe connection to go through the complete procedure, set the value to FIN.

Note: The monitorConnectionClose setting is applicable to all the monitors bound to all the services configured on the NetScaler appliance.

To configure monitor-connection closure by using the command line interface

At the command prompt, type:

set lb parameter -monitorConnectionClose <monitor_conn_close_option>

Example

set lb parameter -monitorConnectionClose RESET

To configure monitor-connection closure by using the configuration utility

1. Navigate to Traffic Management > Load Balancing.
2. Under Settings, click Configure Load Balancing Parameters.
3. In the Configure Load Balancing Parameters dialog box, for Connection Close for Monitor, select FIN or RESET.
4. Click OK.

Ignoring the Upper Limit on Client Connections for Monitor Probes

Aug 29, 2013

Depending on considerations such as the capacity of a physical server, you can specify a limit on the maximum number of client connections made to any service. If you have set such a limit on a service, the NetScaler appliance stops sending requests to the service when the threshold is reached and resumes sending connections to the service after the number of existing connections falls to within the limits. You can configure the NetScaler to skip this check when it sends monitor-probe connections to a service.

Note: You cannot skip the maximum-client-connections check for an individual service. If you specify this option, it applies to all the monitors bound to all the services configured on the NetScaler appliance.

To set the Skip MaxClients for Monitor Connections option by using the command line interface

At the command prompt, type:

set lb parameter -monitorSkipMaxClient (ENABLED | DISABLED)

Example

```
set lb parameter -monitorSkipMaxClient enabled
```

To set the Skip MaxClients for Monitor Connections option by using the configuration utility

1. Navigate to Traffic Management > Load Balancing.
2. Under Settings, click Configure Load Balancing Parameters.
3. To ignore the upper limit on client connections for monitor probes, in the Configure Load Balancing Parameters dialog box, select the Skip MaxClients for Monitor Connections checkbox.
4. Click OK.

Managing a Large Scale Deployment

Mar 19, 2012

The NetScaler appliance contains several features that are helpful when you are configuring a large load balancing deployment. Instead of configuring virtual servers and services individually, you can create groups of virtual servers and services. You can also create a range of virtual servers and services, and you can translate or mask virtual server and service IP addresses.

You can set persistence for a group of virtual servers. You can bind monitors to a group of services. Creating a range of virtual servers and services of identical type allows you to set up and configure those servers in a single procedure, which significantly shortens the time required to configure those virtual servers and services.

By translating or masking IP addresses, you can take down virtual servers and services, and make changes to your infrastructure, without extensive reconfiguration of your service and virtual server definitions.

Ranges of Virtual Servers and Services

Mar 19, 2012

When you configure load balancing, you can create ranges of virtual servers and services, eliminating the need to configure virtual servers and services individually. For example, you can use a single procedure to create three virtual servers with three corresponding IP addresses. When more than one argument uses a range, all of the ranges must be of the same size.

The following are the types of ranges you can specify when adding services and virtual servers to your configuration:

- **Numeric ranges.** Instead of typing a single number, you can specify a range of consecutive numbers.

  For example, you can create a range of virtual servers by specifying a starting IP address, such as 10.102.29.30, and then typing a value for the last byte that indicates the range, such as 34. In this example, five virtual servers will be created with IP addresses that range between 10.102.29.30 and 10.102.29.34.

  Note: The IP addresses of the virtual servers and services must be consecutive.
- **Alphabetic ranges.** Instead of typing a literal letter, you can substitute a range for any single letter, for example, [C-G]. This results in all letters in the range being included, in this case C, D, E, F, and G.

  For example, if you have three virtual servers named Vserver-x, Vserver-y, and Vserver-z, instead of configuring them separately, you can type vserver [x-z] to configure them all.

Creating a Range of Virtual Servers

Updated: 2013-11-12

You create a range of virtual servers as described below.

To create range of virtual servers by using the command line interface

At the command prompt, type one of the following commands:

- add lb vserver <name>@ <protocol> -range <rangeValue> <IPAddress> [<port>]
- add lb vserver <name>@**[**<rangeValue>**]**> <protocol> <IPAddress[<rangeValue>]> [<port>]

Example

```
add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
```

OR

```
> add lb vserver vserver[P-R] http 10.102.29.[26-28] 80
vserver "vserverP" added
vserver "vserverQ" added
vserver "vserverR" added
 Done
```

To create range of virtual servers by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add Range.

3. In the Create Virtual Server (Load Balancing) - Range dialog box, in the Name Prefix, IP Address Range, and Port text boxes, type the virtual server name, IP address with which to begin the range, and port.
4. Select the Network VServer check box, and in Range, type the last value of the virtual server range.
5. In the Protocol drop-down list box, select the protocol type.
6. Click Create, and then click Close. The range of virtual servers you created appears in the Load Balancing Virtual Servers pane.

Creating a Range of Services

Updated: 2013-11-12

You create a range of services as described below. If you specify a range for the service name, specify a range for the IP address too.

To create range of services by using the command line interface

At the command prompt, type the command:

add service <name>@ <IP>@ <protocol> <port>
Example

```
> add service serv[1-3] 10.102.29.[102-104] http 80
service "serv1" added
service "serv2" added
service "serv3" added
 Done
```

To create range of services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add Range.
3. In the Create Service (Range) dialog box, in the IP Address Range and Port text boxes, type the start value of the IP address range and the port.
4. In the text box next to the IP Address Range text box, type the last value of the last service (for example, 104).
5. In the Protocol drop-down list box, select the protocol type.
6. Click Create, and then click Close. The range of services you created appears in the Services pane.

Configuring Service Groups

Mar 19, 2012

Configuring a service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable any option, such as compression, health monitoring or graceful shutdown, for a service group, the option gets enabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to service groups.

The members of a service group can be identified by IP address or server name.

Using domain-name based service (DBS) group members is advantageous because you need not reconfigure the member on the NetScaler appliance if the IP address of the member changes. The appliance automatically senses such changes through the configured name server. This feature is particularly useful in cloud scenarios, where the service provider can change a physical server or change the IP address for a service. If you specify a DBS group member, the NetScaler learns the IP address dynamically.

You can bind both IP-based and DBS members to the same service group.

Note: If you use DBS service group members, make sure that either a name server is specified or a DNS server is configured on the NetScaler. A domain name will be resolved into an IP address only if the corresponding address record is present on the NetScaler or the name server.

Creating Service Groups

Updated: 2013-09-04

You can configure up to 8192 service groups on the NetScaler appliance.

To create a service group by using the command line

At the command prompt, type:

add servicegroup <ServiceGroupName> <Protocol>

Example

```
add servicegroup Service-Group-1 HTTP
```

To create a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the details pane, click Add.
3. In the Create Service Group dialog box, in the Service Group Name text box, type name of the service group.
4. In the Protocol list, select the protocol type.
5. Click Create, and then click Close. The service group you created appears in the Service Groups pane.

Binding a Service Group to a Virtual Server

Updated: 2013-11-12

When you bind a service group to a virtual server, the member services are bound to the virtual server.

To bind a service group to a virtual server by using the command line interface

At the command prompt, type:

bind lb vserver <name>@ <serviceGroupName>
Example

```
bind lb vserver Vserver-LB-1 Service-Group-1
```

To bind a service group to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server to which you want to bind the service group, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Services Groups tab.
4. In the Active column, select check box next to the service group that you want to bind to the virtual server (for example, Service-Group-1), and then click OK.

Binding a Member to a Service Group

Updated: 2013-11-12

Adding services to a service group enables the service group to manage the servers. You can add the servers to a service group by specifying the IP addresses or the names of the servers.

To add members to a service group by using the command line interface

To configure a service group, at the command prompt, type:

bind servicegroup <serviceGroupName> (<IP>@ | <serverName>) <port>
Examples

```
bind servicegroup Service-Group-1 10.102.29.30 80

bind servicegroup Service-Group-2 1000:0000:0000:0000:0005:0600:700a:888b 80

bind servicegroup CitrixEdu s1.citrite.net
```

To add members to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the details pane, select the service group to which you want to bind members, and then click Open.
3. In the Configure Service Group dialog box, under Specify Member(s), do one of the following:
   - To add a new IP based service group member, select IP Based.
   - To add a server-name based service group member, select Server Based.

   If you want to add a domain-name based service group member, select **Server Based**. With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.
4. If adding a new IP based member, in the IP Address text box, type the IP address. If the IP address uses IPv6 format, select the IPv6 check box and then enter the address in the IP Address text box.

   Note: You can add a range of IP addresses. The IP addresses in the range must be consecutive. Specify the range by entering the starting IP address in the IP Address text box (for example, 10.102.29.30). Specify the end byte of the IP address range in the text box under Range (for example, 35). In the Port text box type the port (for example, 80), and

then click Add.

5. Click OK.

Binding a Monitor to a Service Group

Updated: 2013-12-10

When you create a service group, the default monitor of the type appropriate for the group is automatically bound to it. Monitors periodically probe the servers in the service group to which they are bound and update the state of the service groups.

You can bind a different monitor of your own choice to the service group.

To bind a monitor to a service group by using the command line interface

At the command prompt, type:

bind serviceGroup <serviceGroupName> -monitorName <string> -monState (ENABLED | DISABLED)

Example

bind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1

To a bind monitor to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the details pane, select the service group for which you want to bind monitors, and then click Open.
3. On the Monitors tab, under Available, select a monitor name.
4. Click Add, and then click OK.

Managing Service Groups

Jun 04, 2015

You can change the settings of the services in a service group, and you can perform tasks such as enabling, disabling, and removing service groups. You can also unbind members from a service group.

To manage service groups, see the following sections:

- Modifying a Service Group
- Removing a Service Group
- Unbinding a Member from a Service Group
- Unbinding a Service Group from a Virtual Server
- Unbinding Monitors from Service Groups
- Enabling or Disabling a Service Group
- Viewing the Properties of a Service Group
- Viewing Service Group Statistics
- Load Balancing Virtual Servers Bound to a Service Group

Modifying a Service Group

Updated: 2013-11-12

You can modify attributes of service group members. You can set several attributes of the service group, such as maximum client, SureConnect, and compression. The attributes are set on the individual servers in the service group. You cannot set parameters on the service group such as transport information (IP address and port), weight, and server ID.

Note: A parameter you set for a service group is applied to the member servers in the group, not to individual services.

To modify a service group by using the command line interface

At the command prompt, type the following command with one or more of the optional parameters:

set servicegroup <serviceGroupName> [-type <type>] [-maxClient <maxClient>] [-maxReq <maxReq>] [-cacheable (YES | NO)] [-cip (ENABLED | DISABLED)] [-cipHeader <cipHeader>] [-usip (YES | NO)] [-sc (ON | OFF)] [-sp (ON | OFF)] [-cltTimeout <cltTimeout>] [-svrTimeout <svrTimeout>] [-cka (YES | NO)] [-TCPB (YES | NO)] [-CMP (**YES** | **NO**)] [-maxBandwidth <maxBandwidth>] [-maxThreshold <maxThreshold>] [-state (ENABLED | DISABLED)] [-downStateFlush (ENABLED | DISABLED)

Example

```
set servicegroup Service-Group-1 -type TRANSPARENT

set servicegroup Service-Group-1 -maxClient 4096

set servicegroup Service-Group-1 -maxReq 16384

set servicegroup Service-Group-1 -cacheable YES
```

To modify a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the details pane, select the service group that you want to modify (for example, Service-Group-1), and then click Open.

3. Change any of the parameters and then click OK.

Removing a Service Group

Updated: 2013-09-04

When you remove a service group, the servers bound to the group retain their individual settings and continue to exist on the NetScaler.

To remove a service group by using the command line interface

At the command prompt, type:

rm servicegroup <ServiceGroupName>
Example

rm servicegroup Service-Group-1

To remove a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the details pane, select the service group that you want to remove (for example, Service-Group-1), and then click Remove.
3. In the Remove dialog box, click Yes.

Unbinding a Member from a Service Group

Updated: 2013-11-12

When you unbind a member from the service group, the attributes set on the service group will no longer apply to the member that you unbound. The member services retains its individual settings, however, and continues to exist on the NetScaler.

To unbind members from a service group by using the command line interface

At the command prompt, type:

unbind servicegroup <serviceGroupName> <IP>@ [<port>]
Example

unbind servicegroup Service-Group-1 10.102.29.30 80

To unbind members from a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the details pane, select the service group from which you want to unbind members, and then click Open.
3. In the Configure Service Group dialog box, in the Configured Members list box, select a service.
4. Click Remove, and then click OK.

Unbinding a Service Group from a Virtual Server

Updated: 2013-11-12

When you unbind a service group from a virtual server, the member services are unbound from the virtual server and

continue to exist on the NetScaler appliance.

To unbind a service group from a virtual server by using the command line interface

At the command prompt, type:

unbind lb vserver <name>@ <ServiceGroupName>
Example

```
unbind lb vserver Vserver-LB-1 Service-Group-1
```

To unbind a service group from a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server from which you want to unbind the service group, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Services Group tab.
4. Clear the Active check box next to the service group that you want to unbind from the virtual server (for example, Service-Group-1).
5. Click OK.

Unbinding Monitors from Service Groups

Updated: 2013-12-10

When you unbind a monitor from a service group, the monitor that you unbound no longer monitors the individual services that constitute the group.

To unbind a monitor from a service group using the command line interface

At the command prompt, type:

unbind serviceGroup <serviceGroupName> -monitorName <string>
Example

```
unbind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
```

To unbind a monitor from a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the details pane, select the service group from which you want to unbind the monitor, click Open.
3. In the Configure Service Group dialog box, click the Monitors tab.
4. Under Configured, select the monitor that you want to unbind from the service group, and then click Remove.
5. Click OK.

Enabling or Disabling a Service Group

Updated: 2013-09-04

When you enable a service group and the servers, the services belonging to the service group are enabled. Similarly, when a service belonging to a service group is enabled, the service group and the service are enabled. By default, service groups are enabled.

After disabling an enabled service, you can view the service using the configuration utility or the command line to see the amount of time that remains before the service goes DOWN.

To disable a service group by using the command line interface

At the command prompt, type:

disable servicegroup <ServiceGroupName>
Example

```
disable servicegroup Service-Group-1
```

To disable a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the Service Groups pane, select the service group that you want to disable, and then click Disable.
3. In the Wait Time dialog box type the wait time value.
4. Click Enter.

To enable a service group by using the command line interface

At the command prompt, type:

enable servicegroup <ServiceGroupName>
Example

```
enable servicegroup Service-Group-1
```

To enable a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the Service Groups pane, select the service group that you want to enable (for example, Service-Group-1), and then click Enable.
3. In the Enable dialog box, click Yes.

Viewing the Properties of a Service Group

Updated: 2013-09-04

You can view the following settings of the configured service groups: name, IP address, state, protocol, maximum client connections, maximum requests per connection, maximum bandwidth, and monitor threshold. Viewing the details of the configuration can be helpful for troubleshooting your configuration.

To view the properties of a service group by using the command line interface

At the command prompt, type one of the following commands to display the group properties or the properties and the group members:

- show servicegroup <ServiceGroupName>
- show servicegroup <ServiceGroupName> -includemembers

Example

```
show servicegroup Service-Group-1
```

To view the properties of a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the details pane, click the name of the service group whose properties you want to view, and then click Open.

Viewing Service Group Statistics

Updated: 2013-09-04

You can view service-group statistical data, such as rate of requests, responses, request bytes, and response bytes. The NetScaler appliance uses the statistics of a service group, such as these, to balance the load on the services.

To view the statistics of a service group by using the command line interface

At the command prompt, type:

stat servicegroup <ServiceGroupName>
Example

```
stat servicegroup Service-Group-1
```

To view the statistics of a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the details pane, select the service group for which statistics you want to view (for example, Service-Group-1), and then click Statistics. The statistics of the service group you selected appear in a new window.

Load Balancing Virtual Servers Bound to a Service Group

Updated: 2013-09-04

In large-scale deployments, the same service group can be bound to multiple load balancing virtual servers. In such a case, instead of viewing each virtual server to see the service group it is bound to, you can view a list of all the load balancing virtual servers bound to a service group. You can view the following details of each virtual server:

- Name
- State
- IP address
- Port

To display the virtual servers bound to a service group by using the command line interface

At the command prompt, type the following command to display the virtual servers bound to a service group:

show servicegroupbindings <serviceGroupName>
Example

```
> show servicegroupbindings SVCGRPDTLS
SVCGRPDTLS - State :ENABLED
1) Test-pers (10.10.10.3:80) - State : DOWN
```

```
2) BRVSERV (10.10.1.1:80) - State : DOWN
3) OneMore (10.102.29.136:80) - State : DOWN
4) LBVIP1 (10.102.29.66:80) - State : UP
Done
>
```

To display the virtual servers bound to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and then click Show Bindings. The Binding details for Service Group box then displays all the load balancing virtual servers bound to the selected service group.

Configuring Automatic Domain Based Service Group Scaling

Sep 04, 2013

A domain based service group consists of members whose IP addresses are obtained by resolving the domain names of servers that are bound to the service group. The domain names are resolved by a name server whose details you configure on the appliance. A domain based service group can also include IP-address based members.

The process of name resolution for a domain based server might return more than one IP address. The number of IP addresses in the DNS response is determined by the number of address (A) records configured for the domain name, on the name server. Even if the name resolution process returns multiple IP addresses, only one IP address is bound to the service group. To scale up or scale down a service group, you need to manually bind and unbind additional domain based servers to and from the service group, respectively.

However, you can configure a domain based service group to scale automatically on the basis of the complete set of IP addresses returned by a DNS name server for a domain based server. To configure automatic scaling, when binding a domain based server to a service group, enable the automatic scaling option. Following are the steps for configuring a domain based service group that scales automatically:

- Add a name server for resolving domain names. For more information about configuring a name server on the appliance, see Adding a Name Server.
- Add a domain based server. For information about adding a domain based server, see Adding a Server.
- Add a service group and associate the domain based server to the service group, with the autoscale option set to DNS. For information about adding a service group, see Configuring Service Groups.

When a domain based server is bound to a service group and the automatic scaling option is set on the binding, a UDP monitor and a TCP monitor are automatically created and bound to the domain based server. The two monitors function as resolvers. The TCP monitor is disabled by default, and the appliance uses the UDP monitor to send DNS queries to the name server to resolve the domain name. If the DNS response is truncated (has the TC flag set to 1), the appliance falls back to TCP and uses the TCP monitor to send the DNS queries over TCP. Thereafter, the appliance continues to use only the TCP monitor.

The DNS response from the name server might contain multiple IP addresses for the domain name. With the automatic scaling option set, the appliance polls each of the IP addresses by using the default monitor, and then includes in the service group only those IP addresses that are up and available. After the IP address records expire, as defined by their time-to-live (TTL) values, the UDP monitor (or the TCP monitor, if the appliance has fallen back to using the TCP monitor) queries the name server for domain resolution and includes any new IP addresses in the service group. If an IP address that is part of the service group is not present in the DNS response, the appliance removes that address from the service group after gracefully closing existing connections to the group member, a process during which it does not allow any new connections to be established with the member. If a domain name that resolved successfully in the past results in an NXDOMAIN response, all the service group members associated with that domain are removed.

Static (IP-address based) members and dynamically scaling domain based members can coexist in a service group. You can also bind members with different domain names to a service group with the automatic scaling option set. However, each domain name associated with a service group must be unique within the service group. You must enable the automatic scaling option for each domain based server that you want to use for automatic service group scaling. If an IP address is common to one or more domains, the IP address is added to the service group only once.

To configure a service group to scale automatically by using the command line interface

At the command prompt, type the following commands to configure the service group and verify the configuration:

- bind serviceGroup <serviceGroupName> <serverName> <port> -autoScale (**YES** | **NO**)
- show serviceGroup <serviceGroupName>

Example

In the following example, server1 is a domain based server. The DNS response contains multiple IP addresses. Five addresses are available and are added to the service group.

```
> bind serviceGroup servGroup server1 80 -autoScale YES
 Done
> sh servicegroup servGroup
      servGroup - HTTP
       State: ENABLED  Monitor Threshold : 0
           . . .
           . . .
       1)  192.0.2.31:80   State: UP      Server Name: server1 (Auto scale)   Server ID: None Weight: 1

            Monitor Name: tcp-default      State: UP
            Probes: 2      Failed [Total: 0 Current: 0]
            Last response: Success - TCP syn+ack received.

       2)  192.0.2.32:80   State: UP      Server Name: server1 (Auto scale)   Server ID: None Weight: 1

            Monitor Name: tcp-default      State: UP
            Probes: 2      Failed [Total: 0 Current: 0]
            Last response: Success - TCP syn+ack received.

       3)  192.0.2.36:80   State: UP      Server Name: server1 (Auto scale)   Server ID: None Weight: 1

            Monitor Name: tcp-default      State: UP
            Probes: 2      Failed [Total: 0 Current: 0]
            Last response: Success - TCP syn+ack received.

       4)  192.0.2.55:80   State: UP      Server Name: server1 (Auto scale)   Server ID: None Weight: 1

            Monitor Name: tcp-default      State: UP
            Probes: 2      Failed [Total: 0 Current: 0]
            Last response: Success - TCP syn+ack received.

       5)  192.0.2.80:80   State: UP      Server Name: server1 (Auto scale)   Server ID: None Weight: 1

            Monitor Name: tcp-default      State: UP
            Probes: 2      Failed [Total: 0 Current: 0]
            Last response: Success - TCP syn+ack received.
 Done
```

To configure a service group to scale automatically by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In the details pane, do one of the following:
   - To create a domain based service, click Add.
   - To bind a domain based server to an existing service group, click the name of the service group, and then click Open.
3. In the Create Service Group or Configure Service Group dialog box, set the following parameters:
   - Server Based (Specifies that you want to bind a domain based server to the service group. A list that contains all the IP addresses and servers configured on the NetScaler appliance appears. Select the domain based server that you want.)
   - Port
   - Auto Scale
     After you set the parameters, to bind the server to the service group, click Add.
4. Click Create or OK, and then click Close.

Translating the IP Address of a Domain-Based Server

Nov 12, 2013

To simplify maintenance on the NetScaler appliance and on the domain-based servers that are connected to it, you can configure IP address masks and translation IP addresses. These functions work together to parse incoming DNS packets and substitute a new IP address for a DNS-resolved IP address.

When configured for a domain-based server, IP address translation enables the appliance to locate an alternate server IP address in the event that you take the server down for maintenance or if you make any other infrastructure changes that affect the server.

When configuring the mask, you must use standard IP mask values (a power of two, minus one) and zeros, for example, 255.255.0.0. Non-zero values are only permitted in the starting octets.

When you configure a translation IP for a server, you create a 1:1 correspondence between a server IP address and an alternate server that shares leading or trailing octets in its IP address. The mask blocks particular octets in the original server's IP address. The DNS-resolved IP address is transformed to a new IP address by applying the translation IP address and the translation mask.

For example, you can configure a translation IP address of 10.20.0.0 and a translation mask of 255.255.0.0. If a DNS-resolved IP address for a server is 40.50.27.3, this address is transformed to 10.20.27.3. In this case, the translation IP address supplies the first two octets of the new address, and the mask passes through the last two octets from the original IP address. The reference to the original IP address, as resolved by DNS, is lost. Monitors for all services to which the server is bound also report on the transformed IP address.

When configuring a translation IP address for a domain-based server, you specify a mask and an IP address to which the DNS-resolved IP address is to be translated.

Note: Translation of the IP address is only possible for domain-based servers. You cannot use this feature for IP-based servers. The address pattern can be based on IPv4 addresses only.

To configure a translation IP address for a server by using the command line interface

At the command prompt, type:

add server <name>@ <serverDomainName> -translationIp <translationIPAddress> -translationMask <netMask> -state <ENABLED|DISABLED>

Example

```
add server myMaskedServer www.example.com -translationIp 10.10.10.10 -translationMask
255.255.0.0 -state ENABLED
```

To configure a translation IP address for a server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Servers.
2. In the details pane, click Add.
3. In the Create Server dialog box, in the Server Name field, enter a name.
4. In the IP Address / Domain Name field, enter the server's domain name.
   Note: Do not enter an IP address if you are entering a mask.
5. In the Translation IP Address field, enter the IP address of a server on the same subnet.
6. In the Translation Mask field, enter a valid mask (for example, 255.255.0.0).

7. Click Create.

Masking a Virtual Server IP Address

Nov 12, 2013

You can configure a mask and a pattern instead of a fixed IP address for a virtual server. This enables traffic that is directed to any of the IP addresses that match the mask and pattern to be rerouted to a particular virtual server. For example, you can configure a mask that allows the first three octets of an IP address to be variable, so that traffic to 111.11.11.198, 22.22.22.198, and 33.33.33.198 is all sent to the same virtual server.

By configuring a mask for a virtual server IP address, you can avoid reconfiguration of your virtual servers due to a change in routing or another infrastructure change. The mask allows the traffic to continue to flow without extensive reconfiguration of your virtual servers.

The mask for a virtual server IP address works somewhat differently from the IP pattern definition for a server described in Translating the IP Address of a Domain-Based Server. For a virtual server IP address mask, a non-zero mask is interpreted as an octet that is considered. For a service, the non-zero value is blocked.

Additionally, for a virtual server IP address mask, either leading or trailing values can be considered. If the virtual server IP address mask considers values from the left of the IP address, this is known as a forward mask. If the mask considers the values to the right side of the address, this is known as a reverse mask.

Note: The NetScaler appliance evaluates all forward mask virtual servers before evaluating reverse mask virtual servers. When masking a virtual server IP address, you also need to create an IP address pattern for matching incoming traffic with the correct virtual server. When the appliance receives an incoming IP packet, it matches the destination IP address in the packet with the bits that are considered in the IP address pattern, and after it finds a match, it applies the IP address mask to construct the final destination IP address.

Consider the following example:

- Destination IP address in the incoming packet: 10.102.27.189
- IP address pattern: 10.102.0.0
- IP mask: 255.255.0.0
- Constructed (final) destination IP address: 10.102.27.189.

In this case, the first 16 bits in the original destination IP address match the IP address pattern for this virtual server, so this incoming packet is routed to this virtual server.

If a destination IP address matches the IP patterns for more than one virtual server, the longest match takes precedence. Consider the following example:

- Virtual Server 1: IP pattern 10.10.0.0, IP mask 255.255.0.0
- Virtual Server 2: IP pattern 10.10.10.0, IP mask 255.255.255.0
- Destination IP address in the packet: 10.10.10.45.
- Selected virtual server: Virtual Server 2.

The pattern associated with Virtual Server 2 matches more bits than that associated with Virtual Server 1, so IPs that match it will be sent to Virtual Server 2.

Note: Ports are also considered if a tie-breaker is required.

To configure a virtual server IP address mask by using the command line interface

At the command prompt, type:

add lb vserver <name>@ http -ipPattern <ipAddressPattern> -ipMask <ipMask> <listenPort>

Example

Pattern matching based on prefix octets:

```
add lb vserver myLBVserver http -ippattern 10.102.0.0 -ipmask 255.255.0.0 80
```

Pattern matching based on trailing octets:

```
add lb vserver myLBVserver1 http -ippattern 0.0.22.74 -ipmask 0.0.255.255 80
```

Modify a pattern-based virtual server:

```
set lb vserver myLBVserver1 -ippattern 0.0.22.74 -ipmask 0.0.255.255
```

To configure a virtual server IP address mask by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server dialog box, in the Name field, enter a name.
4. In the Protocol field, select the protocol.
5. In the Port field, enter the listen port.
6. In the IP Pattern field, enter a pattern for an IP address. The fixed part of the pattern must be entered in contiguous octets. Enter zeros for the pattern values that can vary in the IP address.
7. In the IP Mask field, enter a standard network mask. Use non-zero mask values for the portion of the IP address that constitutes the fixed part of the pattern.

Configuring Load Balancing for Commonly Used Protocols

Jun 05, 2015

In addition to Web sites and Web-based applications, other types of network-deployed applications that use other common protocols often receive large amounts of traffic and therefore benefit from load balancing. Several of these protocols require specific configurations for load balancing to work properly. Among them are FTP, DNS, SIP, and RTSP.

If you configure your NetScaler appliance to use domain names for your servers rather than IPs, you may also need to set up IP translation and masking for those servers.

To configure load balancing for commonly used protocols, see the following sections:

- Load Balancing for a Group of FTP Servers
- Load Balancing DNS Servers
- Load Balancing Domain-Name Based Services
- Load Balancing a Group of SIP Servers
- Load Balancing RTSP Servers
- Load Balancing of Remote Desktop Protocol (RDP) Servers

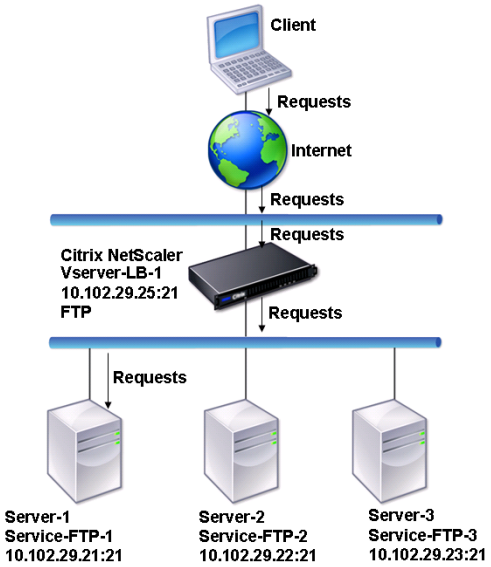
Load Balancing for a Group of FTP Servers

Feb 11, 2015

The NetScaler appliance can be used to load balance FTP servers. FTP requires that the user initiate two connections on two different ports to the same server: the control connection, through which the client sends commands to the server, and the data connection, through which the server sends data to the client. When the client initiates an FTP session by opening a control connection to the FTP server, the appliance uses the configured load balancing method to select an FTP service, and forwards the control connection to it. The load balanced FTP server then opens a data connection to the client for information exchange.

The following diagram describes the topology of a load balancing configuration for a group of FTP servers.

Figure 1. Basic Load Balancing Topology for FTP Servers



In the diagram, the services Service-FTP-1, Service-FTP-2, and Service-FTP-3 are bound to the virtual server Vserver-LB-1. Vserver-LB-1 forwards the client's connection request to one of the services using the least connection load balancing method. Subsequent requests are forwarded to the service that the appliance initially selected for load balancing.

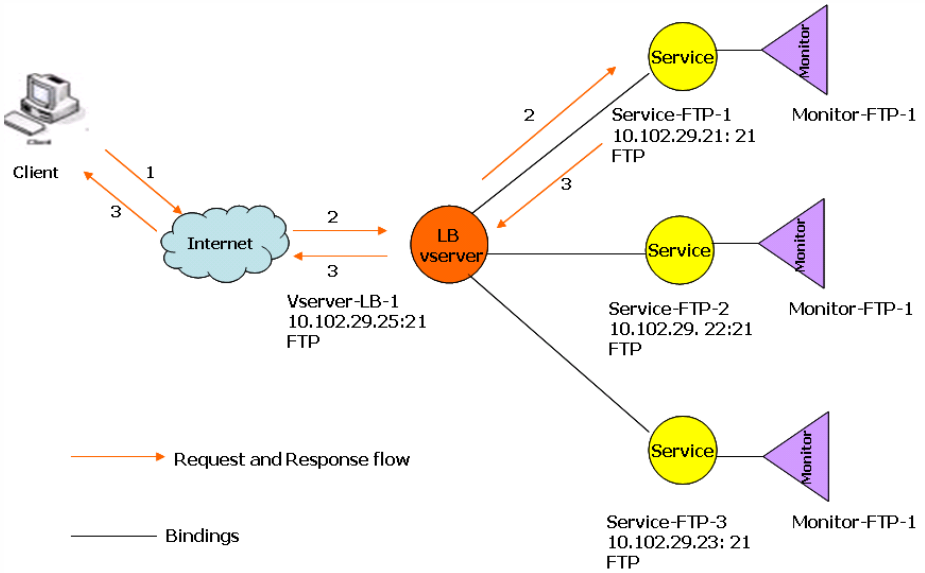
The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Vserver	Vserver-LB-1	10.102.29.25	21	FTP
Services	Service-FTP-1	10.102.29.21	21	FTP
	Service-FTP-2	10.102.29.22	21	FTP
	Service-FTP-3	10.102.29.23	21	FTP

Entity type	Name	IP address	Port	Protocol
Monitors	FTP	None	None	None

The following diagram shows the load balancing entities, and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing FTP Servers Entity Model



The appliance can also provide a passive FTP option to access FTP servers from outside of a firewall. When a client uses the passive FTP option and initiates a control connection to the FTP server, the FTP server also initiates a control connection to the client. It then initiates a data connection to transfer a file through the firewall.

To create services and virtual servers of type FTP, see Setting Up Basic Load Balancing. Name the entities and set the parameters to the values described in the columns of the previous table. When you configure a basic load balancing setup, a default monitor is bound to the services.

Next, bind the FTP monitor to the services by following the procedure described in the section Binding Monitors to Services.

To create FTP monitors by using the command line interface

At the command prompt, type:

add lb monitor <MonitorName> FTP -interval <Interval> -userName <UserName> -password <Password>

Example

add lb monitor monitor-FTP-1 FTP -interval 360 -userName User -password User

To create FTP monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. On the Standards Parameters tab, in the Name and Interval text boxes, type the monitor name and interval.
4. In the Type list, select FTP.
5. On the Special Parameters tab, in the User Name and Password text boxes, type User.
6. Click Create, and then click Close. The monitor that you created appears in the Monitors pane.

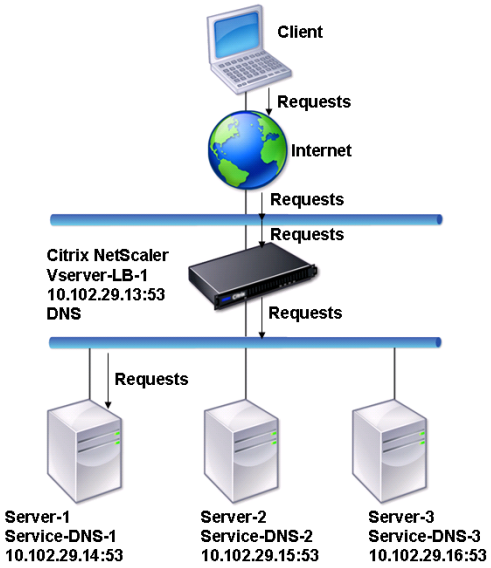
Load Balancing DNS Servers

Sep 03, 2013

When you request DNS resolution of a domain name, the NetScaler appliance uses the configured load balancing method to select a DNS service. The DNS server to which the service is bound then resolves the domain name and returns the IP address as the response. The appliance can also cache DNS responses and use the cached information to respond to future requests for resolution of the same domain name. Load balancing DNS servers improves DNS response times.

The following diagram describes the topology of a load balancing configuration that load balances a group of DNS services.

Figure 1. Basic Load Balancing Topology for DNS Servers

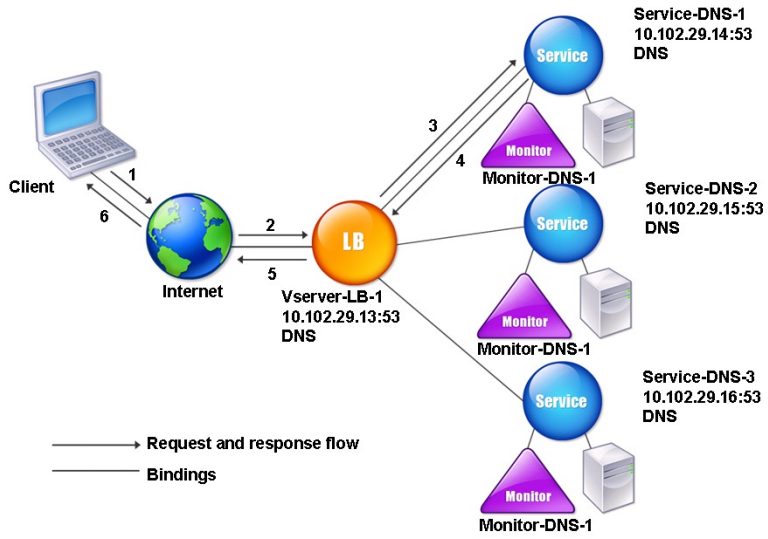


In the diagram, the services Service-DNS-1, Service-DNS-2, and Service-DNS-3 are bound to the virtual server Vserver-LB-1. The virtual server Vserver-LB-1 forwards client requests to a service using the least connection load balancing method. The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.13	53	DNS
Services	Service-DNS-1	10.102.29.14	53	DNS
	Service-DNS-2	10.102.29.15	53	DNS
	Service-DNS-3	10.102.29.16	53	DNS
Monitors	monitor-DNS-1	None	None	None

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DNS Servers Entity Model



To configure a basic DNS load balancing setup, see Setting Up Basic Load Balancing. Follow the procedures to create services and virtual servers of type DNS, naming the entities and setting the parameters using the values described in the previous table. When you configure a basic load balancing setup, the default ping monitor is bound to the services. For instructions on binding a DNS monitor to DNS services, you can also see Binding Monitors to Services.

The following procedure describes the steps to create a monitor that maps a domain name to the IP address based on a query.

To configure DNS monitors by using the command line interface

At the command prompt, type:

add lb monitor <monitorName> DNS -query <domainName> -queryType <**Address** | **ZONE**> -IPAddress <ipAddress>
Example

```
add lb monitor monitor-DNS-1 DNS -query www.citrix.com -queryType Address -IPAddress 10.102.29.66

add lb monitor monitor-DNS-2 DNS -query www.citrix2.com -queryType Address -IPAddress
1000:0000:0000:0000:0005:0600:700a::888b-888d
```

To configure DNS monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, in the Name and Interval text boxes, type a monitor name and a monitoring interval.
4. Select the unit of time for the interval in the drop-down menu.
5. In the Type list, select DNS.
6. Click the Special Parameters tab, in the Query text box type the domain name query to send to the DNS service (for example, www.mycompany.com), and in the Query Type list box, select ADDRESS or ZONE.

7. In the text box below the Query Type list box, type an IP address that is to be checked against the response to the DNS monitoring query (for example, 10.102.29.66), and click Add.
   Note: If you want to enter an IPv6 address, select the IPv6 check box before entering the address.
8. Click Create, and then click Close. The monitor that you created appears in the Monitors pane.

Load Balancing Domain-Name Based Services

Nov 12, 2013

When you create a service for load balancing, you can provide an IP address. Alternatively, you can create a server using a domain name. The server name (domain name) can be resolved using an IPv4 or IPv6 name server, or by adding an authoritative DNS record (A record for IPv4 or AAAA record for IPv6) to the NetScaler configuration.

When you configure services with domain names instead of IPs, if you change the IP address of a server in your load balancing setup, the name server resolves the domain name to the new IP address. The monitor runs a health check on the new IP address, and updates the service IP address only when the IP address is found to be healthy.

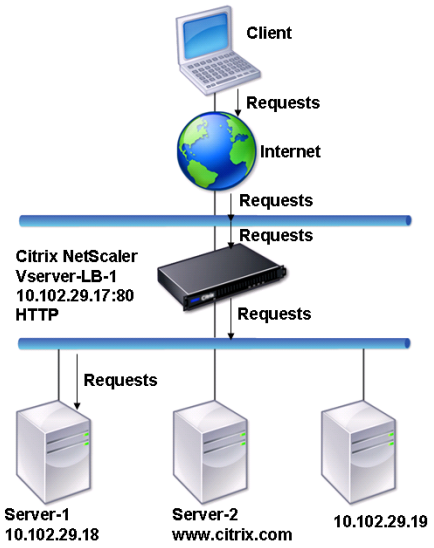
Note: When you change the IP address of a server, the corresponding service is marked down for the first client request. The name server resolves the service IP address to the changed IP address for the next request, and the service is marked UP.

Domain-name based services have the following restrictions:

- The maximum domain name length is 255 characters.
- The Maximum Client parameter is used to configure a service that represents the domain name-based server. For example, a maxClient of 1000 is set for the services bound to a virtual server. When the connection count at the virtual server reaches 2000, the DNS resolver changes the IP address of the services. However, because the connection counter on the service is not reset, the virtual server cannot take any new connections until all the old connections are closed.
- When the IP address of the service changes, persistence is difficult to maintain.
- If the domain name resolution fails due to a timeout, the appliance uses the old information (IP address).
- When monitoring detects that a service is down, the appliance performs a DNS resolution on the service (representing the domain name-based server) to obtain a new IP address.
- Statistics are collected on a service and are not reset when the IP address changes.
- If a DNS resolution returns a code of “name error” (3), the appliance marks the service down and changes the IP address to zero.

When the appliance receives a request for a service, it selects the target service. This way, the appliance balances load on your services. The following diagram describes the topology of a load balancing configuration that load balances a group of domain-name based servers (DBS).

Figure 1. Basic Load Balancing Topology for DBS Servers



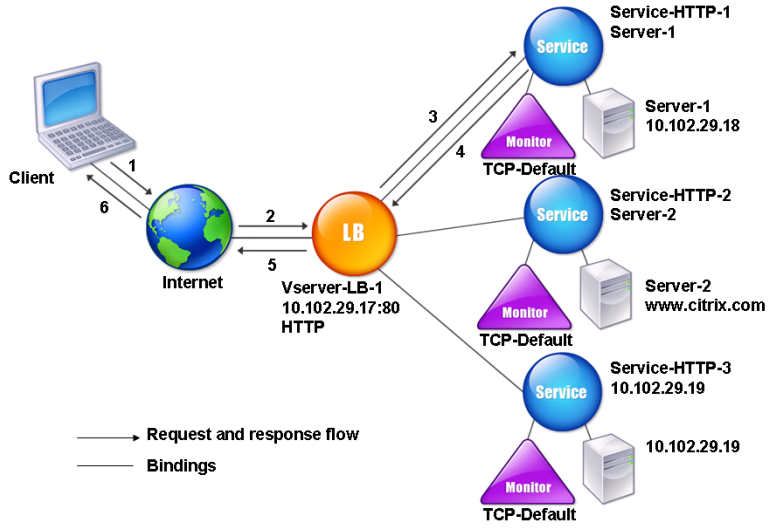
The services Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 are bound to the virtual server Vserver-LB-1. The vserver Vserver-LB-1 uses the least connection load balancing method to choose the service. The IP address of the service is resolved using the name server Vserver-LB-2.

The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.17	80	HTTP
	Vserver-LB-2	10.102.29.20	53	DNS
Servers	server-1	10.102.29.18	80	HTTP
	server-2	www.citrix.com	80	HTTP
Services	Service-HTTP-1	server-1	80	HTTP
	Service-HTTP-2	server-2	80	HTTP
	Service-HTTP-2	10.102.29.19	80	HTTP
Monitors	Default	None	None	None
Name Server	None	10.102.29.19	None	None

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DBS Servers Entity Model



To configure a basic load balancing setup, see Setting Up Basic Load Balancing. Create the services and virtual servers of type HTTP, and name the entities and set the parameters using the values described in the previous table.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

To add a name server by using the command line interface

At the command prompt, type:

add dns nameServer <dnsVserverName>

Example

add dns nameServer Vserver-LB-2

To add a name server by using the configuration utility

1. Navigate to Traffic Management > DNS > Name Servers.
2. In the details pane, click Add.
3. In the Create Name Server dialog box, select DNS Virtual Server.
4. In the DNS Virtual Server drop-down list, select the server name.
   Note: Click New if you want to create a new load balancing vserver. The Create Virtual Server (Load Balancing) dialog box appears.
5. Click Create, and then click Close.

You can also add an authoritative name server that resolves the domain name to an IP address.

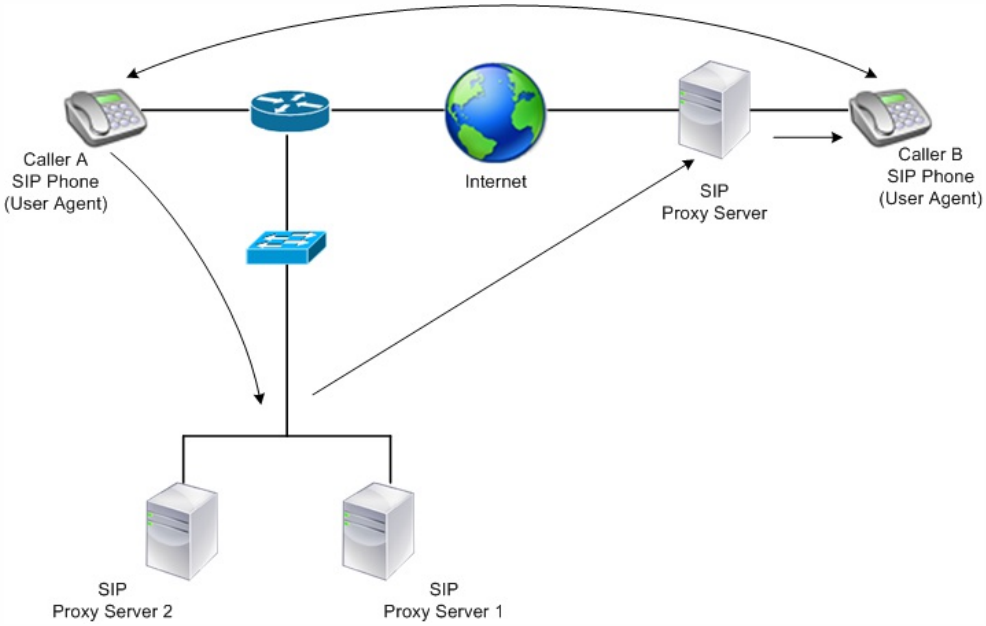
Load Balancing a Group of SIP Servers

Dec 09, 2014

The Session Initiation Protocol (SIP) is designed to initiate, manage, and terminate multimedia communications sessions. It has emerged as the standard for Internet telephony (VoIP). SIP messages can be transmitted over TCP or UDP. SIP messages are of two types: request messages and response messages.

The traffic in a SIP based communication system is routed through dedicated devices and applications (entities). In a multimedia communication session, these entities exchange messages. The following figure shows a basic SIP based communication system:

Figure 1. SIP Based Communication System



A NetScaler ADC enables you to load balance SIP messages over UDP or over TCP (including TLS). You can configure the NetScaler ADC to load balance SIP requests to a group of SIP proxy servers. To do so, you create a load balancing virtual server with the load balancing method and the type of persistence set to one of the following combinations:

- Call-ID hash load balancing method with no persistence setting
- Call-ID based persistence with least connection or round robin load balancing method
- Rule based persistence with least connection or round robin load balancing method

Also, by default, the NetScaler ADC appends RPORT to the via header of the SIP request, so that the server sends the response back to the source IP address and port from which the request originated.

Note: For load balancing to work, you must configure the SIP proxies so that they do not add private IP addresses or private domains to the SIP header/payload. SIP proxies must add to the SIP header a domain name that resolves to the IP address of the SIP virtual server. Also, the SIP proxies must communicate with a common database to share registration information.

Server Initiated Traffic

For SIP-server initiated outbound traffic, configure RNAT on the NetScaler ADC so that the private IP addresses used by the clients are translated into public IP addresses.

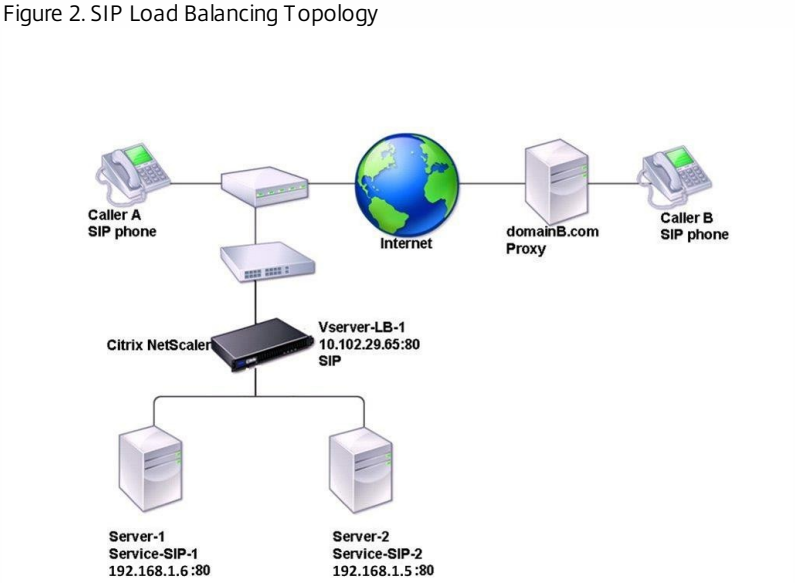
If you have configured SIP parameters that include the RNAT source or destination port, the appliance compares the values of the source and destination ports of the request packets with the RNAT source port and RNAT destination port. If one of the values matches, the appliance updates the VIA header with RPORT. The SIP response from the client then traverses the same path as the request.

For server-initiated SSL traffic, the NetScaler ADC uses a built-in certificate-key pair. If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named **nsrnatsip-127.0.0.1-5061**.

Support for Policies and Expressions

The NetScaler default expressions language contains a number of expressions that operate on Session Initiation Protocol (SIP) connections. These expressions can be bound only to SIP based (`sip_udp`, `sip_tcp` or `sip_ssl`) virtual servers, and to global bind points. You can use these expressions in content switching, rate limiting, responder, and rewrite policies.
For more information, see SIP Expressions.

Figure 2. SIP Load Balancing Topology

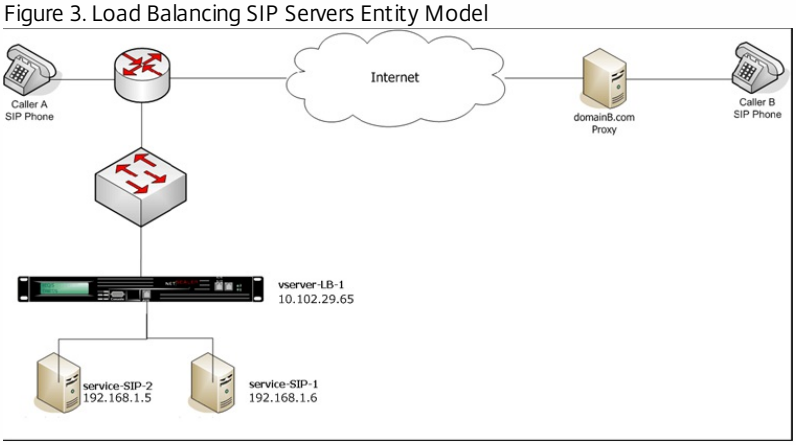


In the example, the services Service-SIP-1 and Service-SIP-2 are bound to the virtual server Vserver-LB-1. The following table lists the names and values of the entities that you need to configure on the appliance in inline mode (also called two-arm mode).

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.65	80	SIP-UDP
Services	Service-SIP-1	192.168.1.6	80	SIP-UDP
	Service-SIP-2	192.168.1.5	80	SIP-UDP
Monitors	Default	None	80	SIP-UDP

The following diagram shows the load balancing entities and the values of the parameters to be configured on the appliance.

Figure 3. Load Balancing SIP Servers Entity Model



To configure a basic load balancing setup for SIP, see Setting Up Basic Load Balancing. You create services and virtual servers of type SIP-UDP, naming the entities and setting the parameters as described in the previous table. You must then configure RNAT.

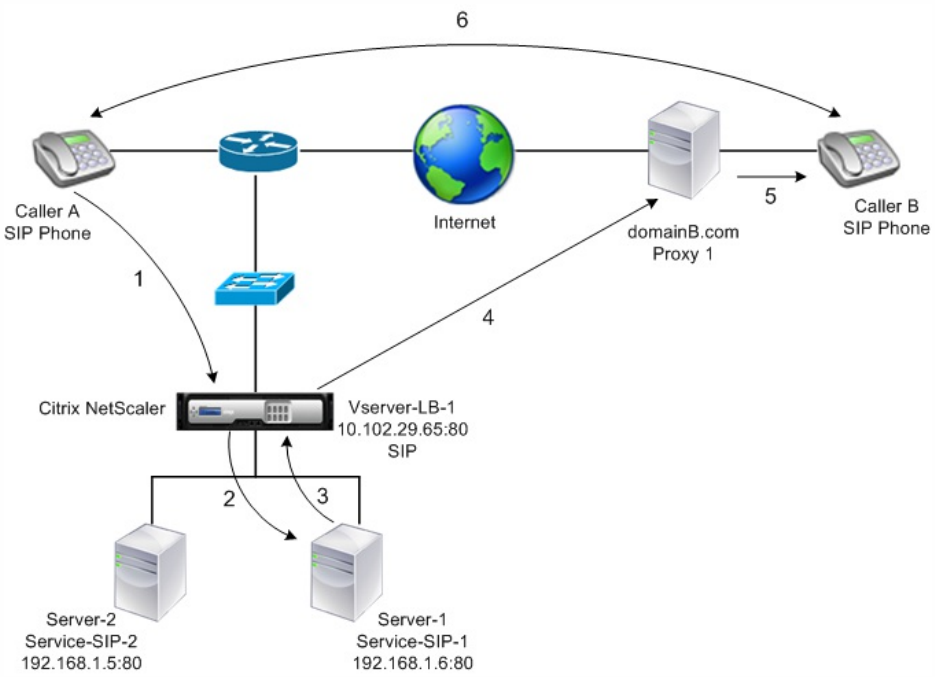
Configuring Load Balancing for SIP Signaling Traffic over TCP or UDP

The NetScaler ADC can load balance SIP servers that send requests over UDP or TCP, including TCP traffic secured by TLS. The ADC provides the following service types to load balance the SIP servers:

- SIP_UDP – Used when SIP servers send SIP messages over UDP.
- SIP_TCP – Used when SIP servers send SIP messages over TCP.
- SIP_SSL – Used to secure SIP signaling traffic over TCP by using SSL or TLS. The NetScaler ADC supports the following modes:
  - End-to-end TLS connection between the client, the ADC, and the SIP server.
  - TLS connection between the client and the ADC, and TCP connection between the ADC and the SIP server.
  - TCP connection between the client and the ADC, and TLS connection between the ADC and the SIP server.

The following figure shows the topology of a setup configured to load balance a group of SIP servers sending SIP messages over TCP or UDP.

Figure 4. SIP Load Balancing Topology



Entity type	Name	IP address	Port	Service type / Protocol
Virtual Server	Vserver-LB-1	10.102.29.65	80	SIP_UDP / SIP_TCP / SIP_SSL
Services	Service-SIP-1	192.168.1.6	80	SIP_UDP / SIP_TCP / SIP_SSL
	Service-SIP-2	192.168.1.5	80	SIP_UDP / SIP_TCP / SIP_SSL
Monitors	Default	None	80	SIP_UDP / SIP_TCP / SIP_SSL

Following is an overview of configuring basic load balancing for SIP traffic:

1. Configure services, and configure a virtual server for each type of SIP traffic that you want to load balance:
   - **SIP_UDP** – If you are load balancing the SIP traffic over UDP.
   - **SIP_TCP** – If you are load balancing the SIP traffic over TCP.
   - **SIP_SSL** – If you are load balancing and securing the SIP traffic over TCP.

   Note: If you use SIP_SSL, be sure to create an SSL certificate-key pair. For more information, see Adding a Certificate Key Pair.

2. Bind the services to the virtual servers.
3. If you want to monitor the states of the services with a monitor other than the default (**tcp-default**), create a custom monitor and bind it to the services. The NetScaler ADC provides two custom monitor types, **SIP-UDP** and **SIP-TCP**, for monitoring SIP services.
4. If using a SIP_SSL virtual server, bind an SSL certificate-key pair to the virtual server.
5. If you are using the NetSCaler ADC as the gateway for the SIP servers in your deployment, configure RNAT.
6. If you want to append RPORT to the SIP messages that are initiated from the SIP server, configure the SIP parameters.

To configure a basic load balancing setup for SIP traffic by using the command line interface

1. Create one or more services. At the command prompt, type:
   add service <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>

   Example
   add service Service-SIP-UDP-1 192.0.2.5 SIP_UDP 80

2. Create as many virtual servers as necessary to handle the services that you created. The virtual server type must match the type of services that you will bind to it. At the command prompt, type:
   add lb vserver <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>

   Example
   add lb vserver Vserver-LB-1 SIP_UDP 10.102.29.60 80

3. Bind each service to a virtual server. At the command prompt, type:
   bind lb vserver <name> <serverName>

   Example
   bind lb vserver Vserver-LB-1 Service-SIP-UDP-1

4. (Optional) Create a custom monitor of type SIP-UDP or SIP-TCP, and bind the monitor to the service. At the command prompt, type:
   add lb monitor <monitorName> <monitorType> [<interval>]

   bind lb monitor <monitorName> <ServiceName>

   Example
   add lb monitor mon1 sip-UDP -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200

   bind monitor mon1 Service-SIP-UDP-1

5. If you created a SIP_SSL virtual server, bind an SSL certificate key pair to the virtual server. At the command prompt, type: At the command prompt, type:
   bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -CA –skipCAName

   Example
   bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1

6. Configure RNAT as required by your network topology. At the command prompt, type one of the following commands to create, respectively, an RNAT entry that uses a network address as the condition and a MIP or SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a MIP or SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:
   set rnat <IPAddress> <netmask>

   set rnat <IPAddress> <netmask> -natip <NATIPAddress>

   set rnat <aclname> [-redirectPort <port>]

   set rnat <aclname> [-redirectPort <port>] -natIP <NATIPAddress>

   Example
   set rnat 192.168.1.0 255.255.255.0 -natip 10.102.29.50

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named **nsrnatsip-127.0.0.1-5061**.

add ssl certKey <certkeyName> -cert <string> [-key <string>]

bind ssl service <serviceName> -certkeyName <string>

Example

add ssl certKey c1 -cert cert.epm -key key.ky

bind ssl service nsrnatsip-127.0.0.1-5061 -certkeyName c1

7. If you want to append RPORT to the SIP messages that the SIP server initiates, type the following command at the command prompt: set lb sipParameters -rnatSrcPort <rnatSrcPort> -rnatDstPort<rnatDstPort> -retryDur <integer> -addRportVip <addRportVip> -sip503RateThreshold <sip503_rate_threshold_value>

Sample Configuration for load balancing the SIP traffic over UDP

> add service service-UDP-1 10.102.29.5 SIP_UDP 80

Done

> add lb vserver vserver-LB-1 SIP_UDP 10.102.29.60 80

Done

> bind lb vserver vserver-LB-1 service-UDP-1

Done

> add lb mon mon1 sip-udp -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200

Done

> bind mon mon1 service-UDP-1

Done

> set rnat 192.168.1.0 255.255.255.0

Done

> set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 1000

Done

Sample Configuration for load balancing the SIP traffic over TCP

> add service service-TCP-1 10.102.29.5 SIP_TCP 80

Done

> add lb vserver vserver-LB-1 SIP_TCP 10.102.29.60 80

Done

> bind lb vserver vserver-LB-1 service-TCP-1

Done

> add lb mon mon1 sip-tcp -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200

Done

```
> bind mon mon1 service-TCP-1

Done

> set rnat 192.168.1.0 255.255.255.0

Done

> set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold
1000

Done
```

Sample Configuration for load balancing and securing SIP traffic over TCP

```
> add service service-SIP-SSL-1 10.102.29.5 SIP_SSL 80

Done

> add lb vserver vserver-LB-1 SIP_SSL 10.102.29.60 80

Done

> bind lb vserver vserver-LB-1 service-SIP-SSL

Done

> add lb mon mon1 sip-tCP -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200

Done

> bind mon mon1 service-SIP-SSL

Done

> bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1

Done

> set rnat 192.168.1.0 255.255.255.0

Done

> set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold
1000

Done
```

To configure a basic load balancing setup for SIP traffic by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a virtual server of type SIP_UDP, SIP_TCP, or SIP_SSL.
2. Click the Service section, and add a service of type SIP_UDP, SIP_TCP, or SIP_SSL.
3. (Optional) Click the Monitor section, and add a monitor of type: SIP-UDP or SIP-TCP.
4. Bind the monitor to the service, and bind the service to the virtual server.
5. If you created a SIP_SSL virtual server, bind an SSL certificate key pair to the virtual server. Click the Certificates section, and bind a certificate key pair to the virtual server.
6. Configure RNAT as required by your network topology. To configure RNAT:
   1. Navigate to System > Network > Routes.
   2. On the Routes page, click the RNAT tab.
   3. In the details pane, click Configure RNAT.
   4. In the Configure RNAT dialog box, do one of the following:
      - If you want to use the network address as a condition for creating an RNAT entry, click Network and set the following parameters:
        - Network

- Netmask
- If you want to use an extended ACL as a condition for creating an RNAT entry, click ACL and set the following parameters:
  - ACL Name
  - Redirect Port

5. To set a MIP or SNIP address as a NAT IP address, skip to step 7.
6. To set a unique IP address as a NAT IP, in the Available NAT IP (s) list, select the IP address that you want to set as the NAT IP, and then click Add. The NAT IP you selected appears in the Configured NAT IP(s) list.
7. Click Create, and then click Close.

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named **nsrnatsip-127.0.0.1-5061**. To bind the pair:

1. Navigate to Traffic Management > Load Balancing > Services and click the Internal Services tab.
2. Select nsrnatsip-127.0.0.1-5061 and click **Edit**.
3. Click the **Certificates** section and bind a certificate key pair to the internal service.

7. If you want to append RPORT to the SIP messages that the SIP server initiates, configure the SIP parameters. Navigate to Traffic Management > Load Balancing and click Change SIP settings, set the various SIP parameters.

SIP Expression and Policy Example: Compression Enabled in Client Requests

A NetScaler ADC cannot process compressed client SIP requests, so the client SIP request fails.

You can configure a responder policy that intercepts the SIP NEGOTIATE message from the client and looks for the compression header. If the message includes a compression header, the policy responds with "400 Bad Request," so that the client resends the request without compressing it.

At the command prompt, type the following commands to create the responder policy:

```
> add responder action sipaction1 respondwith q{"SIP/2.0 400 Bad Request\r\n\r\n"}

Done.

> add responder policy sippol1

> add responder policy sippol1 "SIP.REQ.METHOD.EQ(\"NEGOTIATE\")&&SIP.REQ.HEADER(\"Compression\").EXISTS" sipaction1
```

To configure RNAT by using the command line interface

At the command prompt, type:

set rnat<network> <netmask>
Example

```
set rnat 192.168.1.0 255.255.255.0
```

To configure RNAT by using the configuration utility

1. Navigate to System > Network > Routes.
2. On the Routes page, click the RNAT tab.
3. In the details pane, click Configure RNAT.
4. In the Configure RNAT dialog box, do one of the following:
   - If you want to use the network address as a condition for creating an RNAT entry, click Network and set the following parameters:
     - Network
     - Netmask
   - If you want to use an extended ACL as a condition for creating an RNAT entry, click ACL and set the following parameters:
     - ACL Name
     - Redirect Port
5. To set a MIP or SNIP address as a NAT IP address, skip to step 7.
6. To set a unique IP address as a NAT IP, in the Available NAT IP (s) list, select the IP address that you want to set as the NAT IP, and then click Add. The NAT IP you selected appears in the Configured NAT IP(s) list.

7. Click Create, and then click Close.

After you configure RNAT, the appliance sends SIP responses to the IP address and port that the client uses to send the request. The appliance also adds the RPORT tag in the VIA header of the message. The appliance compares the values of the source and destination ports of the request packets with the RNAT source port and RNAT destination port. If one of the values matches, the appliance updates the VIA header with the RPORT setting.

You must enable this setting when RPORT is not configured on either client.

To configure SIP parameters by using the command line interface

At the command prompt, type:

set lb sipParameters -rnatSrcPort <rnatSrcPort> -rnatDstPort<rnatDstPort> -retryDur <integer> -addRportVip <addRportVip> -sip503RateThreshold <sip503_rate_threshold_value>

Example

```
set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 1000
```

To configure SIP parameters by using the configuration utility

1. Navigate to Traffic Management > DNS > Name Servers.
2. Create a DNS name server of type DNS Virtual Server, and select a server from the DNS Virtual Server list.

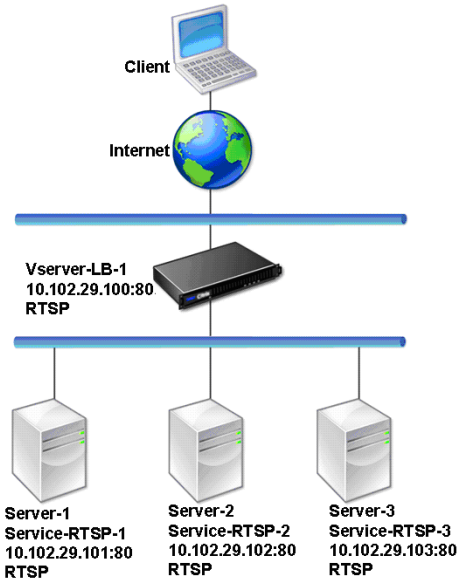
1. Navigate to Traffic Management > Load Balancing.
2. On the Load Balancing landing page, under Settings, click Change SIP settings.
3. In the Set SIP Parameters dialog box, set values for the following parameters:
   - RNAT Source Port
   - RNAT Destination Port
   - Retry Duration (secs)
   - SIP503 Rate Threshold
4. Select Enable Add Rport VIP.
5. Click OK.

Load Balancing RTSP Servers

Nov 12, 2013

The NetScaler appliance can balance load on RTSP servers to improve the performance of audio and video streams over networks. The following diagram describes the topology of an load balancing setup configured to load balance a group of RTSP servers.

Figure 1. Load Balancing Topology for RTSP

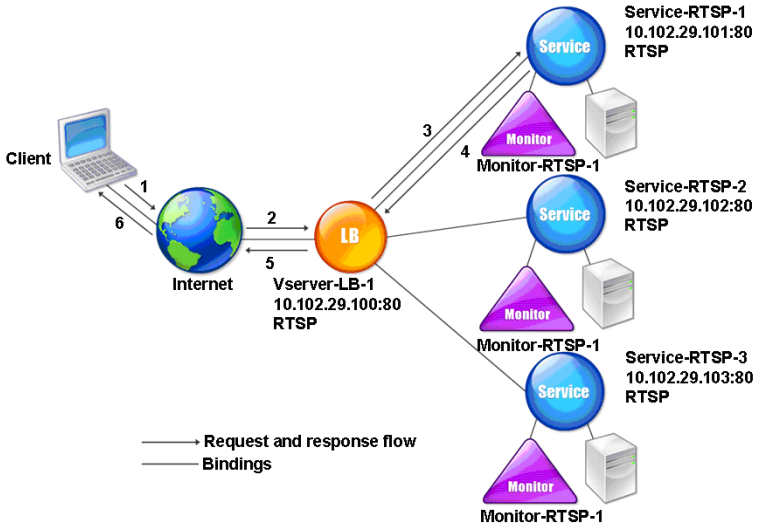


In the example, the services Service-RTSP-1, Service-RTSP-2, and Service-RTSP-3 are bound to the virtual server Vserver-LB-1. The following table lists the names and values of the example entities.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.100	554	RTSP
Services	Service-RTSP-1	10.102.29.101	554	RTSP
	Service-RTSP-2	10.102.29.102	554	RTSP
	Service-RTSP-3	10.102.29.103	554	RTSP
Monitors	Monitor-RTSP-1	None	554	RTSP

The following diagram shows the load balancing entities used in RTSP configuration.

Figure 2. Load Balancing RTSP Servers Entity Model



To configure a basic load balancing setup for RTSP servers, see Setting Up Basic Load Balancing. Create services and virtual servers of type RTSP. When you configure a basic load balancing setup, the default TCP-default monitor is bound to the services. To bind an RTSP monitor to these services, see Binding Monitors to Services. The following procedure describes how create a monitor that checks RTSP servers.

To configure RTSP monitors by using the command line interface

At the command prompt, type:

add lb monitor <monitorName> <type>

Example

add lb monitor Monitor-RTSP-1 RTSP

To configure RTSP monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, in the Name and Interval text boxes, type the name and probing interval of a monitor.
4. In the Type list, select the type of the monitor.
5. Click Create, and then click Close.

Load Balancing of Remote Desktop Protocol (RDP) Servers

Nov 12, 2013

Remote Desktop Protocol (RDP) is a multichannel-capable protocol that allows for separate virtual channels for carrying presentation data, serial device communication, licensing information, highly encrypted data (keyboard and mouse activity), and so on.

RDP is used for providing a graphical user interface to another computer on the network. RDP is used with Windows terminal servers for providing fast access with almost real-time transmission of mouse movements and key presses even over low-bandwidth connections.

When multiple terminal servers are deployed to provide remote desktop services, the NetScaler appliance provides load balancing of the terminal servers (Windows 2003 and 2008 Server Enterprise Editions). In some cases, a user who is accessing an application remotely may want to leave the application running on the remote machine but shut down the local machine. The user therefore closes the local application without logging out of the remote application. After reconnecting to the remote machine, the user should be able to continue with the remote application. To provide this functionality, the NetScaler RDP implementation honors the routing token (cookie) set by the Terminal Services Session Directory or Broker so that the client can reconnect to the same terminal server to which it was connected previously. The Session Directory, implemented on Windows 2003 Terminal Server, is referred to as Broker on Windows 2008 Terminal Server.

When a TCP connection is established between the client and the load balancing virtual server, the NetScaler applies the specified load balancing method and forwards the request to one of the terminal servers. The terminal server checks the session directory to determine whether the client has a session running on any other terminal server in the domain.

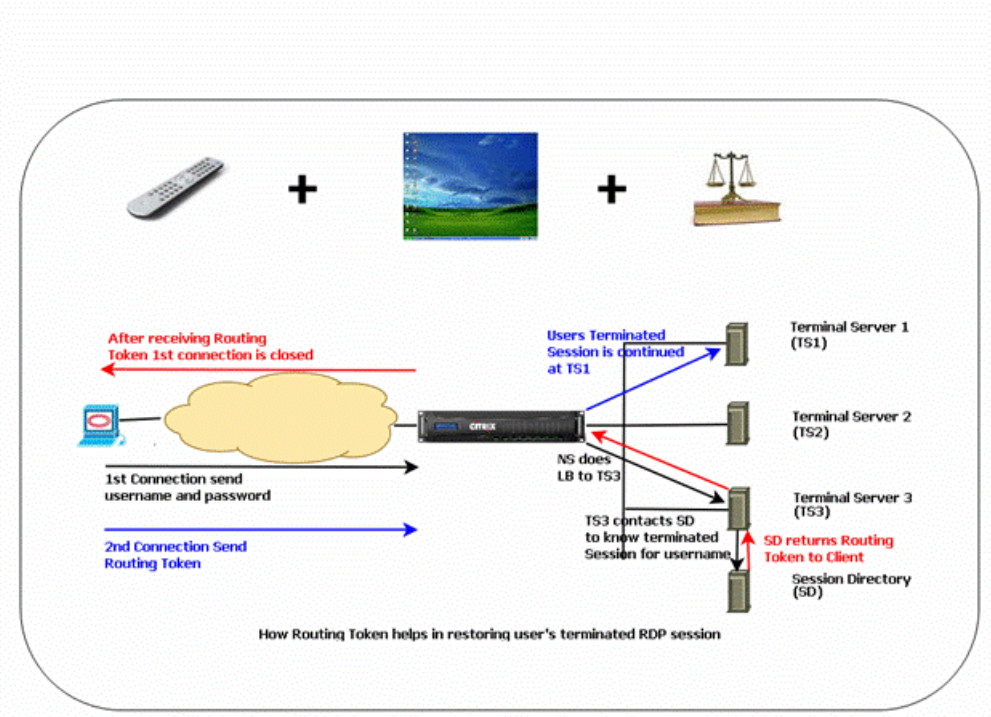
If there is no active session on any other terminal server, the terminal server responds by serving the client request, and the NetScaler forwards the response to the client.

If there is an active session on any other terminal server, the terminal server that receives the request inserts a cookie (referred to as routing token) with the details of the active session and returns the packets to the NetScaler, which returns the packet to the client. The server closes the connection with the client. When the client retries to connect, the NetScaler reads the cookie information and forwards the packet to the terminal server on which the client has an active session.

The user on the client machine experiences a continuation of the service and does not have to take any specific action.

Note: The Windows Session Directory feature requires the Remote Desktop client that was first released with Windows XP. If a session with a Windows 2000 or Windows NT 4.0 Terminal Server client is disconnected and the client reconnects, the server with which the connection is established is selected by the load balancing algorithm.
The following diagram describes RDP load balancing.

Figure 1. Load Balancing Topology for RDP



Note: When an RDP service is configured, persistence is automatically maintained by using a routing token. You need not enable persistence explicitly.
Ensure that the disconnected RDP sessions are cleared on the terminal servers at the backend to avoid flapping between two terminal servers when an RDP session is disconnected without logging out. For more information, see http://technet.microsoft.com/en-us/library/cc758177(WS.10).aspx#BKMK_2

When you add an RDP service, by default, NetScaler adds a monitor of the type TCP and binds it to the service. The default monitor is a simple TCP monitor that checks whether or not a listening process exists at the 3389 port on the server specified for the RDP service. If there is a listening process at 3389, NetScaler marks this service as UP and if there is no listening process, it marks the service as DOWN.

For more efficient monitoring of an RDP service, in addition to the default monitor, you can configure a script monitor that is meant for the RDP protocol. When you configure the scripting monitor, the NetScaler opens a TCP connection to the specified server and sends an RDP packet. The monitor marks the service as UP only if it receives a confirmation of the connection from the physical server. Therefore, from the scripting monitor, the NetScaler can know whether the RDP service is ready to service a request.

The monitor is a user-type monitor and the script is located on the NetScaler at /nsconfig/monitors/nsrdp.pl. When you configure the user monitor, the NetScaler runs the script automatically. To configure the scripting monitor, add the monitor and bind it to the RDP service.

To configure RDP load balancing, create services of type RDP and bind them to an RDP virtual server.

To configure RDP load balancing services by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing setup and verify the configuration:

add service <name>@ <serverName> <serviceType> <port>

Note: Repeat the above command to add more services.

Example

```
> add service ser1 10.102.27.182 RDP 3389
Done
> add service ser2 10.102.27.183 RDP 3389
Done
>show service ser1
ser1 (10.102. 27.182:3389) - RDP
      State: UP
…
  Server Name: 10.102.27.182
  Server ID : 0    Monitor Threshold : 0
      Down state flush: ENABLED
…
1)     Monitor Name: tcp-default
            State: UP      Weight: 1
…
            Response Time: 4.152 millisec
 Done
```

To configure RDP load balancing services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box:
   - Service Name*—serviceName
   - Protocol*—serviceType
   - Server*—serverName
   - Port*—port

   *A required parameter
4. Click Create.
5. Create all the RDP services to be load balanced.
6. From the services pane, open the service you added, and verify the addition.

To configure an RDP load balancing virtual server by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing virtual server and verify the configuration:

- add lb vserver <name>@ <serviceType> <ipAddress> <port>
- bind lb vserver <name>@ <serviceName>

  Bind all the RDP services to be load balanced to the virtual server.

Example

This example has two RDP services bound to the RDP virtual server.

```
> add lb vs v1 rdP 10.102.27.186 3389
Done

> bind lb vs v1 ser1
service "ser1" bound
> bind lb vs v1 ser2
service "ser2" bound
Done

>sh lb vs v1
v1 (10.102.27.186:3389) - RDP   Type: ADDRESS
State: UP
...
No. of Bound Services :  2 (Total)      2 (Active)
Configured Method: LEASTCONNECTION
  Current Method: Round Robin, Reason: A new service is bound
Mode: IP
Persistence: NONE
  L2Conn: OFF

1) ser1 (10.102.27.182: 3389) - RDPState: UP   Weight: 1
2) ser2 (10.102.27.183: 3389) - RDPState: UP   Weight: 1
Done
```

To configure an RDP load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for configuring a virtual server" as shown:
   - Name*—vServerName
   - IP Address*—ipAddress
   - Protocol*—serviceType
   - Port*—port

   *A required parameter
4. In the Services tab, select the services to be bound to the virtual server by checking the service names.
5. Click Create.
6. In the Load Balancing Virtual Servers pane, select the RDP virtual server you configured, and then click Open to verify the configuration.

To configure a scripting monitor for RDP services by using the command line interface

At the command prompt, type the following commands:

- add lb monitor <monitorName> USER -scriptName nsrdp.pl
- bind lb monitor <monitorName> <rdpServiceName>

Example

```
add service ser1 10.102.27.182 RDP 3389
add lb monitor RDP_MON USER -scriptName nsrdp.pl
bind lb monitor RDP_MON ser1
```

To configure a scripting monitor for RDP services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify a name for the RDP monitor.
4. In the Type drop-down list, select USER.
5. On the Special Parameters tab, for the Script Name, click Browse and select nsrdp.pl from the default location.
6. Click Create.
7. From the Monitors pane, open the monitor you added, and verify the addition.
8. Navigate to Traffic Management > Load Balancing > Services.
9. In the details pane, select the RDP service, and then click Open.
10. In the Configure Service dialog box, select the RDP scripting monitor that you added and click Add.
11. Click OK.

Use Case 1: Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream

Jun 08, 2015

Some protocols transmit name-value pairs in a TCP byte stream. The protocol in the TCP byte stream in this example is the Financial Information eXchange (FIX) protocol. In its traditional, non-XML implementation, the FIX protocol enables two hosts communicating over a network to exchange business or trade-related information as a list of name-value pairs (called "FIX fields"). The field format is <tag>=<value><delimiter>. This traditional tag-value format makes the FIX protocol ideal for the use case.

The tag in a FIX field is a numeric identifier that indicates the meaning of the field. For example, the tag 35 indicates the message type. The value after the equal sign holds a specific meaning for the given tag and is associated with a data type. For example, a value of A for the tag 35 indicates that the message is a logon message. The delimiter is the nonprinting "Start of Header" (SOH) ASCII character (0x01), which is the caret symbol (^). Each field is also assigned a name. For example, the field with tag 35 is the msgType field. Following is an example of a logon message.

```
8=FIX.4.1 9=61 35=A 49=INVMGR 56=BRKR 34=1 52=20000426-12:05:06 98=0 108=30 10=157
```

Your choice of persistence type for a tag-value list such as the one shown above is determined by the options that are available to you for extracting a particular string from the list. Token-based persistence methods require you to specify the offset and length of the token that you want to extract from the payload. The FIX protocol does not allow you to do that, because the offset of a given field and the length of its value can vary from one message to another (depending on the message type, the preceding fields, and the lengths of the preceding values) and from one implementation to another (depending on whether custom fields have been defined). Such variations make it impossible to predict the exact offset of a given field or to specify the length of the value that is to be extracted as the token. In this case, therefore, rule based persistence is the preferred persistence type.

Assume that a virtual server fixlb1 is load balancing TCP connections to a farm of servers hosting instances of a FIX-enabled application, and that you want to configure persistence for connections on the basis of the value of the SenderCompID field, which identifies the firm sending the message. The tag for this FIX field is 49 (shown in the earlier logon message example).

To configure rule based persistence for the load balancing virtual server, set the persistence type for the load balancing virtual server to RULE and configure the rule parameter with an expression. The expression must be one that extracts the portion of the TCP payload in which you expect to find the SenderCompID field, typecasts the resulting string to a name-value list based on the delimiters, and then extracts the value of the SenderCompID field (tag 49), as follows:

```
set lb vserver fixlb1 -persistenceType RULE -rule
"CLIENT.TCP.PAYLOAD(300).TYPECAST_NVLIST_T('=','^').VALUE(\"49\")"
```

Note: Backslash characters have been used in the expression because this is a CLI command. If you are using the configuration utility, do not enter the backslash characters.
If the client sends a FIX message that contains the name-value list in the earlier logon message example, the expression extracts the value INVMGR, and the NetScaler appliance creates a persistence session based on this value.

The argument to the PAYLOAD() function can be as large as you deem is necessary to include the SenderCompID field in the string extracted by the function. Optionally, you can use the SET_TEXT_MODE(IGNORECASE) function if you want

the appliance to ignore case when extracting the value of the field, and the HASH function to create a persistence session based on a hash of the extracted value. The following expression uses the SET_TEXT_MODE(IGNORECASE) and HASH functions:

```
CLIENT.TCP.PAYLOAD(500).TYPECAST_NVLIST_T('=','^').SET_TEXT_MODE(IGNORECASE).VALUE("49").HASH
```

Following are more examples of rules that you can use to configure persistence for FIX connections (replace <tag> with the tag of the field whose value you want to extract):

- To extract the value of any FIX field in the first 300 bytes of the TCP payload, you can use the expression CLIENT.TCP.PAYLOAD(300).BEFORE_STR("^").AFTER_STR("<tag>=").
- To extract a string that is 20 bytes long at offset 80, cast the string to a name-value list, and then extract the value of the field that you want, use the expression CLIENT.TCP.PAYLOAD(100).SUBSTR(80,20).TYPECAST_NVLIST_T('=','^').VALUE("<tag>").
- To extract the first 100 bytes of the TCP payload, cast the string to a name-value list, and extract the value of the third occurrence of the field that you want, use the expression CLIENT.TCP.PAYLOAD(100).TYPECAST_NVLIST_T('=','^').VALUE("<tag>",2).
  Note: If the second argument that is passed to the VALUE() function is n, the appliance extracts the value of the $(n+1)^{th}$ instance of the field because the count starts from zero (0).

Following are more examples of rules that you can use to configure persistence. Only the payload-based expressions can evaluate data being transmitted through the FIX protocol. The other expressions are more general expressions for configuring persistence based on lower networking protocols.

- CLIENT.TCP.PAYLOAD(100)
- CLIENT.TCP.PAYLOAD(100).HASH
- CLIENT.TCP.PAYLOAD(100).SUBSTR(5,10)
- CLIENT.TCP.SRCPORT
- CLIENT.TCP.DSTPORT
- CLIENT.IP.SRC
- CLIENT.IP.DST
- CLIENT.IP.SRC.GET4
- CLIENT.IP.DST.GET4
- CLIENT.ETHER.SRCMAC.GET6
- CLIENT.ETHER.DSTMAC.GET5
- CLIENT.VLAN.ID

Use Case 2: Configuring Load Balancing in Direct Server Return Mode

Jun 08, 2015

Load balancing in direct server return (DSR) mode allows the server to respond to clients directly by using a return path that does not flow through the NetScaler appliance. In DSR mode, however, the appliance can continue to perform health checks on services. In a high-data volume environment, sending server traffic directly to the client in DSR mode increases the overall packet handling capacity of the appliance because the packets do not flow through the appliance.

DSR mode has the following features and limitations:

- It supports one-arm mode and inline mode.
- The appliance ages out sessions based on idle timeout.
- Because the appliance does not proxy TCP connections (that is it does not send SYN-ACK to the client), it does not completely shut out SYN attacks. By using the SYN packet rate filter, you can control the rate of SYNs to the server. To control the rate of SYNs, set a threshold for the rate of SYNs. To get protection from SYN attacks, you must configure the appliance to proxy TCP connections. However, that requires the reverse traffic to flow through the appliance.
- In a DSR configuration, the NetScaler appliance does not replace the load balancing virtual server's IP address with the destination server's IP address. Instead, it forwards packets to a service by using the server's MAC address, which it obtains from the monitor bound to the service. However, custom user monitors (monitors of type USER), which use scripts stored on the NetScaler appliance, do not learn a server's MAC address. If you use only custom monitors in a DSR configuration, for each request the virtual server receives, the appliance attempts to resolve the destination IP address to a MAC address (by sending ARP requests). Because the destination IP address is a virtual IP address owned by the NetScaler appliance, the ARP requests always resolve to the MAC address of the NetScaler interface. Consequently, all traffic received by the virtual server is looped back to the appliance. If you use user monitors in a DSR configuration, you must also configure another monitor of a different type (for example, a PING monitor) for the services, ideally with a longer interval between probes, so that the MAC address of the servers can be learned.

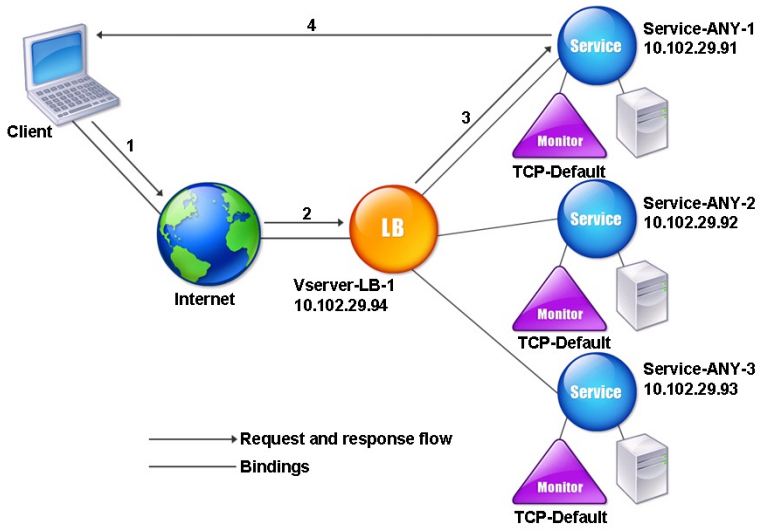
In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service, and the service responds to clients directly, bypassing the NetScaler. The following table lists the names and values of the entities configured on the NetScaler in DSR mode.

Entity type	Name	IP address	Protocol
Virtual server	Vserver-LB-1	10.102.29.94	ANY
Services	Service-ANY-1	10.102.29.91	ANY
	Service-ANY-2	10.102.29.92	ANY
	Service-ANY-3	10.102.29.93	ANY

Entity type	Name	IP address	Protocol
Monitors	TCP	None	None

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 1. Entity Model for Load Balancing in DSR Model



For the appliance to function correctly in DSR mode, the destination IP in the client request must be unchanged. Instead, the appliance changes the destination MAC to that of the selected server. This setting enables the server to determine the client MAC address for forwarding requests to the client while bypassing the server. To enable the appliance to do this, you must enable MAC-based forwarding.

To enable MAC-based forwarding by using the command line interface

At the command prompt, type:

enable ns mode MACbasedforwarding

To enable MAC-based forwarding by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. On the Settings pane, under Modes and Features, click Configure modes.
3. In the Configure Modes dialog box, select the MAC Based Forwarding check box, and then click OK.
4. In the Enable/Disable Mode(s)? dialog box, click Yes.

Next, you configure a basic load balancing setup as described in Setting Up Basic Load Balancing, naming the entities and setting the parameters using the values described in the previous table.

After you configure the basic load balancing setup, you must customize it for DSR mode. To do this, you configure a supported load balancing method, such as the Source IP Hash method with a sessionless virtual server. You also need to set the redirection mode to allow the server to determine the client MAC address for forwarding responses and bypass the appliance.

After you configure the load balancing method and redirection mode, you need to enable the USIP mode on each service.

The service then uses the source IP address when forwarding responses.

To configure the load balancing method and redirection mode for a sessionless virtual server by using the command line interface

At the command prompt, type:

set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <RedirectionMode> -sessionless <Value>

Example

```
set lb vserver Vserver-LB-1 -lbMethod SourceIPHash -m MAC -sessionless enabled
```

To configure the load balancing method and redirection mode for a sessionless virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server (for example, Vserver-LB-1), and then click Open.
3. On the Method and Persistence tab, under LB Method, select SOURCE IP Hash.
4. On the Advanced tab, under Redirection Mode, select MAC Based.
5. Select the Sessionless check box and click OK.

To configure a service to use source IP address by using the command line interface

At the command prompt, type:

set service <ServiceName> -usip <Value>

Example

```
set service Service-ANY-1 -usip yes
```

To configure a service to use source IP address by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. On the Services pane, click Service-ANY-1, and then click Open.
3. On the Advanced tab, under Settings, select the Use Source IP check box, and then click OK.
4. Repeat steps 1-5 for the services Service-ANY-2 and Service-ANY-3.

Some additional steps are required in certain situations, which are described in the succeeding sections.

Use Case 3: Configuring LINUX Servers in DSR Mode

Jun 08, 2015

The LINUX operating system requires that you set up a loopback interface with the NetScaler appliance virtual IP address (VIP) on each load balanced server in the DSR cluster.

To configure LINUX server in DSR mode

To create a loop back interface with the NetScaler appliance's VIP on each load balanced server, at the Linux OS prompt type the following commands:

ifconfig dummy0 up

ifconfig dummy0:0 inet <netscaler vip> netmask 255.255.255.255 up

echo 1 > /proc/sys/net/ipv4/conf/dummy0/arp_ignore

echo 2 > /proc/sys/net/ipv4/conf/dummy0/arp_announce

Then, run the software that re-maps the TOS id to VIP.

Note: Add the correct mappings to the software before running it. In the preceding commands, the LINUX server uses dummy0 to connect to the network. When you use this command, type the name of the interface that your LINUX server uses to connect to the network.

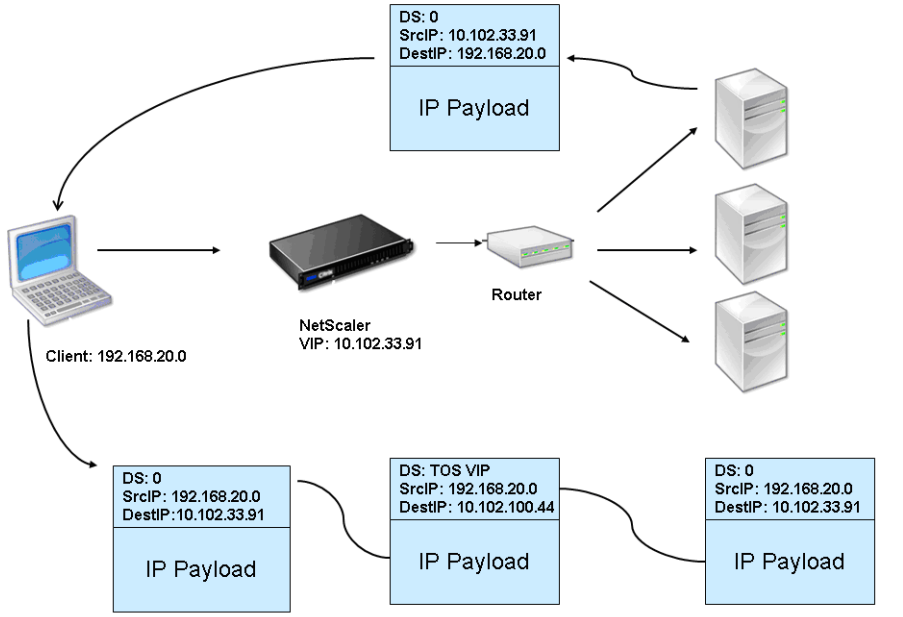
Use Case 4: Configuring DSR Mode When Using TOS

Jun 08, 2015

Differentiated services (DS), also known as TOS (Type of Service), is a field that is part of the TCP packet header. TOS is used by upper layer protocols for optimizing the path for a packet. The TOS information encodes the NetScaler appliance virtual IP address (VIP), and the load balanced servers extract the VIP from it.

In the following scenario, the appliance adds the VIP to the TOS field in the packet and then forwards the packet to the load balanced server. The load balanced server then responds directly to the client, bypassing the appliance, as illustrated in the following diagram.

Figure 1. The NetScaler Appliance in DSR mode with TOS



The TOS feature is specifically customized for a controlled environment, as described below:

- The environment must not have any stateful devices, such as stateful firewall and TCP gateways, in the path between the appliance and the load balanced servers.
- Routers at all the entry points to the network must remove the TOS field from all incoming packets to make sure that the load balanced server does not confuse another TOS field with that added by the appliance.
- Each server can have only 63 VIPs.
- The intermediate router must not send out ICMP error messages regarding fragmentation. The client will not understand the message, as the source IP address will be the IP address of the load balanced server and not the NetScaler VIP.
- TOS is valid only for IP-based services. You cannot use domain name based services with TOS.

In the example, Service-ANY-1 is created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to the service, and the service responds to clients directly, bypassing the appliance. The following table lists the names and values of the entities configured on the appliance in DSR mode.

Entity Type	Name	IP Address	Protocol

Entity Type	Name	IP Address	Protocol
Virtual server	Vserver-LB-1	10.102.33.91	ANY
Services	Service-ANY-1	10.102.100.44	ANY
Monitors	PING	None	None

DSR with TOS requires that load balancing be set up on layer 3. To configure a basic load balancing setup for Layer 3, see Setting Up Basic Load Balancing. Name the entities and set the parameters using the values described in the previous table.

After you configure the load balancing setup, you must customize the load balancing setup for DSR mode by configuring the redirection mode to allow the server to decapsulate the data packet and then respond directly to the client and bypass the appliance.

After specifying the redirection mode, you can optionally enable the appliance to transparently monitor the server. This enables the appliance to transparently monitor the load balanced servers.

To configure the redirection mode for the virtual server by using the command line interface

At the command prompt, type:

set lb vserver <vServerName> -m <Value> -tosId <Value>
Example

set lb vserver Vserver-LB-1 -m TOS -tosId 3

To configure the redirection mode for the virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers pane, select the virtual server and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in Redirection Mode, click TOS Based.
4. In the TOS Id box, enter a value for the TOS ID.
5. Click OK.

To configure the transparent monitor for TOS by using the command line interface

At the command prompt, type:

add monitor <MonitorName> <Type> -destip <DestinationIP> -tos <Value> -tosId <Value>
Example

add monitor mon1 PING -destip 10.102.33.91 -tos Yes -tosId 3

To create the transparent monitor for TOS by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, select the monitor (for example, tcp), and click Add.
3. In the Create Monitor dialog box, in the Name and Destination IP boxes, enter the monitor name and the destination IP address (for example, PING and 10.102.33.91).
4. In the Type list, select the type of monitor (for example, PING).
5. To configure the monitor for TOS, select the TOS check box.
6. In the TOS Id box, enter the same TOS ID that you had entered for the virtual server (for example, 3.)

7. Click OK.

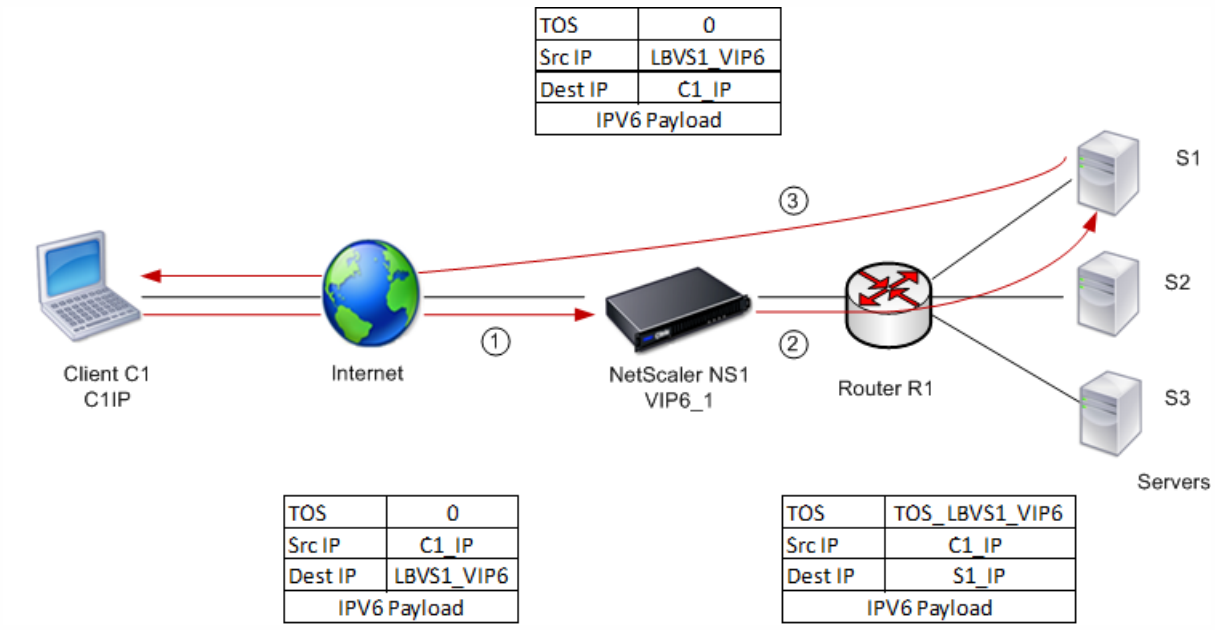
Use Case 5: Configuring Load Balancing in DSR Mode for IPv6 Networks by Using the TOS Field

Jun 08, 2015

You can configure load balancing in Direct Server Return (DSR) mode for IPv6 networks by using the Type of Service (TOS) field when the NetScaler appliance and the servers are in different networks.

Note: The TOS field is also called the Traffic Class field.
In DSR mode, when a client sends a request to a VIP6 address on a NetScaler appliance, the appliance forwards this request to the server by changing the destination IPv6 address of the packet to the IPv6 address of the server and sets an encoded value of the VIP6 address in the TOS (also called traffic class) field of the IPv6 header. You can configure the server to use the information in the TOS field to derive the VIP6 address from the encoded value, which is then used as source IP address in response packets. Response traffic directly goes to the client, bypassing the NetScaler.

Consider an example where a load balancing virtual server LBVS1, configured on a NetScaler appliance NS1, is used to load balance traffic across servers S1, S2, and S3. The NetScaler appliance NS1 and the servers S1, S2, and S3 are in different networks so router R1 is deployed between NS1 and the servers.



The following table lists the settings used in this example.

Entities	Name
IPv6 address of client C1	C1_IP (for reference purposes only)
Load balancing virtual server on NS1	LBVS1
IPv6 address of LBVS1	LBVS1_VIP6 (for references purpose only)

TOS value **Entities**	TOS_ LBVS1_VIP6 (for references purpose only) **Name**
Service for server S1 on NS1	SVC_S1
IPv6 address for server S1	S1_IP (for references purpose only)
Service for server S2 on NS1	SVC_S2
IPv6 address for server S1	S2_IP (for references purpose only)
Service for server S3 on NS1	SVC_S3
IPv6 address for server S1	S3_IP (for references purpose only)

Following is the traffic flow in the example scenario:

1. Client C1 sends a request to virtual server LBVS1.
2. LBVS1's load balancing algorithm selects server S1 and the appliance opens a connection to S1. NS1 sends the request to S1 with:
   - TOS field set to TOS_ LBVS1_VIP6.
   - Source IP address as C1_IP.
3. The server S1, on receiving the request, uses the information in the TOS field to derive the LBVS1_VIP6 address, which is the IP address of the virtual server LBVS1 on NS1. The server directly sends the response to C1, bypassing the NetScaler, with:
   - Source IP address set to the derivedLBVS1_VIP6 address so that the client communicates to the virtual server LBVS1 on NS1 and not to server S1.

To configure load balancing in DSR Mode using TOS, perform the following steps on the appliance:

1. Enable USIP mode globally.
2. Add the servers as services.
3. Configure a load balancing virtual server with a TOS value.
4. Bind the services to the virtual server.

To configure load balancing in DSR Mode using TOS by using the command line interface

At the command prompt, type:

- enable ns mode USIP
- add service <serviceName> <IP> <serviceType> <port>
  Repeat the above command as many times as necessary to add each server as a service on the NetScaler appliance.
- add lb vserver <name> <serviceType> <ip> <port> -m <redirectionMode> -tosId <positive_integer>
- bind lb vserver <vserverName> <serviceName>

To enable USIP mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. In the Modes and Features group, click Configure Modes.
3. In the Configure Modes dialog box, select the Use Source IP check box.

To create services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, set the following parameters.
   - Service Name*
   - Server*
   - Protocol* (Select ANY from the drop-down list.)
   - Port*
4. Click **Create**.
5. Repeat steps 3-4 to create another service.
6. Click Close.
7. In the Services pane, select the services that you just configured and verify that the settings displayed at the bottom of the screen are correct.

To create a load balancing virtual server and bind services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers pane, click Add.
3. In the Create Virtual Servers (Load Balancing) dialog box, select IP Address Based and then select IPv6.
4. Set the following parameters.
   - Name*
   - IP Address*
   - Protocol* (Select ANY from the drop-down list.)
   - Port*

   * A required parameter
5. On the Advanced tab, under Redirection Mode, click TOS Based. In the TOS Id box, enter a value.
6. Under the Services tab, in the Active column, select the check box for the service that you want to bind to the virtual server.
7. Click Create, and then click Close. In the Load Balancing Virtual Servers tab, select the virtual server that you just created, and verify that the settings displayed in the Details pane are correct.

Use Case 6: Configuring Load Balancing in DSR Mode by Using IP Over IP

Jun 08, 2015

You can configure your NetScaler appliance to use direct server return (DSR) mode across Layer 3 networks by using IP tunneling, also called *IP over IP* configuration. As with standard load balancing configurations for DSR mode, this allows servers to respond to clients directly instead of using a return path through the NetScaler appliance, improving response times and throughput. As with standard DSR mode, the NetScaler appliance monitors the servers and performs health checks on the application ports.

With IP over IP configuration, the NetScaler appliance and the servers do not need to be on the same Layer 2 subnet. Instead, the NetScaler appliance encapsulates the packets before sending them to the destination server. After the destination server receives the packets, it decapsulates the packets, and then sends its responses directly to the client.

To configure IP over IP DSR mode on your NetScaler appliance, you must do the following:

- **Create a load balancing virtual server.** Set the protocol to ANY and set the mode to IPTUNNEL.
- **Create services.** Create a service for each of your back-end applications. Bind the services that you created to the virtual server.

Configuring a Load Balancing Virtual Server

Updated: 2013-11-29

Configure a virtual server to handle requests to your applications. Assign a service type of ANY and set the forwarding method to IPTUNNEL. Optionally, configure the virtual server to operate in sessionless mode. You can configure any load balancing method that you want to use.

To create and configure a load balancing virtual server for IP over IP DSR by using the command line interface

At the command prompt type the following command to configure a load balancing virtual server for IP over IP DSR and verify the configuration:

- add lb vserver <name> serviceType <serviceType> IPAddress <ip> Port <port> -lbMethod <method> -m <ipTunnelTag> -sessionless <sessionless>
- show lb vserver <name>

Example

In the following example, we have selected the load balancing method as sourceIPhash and configured sessionless load balancing.

```
add lb vserver Vserver-LB-1 ANY 10.102.29.60 * -lbMethod SourceIPHash -m IPTUNNEL -sessionless enabled
```

To create and configure a load balancing virtual server for IP over IP DSR by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.

2. In the details pane, click Add.
3. In the Create Virtual Server dialog box, specify values for the following parameters:
   - Name*—name
   - Protocol*—protocol
   - IP address*—IPAddress
   - Port*—port

   * A required parameter
4. On the Advanced tab, under Redirection Mode, select IP Tunnel Based.
5. Click Create, and then click Close. The virtual server that you created now appears in the Virtual Servers pane.

Configuring Services for IP over IP DSR

Updated: 2013-11-29

After creating your load-balanced server, You must configure one service for each of your applications. The service handles traffic from the NetScaler appliance to those applications, and allows the NetScaler appliance to monitor the health of each application.

You assign a service type of ANY and configure it for USIP mode. Optionally, you can also bind a monitor of type IPTUNNEL to the service for tunnel-based monitoring.

To create and configure a service for IP over IP DSR by using the command line interface

At the command prompt, type the following commands to create a service and optionally, create a monitor and bind it to the service:

- add service <serviceName> <serverName> <serviceType> <port> -usip <usip>
- add monitor <monitorName> <monitorType> -destip <ip> -iptunnel <iptunnel>
- bind service <serviceName> -monitorName <monitorName>

Example

In the following example, we are creating a monitor of type IPTUNNEL:

```
add monitor mon-1 PING -destip 10.102.29.60 -iptunnel yes
add service Service-DSR-1 10.102.30.5 ANY * -usip yes
bind service Service-DSR-1 -monitorName mon-1
```

To configure a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify values for the following parameters:
   - Monitor Name*—name
   - Type*—type
   - Destination IP—destip. Specify the IP address of the virtual server that you created earlier.

   * A required parameter
4. Select IP Tunnel.
5. Click Create, and then click Close.

To create and configure a service for IP over IP DSR by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters:
   - Service Name*—name
   - Protocol*—type
   - Server*—IP
   - Port*—port

   * A required parameter
4. On the Monitors tab, from the Available list, select the monitor that you created earlier and add it to the Configured list.
5. On the Advanced tab, select Use Source IP.
6. Click Create, and then click Close.

To bind a service to a load balancing virtual server by using the command line interface

At the command prompt type the following command:

bind lb vserver <name> <serviceName>

Example

bind lb vserver Vserver-LB-1 Service-DSR-1

To bind a service to a load balancing virtual server by using the configuration utility

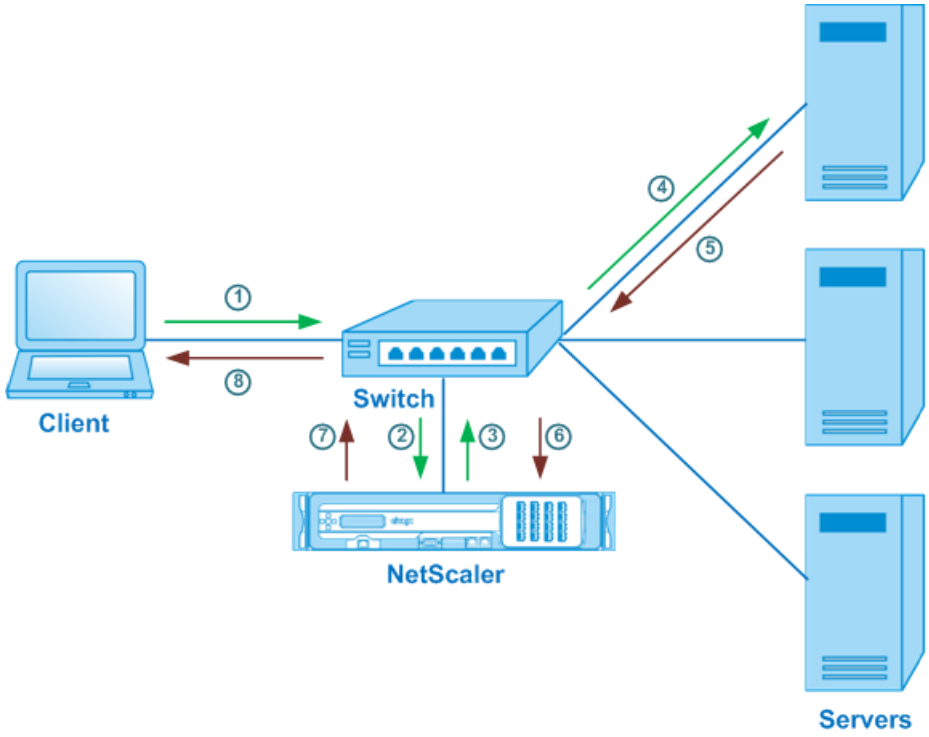
1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the load balancing virtual server that you created earlier, and then select Open.
3. In the Services tab, select the check box beside the name of the service(s) that you created earlier.
4. Click OK.

Use Case 7: Configuring Load Balancing in One-arm Mode

Feb 19, 2016

In a one-arm setup, you connect the NetScaler appliance to the network through a single VLAN. The appliance receives the request from the client on a single VLAN and it sends the request to the server on the same VLAN. This is one of the simplest deployment scenarios, where the router, the servers and the appliance are all connected to the same switch. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service, as is shown in the following diagram.

Figure: Load Balancing in One-Arm Mode



In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service. The following table lists the names and values of the entities configured on the appliance in one-arm mode.

Entity type	Name	IP address	Protocol
Virtual server	Vserver-LB-1	10.102.29.94	ANY
Services	Service-ANY-1	10.102.29.91	ANY
	Service-ANY-2	10.102.29.92	ANY

Entity type	Name	IP address	Protocol
	Service-ANY-3	10.102.29.93	ANY
Monitors	TCP	None	None

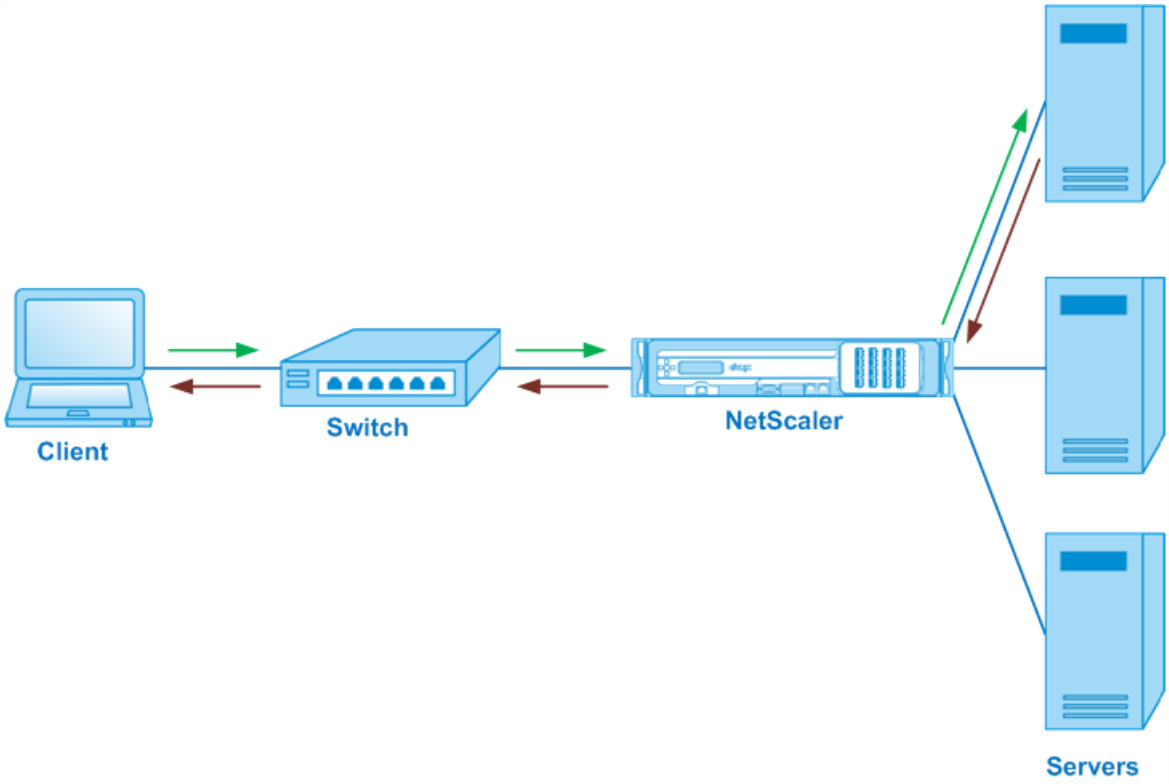
To configure a load balancing setup in one-arm mode, see "Setting Up Basic Load Balancing."

Use Case 8: Configuring Load Balancing in the Inline Mode

Feb 19, 2016

In an inline mode (also called two-arm mode) setup, you connect the NetScaler appliance to the network through multiple VLANs. The appliance receives the request from the client on one VLAN and it sends the request to the server on another VLAN. In the two-arm setup, the appliance is connected between the servers and the client. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service. This is shown in the following diagram.

Figure: Load Balancing in Inline Mode



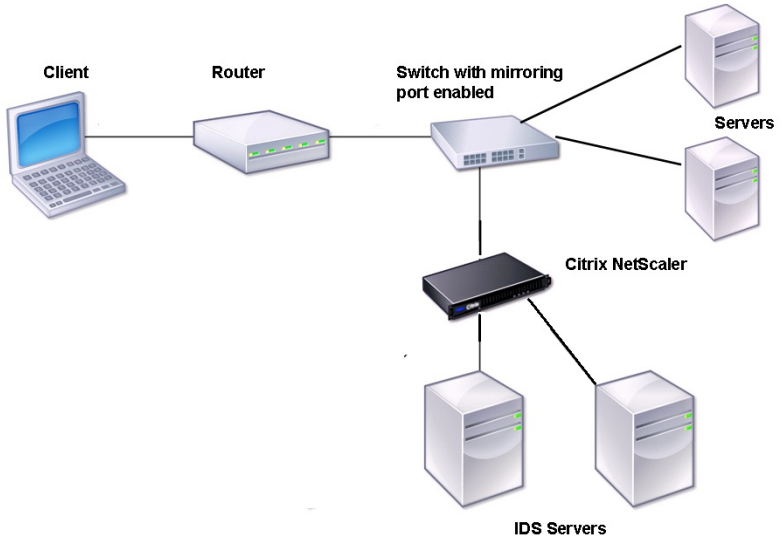
The configuration and the entity diagram for inline mode are the same as described in "Configuring Load Balancing in One-arm Mode."

Use Case 9: Load Balancing of Intrusion Detection System Servers

Jun 08, 2015

To enable the NetScaler appliance to support load balancing of intrusion detection system (IDS) servers, the IDS servers and clients must be connected through a switch that has port mirroring enabled. The client sends a request to the server. Because port mirroring is enabled on the switch, the request packets are copied or sent to the NetScaler appliance virtual server port. The appliance then uses the configured load balancing method to select an IDS server, as shown in the following diagram.

Figure 1. Topology of Load Balanced IDS Servers



Note: Currently, the appliance supports load balancing of passive IDS devices only.
As illustrated in the preceding diagram, the IDS load balancing setup functions as follows:

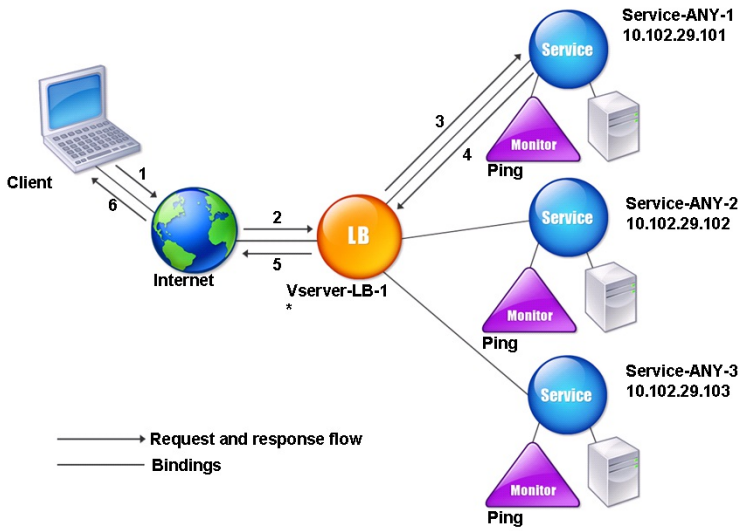
1. The client request is sent to the IDS server, and a switch with a mirroring port enabled forwards these packets to the IDS server. The source IP address is the IP address of the client, and the destination IP address is the IP address of the server. The source MAC address is the MAC address of the router, and the destination MAC address is the MAC address of the server.
2. The traffic that flows through the switch is mirrored to the appliance. The appliance uses the layer 3 information (source IP address and destination IP address) to forward the packet to the selected IDS server without changing the source IP address or destination IP address. It modifies the source MAC address and the destination MAC address to the MAC address of the selected IDS server.

Note: When load balancing IDS servers, you can configure the SRCIPHASH, DESTIPHASH, or SRCIPDESTIPHASH load balancing methods. The SRCIPDESTIPHASH method is recommended because packets flowing from the client to a service on the appliance must be sent to a single IDS server.
Suppose Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to Vserver-LB-1. The virtual server balances the load on the services. The following table lists the names and values of the entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Virtual server	Vserver-LB-1	*	*	ANY
Services	Service-ANY-1	10.102.29.101	*	ANY
	Service-ANY-2	10.102.29.102	*	ANY
	Service-ANY-3	10.102.29.103	*	ANY
Monitors	Ping	None	None	None

Note: You can use inline mode or one-arm mode for an IDS load balancing setup.
The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 2. Entity Model for Load Balancing IDS Servers



To configure an IDS load balancing setup, you must first enable MAC-based forwarding. You must also disable layer 2 and layer 3 modes on the appliance.

To enable MAC-based forwarding by using the command line interface

At the command prompt, type:

enable ns mode <ConfigureMode>

Example

enable ns mode MAC

To enable MAC-based forwarding by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. On the Settings landing page, under Modes and Features, click modes.
3. In the Configure Modes dialog box, select the MAC Based Forwarding check box, and then click OK.
4. In the Enable/Disable Feature(s)? dialog box, and then click Yes.

Next, see "Setting Up Basic Load Balancing", to configure a basic load balancing setup.

After you configure the basic load balancing setup, you must customize it for IDS by configuring a supported load balancing method (such as the SRCIPDESTIP Hash method on a sessionless virtual server) and enabling MAC mode. The appliance does not maintain the state of the connection and only forwards the packets to the IDS servers without processing them. The destination IP address and port remains unchanged because the virtual server is in the MAC mode.

To configure LB method and redirection mode for a sessionless virtual server by using the command line interface

At the command prompt, type:

set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <RedirectionMode> -sessionless <Value>

Example

```
set lb vserver Vserver-LB-1 -lbMethod SourceIPDestIPHash -m MAC -sessionless enabled
```

To configure LB method and redirection mode for a sessionless virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers pane, click the virtual server Vserver-LB-1, and then click Open.
3. On the Method and Persistence tab, under LB Method, select Source IP Destination IP Hash.
4. On the Advanced tab, under Redirection Mode, click MAC Based.
5. Select the Sessionless check box, and then click OK.

To set a service to use source IP address by using the command line interface

At the command prompt, type:

set service <ServiceName> -usip <Value>

Example

```
set service Service-ANY-1 -usip yes
```

To set a service to use source IP address by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. On the Services pane, select the service, Service-ANY-1, and then click Open.
3. On the Advanced tab, under Settings, select the Use Source IP check box.
4. Click OK.
5. Repeat steps 1-5 for the services Service-ANY-2 and Service-ANY-3.

For USIP to function correctly, you must set it globally. For more information about configuring USIP globally, see "IP Addressing."

Use Case 10: Isolating Network Traffic using Listen Policies

Jun 08, 2015

A very common security requirement in a data center is to maintain network path isolation between the traffic of various applications or tenants. One application or tenant's traffic must be isolated from the traffic of other applications or tenants. For example, a financial services company would want to keep the traffic of its insurance department's applications separate from that of its financial services applications. In the past, this was easily achieved through physical separation of network service devices such as firewalls, load balancers, and IDP, and network monitoring and logical separation in the switching fabric.

As data center architectures evolve toward multi-tenant virtualized data centers, networking services in the aggregation layer of a data center are getting consolidated. This development has made network path isolation a critical component for network service devices and is driving the requirement for ADCs to be able to isolate traffic at the L4 to L7 levels. Furthermore, all the traffic of a particular tenant must go through a firewall before reaching the service layer.

To address the requirement of isolating the network paths, a NetScaler appliance identifies network domains and controls the traffic across the domains. The NetScaler solution has two main components: listen policies and shadow virtual servers.

Each network path to be isolated is assigned a virtual server on which a listen policy is defined so that the virtual server listens to traffic only from a specified network domain.

To isolate the traffic, listen policies can be based on a number of client parameters or their combinations, and the policies can be assigned priorities. The following table lists the parameters that can be used in listen policies for identifying the traffic.

Table 1. Client Parameters Used to Define Listen Policies

Category	Parameters
Ethernet protocol	Source MAC address, destination MAC address
Network interface	Network ID, receiving throughput, sending throughput, transmission throughput
IP protocol	Source IP address, destination IP address
IPv6 protocol	Source IPv6 address, destination IPv6 address
TCP protocol	Source port, destination port, maximum segment size, payload, and other options
UDP protocol	Source port, destination port
VLAN	ID

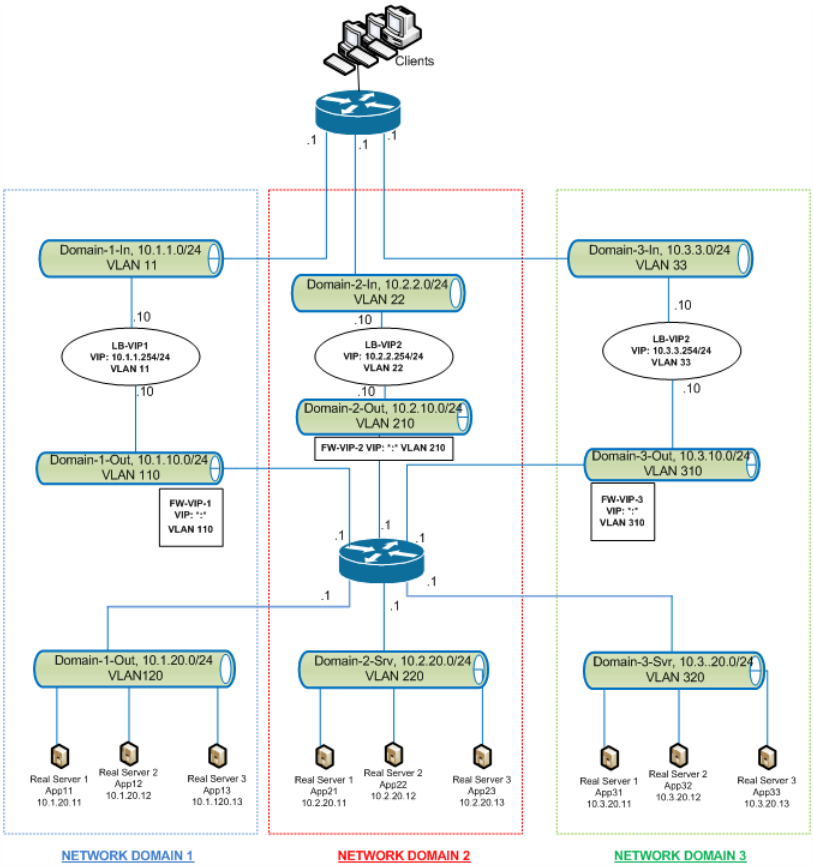
On the NetScaler appliance, a virtual server is configured for each domain, with a listen policy specifying that the virtual server is to listen only to traffic for that domain. Also configured for each domain is a shadow load balancing virtual server, which listens to traffic destined for any domain. Each of the shadow load balancing virtual servers has a wildcard (*) IP address and port, and its service type is set to ANY.

In each domain, a firewall for the domain is bound as a service to the shadow load balancing virtual server, which forwards all traffic through the firewall. Local traffic is forwarded to its destination, and traffic destined for another domain is forwarded to the firewall for that domain. The shadow load balancing virtual servers are configured for MAC mode redirection.

How Network Paths Are Isolated

The following figure shows a typical traffic flow across domains. Consider the traffic flow within Network Domain 1, and between Network Domain 1 and Network Domain 2.

Figure 1. Isolating Network Path



Traffic within Network Domain 1

Network Domain 1 has three VLANs: VLAN 11, VLAN110, and VLAN120. The following steps describe the traffic flow.

- A client from VLAN 11 sends a request for a service available from the service pool in VLAN 120.
- The load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110. The virtual server in VLAN 110 forwards the request to shadow load balancing virtual server FW-VIP-1.
- FW-VIP-1, which is configured to listen to traffic from VLAN 110, receives the request and forwards it to VLAN 120.
- The load balancing virtual server in VLAN 120 load balances the request to one of the physical servers, App11, App12, or App13.
- The response sent by the physical server returns by the same path to the client in VLAN 11.

This configuration ensures that traffic is always segregated inside the NetScaler for all the traffic that originates from a client.

Traffic between Network Domain 1 and Network Domain 2

Network Domain 1 has three VLANs: VLAN 11, VLAN 110, and VLAN 120. Network Domain 2 also has three VLANS: VLAN 22, VLAN 210, and VLAN 220. The following steps describe the traffic flow from VALN 11 to VLAN 22.

- A client from VLAN 11, which belongs to Network Domain 1, sends a request for a service available from the service pool in VLAN 220, which belongs to the Network Domain 2.
- In Network Domain 1, the load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110.
- Shadow load balancing virtual server FW-VIP-1, which is configured to listen to VLAN 110 traffic destined to any other domain, receives the request and forwards it to firewall virtual server FW-VIP-2 because the request is destined to a physical server in Network Domain 2.
- In Network Domain 2, FW-VIP-2 forwards the request to VLAN 220.
- The load balancing virtual server in VLAN 220 load balances the request to one of the physical servers, App21, App22, or App23.
- The response sent by the physical server returns by the same path through the firewall in Network Domain 2 and then to Network Domain 1 to reach the client in VLAN 11.

Configuration Steps

To configure network path isolation by using listen policies, do the following:

- Add listen policy expressions. Each expression specifies a domain to which traffic is destined. You can use the VLAN ID or other parameters to identify the traffic. For more details, see "Client Parameters Used to Define Listen Policies."
- For each network domain, configure two virtual servers as follows:

- Create a load balancing virtual server for which you specify a listen policy that identifies the traffic destined for this domain. You can specify the name of an expression created earlier, or you can create a new expression while creating the virtual server.
- Create another load balancing virtual server, referred to as shadow virtual server, for which you specify a listen policy expression that applies to traffic destined for any domain. On this virtual server, set the service type to ANY and the IP address and port to an asterisk (*). Enable MAC-based forwarding on this virtual server.
- Enable the L2 Connection option on both the virtual servers.
  Generally, to identify a connection, the NetScaler uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.

- Add services representing the server pools in the domain, and bind them to the virtual server.
- Configure the firewall for each domain as a service, and bind all of the firewall services to the shadow virtual server.

To isolate network traffic by using the command line interface

At the command prompt, type the following commands:

- add policy expression <expressionName> <listenPolicyExpression>
- add lb vserver <name> <serviceType> <ip> <port> -l2conn ON -listenPolicy <expressionName>
  Add a load balancing virtual server for each domain. This virtual server is for traffic of the same domain.
- add lb vserver <name> ANY * * -l2conn ON -m MAC -listenPolicy <expressionName>
  Add a shadow load balancing virtual server for each domain. This virtual server is for traffic of other domains.

Example

```
add policy expression e110 client.vlan.id==110
add policy expression e210 client.vlan.id==210
add policy expression e310 client.vlan.id==310
add policy expression e11 client.vlan.id==11
add policy expression e22 client.vlan.id==22
add policy expression e33 client.vlan.id==33

add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -persistenceType NONE -listenPolicy e11
-cltTimeout 180 -l2Conn ON

add lb vserver LB-VIP2 HTTP 10.2.2.254 80 -persistenceType NONE - listenPolicy e22
-cltTimeout 180 -l2Conn ON

add lb vserver LB-VIP3 HTTP 10.3.3.254 80 -persistenceType NONE - listenPolicy e33
-cltTimeout 180 -l2Conn ON

add lb vserver FW-VIP-1 ANY * * -persistenceType NONE -lbMethod ROUNDROBIN - listenPolicy e110 -Listenpriority 1 -m MAC -cltTimeout 120

add lb vserver FW-VIP-2 ANY * * -persistenceType NONE -lbMethod ROUNDROBIN - listenPolicy e210 -Listenpriority 2 -m MAC -cltTimeout 120

add lb vserver FW-VIP-3 ANY * * -persistenceType NONE -lbMethod ROUNDROBIN - listenPolicy e310 -Listenpriority 3 -m MAC -cltTimeout 120

add service RD-1 10.1.1.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED
-usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA NO -TCPB NO -CMP NO

add service RD-2 10.2.2.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED
-usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA NO -TCPB NO -CMP NO

add service RD-3 10.3.3.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED
-usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA NO -TCPB NO -CMP NO

bind lb vserver FW-VIP-1 RD-1

bind lb vserver FW-VIP-2 RD-2
```

bind lb vserver FW-VIP-3 RD-3

To isolate network traffic by using the configuration utility

1. Add services representing the servers, as described in "Creating a Service."
2. Add each firewall as a service:
   1. Navigate to Traffic Management > Load Balancing > Services
   2. In the details pane, click Add.
   3. In the Create Service dialog box, specify values for the following parameters:

      - Service Name*—The name that you assign to the service.
      - Protocol*—Select ANY from the drop-down list.
      - Server*—The firewall's IP address.
      - Port*—Specify a value of 80.

      *A required parameter

   4. Click Create.
   5. From the Services pane, open the services you created and verify the settings.
3. Configure a load balancing virtual server.
   1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
   2. In the details pane, click Add.
   3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which are described in "Creating a Virtual Server."

      - Name*
      - Protocol*
      - IP Address*
      - Port*

      *A required parameter

   4. On the Services tab, select the corresponding services.
   5. On the Advanced tab, select the L2 Connection check box and, for Redirection Mode, select MAC Based. Then, click the Listen Policy link and create the listen policy for the virtual server.
   6. Click Create.
4. Configure the shadow load balancing virtual server.
