

NetScaler 10.5

About the NetScaler 10.5 Release

Oct 23, 2017

The release notes describe the changes or enhancements, fixed issues, and known issues in a build. The list of known issues is cumulative, that is, it includes issues that are newly found in that build and also issues from previous builds.

The release notes document includes all or some of the following sections:

What's New: The enhancements and other changes released in the build.

Fixed Issues: The issues that are fixed in the build.

Known Issues: The issues that exist in the build.

Points to Note: The important aspects to keep in mind while using the build.

Limitations: The limitations that exist in the build.

Note

- The [# XXXXXX] labels under the issue descriptions are internal tracking IDs used by the NetScaler team.
- These release notes do not document security related fixes. For a list of security related fixes and advisories, see the Citrix security bulletin.

For the latest release notes (10.5 67.10), click this [link](#).

Configuration Utility Changes

Jun 30, 2014

In release 10.5, NetScaler graphical user interface (GUI) has been designed in a new and improved format that provides better user interaction experience. You can see the following enhancements on the GUI:

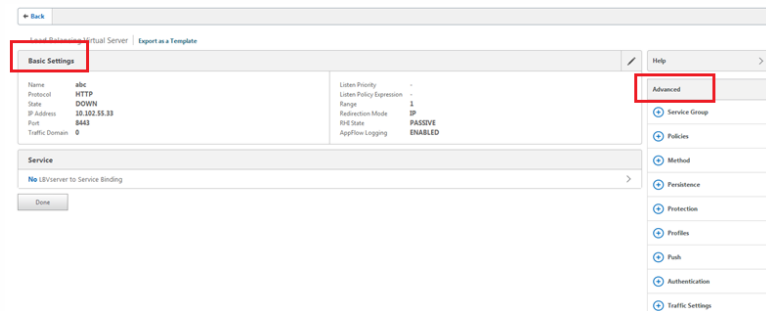

- The login page has been enhanced to provide a new look and now displays only the two fields as shown in the following image:

Figure 1. Login Page

- The GUI has been enhanced to provide you with a workflow-based experience which guides you through the entire configuration. The configuration settings have now been classified as basic and advanced for some features. The following image illustrates the basic and advanced features of a load balancing virtual server:

Figure 2. Basic and Advanced Features

First, specify the basic parameters required to configure a load balancing virtual server. Then, from the Advanced options select the required options such as, Policies or Protection to configure them until you have all the required details needed to configure a load balancing virtual server.

- The NetScaler ADC configuration utility has also been reimplemented in HTML and you no longer need Java Runtime Environment (JRE) to access most features through the GUI. As a result of these enhancements, the GUI does not display pop-up dialog boxes for those features. Instead, each view is displayed as an inline expansion with intelligent pagination.

The following features or nodes still require JRE:

- System

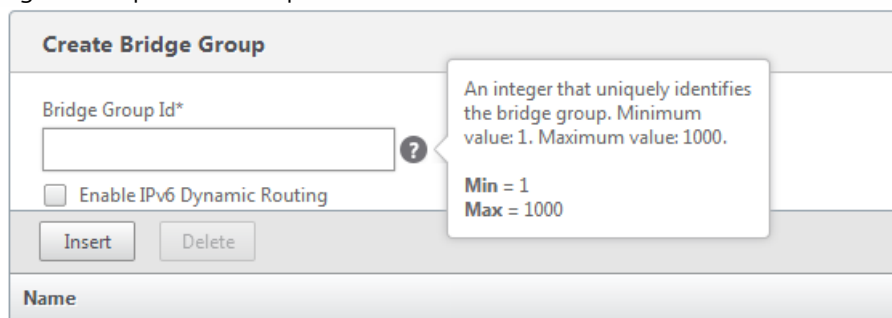

- Upgrade Wizard
 - Diagnostics
 - User Administration
 - Command Policies
 - Command Policy RegEx Editor
 - Visualizers
 - Network > Network Visualizer
 - Network > TCP/IP connections
 - Traffic Management > Load Balancing > Visualizer
 - Traffic Management > Content Switching > Visualizer
 - Traffic Management > GSLB > Visualizer
 - Security
 - Application Firewall
 - Application Firewall wizard
 - Add/ Edit/ Import profiles
 - Signatures
 - Add
 - Update Version
 - Auto Update Settings
 - Add/ Edit Policies
- The GUI header displays appliance details from a drop-down list, thereby, decluttering the header as shown in the following image:

Figure 3. GUI Header display

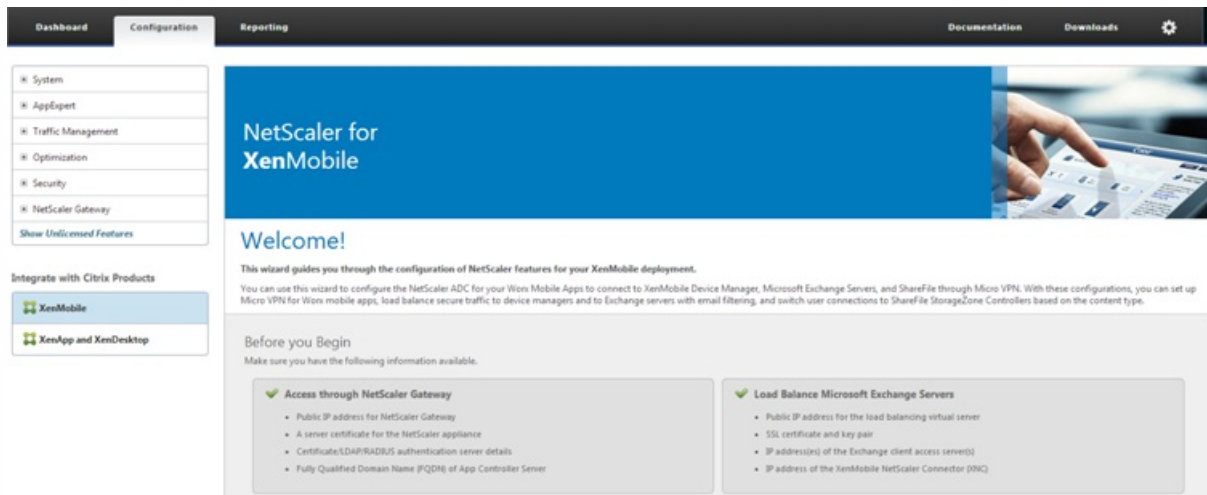

- The tooltips are now displayed on demand. If you want to view the description of a field, click on that field, and then click the question mark symbol that appears next to the field. Also, the tooltips box appears on the side of the field without obstructing your view of the field.

Figure 4. Improved Tooltips

- NetScaler ADC configuration utility is now integrated with Citrix XenMobile, Citrix XenApp and XenDesktop. These wizards now appear in the configuration utility. You can use this wizard to configure the NetScaler ADC for your Worx Mobile App and to provide access to hosted virtual desktops (XenDesktop) and hosted Windows virtual apps through NetScaler Gateway.

Figure 5. XenMobile, XenApp and XenDesktop Integration

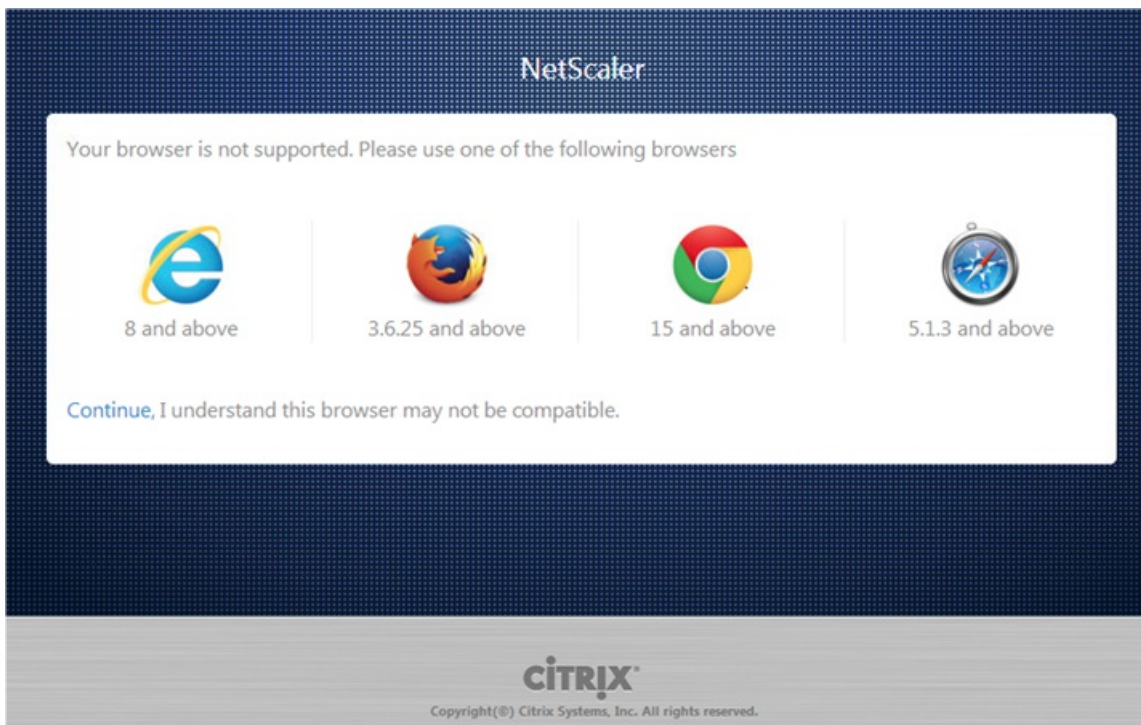

Browser Compatibility

To access the enhanced GUI, your workstation must have any of the following supported web browsers:

Operating System	Browser	Version
Windows 7 32 bit and 64 bit	Internet Explorer	IE 8, 9,10 and 11
Windows 8 32 bit and 64 bit	Internet Explorer	IE 10 and 11
Windows 8 64 bit	Chrome	Latest
	Firefox	3.6.25 and above
Mac 32 bit and 64 bit	Safari	5.1.3 and above
	Firefox	3.6.25 and above
Mac	Safari	5.1.3 and above
Windows 8, 32 bit	Internet explorer	10
Windows 8, 64 bit	Internet explorer	11
	Firefox	3.6.25 and above
	Chrome	Latest

The following error message appears, if you use a browser which is not compatible with NetScaler ADC.
Figure 6. Browser Incompatibility Error Message

Licensing

Jul 01, 2014

If you want to upgrade your software to this release, you can use your existing license. Contact your Citrix sales representative for new licenses if you are using the standard edition and want to upgrade to the enterprise or platinum edition, or if you are using the enterprise edition and want to upgrade to the platinum edition.

For more information, see [NetScaler Licenses](#).

Upgrading the NetScaler Software to Release 10.5

Oct 24, 2016

To upgrade your software, download release 10.5 and use the Upgrade Wizard (MPX or VPX) or Management Service (SDX).

To download the latest build

1. In a browser, go to www.citrix.com and click the Downloads tab.
2. In the Product list, select NetScaler ADC.
3. In the Download Type list, select Firmware, and then select the release and build that you want to download.
4. Click Download.
5. Accept the Download Agreement.
6. Select Save As, and then browse to the location of the folder on your local computer where you want to save the firmware.
7. Select the documentation file and repeat steps 5 and 6 to save the file on your local computer.

To upgrade an MPX Appliance or VPX Virtual Appliance

1. Log on to the configuration utility.
2. In the details pane, click Upgrade Wizard.
3. In the wizard, in File Location, select Local Computer, and then navigate to the folder that contains the software and the documentation file. Click OK.
4. Follow the instructions in the wizard.
5. When prompted, select Reboot.

To upgrade an SDX Appliance

1. Log on to the configuration utility and navigate to Management Service > Software Images.
2. Upload the software image and documentation file downloaded from the Citrix website to your SDX appliance.
3. In the System pane, under System Administration, click Upgrade Management Service.
4. In the Upgrade Management Service dialog box, select the software image and documentation file.
5. Click OK. The Management Service restarts after the upgrade.

Note: Your configuration is saved before you restart the appliance, and is available after you upgrade the appliance. For more information about upgrading and downgrading, see [Upgrading or Downgrading the System Software](#).

AppFlow

Jul 08, 2013

Which build of NetScaler supports AppFlow?

AppFlow is supported on NetScaler appliances running version 9.3 and above with nCore build.

What is the format used by AppFlow to transmit data?

AppFlow transmits information in the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. IPFIX (the standardized version of Cisco's NetFlow) is widely used to monitor network flow information.

What do AppFlow records contain?

AppFlow records contain standard NetFlow or IPFIX information, such as time stamps for the beginning and end of a flow, packet count, and byte count. AppFlow records also contain application-level information (such as HTTP URLs, HTTP request methods and response-status codes, server response time, and latency). IPFIX flow records are based on templates that must be sent before sending flow records.

After an upgrade to NetScaler Version 9.3 Build 48.6 CI, why does an attempt to open a virtual server from the GUI result in the error message "The AppFlow feature is only available on Citrix Netscaler Ncore"

AppFlow is supported only on nCore appliances. When you open the virtual server configuration tab, clear the **AppFlow** checkbox.

What does the transaction ID in an AppFlow records contain?

A transaction ID is an unsigned 32-bit number identifying an application-level transaction. For HTTP, a transaction corresponds to a request and response pair. All flow records that correspond to this request and response pair have the same transaction ID. A typical transaction has four uniflow records. If the NetScaler generates the response by itself (served from the integrated cache or by a security policy), there might be only two flow records for the transaction.

What is an AppFlow action ?

An Appflow action is a set of collectors to which the flow records are sent if the associated AppFlow policy matches.

What commands can I run on the NetScaler appliance to verify that the AppFlow action is a hit?

The show appflow action. For example:

```
> show appflow action
```

- 1) Name: aFL-act-collector-1
Collectors: collector-1
Hits: 0
Action Reference Count: 2
- 2) Name: apfl-act-collector-2-and-3
Collectors: collector-2, collector-3
Hits: 0
Action Reference Count: 1
- 3) Name: apfl-act-collector-1-and-3
Collectors: collector-1, collector-3
Hits: 0
Action Reference Count: 1

What is an AppFlow collector?

A collector receives flow records generated by the NetScaler appliance. To be able to send flow records, you must specify at least one collector. You can specify up to four. You can remove unused collectors.

What NetScaler version is required for using AppFlow?

Use NetScaler version 9.3.49.5 or higher, and remember that AppFlow is available in only the nCore builds.

What transport protocol does AppFlow use?

AppFlow uses UDP as the transport protocol.

What ports need to be opened if I have a firewall in the network?

Port 4739. It is the default UDP port the AppFlow collector uses for listening on IPFIX messages. If the user changes the default port, that port should be opened on the firewall.

How can I change the default port AppFlow uses?

When you add an AppFlow collector by using the `add appflowCollector` command, you can specify the port to be used.

```
> add appflowCollector coll1 -IPAddress  
10.102.29.251 -port 8000  
Done
```

What does setting `clientTrafficOnly` do?

NetScaler generates AppFlow records only for client-side traffic.

How many collectors can be configured at a time?

You can configure up to four AppFlow collectors at a time on the NetScaler appliance. Please note that the maximum number of collectors that can be configured on a NetScaler appliance is four.

AutoScale

Sep 18, 2013

What are the prerequisites for setting up AutoScale?

For prerequisites for setting up AutoScale, see "[Prerequisites](#)".

Can the CloudPlatform AutoScale feature be used without a NetScaler appliance?

No. The NetScaler appliance is currently required for the AutoScale feature to work. If the CloudPlatform administrator configures AutoScale in a network that does not include a NetScaler appliance, CloudPlatform throws an error.

What happens if the AutoScale feature is used with a NetScaler release that does not support AutoScale?

If the AutoScale feature is used with a NetScaler release that does not support AutoScale, the CloudPlatform user interface throws an error. CloudPlatform also writes a message to the log file, indicating that the configured NetScaler does not support AutoScale.

What versions of CloudPlatform and NetScaler should I use to implement AutoScale?

For information about NetScaler releases that support AutoScale, see [Supported Environment](#).

In a load balancing rule, can manually provisioned virtual machine instances coexist with instances provisioned by the AutoScale feature?

No. The CloudPlatform virtual machine group in a load balancing rule can contain only manually provisioned instances or only instances provisioned by the AutoScale feature. They cannot coexist.

Is there a limit on the number of virtual machine instances to which we can scale up by using AutoScale?

Yes. The CloudPlatform administrator specifies the maximum number of members to which the configuration can scale up. When the limit is reached, virtual machines are not provisioned even if the scale-up condition is satisfied. The upper limit prevents uncontrolled spawning of VMs due to misconfiguration of the AutoScale feature or unexpected load conditions.

Are AutoScale events observable?

The events generated for deploying or destroying virtual machines are observable. These events are logged in the NetScaler logs (ns.log) and in the CloudPlatform logs (management-server.log). However, you cannot observe the metric values collected by NetScaler monitors.

What metrics can be used in AutoScale policies?

In an AutoScale policy, you can use any metric that is exposed through SNMP, or any NetScaler statistics associated with the load balancing virtual server used in the AutoScale configuration. For example, you can use metrics associated with CPU, memory, or disk usage, and NetScaler metrics such as throughput or response time.

What should a CloudPlatform administrator do before performing maintenance tasks on a CloudPlatform network in which AutoScale is configured?

The CloudPlatform administrator should disable the AutoScale configuration from the CloudPlatform user interface. Disabling the AutoScale configuration temporarily disables any scale-up or scale-down events. However, disabling AutoScale for an application, in CloudPlatform, does not affect the ability of the NetScaler appliance to serve traffic to existing virtual machines.

With AutoScale configured, are any configured VM limits enforced on the user account?

The NetScaler appliance works in the context of an AutoScale user account. Therefore, any limits that the CloudPlatform

administrator has imposed on the number of VMs that can be created by the account are automatically enforced when the NetScaler appliance attempts to create more VMs than are permitted.

Is AutoScale supported in a high availability (HA) NetScaler pair?

No. Currently, HA mode is not supported for AutoScale.

Call Home

Jun 14, 2016

What is the Call Home feature on a NetScaler appliance?

The Call Home feature registers your NetScaler appliance with the Citrix Technical Support server (TaaS) and monitors the appliance for common error conditions. If your appliance is successfully registered with TaaS server, Call Home automatically uploads system debug data to that server in the event that one of the conditions occurs. The appliance keeps a full log of all upload events. If you are unable to correct the problem after reviewing the appliance's log, you can contact the Citrix Technical Support team and open a service request. The team can analyze the uploaded system data and recommend possible solutions.

How to configure a Call Home email address? Where is the information available?

The Call Home enables you to configure the administrator's email address for Call Home service support.

Which release of NetScaler Software supports Call Home?

Release 10 and later.

Does Call Home support monitoring of any error conditions in a NetScaler virtual appliance?

No. Call Home does not currently support monitoring of virtual appliances.

Which NetScaler hardware models support Call Home?

Any NetScaler MPX appliance running release 10 or later of the NetScaler software supports Call Home.

Do you need a separate license for Call Home?

No. The Call Home feature does not require a separate license. It is available with all NetScaler platform licenses.

Does Call Home support monitoring of cluster events or error conditions?

No. Call Home does not currently support monitoring of NetScaler clusters.

What error conditions does Call Home monitor in a NetScaler appliance?

Call Home supports monitoring of the following events in a NetScaler appliance:

- Compact flash drive errors
- Hard disk drive errors
- Power supply unit failure
- SSL card failure
- Warm restart

What mechanism does Call Home use to upload the Call Home tar file to TaaS?

Call Home uses the HTTPS protocol to upload the Call Home tar file.

Does Call Home support automatic Technical Support service request creation?

No. You have to contact the Citrix Technical Support team to open a service request.

What is the frequency of Call Home tar file uploads to TaaS?

Call Home creates the Call Home tar file and uploads it to the Citrix Technical Support server (TaaS) upon first occurrence of a particular error condition since the appliance was last started. That is, a reoccurrence of same error condition does not trigger another upload unless the appliance was rebooted after the previous occurrence.

Must I configure SNMP for Call Home to monitor error conditions?

No. Call Home creates and uploads a Call Home tar file for the first occurrence of a monitored error condition since the appliance was last started. If you want to be alerted each time the error condition occurs, you can configure the corresponding SNMP alarm for the error condition.

Is the Call Home feature enabled by default on the appliance?

No, the Call Home feature is disabled, by default. You must first enable the feature to register the appliance for critical error conditions.

Clustering

Feb 04, 2016

Click [here](#) for clustering FAQs for NetScaler versions 11.0, 10.5, and 10.1.

Connection Management

Feb 16, 2015

What is an admin connection?

An admin connection establishes a connection to the NetScaler IP (NSIP) address and allows administrators to configure and monitor the NetScaler appliance.

What are the types of admin connections?

There are two types of admin connections:

- SSH connection – Admin users use an SSH client to logon through the NetScaler IP (NSIP) address.
- NITRO API connection – Admin users use NITRO API's to automate the logon process to NetScaler appliance.

Note: Admin users can also log on through the NetScaler GUI to log on, by using a browser to connect to the NSIP address. The GUI internally opens a NITRO API connection. Therefore, a GUI session is equivalent to a NITRO API connection, and FAQs related to NITRO API apply to GUI.

How many concurrent admin connections are allowed on a NetScaler appliance?

The appliance allows up to 20 concurrent admin connections.

Which login credentials are required for an admin logon?

Admin logon requires a user name and a password.

Note: An authentication key can be used instead of a password.

Which external authentication methods does a NetScaler appliance support?

The appliance supports the following external authentication methods:

- RADIUS
- LDAP
- TACACS

For more details, see [External Authentication](#).

What is a client?

A client is a device (laptop or desktop), used by admin user to open an admin connection.

What is a session token?

A session token is a unique identifier that the NetScaler appliance issues to a client that sends a NITRO API logon request.

- API clients can reuse the session token, if it has not expired, for subsequent API requests on new TCP connections
- GUI clients internally open NITRO API connections and keep the session token active for the duration of the GUI session.

What is an active session on a NetScaler appliance?

A CLI session is considered active if the session has not expired and has an open SSH connection with a NetScaler appliance.

A NITRO API session is considered active if the session token timeout has not expired on the NetScaler appliance.

How does NetScaler enforce the concurrent connection limit?

Every time the NetScaler appliance receives an admin connection request (SSH or NITRO API), it checks the number of

admin connections it has open. If the number is lower than 20, a new connection is opened.

Which counter reflects the number of admin connections on a NetScaler appliance?

The connection counter (`nsconfigd_cur_clients`) reflects the number of active connections. This counter is incremented when a client opens new connection to the appliance, and is decremented when a connection is closed.

Which counter reflects the number of active tokens on the NetScaler appliance?

The `configd_cur_tokens` counter reflects the number of active tokens on NetScaler appliance.

How does NetScaler appliance handle errors on a connection?

The NetScaler appliance immediately closes the client (CLI, API, and GUI) connection if it encounters errors on a connection.

Does a CLI or GUI session on a connection to the management address count against the admin connection limit?

Yes, all CLI and GUI connections are TCP based connections, and every TCP connection to the management address counts against the admin connection limit.

Does a NITRO session count against the admin connection limit?

A NITRO session counts against the admin connection limit if there is an open TCP connection using the session token issued by the NetScaler appliance.

What is the default timeout period for API, GUI, and CLI sessions on NetScaler appliance?

The following table lists the default timeout period for API, GUI and CLI sessions on the NetScaler appliance:

NetScaler Releases	CLI default timeout period (min)	API default timeout period (min)	GUI default timeout period (min)
NetScaler 9.3	None	30 Minutes	30 Minutes
NetScaler 10.1	None	30 Minutes	30 Minutes
NetScaler 10.5 Onwards	15 Minutes	30 Minutes	15 Minutes

How can you set the CLI sessions time out on a NetScaler appliance?

The CLI session timeout can be configured by executing the following command at the CLI prompt:

```
set cli mode -timeout <xx seconds>
```

How do you override the default timeout period when using the NITRO API?

You can override the default timeout period for a NITRO API by setting the timeout duration in the “timeout” field of the login object. If the session timeout is set to zero, the session token has an infinite timeout.

Note: An infinite timeout is not advisable, because sessions that do not time out continue to count against the admin connection count.

What happens if a user account is deleted from the NetScaler appliance after an admin session is created?

For internal system users, NetScaler appliance closes the existing CLI or NITRO API session.

For external system users, session remains active until it expires.

Can NITRO API clients use a single session token to open multiple admin connections on the NetScaler appliance?

Yes. Each such connection counts against the admin connection limit.

If management access is enabled for a MIP or SNIP address, do admin connections to that address count against the limit for the number of admin connections?

Yes, admin connections to management address (MIP or SNIP) count against the admin connection limit on NetScaler ADC.

Can a NetScaler admin log on to the NetScaler appliance after the maximum connections limit is reached?

Yes. One additional admin connection is allowed after the maximum connection limit is reached.

Can NITRO API endpoints open multiple admin connections on NetScaler the appliance?

Yes, NITRO API endpoints can open multiple admin connections and exhaust the concurrent admin connection limit on a NetScaler appliance. In such situations, an additional SSH/CLI connection is allowed and the admin can force closure of old API sessions, or reduce the session timeout duration for the existing API sessions.

Can same client open multiple API sessions on a NetScaler appliance?

Yes, a client can open multiple API session by repeatedly logging on. For example, the client might log back on after a reboot.

Note: Repeated client logons count against the admin connection limit on NetScaler appliance.

Can API clients use the entire API session token limit?

Yes, API clients can use the entire API session token limit, provided by repeatedly logging on without using a previously issued token.

Note: If a client’s session timeout is zero, the token is valid forever. Repeated logons using new session tokens can count against the limit for API session tokens.

Do CLI sessions count against the API session token limit?

No, CLI sessions are not counted against the API session token limit.

Can admin users use telnet to open a CLI session?

No. Only an SSH client can open a CLI session.

What is connection limit and API session limit applicable for various NetScaler releases?

The following table lists the maximum concurrent admin connection and active API session limits applicable for various NetScaler releases:

NetScaler Releases	9.3	10.1 (Before 130.x)	10.1 (Before 130.10)	10.1 (From 130.10)
Maximum number of concurrent admin connections	20	20	20	20
Maximum number of active API sessions*	1000	20	1000	1000

Note*:

- API sessions are considered active if they have not timed out. For example, if 500 API sessions were created but 100

have expired, 400 API sessions are active.

- An API session need not open a TCP connection to the NetScaler appliance.

Configuration Utility

Dec 14, 2015

Q: When I use Firefox to compare two NetScaler configurations, the browser seems to freeze.

A: Firefox will eventually display the differences in the configurations, but the process takes a considerable amount of time if there are more than 1000 differences. Use Chrome for a faster response.

Q: I am using a MAC Safari browser to upgrade a NetScaler ADC. On the upgrade wizard, when I click the Browse button to choose the build file from the appliance, the dialog box does not show any files or folders. Also, when I navigate back to the root folder, the dialog box displays the top level folder, but I cannot browse it. What should I do?

A: On the Safari browser, click the Settings icon and navigate to Preferences > Security > Manage Website Settings > Java, and then change value of the When visiting other websites setting to Run in unsafe mode.

Q: Is there any security restriction on Internet Explorer version 10 because of which the browser displays the following error message: There is a problem with this website's security certificate, and does not allow me to proceed further?

A: Yes, a security update by Microsoft restricts the use of certificates with RSA keys less than 1024 bits in length. For more information, see: <https://technet.microsoft.com/library/security/2661254>

Q: After I upgraded the JRE on my appliance to version 7.51, the graphical user interface (GUI) applet does not load when I access the NetScaler configuration utility. The applet download stops at 1%, and Java generates a security error. What should I do?

A: You can use the configuration utility with JRE 7.51 if, in the Java Control Panel, you lower the security level or add the NetScaler appliance's URL to the Exception Site List.

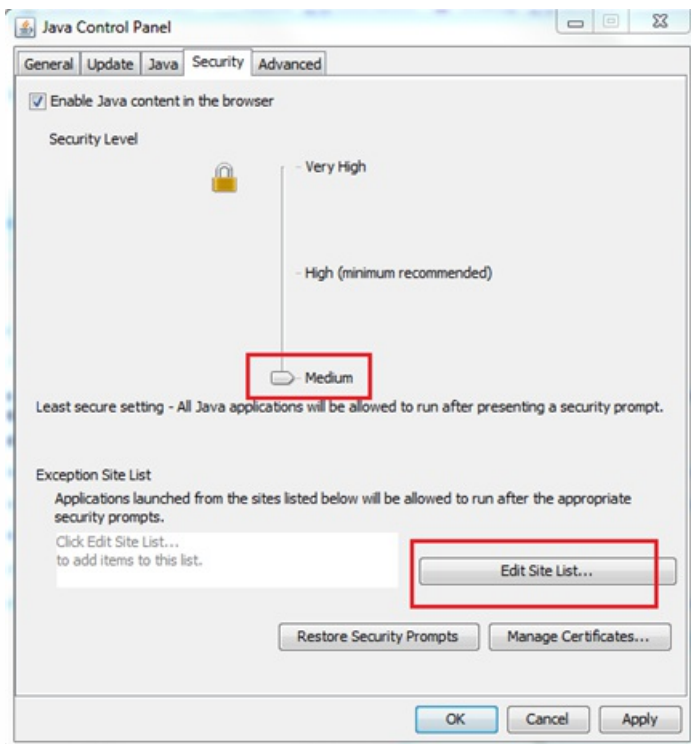

If using a Windows computer, navigate to Control Panel and click Java.

If using a MAC computer, navigate to System Preferences and click Java.

Then, in the Java Control Panel dialog box, do either of the following:

- Click the Security tab, and then set the Security Level to medium.
- Click the Security tab, click the Edit Site List button, and then add the URL of the NetScaler appliance in the Exception Site List box.

Figure 1. Java Control Panel

Q: After I upgraded the JRE on my appliance to version 7.45, the graphical user interface (GUI) applet does not load when I access the NetScaler configuration utility. The applet download stops at 1%, and Java throws a security error. What should I do?

A: The NetScaler GUI is not compatible with JRE version 7.45. Citrix recommends using a JRE version earlier than 7.45 to access the configuration utility. If you have already upgraded to version 7.45 and do not want to downgrade, you can configure Java to not keep temporary files. However, you will have to download the JAR files every time you access the configuration utility.

To downgrade JRE 7.45 to an earlier version:

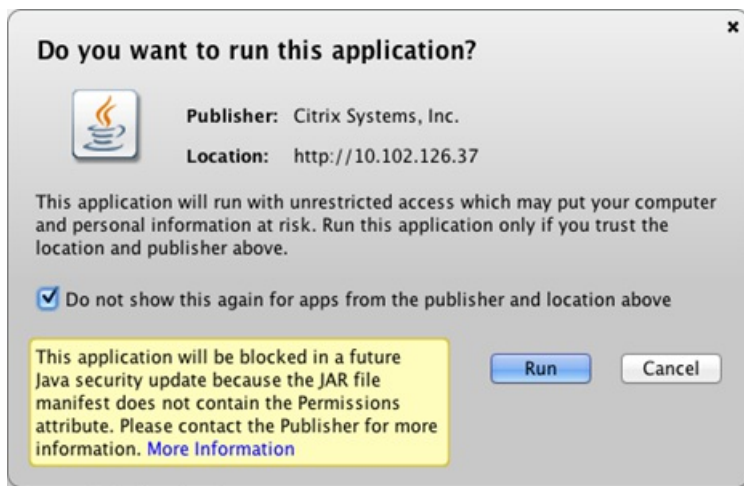

1. Uninstall JRE 7.45 by following the instructions at http://www.java.com/en/download/help/uninstall_java.xml.
2. Download an earlier version of JRE from the following location:
<http://www.oracle.com/technetwork/java/javase/archive-139210.html>.

To continue using JRE 7.45:

If you are using a Windows system, navigate to Control Panel and click Java. The Java Control Panel opens.

If you are using a MAC system, navigate to System Preferences and click Java. The Java Control Panel opens.

1. Click the General tab.
2. Under Temporary Internet Files, click Settings.
3. Clear the Keep temporary files on my computer option.
4. Close the browser and re-launch the GUI.
5. Open the configuration utility and click Run and Allow, respectively, when the following warnings appear:

Note:

- The Jar files will not be cached and you will have to download the files every time you access the configuration utility.
- This problem is fixed in the following releases:
 - Release 9.3, build 65.x and later
 - Release 10.0, build 78.x and later
 - Release 10.1, build 122.x and later
 - Release 10.1.e, build 120.13xx.e

Q: What should I do before accessing the NetScaler configuration utility?

A: Before accessing a new version of the NetScaler software:

- Clear your browser cache.
- Make Sure that JavaScript, Java, and plug-ins are enabled in your browser. For help with enabling Java for your browser, see http://java.com/en/download/help/enable_browser.xml.
- Clear the “Temporary internet files” in the Java console.
- On the Java tab of the Java console, in Java Runtime Environment Settings, make sure that the latest version of JRE is present and is enabled.

Q: I am using HTTP to access the configuration utility. Which port should I open?

A: Open TCP port 3010 when using HTTP to access the configuration utility.

Q: I am using HTTPS to access the configuration utility. Which port should I open?

A: Open TCP port 3008 when using HTTPS to access the configuration utility.

Q: After entering the IP address of the NetScaler appliance in the address bar, I get the following error: "Java Applet could not be loaded". What should I do?

A: Verify that Java is installed properly. You can download Java from www.java.com. If you are using a MAC Safari browser, Java is disabled if it is not used for 35 days.

To enable Java plug-in in Safari, follow these steps:

1. In the Safari browser, choose Safari > Preferences or press Command-comma (⌘-,) on your keyboard.
2. Click Security, and then select Enable Java.

3. Close the Safari Preferences window.

Q: With which browsers is the configuration utility compatible for different operating systems?

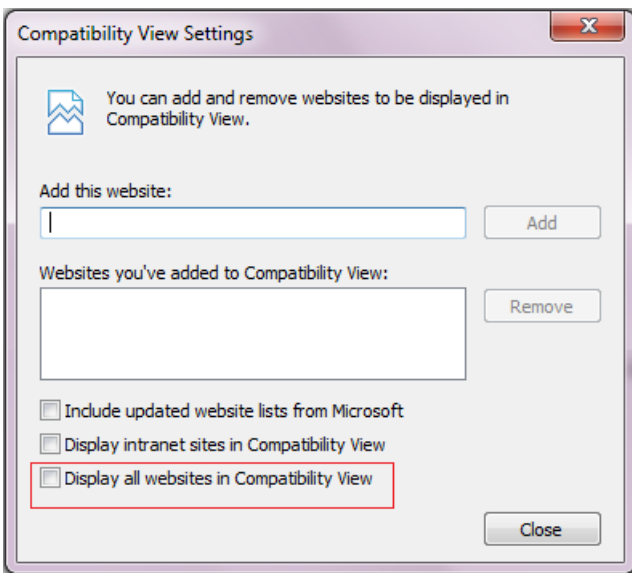

A: The following table lists the compatible browsers:

Operating System	Browser	Versions

Windows 7 Operating System	Internet Explorer Browser	8 and 9 Versions
	Mozilla Firefox	3.6.25 and above
	Chrome	15 and above
Windows 64 bit	Internet Explorer	8 and 9
	Chrome	15 and above
MAC OS	Mozilla Firefox	12 and above
	Safari	5.1.3

Q: When I access the NetScaler configuration utility by using Internet Explorer version 8 or 9, the browser displays only a grey bar at the top of the screen. What should I do?

A: The browser might be set in compatibility mode. To disable compatibility mode, go to **Tools > Compatibility View Settings** and clear the **Display all websites in Compatibility View** check box.

Q: Even after I disable compatibility mode in Internet Explorer version 8 or 9, the configuration utility does not appear. What should I do?

A: Make sure that the browser mode and document mode in the browser are set to the same version. To view the configuration, press F12. Set the values to either Internet Explorer 8 or Internet Explorer 9.

Q: When I access the NetScaler configuration utility by using Internet Explorer version 9, the utility displays the following error message: "You are not logged in. Please login." What should I do?

A: Make sure that the cookies are not blocked in your Internet Explorer settings. Go to **Tools > Internet Options**. Click the **Privacy** tab, and then under **Settings**, make sure that the slider is set to **Medium** or any lower value.

Q: After logging into the NetScaler appliance, the page appears blank. What should I do?

A: Make sure you have disabled the Protected mode in your browser settings. If this is enabled, the Java Script is causing the NetScaler user interface screen to appear blank.

To disable this option:

1. In your IE browser settings, go to **Internet Options**.
2. Go to **Security** tab settings, click **Restricted sites** zone to disable **Enable Protected Mode** check box.
3. Click **Apply** and **OK**.

Q: I am using a MAC OS with JRE 1.7. After logging on to the configuration utility, I am not able to enter value in any of the text fields. What should I do?

A: Install Java 7, update 21 or higher.

Q: I am using a MAC OS. When I click outside a dialog window, the screen goes out of focus. Now, my browser looks disabled and hung. What should I do?

A: Click on the Java icon in the system dock, and in the JRE Security Warning window, click **Don't Block**. For details, see <http://www.oracle.com/technetwork/java/javase/7u21-relnotes-1932873.html>

Q: Is there any compatibility issue in using JRE version 7_11 with the latest version of browsers?

A: Yes. Internet Explorer 9 and Firefox 18.0.1 block Java on computers running JRE version 7_11. You have to manually activate Java in the browser or upgrade to a later version of JRE (JRE 7_13).

Content Switching

Nov 03, 2016

I have installed a non-NetScaler load balancing appliance on the network. However, I would like to use the content switching feature of the NetScaler appliance to direct the client requests to the load balancing appliance. Is it possible to use the Content switching feature of the NetScaler appliance with a non-NetScaler load balancing appliance?

Yes. You can use the Content switching feature of the NetScaler appliance with the load balancing feature of the NetScaler appliance or a non-NetScaler load balancing appliance. However, when using the non-NetScaler load balancing appliance, make sure that you create a load balancing virtual server on the NetScaler appliance and bind it to the non-NetScaler load balancing appliance as a service.

How is a Content switching virtual server different from a load balancing virtual server?

A Content switching virtual server is capable only of sending the client requests to other virtual servers. It does not communicate with the servers.

A Load balancing virtual server balances the client load among servers and communicates with the servers. It monitors server availability and can be used to apply different load balancing algorithms to distribute the traffic load.

Content switching is a method used to direct client requests for specific types of content to targeted servers by way of load balancing virtual servers. You can direct the client requests to the servers best suited to handle them. This result in reduced overheads to process the client requests on the servers.

I want to implement the Content switching feature of the NetScaler appliance to direct the client requests. What types of client request can I direct by using the Content switching feature?

You can direct only HTTP, HTTPS, FTP, TCP, Secure TCP, and RTSP client requests by using the Content switching feature. To direct HTTPS client requests, you must configure the SSL offload feature on the appliance.

I want to create Content switching rules on the NetScaler appliance. What are the various elements of the client request on which I can create a content switching rule?

You can create the content switching rules based on the following elements and their values in the client request:

- URL
- URL tokens
- HTTP version
- HTTP Headers
- Source IP address of the client
- Client version
- Destination TCP port

I understand that the content switching feature of the NetScaler appliance helps enhance the performance of the network. Is this correct?

Yes. You can direct the client requests you the servers best suited to handle them. The result is reduced overhead for processing the client requests on the servers.

Which feature of the NetScaler appliance should I configure on the NetScaler appliance to enhance the site manageability and response time to the client requests?

You can configure the content switching feature of the NetScaler appliance to enhance the site manageability and

response time to the client request. This feature enables you to create content groups within the same domain name and IP address. This approach is flexible, unlike the common approach of explicitly partitioning the content into different domain names and IP addresses, which are visible to the user.

Multiple partitions dividing a Web site into various domain names and IP addresses force the browser to create a separate connection for each domain it finds when rendering and fetching the content of a web page. These additional WAN connections degrade the response time for the web page.

I have hosted a web site on a web server farm. What advantages does the NetScaler content switching feature offer for this type of setup?

The content switching feature provides the following advantages on a NetScaler appliance in a site that is based in a web server farm:

- Manage the site content by creating a content group within the same domain and IP address.
- Enhance the response time to client requests by using the content group within the same domain and IP address.
- Avoid the need for full content replication across domains.
- Enable application-specific content partitioning. For example, you can direct client requests to a server that handles only dynamic content or only static content, as appropriate for the request.
- Support multi-homing of multiple domains on the same server and use the same IP address.
- Reuse connections to the servers.

I want to implement the content switching feature on the NetScaler appliance. I want to direct the client requests to the various servers after evaluating the various parameters of each request. What approach should I follow to implement this setup when configuring the content switching feature?

You can use policy expressions to create policies for the content switching feature. An expression is a condition evaluated by comparing the qualifiers of the client request to an operand by using an operator. You can use the following parameters of the client request to create an expression:

- **Method**- HTTP request method.
- **URL**- URL in the HTTP header.
- **URL TOKENS**- Special tokens in the URL.
- **VERSION**- HTTP request version.
- **URL QUERY**- Contains the URL Query LEN, URL LEN, and HTTP header.
- **SOURCEIP**- IP address of the client.

Following is a complete list of the operators that you can use to create an expression:

- == (equals)
- != (not equals)
- EXISTS
- NOT EXISTS
- CONTAINS
- NOT CONTAINS
- GT (greater than)
- LT (less than)

You can also create various rules, which are logical aggregations of a set of expressions. You can combine multiple expressions to create rules. To combine expressions, you can use the && (AND) and || (OR) operators. You can also use parenthesis to create nested and complex rules.

I want to configure a rule based policy along with a URL based policy for the same content switching virtual

server. Is it possible to create both types of policies for the same content switching virtual server?

Yes. You can create both type of policies for the same content switching virtual server. However, be sure to assign priorities to set an appropriate precedence for the policies.

I want to create content switching policies that evaluate the domain name, along with a prefix and suffix of a URL, and direct the client requests accordingly. Which type of content switching policy should I create?

You can create a Domain and Exact URL policy. When this type of policy is evaluated, the NetScaler appliance selects a content group if the complete domain name and the URL in the client request match the ones configured. The client request must match the configured domain name and exactly match the prefix and suffix of the URL if they are configured.

I want to create content switching policies that evaluate the domain name, along with a partial prefix and suffix of URL, and direct the client requests accordingly. Which type of content switching policy should I create?

You can create a Domain and Wildcard URL policy for the content switching virtual server. When this type of policy is evaluated, the NetScaler appliance selects a content group if the request matches the complete domain name and partially matches the URL prefix.

What is a Wildcard URL policy?

You can use wildcards to evaluate partial URLs in client requests to the URL you have configured on the NetScaler appliance. You can use wildcards in the following types of URL-based policies:

- **Prefix only.** For example, the `/sports/*` expression matches all URLs available under the `/sports` URL. Similarly, the `/sports*` expression matches all URLs whose prefix is `/sports`.
- **Suffix only.** For example the `/*.jsp` expression matches all URLs with a file extension of `.jsp`.
- **Prefix and Suffix.** For example, the `/sports/*.jsp` expression matches all URLs under the `/sports/` URL that also have the `.jsp` file extension. Similarly, the `/sports*.jsp` expression matches all URLs with a prefix of `/sports*` and a file extension of `.jsp`.

What is a Domain and Rule policy?

When you create a Domain and Rule policy, the client request must match the complete domain and the rule configured on the NetScaler appliance.

What is the default precedence set for evaluating policies?

By default, the rule based policies are evaluated first.

If some of the content is the same for all client requests, what type of precedence should I use for evaluating policies?

If some of the content is same for all the users and different content should be served on the basis of client attributes, you can use URL-based precedence for policy evaluation.

What policy expression syntaxes are supported in content switching?

Content switching supports two types of policy expressions:

- **Classic Syntax-** Classic syntax in content switching starts with the keyword `REQ` and is more advanced than the default syntax. Classic policies cannot be bound to an action. Therefore, the target load balancing virtual server can be added only after binding the content switching virtual server.
- **Default Syntax:** Default syntax generally starts with key word `HTTP` and is easier to configure. A target load balancing virtual server action can be bound to a Default Syntax policy, and the policy can be used on multiple content switching virtual servers.

Can I bind a single content switching policy to multiple virtual servers?

Yes. You can bind a single content switching policy to multiple virtual servers by using policies with defined actions. Content switching policies that use an action can be bound to multiple content switching virtual servers because the target load balancing virtual server is no longer specified in the content switching policy. The ability to bind a single policy to multiple content switching virtual servers helps to further reduce the size of the content switching configuration.

For more information, see the following Knowledge Center articles and eDocs topics:

- "How to Bind the Same Content Switching Policy to Two Content Switching vServers on a NetScaler Appliance," at <http://support.citrix.com/article/CTX122918> .
- "How to Bind the Same Advanced Policy to Multiple Content Switching Virtual Servers using Policy Labels," at <http://support.citrix.com/article/CTX122736>.
- "Configuring a Content Switching Action," at <http://support.citrix.com/proddocs/topic/netscaler-traffic-management-10-map/ns-cs-basicconfig-config-cs-action-con.html>

Can I create an action based policy using classic expressions?

No. As of now NetScaler does not support policies using classic syntax expressions with actions. The target load balancing virtual server should be added when binding the policy instead of defining it in an action.

Debugging

Feb 26, 2014

How can I determine the interface (CLI, GUI, or API) through which an operation was performed?

The NetScaler keeps track of the interfaces through which operations are performed. You can view this information in syslogs (in the NetScaler GUI, navigate to Configuration > System > Auditing > Audit Messages > Syslog messages) or in the ns.log (located at the /var/log/ directory) file.

For example, operations that are performed through the API are flagged as "API_CMD_EXECUTED."

High Availability

Aug 29, 2017

What are the various ports used to exchange the HA-related information between the nodes in an HA configuration?

In an HA configuration, both nodes use the following ports to exchange HA-related information:

- UDP Port 3003, to exchange heartbeat packets
- Port 3010, for synchronization and command propagation

What configurations are not synced or propagated in an HA configuration in either INC or non-INC mode?

Configurations implemented with the following commands are neither propagated nor synced to the secondary node:

- All node specific HA configuration commands. For example, add ha node, set ha node, and bind ha node.
- All Interface related configuration commands. For example, set interface and unset interface.
- All channel related configuration commands. For example, add channel, set channel, and bind channel.

Note: For more information about HA Configuration in INC mode, see [Configuring High Availability Nodes in Different Subnets](#).

What configurations are not synced or propagated in an HA configuration in INC mode?

The following configurations are neither synced nor propagated. Each node has its own.

- MIPs
- SNIPs
- VLANs
- Routes (except LLB routes)
- Route monitors
- RNAT rules (except any RNAT rule with VIP as the NAT IP)
- Dynamic routing configurations.

What are the conditions that trigger synchronization?

Synchronization is triggered by any of the following conditions:

- The incarnation number of the primary node, received by the secondary, does not match that of the secondary node.
Note: Both nodes in an HA configuration maintain a counter called *incarnation number*, which counts the number of configurations in the node's configuration file. Each node sends its incarnation number to each other node in the heartbeat messages. The incarnation number is not incremented for the following commands:
 - All HA configuration related commands. For example, add ha node, set ha node, and bind ha node.
 - All Interface related commands. For example, set interface and unset interface.
 - All channel-related commands. For example, add channel, set channel, and bind channel.
- The secondary node comes up after a restart.
- The primary node becomes secondary after a failover.

Does a configuration added to the secondary node get synchronized on the primary?

No, a configuration added to the secondary node is not synchronized to the primary.

What could be the reason for both nodes claiming to be the primary in an HA configuration?

The most likely reason is that the primary and secondary nodes are both healthy but the secondary does not receive the heartbeat packets from the primary. The problem could be with the network between the nodes.

Does an HA configuration run into any issues if you deploy the two nodes with different system clock settings?

Different system-clock settings on the two nodes can cause the following issues:

- The time stamps in the log file entries do not match. This situation makes it difficult to analyze the log entries for any issues.
- After a failover, you might have problems with any type of cookie based persistence for load balancing. A significant difference between the times can cause a cookie to expire sooner than expected, resulting in termination of the persistence session.
- Similar considerations apply to any time related decisions on the nodes.

What are the conditions for failure of the *force HA sync* command?

Forced synchronization fails in any of the following circumstances:

- You force synchronization when synchronization is already in progress.
- The secondary node is disabled.
- HA synchronization is disabled on the current secondary node.
- HA propagation is disabled on the current primary node and you force synchronization from the primary.

What are the conditions for failure of the *sync HA files* command?

Synchronizing configuration files fail if the secondary node is disabled.

In an HA configuration, if the secondary node takes over as the primary, does it switch back to secondary status if the original primary comes back online?

No. After the secondary node takes over as the primary, it remains as primary even if the original primary node comes back online again. To interchange the primary and secondary status of the nodes, run the *force failover* command.

What are the conditions for failure of the *force failover* command?

A forced failover fails in any of the following circumstances:

- The secondary node is disabled.
- The secondary node is configured to remain secondary.
- The primary node is configured to remain primary.
- The state of the peer node is unknown.

Integrated Caching

Sep 30, 2013

Content Groups

How is a DEFAULT content group different from other content groups?

The behavior of the DEFAULT content group is exactly the same as any other group. The only attribute that makes the DEFAULT content group special is that if an object is being cached and no content group has been created, the object is cached in the DEFAULT group.

What is the 'cache-Control' option of the content group level?

You can send any cache-control header the browser. There is a content group level option, -cacheControl, which enables you to specify the cache-control header that you want to be inserted in the response to the browser.

What is the 'Minhit' option in content group level?

Minhit is an integer value specifying the minimum number of hits to a cache policy before the object is cached. This value is configurable at the content group level. Following is the syntax to configure this value from the command line interface.

```
add/set cache contentGroup <Content_Group_Name> [-minHits <Integer>]
```

What is the use of the expireAtLastByte option?

The expireAtLastByte option enables the integrated cache to expire the object as soon as it has been downloaded. Only requests that are outstanding requests at that time are served from cache. any new requests are sent to the server. This setting is useful when the object is frequently modified, as in the case of stock quotes. This expiry mechanism works along with the Flash Cache feature. To configure expireAtLastByte option, run the following command from the command line interface:

```
add cache contentGroup <Group_Name> -expireAtLastByte YES
```

Cache policy

What is a caching policy?

Policies determine which transactions are cacheable and which are not. Additionally, policies add or override the standard HTTP caching behavior. Policies determine an action, such as CACHE or NOCACHE, depending on the specific characteristics of the request or response. If a response matches policy rules, the object in the response is added to the content group configured in the policy. If you have not configured a content group, the object is added to the DEFAULT content group.

What is a policy hit?

A hit occurs when a request or response matches a cache policy.

What is a miss?

A miss occurs when a request or response does not match any cache policy. A miss can also occur if the request or response matches a cache policy but some override of RFC behavior prevents the object from being stored in the cache.

I have configured Integrated Caching feature of the NetScaler appliance. When adding the following policy, an error message appears. Is there any error in the command?

```
add cache policy image_caching -rule exp1 | ns_ext_not_jpeg -action cache
> ERROR: No such command
```

In the preceding command, the expression should be within the quotation marks. Without quotation marks, the operator is considered to be the pipe operator.

Memory Requirements

What are the commands that I can run on the NetScaler appliance to check the memory allocated to cache?

To display the memory allocated for cache in the NetScaler appliance, run any of the following commands from the command line interface:

- show cache parameter
In the output, check the value of the Memory usage limit parameter. This is the maximum memory allocated for cache.
- show cache <Content_Group_Name>
In the output, check the values of the Memory usage and Memory usage limit parameters indicating the memory used and allocated for the individual content group.

My NetScaler appliance has 2 GB of memory. Is there any recommended memory limit for cache?

For any model of the NetScaler appliance, you can allocate half of the memory to the cache. However, Citrix recommends allocating a little less than half of the memory, because of internal memory dependency. You can run the following command to allocate 1 GB of memory to cache:

```
set cache parameter -memLimit 1024
```

Is it possible to allocate memory for individual content groups?

Yes. Even though you allocate memory for the integrated cache globally by running the set cache parameter -memlimit <Integer>, you can allocate memory to individual content groups by running the set cache <Content_Group_Name> -memLimit <Integer> command. The maximum memory you can allocate to content groups (combined) cannot exceed the memory you have allocated to the integrated cache.

What is the dependency of memory between integrated cache and TCP buffer?

If the NetScaler appliance has 2 GB memory, then the appliance reserves approximately 800 to 900 MB of memory and remaining is allocated to FreeBSD operating system. Therefore, you can allocate up to 512 MB of memory to integrated cache and the rest is allocated to TCP buffer.

Does it affect the caching process if I do not allocate global memory to the integrated cache?

If you do not allocate memory to integrated cache, all requests are sent to the server. To make sure that you have allocated memory to the integrated cache, run the show cache parameter command. Actually no objects will be cached if global memory is 0, so this needs to be set first.

Verification commands

What are the options for displaying cache statistics?

You can use either of the following options to display the statistics for cache:

- stat cache
To display the summary of the cache statistics.
- stat cache -detail
To display the full details of the cache statistics.

What are the options for displaying the cached content?

To display the cached content, you can run the show cache object command.

What is the command that I can run to display the characteristics of an object stored in cache?

If the object stored in the cache is, for example, GET //10.102.12.16:80/index.html, you can display the details about the object by running the following command from the command line interface of the appliance:

```
show cache object -url '/index.html' -host 10.102.3.96 -port 80
```

Is it mandatory to specify the group name as a parameter to display the parameterized objects in cache?

Yes. It is mandatory to specify the group name as a parameter to display the parameterized objects in cache. For example, consider that you have added the following policies with the same rule:

```
add cache policy p2 -rule ns_url_path_cgibin -action CACHE --storeInGroup g1
add cache policy p1 -rule ns_url_path_cgibin -action CACHE -storeInGroup g2
```

In this case, for the multiple requests, if policy p1 is evaluated, its hit counter is incremented and the policy stores the object in the g1 group, which has hit parameters. Therefore, you have to run the following command to display the objects from the cache:

```
show cache object -url "/cgi-bin/setCookie.pl" -host 10.102.18.152 groupName g1
```

Similarly, for another set of multiple requests, if policy p2 is evaluated, its hit counter is incremented and the policy stores the object in the g2 group, which does not have hit parameters. Therefore, you have to run the following command to display the objects from the cache:

```
show cache object -url "/cgi-bin/setCookie2.pl" -host 10.102.18.152
```

I notice that there are some blank entries in the output of the nscachemgr command. What are those entries?

Consider the following sample output of the nscachemgr command. The blank entries in this output are highlighted in bold face for your reference:

```
root@ns# /netScaler/nscachemgr -a
//10.102.3.89:80/image8.gif
//10.102.3.97:80/staticdynamic.html
//10.102.3.97:80/
//10.102.3.89:80/image1.gif
//10.102.3.89:80/file5.html
//10.102.3.96:80/
//10.102.3.97:80/bg_logo_segue.gif
//10.102.3.89:80/file500.html
//10.102.3.92:80/
//10.102.3.96:80/cgi-bin/rfc/ccProxyReval.pl
Total URLs in IC = 10
```

The blank entries in the output are due to the default caching properties for GET / HTTP/1.1.

Flushing Objects

How can I flush a selective object from the cache?

You can identify an object uniquely by its complete URL. To flush such object, you can perform any of the following tasks:

- Flush cache
- Flush content group
- Flush the specific object

To flush the specific object, you have to specify the query parameters. You specify the invalParam parameter to flush the object. This parameter applies only to a query.

Does any change in the cache configuration trigger flushing of cache?

Yes. When you make any changes to the cache configuration, all the SET cache commands inherently flush the appropriate content groups.

I have updated the objects on the server. Do I need to flush the cached objects?

Yes. When you update objects on the server, you must flush the cached objects, or at least the relevant objects and content groups. The integrated cache is not affected by an update to the server. It continues to serve the cached objects until they expire.

Flash Cache

What is Flash Cache feature of the NetScaler appliance?

The phenomenon of Flash crowds occurs when a large number of clients access the same content. The result is a sudden surge in traffic toward the server. The Flash Cache feature enables the NetScaler appliance to improve performance in such situation by sending only one request to the server. All other requests are queued on the appliance and the single response is served to all of the requests. You can use either of the following commands to enable the Fast Cache feature:

- add cache contentGroup <Group_Name> -flashCache YES
- set cache contentGroup <Group_Name> -flashCache YES

What is the limit for Flash Cache clients?

The number of Flash Cache clients depends on the availability of resources on the NetScaler appliance.

Default Behaviour

Does the NetScaler appliance proactively receive objects upon expiry?

The NetScaler appliance never proactively receives objects on expiry. This is true even for the negative objects. The first access after expiry triggers a request to the server.

Does the integrated cache add clients to the queue for serving even before it starts receiving the response?

Yes. The integrated cache adds clients to the queue for serving even before it starts receiving the response.

What is the default value for the Verify cached object using parameter of the cache configuration?

HOSTNAME_AND_IP is the default value.

Does the NetScaler appliance create log entries in the log files?

Yes. The NetScaler appliance creates log entries in the log files.

Are compressed objects stored in the cache?

Yes. Compressed objects are stored in the cache.

Interoperability with other features

What happens to objects that are currently stored in cache and are being accessed through SSL VPN?

Objects stored in the cache and accessed regularly are served as cache hits when accessed through SSL VPN.

What happens to objects stored in the cache when accessed through SSL VPN and later accessed through a regular connection?

The objects stored through the SSL VPN access are served as a hit when accessed through the regular connection.

When using weblogging, how do I differentiate entries that indicate response served from cache from those served by the server?

For responses served from the integrated cache, the server log field contains the value IC. For responses served from a server, the server log field contains the value sent by the server. Following is a sample log entry for an integrated caching transaction:

```
"10.102.152 - "Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 4.0; .NET CLR 10.3705)" "GET /" 200 0 "IC" 10.102.145"
```

Along with a client request, the response logged is the one sent to the client and not necessarily the one sent by the server.

Miscellaneous

What do you mean by configuring relexpiry and absexpiry?

By configuring relexpiry and absexpiry, it means that you are overriding the header irrespective of what appears in the header. You can configure different expiry setting and the content group level. With relexpiry, expiration of the header is based on the time at which the object was received by the NetScaler. With absexpiry, expiration is based on the time configured on the NetScaler. Relexpiry is configured in terms of seconds. Absexpiry is a time of day.

What do you mean by configuring weakpos and heuristic?

The weakpos and heuristic are like fall back values. If there is an expiry header, it is considered only if the last-modified header is present. The NetScaler appliance sets expiry on the basis of the last-modified header and the heuristic parameter. The heuristic expiry calculation determines the time to expiry by checking the last-modified header. Some percentage of the duration since the object was last modified is used as time to expiry. The heuristic of an object that remains unmodified for longer periods of time and is likely to have longer expiry periods. The -heurExpiryParam specifies what percentage value to use in this calculation. Otherwise, the appliance uses the weakpos value.

What should I consider before configuring dynamic caching?

If there is some parameter that is in name-value form and does not have the full URL query, or the appliance receives the parameter in a cookie header or POST body, consider configuring dynamic caching. To configure dynamic caching, you have to configure hitParams parameter.

How is hexadecimal encoding supported in the parameter names?

On the NetScaler appliance, the %HEXHEX encoding is supported in the parameter names. In the names that you specify for hitParams or invalParams, you can specify a name that contains %HEXHEX encoding in the names. For example, name, nam%65, and n%61m%65 are equivalent.

What is the process for selecting a hitParam parameter?

Consider the following excerpt of an HTTP header for a POST request:

How do we select a hitparam?

```
POST /data2html.asp?param1=value1&param2=&param3&param4=value4
```

```
HTTP/1.1
```

```
Accept: image/gif, image/x-bitmap, image/jpeg, image/pjpeg,  
application/vnd.ms-powerpoint, application/vnd.ms-excel,  
application/msword, application/x-shockwave-flash, */*
```

Referer: http://10.102.3.97/forms.html
Accept-Language: en-us
Content-Type: application/x-www-form-urlencoded
Accept-Encoding: gzip, deflate
User-Agent: Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1)
Host: 10.102.3.97
Content-Length: 153
Connection: Keep-Alive
Cache-Control: no-cache
Cookie: ASPSESSIONIDQGQGRNY=NNLLKDADEENOAFLCDDGFGDMO

S1=This+text+is+only+text%2C+not+more+and+not+less%2C+%0D%0Ajust+text+to+be+itself%2C+namely+%22Text%22+to+be+posted+as+text+%28what+else...%29&**B1**=Submit
In the above request, you can use S1 and B1, highlighted in bold face for your reference, as hitParams depending on your requirements. Additionally, if you use -matchCookies YES in the ASPSESSIONIDQGQGRNY content group, then you can also use these parameters as hitParams.

What happens to the queued clients if the response is not cacheable?

If the response is not cacheable, all of the clients in the queue receive the same response that the first client receives.

Can I enable the Poll every time (PET) and Flash Cache features on the same content group?

No. You cannot enable PET and Flash Cache on the same content group. The integrated cache does not perform AutoPET function on Flash Cache content groups. The PET feature ensures that the integrated cache does not serve a stored object without consulting the server. You can configure PET explicitly for a content group.

When are the log entries created for the queued clients?

The log entries are created for the queued clients soon after the appliance receives the response header. The log entries are created only if the response header does not make the object non-cacheable.

What is the meaning of the DNS, HOSTNAME, and HOSTNAME_AND_IP values of the Verify cached object using parameter of the cache configuration?

The meanings are as follows:

- set cache parameter -verifyUsing HOSTNAME
This ignores the destination IP address.
- set cache parameter -verifyUsing HOSTNAME_AND_IP
This matches the destination IP address.
- set cache parameter -verifyUsing DNS
This uses the DNS server.

I have set weakNegRelExpiry to 600, which is 10 minutes. I noticed that 404 responses are not getting cached. What is the reason ?

This completely depends on your configuration. By default, 404 responses are cached for 10 minutes. If you want all 404 responses to be fetched from the server, specify -weakNegRelExpiry 0. You can fine tune the -weakNegRelExpiry to a desired value, such as higher or lower to get the 404 responses cached appropriately. If you have configured -absExpiry for positive responses, then it might not yield desired results.

When the user accesses the site by using the Mozilla Firefox browser, the updated content is served. However, when the user accesses the site by using the Microsoft Internet Explorer browser, stale content is served. What could be the reason?

The Microsoft Internet Explorer browser might be taking the content from its local cache instead of the NetScaler integrated cache. The reason could be that the Microsoft Internet Explorer browser is not respecting the expiry related header in the response.

To resolve this issue, you can disable the local cache of the Internet Explorer and clear the offline content. After clearing the offline content, the browser should display the updated content

What if Hits are zero?

Check to see if the server time and NS time are in sync. And the weakPosrelexpiry limit set should bear the time difference between NS and server as shown below

```
root@ns180# date
```

```
Tue May 15 18:53:52 IST 2012
```

Why are policies getting hits but nothing is being cached?

Verify that memory is allocated to the integrated cache and that the allocation is greater than zero.

Is it possible to zero the cache counters?

There is no command line or GUI option for setting the cache counters to zero, and flushing the cache does not do so either. Rebooting the box automatically sets these counters to zero.

Load Balancing

Nov 10, 2016

What are the various load balancing policies I can create on the NetScaler appliance?

You can create the following types of load balancing policies on the NetScaler appliance:

- Least Connections
- Round Robin
- Least response time
- Least bandwidth
- Least packets
- URL hashing
- Domain name hashing
- Source IP address hashing
- Destination IP address hashing
- Source IP - Destination IP hashing
- Token
- LRTM

Can I achieve the Web farm security by implementing load balancing using the NetScaler appliance?

Yes. You can achieve Web farm security by implementing load balancing using the NetScaler appliance. NetScaler appliance enables you to implement the following options of the load balancing feature:

- IP Address hiding: Enables you to install the actual servers to be on private IP address space for security reasons and for IP address conservation. This process is transparent to the end-user because the NetScaler appliance accepts requests on behalf of the server. While in the address hiding mode, the appliance completely isolates the two networks. Therefore, a client can access a service running on the private subnet, such as FTP or a Telnet server, through a different VIP on the appliance for that service.
- Port Mapping: Enables the actual TCP services to be hosted on non-standard ports for security reasons. This process is transparent to the end-user as the NetScaler appliance accepts requests on behalf of the server on the standard advertised IP address and port number.

What are various devices that I can use to load balance with a NetScaler appliance?

You can load balance following devices with a NetScaler appliance:

- Server farms
- Caches or Reverse Proxies
- Firewall devices
- Intrusion detection systems
- SSL offload devices
- Compression devices
- Content Inspection servers

Why should I implement the load balancing feature for the website?

You can implement the Load balancing feature for the website to take the following advantages:

- Reduce the response time: When you implement the load balancing feature for the website, one of the major benefits is the boost you can look forward to in load time. With two or more servers sharing the load of the web traffic, each of the servers runs less traffic load than a single server alone. This means there are more resources available to fulfill the client requests. This results in a faster website.

- Redundancy: Implementing the load balancing feature introduces a bit of redundancy. For example, if the website is balanced across three servers and one of them does not respond at all, the other two can keep running and the website visitors do not even notice any downtime. Any load balancing solution immediately stops sending traffic to the backend server that is not available.

Why do I need to disable the Mac Based Forwarding (MBF) option for Link Load Balancing (LLB)?

- If you enable the MBF option, the NetScaler appliance considers that the incoming traffic from the client and the outgoing traffic to the same client flow through the same upstream router. However, the LLB feature requires that the best path be chosen for the return traffic.
- Enabling the MBF option breaks this topology design by sending the outgoing traffic through the router that forwarded the incoming client traffic.

What are the various persistence types available on the NetScaler appliance?

The NetScaler appliance supports the following persistence types:

- Source IP
- Cookie insert
- SSL session ID
- URL passive
- Custom Server ID
- Rule
- DESTIP

Migration

Aug 26, 2014

How is the rollback procedure performed on a NetScaler appliance?

The rollback procedure is similar to the basic upgrade procedure. Select the target build that you want to roll back to and perform the downgrade.

Before rolling back to a different release, Citrix recommends that you create a copy of your current configuration files. To downgrade from release 10.1, see [Downgrading from Release 10.1](#) or to downgrade to an earlier build in 10.1, see [Downgrading to an Earlier Build within Release 10.1](#).

Can I upgrade a NetScaler appliance directly from release 10.0 to 10.5, or should I upgrade to 10.1 first and then to 10.5?

You can directly upgrade a NetScaler appliance regardless of the version or the build number.

Is the procedure for upgrading a NetScaler from classic to nCore different?

Yes. Only version 9.3 or earlier supports classic builds. For details, see [Upgrading from a Classic to an nCore Release](#).

Does 10.0 support classic builds?

No. Release 10.0 supports only nCore builds. You must have a multi-processor Netscaler (MPX or higher) to upgrade to 10.0.

Can the primary appliance and secondary appliance have separate builds?

Recommended practice is to use the same version and build number on both the primary and the secondary appliance.

Can both the appliances in an High Availability (HA) pair be upgraded at the same time?

No. In an HA pair, first upgrade the secondary node and then upgrade the primary node. For details, refer [Upgrading a High Availability Pair](#) or [Upgrading a NetScaler High Availability Pair to a Later Build](#).

Does Citrix support firmware upgrades in the amazon AWS cloud?

Yes.

Can I upgrade the NetScaler instance independently of the SDX version.

It is not required to upgrade the SDX version when the NetScaler appliance is upgraded. However, some features might not work.

Can I use the FTP server to upgrade the NetScaler appliance?

No. You must first download the firmware from the Citrix download site, save it on your local computer and then upgrade the appliance.

Is the procedure for upgrading the NetScaler appliance with GSLB configurations different from an upgrade of an appliance that is not involved in GSLB?

No. The upgrade procedure is similar to the basic upgrade procedure. The only difference is that you can upgrade the standalone or HA appliances on different sites in a phased manner.

SDX

Sep 04, 2013

Basic Questions

What is SDX?

SDX is a true service delivery networking platform for enterprises and cloud datacenters. SDX features an advanced virtualization architecture that supports multiple NetScaler instances on a single hardware appliance.

When do I need SDX?

If you have multiple enterprise applications that have independent life cycle needs for L4–L7 networking services, or if you have a need to consolidate multiple underutilized load balancing appliances, you benefit from SDX.

What's unique about SDX?

SDX uniquely delivers key benefits from advancements in server hardware virtualization, hardware-assisted SSL acceleration, and the market-proven, award-winning NetScaler product line. The Management Service features an advanced control plane to unify provisioning, monitoring, and management in the most demanding multitenant environments, while providing full resource isolation for data separation and to meet service level agreement guarantees, such as availability, reliability, and performance.

How will I benefit from SDX?

SDX delivers isolated multitenancy with up to 40:1 consolidation. As a key pillar in Citrix's TriScale technology framework, SDX addresses the growing need to "scale in" within virtual data centers and cloud network infrastructures. The TriScale scale-in factor enables IT to provide the foundation for consolidating L4–L7 network services today, thereby simplifying the build-out of cloud based services down the line, in accordance with business requirements.

Will I need to go outside my normal procurement procedure to purchase SDX?

SDX is a fully contained networking appliance, designed for network deployment. SDX is not designed to be managed through standard hypervisor management tools such as XenCenter.

How do I purchase an SDX?

An SDX order has three basic product components: SDX appliance SKU, SDX support contract SKU, and Add-On Instance Packs. SKUs are also available for platform conversion (MPX-to-SDX) and platform upgrade (SDX-to-SDX). SDX today is available in Platinum Edition only.

Is there SDX-specific documentation?

Yes, please visit <http://support.citrix.com/proddocs/topic/netscaler/sdx-ag-wrapper-con.html>.

Do NetScaler editions apply to NetScaler SDX?

The editions do not apply from a packaging perspective. NetScaler SDX appliances and the instance 5-packs are priced the same regardless of the edition. However, when provisioning new instances, the administrator is free to deploy the Standard, Enterprise, or Platinum edition of the NetScaler software.

Configuration

How much memory can I assign to each instance?

There is no maximum limit to the memory that can be assigned to each instance. Minimum memory required per instance is 2GB.

Can we migrate the existing configuration (ns.conf) from the MPX platform to SDX VPX instance?

Yes, but some configuration, such as RBA policies and SNMP community configuration, is deleted.

Features and Functionality**What NetScaler features do I get with SDX?**

All NetScaler features are available on SDX.

Does SDX accelerate SSL in hardware like MPX does?

Yes. You can assign SSL cores to an instance during provisioning.

What changes to my network are required for me to deploy SDX?

SDX fits into your network environment through standard Ethernet interfaces. You must disable link aggregation control protocol (LACP) on any external switch ports connected to the appliance.

Is SDX interoperable with my routing and switching infrastructure?

Yes, although link aggregation control protocol (LACP) is currently not supported. However, SDX supports manual link aggregation.

Is SDX interoperable with my existing NetScaler deployment?

Yes, although standard VPX-to-MPX limitations apply. For example, high availability is supported only across homogeneous devices (you cannot pair a virtual device with a physical device), some configuration, such as RBA policies and SNMP configuration, is deleted, and license transfer is not supported.

Can I manage SDX from Command Center?

Yes. You can identify SDX appliances and provision and de-provision VPX instances by using Command Center.

How does SDX deliver multitenancy?

Each instance runs as a separate virtual machine with its own dedicated NetScaler kernel, CPU resources, memory resources, address space, and bandwidth allocation. Network I/O is done in a way that not only maintains aggregate system performance but also enables complete segregation of each tenant's data-plane and management-plane traffic.

Do I need to manage an SDX through XenCenter?

No. XenCenter is not supported. Use the Management Service to manage XenServer.

We are a VMware shop. We have no infrastructure available to support XenServer, do you have a VMware variant of SDX?

No additional XenServer infrastructure is necessary. SDX is a fully contained networking appliance with its own control plane, and the virtualization layer is transparent to the deployment.

Why is the system health monitoring page not showing any data?

You have to install the supplemental pack before you can use this feature. For installation instructions for the supplemental pack, see <http://support.citrix.com/article/CTX132877>.

How do I verify that the supplemental pack installation was successful?

After installation, a pop up window shows whether installation was successful or if there was an error.

Why is the VPX instance not reachable after interfaces on the appliance are modified?

When you provision a NetScaler VPX instance with L2VLAN configuration, physical interfaces on the SDX appliance are mapped to virtual interfaces on the VPX instance. If you remove an interface, you might change the mapping between the physical interfaces and VPX instances, and therefore you might lose connectivity to the VPX instance.

For example,

1. You provision a VPX instance, by using the Management Service, with interfaces 10/1, 10/2, 10/7, and tag VLAN 512 to interface 10/2. When you log on to that VPX instance, you see that interfaces 10/1, 10/2, and 10/3 are configured.
2. If you later modify the instance and remove interface 10/1, you lose connectivity to the instance, because interface 10/2 is renamed to 10/1 in the VPX instance.

Are IPv6 addresses supported on the NetScaler SDX appliance?

Yes. All NetScaler-supported IPv6 functionality is available on the SDX appliance.

Where are link parameters, such as speed and duplex, configured?

Link parameters are configured from the Management Service.

Should the appliance be restarted if the platform license is upgraded?

No. You do not need to restart the appliance for the new license to apply.

Do I need to restart the appliance to upgrade the device-level firmware?

Yes, this upgrade is handled through the Management Service and requires that the appliance be restarted. This is the only time that the SDX appliance needs a complete restart.

Do I need to restart the appliance when I upgrade it by using a Pay-As-You-Grow license?

No. Upgrading the appliance upgrades the platform license. Restart the Management Service but not the instances running on the SDX appliance. Once upgraded, the Management Service detects the higher throughput available for the instances. If you decide to increase the bandwidth limit for an instance, restart that instance after modifying the bandwidth limit.

What happens to production instances if I remove my platform license?

There is no change to the production instances. However, you cannot add new instances.

How can we readd a gadget to the Home page?

Click the << button in the top-right corner of the Home page. Then, type the name of the gadget, or press Enter for all gadgets. Click "Add to Dashboard".

Should member interfaces in manual link aggregation be part of same VLAN?

Yes. Member interfaces in manual link aggregation should be part of the same VLAN.

How many VLANs are supported per interface with VLAN filtering enabled? What happens if I configure more?

With VLAN filtering enabled, 10G interfaces support up to 63 VLANs, and 1G interfaces support up to 31 VLANs. This is a hard limit based on the number of the queues supported by the NIC. An error message appears if the limit is exceeded.

How many instances can be shared on a single NIC?

For a 10G interface, SDX supports up to 63 virtual functions per physical port, which translates to 63 instances per 10G NIC. For 1G interfaces, the maximum number of shared instances per NIC is 7.

Why is the XenServer password the same as the Management Service password?

The XenServer password and the Management Service password are the same to maintain administrative consistency. Changing the XenServer password causes the internal communication between the Management Service and XenServer to

fail.

If I have separate management networks, do I need to manually add these networks to the Management Service?

No. Communication is over an external device.

Why can't I modify the default administrator profile?

The default administrator profile enables multiple administrative roles to exist on the SDX. You cannot change the password of the nsroot administrator profile, but you can create a new administrator profile and make it the default profile.

Why does Core usage show 50% when I'm not passing any traffic through my NetScaler instance?

CPU core usage shows, from the hypervisor perspective, the CPU utilization of one physical CPU, which has two hyperthreads: one for the packet engine and one for the management CPU. For example, assume a single instance with one dedicated core. Even if you are not passing any traffic through your appliance, PE CPU utilization will be 100%, and average core utilization will be 50%.

Will restarting the Management Service interrupt my production instances?

No. Your production instances will continue to pass traffic without interruption while the Management Service restarts. The same applies when you upgrade the Management Service.

Can I configure the Management Service to send syslog?

Syslog through the Management Service is currently not supported.

Am I required to upgrade all VPX instances if I upgrade the Management Service?

No, instance life cycles can be managed independently of one other and of the life cycle of the Management Service.

If my Management Service and VPX instances are on different networks, how can I manage the VPX instance through HTTPS?

The same way as if they are on the same network.

If my Management Service and VPX instances are on different networks, how can I manage the VPX instance through the Management Service?

If the Management Service and the VPX instance are in different networks but the instance can be reached from Management Service, the Management Service shows the instance as UP. If an instance is UP, you can manage it from the Management Service. However, if communication between the two fails, the Management Service shows the instance as "Out of Service".

I forgot the IP address of my Management Service. What can I do?

Log on to XenServer, and then use the default IP address (169.254.0.10) to log on to the Management Service. At the shell prompt, type networkconfig to view or modify the IP address of the Management Service.

Can I specify VLANs on management interfaces?

VLANs on management interfaces are currently not supported.

How do I restart XenServer?

The only supported method for restarting XenServer is from the Management Service. It is equivalent to restarting the appliance.

How many instances can I provision on the SDX appliance? How much aggregate throughput can I expect?

This number is dependent on the hardware and the license that you purchased, as shown below:

- 11500, 13500, 14500, 16500, 18500, 20500—5 to 20 instances. Throughput ranges from 8 to 42 Gbps.
- 17500, 19500, 21500—5 to 20 instances. Throughput ranges from 20 to 50 Gbps.
- 17550, 19550, 20550, 21550—5 to 40 instances. Throughput ranges from 20 to 50 Gbps.
- 8400, 8600—2 to 5 instances. Throughput ranges from 4 to 6 Gbps.

Note: For more information, see the NetScaler datasheet at

http://www.citrix.com/content/dam/citrix/en_us/documents/products/netscaler-data-sheet.pdf

Can I restrict functionality on the VPX instances?

Some functionality can be restricted by specifying the license (Standard, Enterprise, or Platinum) when you provision the instance.

Platforms

How many SDX models are there, and how do they differ?

The NetScaler SDX appliance comes in the following variants:

- SDX 11500/13500/14500/16500/18500/20500—8 to 42 Gbps, maximum 20 instances, 8x1G ports, 4x10G ports.
- SDX 17500/19500/21500—20 to 50 Gbps, maximum 20 instances, 8x10G ports.

Note: This platform is going EOS this year.

- SDX 17550/19550/20550/ 21550—20 to 50 Gbps, maximum 40 instances, 8x10G ports.
- SDX 8400/8600—4 to 6 Gbps, maximum 5 instances, (6x10/100/1000Base-T copper Ethernet ports + 6x1G SFP) and (6x10/100/1000Base-T copper Ethernet ports + 2x10G SFP+)

What is the minimum NetScaler software version required for SDX instances?

NetScaler VPX instances should run release 9.3 and later to be able to work on SDX.

How many physical interfaces will I need to use?

If you have a single management network, you'll need on an average 1 or 2 physical NICs per instance. For 2 or more management networks (multiple VLANs for NetScaler IP addresses), you'll need a dedicated separate physical NIC for each management VLAN trunk. You can share physical NICs among multiple instances with L2 separation. Therefore, depending on your topology, you can offset the management VLAN trunk count with multiple instances sharing a physical NIC.

Can I upgrade my MPX to an SDX? What about my MPX FIPS platform?

A non-FIPS MPX platform that supports the SDX architecture can be converted to a similar class of SDX platform. The MPX platform must have a platinum license to be eligible for this upgrade. This is a one way upgrade, and it wipes out the entire configuration on that MPX platform. For more information about this upgrade, see

<http://support.citrix.com/article/CTX129423>.

How many SSL cards (cores) are supported on a NetScaler SDX appliance?

The number of SSL cards supported varies by the platform as follows:

- SDX 17500/19500/21500—16 cards.
- SDX 11500/13500/14500/16500/18500/20500—16 cards.
- SDX 17550/19550/20550/21550—36 cards.
- SDX 8400/8600—4 cards.

Note: Instances cannot share SSL cores. Any SSL cores that are allocated at the time of provisioning an instance are

dedicated to that instance.

Can I apply my VPX license to SDX?

No. NetScaler SDX and NetScaler VPX have different licensing models. One license cannot be used for the other.

Why are the hardware sensors not displayed on the NetScaler SDX 17500/19500/21500 appliance?

The NetScaler SDX 17500/19500/21500 is built on the MPX 17500/19500/21500 hardware platform. These appliance configurations do not support monitoring of hardware components.

When I upgraded my MPX to an SDX, the LCD panel went dark. Is that expected?

Yes, that is normal behavior. SDX does not support the LCD panel.

What are RX and TX errors on the NetScaler SDX appliance?

RX and TX errors include cyclic redundancy check (CRC) errors and small or runt packet errors.

What happens if a hardware component is removed from the SDX appliance?

If a hardware component is physically removed from the appliance, it no longer appears in the Management Service user interface.

Do I need to restart my appliance after I reconfigure VLAN filtering?

No. However, you need to restart the VPX instances that are affected by this change. The Management Service restarts the affected instances if you select "Reboot associated Instances" in the Enable/Disable VLAN Filter dialog box.

What is the NMI button for on the SDX appliance?

The NMI button is not operational on the SDX appliance.

SSL

May 10, 2017

Basic Questions

HTTPS access to the NetScaler configuration utility fails on a VPX instance. How do I gain access?

A certificate-key pair is required for HTTPS access to the NetScaler configuration utility. On a NetScaler ADC, a certificate-key pair is automatically bound to the internal services. On an MPX or SDX appliance, the default key size is 1024 bytes, and on a VPX instance, the default key size is 512 bytes. However, most browsers today do not accept a key that is less than 1024 bytes. As a result, HTTPS access to the VPX configuration utility is blocked.

Citrix recommends that you install a certificate-key pair of at least 1024 bytes and bind it to the internal service for HTTPS access to the configuration utility or update the ns-server-certificate to 1024 bytes. You can use HTTP access to the configuration utility or the NetScaler command line to install the certificate.

If I add a license to an MPX appliance, the certificate-key pair binding is lost. How do I resolve this problem?

If a license is not present on an MPX appliance when it starts, and you add a license later and restart the appliance, you might lose the certificate binding. You must reinstall the certificate and bind it to the internal service.

Citrix recommends that you install an appropriate license before starting the appliance.

What are the various steps involved in setting up a secure channel for an SSL transaction?

Setting up a secure channel for an SSL transaction involves the following steps:

1. The client sends an HTTPS request for a secure channel to the server.
2. After selecting the protocol and cipher, the server sends its certificate to the client.
3. The client checks the authenticity of the server certificate.
4. If any of the checks fail, the client displays the corresponding feedback.
5. If the checks pass or the client decides to continue even if a check fails, the client creates a temporary, disposable key called the *pre-master secret* and encrypts it by using the public key of the server certificate.
6. The server, upon receiving the pre-master secret, decrypts it by using the server's private key and generates the session keys. The client also generates the session keys from the pre-master secret. Thus both client and server now have a common session key, which is used for encryption and decryption of application data.

I understand that SSL is a CPU-intensive process. What is the CPU cost associated with the SSL process?

The following two stages are associated with the SSL process:

- The initial handshake and secure channel setup by using the public and private key technology.
- Bulk data encryption by using the asymmetric key technology.

Both of the preceding stages can affect server performance, and they require intensive CPU processing for of the following reasons:

1. The initial handshake involves public-private key cryptography, which is very CPU intensive because of large key sizes (1024bit, 2048bit, 4096bit).
2. Encryption/decryption of data is also computationally expensive, depending on the amount of data that needs to be encrypted or decrypted.

What are the various entities of an SSL configuration?

An SSL configuration has the following entities:

- Server certificate
- Certificate Authority (CA) certificate
- Cipher suite that specifies the protocols for the following tasks:
 - Initial key exchange
 - Server and client authentication
 - Bulk encryption algorithm
 - Message authentication
- Client authentication
- CRL
- SSL Certificate Key Generation Tool that enables you to create the following files:
 - Certificate request
 - Self signed certificate
 - RSA and DSA keys
 - DH parameters

I want to use the SSL offloading feature of the Citrix NetScaler appliance. What are the various options for receiving an SSL certificate?

You must receive an SSL certificate before you can configure the SSL setup on the Citrix NetScaler appliance. You can use any of the following methods to receive an SSL certificate:

- Request a certificate from an authorized CA.
- Use the existing server certificate.
- Create a certificate-key pair on the Citrix NetScaler appliance.
 Note: This is a test certificate signed by the test Root-CA generated by the NetScaler. Test certificates signed by this Root-CA are not accepted by browsers. The browser throws a warning message stating that the server's certificate cannot be authenticated.
- For anything other than test purposes, you must provide a valid CA certificate and CA key to sign the server certificate.

What are the minimum requirements for an SSL setup?

The minimum requirements for configuring an SSL setup are as follows:

- Obtain the certificates and keys.
- Create a load balancing SSL virtual server.
- Bind HTTP or SSL services to the SSL virtual server.
- Bind certificate-key pair to the SSL virtual server.

What are the limits for the various components of SSL?

SSL components have the following limits:

- Bit size of SSL certificates: 4096.
- Number of SSL certificates: Depends on the available memory on the appliance.
- Maximum linked intermediate CA SSL certificates: 9 per chain.
- CRL revocations: Depends on the available memory on the appliance.

What are the various steps involved in the end-to-end data encryption on a Citrix NetScaler appliance?

The steps involved in the server-side encryption process on a Citrix NetScaler appliance are as follows:

1. The client connects to the SSL VIP configured on the Citrix NetScaler appliance at the secure site.
2. After receiving the secure request, the appliance decrypts the request, applies layer 4-7 content switching techniques and load balancing policies, and selects the best available backend Web server for the request.
3. The Citrix NetScaler appliance creates an SSL session with the selected server.

4. After establishing the SSL session, the appliance encrypts the client request and sends it to the Web server by using the secure SSL session.
5. When the appliance receives the encrypted response from the server, it decrypts and re-encrypts the data, and sends the data to the client by using the client side SSL session.

The multiplexing technique of the Citrix NetScaler appliance enables the appliance to reuse SSL sessions that have been established with the Web servers. Therefore, the appliance avoids the CPU intensive key exchange, known as *full handshake*. This process reduces the overall number of SSL sessions on the server and maintains end-to-end security.

Certificates and Keys

Can I place the certificate and key files at any location? Is there any recommended location to store these files?

You can store the certificate and key files on the Citrix NetScaler appliance or a local computer. However, Citrix recommends that you store the certificate and key files in the `/nsconfig/ssl` directory of the Citrix NetScaler appliance. The `/etc` directory exists in the flash memory of the Citrix NetScaler appliance. This provides portability and facilitates backup and restoration of the certificate files on the appliance.

Note: Make sure that the certificate and the key files are stored in the same directory.

What is the maximum size of the certificate key supported on the Citrix NetScaler appliance?

A Citrix NetScaler appliance running a software release earlier than release 9.0 supports a maximum certificate key size of 2048 bits. Release 9.0 and later support a maximum certificate key size of 4096 bits. This limit is applicable to both RSA and DSA certificates.

An MPX appliance supports certificates from 512-bits up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

A virtual appliance supports certificates from 512-bits up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 2048-bit certificate on the back end server
- 2048-bit client certificate (if client authentication is enabled on the virtual server)

What is the maximum size of the DH parameter supported on the Citrix NetScaler appliance?

The Citrix NetScaler appliance supports a DH parameter of maximum 2048 bits.

What is the maximum certificate-chain length, that is, the maximum number of certificates in a chain, supported on a Citrix NetScaler appliance?

A Citrix NetScaler appliance can send a maximum of 10 certificates in a chain when sending a server certificate message. A chain of the maximum length includes the server certificate and nine intermediate CA certificates.

What are the various certificate and key formats supported on the Citrix NetScaler appliance?

The Citrix NetScaler appliance supports the following certificate and key formats:

- Privacy Enhanced Mail (PEM)
- Distinguished Encoding Rule (DER)

Is there a limit for the number of certificates and keys that I can install on the Citrix NetScaler appliance?

No. The number of certificates and keys that can be installed is limited only by the available memory on the Citrix NetScaler appliance.

I have saved the certificate and key files on the local computer. I want to transfer these files to the Citrix NetScaler appliance by using the FTP protocol. Is there any preferred mode for transferring these files to the Citrix NetScaler appliance?

Yes. If using the FTP protocol, you should use binary mode to transfer the certificate and key files to the Citrix NetScaler appliance.

Note: By default, FTP is disabled. Citrix recommends using the SCP protocol for transferring certificate and key files. The configuration utility implicitly uses SCP to connect to the appliance.

What is the default directory path for the certificate and key?

The default directory path for the certificate and key is /nsconfig/ssl.

When adding a certificate and key pair, what happens if I do not specify an absolute path to the certificate and key files?

When adding a certificate and key pair, if you do not specify an absolute path to the certificate and key files, the Citrix NetScaler appliance searches the default directory, /nsconfig/ssl, for the specified files and attempts to load them to the kernel. For example, if the cert1024.pem and rsa1024.pem files are available in the /nsconfig/ssl directory of the appliance, both of the following commands are successful:

```
add ssl certKey cert1 -cert cert1204.pem -key rsa1024.pem
```

```
add ssl certKey cert1 -cert /nsconfig/ssl/cert1204.pem -key /nsconfig/ssl/rsa1024.pem
```

I have configured a high availability setup. I want to implement the SSL feature on the setup. How should I handle the certificate and key files in a high availability setup?

In a high availability setup, you must store the certificate and key files on both the primary and the secondary Citrix NetScaler appliance. The directory path for the certificate and key files must be the same on both appliances before you add an SSL certificate-key pair on the primary appliance.

Ciphers

What is a NULL-Cipher?

Ciphers with no encryption are known as NULL-Ciphers. For example, NULL-MD5 is a NULL-Cipher.

Are the NULL-Ciphers enabled by default for an SSL VIP or an SSL service?

No. NULL-Ciphers are not enabled by default for an SSL VIP or an SSL service.

What is the procedure to remove NULL-Ciphers?

To remove the NULL-Ciphers from an SSL VIP, run the following command:

```
bind ssl cipher <SSL_VIP> REM NULL
```

To remove the NULL-Ciphers from an SSL Service, run the following command:

```
bind ssl cipher <SSL_Service> REM NULL -service
```

What are the various cipher aliases supported on the Citrix NetScaler appliance?

The Citrix NetScaler appliance supports the following cipher aliases:

1. Alias Name: ALL
Description: All NetScaler-supported ciphers, excluding NULL ciphers
2. Alias Name: DEFAULT
Description: Default cipher list with encryption strength \geq 128bit
3. Alias Name: kRSA
Description: Ciphers with RSA key exchange algorithm
4. Alias Name: kEDH
Description: Ciphers with Ephemeral-DH key exchange algorithm
5. Alias Name: DH
Description: Ciphers with DH key exchange algorithm
6. Alias Name: EDH
Description: Ciphers with DH key exchange algorithm and authentication algorithm
7. Alias Name: aRSA
Description: Ciphers with RSA authentication algorithm
8. Alias Name: aDSS
Description: Ciphers with DSS authentication algorithm
9. Alias Name: aNULL
Description: Ciphers with NULL authentication algorithm
10. Alias Name: DSS
Description: Ciphers with DSS authentication algorithm
11. Alias Name: DES
Description: Ciphers with DES encryption algorithm
12. Alias Name: 3DES
Description: Ciphers with 3DES encryption algorithm
13. Alias Name: RC4
Description: Ciphers with RC4 encryption algorithm
14. Alias Name: RC2
Description: Ciphers with RC2 encryption algorithm
15. Alias Name: eNULL
Description: Ciphers with NULL encryption algorithm
16. Alias Name: MD5
Description: Ciphers with MD5 message authentication code (MAC) algorithm
17. Alias Name: SHA1
Description: Ciphers with SHA-1 MAC algorithm
18. Alias Name: SHA

Description: Ciphers with SHA MAC algorithm

19. Alias Name: NULL

Description: Ciphers with NULL encryption algorithm

20. Alias Name: RSA

Description: Ciphers with RSA key exchange algorithm and authentication algorithm

21. Alias Name: ADH

Description: Ciphers with DH key exchange algorithm, and NULL authentication algorithm

22. Alias Name: SSLv2

Description: SSLv2 protocol ciphers

23. Alias Name: SSLv3

Description: SSLv3 protocol ciphers

24. Alias Name: TLSv1

Description: SSLv3/TLSv1 protocol ciphers

25. Alias Name: TLSv1_ONLY

Description: TLSv1 protocol ciphers

26. Alias Name: EXP

Description: Export ciphers

27. Alias Name: EXPORT

Description: Export ciphers

28. Alias Name: EXPORT40

Description: Export ciphers with 40-bit encryption

29. Alias Name: EXPORT56

Description: Export ciphers with 56-bit encryption

30. Alias Name: LOW

Description: Low strength ciphers (56-bit encryption)

31. Alias Name: MEDIUM

Description: Medium strength ciphers (128-bit encryption)

32. Alias Name: HIGH

Description: High strength ciphers (168-bit encryption)

33. Alias Name: AES

Description: AES ciphers

34. Alias Name: FIPS

Description: FIPS-approved ciphers

35. Alias Name: ECDHE

Description: Elliptic Curve Ephemeral DH Ciphers

What is the command to display all the predefined ciphers of the Citrix NetScaler appliance?

To display all the predefined ciphers of the Citrix NetScaler appliance, at the NetScaler command line, type:
show ssl cipher

What is the command to display the details of an individual cipher of the Citrix NetScaler appliance?

To display the details of an individual cipher of the Citrix NetScaler appliance, at the NetScaler command line, type:
show ssl cipher <Cipher_Name/Cipher_Alias_Name/Cipher_Group_Name>

Example:

```
> show cipher SSL3-RC4-SHA
1) Cipher Name: SSL3-RC4-SHA
Description: SSLv3 Kx=RSA Au=RSA Enc=RC4(128)
Mac=SHA1
Done
```

What is the significance of adding the predefined ciphers of the Citrix NetScaler appliance?

Adding the predefined ciphers of the Citrix NetScaler appliance causes the NULL-Ciphers to get added to an SSL VIP or an SSL service.

Certificates

Why do I need to bind the server certificate?

Binding the server certificates is the basic requirement for enabling the SSL configuration to process SSL transactions. To bind the server certificate to an SSL VIP, at the NetScaler command line, type:

```
bind ssl vsrver <vServerName> -certkeyName <cert_name>
```

To bind the server certificate to an SSL service, at the NetScaler command line, type:

```
bind ssl service <serviceName> -certkeyName <cert_name>
```

How many certificates can I bind to an SSL VIP or an SSL service?

On a NetScaler virtual appliance, you can bind a maximum of two certificates to an SSL VIP or an SSL service, one each of type RSA and type DSA. On a NetScaler MPX or MPX-FIPS appliance, if SNI is enabled, you can bind multiple server certificates of type RSA. If SNI is disabled, you can bind a maximum of one certificate of type RSA.

Note: DSA certificates are not supported on MPX or MPX-FIPS platforms.

Does SNI support Subject Alternative Name (SAN) certificates?

No. On a NetScaler appliance, SNI is not supported with a SAN extension certificate.

What happens if I unbind or overwrite a server certificate?

When you unbind or overwrite a server certificate, all the connections and SSL sessions created by using the existing certificate are terminated. When you overwrite an existing certificate, the following message appears:

ERROR:

Warning: Current certificate replaces the previous binding.

How do I install an intermediate certificate on Citrix NetScaler and link to a server certificate?

See the article at <http://support.citrix.com/article/ctx114146> for information about installing an intermediate certificate.

Why am I getting a "resource already exists" error when I try to install a certificate on the Citrix NetScaler?

See the article at <http://support.citrix.com/article/CTX117284> for instructions for resolving the "resource already exists" error.

I want to create a server certificate on a Citrix NetScaler appliance to test and evaluate the product. What is the procedure to create a server certificate?

Perform the following procedure to create a test certificate.

Note: A certificate created with this procedure cannot be used to authenticate all the users and browsers. After using the certificate for testing, you should obtain a server certificate signed by an authorized Root CA.

To create a self-signed server certificate:

1. To create a Root CA certificate, at the NetScaler command line, type:

```
create ssl rsakey /nsconfig/ssl/test-ca.key 1024
```

```
create ssl certreq /nsconfig/ssl/test-ca.csr -keyfile /nsconfig/ssl/test-ca.key
```

Enter the required information when prompted, and then type the following command:

```
create ssl cert /nsconfig/ssl/test-ca.cer /nsconfig/ssl/test-ca.csr ROOT_CERT -keyfile /nsconfig/ssl/test-ca.key
```

2. Perform the following procedure to create a server certificate and sign it with the root CA certificate that you just created

1. To create the request and the key, at the NetScaler command line, type:

```
create ssl rsakey /nsconfig/ssl/test-server.key 1024
```

```
create ssl certreq /nsconfig/ssl/test-server.csr -keyfile /nsconfig/ssl/test-server.key
```

2. Enter the required information when prompted.

3. To create a serial-number file, at the NetScaler command line, type:

```
shell
```

```
# echo '01' >
```

```
/nsconfig/ssl/serial.txt
```

```
# exit
```

3. To create a server certificate signed by the root CA certificate created in step 1, at the NetScaler command line, type:

```
create ssl cert /nsconfig/ssl/test-server.cer /nsconfig/ssl/test-server.csr SRVR_CERT -CAcert /nsconfig/ssl/test-ca.cer -CAkey /nsconfig/ssl/test-ca.key -CAserial /nsconfig/ssl/serial.txt
```

4. To create a Citrix NetScaler certkey, which is the in-memory object that holds the server certificate information for SSL handshakes and bulk encryption, at the NetScaler command line, type:

```
add ssl certkey test-certkey -cert /nsconfig/ssl/test-server.cer -key /nsconfig/ssl/test-server.key
```

5. To bind the certkey object to the SSL virtual server, at the NetScaler command line, type:

```
bind ssl vserver <vServerName> -certkeyName <cert_name>
```

I have received a Citrix NetScaler appliance on which Citrix NetScaler software release 9.0 is installed. I have noticed an additional license file on the appliance. Is there any change in the licensing policy starting with Citrix NetScaler software release 9.0?

Yes. Starting with Citrix NetScaler software release 9.0, the appliance might not have a single license file. The number of license files depends on the Citrix NetScaler software release edition. For example, if you have installed the Enterprise edition, you might need additional license files for the full functionality of the various features. However, if you have

installed the Platinum edition, the appliance has only one license file.

How do I export the certificate from Internet Information Service (IIS)?

There are many ways to do this, but by using the following method the appropriate certificate and private key for the Web site are exported. This procedure **must** be performed on the actual IIS server.

1. Open the Internet Information Services (IIS) Manager administration tool.
2. Expand the Web Sites node and locate the SSL-enabled Web site that you want to serve through the Citrix NetScaler.
3. Right-click this Web site and click Properties.
4. Click the Directory Security tab and, in the Secure Communications section of the window, select the View Certificate box.
5. Click the Details tab, and then click Copy to File.
6. On the Welcome to the Certificate Export Wizard page, click Next.
7. Select Yes, export the private key and click Next.

Note: The private key **MUST** be exported for SSL Offload to work on the Citrix NetScaler

8. Make sure that the Personal Information Exchange -PKCS #12 radio button is selected, and select *only* the Include all certificates in the certification path if possible check box. Click Next.
9. Enter a password and click Next.
10. Enter a file name and location, and then click Next. Give the file an extension of .PFX.
11. Click Finish.

How do I convert the PKCS#12 certificate and install it on the Citrix NetScaler?

1. Move the exported .PFX certificate file to a location from where it may be copied to the Citrix NetScaler (that is, to a machine that permits SSH access to the management interface of a Citrix NetScaler appliance). Copy the certificate to the appliance by using a secure copy utility such as SCP.
2. Access the BSD shell and convert the certificate (for example, cert.PFX) to .PEM format:

```
root@ns# openssl pkcs12 -in cert.PFX -out cert.PEM
```

3. To make sure that the converted certificate is in correct x509 format, verify that the following command produces no error:

```
root@ns# openssl x509 -in cert.PEM -text
```

4. Verify that the certificate file contains a private key. Begin by issuing the following command:

```
root@ns# cat cert.PEM
```

Verify that the output file includes an RSA PRIVATE KEY section.

```
-----BEGIN RSA PRIVATE KEY-----
```

```
Mkm^s9KMs9023pz/s...
```

```
-----END RSA PRIVATE KEY-----
```

The following is another example of an RSA PRIVATE KEY section:

... (more random characters) 5pLDWYVHhLkA1pSxvFjNJHRSlydWHc5ltGyKqIUcBezVaXyel94pNSUYx07NpPV/

MY2ovQyQZM8gGe3+IGFum0VHbv/y/gB9HhFesog=

-----END CERTIFICATE-----

The following is an INTERMEDIATE CA CERTIFICATE section:

Bag Attributes: <Empty Attributes>

subject=/DC=lan/DC=food/CN=hotdog

issuer=/DC=lan/DC=food/CN=hotdog

-----BEGIN CERTIFICATE-----

MIIESDCCAzCgAwIBAgIQah20fCRYTY9LRXYMIRaKGjANBqkqhkiG9w0BAQUFADA8

... (more random characters) Nt0nksawDnbKo86rQcNnY5xUs7c7pj2zxj/IOsgNHUp5W6dDI9pQoqFFaDk=

-----END CERTIFICATE-----

Further Intermediate CA certificates may follow, depending on the certification path of the exported certificate.

5. Open the .PEM file in a text editor
6. Locate the first line of the .PEM file and the first instance of the following line, and copy those two lines and all the lines between them:

-----END CERTIFICATE-----

Note: Make sure that last copied line is the first -----END CERTIFICATE----- line in the .PEM file.

7. Paste the copied lines into a new file. Call the new file something intuitive, such as cert-key.pem. This is the certificate-key pair for the server hosting the HTTPS service. This file should contain both the section labeled RSA PRIVATE KEY

and the section labeled **SERVER CERTIFICATE** in the example above.

Note: The certificate-key pair file contains the private key and must therefore be kept secure.

8. Locate any subsequent sections beginning with -----BEGIN CERTIFICATE----- and ending with ---END CERTIFICATE----, and copy each such section to a separate new file.

These sections correspond to certificates of trusted CAs that have been included in the certification path. These sections should be copied and pasted into new individual files for these certificates. For example, the **INTERMEDIATE CA CERTIFICATE** section of the example above should be copied and pasted into a new file).

For multiple intermediate CA certificates in the original file, create new files for each intermediate CA certificate in the order in which they appear in the file. Keep track (using appropriate filenames) of the order in which the certificates appear, as they need to be linked together in the correct order in a later step.

9. Copy the certificate-key file (cert-key.pem) and any additional CA certificate files into the /nsconfig/ssl directory on the Citrix NetScaler.
10. Exit the BSD shell and access the Citrix NetScaler prompt.
11. Follow the steps in "Install the certificate-key files on the appliance" to install the key/certificate once uploaded on the device.

How do I convert the PKCS#7 certificate and install it on the NetScaler appliance?

You can use OpenSSL to convert a PKCS #7 Certificate to a format recognizable by the NetScaler appliance. The procedure is identical to the procedure for PKCS #12 certificates, except that you invoke OpenSSL with different parameters. The steps for converting PKCS #7 certificates are as follows:

1. Copy the certificate to the appliance by using a secure copy utility, such as SCP.
2. Convert the certificate (for example, cert.P7B) to PEM format:
> openssl pkcs7 -inform DER -in cert.p7b -print_certs -text -out cert.pem
3. Follow steps 3 through 7 as described in the answer to Q32 for PKCS #12 certificates.

Note: Before loading the converted PKCS #7 certificate to the appliance, be sure to verify that it contains a private key, exactly as described in step 3 for the PKCS #12 procedure. PKCS #7 certificates, particularly those exported from IIS, do not typically contain a private key.

When I bind a cipher to a virtual server or service by using the bind cipher command, I see the error message "Command deprecated."

The command for binding a cipher to a virtual server or service has changed.

Use the bind ssl vserver <vservername> -ciphername <ciphername> command to bind an SSL cipher to an SSL virtual server.

Use the bind ssl service <serviceName> -ciphername <ciphername> command to bind an SSL cipher to an SSL service.

Note: New ciphers and cipher groups are added to the existing list and not replaced.

Why can't I create a new cipher group and bind ciphers to it by using the add cipher command?

The add cipher command functionality has changed in release 10. The command only creates a cipher group. To add ciphers to the group, use the bind cipher command.

OpenSSL

How do I use OpenSSL to convert certificates between PEM and DER?

To use OpenSSL, you must have a working installation of the OpenSSL software and be able to execute Openssl from the

command line.

x509 certificates and RSA keys can be stored in a number of different formats.

Two common formats are DER (a binary format used primarily by Java and Macintosh platforms) and PEM (a base64 representation of DER with header and footer information, which is used primarily by UNIX and Linux platforms). There is also an obsolete NET (Netscape server) format that was used by earlier versions of IIS (up to and including 4.0) and various other less common formats that are not covered in this article.

A key and the corresponding certificate, as well as the root and any intermediate certificates, can also be stored in a single PKCS#12 (.P12, .PFX) file.

Procedure

Use the Openssl command to convert between formats as follows:

1. To convert a certificate from PEM to DER:

```
x509 -in input.crt -inform PEM -out output.crt -outform DER
```

2. To convert a certificate from DER to PEM:

```
x509 -in input.crt -inform DER -out output.crt -outform PEM
```

3. To convert a key from PEM to DER:

```
rsa -in input.key -inform PEM -out output.key -outform DER
```

4. To convert a key from DER to PEM:

```
rsa -in input.key -inform DER -out output.key -outform PEM
```

Note: If the key you are importing is encrypted with a supported symmetric cipher, you are prompted to enter the pass-phrase.

Note: To convert a key to or from the obsolete NET (Netscape server) format, substitute NET for PEM or DER as appropriate. The stored key is encrypted in a weak unsalted RC4 symmetric cipher, so a pass-phrase will be requested. A blank pass-phrase is acceptable.

System Limits

What are the important numbers to remember?

1. Create Certificate Request:
 - Request File Name: Maximum 63 characters
 - Key File Name: Maximum 63 characters
 - PEM Passphrase (For Encrypted Key): Maximum 31 characters
 - Common Name: Maximum 63 characters
 - City: Maximum 127 characters
 - Organization Name: Maximum 63 characters
 - State/Province Name: Maximum 63 characters
 - Email Address: Maximum 39 Characters
 - Organization Unit: Maximum 63 characters
 - Challenge Password: Maximum 20 characters
 - Company Name: Maximum 127 characters

2. Create Certificate:
 - Certificate File Name: Maximum 63 characters
 - Certificate Request File Name: Maximum 63 characters
 - Key File Name: Maximum 63 characters
 - PEM Passphrase: Maximum 31 characters
 - Validity Period: Maximum 3650 days
 - CA Certificate File Name: Maximum 63 characters
 - CA Key File Name: Maximum 63 characters
 - PEM Passphrase: Maximum 31 characters
 - CA Serial Number File: Maximum 63 characters
3. Create and Install a Server Test Certificate:
 - Certificate File Name: Maximum 31 characters
 - Fully Qualified Domain Name: Maximum 63 characters
4. Create Diffie-Hellman (DH) key:
 - DH Filename (with path): Maximum 63 characters
 - DH Parameter Size: Maximum 2048 bits
5. Import PKCS12 key:
 - Output File Name: Maximum 63 characters
 - PKCS12 File Name: Maximum 63 characters
 - Import Password: Maximum 31 characters
 - PEM Passphrase: Maximum 31 characters
 - Verify PEM Passphrase: Maximum 31 characters
6. Export PKCS12
 - PKCS12 File Name: Maximum 63 characters
 - Certificate File Name: Maximum 63 characters
 - Key File Name: Maximum 63 characters
 - Export Password: Maximum 31 characters
 - PEM Passphrase: Maximum 31 characters
7. CRL Management:
 - CA Certificate File Name: Maximum 63 characters
 - CA Key File Name: Maximum 63 characters
 - CA Key File Password: Maximum 31 characters
 - Index File Name: Maximum 63 characters
 - Certificate File Name: Maximum 63 characters
8. Create RSA Key:
 - Key Filename: Maximum 63 characters
 - Key Size: Maximum 4096 bits
 - PEM Passphrase: Maximum 31 characters
 - Verify Passphrase: Maximum 31 characters
9. Create DSA Key:
 - Key Filename: Maximum 63 characters
 - Key Size: Maximum 4096 bits
 - PEM Passphrase: Maximum 31 characters
 - Verify Passphrase: Maximum 31 characters
10. Change advanced SSL settings:
 - Maximum CRL memory size: Maximum 1024 Mbytes

- Encryption trigger timeout (10 mS ticks): Maximum 200
 - Encryption trigger packet count: Maximum 50
 - OCSP cache size: Maximum 512 Mbytes
11. Install Certificate:
 - Certificate-Key pair Name: Maximum 31 characters
 - Certificate File Name: Maximum 63 characters
 - Private Key File Name: Maximum 63 characters
 - Password: Maximum 31 characters
 - Notification Period: Maximum 100
 12. Create Cipher Group:
 - Cipher Group Name: Maximum 39 characters
 13. Create CRL:
 - CRL Name: Maximum 31 characters
 - CRL File: Maximum 63 characters
 - URL: Maximum 127 characters
 - Base DN: Maximum 127 characters
 - Bind DN: Maximum 127 characters
 - Password: Maximum 31 characters
 - Day(s): Maximum 31
 14. Create SSL Policy:
 - Name: Maximum 127 characters
 15. Create SSL Action:
 - Name: Maximum 127 characters
 16. Create OCSP Responder:
 - Name: Maximum 32 characters
 - URL: Maximum 128 characters
 - Batching Depth: Maximum 8
 - Batching Delay: Maximum 10000
 - Produced At Time Skew: Maximum 86400
 - Request Time-out: Maximum 120000
 17. Create Virtual Server:
 - Name: Maximum 127 characters
 - Redirect URL: Maximum 127 characters
 - Client Time-out: Maximum 31536000 secs
 18. Create Service:
 - Name: Maximum 127 characters
 - Idle Time-out (secs):
Client: Maximum 31536000

Server: Maximum 31536000
 19. Create Service Group:
 - Service Group Name: Maximum 127 characters
 - Server ID: Maximum 4294967295
 - Idle Time-out (secs):
Client: Maximum value 31536000

Server: Maximum 31536000

20. Create Monitor:

- Name: Maximum 31 characters

21. Create Server:

- Server Name: Maximum 127 characters
- Domain Name: Maximum 255 characters
- Resolve Retry: Maximum 20939 secs

Installing, Upgrading, and Downgrading

Aug 13, 2013

What is the use of the zebos.conf file available in a NetScaler release?

A NetScaler appliance uses Zebos as the routing suite. The zebos.conf file available in a NetScaler release is the configuration file for Zebos.

I want to change the SSH port (22) on the NetScaler appliance to some other port. Is it possible to change the SSH port on the appliance?

Yes. You can change the SSH port on the NetScaler appliance by editing the sshd_config file in the /nsconfig directory. If the file does not exist in the /nsconfig directory, copy it from the /etc directory.

In the sshd_config file, edit the entry for Port 22 to Port <Number>, where <Number> is the target port number. If you do not want to restart the appliance and make the changes effective, terminate the sshd process by using the kill command, and then restart the process.

The flash directory is missing from the NetScaler appliance. What procedure should I follow to mount the flash directory?

To mount the flash directory, do the following:

1. Start the NetScaler appliance in single-user mode.

When the appliance starts, the following message appears:

Hit [Enter] to boot immediately, or any other key for command prompt. Booting [kernel] in 10 seconds..." Hit space and you should see the following prompt:

Type '?' for a list of commands, 'help' for more detailed help.

2. Enter the following command to start FreeBSD in single-user mode:

```
boot -s
```

After the appliance starts, the following message appears:

Enter full pathname of shell or RETURN for /bin/sh:

3. Press Enter to display the # prompt.
4. Run the following command to mount the flash directory:

```
mount /dev/ad0s1a /flash
```

Note: If the preceding command displays an error message about permissions, run the following command to check the disk for consistency:

```
fsck /dev/ad0s1a
```

Run the mount command again to mount the flash directory.

5. Restart the appliance.
6. From the shell prompt, run the following command to verify that the flash directory is mounted:

```
df -kh
```

I want to log on to the NetScaler appliance without entering the password. Is it possible to configure SSH on the appliance to allow that?

Yes. You can configure SSH on the NetScaler appliance to log on without a password. However, you must provide your user name. To configure SSH for logging in without a password, do the following:

1. Run the following command to generate the public and private keys:

```
# ssh-keygen -t rsa
```
2. Run the following command to copy the id_rsa.pub file to the .ssh directory of the remote host that you want to log on to:

```
# scp id_dsa.pub <user>@<remote_host>/.ssh/id_dsa.pub
```
3. Log on to the remote host.
4. Change to the .ssh directory.
5. Run the following commands to add the public key of the client to the known public keys:

```
# cat id_dsa.pub >> authorized_keys2
```

```
# chmod 640 authorized_keys2
```

```
# rm id_dsa.pub
```

What is the procedure to reset the NetScaler appliance BIOS? Under what circumstances should I reset the BIOS?

To reset BIOS of the NetScaler appliance, complete the following procedure:

1. Connect to the appliance through the serial port.
2. Start the appliance and press Delete as soon as the boot-up process starts.
 Pressing Delete during the POST process displays the appliance’s BIOS settings.
3. Activate the Exit page of the BIOS settings.
4. Select the Load Optimal Defaults option.
 The Load Optimal Settings message box appears.
5. Select OK.
6. Make the following changes to the BIOS settings on the various tabs:

Tab	Group	Component	Set to...
Advanced	SuperIO Configuration	Parallel Port Address	Disabled
	Floppy Configuration	Floppy A	Disabled
	Boot Settings Configuration	Quiet Boot	Disabled
		PS/2 Mouse Support	Disabled
		Parity Check	Enable
	Remote Access Configuration	Remote Access	COM1
		Serial Port Mode	9600 8'n1

Chipset Tab	Group	Component	Hyper-threading Disabled Set to...
PCI PnP		Allocate IRQ to PCIVGA	NO
		USB Function	Disabled
		Legacy USB Support	Disabled
Power		ACPI Aware OS	NO
		Power Management	Enabled

Note: The BIOS options differs by appliance model.

7. Activate the Exit page of the BIOS settings.
8. Select Save changes and Exit.
9. Select OK to confirm.
10. Verify that the appliance starts cleanly and the serial console displays output after the appliance starts.

You need to reset BIOS when the serial console does not respond. This usually happens after you upgrade the appliance and the serial console is disabled. However, you can still access the appliance by using the telnet or SSH utility.

I need to reset the NetScaler appliance to the factory defaults. What procedure should I follow?

To reset the NetScaler appliance to the factory defaults, you need to reset two environments: the NetScaler application environment and the base FreeBSD environment.

To reset the NetScaler application environment of the appliance to the factory defaults, do the following:

1. Make a backup of the appliance's `/nsconfig/ns.conf`.
2. Delete the `/nsconfig/ns.conf` file.
3. Restart the appliance.

To reset the FreeBSD environment of the appliance to the factory defaults, do the following:

1. Install a fresh NetScaler code image on the appliance. This overwrites a number of FreeBSD-level configuration files with default values.
2. Delete any users and groups that are added to the appliance, that is, all except the default users.
3. Delete the `/etc/resolv.conf` file.
4. Delete the entries that you have added to the `/etc/hosts` file.
5. If the `/etc/rc.netscaler` file exists, delete it.
6. Open the `/etc/nsperm_group_suser` file and make sure that all IOCTL entries are comment entries.
7. Open the `/etc/rc.conf` file and make sure that the `syslogd_enable=NO` entry is not changed to `syslogd_enable=YES`.
8. Open the `/etc/syslog.conf` file and make sure that there are no additional entries in the file.
9. Delete the contents of the `/var/nslog`, `/var/nstrace`, and `/var/crash` files.
10. If the `syslog` process is enabled on the appliance and the appliance creates log files locally, delete the contents of the log files listed in the `/etc/syslog.conf` file. The files are created in the `/var/log` directory. For example, if `syslog` process writes system events to the `/var/log/events` file, and `sslvpn` access events to the `/var/log/sslvpnevents` file, delete these files.

The appliance displays a message similar to the “Jun 21 12:20:18 ns /flash/ns-10.0-47.15: [1/2]dc0: NIC hang condition #663: TX 10000/10000, RX 0, HF 0” message on the console. What is the meaning of this message?

The message consists of the following components (shown here as examples):

- #663: Number of times this condition has occurred on the appliance.
- TX 10000/10000: Number of packets that the appliance attempted to transmit, and number of packets transmitted. If both numbers are the same, as in this example, the NIC transmitted all the packets that the appliance attempted to transmit.
- RX 0: Number of packets received. In this example, no packet was received.
- HF0: Number of hardware issues reported by the NIC. In this example, the NIC did not report any hardware issue.

If the appliance does not receive any packets, it reports a hang condition, because on a network it is very unlikely not to receive any packets. However, if the appliance is plugged into a network interface, you can ignore this error message.

After I upgraded the NetScaler release on the appliance, the appliance still displays the earlier release/build. What could be the reason?

The appliance displays the software version number from the `/flash/boot/loader.conf` file. If the kernel entry for the current NetScaler release is missing from that file, the appliance displays the last NetScaler release version for which the entry was available.

To resolve this issue, do the following:

1. Verify that the kernel file exists in the `/nsconfig` directory.
2. Check the `/flash/boot/loader.conf` file for an entry for the kernel.
(You can expect the entry for the kernel of the release/build that you just installed to be missing from the file.)
3. Open the `loader.conf` file in a text editor, such as the `vi` editor, and update the kernel entry for the new release/build.
4. Save and close the file.
5. Repeat step 2 through step 4 for the `/flash/boot/loader.conf.local` file.
6. Update the release/build entry in the `ns.conf` file.
7. Restart the appliance.

Since I upgraded the NetScaler release on the appliance, the LCD display on the front panel of the appliance displays the out of service message or does not display anything. How can I resolve this issue?

Run the following command from the appliance's shell prompt:

```
/netscaler/nslcd -k
```

I have upgraded the NetScaler release/build. However, after the upgrade process, the appliance fails to start. Can I downgrade the appliance's software to the previous release/build?

Yes. You can start the appliance with the `kernel.old` kernel file. When you restart the appliance, press the F1 key as soon as the appliance console displays the Press F1 message. Type `kernel.old` and press Enter.

After upgrading the NetScaler release on the appliance, I accidentally deleted the kernel file from the /flash directory. As a result, I am not able to start the appliance. Is there a method for starting the appliance in this situation?

Yes. You can start the appliance by using the `kernel.GENERIC` kernel file, as follows:

1. When you restart the appliance, press the F1 key as soon as the appliance console displays the Press F1 message.
2. Type `kernel.GENERIC` and press Enter.
3. Login as the root user.
4. Reinstall the NetScaler release.
5. Restart the appliance.

I have received a NetScaler appliance with the latest NetScaler release installed on it. However, I want to downgrade the software release. Can I do so?

No. If you attempt to downgrade the software release, the appliance might not work as expected, because the ns.conf file of the later release might not be compatible with the earlier release, and the appliance might restore to the factory settings.

When downgrading the NetScaler release, I followed the instructions. However, the appliance displays the following message:

```
root@LBCOL03B# ./installns
installns version (10.0-47.7) kernel (ns-10.0-47.7.gz)
```

Note:

Installation may pause for up to 3 minutes while data is written to the flash.

Caution:

Do not interrupt the installation process.

Doing so may cause the system to become unusable.

Installation will proceed in 5 seconds, CTRL-C to abort

No Valid Netscaler Version Detected

```
root@LBCOL03B#
```

Am I doing something incorrectly?

This issue could be the result of incorrect version information in the ns.conf file. To resolve this issue, open the ns.conf file in a text editor, such as the vi editor. Update the release-specific entry in the ns.conf file to #NS<Release_No> Build <Build_No>. Here, <Release_No> is the NetScaler release number to which you want to downgrade the software, and the <Build_No> is the build number of the software release to which you want to downgrade the software.

After upgrading the appliance software to NetScaler release 10.0, I am not able to log on to the appliance, and the following message is appears:

```
login: nsroot
```

```
Password:
```

```
connect: No such file or directory
```

```
nsnet_connect: No such file or directory
```

```
Login incorrect
```

I tried to resolve this issue by using the password recovery procedure, but I was not successful. Have I done something incorrectly?

You cannot resolve this issue by using the password recovery procedure. NetScaler releases 8.0 and later use the new licensing system, based on the Imgrd daemon, which runs during the startup procedure. For this daemon to work properly, the host name of NetScaler appliance, which is set in the /nsconfig/rc.conf file, must be resolved by a name server to the NetScaler IP address. Alternately, you can create a hosts file in the /nsconfig directory and add the 127.0.0.1 <Host_Name> entry in file.

Additionally, make sure that you have copied the license files to the /nsconfig/license/ directory.

During an upgrade of a high availability pair, the following message appears repeatedly:

```
<auth.err> ns sshd[5035]: error: Invalid username or password
```

What could be the reason?

This error message appears when the appliances involved in the high availability pairing have either a different NetScaler

release or a different builds of the same release installed. The appliances can have different version installed if you have upgraded or downgraded one appliance but not the other.

I want to change the netmask of the NetScaler IP address on a NetScaler appliance. Can I do so without causing an outage?

Changing the netmask of the NetScaler IP might result in a short outage. Make sure that you change the netmask on the secondary appliance, and then break the high availability pairing. Check the functionality of the appliance. If everything works as expected, rebuild the high availability pairing.

To change the netmask on the appliance, run the configs command from the CLI prompt, and then choose the second option in the menu.

I have configured a High Availability pair of NetScaler appliances. After upgrading the software release from a beta release to a final release, I noticed that some of the appliance configurations are missing. Can I retrieve the lost configurations?

You can use the following procedure to restore the configuration:

1. Log on to the command line interface of the primary appliance.
2. Run the following commands:

```
save config
```

```
shell
```

```
#cp /nsconfig/ns.conf /nsconfig/ns.conf.bkup
```

The ns.conf.bkup file is a backup for the running configuration.

3. Upgrade software of both the appliances to the final release.
4. Log on to the command line interface of the primary appliance.

NetScaler Solutions

Oct 06, 2015

NetScaler solutions simplify the task of setting up frequently deployed configurations. Check this space from time to time for additional solutions.

This document includes the following solutions:

- [Setting Up NetScaler for XenApp/XenDesktop](#)
- [RISE Integration: NetScaler ADC and Cisco Nexus 7000 Series Switch](#)
- [Web Interface](#)

Setting Up NetScaler for XenApp/XenDesktop

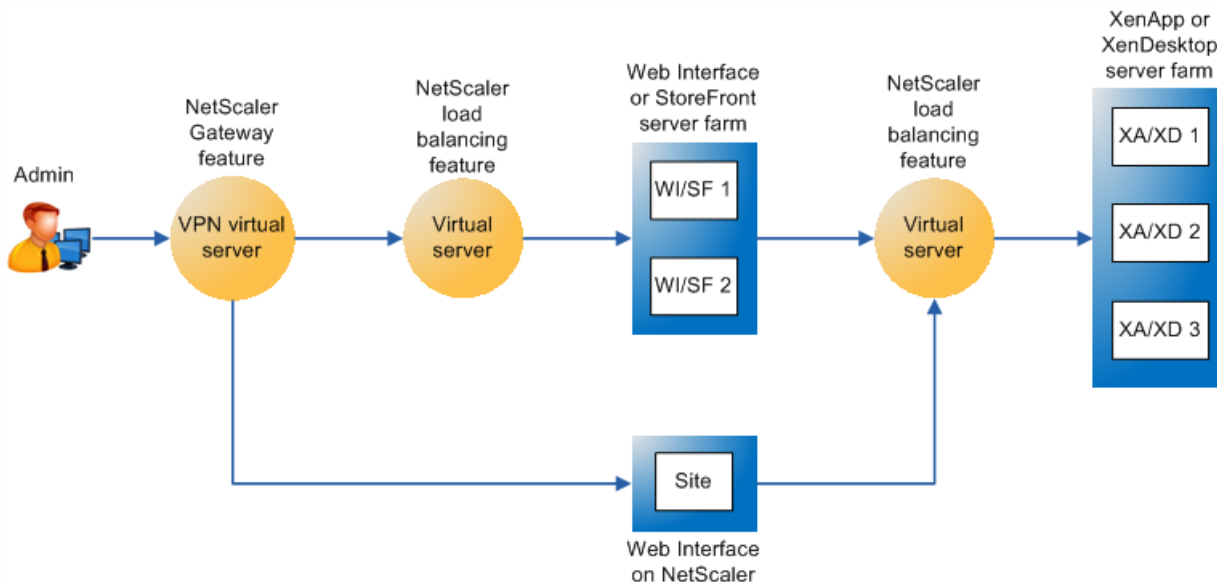

Dec 10, 2013

A NetScaler appliance can provide load balanced, secure remote access to your XenApp/XenDesktop applications. You can use the NetScaler load balancing feature to distribute traffic across the XenApp/XenDesktop servers, and the NetScaler Gateway feature to provide secure remote access to the servers. NetScaler can also accelerate and optimize the traffic flow and offer visibility features that are useful for XenApp/XenDesktop deployments.

The configurations that are required to be performed on the NetScaler are consolidated in a wizard that simplifies the deployment. You can also apply the following preset configurations:

- Optimization settings such as TCP profiles, compression, caching, and SSL quantum settings.
- Security settings such as application firewall profiles and policies.
- Visibility settings such as HDX Insight policies.

Figure 1. NetScaler Appliance in XenApp/XenDesktop Setup

The above figure shows the components involved in this deployment:

- **NetScaler Gateway.** Provides the URL for user access, and provides security by authenticating the users.
- **NetScaler load balancing virtual server.** Load balances the traffic for the Web Interface or StoreFront servers. You can also deploy a load balancing virtual server in front of the XenApp/XenDesktop servers to load balance key components such as XML Broker and Desktop Delivery Controller (DDC) server.
- **Web Interface or StoreFront or Web Interface on NetScaler.** Provides the interface through which you can access the applications.

Note: Web Interface on NetScaler (WIONNS) is a customization of the Web Interface product, hosted on the NetScaler appliance.

- **XenApp/XenDesktop.** Provides the applications that your users want to access.

Prerequisites

Before using the wizard, make sure of the following:

- XenApp/XenDesktop servers are configured and available.
- Web Interface, StoreFront, or Web Interface on NetScaler servers are configured and available.
- You have a working knowledge of NetScaler Gateway, NetScaler, XenApp, XenDesktop, and StoreFront/Web Interface/Web Interface on NetScaler. For more information, see "[Citrix eDocs](#)."

To set up the NetScaler for XenApp/XenDesktop by using the wizard

1. Log on to the NetScaler appliance and, on the Configuration tab, navigate to Traffic Management > Load Balancing.
2. In the details pane, under XenApp/XenDesktop, click Set Up NetScaler for XenApp/XenDesktop.
Note: If the setup exists on the NetScaler, click the Edit link corresponding to each of the section that you want to modify.
3. Select the XenApp/XenDesktop deployment type.
Note: The wizard supports only the single-hop deployment of XenApp/XenDesktop.
4. Select the product (StoreFront, Web Interface, or Web Interface on NetScaler) that in your deployment provides the interface for access to the XenApp/XenDesktop applications.
5. Set up secure remote access.
 1. In the NetScaler Gateway Settings section, specify the details for the VPN virtual server.
 2. In the Certificate section, choose an existing certificate or install a new certificate.
 3. In the Authentication Settings section, configure the primary authentication mechanism to be used and specify the server details. You can also configure secondary authentication to provide two-factor authentication.
Note: While configuring the primary authentication mechanism, you can select the Load Balancing check box to distribute traffic among authentication servers. In the address field that appears, specify the IP address to assign to the load balancing virtual server.
6. Set up the interface used to access the applications. In the Web Interface, StoreFront, or Web Interface on NetScaler section, do the following:
 1. Specify the details of the server that provides the interface for accessing the applications.
 2. Select the Load Balancing check box to distribute load among the servers. In the address field that appears, specify the IP address to assign to the load balancing virtual server.
Note: If Web Interface on NetScaler is selected in this wizard, but it is not installed on the NetScaler appliance, you are prompted to upload the TAR and JRE files. For more information, see "[Installing the Web Interface](#)."
7. Specify the XenApp/XenDesktop server(s) from which the applications are to be accessed. In the Xen Farm section, do the following:
 1. Provide details of the servers from which your users want to access applications.
 2. Select the Load Balancing check box to distribute load among the servers. In the address field that appears, specify the IP address to assign to the load balancing virtual server.
8. Configure optimization, security, and visibility on the NetScaler appliance.
 - In the Optimization section, click Apply. The following configurations are executed internally:

TCP Profile

```
> set vpn vserver ag_vsvr1 -tcpProfileName nstcp_default_XA_XD_profile
> set servicegroup WI_servicegroup -tcpProfileName nstcp_default_XA_XD_profile
> set servicegroup SF_servicegroup -tcpProfileName nstcp_default_XA_XD_profile
> set servicegroup XA_Primary_Broker_servicegroup -tcpProfileName nstcp_default_XA_XD_profile
> set servicegroup XA_Secondary_Broker_servicegroup -tcpProfileName nstcp_default_XA_XD_profile
```

```
> set servicegroup XD_servicegroup -tcpProfileName nstcp_default_XA_XD_profile
```

Compression

```
> enable ns feature cmp
> set servicegroup WI_servicegroup -cmp on
> set servicegroup SF_servicegroup -cmp on
> set servicegroup XA_Primary_Broker_servicegroup -cmp on
> set servicegroup XA_Secondary_Broker_servicegroup -cmp on
> set servicegroup XD_servicegroup -cmp on
```

Caching

```
> enable ns feature IC
> add cache contentgroup cache_group_XA-XD
> set cache parameter -memLimit 100
> add cache policy cache_pol1 -rule TRUE -action CACHE -storeInGroup cache_group_XA-XD
> bind cache global XA_XD_10.102.87.108_cachepol -priority 10 -gotoPriorityExpression END -type REQ_DEFAULT
```

SSL quantum settings

```
> set ssl parameter -quantumSize 4 -sslTriggerTimeout 10 -encryptTriggerPktCount 10 -pushEncTriggerTimeout 10
```

- In the Security section, click Apply.

Note: The security settings are not applicable for this release.

- In the Visibility section, click Apply. The following configurations are executed internally:

```
> enable feature Appflow
> set vpn vserver ag_vsvr1 -appflowLog ENABLED
```

Note: Make sure that the appliance is added to the NetScaler Insight Center appliance.

9. Click Done to complete the configuration.

RISE Integration: NetScaler ADC and Cisco Nexus 7000 Series Switch

May 19, 2014

Application-delivery solutions that use service modules or switches have required complex configurations and changes in the networking stack. Cisco Remote Integrated Service Engine (RISE) technology can logically integrate a Citrix NetScaler application delivery controller (ADC) with a Cisco Nexus 7000 Series switch as a virtual service module. The integration eliminates the complexities and limitations of traditional inline and one-arm mode configurations. The NetScaler functionality is available as a centralized resource that can be leveraged across the application infrastructure supported by the Cisco Nexus 7000 series switch. The RISE integration provides a service module's streamlined deployment and simplified configuration and operation, and the complete NetScaler application-delivery capabilities that can accelerate application performance for all users.

An ADC deployed in an inline mode can create a bottleneck in the data center. Today, data-center traffic can handle traffic in the terms of terabytes per second, but the ADC capacity can scale up only to gigabytes per second range. The NetScaler ADC, with the new capability to integrate with Cisco Nexus 7000 switch using RISE, can be deployed in a one-arm mode and can provide ADC capabilities to data-center traffic with minimal configuration and maintenance overhead.

A one-arm mode deployment uses Source NAT (SNAT) and Policy Based Routing (PBR) to send only the necessary traffic through the ADC. With SNAT, the servers do not have visibility of client IP addresses. PBR resolves this issue, but it requires complex, manual configuration and is prone to errors. The Automatic Policy Based Routing (APBR) feature in RISE eliminates the need for Source NAT or manual PBR configuration in a one-arm mode design.

For more information about RISE functionality and other features, see [Cisco Remote Integrated Service Engine for Citrix NetScaler Appliances and Cisco Nexus 7000 Series Switches Configuration Guide](#).

Understanding RISE

May 29, 2014

Cisco RISE technology logically integrates a Citrix NetScaler ADC with a Cisco Nexus 7000 Series switch as a virtual service module. After you connect the NetScaler ADC and the Cisco Nexus 7000 series switch, an initial handshake is performed and a control channel is established between the two devices to exchange port-channel information. The following figure shows the RISE deployment:

Figure 1. RISE Deployment

Because the NetScaler ADC appears to be a virtual module in the switch, client traffic that reaches the Cisco Nexus 7000 series switch is intelligently routed to the NetScaler ADC and then to the servers. The return traffic flows to the ADC through the Cisco switch, and then back to the client.

The interface or port-channel that connects the NetScaler ADC and Cisco Nexus 7000 series switch is a single trunk carrying both control and data VLANs. The control VLAN is used for all control channel communication, and the data VLAN is used for communicating data traffic.

For more information, see [Cisco RISE Integration Overview](#).

This document includes the following:

- RISE Functionality
- RISE Network Topologies
- RISE Connection Modes

RISE Functionality

Updated: 2014-05-19

The feature integration that RISE enables between the NetScaler ADC and the Cisco Nexus 7000 Series switch provides the following functionalities:

- Plug and play auto-provisioning
RISE provides a plug and play auto-provisioning feature. You can directly connect the NetScaler ADC to the Cisco Nexus 7000 series switch.
- Discovery and bootstrapping
The discovery and bootstrap mechanism enables the Cisco Nexus 7000 Series switch to perform the initial setup of NetScaler automatically by exchanging information such as NSIP and VLANs to set up a RISE channel, which transmits control and data packets. For details, see [Discovery and Bootstrap](#).
- Health Monitoring
The NetScaler ADC uses its health monitoring feature to track and support server health by sending health probes to verify server responses. The Intelligent Services Control Manager (iSCM) on the Cisco Nexus 7000 Series switch and the Intelligent Services Control Client (iSCC) on the NetScaler ADC also periodically send heartbeat packets to each other. If a critical error occurs and health monitoring detects a service instance failure, or if the heartbeat is missed six times successively, the RISE channel becomes nonoperational. For details, see [Health Monitoring](#).
- APBR
Automatic Policy Based Routing (APBR) automatically routes the return traffic from the servers to the NetScaler ADC, preserving the client IP addresses. The automatic policy based routes are defined on the Cisco Nexus 7000 series switch. When the return traffic from the server reaches the Cisco Nexus 7000 series switch, the APBR policies defined on the switch route the traffic to the NetScaler ADC, which in turn routes the traffic to the client.

Note:

- APBR can function only if USIP is enabled on the NetScaler ADC.
- APBR can be deployed in a VPC mode or a non-VPC mode. For more details on VPC mode, see [Cisco VPC](#).

For details on configuring APBR, see [Configuring Auto Policy-Based Routing](#).

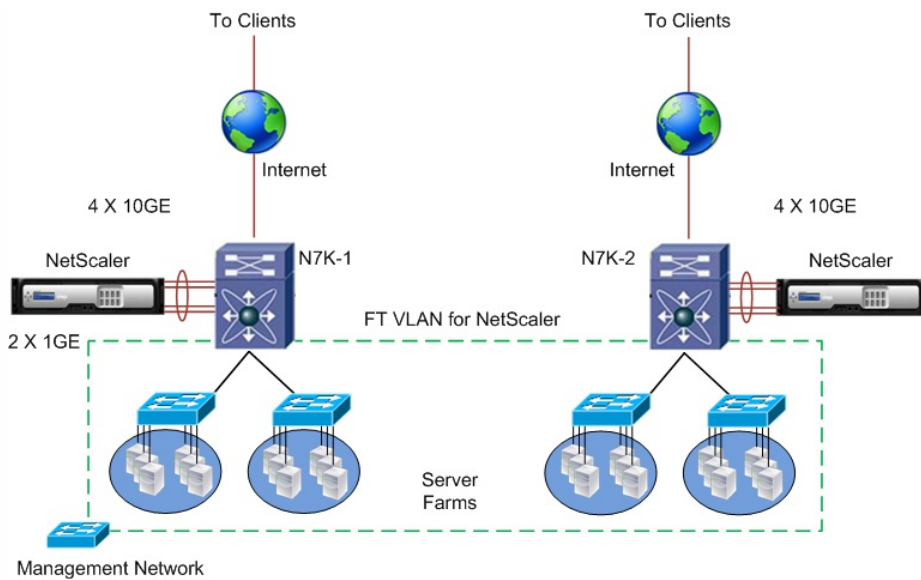

RISE Network Topologies

Updated: 2014-05-19

RISE can be deployed in any of the following modes:

- One-Arm mode— The NetScaler ADC's ports are bundled as a port channel connected to the Cisco Nexus 7000 Series switch. In one-arm mode, the ADC is configured with a VLAN that handles both client and server requests.

Figure 2. One-Arm Mode

- Bridged mode— In bridged mode, the NetScaler ADC bridges traffic between two VLANs in the same IP subnet. The VLAN facing the WAN is the client VLAN. The VLAN facing the data center is the server VLAN. A bridge group virtual interface (BVI) joins the two VLANs into one bridge group.

Figure 3. Bridged Mode

- Routed mode— In routed mode, the NetScaler ADC is the next hop in the network, typically with the client-side VLAN and the server-side VLAN in different IP subnets or in different IP networks.

Figure 4. Routed Mode

RISE Connection Modes

Updated: 2014-05-27

You can connect the Citrix NetScaler appliance to the Cisco Nexus 7000 Series switch in one of the following ways:

Direct Connect Mode for a Standalone Switch

In a direct mode deployment, the NetScaler ADC is attached to a single Nexus 7000 Series switch. The switch can be standalone device or a vPC peer.

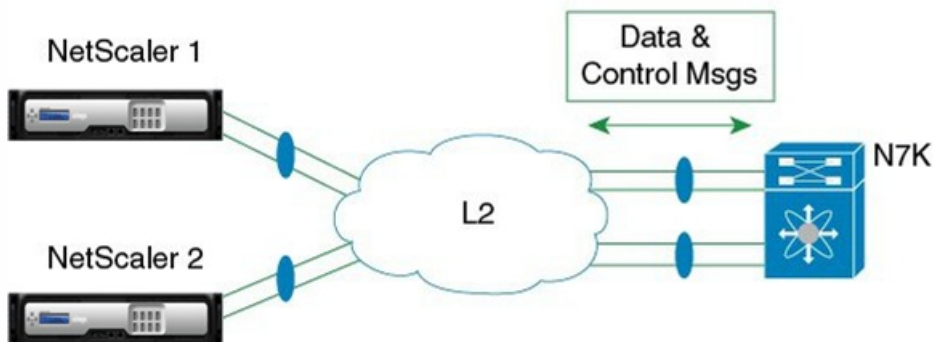

Figure 5. Direct Connect Mode

Indirect Connect Mode

In an indirect mode deployment, a virtual NetScaler ADC is connected to a Cisco Nexus 7000 Series switch through a switched layer 2 network.

Figure 6. Indirect Connect Mode

Virtual Port Channel (vPC) Connect Mode

In a virtual port channel (vPC) direct mode deployment, the NetScaler ADC is attached to a single Nexus 7000 Series switch that is a vPC peer.

Figure 7. Virtual Port Channel (vPC) Connect Mode

vPC Indirect Connect Mode

In a vPC indirect mode deployment, the NetScaler ADC is indirectly attached to a Cisco Nexus vPC peer through a layer 2 network.

Figure 8. vPC Indirect Connect Mode

For more information on connection modes, see [Connection Modes](#).

Getting Started with RISE

May 19, 2014

To begin using the RISE features, first install the Cisco Nexus 7000 series switch and the NetScaler ADC. Then, connect the NetScaler ADC to the Cisco Nexus 7000 switch either directly or indirectly. If you plan to connect the NetScaler ADC directly to the Cisco Nexus 7000 switch, the initial setup is done automatically by the auto-discovery feature. The following figure explains the flow of steps in the configuration of RISE.

This document includes the following:

- Installing the Cisco Nexus Switch and the NetScaler ADC
- Accessing the Cisco Nexus Switch and the NetScaler ADC
- Configuring RISE
- Configuring High Availability

Installing the Cisco Nexus Switch and the NetScaler ADC

Updated: 2014-05-26

You need to first install the Cisco Nexus 7000 series switch, and then install the NetScaler ADC.

Installing Cisco Nexus 7000 Series Switch

To install the Cisco Nexus 7000 Series Switch, see [Installing Cisco Nexus 7000 Series Switch](#).

Installing NetScaler ADC

To install the NetScaler ADC, see [Installing NetScaler ADC](#).

To install a virtual NetScaler ADC appliance, see [Installing NetScaler Virtual Appliances on XenServer](#) or [Installing NetScaler Virtual Appliances on VMware ESX](#).

Accessing the Cisco Nexus Switch and the NetScaler ADC

Updated: 2014-05-26

After you have completed the installation process, you can access the Cisco Nexus Series 7000 switch through the command-line interface (CLI) and the Citrix NetScaler appliance through the graphical user interface (GUI) or the CLI. To perform administrative tasks and also, to configure RISE, you need to access the Cisco switch and the NetScaler ADC.

Accessing the Cisco Nexus Series 7000 Switch

After installing the Cisco Nexus 7000 series switch, you can access it using the command line interface. To access the Cisco Nexus 7000 Series Switch, see [Accessing the Cisco Nexus 7000 series switch](#).

Accessing the NetScaler ADC

A NetScaler appliance has both a command line interface (CLI) and a graphical user interface (GUI). The GUI includes a configuration utility for configuring the appliance and a statistical utility, called Dashboard. For initial access, all appliances ship with the default NetScaler IP address (NSIP) of 192.168.100.1 and default subnet mask of 255.255.0.0. You can assign a new NSIP and an associated subnet mask during initial configuration.

Note: If you are using the direct connect mode to connect the appliance to the Cisco Nexus switch, you are not required to access the Citrix Netscaler appliance to configure RISE. For direct connect mode, the IP address and VLAN for management are pushed from the Cisco Nexus switch as part of RISE simplified provisioning.

For information about the procedures to access through CLI and GUI, see [Using the Command Line Interface](#) and [Using Graphical User Interface](#).

Configuring RISE

Updated: 2015-03-18

After you install the Cisco Nexus 7000 series switch and the NetScaler ADC, configure the appliance to work in direct mode, indirect mode, VPC direct mode, or VPC indirect mode.

Direct Mode

The NetScaler ADC which is directly connected to the switch is automatically configured for RISE mode and all of its ports are in operation mode. No configuration is required on the appliance in a direct mode deployment. For details on configuring RISE in direct mode, see [Configuring RISE in Direct Mode](#).

Indirect Mode

For indirect mode deployment, configure RISE on Cisco Nexus switch, and then configure NSIP and NSVLAN on NetScaler

ADC.

- [Configuring RISE on Cisco Nexus Switch](#)
- [Configuring NSIP on NetScaler ADC](#)
- [Configuring NSVLAN on NetScaler ADC](#)

If the direct mode is disabled, all Layer 2 (L2) discovery messages are dropped and L2 RISE discovery does not take place. While, if the direct mode is enabled, the L2 discovery messages are parsed. If L2 RISE discovery messages are successfully parsed, the Indirect Mode is automatically enabled.

If indirect mode is disabled, NetScaler RISE daemon does not listen on TCP ports 8000 and 8001. As a result, RISE heartbeats stop and RISE profiles go down. While, if indirect mode is enabled, NetScaler RISE daemon starts listening on TCP ports 8000 and 8001. As a result, RISE heartbeats may be exchanged and RISE profiles may come up.

The default setting for RISE is direct attach mode as enabled and indirect mode as disabled. With these settings, the direct attach mode works. However, indirect mode will not work. If you want to deploy NetScaler in an indirect mode setting with N7K then use the following setting:

```
set rise param -indirectMode ENABLED
```

With active RISE profiles in direct mode, you must consider the followings points:

1. The set rise param -directMode DISABLED command displays a warning message; Warning: Disabling direct mode with one or more active RISE profile(s) on DIRECT ATTACH mode may cause corresponding RISE profile(s) to not come UP on reboot
2. The set rise param -indirectMode DISABLED displays a warning message; Warning: Disabling indirect mode will cause any active RISE profile(s) to go down

However, if the direct mode is enabled, and NetScaler starts receiving L2 RISE discovery messages, it automatically turns the indirect mode as enabled. Otherwise, RISE direct mode does not work.

With active RISE profiles in Indirect Attach mode, the set rise param -indirectMode DISABLED command displays a warning message; Warning: Disabling indirect mode will cause any active RISE profile(s) to go down leading to RISE profiles on Indirect Attach going down.

vPC Direct Mode

The NetScaler ADC which is directly connected to the switch is automatically configured for RISE mode and all of its ports are in operation mode. No configuration is required on the appliance in a direct mode deployment. For details on configuring RISE in direct mode, see [Configuring RISE in vPC Direct Mode](#).

vPC Indirect Mode

In a vPC indirect mode deployment, the NetScaler ADC is indirectly attached to a Cisco Nexus vPC peer through a Layer 2 network.

- [Configuring RISE on Cisco Nexus Switch](#)
- [Configuring NSIP on NetScaler ADC](#)
- [Configuring NSVLAN on NetScaler ADC](#)

For details on configuring RISE in direct mode, see [Configuring RISE in vPC Direct Mode](#).

For information on configuring RISE, see [Configuring RISE](#).

Configuring High Availability

Updated: 2014-05-26

In a High Availability setup, the RISE deployment uses a maximum of two NetScaler ADCs. If one ADC becomes unavailable, the traffic flow is seamlessly switched to the other ADC.

Figure 1. High Availability

For information about high availability configuration, see [High Availability](#).

Use Case: Configuring Auto Policy-Based Routing

May 27, 2014

Auto Policy-Based Routing (APBR) automatically routes the return traffic from the servers to the NetScaler ADC, preserving the client IP addresses. The automatic policy based routes are defined on the Cisco Nexus 7000 series switch. When the return traffic from the server reaches the Cisco Nexus 7000 series switch, the APBR policies defined on the switch route the traffic to the NetScaler ADC, which in turn routes the traffic to the client.

To understand the need for APBR, first consider a NAT based scenario in which a packet flows from the client to the server and from the server back to the client.

Figure 1. Packet Flow

1. Client initiates the traffic to the virtual IP (VIP) address.
SRC_IP= Client IP; DST_IP= VIP
2. The Cisco Nexus switch forwards the packet to the NetScaler ADC.
SRC_IP= Client IP; DST_IP= VIP
3. The ADC performs source NAT and destination NAT (Network Address Translation), changes the source IP and destination IP addresses, and sends the packet to the Cisco Nexus switch.
SRC_IP= NAT_IP; DST_IP= RS_IP
4. The Cisco Nexus switch receives the packet and forwards it to a server.
SRC_IP= NAT_IP; DST_IP= RS_IP
5. The server processes the packet and forwards it to the Cisco Nexus 7000 series switch.
SRC_IP= RS_IP IP; DST_IP= NAT_IP
6. The Cisco Nexus switch forwards the packet to the NetScaler ADC.
SRC_IP= RS_IP IP; DST_IP= NAT_IP
7. The NetScaler ADC changes the source IP address and forwards the packet to the Cisco Nexus 7000 series switch.
SRC_IP= VIP; DST_IP= Client_IP

8. The Cisco Nexus 7000 series switch forwards the packet to the client.

SRC_IP= VIP; DST_IP= Client_IP

The client receives the packet. However, the client IP address is not visible to the server.

Now, consider a scenario in which policy based routing (PBR) directs packet flow.

1. Client initiates the traffic to the virtual IP (VIP) address.

SRC_IP= Client IP; DST_IP= VIP

2. The Cisco Nexus switch forwards the packet to the NetScaler ADC.

SRC_IP= Client IP; DST_IP= VIP

3. The ADC performs destination NAT (Network Address Translation), changes the destination IP, and then sends the packet to the Cisco Nexus switch.

SRC_IP= Client IP; DST_IP= RS_IP

4. The Cisco Nexus switch receives the packet and forwards it to a server.

SRC_IP= Client IP; DST_IP= RS_IP

5. The server processes the packet and forwards it to the Cisco Nexus 7000 series switch.

SRC_IP= RS_IP IP; DST_IP= Client IP

6. The Cisco Nexus switch forwards the packet to the NetScaler ADC.

SRC_IP= RS_IP IP; DST_IP= Client IP

7. The NetScaler ADC changes the source IP address and forwards the packet to the Cisco Nexus 7000 series switch.

SRC_IP= VIP; DST_IP= Client_IP

8. The Cisco Nexus 7000 series switch forwards the packet to the client.

SRC_IP= VIP; DST_IP= Client_IP

9. The client receives the packet. The client IP address is visible to the server. However, PBR requires manual and complex configurations and is prone to errors.

To overcome these drawbacks, configure APBR rules on the RISE appliance. When APBR is configured, the packets flow as described in the following procedure:

1. Client initiates the traffic to the virtual IP (VIP) address.

SRC_IP= Client IP; DST_IP= VIP

2. The Cisco Nexus switch forwards the packet to the NetScaler ADC.

SRC_IP= Client IP; DST_IP= VIP

3. The ADC performs load balancing and changes the destination IP address to the appropriate server IP address and forwards the packet to the Cisco Nexus switch in an APBR message.

SRC_IP= Client IP; DST_IP= RS_IP

4. The Cisco Nexus switch receives the packet and forwards it to a server by using a route map.

SRC_IP= Client IP; DST_IP= RS_IP

5. The server processes the packet and forwards it to the Cisco Nexus 7000 series switch.

SRC_IP= RS_IP IP; DST_IP= Client_IP

6. When the packet reaches the Nexus switch, the switch applies the APBR rules, sets the next hop IP address to that of the NetScaler ADC, and forwards the packet to the NetScaler ADC.

SRC_IP= RS_IP IP; DST_IP= Client_IP

7. The NetScaler ADC changes the source IP address and forwards the packet to the Cisco Nexus 7000 series switch.

SRC_IP= VIP; DST_IP= Client_IP

8. The Cisco Nexus 7000 series switch forwards the packet to the client.

SRC_IP= VIP; DST_IP= Client_IP

9. The client receives the packet successfully.

Note: APBR rules are configured on the Cisco Nexus switch by the Citrix Netscaler appliance only if the Use Source IP (USIP) option is enabled in the services or service groups on the Citrix Netscaler appliance.

The APBR message control flow is explained below

1. After USIP is enabled in the services on Netscaler ADC, it publishes the IP address, port number and protocol details of the server to the Cisco Nexus 7000 series switch over the RISE control channel.

2. Using the IP address, port number and protocol details of the server, the Cisco Nexus 7000 series switch creates an APBR rule which consists of ACLs and route maps.

Note:

- For local servers, the switch creates ACLs and route maps.
- For remote servers, the switch forwards the APBR messages to other Cisco Nexus 7000 series switches.

3. The RISE appliance then applies the APBR rules to the switch virtual interface on the Cisco Nexus 7000 series switch connected to server.

To configure the APBR functionality:

- Enable the feature on the Cisco Nexus switch
- Configure APBR on NetScaler ADC
 - Configure NSIP
 - Configure NSVLAN
 - Enable USIP option

For more information, see [Configuring Auto Policy-Based Routing](#).

Web Interface

Aug 30, 2013

The Web Interface on Citrix NetScaler appliances is based on Java Server Pages (JSP) technology and provides access to Citrix XenApp and Citrix XenDesktop applications. Users access resources through a standard Web browser or by using the Citrix XenApp plug-in.

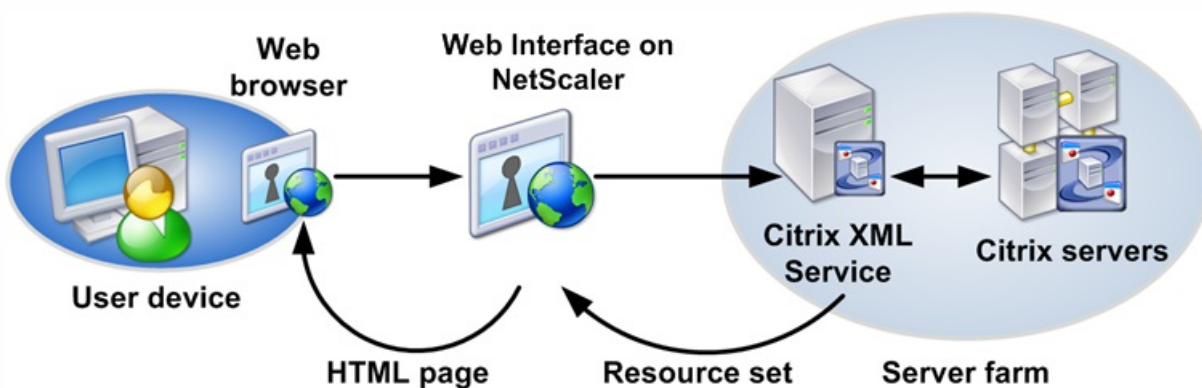

The Web Interface runs as a service on port 8080 on the NetScaler appliance. To create Web Interface sites, Java is executed on Apache Tomcat Web server version 6.0.35 on the NetScaler appliance. The Web Interface sites provide user access to the XenApp and XenDesktop resources, which include applications, content, and desktops.

The Web Interface installation includes installing the Web Interface tar file and JRE tar file on the NetScaler appliance. To configure the Web Interface, you create a Web Interface site and bind one or more XenApp or XenDesktop farms to it.

How Web Interface Works

The following figure illustrates a basic Web interface session.

Figure 1. *A Basic Web Interface Session*

Following is a typical set of interactions among a user device, a NetScaler running the Web interface, and a server farm.

1. A user authenticates to the Web interface through a Web browser or by using the XenApp plug-in.
2. The Web interface reads the user's credentials and forwards the information to the Citrix XML Service running on servers in the server farm.
3. The Citrix XML Service on the designated server retrieves from the servers a list of resources that the user can access. These resources constitute the user's resource set and are retrieved from the Independent Management Architecture (IMA) system.
4. The Citrix XML Service then returns the user's resource set to the Web interface running on the NetScaler.
5. The user clicks an icon that represents a resource on the HTML page.
6. The Web interface queries the Citrix XML Service for the least busy server.
7. The Citrix XML Service returns the address of this server to the Web interface.
8. The Web interface sends the connection information to the Web browser.
9. The Web browser initiates a session with the server.

Installing and Configuring the Web Interface

Feb 08, 2016

To configure the web interface, you create a web interface site and bind one or more XenApp or XenDesktop farms to it. You then configure the web interface to work behind an HTTP or an HTTPS virtual server or NetScaler Gateway.

- **Using an HTTP or an HTTPS virtual server.** You create an HTTP or an HTTPS virtual server on the NetScaler appliance and bind the web interface service, running on port 8080 of the NetScaler appliance, to the virtual server. Clients on the LAN use the virtual server IP address to access the web interface. When using this access method, the URL format for the web interface site is as follows:

<HTTP or HTTPS>://<HTTP or HTTPS vserver IP address>:<vserver port number>/<web interface site path>

The following access methods are available for clients accessing the web interface site when it is configured using an HTTP or an HTTPS virtual server:

- **Direct.** Actual address of a XenApp or XenDesktop server is sent to the clients.
- **Alternate.** Alternate address of a XenApp or XenDesktop server is sent to the clients.
- **Translated.** Translated address, from the defined internal addresses to external addresses and ports mapping table, is sent to the clients from a specified network. When you use this option, you have to define internal address to external address and port mappings.
- **Using NetScaler Gateway.** You associate the web interface site with NetScaler Gateway. Remote clients use the NetScaler Gateway URL to access the web interface site. With this access method, the URL format for the web interface site is as follows:

HTTPS://<Access Gateway URL>/<web interface site path>

The following access methods are available for clients accessing the web interface site when it is configured using a NetScaler Gateway:

- **Gateway Direct.** Actual address of a XenApp or XenDesktop server is sent to NetScaler Gateway.
- **Gateway Alternate.** Alternate address of a XenApp server is sent to NetScaler Gateway. You cannot use this mode to access XenDesktop servers.
- **Gateway Translated.** Translated address, from the defined internal addresses to external addresses and ports mapping table, is sent to NetScaler Gateway. When you use this option, you have to define internal address to external address and port mappings.

Prerequisites

The following prerequisites are required before you begin installing and configuring the Web interface.

- XenApp or XenDesktop farms are set up and running in your environment.
- Conceptual knowledge of the Web interface.

Installing the Web Interface

To install the Web interface, you need to install the following files:

- **Web interface tar file.** The setup file for installing the Web interface on the NetScaler appliance. This tar file also includes Apache Tomcat Web server version 6.0.35. The file name has the following format: nswi-<version number>.tgz (for example, nswi-1.5.tgz).
- **JRE tar file.** The JRE tarball. You must use the OpenJDK7 package for FreeBSD 8.x/amd64. The package named openjdk-7.17.02_2.tbz can be downloaded from http://ftp-archive.freebsd.org/pub/FreeBSD-Archive/old-releases/amd64/8.4-RELEASE/packages/java/openjdk-7.17.02_2.tbz or ftp://mirror.is.co.za/FreeBSD/ports/amd64/packages-8.4-release/dev/openjdk-7.17.02_2.tbz.

Note: On a high availability setup, when installing the web interface with tar files (web interface and JRE) that are already available on the appliance, ensure that the files are available in the same location on both the primary and secondary appliances; otherwise, the web interface will not be installed on the secondary appliance.

Copy the tar files to a local workstation or to the /var directory of the appliance.

These files install all the Web interface components and JRE on the hard drive and configure automatic startup of the Tomcat Web server with Web interface at appliance startup time. Both tar files are internally expanded in the /var/wi directory on the hard drive.

Note: After installing web interface on the appliance and before creating a web interface site, you must place the client plugin in the appliance by using the appropriate Upload Plugins utility provided on the web interface details pane.

To install the Web interface and JRE tar files by using the command line interface

At the command prompt, type:

```
install wi package -wi <URL> -jre <URL>
```

Examples

```
> install wi package -wi sftp://username:password@10.102.29.12/var/ nswi-1.5.tgz -jre <url> > install wi package -wi ftp://username:password@10.102.29.15/var/ nswi-1.5.tgz -jre <url>
```

To install the Web interface and JRE tar files by using the configuration utility

1. Navigate to System > Web Interface and, in the Getting Started group, click Install Web Interface.
2. Specify the install path for web interface tar file and JRE tar file.

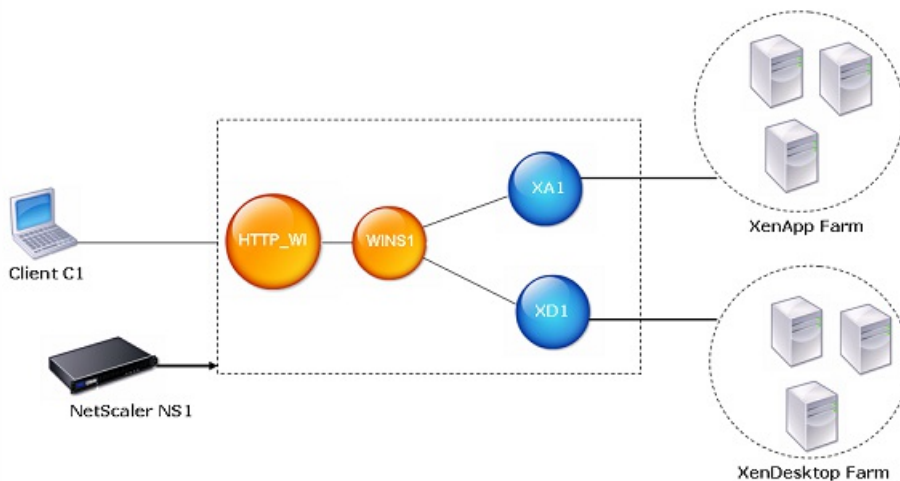

Configuring a Web Interface Site for LAN Users Using HTTP

Aug 08, 2014

In this scenario, user and the Web interface setup are on the same enterprise LAN. The enterprise has both a XenApp and a XenDesktop farm. Users access the Web interface by using an HTTP vserver. The Web interface exposes its own login page for authentication. The vserver IP address is used to access the Web interface.

The following figure illustrates the Web interface running on the NetScaler appliance NS1. A Web interface site WINS1 is created and a XenApp farm XA1 and a XenDesktop farm XD1 are bound to it. An HTTP vserver HTTP_WI is also created. Client C1 uses the IP address of the HTTP_WI vserver to access the WINS1 site.

Figure 1. A Web Interface Site Configured for LAN Users Using HTTP

To configure a Web interface site for LAN users using HTTP by using the configuration utility

1. Navigate to System > Web Interface, click Web Interface Wizard, and configure the web interface parameters.
2. In Default Access Methods, select the required access option and configure the access method parameters.
Note: When you create the HTTP vserver by using the configuration utility, the configuration utility automatically creates a service, which logically represents the Web interface service running on the NetScaler appliance, and binds the service to the HTTP virtual server.
3. On Configure Access Methods page, create the access method for a client IP address or network.
Note: Before you configure access method based on the client IP address, you must enable USIP mode on the web interface service to make the client's IP address available with the web interface.
4. On Configure Address Translations page, create the address translation for mapping between an Internal IP address and an external IP address.
Note: The Configure Address Translations page appears on the wizard when you set the Translated access method for a Client's IP address or network.

5. On Configure XenApp/XenDesktop Farm page, create the XenApp or XenDesktop farm.
6. Verify the Web interface configuration by viewing the Details section at the bottom of the pane.
To view the Web interface site, Navigate to System > Web Interface > Sites.

To configure a Web interface site for LAN users using HTTP by using the command line interface

1. Add a Web interface site. Set Direct or Alternate or Translated for the defaultAccessMethod parameter. At the command prompt, type:

```
add wi site <sitePath> -siteType ( XenAppWeb | XenAppServices ) -publishedResourceType ( Online | Offline | DualMode ) -kioskMode ( ON | OFF ) -wiAuthenticationMethods ( Explicit | Anonymous ) -webSessionTimeout <positive_integer> -defaultAccessMethod <defaultAccessMethod> -loginTitle <string>
```

Example

- ```
> add wi site WINS1 -siteType XenAppWeb -publishedResourceType Online -kioskMode ON -defaultAccessMethod Direct
```
2. (Optional) Set an access method for a Client's IP address or network. At the command prompt, type:  

```
bind wi site <sitePath> -accessMethod <accessMethod> -clientIpAddress <ip_addr> -clientNetMask <netmask>
```
  3. If you have set the Translated access method for a Client's IP address or network then provide Internal IP and external IP address mappings. At the command prompt, type:  

```
bind wi site <sitePath> -translationInternalIp <ip_addr> -translationInternalPort <port | *> -translationExternalIp <ip_addr> -translationExternalPort <port | *> [-accessType <accessType>]
```
  4. Bind XenApp or XenDesktop farms to the Web interface site. At the command prompt, type:  

```
bind wi site <sitePath> <farmName> <xmlServerAddresses> -xmlPort <value> -transport (HTTP | HTTPS) -loadBalance (ON | OFF)
```

#### Example

- ```
> bind wi site WINS1 XA1 10.102.46.6 -xmlPort 80 -transport HTTP -LoadBalance OFF
> bind wi site WINS1 XD1 10.102.46.50 -xmlPort 80 -transport HTTP -LoadBalance OFF
```
5. Create a service that is a logical representation of the Web interface service running on the NetScaler appliance. At the command prompt, type:

```
add service <name> <IP address> <serviceType> <port>
```

Example

- ```
> add service WI_Loopback_Service 127.0.0.1 HTTP 8080
```
6. Add an HTTP vserver. At the command prompt, type:  

```
add lb vserver <virtualServerName> <protocol> <IPAddress> <port>
```

#### Example

- ```
> add lb vserver HTTP_WI HTTP 10.102.29.5 80
```
7. Bind the Web interface service to the HTTP vserver. At the command prompt, type:

```
bind lb vserver <virtualServerName> <serviceName>
```

Example

```
> bind lb vserver HTTP_WI WI_Loopback_Service
```

Configuring a Web Interface Site for LAN Users Using HTTPS

Aug 08, 2014

In this scenario, user accounts and the Web interface setup are on the same enterprise LAN. Users access the Web interface by using an SSL-based (HTTPS) vserver. The Web interface exposes its own login page for authentication. SSL offloading is done by this vserver on the NetScaler. The vserver IP address is used to access the Web interface instead of the NetScaler IP address (NSIP).

The following figure illustrates the Web interface running on the NetScaler appliance NS1. A Web interface site WINS1 is created and a XenApp farm XA1 and a XenDesktop farm XD1 are bound to it. An HTTPS vserver HTTPS_WI is also created. Client C1 uses the IP address of the HTTPS_WI vserver to access the WINS1 site.

Figure 1. A Web Interface Site Configured for LAN Users Using HTTPS

To configure a Web interface site for LAN users using HTTPS by using the configuration utility

1. Navigate to **System > Web Interface**, click **Web Interface Wizard**, and configure the web interface parameters.
2. In **Default Access Methods**, select the required access option and configure the access method parameters.
Note: When you create the HTTPS vserver by using the configuration utility, the configuration utility automatically creates a service, which logically represents the Web interface service running on the NetScaler appliance, and binds the service to the HTTPS virtual server.
3. On **Specify a server Certificate** page, create or specify an existing SSL certificate–key pair. The SSL certificate–key pair is automatically bound to the HTTPS vserver.
4. On **Configure Access Methods** page, create the access method for a client IP address or network.
Note: Before you configure access method based on the client IP address, you must enable USIP mode on the web interface service to make the client's IP address available with the web interface.
5. On **Configure Address Translations** page, create the address translation for mapping between an Internal IP address and an external IP address.
Note: The **Configure Address Translations** page appears on the wizard when you set the Translated access method for a Client's IP address or network.
6. On the wizard's **Configure XenApp/XenDesktop Farm** page, create the XenApp or XenDesktop farm.
7. Verify the Web interface configuration by viewing the **Details** section at the bottom of the pane.
To view the Web interface site, Navigate to **System > Web Interface > Sites**.

To configure a Web interface site for LAN users using HTTPS by using the command line

1. Add a Web interface site. Set **Direct** or **Alternate** or **Translated** for the **defaultAccessMethod** parameter. At the command prompt, type:
`add wi site <sitePath> -siteType (XenAppWeb | XenAppServices) -publishedResourceType (Online | Offline | DualMode) -kioskMode (ON | OFF)
-wiAuthenticationMethods (Explicit | Anonymous) -webSessionTimeout <positive_integer> -defaultAccessMethod <defaultAccessMethod> -loginTitle
<string>`

Example

- ```
> add wi site WINS1 -siteType XenAppWeb -publishedResourceType Online -kioskMode ON -defaultAccessMethod Direct
```
2. (Optional) Set an access method for a Client's IP address or network. At the command prompt, type:  
`bind wi site <sitePath> -accessMethod <accessMethod> -clientIpAddress <ip_addr> -clientNetMask <netmask>`
  3. If you have set the Translated access method for a Client's IP address or network then provide Internal IP and external IP address mappings. At the command prompt, type:  
`bind wi site <sitePath> -translationInternalIp <ip_addr> -translationInternalPort <port | *> -translationExternalIp <ip_addr> -translationExternalPort <port | *>`

[-accessType <accessType>]

4. Bind XenApp or XenDesktop farms to the Web interface site. At the command prompt, type:  
bind wi site <sitePath> <farmName> <xmlServerAddresses> -xmlPort <value> -transport ( HTTP | HTTPS) -loadBalance ( ON | OFF)

**Example**

```
> bind wi site WINS1 XA1 10.102.46.6 -xmlPort 80 -transport HTTP -LoadBalance OFF
> bind wi site WINS1 XD1 10.102.46.50 -xmlPort 80 -transport HTTP -LoadBalance OFF
```

5. Create a service that is a logical representation of the Web interface service running on the NetScaler appliance. At the command prompt, type:  
add service <name> <IPAddress> <serviceType> <port>

**Example**

```
> add service WI_Loopback_Service 127.0.0.1 HTTP 8080
```

6. Add an HTTPS vserver. At the command prompt, type:  
add lb vserver <name>@ <protocol> <IPAddress> <port>

**Example**

```
> add lb vserver HTTPS_WI SSL 10.102.29.3 443
```

7. Bind the Web interface service to the HTTPS vserver. At the command prompt, type:  
bind lb vserver <name>@ <serviceName>

**Example**

```
> bind lb vserver HTTPS_WI WI_Loopback_Service
```

8. Create an SSL certificate key pair. At the command prompt, type:  
add ssl certkey <certificate-KeyPairName> -cert <certificateFileName> -key <privateKeyFileName>

**Example**

```
> add ssl certkey SSL-Certkey-1 -cert /nsconfig/ssl/test1.cer -key /nsconfig/ssl/test1
```

9. Bind the SSL certificate key pair to the HTTPS vserver. At the command prompt, type:  
bind ssl vserver <vserverName> -certkeyName <certificate- KeyPairName>

**Example**

```
> bind ssl vserver HTTPS_WI -certkeyName SSL-Certkey-1
```

10. Add a rewrite action. At the command prompt, type:  
add rewrite action <name> <type> <target> [<stringBuilderExpr>][[-pattern <expression>]

**Example**

```
> add rewrite action Replace_HTTP_to_HTTPS INSERT_AFTER "HTTP.RES.HEADER("Location").Value(0).Prefix(4)" "s"
```

11. Create a rewrite policy and bind the rewrite action to it. At the command prompt, type:  
add rewrite policy <name> <rule> <action>

**Example**

```
> add rewrite policy rewrite_location "HTTP.RES.STATUS == 302 && HTTP.RES.HEADER("Location").Value(0).startswith("http:")" Replace_HTTP_to_HTTPS
```

12. Bind the rewrite policy to the HTTPS vserver. At the command prompt, type:  
bind lb vserver <VserverName> -policyname <rewritePolicyName> -priority <value> -type response

**Example**

```
> bind lb vserver HTTPS_WI -policyname rewrite_location -priority 10 -type response
```

# Configuring a Web Interface Site for Remote Users Using NetScaler Gateway

Aug 08, 2014

In this scenario, user accounts and the Web interface setup are on different networks. Users access a Web interface site by using the NetScaler Gateway URL. SmartAccess is automatically enabled.

The following figure illustrates the Web interface running on the NetScaler appliance NS1. A Web interface site WINS1 is created and a XenApp farm XA1 and a XenDesktop XD1 are bound to it. An NetScaler Gateway VPN vserver AGEE\_WI is also configured. The client uses the NetScaler Gateway URL of the AGEE\_WI to access the WINS1 site.

Figure 1. A Web Interface Site Configured for Remote Users Using NetScaler Gateway

To configure a Web interface site for remote users using NetScaler Gateway by using the configuration utility

1. Navigate to System > Web Interface, click Web Interface Wizard, and configure the web interface parameters.
2. In Default Access Methods, select the required access option and configure the access method parameters.
3. On Configure Access Methods page, create the access method for a client IP address or network.  
Note: Before you configure access method based on the client IP address, you must enable USIP mode on the web interface service to make the client's IP address available with the web interface.
4. On Configure Address Translations page, create the address translation for mapping between an Internal IP address and an external IP address.  
Note: The Configure Address Translations page appears on the wizard when you set the Translated access method for a Client's IP address or network.
5. On Configure XenApp/XenDesktop Farm page, create the XenApp or XenDesktop farm.
6. Verify the Web interface configuration by viewing the Details section at the bottom of the pane.  
To view the Web interface site, Navigate to System > Web Interface > Sites.

To configure a Web interface site for remote users using NetScaler Gateway by using the command line interface

1. Add a Web interface site. Set GatewayDirect or GatewayAlternate or GatewayTranslated for the defaultAccessMethod parameter. At the command prompt, type:  
add wi site <sitePath> <agURL> <staURL> -sessionReliability ( ON | OFF ) -useTwoTickets ( ON | OFF ) -secondSTAURL <string> -authenticationPoint ( WebInterface | AccessGateway ) -siteType ( XenAppWeb | XenAppServices ) -publishedResourceType ( Online | Offline | DualMode ) -kioskMode ( ON | OFF ) -wiAuthenticationMethods ( Explicit | Anonymous ) -webSessionTimeout <positive\_integer> -defaultAccessMethod <defaultAccessMethod> -loginTitle <string>

#### Example

- ```
> add wi site WINS1 https://ag.mycompany.com http://ag.staserver.com -sessionReliability OFF -authenticationPoint AccessGateway -siteType XenAppWeb -publishedResourceType Online -kioskMode OFF
```
2. (Optional) Set an access method for a Client's IP address or network. At the command prompt, type:
bind wi site <sitePath> -accessMethod <accessMethod> -clientIpAddress <ip_addr> -clientNetMask <netmask>
 3. If you have set the Translated access method for a Client's IP address or network then provide Internal IP and external IP address mappings. At the command prompt, type:
bind wi site <sitePath> -translationInternalIp <ip_addr> -translationInternalPort <port | *> -translationExternalIp <ip_addr> -translationExternalPort <port | *> [-accessType <accessType>]
 4. Bind XenApp or XenDesktop farms to the Web interface site. At the command prompt, type:
bind wi site <sitePath> <farmName> <xmlServerAddresses> -xmlPort <value> -transport (HTTP | HTTPS) -loadBalance (ON | OFF)

Example

```
> bind wi site WINS1 XA1 10.102.46.6 -xmlPort 80 -transport HTTP -LoadBalance OFF  
> bind wi site WINS1 XD1 10.102.46.50 -xmlPort 80 -transport HTTP -LoadBalance OFF
```

Using Smart Card Authentication for Web Interface through NetScaler Gateway

Aug 08, 2014

The web interface on the NetScaler appliance supports single sign-on with a smart card through NetScaler Gateway. You log on to NetScaler Gateway by using a valid client certificate, either served from the local certificate store or from a smart card. After successful authentication, you are redirected to the web interface.

Requirements

- Make sure that you install the latest web interface tar file (nswi-1.5.tgz). This tar file provides support for smart card authentication.
- You must configure Delegation on the Active Directory. Follow the **Active Directory Configuration** section under **Procedure**, as described in the article at <http://support.citrix.com/article/CTX124603>.

To use smart card authentication for a web interface site through NetScaler Gateway by using the configuration utility

1. Navigate to System > Web Interface, click Web Interface Wizard, and configure the web interface parameters.
2. Select GatewayDirect as the Default Access Method.
3. Select Access Gateway as the Authentication Point.
4. Create the Access Gateway Vserver. For more information, see "<http://support.citrix.com/proddocs/topic/access-gateway-10/agee-config-settings-ag-wizard-tsk.html>."
5. Click Settings to set the ICA mode, SSO, and WHome and select SmartCard as the Access Gateway Authentication Method.
6. Click the SmartCard Settings link to configure certificate-based authentication on Access Gateway. You can skip these steps if certificate-based authentication is already configured on Access Gateway. In the Smart Card Settings wizard do the following:
 1. Specify the CA certificate. Install a CA certificate or use an already installed certificate for the NetScaler Gateway virtual server to authenticate the client certificate.
 2. Configure authentication policies. Create a certificate-based authentication policy and bind it to NetScaler Gateway vserver as follows:
 1. Click Insert Policy. In the Policy Name column, select New Policy.
 2. In the Create Authentication Policy dialog box, specify a name for the policy, select Authentication Type as CERT, and click New.
 3. In the Create Authentication Server dialog box, specify the server Name and the User Name Field and click Create.
 4. Bind the policy to the NetScaler Gateway Vserver with **ns_true** as expression and default priority.
 3. Configure SSL-based client authentication with Client Certificate set as Optional.
7. Continue with the wizard as described in "[Configuring a Web Interface Site for Remote Users Using NetScaler Gateway](#)."

To use smart card authentication for a web interface site through NetScaler Gateway by using the command line interface

At the command prompt, type:

```
add wi site <sitePath> <agURL> <staURL> -authenticationPoint AccessGateway -agAuthenticationMethod SmartCard -defaultAccessMethod GatewayDirect
```

Additionally, smart card support on web interface requires certificate-based authentication on the NetScaler Gateway. Additionally, smart card support on web interface requires certificate-based authentication on the Access Gateway. If you do not have certificate-based authentication already configured on the NetScaler Gateway vserver, do the following:

1. Configure a NetScaler Gateway vserver and bind the server and CA certificate to it.

```
add vpn vserver <vpnserver_name> SSL <AccessGateway_VIP> <port>

bind ssl vserver <vpnserver_name> -certKeyName <Server_Cert_Key_Pair>

bind ssl vserver <vpnserver_name> -certKeyName <Root_Cert_as_CKP> -CA

set ssl vserver <vpnserver_name> -clientAuth ENABLED -clientCert Optional

add dns nameserver <dns_server_ip>
```

2. Configure a certificate-based authentication policy and bind it to the NetScaler Gateway vserver.

```
add authentication certAction <certAction_name> -userNameField <string>

add authentication certPolicy <certPolicy_name> <rule> <certAction_name>

bind vpn vserver <vserver_name> -policy <certPolicy_name>
```

3. Configure the web interface site in ICA proxy mode through a session policy and then bind it to NetScaler Gateway vserver.

```
add vpn sessionAction <sessionAction_name> -defaultAuthorizationAction ALLOW -SSO ON -wihome "<WI_URL>" -
wiPortalMode NORMAL -icapproxy ON

add vpn sessionPolicy <sessionPolicy_name> <rule> <sessionAction_name>

bind vpn vserver <vpnserver_name> -policyName <sessionPolicy_name>

bind vpn vserver <vpnserver_name> -staServer "<sta_server_url>"
```

Using the WebInterface.conf Dialog Box

Aug 08, 2014

The WebInterface.conf dialog box in the configuration utility displays the content of the webinterface.conf file for a Web Interface site.

You can do the following from this dialog box:

- Edit the WebInterface.conf file and save the changes.
- Search the file's content for instances of a text string.
- Easily save the WebInterface.conf file to your local computer.

To search a string in the webinterface.conf file by using the configuration utility

1. Navigate to System > Web Interface > Sites, select the web interface site, and click WebInterface.conf.
2. In the WebInterface.conf dialog box, use the following controls:
 - Find. Displays the following search options that you can use to find one or more instances of a text string in a configuration:
 - Look for. Provides a space for you to type the text string that you want to locate in the configuration. As you type the text, the first instance is displayed. If the word you are looking for is not in the file, the Look for text box will change color.
 - Next. Finds and highlights the next occurrence of the text string you typed in Look for.
 - Previous. Finds and highlights the previous occurrence of the text string you typed in Look for.
 - Mark All. Highlights all instances of the text string at one time you typed in Look for. Scroll to review each highlighted instance.

To save the content of the webinterface.conf to your local system by using the configuration utility

1. Navigate to System > Web Interface > Sites, click WebInterface.conf, and select Save output text to a file.

Using the config.xml Dialog Box

Aug 08, 2014

The Config.xml dialog box in the configuration utility displays the content of the config.xml file for a Web Interface site of site type XenApp/XenDesktop Services Site.

You can do the following from this dialog box:

- Edit the config.xml file and save the changes.
- Search the file's content for instances of a text string.
- Easily save the config.xml file to your local computer.

To search a string in the config.xml file by using the configuration utility

1. Navigate to System > Web Interface > Sites, select XenApp/XenDesktop services site, and click Config.xml.
2. In the Config.xml dialog box, use the following controls:
 - Find. Displays the following search options that you can use to find one or more instances of a text string in a configuration:
 - Look for. Provides a space for you to type the text string that you want to locate in the configuration. As you type the text, the first instance is displayed. If the word you are looking for is not in the file, the Look for text box will change color.
 - Next. Finds and highlights the next occurrence of the text string you typed in Look for.
 - Previous. Finds and highlights the previous occurrence of the text string you typed in Look for.
 - Mark All. Highlights all instances of the text string at one time you typed in Look for. Scroll to review each highlighted instance.

To save the content of the config.xml to the local system by using the configuration utility

1. Navigate to System > Web Interface > Sites, and select XenApp/XenDesktop Services Site.
2. Click Config.xml and select Save output text to a file.

Getting Started with Citrix NetScaler

Mar 15, 2012

Intended for system and network administrators who install and configure complex networking equipment, this section of the library describes initial set-up and basic configuration of the NetScaler, including the following topics.

- [Understanding the NetScaler](#)
- [Processing Order of Features](#)
- [Where Does a NetScaler Appliance Fit in the Network?](#)
- [How a NetScaler Communicates with Clients and Servers](#)
- [Introduction to the Citrix NetScaler Product Line](#)
- [Installing the NetScaler Hardware](#)
- [Accessing a Citrix NetScaler](#)
- [Configuring a NetScaler for the First Time](#)
- [Configuring a High Availability Pair for the First Time](#)
- [Configuring a FIPS Appliance for the First Time](#)
- [Understanding Common Network Topologies](#)
- [Configuring System Management Settings](#)
- [Load Balancing Traffic on a NetScaler Appliance](#)
- [Accelerating Load Balanced Traffic by Using Compression](#)
- [Securing Load Balanced Traffic by Using SSL](#)
- [Features at a Glance](#)

Understanding the NetScaler

The Citrix NetScaler product is an application switch that performs application-specific traffic analysis to intelligently distribute, optimize, and secure Layer 4-Layer 7 (L4–L7) network traffic for web applications. For example, a NetScaler bases load balancing decisions on individual HTTP requests instead of on long-lived TCP connections, so that the failure or slowdown of a server is managed much more quickly and with less disruption to clients. The NetScaler feature set can be broadly categorized as consisting of switching features, security and protection features, and server-farm optimization features.

Switching Features

When deployed in front of application servers, a NetScaler ensures optimal distribution of traffic by the way in which it directs client requests. Administrators can segment application traffic according to information in the body of an HTTP or TCP request, and on the basis of L4–L7 header information such as URL, application data type, or cookie. Numerous load balancing algorithms and extensive server health checks improve application availability by ensuring that client requests are directed to the appropriate servers.

Security and Protection Features

NetScaler security and protection features protect web applications from Application Layer attacks. A NetScaler allows legitimate client requests and can block malicious requests. It provides built-in defenses against denial-of-service (DoS) attacks and supports features that protect against legitimate surges in application traffic that would otherwise overwhelm the servers. An available built-in firewall protects web applications from Application Layer attacks, including buffer overflow exploits, SQL injection attempts, cross-site scripting attacks, and more. In addition, the firewall provides identity theft

protection by securing confidential corporate information and sensitive customer data.

Optimization Features

Optimization features offload resource-intensive operations, such as Secure Sockets Layer (SSL) processing, data compression, client keep-alive, TCP buffering, and the caching of static and dynamic content from servers. This improves the performance of the servers in the server farm and therefore speeds up applications. A NetScaler supports several transparent TCP optimizations, which mitigate problems caused by high latency and congested network links, accelerating the delivery of applications while requiring no configuration changes to clients or servers.

Understanding Policies and Expressions

A policy defines specific details of traffic filtering and management on a NetScaler. It consists of two parts: the expression and the action. The expression defines the types of requests that the policy matches. The action tells the NetScaler what to do when a request matches the expression. As an example, the expression might be to match a specific URL pattern to a type of security attack, with the action being to drop or reset the connection. Each policy has a priority, and the priorities determine the order in which the policies are evaluated.

When a NetScaler receives traffic, the appropriate policy list determines how to process the traffic. Each policy on the list contains one or more expressions, which together define the criteria that a connection must meet to match the policy.

For all policy types except Rewrite policies, a NetScaler implements only the first policy that a request matches, not any additional policies that it might also match. For Rewrite policies, the NetScaler evaluates the policies in order and, in the case of multiple matches, performs the associated actions in that order. Policy priority is important for getting the results you want.

Processing Order of Features

Depending on requirements, you can choose to configure multiple features. For example, you might choose to configure both compression and SSL offload. As a result, an outgoing packet might be compressed and then encrypted before being sent to the client.

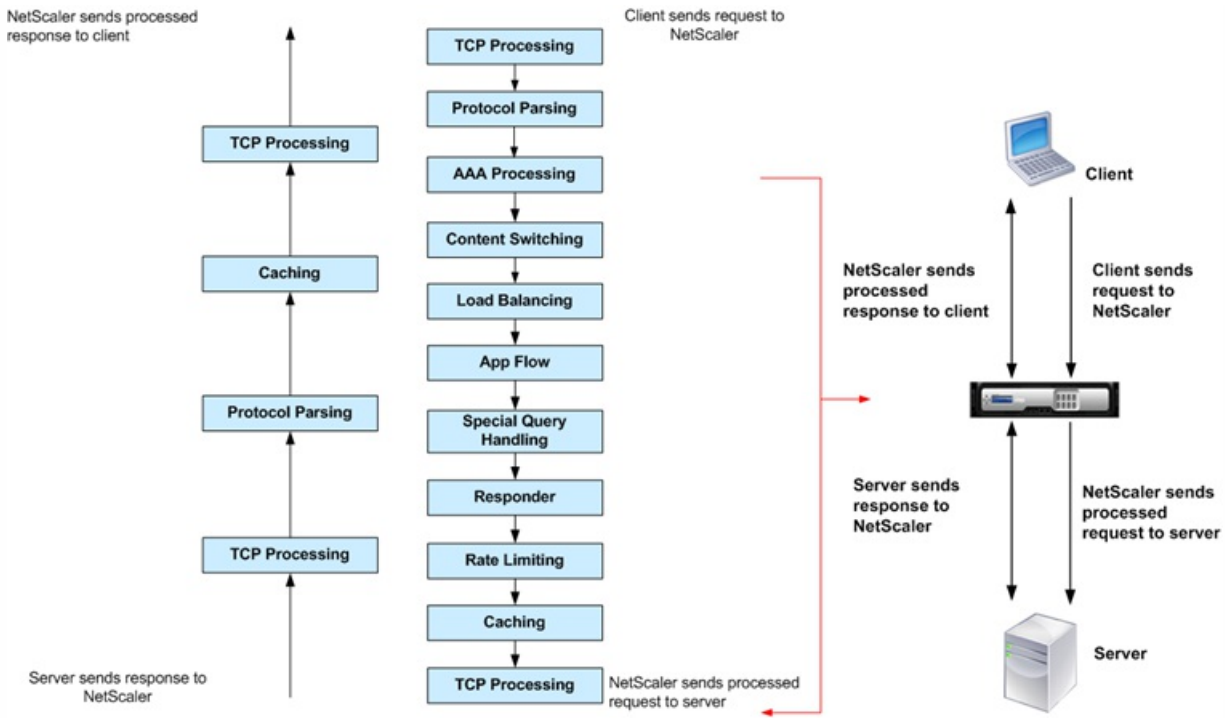

The following figure shows the L7 packet flow in the NetScaler.

Figure 1. L7 Packet Flow Diagram

The following figure shows the DataStream packet flow in the NetScaler. DataStream is supported for MySQL and MS SQL databases. For information about the DataStream feature, see "[DataStream](#)."

Figure 2. DataStream Packet Flow Diagram

Where Does a NetScaler Appliance Fit in the Network?

Jun 24, 2013

A NetScaler appliance resides between the clients and the servers, so that client requests and server responses pass through it. In a typical installation, virtual servers configured on the appliance provide connection points that clients use to access the applications behind the appliance. In this case, the appliance owns public IP addresses that are associated with its virtual servers, while the real servers are isolated in a private network. It is also possible to operate the appliance in a transparent mode as an L2 bridge or L3 router, or even to combine aspects of these and other modes.

Physical Deployment Modes

Updated: 2013-09-04

A NetScaler appliance logically residing between clients and servers can be deployed in either of two physical modes: inline and one-arm. In inline mode, multiple network interfaces are connected to different Ethernet segments, and the appliance is placed between the clients and the servers. The appliance has a separate network interface to each client network and a separate network interface to each server network. The appliance and the servers can exist on different subnets in this configuration. It is possible for the servers to be in a public network and the clients to directly access the servers through the appliance, with the appliance transparently applying the L4-L7 features. Usually, virtual servers (described later) are configured to provide an abstraction of the real servers. The following figure shows a typical inline deployment.

Figure 1. Inline Deployment

In one-arm mode, only one network interface of the appliance is connected to an Ethernet segment. The appliance in this case does not isolate the client and server sides of the network, but provides access to applications through configured virtual servers. One-arm mode can simplify network changes needed for NetScaler installation in some environments.

For examples of inline (two-arm) and one-arm deployment, see "[Understanding Common Network Topologies](#)."

Citrix NetScaler as an L2 Device

Updated: 2013-09-04

A NetScaler functioning as an L2 device is said to operate in L2 mode. In L2 mode, the NetScaler forwards packets between network interfaces when all of the following conditions are met:

- The packets are destined to another device's media access control (MAC) address.
- The destination MAC address is on a different network interface.
- The network interface is a member of the same virtual LAN (VLAN).

By default, all network interfaces are members of a pre-defined VLAN, VLAN 1. Address Resolution Protocol (ARP) requests and responses are forwarded to all network interfaces that are members of the same VLAN. To avoid bridging loops, L2 mode must be disabled if another L2 device is working in parallel with the NetScaler.

For information about how the L2 and L3 modes interact, see "[Configuring Modes of Packet Forwarding](#)."

For information about configuring L2 mode, see "[Enabling and Disabling Layer 2 Mode](#)."

Citrix NetScaler as a Packet Forwarding Device

Updated: 2014-03-14

A NetScaler appliance can function as a packet forwarding device, and this mode of operation is called L3 mode. With L3 mode enabled, the appliance forwards any received unicast packets that are destined for an IP address that does not belong to the appliance, if there is a route to the destination. The appliance can also route packets between VLANs.

In both modes of operation, L2 and L3, the appliance generally drops packets that are in:

- Multicast frames
- Unknown protocol frames destined for an appliance's MAC address (non-IP and non-ARP)
- Spanning Tree protocol (unless BridgeBPDUs is ON)

For information about how the L2 and L3 modes interact, see "[Configuring Modes of Packet Forwarding](#)."

For information about configuring the L3 mode, see "[Enabling and Disabling Layer 3 Mode](#)."

How a NetScaler Communicates with Clients and Servers

Nov 10, 2016

A NetScaler appliance is usually deployed in front of a server farm and functions as a transparent TCP proxy between clients and servers, without requiring any client-side configuration. This basic mode of operation is called Request Switching technology and is the core of NetScaler functionality. Request Switching enables an appliance to multiplex and offload the TCP connections, maintain persistent connections, and manage traffic at the request (application layer) level. This is possible because the appliance can separate the HTTP request from the TCP connection on which the request is delivered.

Depending on the configuration, an appliance might process the traffic before forwarding the request to a server. For example, if the client attempts to access a secure application on the server, the appliance might perform the necessary SSL processing before sending traffic to the server.

To facilitate efficient and secure access to server resources, an appliance uses a set of IP addresses collectively known as NetScaler-owned IP addresses. To manage your network traffic, you assign NetScaler-owned IP addresses to virtual entities that become the building blocks of your configuration. For example, to configure load balancing, you create virtual servers to receive client requests and distribute them to services, which are entities representing the applications on your servers.

Understanding NetScaler-Owned IP Addresses

To function as a proxy, a NetScaler appliance uses a variety of IP addresses. The key NetScaler-owned IP addresses are:

NetScaler IP (NSIP) address

The NSIP address is the IP address for management and general system access to the appliance itself, and for communication between appliances in a high availability configuration.

Virtual server IP (VIP) address

A VIP address is the IP address associated with a virtual server. It is the public IP address to which clients connect. An appliance managing a wide range of traffic may have many VIPs configured.

Subnet IP (SNIP) address

A SNIP address is used in connection management and server monitoring. You can specify multiple SNIP addresses for each subnet. SNIP addresses can be bound to a VLAN.

IP Set

An IP set is a set of IP addresses, which are configured on the appliance as SNIP. An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it.

Net Profile

A net profile (or network profile) contains an IP address or an IP set. A net profile can be bound to load balancing or content switching virtual servers, services, service groups, or monitors. During communication with physical servers or peers, the appliance uses the addresses specified in the profile as source IP addresses.

How Traffic Flows Are Managed

Because a NetScaler appliance functions as a TCP proxy, it translates IP addresses before sending packets to a server. When you configure a virtual server, clients connect to a VIP address on the NetScaler instead of directly connecting to a

server. As determined by the settings on the virtual server, the appliance selects an appropriate server and sends the client's request to that server. By default, the appliance uses a SNIP address to establish connections with the server, as shown in the following figure.

Figure 1. Virtual Server Based Connections

In the absence of a virtual server, when an appliance receives a request, it transparently forwards the request to the server. This is called the transparent mode of operation. When operating in transparent mode, an appliance translates the source IP addresses of incoming client requests to the SNIP address but does not change the destination IP address. For this mode to work, L2 or L3 mode has to be configured appropriately.

For cases in which the servers need the actual client IP address, the appliance can be configured to modify the HTTP header by inserting the client IP address as an additional field, or configured to use the client IP address instead of a SNIP address for connections to the servers.

Traffic Management Building Blocks

The configuration of a NetScaler appliance is typically built up with a series of virtual entities that serve as building blocks for traffic management. The building block approach helps separate traffic flows. Virtual entities are abstractions, typically representing IP addresses, ports, and protocol handlers for processing traffic. Clients access applications and resources through these virtual entities. The most commonly used entities are virtual servers and services. Virtual servers represent

groups of servers in a server farm or remote network, and services represent specific applications on each server.

Most features and traffic settings are enabled through virtual entities. For example, you can configure an appliance to compress all server responses to a client that is connected to the server farm through a particular virtual server. To configure the appliance for a particular environment, you need to identify the appropriate features and then choose the right mix of virtual entities to deliver them. Most features are delivered through a cascade of virtual entities that are bound to each other. In this case, the virtual entities are like blocks being assembled into the final structure of a delivered application. You can add, remove, modify, bind, enable, and disable the virtual entities to configure the features. The following figure shows the concepts covered in this section.

Figure 2. How Traffic Management Building Blocks Work

A Simple Load Balancing Configuration

In the example shown in the following figure, the NetScaler appliance is configured to function as a load balancer. For this configuration, you need to configure virtual entities specific to load balancing and bind them in a specific order. As a load balancer, an appliance distributes client requests across several servers and thus optimizes the utilization of resources.

The basic building blocks of a typical load balancing configuration are services and load balancing virtual servers. The services represent the applications on the servers. The virtual servers abstract the servers by providing a single IP address to which the clients connect. To ensure that client requests are sent to a server, you need to bind each service to a virtual server. That is, you must create services for every server and bind the services to a virtual server. Clients use the VIP address to connect to a NetScaler appliance. When the appliance receives client requests sent to the VIP address, it sends them to a server determined by the load balancing algorithm. Load balancing uses a virtual entity called a monitor to track whether a specific configured service (server plus application) is available to receive requests.

Figure 3. Load Balancing Virtual Server, Services, and Monitors

In addition to configuring the load balancing algorithm, you can configure several parameters that affect the behavior and performance of the load balancing configuration. For example, you can configure the virtual server to maintain persistence based on source IP address. The appliance then directs all requests from any specific IP address to the same server.

Understanding Virtual Servers

A virtual server is a named NetScaler entity that external clients can use to access applications hosted on the servers. It is represented by an alphanumeric name, virtual IP (VIP) address, port, and protocol. The name of the virtual server is of only local significance and is designed to make the virtual server easier to identify. When a client attempts to access applications on a server, it sends a request to the VIP instead of the IP address of the physical server. When the appliance receives a request at the VIP address, it terminates the connection at the virtual server and uses its own connection with the server on behalf of the client. The port and protocol settings of the virtual server determine the applications that the virtual server represents. For example, a web server can be represented by a virtual server and a service whose port and protocol are set to 80 and HTTP, respectively. Multiple virtual servers can use the same VIP address but different protocols and ports.

Virtual servers are points for delivering features. Most features, like compression, caching, and SSL offload, are normally enabled on a virtual server. When the appliance receives a request at a VIP address, it chooses the appropriate virtual server by the port on which the request was received and its protocol. The appliance then processes the request as appropriate for the features configured on the virtual server.

In most cases, virtual servers work in tandem with services. You can bind multiple services to a virtual server. These services represent the applications running on physical servers in a server farm. After the appliance processes requests received at a VIP address, it forwards them to the servers as determined by the load balancing algorithm configured on the virtual server. The following figure illustrates these concepts.

Figure 4. Multiple Virtual Servers with a Single VIP Address

The preceding figure shows a configuration consisting of two virtual servers with a common VIP address but different ports and protocols. Each of the virtual servers has two services bound to it. The services s1 and s2 are bound to VS_HTTP and represent the HTTP applications on Server 1 and Server 2. The services s3 and s4 are bound to VS_SSL and represent the SSL applications on Server 2 and Server 3 (Server 2 provides both HTTP and SSL applications). When the appliance receives an HTTP request at the VIP address, it processes the request as specified by the settings of VS_HTTP and sends it to either Server 1 or Server 2. Similarly, when the appliance receives an HTTPS request at the VIP address, it processes it as specified by the settings of VS_SSL and it sends it to either Server 2 or Server 3.

Virtual servers are not always represented by specific IP addresses, port numbers, or protocols. They can be represented by wildcards, in which case they are known as wildcard virtual servers. For example, when you configure a virtual server with a wildcard instead of a VIP, but with a specific port number, the appliance intercepts and processes all traffic conforming to that protocol and destined for the predefined port. For virtual servers with wildcards instead of VIPs and port numbers, the appliance intercepts and processes all traffic conforming to the protocol.

Virtual servers can be grouped into the following categories:

Load balancing virtual server

Receives and redirects requests to an appropriate server. Choice of the appropriate server is based on which of the various load balancing methods the user configures.

Cache redirection virtual server

Redirects client requests for dynamic content to origin servers, and requests for static content to cache servers. Cache redirection virtual servers often work in conjunction with load balancing virtual servers.

Content switching virtual server

Directs traffic to a server on the basis of the content that the client has requested. For example, you can create a content switching virtual server that directs all client requests for images to a server that serves images only. Content switching virtual servers often work in conjunction with load balancing virtual servers.

Virtual private network (VPN) virtual server

Decrypts tunneled traffic and sends it to intranet applications.

SSL virtual server

Receives and decrypts SSL traffic, and then redirects to an appropriate server. Choosing the appropriate server is similar to

choosing a load balancing virtual server.

Understanding Services

Services represent applications on a server. While services are normally combined with virtual servers, in the absence of a virtual server, a service can still manage application-specific traffic. For example, you can create an HTTP service on a NetScaler appliance to represent a web server application. When the client attempts to access a web site hosted on the web server, the appliance intercepts the HTTP requests and creates a transparent connection with the web server.

In service-only mode, an appliance functions as a proxy. It terminates client connections, uses a SNIP address to establish a connection to the server, and translates the source IP addresses of incoming client requests to a SNIP address. Although the clients send requests directly to the IP address of the server, the server sees them as coming from the SNIP address. The appliance translates the IP addresses, port numbers, and sequence numbers.

A service is also a point for applying features. Consider the example of SSL acceleration. To use this feature, you must create an SSL service and bind an SSL certificate to the service. When the appliance receives an HTTPS request, it decrypts the traffic and sends it, in clear text, to the server. Only a limited set of features can be configured in the service-only case.

Services use entities called monitors to track the health of applications. Every service has a default monitor, which is based on the service type, bound to it. As specified by the settings configured on the monitor, the appliance sends probes to the application at regular intervals to determine its state. If the probes fail, the appliance marks the service as down. In such cases, the appliance responds to client requests with an appropriate error message or re-routes the request as determined by the configured load balancing policies.

Introduction to the Citrix NetScaler Product Line

Dec 28, 2016

The Citrix NetScaler product line optimizes delivery of applications over the Internet and private networks, combining application-level security, optimization, and traffic management into a single, integrated appliance. You install a NetScaler appliance in your server room and route all connections to your managed servers through it. The NetScaler features that you enable and the policies you set are then applied to incoming and outgoing traffic.

A NetScaler can be integrated into any network as a complement to existing load balancers, servers, caches, and firewalls. It requires no additional client or server side software, and can be configured using the NetScaler web-based GUI and CLI configuration utilities.

NetScaler appliances are available in a variety of hardware platforms that have a range of specifications, including multicore processors.

The NetScaler operating system is the base operating system for all NetScaler hardware platforms. The NetScaler operating system is available in three editions: Standard, Enterprise, and Platinum.

Citrix NetScaler Hardware Platforms

Updated: 2013-11-08

NetScaler hardware is available in a variety of platforms that have a range of hardware specifications, including multicore processors. All hardware platforms support some combination of Fast Ethernet, Gigabit Ethernet, and 10 Gigabit Ethernet interfaces.

The following platforms are available for NetScaler .

- Citrix NetScaler MPX 5500
- Citrix NetScaler MPX 5550/5650
- Citrix NetScaler MPX 7500/9500
- Citrix NetScaler MPX 8200/8400/8600
- Citrix NetScaler MPX 9700/10500/12500/15500
- Citrix NetScaler MPX 11500/13500/14500/16500/18500/20500
- Citrix NetScaler MPX 15000
- Citrix NetScaler MPX 17000
- Citrix NetScaler MPX 17500/19500/21500
- Citrix NetScaler MPX 17550/19550/20550/21550

For more information about the hardware platform specifications, see "[Introduction to the Hardware Platforms.](#)"

The following tables list different editions of the NetScaler and the hardware platforms on which they are available.

Table 1. Product Editions and MPX Hardware Platforms

Hardware	MPX 5500	MPX 5550/5650	MPX 7500/9500	MPX 8200/8400/8600	MPX 15000	MPX 17000
Platinum Edition	Yes	Yes	Yes	Yes	Yes	Yes
Enterprise Edition	Yes	Yes	Yes	Yes	Yes	Yes
Standard Edition	Yes	Yes	Yes	Yes	Yes	Yes

Table 2. Product Editions and MPX Hardware Platforms (contd.)

Hardware	MPX 9700/10500/12500/15500	MPX 11500/13500/14500/16500/18500/20500	MPX 17500/19500/21500	MPX 17550/19550/20550/21550	MPX 22040/22060/22080/22100/22120
Platinum Edition	Yes	Yes	Yes	Yes	Yes
Enterprise Edition	Yes	Yes	Yes	Yes	Yes
Standard Edition	Yes	Yes	Yes	Yes	Yes

Citrix NetScaler Editions

Updated: 2013-09-04

The NetScaler operating system is available in Standard, Enterprise, and Platinum editions. The Enterprise and Standard editions have limited features available. Feature licenses are required for all editions.

For instructions on how to obtain and install licenses, see "[http://support.citrix.com/article/ctx121062.](http://support.citrix.com/article/ctx121062)"

The Citrix NetScaler editions are described as follows:

- — *Citrix NetScaler, Standard Edition*

. Provides small and medium enterprises with comprehensive Layer 4- Layer 7 (L4-L7) traffic management, enabling increased web application availability.

- Citrix NetScaler, Enterprise Edition

. Provides web application acceleration and advanced L4-L7 traffic management, enabling enterprises to increase web application performance and availability and reduce datacenter costs.

- Citrix NetScaler, Platinum Edition

. Provides a web application delivery solution that reduces data center costs and accelerates application performance, with end-to-end visibility of application performance, and provides advanced application security.

The following table summarizes the features supported by each edition in the Citrix NetScaler product line:

Table 3. Citrix NetScaler Application Delivery Product Line Features

Key Features	Platinum Edition	Enterprise Edition	Standard Edition
Application availability			
Layer 4 load balancing	Yes	Yes	Yes
Layer 7 content switching	Yes	Yes	Yes
AppExpert rate controls	Yes	Yes	Yes
IPv6 support	Yes	Yes	Yes
Global server load balancing (GSLB)	Yes	Yes	Optional
Dynamic routing protocols	Yes	Yes	No
Surge protection	Yes	Yes	No
Priority queuing	Yes	Yes	No
Application acceleration			
Client and server TCP optimizations	Yes	Yes	Yes
Citrix AppCompress for HTTP	Yes	Yes	Optional
Citrix AppCache	Yes	Optional	No
Citrix Branch Repeater client	Yes	No	No
Application security			
Layer 4 DoS defenses	Yes	Yes	Yes
Layer 7 content filtering	Yes	Yes	Yes
HTTP/URL Rewrite	Yes	Yes	Yes
NetScaler Gateway, EE SSL VPN	Yes	Yes	Yes
Layer 7 DoS Defenses	Yes	Yes	No
AAA security	Yes	Yes	No
Application firewall with XML security	Yes	Optional	No
Simple manageability			
AppExpert visual policy builder	Yes	Yes	Yes

AppExpert service callouts Key Features	Yes Platinum Edition	Yes Enterprise Edition	Yes Standard Edition
AppExpert templates	Yes	Yes	Yes
Role-based administration	Yes	Yes	Yes
Configuration wizards	Yes	Yes	Yes
Citrix Command Center	Yes	Yes	No
Citrix EdgeSight for NetScaler	Yes	Optional	No
Web 2.0 optimization			
Rich Internet application support	Yes	Yes	Yes
Advanced server offload	Yes	Yes	No
Lower total cost of ownership (TCO)			
TCP buffering	Yes	Yes	Yes
TCP multiplexing	Yes	Yes	Yes
SSL offload and acceleration	Yes	Yes	Yes
Cache redirection	Yes	Yes	No
Citrix EasyCall	Yes	No	No

Note: While we have taken care to ensure absolute accuracy when compiling this information, it might change. For the latest information, see Citrix Support at "<http://www.citrix.com>." Supported Releases on NetScaler Hardware

Updated: 2014-06-30

The following table lists the earliest NetScaler builds for releases that are supported on the NetScaler MPX platforms.

Hardware	Software Release	Software Build #
MPX 5500	10.5	All
	10.1	All
	10.0	All
	9.3	All
MPX 5550/5650	10.5	All
	10.1	All
	10.0	71.6.nc and later
	9.3	59.5.nc and later
MPX 7500/9500	10.5	All
	10.1	All
	10.0	All
	9.3	All

Hardware	Software Release	Software Build #
MPX 8005/8015	10.5	All
	10.1	122.17.nc and later
	9.3	65.8.nc and later
MPX 8200/8400/8600	10.5	All
	10.1	All
	10.0	70.7.nc and later
	9.3	58.5.nc and later

	10.1	123.11.nc and later
	9.3	65.8.nc and later
MPX 24100/24150	10.5	51.10.nc and later
	10.1	129.11.nc and later

Supported Browsers

Updated: 2014-06-24

To access the configuration utility and Dashboard, your workstation must have a supported web browser and version 1.6 or above of the Java applet plug-in installed.

Operating System	Browser	Versions
Windows 7	Internet Explorer	8, 9, 10, and 11
	Mozilla Firefox	3.6.25 and above
	Google Chrome	Latest
Windows 64 bit	Internet Explorer	8, 9, 10, and 11
	Google Chrome	Latest

MAC Operating System	Mozilla Firefox Browser	3.6.25 and above Versions
	Safari	5.1.3 and above
	Google Chrome	Latest

Installing the NetScaler Hardware

Sep 04, 2013

Before installing a NetScaler appliance, review the pre-installation checklist. A NetScaler is typically mounted in a rack, and all models ship with rack-rail hardware. All models except the 7000 support small form factor pluggable SFP, XFP, or SFP+ transceivers. After mounting the appliance and installing the transceivers, connect the NetScaler to your network. Use a console cable to connect the NetScaler to a personal computer so that you can perform an initial configuration. After connecting everything else, connect the NetScaler to a power source.

This document includes the following:

- [Unpacking the Appliance](#)
- [Rack Mounting the Appliance](#)
- [Installing and Removing 1G SFP Transceivers](#)
- [Installing and Removing XFP and 10G SFP+ Transceivers](#)
- [Connecting the Cables](#)

Unpacking the Appliance

May 08, 2014

The hardware accessories for your particular appliance, such as cables, adapters, and rail kit, vary depending on the hardware platform you ordered. Unpack the box that contains your new appliance on a sturdy table with plenty of space and inspect the contents.

Use the following list to verify that you received everything that should have been included in the box.

- The appliance you ordered
- One RJ-45 to DB-9 adapter
- One 6 ft RJ-45/DB-9 cable
- The following list specifies the number of power cables included for each appliance model:
 - One power cable for the MPX 5500, MPX 5550/5650, MPX 7500/9500, and MPX 8005/8015/8200/8400/8600/8800 appliances
 - Two power cables for the MPX 15000, MPX 17000, MPX 9700/10500/12500/15500, MPX 11500/13500/14500/16500/18500/20500, MPX 11515/11520/11530/11540/11542, MPX 14000, MPX 17500/19500/21500, and MPX 25100T/25160T appliances
 - Four power cables for the MPX 22040/22060/22080/22100/22120 and MPX 24100/24150 appliances

Note: Make sure that a power outlet is available for each cable.
Note: For Brazilian customers, Citrix does not ship a power cable. Use a cable that conforms to the **ABNT NBR 14136:2002** standard.

- One standard 4-post rail kit
Note: If the kit that you received does not fit your rack, contact your Citrix sales representative to order the appropriate kit.

In addition to the items included in the box with your new appliance, you will need the following items to complete the installation and initial configuration process.

- Ethernet cables for each additional Ethernet port that you will connect to your network
- One available Ethernet port on your network switch or hub for each NetScaler Ethernet port you want to connect to your network
Note: Transceiver modules are sold separately. Contact your Citrix sales representative to order transceiver modules for your appliance. Only transceivers supplied by Citrix are supported on the appliance.
- A computer to serve as a management workstation

Rack Mounting the Appliance

May 08, 2014

Most appliances can be installed in standard server racks that conform to EIA-310-D specification. The appliances ship with a set of rails, which you must install before you mount the appliance. The only tools that you need for installing an appliance are a Phillips screwdriver and a flathead screwdriver.

Caution: If you are installing the appliance as the only unit in the rack, mount it at the bottom. If the rack contains other units, make sure that the heaviest unit is at the bottom. If the rack has stabilizing devices available, install them before mounting the appliance.

The following table lists the different hardware platforms and the rack units required for each platform.

Table 1. Height Requirements For Each Platform

Platform	Number of rack units
MPX 5500	One rack unit
MPX 5550/5650	One rack unit
MPX 7500/9500	One rack unit
MPX 8005/8015/8200/8400/8600/8800	One rack unit
MPX 9700/10500/12500/15500	Two rack units
MPX 14000	One rack unit
MPX 15000, MPX 17000	Two rack units
MPX 11500/13500/14500/16500/18500/20500	Two rack units
MPX 11515/11520/11530/11540/11542	Two rack units
MPX 17500/19500/21500	Two rack units
MPX 17550/19550/20550/21550	Two rack units
MPX 22040/22060/22080/22100/22120	Two rack units
MPX 24100/24150	Two rack units

Each appliance ships with a mounting rail kit that contains two rail assemblies, one for the left side and the other for the right side of the appliance, and screws to attach the rails. An assembly consists of an inner rail and a rack rail. The supplied rail kit is 28 inches long (38 inches extended). Contact your Citrix sales representative to order a 23-inch (33 inches extended) rail kit.

Note: The same rail kit is used for both square-hole and round-hole racks. See "[Installing the Rail Assembly to the Rack](#)" for specific instructions for threaded, round-hole racks.

To mount the appliance, you must first install the rails and then install the appliance in the rack.

Perform the following tasks to mount the appliance:

- Remove the inner rails from the rail assembly.
- Attach the inner rails to the appliance.
- Install the rack rails on the rack.
- Install the appliance in the rack.

The appliance is shipped with rack-rail hardware. This hardware consists of two inner rails that you attach to the appliance, one on each side, and a rack-rail assembly that you attach to the rack. The following figure illustrates the steps involved in mounting the Citrix NetScaler appliance to a rack.

To remove the inner rails from the rail assembly

1. Place the rail assembly on a flat surface.
2. Slide out the inner rail toward the front of the assembly.
3. Depress the latch until the inner rail comes all the way out of the rail assembly.
4. Repeat steps 1 through 3 to remove the second inner rail.

To attach the inner rails to the appliance

1. Position the right inner rail behind the handle on the right side of the appliance.
2. Align the holes on the rail with the corresponding holes on the side of the appliance.
3. Attach the rail to the appliance with the provided screws: 4 per side for a 1U appliance and 5 per side for a 2U appliance, as shown in the following figure.

Figure 1. Attaching inner rails

4. Repeat steps 1 through 3 to install the left inner rail on the other side of the appliance.

To install the rack rails on the rack

1. If you have a round-hole, threaded rack, skip to step 3.
2. Install square nut retainers into the front post and back post of the rack as shown in the following figures. Before

inserting a screw, be sure to align the square nut with the correct hole for your 1U or 2U appliance. The three holes are not evenly spaced.

Figure 2. Installing Retainers into the Front Rack Posts

Figure 3. Installing Retainers into the Rear Rack Posts

3. Install the adjustable rail assembly into the rack as shown in the following figures. Use a screw to lock the rear rail flange into the rack. With the screw securing the rail in place, you can optionally remove the latching spring.

Figure 4. Installing the Rail Assembly to the Rack

To install the appliance in the rack

1. Align the inner rails, attached to the appliance, with the rack rails.
2. Slide the appliance into the rack rails, keeping the pressure even on both sides.
3. Verify that the appliance is locked in place by pulling it all the way out from the rack.

Figure 5. Rack Mounting the Appliance

Installing and Removing 1G SFP Transceivers

Mar 01, 2014

Note: This section applies to the MPX 8005/8015/8200/8400/8600/8800, MPX 9700/10500/12500/15500, MPX 11500/13500/14500/16500/18500/20500, MPX 11515/11520/11530/11540/11542, MPX 22040/22060/22080/22100/22120, and MPX 24100/24150 appliances.

A Small Form-Factor Pluggable (SFP) is a compact transceiver that can operate at speeds of up to 1 gigabit per second and is available in both copper and fiber types. Inserting a 1G SFP copper transceiver converts the 1G SFP port to a 1000BASE-T port. Inserting a 1G SFP fiber transceiver converts the 1G SFP port to a 1000BASE-X port. Auto-negotiation is enabled by default on the 1G SFP port into which you insert your 1G SFP transceiver. As soon as a link between the port and the network is established, the speed and mode are matched on both ends of the cable.

Note: The 1G SFP transceiver is hot-swappable from release 9.3 build 47.5 and later on the NetScaler appliances that use the e1k interface. The following platforms support 1G SFP transceivers:

- MPX 7500/9500
- MPX 8005/8015/8200/8400/8600/8800
- MPX 9700/10500/12500/15500
- MPX 11500/13500/14500/16500/18500/20500
- MPX 11515/11520/11530/11540/11542
- MPX 22040/22060/22080/22100/22120
- MPX 24100/24150

Caution: NetScaler appliances do not support 1G SFP transceivers from vendors other than Citrix Systems. Attempting to install third-party 1G SFP transceivers on your NetScaler appliance voids the warranty.

Insert 1G SFP transceivers into the 1G SFP ports on the front panel of the appliance. Frequent installation and removal of transceivers shortens their life span. Follow the removal procedure carefully to avoid damaging the 1G SFP transceiver or the appliance.

Caution: Do not install the transceivers with the cables attached. Doing so can damage the cable, the connector, or the optical interface of the transceiver.

To install a 1G SFP transceiver

1. Remove the 1G SFP transceiver carefully from its box.

Danger: Do not look directly into fiber optic transceivers or cables. They emit laser beams that can damage your eyes.

2. Align the 1G SFP transceiver to the front of the 1G SFP transceiver port on the front panel of the appliance, as shown in the following figure.

Note: The illustration in the following figures might not represent your actual appliance.

Figure 1. Installing a 1G SFP transceiver

3. Hold the 1G SFP transceiver between your thumb and index finger and insert it into the 1G SFP transceiver port, pressing it in until you hear the transceiver snap into place.
4. Lock the transceiver.
5. Verify that the LED is green and blinks twice, which indicates that the transceiver is functioning correctly.
6. If you are using a fiber 1G SFP transceiver, do not remove the dust caps attached to the transceiver and the cable until you are ready to insert the cable.

To remove a 1G SFP transceiver

1. Disconnect the cable from the 1G SFP transceiver. If you are using a fiber optic cable, replace the dust cap on the cable before putting it away.
Danger: Do not look directly into fiber optic transceivers or cables. They emit laser beams that can damage your eyes.
2. Unlock the 1G SFP transceiver.
3. Hold the 1G SFP transceiver between your thumb and index finger and slowly pull it out of the port.
4. If you are removing a fiber 1G SFP transceiver, replace the dust cap before putting it away.
5. Put the 1G SFP transceiver into its original box or another appropriate container.

Installing and Removing XFP and 10G SFP+ Transceivers

May 08, 2014

Note: This section applies to the MPX 8005/8015/8200/8400/8600/8800, MPX 9700/10500/12500/15500, MPX 15000, MPX 17000, MPX 11500/13500/14500/16500/18500/20500, MPX 11515/11520/11530/11540/11542, MPX 14000, MPX 17500/19500/21500, MPX 17550/19550/20550/21550, MPX 22040/22060/22080/22100/22120, MPX 24100/24150, and MPX 25100T/25160T appliances.

A 10-Gigabit Small Form-Factor Pluggable (XFP or SFP+) is a compact optical transceiver that can operate at speeds of up to 10 gigabits per second. The MPX 15000 and MPX 17000 appliances use XFP transceivers and the MPX 8005/8015/8200/8400/8600/8800, MPX 9700/10500/12500/15500, MPX 11500/13500/14500/16500/18500/20500, MPX 17500/19500/21500, MPX 17550/19550/20550/21550, MPX 22040/22060/22080/22100/22120, and MPX 24100/24150 appliances use 10G SFP+ transceivers. Autonegotiation is enabled by default on the XFP/10G SFP+ ports into which you insert your XFP/10G SFP+ transceiver. As soon as a link between the port and the network is established, the mode is matched on both ends of the cable and for 10G SFP+ transceivers, the speed is also autonegotiated.

Note: An XFP transceiver is **not hot-swappable** on the NetScaler appliances. You must restart a NetScaler appliance after you insert an XFP transceiver.

However, the 10G SFP+ transceiver is hot-swappable from release 9.3 build 57.5 and later on the NetScaler appliances that use the ixgbe (ix) interface. The following platforms support 10G SFP+ transceivers:

- MPX 8005/8015/8200/8400/8600/8800
- MPX 9700/10500/12500/15500 10G and 10G FIPS
- MPX 11500/13500/14500/16500/18500/20500
- MPX 11515/11520/11530/11540/11542
- MPX 14000
- MPX 17500/19500/21500
- MPX 17550/19550/20550/21550
- MPX 22040/22060/22080/22100/22120
- MPX 24100/24150
- MPX 25100T/25160T

The following platforms support XFP transceivers:

- MPX 15000
- MPX 17000

Caution: NetScaler appliances do not support XFP/10G SFP+ transceivers provided by vendors other than Citrix Systems. Attempting to install third-party XFP/10G SFP+ transceivers on your NetScaler appliance voids the warranty.

Insert the XFP/10G SFP+ transceivers into the XFP/10G SFP+ ports on the front panel of the appliance. Frequent installation and removal of transceivers shortens their life span. Follow the removal procedure carefully to avoid damaging the transceiver or the appliance.

Caution: Do not install the transceivers with the cables attached. Doing so can damage the cable, the connector, or the optical interface of the transceiver.

To install an XFP/10G SFP+ transceiver

1. Remove the XFP/10G SFP+ transceiver carefully from its box.

Danger: Do not look directly into fiber optic transceivers and cables. They emit laser beams that can damage your eyes.

2. Align the XFP/10G SFP+ transceiver to the front of the XFP/10G SFP+ transceiver port on the front panel of the appliance.
3. Hold the XFP/10G SFP+ transceiver between your thumb and index finger and insert it into the XFP/10G SFP+ transceiver port, pressing it in until you hear the transceiver snap into place.
4. Move the locking hinge to the DOWN position as shown in the following figure.

Figure 1. Locking an XFP transceiver

5. Verify that the LED is green and blinks twice, which indicates that the transceiver is functioning correctly.
6. Do not remove the dust caps attached to the transceiver and cable until you are ready to insert the cable.

To remove an XFP/10G SFP+ transceiver

1. Disconnect the cable from the XFP/10G SFP+ transceiver. Replace the dust cap on the cable before putting it away.
Danger: Do not look directly into fiber optic transceivers or cables. They emit laser beams that can damage your eyes.
2. Unlock the XFP/10G SFP+ transceiver by moving the locking hinge to the UP position.
3. Hold the XFP/10G SFP+ transceiver between your thumb and index finger and slowly pull it out of the port.
4. Replace the dust cap on the transceiver before putting it away.
5. Put the XFP/10G SFP+ transceiver into its original box or another appropriate container.

Connecting the Cables

Apr 05, 2011

When the appliance is securely mounted on the rack, you are ready to connect the cables. Ethernet cables and the optional console cable are connected first. Connect the power cable last.

Danger: Before installing or repairing the appliance, remove all jewelry and other metal objects that might come in contact with power sources or wires. When you touch both a live power source or wire and ground, any metal objects can heat up rapidly and cause burns, set clothing on fire, or fuse the metal object to an exposed terminal.

Connecting the Ethernet Cables

Ethernet cables connect your appliance to the network. The type of cable you need depends on the type of port used to connect to the network. Use a category 5e or category 6 Ethernet cable with a standard RJ-45 connector on a 10/100/1000BASE-T port or 1G SFP copper transceiver. Use a fiber optic cable with an LC duplex connector with a 1G SFP fiber transceiver, 10G SFP+, or XFP transceiver. The type of connector at the other end of the fiber optic cable depends on the port of the device that you are connecting to.

To connect an Ethernet cable to a 10/100/1000BASE-T port or 1G SFP copper transceiver

1. Insert the RJ-45 connector on one end of your Ethernet cable into an appropriate port on the front panel of the appliance, as shown in the following figure.

Figure 1. Inserting an Ethernet cable

2. Insert the RJ-45 connector on the other end into the target device, such as a router or switch.
3. Verify that the LED glows amber when the connection is established.

To connect the Ethernet cable to a 1G SFP fiber, 10G SFP+, or XFP transceiver

1. Remove the dust caps from the transceiver and cable.
2. Insert the LC connector on one end of the fiber optic cable into the appropriate port on the front panel of the appliance.
3. Insert the connector on the other end into the target device, such as a router or switch.
4. Verify that the LED glows amber when the connection is established.

Connecting the Console Cable

You can use the console cable to connect your appliance to a computer or terminal, from which you can configure the appliance. Alternatively, you can use a computer connected to the network. Before connecting the console cable, configure the computer or terminal to support VT100 terminal emulation, 9600 baud, 8 data bits, 1 stop bit, parity, and flow control set to NONE. Then connect one end of the console cable to the RS232 serial port on the appliance and the other end to the computer or terminal.

To connect the console cable to a computer or terminal

1. Insert the DB-9 connector at the end of the cable into the console port that is located on the front panel of the appliance, as shown in the following figure.

Figure 2. Inserting a console cable

Note: To use a cable with an RJ-45 converter, insert the optional converter provided into the console port and attach the cable to it.

2. Insert the RJ-45 connector at the other end of the cable into the serial port of the computer or terminal.

Connecting the Power Cable

An MPX 5500, MPX 5550/5650, MPX 7500/9500, MPX 8005/8015/8200/8400/8600/8800 appliance has one power cable. All the other appliances come with two power cables, but they can also operate if only one power cable is connected, except the MPX 22040/22060/22080/22100/22120 and MPX 24100/24150 platforms which come with four power cables and require two power cables for proper operation. A separate ground cable is not required, because the three-prong plug provides grounding.

To connect the appliance to the power source

1. Connect one end of the power cable to the power outlet on the back panel of the appliance, next to the power supply, as shown in the following figure.

Figure 3. Inserting a power cable

2. Connect the other end of the power cable to a standard 110V/220V power outlet.
3. If a second power supply is provided, repeat steps 1 and 2 to connect the second power supply.

Note: The MPX 9700/10500/12500/15500, MPX 11500/13500/14500/16500/18500/20500, MPX 11515/11520/11530/11540/11542, MPX 17500/19500/21500, and MPX 17550/19550/20550/21550 appliance emit a high-pitched alert if one power supply fails or if you connect only one power cable to the appliance. To silence the alarm, you can press the small red button located on the back panel of the appliance.

Accessing a Citrix NetScaler

Dec 28, 2016

A NetScaler appliance has both a command line interface (CLI) and a graphical user interface (GUI). The GUI includes a configuration utility for configuring the appliance and a statistical utility, called Dashboard. For initial access, all appliances ship with the default NetScaler IP address (NSIP) of 192.168.100.1 and default subnet mask of 255.255.0.0. You can assign a new NSIP and an associated subnet mask during initial configuration.

If you encounter an IP address conflict when deploying multiple NetScaler units, check for the following possible causes:

- Did you select an NSIP that is an IP address already assigned to another device on your network?
- Did you assign the same NSIP to multiple NetScaler appliances?
- The NSIP is reachable on all physical ports. The ports on a NetScaler are host ports, not switch ports.

The following table summarizes the available access methods.

Table 1. Methods for Accessing a NetScaler appliance

Access Method	Port	Default IP Address Required? (Y/N)
CLI	Console	N
CLI and GUI	Ethernet	Y

Using the Command Line Interface

Updated: 2013-09-04

You can access the CLI either locally, by connecting a workstation to the console port, or remotely, by connecting through secure shell (SSH) from any workstation on the same network.

Logging on to the Command Line Interface through the Console Port

The appliance has a console port for connecting to a computer workstation. To log on to the appliance, you need a serial crossover cable and a workstation with a terminal emulation program.

To log on to the CLI through the console port

1. Connect the console port to a serial port on the workstation, as described in .
2. On the workstation, start HyperTerminal or any other terminal emulation program. If the logon prompt does not appear, you may need to press ENTER one or more times to display it.
3. Log on by using the administrator credentials. The command prompt (>) appears on the workstation monitor.

Logging on to the Command Line Interface by using SSH

The SSH protocol is the preferred remote access method for accessing an appliance remotely from any workstation on the same network. You can use either SSH version 1 (SSH1) or SSH version 2 (SSH2.)

If you do not have a working SSH client, you can download and install any of the following SSH client programs:

- PuTTY
Open Source software supported on multiple platforms. Available at:

["http://www.chiark.greenend.org.uk/~sgtatham/putty/"](http://www.chiark.greenend.org.uk/~sgtatham/putty/)

- Vandyke Software SecureCRT
Commercial software supported on the Windows platform. Available at:

["http://www.vandyke.com/products/securecrt/"](http://www.vandyke.com/products/securecrt/)

These programs have been tested by the Citrix NetScaler team, which has verified that they work correctly with a NetScaler appliance. Other programs may also work correctly, but have not been tested.

To verify that the SSH client is installed properly, use it to connect to any device on your network that accepts SSH connections.

To log on to a NetScaler by using an SSH client

1. On your workstation, start the SSH client.
2. For initial configuration, use the default NetScaler IP address (NSIP), which is 192.168.100.1. For subsequent access, use the NSIP that was assigned during initial configuration. Select either SSH1 or SSH2 as the protocol.
3. Log on by using the administrator credentials. For example:

```
login as: nsroot
```

```
Using keyboard-interactive authentication.
```

```
Password:
```

```
Last login: Tue Jun 16 10:37:28 2009 from 10.102.29.9
```

```
Done
```

```
>
```

Important

GUI for NetScaler release 10.1 or 10.5 is not supported on systems running Java Runtime Environment (JRE) version 8 update 132 or later.

Workaround: To use the GUI of NetScaler release 10.1 or 10.5 on a system running JRE version 8 update 132 or later, you must downgrade JRE to version 8 update 131 or earlier.

Using the Graphical User Interface

Updated: 2014-06-30

Important: A certificate-key pair is required for HTTPS access to the NetScaler configuration utility. On a NetScaler ADC, a certificate-key pair is automatically bound to the internal services. On an MPX or SDX appliance, the default key size is 1024 bytes, and on a VPX instance, the default key size is 512 bytes. However, most browsers today do not accept a key that is less than 1024 bytes. As a result, HTTPS access to the VPX configuration utility is blocked.

Additionally, if a license is not present on an MPX appliance when it starts, and you add a license later and restart the

appliance, you might lose the certificate binding.

Citrix recommends that you install a certificate-key pair of at least 1024 bytes on a NetScaler ADC for HTTPS access to the configuration utility, and that you install an appropriate license before starting the ADC.

The graphical user interface includes a configuration utility and a statistical utility, called Dashboard, either of which you access through a workstation connected to an Ethernet port on the appliance. If your computer does not have a supported Java plug-in installed, the utility prompts you to download and install the plug-in the first time you log on. If automatic installation fails, you can install the plug-in separately before you attempt to log on to the configuration utility or Dashboard.

The system requirements for the workstation running the GUI are as follows:

- For Windows-based workstations, a Pentium 166 MHz or faster processor with at least 48 MB of RAM is recommended for applets running in a browser using a Java plug-in product. You should have 40 MB free disk space before installing the plug-in.
- For Linux-based workstations, a Pentium platform running Linux kernel v2.2.12 or above, and glibc version 2.12-11 or later. A minimum of 32 MB RAM is required, and 48 MB RAM is recommended. The workstation should support 16-bit color mode, KDE and KWM window managers used in conjunction, with displays set to local hosts.
- For Solaris-based workstations, a Sun running either Solaris 2.6, Solaris 7, or Solaris 8, and the Java 2 Runtime Environment, Standard Edition, version 1.6 or later.

Your workstation must have a supported web browser and version 1.6 or above of the Java applet plug-in installed to access the configuration utility and Dashboard.

The following browsers are supported.

Operating System	Browser	Versions
Windows 7	Internet Explorer	8, 9, 10, and 11
	Mozilla Firefox	3.6.25 and above
	Google Chrome	Latest
Windows 64 bit	Internet Explorer	8, 9, 10, and 11
	Google Chrome	Latest
MAC	Mozilla Firefox	3.6.25 and above
	Safari	5.1.3 and above
	Google Chrome	Latest

Using the Configuration Utility

Once you log on to the configuration utility, you can configure the appliance through a graphical interface that includes context-sensitive help.

If your computer does not have a supported Java plug-in installed, the first time you log on to the appliance, the configuration utility will prompt you to download and install the plug-in.

Note: Prior to installing the Java 2 Runtime Environment, ensure that you have installed the full set of required operating system patches needed for the current Java release.

To log on to the configuration utility

1. Open your web browser and enter the NetScaler IP (NSIP) as an HTTP address. If you have not yet set up the initial configuration, enter the default NSIP (<http://192.168.100.1>). The Citrix Logon page appears.
Note: If you have two NetScaler appliances in a high availability setup, make sure that you do not access the GUI by entering the IP address of the secondary NetScaler. If you do so and use the GUI to configure the secondary NetScaler, your configuration changes will not be applied to the primary NetScaler.
2. In the User Name text box, type nsroot.
3. In the Password text box, type the administrative password you assigned to the nsroot account during initial configuration and click Login. The Configuration Utility page appears.
Note: If your workstation does not already have a supported version of the Java runtime plug-in installed, the NetScaler prompts you to download the Java Plug-in. After the download is complete, the configuration utility page appears. If you need to access the online help, select Help from the Help menu at the top right corner.

Using the Statistical Utility

Dashboard, the statistical utility, is a browser-based application that displays charts and tables on which you can monitor the performance of a NetScaler.

To log on to Dashboard

1. Open your web browser and enter the NSIP as an HTTP address (<http://<NSIP>>). The Citrix Logon page appears.
2. In the User Name text box, type nsroot.
3. In the Password text box, type the administrative password you assigned to the nsroot account during initial configuration.

Installing the Java Runtime Plug-in

If automatic installation of the Java plug-in fails, you can install the plug-in separately before you attempt to log on to the configuration utility.

Note: Before installing the Java 2 Runtime Environment, make sure that you have installed the full set of required operating system patches needed for the current Java release.

To install the Java runtime plug-in on your workstation

1. In your web browser, enter the NSIP and port number of your appliance: <http://<NSIP>:80> The Java plug-in icon appears.
2. Click the Java plug-in icon and follow the screen prompts to copy the plug-in installer to your workstation hard disk. The Java plug-in setup icon (for example, **j2re-1.6.0**) appears on your computer at the location you specified.
3. Double-click the plug-in setup icon, and follow the screen prompts to install the plug-in.
4. Return to your web browser and click the Java plug-in icon a second time to display the GUI logon screen.

Configuring a NetScaler for the First Time

Aug 22, 2013

Initial configuration is the same for the multifunction Citrix NetScaler, the dedicated NetScaler Gateway Enterprise Edition, and the dedicated Citrix NetScaler Application Firewall appliances. You can use any of the following interfaces for initial configuration of your appliance:

- First-time use wizard—If you use a web browser to connect to the appliance, you are prompted to enter the network configuration and licensing information, if it is not already specified.
- LCD keypad—You can specify the network settings, but you must use a different interface to upload your licenses.
- Serial console—After connecting to the serial console, you can use the command line interface to specify the network settings and upload your licenses.
- NITRO API—You can use the NITRO API suite to configure the NetScaler appliance.

For initial configuration, use nsroot as both the administrative user name and the password. For subsequent access, use the password assigned during initial configuration.

If you are setting up two NetScaler appliances as a high availability pair, you configure one as primary and the other as secondary.

The configuration procedure for a FIPS appliance is slightly different from the procedure for a NetScaler MPX appliance or a NetScaler virtual appliance.

Using the First-time Setup Wizard

To configure a NetScaler appliance (or NetScaler virtual appliance) for the first time, you need an administrative computer configured on the same network as the appliance.

You must assign a NetScaler IP (NSIP) address as the management IP address of your NetScaler appliance. This is the address at which you access the NetScaler for configuration, monitoring, and other management tasks. Assign a subnet IP (SNIP) address for your NetScaler to communicate with the backend servers. Specify a host name to identify your NetScaler, an IP address for a DNS server to resolve domain names, and the time zone in which your NetScaler is located.

The wizard automatically appears if any of the following conditions are met:

- The appliance is configured with the default IP address (192.168.100.1).
- A subnet IP address is not configured.
- Licenses are not present on the appliance.

To perform first-time configuration of your appliance

1. In a web browser, type: <http://192.168.100.1>

Note: The NetScaler software is preconfigured with a default IP address. If you have already assigned as NSIP address, type that address in a web browser.

2. In User Name and Password, type the administrator credentials. The following screen appears.

Welcome!

Use this wizard for initial configuration of your NetScaler virtual appliance. To configure or to change a previously configured setting, click each of the sections below. If a parameter has already been configured, a check mark appears within a green circle. An orange circle containing a dash indicates that you have chosen to skip this section.

	NetScaler IP Address IP address at which you access the NetScaler for configuration, monitoring, and other management tasks. NetScaler IP Address: 10.102.29.165 Netmask: 255.255.255.0	
	Subnet IP Address Specify an IP address for your NetScaler to communicate with the backend servers. Subnet IP Address: Not configured	
	Host Name, DNS IP Address, and Time Zone Specify a host name to identify your NetScaler, an IP address for a DNS server to resolve domain names, and the time zone in which your NetScaler is located. Host Name: ns DNS IP Address: Not configured Time Zone: GMT-11:00-SST-Pacific/Midway	
	Licenses Upload licenses from your local computer or allocate licenses from the Citrix licensing portal. There are 3 license file(s) present on this NetScaler.	

[Continue](#)

3. To configure or to change a previously configured setting, click inside each section. When done, click Continue.
4. When prompted, select Reboot.

Using the LCD Keypad

When you first install the appliance, you can configure the initial settings by using the LCD keypad on the front panel of the appliance. The keypad interacts with the LCD display module, which is also on the front panel of these appliances.

Note: You can use the LCD keypad for initial configuration on a new appliance with the default configuration. The configuration file (ns.conf) should contain the following command and default values.

```
set ns config -IPAddress 192.168.100.1 -netmask 255.255.0.0
```

The functions of the different keys are explained in the following table.

Table 1. LCD Key Functions

Key	Function
<	Moves the cursor one digit to the left.
>	Moves the cursor one digit to the right.
^	Increments the digit under the cursor.
v	Decrements the digit under the cursor.
.	Processes the information, or terminates the configuration, if none of the values are changed. This key is also known as the ENTER key.

To perform the initial configuration by using the LCD keypad press the "<" key.

You are prompted to enter the subnet mask, NetScaler IP address (NSIP), and gateway in that order respectively. The subnet mask is associated with both the NSIP and default gateway IP address. The NSIP is the IPv4 address of the NetScaler appliance. The default gateway is the IPv4 address for the router, which will handle external IP traffic that the

NetScaler cannot otherwise route. The NSIP and the default gateway should be on the same subnet.

If you enter a valid value for the subnet mask, such as 255.255.255.224, you are prompted to enter the IP address. Similarly, if you enter a valid value for the IP address, you are prompted to enter the gateway address. If the value you entered is invalid, the following error message appears for three seconds, where xxx.xxx.xxx.xxx is the IP address you entered, followed by a request to re-enter the value.

```
Invalid addr!
```

```
xxx.xxx.xxx.xxx
```

If you press the ENTER (.) key without changing any of the digits, the software interprets this as a user exit request. The following message will be displayed for three seconds.

```
Exiting menu...
```

```
xxx.xxx.xxx.xxx
```

If all the values entered are valid, when you press the ENTER key, the following message appears.

```
Values accepted,
```

```
Rebooting...
```

The subnet mask, NSIP, and gateway values are saved in the configuration file.

Note: For information about deploying a high availability (HA) pair, see "<http://support.citrix.com/proddocs/topic/ns-system-10-5-map/ns-nw-ha-cnfgmg-ha-con.html>."

Using the NetScaler Serial Console

When you first install the appliance, you can configure the initial settings by using the serial console. With the serial console, you can change the system IP address, create a subnet or mapped IP address, configure advanced network settings, and change the time zone.

Note: To locate the serial console port on your appliance, see "RS232 Serial Console Port" in "[Ports](#)."

To configure initial settings by using a serial console

1. Connect the console cable into your appliance. For more information, see "Connecting the Console Cable" in "[Connecting the Cables](#)."
2. Run the vt100 terminal emulation program of your choice on your computer to connect to the appliance and configure the following settings: 9600 baud, 8 data bits, 1 stop bit, parity, and flow control set to NONE.
3. Press ENTER. The terminal screen displays the Logon prompt.

Note: You might have to press ENTER two or three times, depending on which terminal program you are using.

4. Log on to the appliance with the administrator credentials. Your sales representative or Citrix Customer Service can provide you with the administrator credentials.
5. At the prompt, type `config ns` to run the NetScaler configuration script.
6. To complete the initial configuration of your appliance, follow the prompts.

Note: To prevent an attacker from breaching your ability to send packets to the appliance, choose a non-routable IP address on your organization's LAN as your appliance IP address.

You can replace steps 5 and 6 with the following NetScaler commands. At the NetScaler command prompt, type:

```
set ns config -ipaddress<IPAddress> -netmask<subnetMask>
```

```
add ns ip<IPAddress> <subnetMask> -type<type>
```

```
add route<network> <netmask> <gateway>
```

```
set system user <userName> -password
```

```
save ns config
```

```
reboot
```

Example

```
set ns config -ipaddress 10.102.29.60 -netmask 255.255.255.0
```

```
add ns ip 10.102.29.61 255.255.255.0 -type snip
```

```
add route 0.0.0.0 0.0.0.0 10.102.29.1
```

```
set system user nsroot -password
```

```
Enter password: ****
```

```
Confirm password: ****
```

```
save ns config
```

```
reboot
```

You have now completed initial configuration of your appliance. To continue configuring the appliance, choose one of the following options:

Citrix NetScaler.

If you are configuring your appliance as a standard NetScaler with other licensed features, see "[Load Balancing](#)."

Citrix NetScaler Application Firewall.

If you are configuring your appliance as a standalone application firewall, see "[Application Firewall](#)."

NetScaler Gateway.

If you are configuring your appliance as an NetScaler Gateway, see "[NetScaler Gateway 10.5](#)."

Note: For information about deploying a high availability (HA) pair, see "[Configuring High Availability](#)."

Configuring a NetScaler by Using the NITRO API

You can use the NITRO API to configure the NetScaler appliance. NITRO exposes its functionality through Representational State Transfer (REST) interfaces. Therefore, NITRO applications can be developed in any programming language. Additionally, for applications that must be developed in Java or .NET or Python, NITRO APIs are exposed through relevant libraries that are packaged as separate Software Development Kits (SDKs). For more information, see [NITRO API](#).

Configuring a High Availability Pair for the First Time

Sep 04, 2013

You can deploy two NetScaler appliances in a high availability configuration, where one unit actively accepts connections and manages servers while the secondary unit monitors the first. The NetScaler that is actively accepting connections and managing the servers is called a primary unit and the other one is called a secondary unit in a high availability configuration. If there is a failure in the primary unit, the secondary unit becomes the primary and begins actively accepting connections.

Each NetScaler in a high availability pair monitors the other by sending periodic messages, called heartbeat messages or health checks, to determine the health or state of the peer node. If a health check for a primary unit fails, the secondary unit retries the connection for a specific time period. For more information about high availability, see "[High Availability](#)." If a retry does not succeed by the end of the specified time period, the secondary unit takes over for the primary unit in a process called failover. The following figure shows two high availability configurations, one in one-arm mode and the other in two-arm mode.

Figure 1. High availability in one-arm mode

Figure 2. High availability in two-arm mode

In one-arm configuration, both NS1 and NS2 and servers S1, S2, and S3 are connected to the switch.

In two-arm configuration, both NS1 and NS2 are connected to two switches. The servers S1, S2, and S3 are connected to the second switch. The traffic between client and the servers passes through either NS1 or NS2.

To set up a high availability environment, configure one NetScaler as primary and another as secondary. Perform the following tasks on each of the NetScalers:

- Add a node.
- Disable high availability monitoring for unused interfaces.

Adding a Node

Updated: 2013-06-24

A node is a logical representation of a peer NetScaler appliance. It identifies the peer unit by ID and NSIP. An appliance uses these parameters to communicate with the peer and track its state. When you add a node, the primary and secondary units exchange heartbeat messages asynchronously. The node ID is an integer that must not be greater than 64.

To add a node by using the command line interface

At the command prompt, type the following commands to add a node and verify that the node has been added:

- add HA node <id> <IPAddress>
- show HA node <id>

Example

```
add HA node 0 10.102.29.170
Done
> show HA node 0
1) Node ID: 0
   IP: 10.102.29.200 (NS200)
```

```
Node State: UP
Master State: Primary
SSL Card Status: UP
Hello Interval: 200 msec
Dead Interval: 3 secs
Node in this Master State for: 1:0:41:50 (days:hrs:min:sec)
```

To add a node by using the configuration utility

1. In the navigation pane, expand System and click High Availability. The High Availability page appears.
2. On the High Availability page, select the Nodes tab.
3. Click Add. The High Availability Setup dialog box appears.
4. In the High Availability Setup dialog box, in the Remote Node IP Address text box, type an IP Address (for example, 10.102.29.170).
5. Ensure that the Configure remote system to participate in High Availability setup check box is selected. By default, this check box is selected.
6. Select the Turn off HA monitor on interfaces/channels that are down check box to disable the HA monitor on interfaces that are down. By default, this check box is selected.
7. Verify that the node you added appears in the list of nodes under the Nodes tab.

Disabling High Availability Monitoring for Unused Interfaces

Updated: 2013-06-24

The high availability monitor is a virtual entity that monitors an interface. You must disable the monitor for interfaces that are not connected or being used for traffic. When the monitor is enabled on an interface whose status is DOWN, the state of the node becomes NOT UP. In a high availability configuration, a primary node entering a NOT UP state might cause a high availability failover. An interface is marked DOWN under the following conditions:

- The interface is not connected
- The interface is not working properly
- The cable connecting the interface is not working properly

To disable the high availability monitor for an unused interface by using the command line interface

At the command prompt, type the following commands to disable the high availability monitor for an unused interface and verify that it is disabled:

- `set interface <id> -haMonitor OFF`
- `show interface <id>`

Example

```
> set interface 1/8 -haMonitor OFF
Done
> show interface 1/8
Interface 1/8 (Gig Ethernet 10/100/1000 Mbits) #2
flags=0x4000 <ENABLED, DOWN, down, autoneg, 802.1q>
MTU=1514, native vlan=1, MAC=00:d0:68:15:fd:3d, downtime 238h55m44s
```

```
Requested: media AUTO, speed AUTO, duplex AUTO, fctl OFF,  
throughput 0
```

```
RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
```

```
TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
```

```
NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
```

```
Bandwidth thresholds are not set.
```

When the high availability monitor is disabled for an unused interface, the output of the show interface command for that interface does not include "HAMON."

To disable the high availability monitor for unused interfaces by using the configuration utility

1. Navigate to System > Network > Interfaces.
2. Select the interface for which the monitor must be disabled.
3. Click Open. The Modify Interface dialog box appears.
4. In HA Monitoring, select the OFF option.
5. Click OK.
6. Verify that, when the interface is selected, "HA Monitoring: OFF" appears in the details at the bottom of the page.

Configuring a FIPS Appliance for the First Time

Jun 29, 2016

A certificate-key pair is required for HTTPS access to the configuration utility and for secure remote procedure calls. RPC nodes are internal system entities used for system-to-system communication of configuration and session information. One RPC node exists on each appliance. This node stores the password, which is checked against the one provided by the contacting appliance. To communicate with other NetScaler appliances, each appliance requires knowledge of the other appliances, including how to authenticate on the other appliance. RPC nodes maintain this information, which includes the IP addresses of the other NetScaler appliances and the passwords used to authenticate on each.

On a NetScaler MPX appliance and NetScaler virtual appliance, a certificate-key pair is automatically bound to the internal services. On a FIPS appliance, a certificate-key pair must be imported into the hardware security module (HSM) of a FIPS card. To do so, you must configure the FIPS card, create a certificate-key pair, and bind it to the internal services.

To configure secure HTTPS by using the command line interface

1. Initialize the hardware security module (HSM) on the FIPS card of the appliance. For information about initializing the HSM, see "Configuring the HSM."
2. If the appliance is part of a high availability setup, enable the SIM. For information about enabling the SIM on the primary and secondary appliances, see "Configuring FIPS Appliances in a High Availability Setup."
3. Import the FIPS key into the HSM of the FIPS card of the appliance. At the command prompt, type:
`import ssl fipskey serverkey -key ns-server.key -inform PEM`
4. Add a certificate-key pair. At the command prompt, type:
`add certkey server -cert ns-server.cert -fipskey serverkey`
5. Bind the certificate-key created in the previous step to the following internal services. At the command prompt, type:
`bind ssl service nshttps-127.0.0.1-443 -certkeyname server`
`bind ssl service nshttps-::11-443 -certkeyname server`

To configure secure HTTPS by using the configuration utility

1. Initialize the hardware security module (HSM) on the FIPS card of the appliance. For information about initializing the HSM, see "Configuring the HSM."
2. If the appliance is part of a high availability setup, enable the secure information system (SIM). For information about enabling the SIM on the primary and secondary appliances, see "Configuring FIPS Appliances in a High Availability Setup."
3. Import the FIPS key into the HSM of the FIPS card of the appliance. For more information about importing a FIPS key, see "Importing an Existing FIPS Key."
4. Navigate to Traffic Management > SSL > Certificates.
5. In the details pane, click Install.
6. In the Install Certificate dialog box, type the certificate details.
7. Click Create, and then click Close.
8. Navigate to Traffic Management > Load Balancing > Services.
9. In the details pane, on the Action tab, click Internal Services.
10. Select nshttps-127.0.0.1-443 from the list, and then click Open.
11. On the SSL Settings tab, in the Available pane, select the certificate created in step 7, click Add, and then click OK.
12. Select nshttps-::11-443 from the list, and then click Open.

13. On the SSL Settings tab, in the Available pane, select the certificate created in step 7, click Add, and then click OK.
14. Click OK.

To configure secure RPC by using the command line interface

1. Initialize the hardware security module (HSM) on the FIPS card of the appliance. For information about initializing the HSM, see "Configuring the HSM."
2. Enable the secure information system (SIM). For information about enabling the SIM on the primary and secondary appliances, see "Configuring FIPS Appliances in a High Availability Setup."
3. Import the FIPS key into the HSM of the FIPS card of the appliance. At the command prompt, type:
`import ssl fipskey serverkey -key ns-server.key -inform PEM`
4. Add a certificate-key pair. At the command prompt, type:
`add certkey server -cert ns-server.cert -fipskey serverkey`
5. Bind the certificate-key pair to the following internal services. At the command prompt, type:
`bind ssl service nsrpcs-127.0.0.1-3008 -certkeyname server`
`bind ssl service nskrpcs-127.0.0.1-3009 -certkeyname server`
`bind ssl service nsrpcs-::11-3008 -certkeyname server`
6. Enable secure RPC mode. At the command prompt, type:
`set ns rpcnode <IP address> -secure YES`

To configure secure RPC by using the configuration utility

1. Initialize the hardware security module (HSM) on the FIPS card of the appliance. For information about initializing the HSM, see "Configuring the HSM."
2. Enable the secure information system (SIM). For information about enabling the SIM on the primary and secondary appliances, see "Configuring FIPS Appliances in a High Availability Setup."
3. Import the FIPS key into the HSM of the FIPS card of the appliance. For more information about importing a FIPS key, see "Importing an Existing FIPS Key."
4. Navigate to Traffic Management > SSL > Certificates.
5. In the details pane, click Install.
6. In the Install Certificate dialog box, type the certificate details.
7. Click Create, and then click Close.
8. Navigate to Traffic Management > Load Balancing > Services.
9. In the details pane, on the Action tab, click Internal Services.
10. Select nsrpcs-127.0.0.1-3008 from the list, and then click Open.
11. On the SSL Settings tab, in the Available pane, select the certificate created in step 7, click Add, and then click OK.
12. Select nskrpcs-127.0.0.1-3009 from the list, and then click Open.
13. On the SSL Settings tab, in the Available pane, select the certificate created in step 7, click Add, and then click OK.
14. Select nsrpcs-::11-3008 from the list, and then click Open.
15. On the SSL Settings tab, in the Available pane, select the certificate created in step 7, click Add, and then click OK.
16. Click OK.
17. Navigate to System > Network > RPC
18. In the details pane, select the IP address, and click Open.
19. In the Configure RPC Node dialog box, select Secure.
20. Click OK.

Understanding Common Network Topologies

Oct 27, 2015

As described in "[Physical Deployment Modes](#)," you can deploy the Citrix NetScaler appliance either inline between the clients and servers or in one-arm mode. Inline mode uses a two-arm topology, which is the most common type of deployment.

This document includes the following:

- [Setting Up Common Two-Arm Topologies](#)
- [Setting Up Common One-Arm Topologies](#)

Setting Up Common Two-Arm Topologies

In a two-arm topology, one network interface is connected to the client network and another network interface is connected to the server network, ensuring that all traffic flows through the appliance. This topology might require you to reconnect your hardware and also might result in a momentary downtime. The basic variations of two-arm topology are multiple subnets, typically with the appliance on a public subnet and the servers on a private subnet, and transparent mode, with both the appliance and the servers on the public network.

Setting Up a Simple Two-Arm Multiple Subnet Topology

One of the most commonly used topologies has the NetScaler appliance inline between the clients and the servers, with a virtual server configured to handle the client requests. This configuration is used when the clients and servers reside on different subnets. In most cases, the clients and servers reside on public and private subnets, respectively.

For example, consider an appliance deployed in two-arm mode for managing servers S1, S2, and S3, with a virtual server of type HTTP configured on the appliance, and with HTTP services running on the servers. The servers are on a private subnet and a SNIP is configured on the appliance to communicate with the servers. The Use SNIP (USNIP) option must be enabled on the appliance so that it uses the SNIP instead of the MIP.

As shown in the following figure, the VIP is on public subnet 217.60.10.0, and the NSIP, the servers, and the SNIP are on private subnet 192.168.100.0/24.

Figure 1. Topology Diagram for Two-Arm Mode, Multiple Subnets

Task overview: To deploy a NetScaler appliance in two-arm mode with multiple subnets

1. Configure the NSIP and default gateway, as described in "[Configuring the NetScaler IP Address \(NSIP\).](#)"
2. Configure the SNIP, as described in "[Configuring Subnet IP Addresses.](#)"
3. Enable the USNIP option, as described in "[To enable or disable USNIP mode.](#)"
4. Configure the virtual server and the services, as described in "[Creating a Virtual Server](#)" and "[Configuring Services.](#)"
5. Connect one of the network interfaces to a private subnet and the other interface to a public subnet.

Setting Up a Simple Two-Arm Transparent Topology

Use transparent mode if the clients need to access the servers directly, with no intervening virtual server. The server IP addresses must be public because the clients need to be able to access them. In the example shown in the following figure, a NetScaler appliance is placed between the client and the server, so the traffic must pass through the appliance. You must enable L2 mode for bridging the packets. The NSIP and MIP are on the same public subnet, 217.60.10.0/24.

Figure 2. Topology Diagram for Two-Arm, Transparent Mode

Task overview: To deploy a NetScaler in two-arm, transparent mode

1. Configure the NSIP, MIP, and default gateway, as described in "[Configuring a NetScaler by Using the Command Line Interface](#)."
2. Enable L2 mode, as described in "[Enabling and Disabling Layer 2 Mode](#)."
3. Configure the default gateway of the managed servers as the MIP.
4. Connect the network interfaces to the appropriate ports on the switch.

Setting Up Common One-Arm Topologies

The two basic variations of one-arm topology are with a single subnet and with multiple subnets.

Setting Up a Simple One-Arm Single Subnet Topology

You can use a one-arm topology with a single subnet when the clients and servers reside on the same subnet. For example, consider a NetScaler deployed in one-arm mode for managing servers S1, S2, and S3. A virtual server of type HTTP is configured on a NetScaler, and HTTP services are running on the servers. As shown in the following figure, the NetScaler IP address (NSIP), the Mapped IP address (MIP), and the server IP addresses are on the same public subnet, 217.60.10.0/24.

Figure 3. Topology Diagram for One-Arm Mode, Single Subnet

Task overview: To deploy a NetScaler in one-arm mode with a single subnet

1. Configure the NSIP, MIP, and the default gateway, as described in "[Configuring the NetScaler IP Address \(NSIP\)](#)".
2. Configure the virtual server and the services, as described in "[Creating a Virtual Server](#)" and "[Configuring Services](#)".
3. Connect one of the network interfaces to the switch.

Setting Up a Simple One-Arm Multiple Subnet Topology

You can use a one-arm topology with multiple subnets when the clients and servers reside on the different subnets. For example, consider a NetScaler appliance deployed in one-arm mode for managing servers S1, S2, and S3, with the servers connected to switch SW1 on the network. A virtual server of type HTTP is configured on the appliance, and HTTP services are running on the servers. These three servers are on the private subnet, so a subnet IP address (SNIP) is configured to communicate with them. The Use Subnet IP address (USNIP) option must be enabled so that the appliance uses the SNIP instead of a MIP. As shown in the following figure, the virtual IP address (VIP) is on public subnet 217.60.10.0/24; the NSIP, SNIP, and the server IP addresses are on private subnet 192.168.100.0/24.

Figure 4. Topology Diagram for One-Arm Mode, Multiple Subnets

Task overview: To deploy a NetScaler appliance in one-arm mode with multiple subnets

1. Configure the NSIP and the default gateway, as described in "[Configuring the NetScaler IP Address \(NSIP\)](#)".
2. Configure the SNIP and enable the USNIP option, as described in "[Configuring Subnet IP Addresses](#)".
3. Configure the virtual server and the services, as described in "[Creating a Virtual Server](#)" and "[Configuring Services](#)".
4. Connect one of the network interfaces to the switch.

Configuring System Management Settings

Sep 04, 2013

Once your initial configuration is in place, you can configure settings to define the behavior of the Citrix NetScaler appliance and facilitate connection management. You have a number of options for handling HTTP requests and responses. Routing, bridging, and MAC based forwarding modes are available for handling packets not addressed to the NetScaler. You can define the characteristics of your network interfaces and can aggregate the interfaces. To prevent timing problems, you can synchronize the NetScaler clock with a Network Time Protocol (NTP) server. The NetScaler can operate in various DNS modes, including as an authoritative domain name server (ADNS). You can set up SNMP for system management and customize syslog logging of system events. Before deployment, verify that your configuration is complete and correct.

This document includes the following:

- [Configuring System Settings](#)
- [Configuring Modes of Packet Forwarding](#)
- [Configuring Network Interfaces](#)
- [Configuring Clock Synchronization](#)
- [Configuring DNS](#)
- [Configuring SNMP](#)
- [Verifying the Configuration](#)

Note: In addition to the tasks listed above, you can configure Syslog logging. For instructions, see “[Audit Logging](#).”

Configuring System Settings

Sep 04, 2013

Configuration of system settings includes basic tasks such as configuring HTTP ports to enable connection keep-alive and server offload, setting the maximum number of connections for each server, and setting the maximum number of requests per connection. You can enable client IP address insertion for situations in which a proxy IP address is not suitable, and you can change the HTTP cookie version.

You can also configure a NetScaler appliance to open FTP connections on a controlled range of ports instead of ephemeral ports for data connections. This improves security, because opening all ports on the firewall is insecure. You can set the range anywhere from 1,024 to 64,000.

Before deployment, go through the verification checklists to verify your configuration. To configure HTTP parameters and the FTP port range, use the NetScaler configuration utility.

You can modify the types of HTTP parameters described in the following table.

Table 1. HTTP Parameters

Parameter Type	Specifies
HTTP Port Information	<p>The web server HTTP ports used by your managed servers. If you specify the ports, the appliance performs request switching for any client request that has a destination port matching a specified port.</p> <p>Note: If an incoming client request is not destined for a service or a virtual server that is specifically configured on the appliance, the destination port in the request must match one of the globally configured HTTP ports. This allows the appliance to perform connection keep-alive and server off-load.</p>
Limits	<p>The maximum number of connections to each managed server, and the maximum number of requests sent over each connection. For example, if you set Max Connections to 500, and the appliance is managing three servers, it can open a maximum of 500 connections to each of the three servers. By default, the appliance can create an unlimited number of connections to any of the servers it manages. To specify an unlimited number of requests per connection, set Max Requests to 0.</p> <p>Note: If you are using the Apache HTTP server, you must set Max Connections equal to the value of the MaxClients parameter in the Apache httpd.conf file. Setting this parameter is optional for other web servers.</p>
Client IP Insertion	<p>Enable/disable insertion of the client's IP address into the HTTP request header. You can specify a name for the header field in the adjacent text box. When a web server managed by an appliance receives a mapped IP address or a subnet IP address, the server identifies it as the client's IP address. Some applications need the client's IP address for logging purposes or to dynamically determine the content to be served by the web server.</p> <p>You can enable insertion of the actual client IP address into the HTTP header request sent from the client to one, some, or all servers managed by the appliance. You can then access the</p>

Parameter Type	Specifies inserted address through a minor modification to the server (using an Apache module, ISAPI interface, or NSAPI interface).
Cookie Version	The HTTP cookie version to use when COOKIEINSERT persistence is configured on a virtual server. The default, version 0, is the most common type on the Internet. Alternatively, you can specify version 1.
Requests/Responses	Options for handling certain types of requests, and enable/disable logging of HTTP error responses.
Server Header Insertion	Insert a server header in NetScaler-generated HTTP responses.

To configure HTTP parameters by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Settings, click Change HTTP parameters.
3. In the Configure HTTP parameters dialog box, specify values for some or all of the parameters that appear under the headings listed in the table above.
4. Click OK.

To set the FTP port range by using the configuration utility

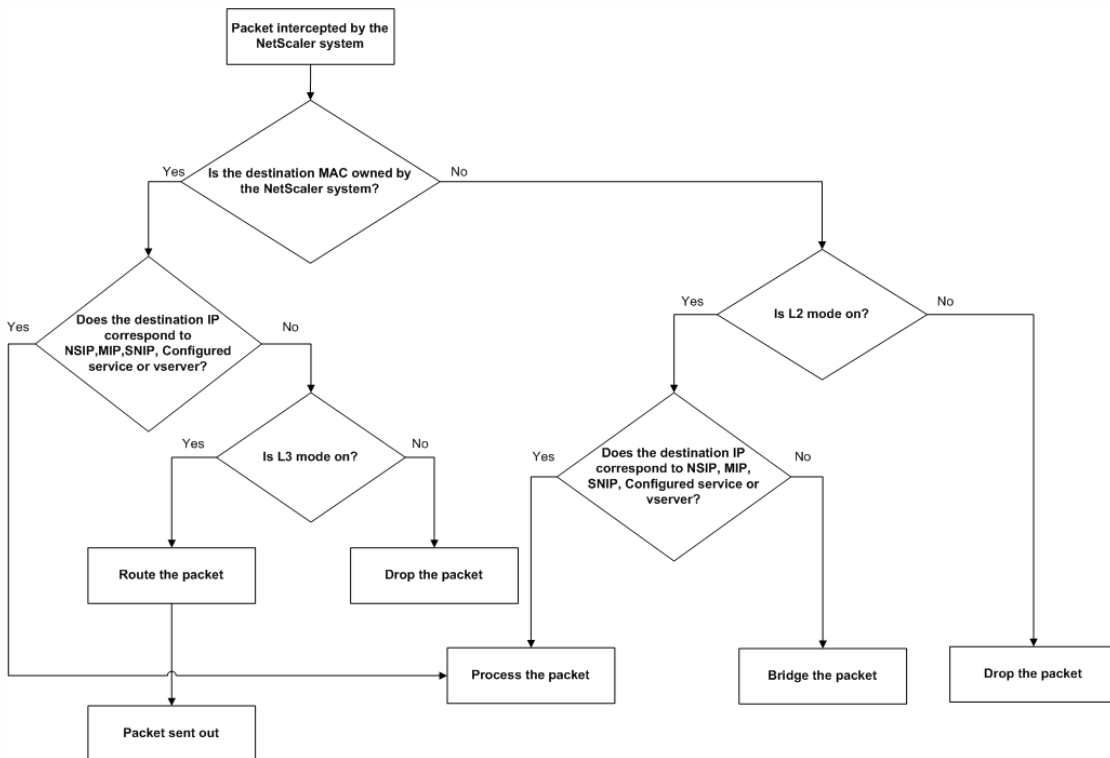

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Settings, click Change global system settings.
3. Under FTP Port Range, in the Start Port and End Port text boxes, type the lowest and highest port numbers, respectively, for the range you want to specify (for example, 5000 and 6000).
4. Click OK.

Configuring Modes of Packet Forwarding

Jun 24, 2013

The NetScaler appliance can either route or bridge packets that are not destined for an IP address owned by the appliance (that is, the IP address is not the NSIP, a MIP, a SNIP, a configured service, or a configured virtual server). By default, L3 mode (routing) is enabled and L2 mode (bridging) is disabled, but you can change the configuration. The following flow chart shows how the appliance evaluates packets and either processes, routes, bridges, or drops them.

Figure 1. Interaction between Layer 2 and Layer 3 Modes

An appliance can use the following modes to forward the packets it receives:

- Layer 2 (L2) Mode
- Layer 3 (L3) Mode
- MAC-Based Forwarding Mode

Enabling and Disabling Layer 2 Mode

Updated: 2013-09-13

Layer 2 mode controls the Layer 2 forwarding (bridging) function. You can use this mode to configure a NetScaler appliance to behave as a Layer 2 device and bridge the packets that are not destined for it. When this mode is enabled, packets are not forwarded to any of the MAC addresses, because the packets can arrive on any interface of the appliance and each interface has its own MAC address.

With Layer 2 mode disabled (which is the default), the appliance drops packets that are not destined for one of its MAC address. If another Layer 2 device is installed in parallel with the appliance, Layer 2 mode must be disabled to prevent

bridging (Layer 2) loops. You can use the configuration utility or the command line to enable Layer 2 mode.

Note: The appliance does not support spanning tree protocol. To avoid loops, if you enable L2 mode, do not connect two interfaces on the appliance to the same broadcast domain.

To enable or disable Layer 2 mode by using the command line interface

At the command prompt, type the following commands to enable/disable Layer 2 mode and verify that it has been enabled/disabled:

- enable ns mode <Mode>
- disable ns mode <Mode>
- show ns mode

Examples

```
> enable ns mode l2
Done
> show ns mode
```

Mode	Acronym	Status
1) Fast Ramp	FR	ON
2) Layer 2 mode	L2	ON
.		
.		
.		

```
Done
>
```

```
> disable ns mode l2
Done
> show ns mode
```

Mode	Acronym	Status
1) Fast Ramp	FR	ON
2) Layer 2 mode	L2	OFF
.		
.		
.		

```
Done
>
```

To enable or disable Layer 2 mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In the Configure Modes dialog box, to enable Layer 2 mode, select the Layer 2 Mode check box. To disable Layer 2 mode, clear the check box.

4. Click OK. The Enable/Disable Mode(s)? message appears in the details pane.
5. Click Yes.

Enabling and Disabling Layer 3 Mode

Updated: 2013-09-13

Layer 3 mode controls the Layer 3 forwarding function. You can use this mode to configure a NetScaler appliance to look at its routing table and forward packets that are not destined for it. With Layer 3 mode enabled (which is the default), the appliance performs route table lookups and forwards all packets that are not destined for any appliance-owned IP address. If you disable Layer 3 mode, the appliance drops these packets.

To enable or disable Layer 3 mode by using the command line interface

At the command prompt, type the following commands to enable/disable Layer 3 mode and verify that it has been enabled/disabled:

- enable ns mode <Mode>
- disable ns mode <Mode>
- show ns mode

Examples

```
> enable ns mode l3
```

```
Done
```

```
> show ns mode
```

Mode	Acronym	Status
-----	-----	-----
1) Fast Ramp	FR	ON
2) Layer 2 mode	L2	OFF
.		
.		
.		
9) Layer 3 mode (ip forwarding)	L3	ON

```
.
```

```
.
```

```
.
```

```
Done
```

```
>
```

```
> disable ns mode l3
```

```
Done
```

```
> show ns mode
```

Mode	Acronym	Status
-----	-----	-----
1) Fast Ramp	FR	ON
2) Layer 2 mode	L2	OFF

9) Layer 3 mode (ip forwarding) L3 OFF

Done

>

To enable or disable Layer 3 mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In the Configure Modes dialog box, to enable Layer 3 mode, select the Layer 3 Mode (IP Forwarding) check box. To disable Layer 3 mode, clear the check box.
4. Click OK. The Enable/Disable Mode(s)? message appears in the details pane.
5. Click Yes.

Enabling and Disabling MAC-Based Forwarding Mode

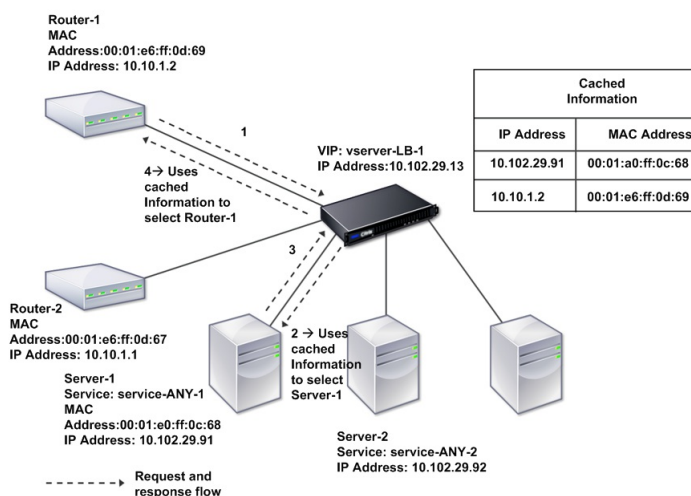

Updated: 2013-09-13

You can use MAC-based forwarding to process traffic more efficiently and avoid multiple-route or ARP lookups when forwarding packets, because the NetScaler appliance remembers the MAC address of the source. To avoid multiple lookups, the appliance caches the source MAC address of every connection for which it performs an ARP lookup, and it returns the data to the same MAC address.

MAC-based forwarding is useful when you use VPN devices because the appliance ensures that all traffic flowing through a particular VPN passes through the same VPN device.

The following figure shows the process of MAC-based forwarding.

Figure 2. MAC-Based Forwarding Process

When MAC-based forwarding is enabled, the appliance caches the MAC address of:

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server responds through an appliance, the appliance sets the destination MAC address of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when an appliance initiates a connection, it uses the route and ARP tables for the lookup function. To enable MAC-based forwarding, use the configuration utility or the command line.

Some deployments require the incoming and outgoing paths to flow through different routers. In these situations, MAC-based forwarding breaks the topology design. For a global server load balancing (GSLB) site that requires the incoming and outgoing paths to flow through different routers, you must disable MAC-based forwarding and use the appliance's default router as the outgoing router.

With MAC-based forwarding disabled and Layer 2 or Layer 3 connectivity enabled, a route table can specify separate routers for outgoing and incoming connections. To disable MAC-based forwarding, use the configuration utility or the command line.

To enable or disable MAC-based forwarding by using the command line interface

At the command prompt, type the following commands to enable/disable MAC-based forwarding mode and verify that it has been enabled/disabled:

- enable ns mode <Mode>
- disable ns mode <Mode>
- show ns mode

Example

```
> enable ns mode mbf
```

```
Done
```

```
> show ns mode
```

Mode	Acronym	Status
-----	-----	-----
1) Fast Ramp	FR	ON
2) Layer 2 mode	L2	OFF
.		
.		
.		
6) MAC-based forwarding	MBF	ON
.		
.		
.		

```
Done  
>
```

```
> disable ns mode mbf
```

Done

> show ns mode

Mode	Acronym	Status
-----	-----	-----
1) Fast Ramp	FR	ON
2) Layer 2 mode	L2	OFF
.		
.		
.		
6) MAC-based forwarding	MBF	OFF
.		
.		
.		

Done

>

To enable or disable MAC-based forwarding by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features group, click Configure modes.
3. In the Configure Modes dialog box, to enable MAC-based forwarding mode, select the MAC Based Forwarding check box. To disable MAC-based forwarding mode, clear the check box.
4. Click OK. The Enable/Disable Mode(s)? message appears in the details pane.
5. Click Yes.

Configuring Network Interfaces

Aug 23, 2013

NetScaler interfaces are numbered in slot/port notation. In addition to modifying the characteristics of individual interfaces, you can configure virtual LANs to restrict traffic to specific groups of hosts. You can also aggregate links into high-speed channels.

Virtual LANs

The NetScaler supports (Layer 2) port and IEEE802.1Q tagged virtual LANs (VLANs). VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface to belong to multiple VLANs by using IEEE 802.1q tagging.

You can bind your configured VLANs to IP subnets. The NetScaler (if it is configured as the default router for the hosts on the subnets) then performs IP forwarding between these VLANs. A NetScaler supports the following types of VLANs.

Default VLAN

By default, the network interfaces on a NetScaler are included in a single, port-based VLAN as untagged network interfaces. This default VLAN has a VID of 1 and exists permanently. It cannot be deleted, and its VID cannot be changed.

Port-Based VLANs

A set of network interfaces that share a common, exclusive, Layer 2 broadcast domain define the membership of a port-based VLAN. You can configure multiple port-based VLANs. When you add an interface to a new VLAN as an untagged member, it is automatically removed from the default VLAN.

Tagged VLAN

A network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of only one VLAN (its native VLAN). The untagged network interface forwards the frames for the native VLAN as untagged frames. A tagged network interface can be a part of more than one VLAN. When you configure tagging, be sure that both ends of the link have matching VLAN settings. You can use the configuration utility to define a tagged VLAN (nsvlan) that can have any ports bound as tagged members of the VLAN. Configuring this VLAN requires a reboot of the NetScaler and therefore must be done during initial network configuration.

Link Aggregate Channels

Link aggregation combines incoming data from multiple ports into a single high speed link. Configuring the link aggregate channel increases the capacity and availability of the communication channel between a NetScaler and other connected devices. An aggregated link is also referred to as a channel.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. A network interface can be bound to only one channel. Binding a network interface to a link aggregate channel changes the VLAN configuration. That is, binding network interfaces to a channel removes them from the VLANs that they originally belonged to and adds them to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you have bound network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then you bind them to link aggregate channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them to VLAN 2.

Note: You can also use Link Aggregation Control Protocol (LACP) to configure link aggregation. For more information, see ""Configuring Link Aggregation by Using the Link Aggregation Control Protocol."

Configuring Clock Synchronization

Aug 23, 2013

You can configure your NetScaler appliance to synchronize its local clock with a Network Time Protocol (NTP) server. This ensures that its clock has the same date and time settings as the other servers on your network. NTP uses User Datagram Protocol (UDP) port 123 as its transport layer. You have to add NTP servers in the NTP configuration file so that the appliance periodically gets updates from these servers.

If you do not have a local NTP server, you can find a list of public, open access, NTP servers at the official NTP site at <http://www.ntp.org>.

To configure clock synchronization on your appliance

1. Log on to the command line and enter the shell command.
2. At the shell prompt, copy the `ntp.conf` file from the `/etc` directory to the `/nsconfig` directory. If the file already exists in the `/nsconfig` directory, make sure that you remove the following entries from the `ntp.conf` file:

```
restrict localhost
```

```
restrict 127.0.0.2
```

These entries are required only if you want to run the device as a time server. However, this feature is not supported on the NetScaler.

3. Edit `/nsconfig/ntp.conf` by typing the IP address for the desired NTP server under the file's `server` and `restrict` entries.
4. Create a file named `rc.netscaler` in the `/nsconfig` directory, if the file does not already exist in the directory.
5. Edit `/nsconfig/rc.netscaler` by adding the following entry: `/usr/sbin/ntpd -c /nsconfig/ntp.conf -l /var/log/ntpd.log &`
This entry starts the `ntpd` service, checks the `ntp.conf` file, and logs messages in the `/var/log` directory.

Note: If the time difference between the NetScaler and the time server is more than 1000 sec, the `ntpd` service terminates with a message to the NetScaler log. To avoid this, you need to start `ntpd` with the `-g` option, which forcibly syncs the time. Add the following entry in `/nsconfig/rc.netscaler`:

```
/usr/sbin/ntpd -g -c /nsconfig/ntp.conf -l /var/log/ntpd.log &
```

If you do not want to forcibly sync the time when there is a large difference, you can set the date manually and then start `ntpd` again. You can check the time difference between the appliance and the time server by running the following command in the shell:

```
ntpdate -q <IP address or domain name of the NTP server>
```

6. Reboot the appliance to enable clock synchronization.

Note: If you want to start time synchronization before you restart the appliance, enter the following command (which you added to the `rc.netscaler` file in step 5) at the shell prompt:

```
/usr/sbin/ntpd -c /nsconfig/ntp.conf -l /var/log/ntpd.log &
```

Configuring DNS

Sep 04, 2013

You can configure a NetScaler appliance to function as an Authoritative Domain Name Server (ADNS), DNS proxy server, End Resolver, or Forwarder. You can add DNS resource records such as SRV Records, AAAA Records, A Records, MX Records, NS Records, CNAME Records, PTR Records, and SOA Records. Also, the appliance can balance the load on external DNS servers.

A common practice is to configure an appliance as a forwarder. For this configuration, you need to add external name servers. After you have added the external servers, you should verify that your configuration is correct.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

When adding name servers, you can specify IP addresses or virtual IP addresses (VIPs). If you use IP addresses, the appliance load balances requests to the configured name servers in a round robin manner. If you use VIPs, you can specify any load balancing method.

To add a name server by using the command line interface

At the command prompt, type the following commands to add a name server and verify the configuration:

- add dns nameServer <IP>
- show dns nameServer <IP>

Example

```
> add dns nameServer 10.102.29.10
Done
> show dns nameServer 10.102.29.10
1) 10.102.29.10 - State: DOWN
Done
>
```

To add a name server by using the configuration utility

1. Navigate to Traffic Management > DNS > Name Servers.
2. In the details pane, click Add.
3. In the Create Name Server dialog box, select IP Address.
4. In the IP Address text box, type the IP address of the name server (for example, 10.102.29.10). If you are adding an external name server, clear the Local check box.
5. Click Create, and then click Close.
6. Verify that the name server you added appears in the Name Servers pane.

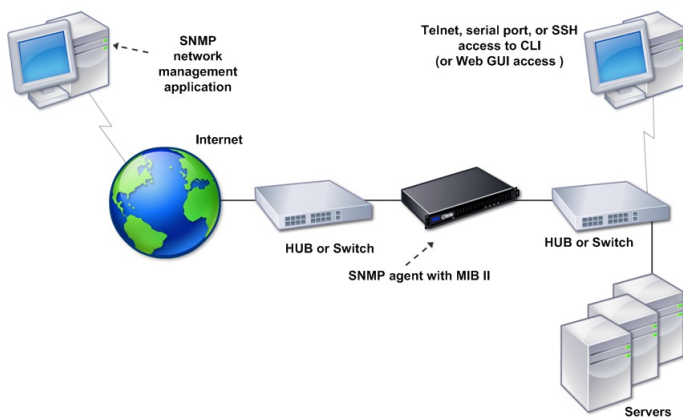

Configuring SNMP

May 14, 2012

The Simple Network Management Protocol (SNMP) network management application, running on an external computer, queries the SNMP agent on the NetScaler. The agent searches the management information base (MIB) for data requested by the network management application and sends the data to the application.

SNMP monitoring uses traps messages and alarms. SNMP traps messages are asynchronous events that the agent generates to signal abnormal conditions, which are indicated by alarms. For example, if you want to be informed when CPU utilization is above 90 percent, you can set up an alarm for that condition. The following figure shows a network with a NetScaler that has SNMP enabled and configured.

Figure 1. SNMP on the NetScaler

The SNMP agent on a NetScaler supports SNMP version 1 (SNMPv1), SNMP version 2 (SNMPv2), and SNMP version 3 (SNMPv3). Because it operates in bilingual mode, the agent can handle SNMPv2 queries, such as Get-Bulk, and SNMPv1 queries. The SNMP agent also sends traps compliant with SNMPv2 and supports SNMPv2 data types, such as counter64. SNMPv1 managers (programs on other servers that request SNMP information from the NetScaler) use the NS-MIB-smiv1.mib file when processing SNMP queries. SNMPv2 managers use the NS-MIB-smiv2.mib file.

The NetScaler supports the following enterprise-specific MIBs:

A subset of standard MIB-2 groups

Provides MIB-2 groups SYSTEM, IF, ICMP, UDP, and SNMP.

A system enterprise MIB

Provides system-specific configuration and statistics.

To configure SNMP, you specify which managers can query the SNMP agent, add SNMP trap listeners that will receive the SNMP trap messages, and configure SNMP Alarms.

Adding SNMP Managers

Updated: 2013-06-05

You can configure a workstation running a management application that complies with SNMP version 1, 2, or 3 to access an appliance. Such a workstation is called an SNMP manager. If you do not specify an SNMP manager on the appliance, the appliance accepts and responds to SNMP queries from all IP addresses on the network. If you configure one or more SNMP managers, the appliance accepts and responds to SNMP queries from only those specific IP addresses. When specifying the IP address of an SNMP manager, you can use the netmask parameter to grant access from entire subnets. You can add a maximum of 100 SNMP managers or networks.

To add an SNMP manager by using the command line interface

At the command prompt, type the following commands to add an SNMP manager and verify the configuration:

- add snmp manager <IPAddress> ... [-netmask <netmask>]
- show snmp manager <IPAddress>

Example

```
> add snmp manager 10.102.29.5 -netmask 255.255.255.255
Done
> show snmp manager 10.102.29.5
1) 10.102.29.5 255.255.255.255
Done
>
```

To add an SNMP manager by using the configuration utility

1. In the navigation pane, expand System, expand SNMP, and then click Managers.
2. In the details pane, click Add.
3. In the Add SNMP Manager dialog box, in the IP Address text box, type the IP address of the workstation running the management application (for example, 10.102.29.5).
4. Click Create, and then click Close.
5. Verify that the SNMP manager you added appears in the Details section at the bottom of the pane.

Adding SNMP Traps Listeners

Updated: 2013-09-13

After configuring the alarms, you need to specify the trap listener to which the appliance will send the trap messages. Apart from specifying parameters like IP address and the destination port of the trap listener, you can specify the type of trap (either generic or specific) and the SNMP version.

You can configure a maximum of 20 trap listeners for receiving either generic or specific traps.

To add an SNMP trap listener by using the command line interface

At the command prompt, type the following command to add an SNMP trap and verify that it has been added:

- add snmp trap specific <IP>
- show snmp trap

Example

```
> add snmp trap specific 10.102.29.3
```

```

Done
> show snmp trap
Type  DestinationIP  DestinationPort  Version  SourceIP  Min-Severity  Community
-----
generic 10.102.29.9  162             V2       NetScaler IP N/A           public
generic 10.102.29.5  162             V2       NetScaler IP N/A           public
generic 10.102.120.101 162             V2       NetScaler IP N/A           public
.
.
.
specific 10.102.29.3  162             V2       NetScaler IP -           public
Done
>

```

To add an SNMP trap listener by using the configuration utility

1. In the navigation pane, expand System, expand SNMP, and then click Traps.
2. In the details pane, click Add.
3. In the Create SNMP Trap Destination dialog box, in the Destination IP Address text box, type the IP address (for example, 10.102.29.3).
4. Click Create and then click Close.
5. Verify that the SNMP trap you added appears in the Details section at the bottom of the pane.

Configuring SNMP Alarms

Updated: 2013-09-13

You configure alarms so that the appliance generates a trap message when an event corresponding to one of the alarms occurs. Configuring an alarm consists of enabling the alarm and setting the severity level at which a trap is generated. There are five severity levels: Critical, Major, Minor, Warning, and Informational. A trap is sent only when the severity of the alarm matches the severity specified for the trap.

Some alarms are enabled by default. If you disable an SNMP alarm, the appliance will not generate trap messages when corresponding events occur. For example, if you disable the Login-Failure SNMP alarm, the appliance will not generate a trap message when a login failure occurs.

To enable or disable an alarm by using the command line interface

At the command prompt, type the following commands to enable or disable an alarm and verify that it has been enabled or disabled:

- `set snmp alarm <trapName> [-state ENABLED | DISABLED]`
- `show snmp alarm <trapName>`

Example

```

> set snmp alarm LOGIN-FAILURE -state ENABLED
Done
> show snmp alarm LOGIN-FAILURE
Alarm      Alarm Threshold  Normal Threshold  Time State  Severity  Logging

```

```

-----
1) LOGIN-FAILURE N/A      N/A      N/A  ENABLED -  ENABLED
Done
>

```

To set the severity of the alarm by using the command line interface

At the command prompt, type the following commands to set the severity of the alarm and verify that the severity has been set correctly:

- set snmp alarm <trapName> [-severity <severity>]
- show snmp alarm <trapName>

Example

```

> set snmp alarm LOGIN-FAILURE -severity Major
Done
> show snmp alarm LOGIN-FAILURE
  Alarm      Alarm Threshold Normal Threshold Time State  Severity Logging
-----
1) LOGIN-FAILURE N/A      N/A      N/A  ENABLED Major  ENABLED
Done
>

```

To configure alarms by using the configuration utility

1. In the navigation pane, expand System, expand SNMP, and then click Alarms.
2. In the details pane, select an alarm (for example, LOGIN-FAILURE), and then click Open.
3. In the Configure SNMP Alarm dialog box, to enable the alarm, select Enabled in the State drop-down list. To disable the alarm, select Disabled.
4. In the Severity drop-down list, select a severity option (for example, Major).
5. Click OK, and then click Close.
6. Verify that the parameters for the SNMP alarm you configured are correctly configured by viewing the Details section at the bottom of the pane.

Verifying the Configuration

Nov 08, 2013

After you finish configuring your system, complete the following checklists to verify your configuration.

Configuration Checklist

- The build running is:
- There are no incompatibility issues. (Incompatibility issues are documented in the build's release notes.)
- The port settings (speed, duplex, flow control, monitoring) are the same as the switch's port.
- Enough mapped IP addresses have been configured to support all server-side connections during peak times.
 - The number of configured mapped IP addresses is: _____
 - The expected number of simultaneous server connections is:
[] 62,000 [] 124,000 [] Other_____

Topology Configuration Checklist

- The routes have been used to resolve servers on other subnets.

The routes entered are:

- If the NetScaler is in a public-private topology, reverse NAT has been configured.
- The failover (high availability) settings configured on the NetScaler resolve in a one arm or two-arm configuration. All unused network interfaces have been disabled:

- If the NetScaler is placed behind an external load balancer, then the load balancing policy on the external load balancer is not "least connection."

The load balancing policy configured on the external load balancer is:

- If the NetScaler is placed in front of a firewall, the session time-out on the firewall is set to a value greater than or equal to 300 seconds.

Note: The TCP idle connection timeout on a NetScaler appliance is 360 seconds. If the timeout on the firewall is also set to 300 seconds or more, then the appliance can perform TCP connection multiplexing effectively because connections will not be closed earlier.

The value configured for the session time-out is: _____

Server Configuration Checklist

- "Keep-alive" has been enabled on all the servers.
The value configured for the keep-alive time-out is: _____
- The default gateway has been set to the correct value. (The default gateway should either be a NetScaler or upstream router.) The default gateway is:

- The server port settings (speed, duplex, flow control, monitoring) are the same as the switch port settings.
-

- If the Microsoft® Internet Information Server is used, buffering is enabled on the server.
- If an Apache Server is used, the MaxConn (maximum number of connections) parameter is configured on the server and on the NetScaler.

The MaxConn (maximum number of connections) value that has been set is:

- If a Netscape® Enterprise Server™ is used, the maximum requests per connection parameter is set on the NetScaler. The maximum requests per connection value that has been set is:
-

Software Features Configuration Checklist

- Does the Layer 2 mode feature need to be disabled? (Disable if another Layer 2 device is working in parallel with a NetScaler.)

Reason for enabling or disabling:

- Does the MAC-based forwarding feature need to be disabled? (If the MAC address used by return traffic is different, it should be disabled.)

Reason for enabling or disabling:

- Does host-based reuse need to be disabled? (Is there virtual hosting on the servers?)

Reason for enabling or disabling:

- Do the default settings of the surge protection feature need to be changed?

Reason for changing or not changing:

Access Checklist

- The system IPs can be pinged from the client-side network.
- The system IPs can be pinged from the server-side network.
- The managed server(s) can be pinged through the NetScaler.
- Internet hosts can be pinged from the managed servers.
- The managed server(s) can be accessed through the browser.
- The Internet can be accessed from managed server(s) using the browser.
- The system can be accessed using SSH.
- Admin access to all managed server(s) is working.

Note: When you are using the ping utility, ensure that the pinged server has ICMP ECHO enabled, or your ping will not succeed.

Firewall Checklist

The following firewall requirements have been met:

- UDP 161 (SNMP)
- UDP 162 (SNMP trap)
- TCP/UDP 3010 (GUI)
- HTTP 80 (GUI)
- TCP 22 (SSH)

Load Balancing Traffic on a NetScaler Appliance

Jun 24, 2013

The load balancing feature distributes client requests across multiple servers to optimize resource utilization. In a real-world scenario with a limited number of servers providing service to a large number of clients, a server can become overloaded and degrade the performance of the server farm. A Citrix NetScaler appliance uses load balancing criteria to prevent bottlenecks by forwarding each client request to the server best suited to handle the request when it arrives.

To configure load balancing, you define a virtual server to proxy multiple servers in a server farm and balance the load among them.

When a client initiates a connection to the server, a virtual server terminates the client connection and initiates a new connection with the selected server, or reuses an existing connection with the server, to perform load balancing. The load balancing feature provides traffic management from Layer 4 (TCP and UDP) through Layer 7 (FTP, HTTP, and HTTPS).

The NetScaler appliance uses a number of algorithms, called load balancing methods, to determine how to distribute the load among the servers. The default load balancing method is the Least Connections method.

A typical load balancing deployment consists of the entities described in the following figure.

Figure 1. Load Balancing Architecture

The entities function as follows:

- **Virtual server.** An entity that is represented by an IP address, a port, and a protocol. The virtual server IP address (VIP) is usually a public IP address. The client sends connection requests to this IP address. The virtual server represents a bank of servers.
- **Service.** A logical representation of a server or an application running on a server. Identifies the server's IP address, a port, and a protocol. The services are bound to the virtual servers.
- **Server object.** An entity that is represented by an IP address. The server object is created when you create a service. The IP address of the service is taken as the name of the server object. You can also create a server object and then create

services by using the server object.

- **Monitor.** An entity that tracks the health of the services. The appliance periodically probes the servers using the monitor bound to each service. If a server does not respond within a specified response timeout, and the specified number of probes fails, the service is marked DOWN. The appliance then performs load balancing among the remaining services.

Configuring Load Balancing

Jun 24, 2013

To configure load balancing, you must first create services. Then, you create virtual servers and bind the services to the virtual servers. By default, the NetScaler appliance binds a monitor to each service. After binding the services, verify your configuration by making sure that all of the settings are correct.

Note: After you deploy the configuration, you can display statistics that show how the entities in the configuration are performing. Use the statistical utility or the `stat lb vserver <vserverName>` command.

Optionally, you can assign weights to a service. The load balancing method then uses the assigned weight to select a service. For getting started, however, you can limit optional tasks to configuring some basic persistence settings, for sessions that must maintain a connection to a particular server, and some basic configuration-protection settings.

The following flow chart illustrates the sequence of the configuration tasks.

Figure 1. Sequence of Tasks to Configure Load Balancing

Enabling Load Balancing

Updated: 2013-06-05

Before configuring load balancing, make sure that the load balancing feature is enabled.

To enable load balancing by using the command line interface

At the command prompt, type the following commands to enable load balancing and verify that it is enabled:

- enable feature lb
- show feature

Example

```
> enable feature lb
Done
> show feature
```

Feature	Acronym	Status
1) Web Logging	WL	OFF
2) Surge Protection	SP	OFF
3) Load Balancing	LB	ON
.		
.		
.		
9) SSL Offloading	SSL	ON
.		
.		
.		

Done

To enable load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click OK.
4. In the Enable/Disable Feature(s)? message, click Yes.

Configuring Services and a Virtual Server

Updated: 2013-06-24

When you have identified the services you want to load balance, you can implement your initial load balancing configuration by creating the service objects, creating a load balancing virtual server, and binding the service objects to the virtual server.

To implement the initial load balancing configuration by using the command line interface

At the command prompt, type the following commands to implement and verify the initial configuration:

- add service <name> <IPaddress> <serviceType> <port>
- add lb vserver <vServerName> <serviceType> [<IPaddress> <port>]
- bind lb vserver <name> <serviceName>

- show service bindings <serviceName>

Example

```
> add service service-HTTP-1 10.102.29.5 HTTP 80
```

```
Done
```

```
> add lb vserver vserver-LB-1 HTTP 10.102.29.60 80
```

```
Done
```

```
> bind lb vserver vserver-LB-1 service-HTTP-1
```

```
Done
```

```
> show service bindings service-HTTP-1
```

```
service-HTTP-1 (10.102.29.5:80) - State : DOWN
```

```
1) vserver-LB-1 (10.102.29.60:80) - State : DOWN
```

```
Done
```

To implement the initial load balancing configuration by using the configuration utility

1. Navigate to Traffic Management > Load Balancing.
2. In the details pane, under Getting Started, click Load Balancing wizard, and follow the instructions to create a basic load balancing setup.
3. Return to the navigation pane, expand Load Balancing, and then click Virtual Servers.
4. Select the virtual server that you configured and verify that the parameters displayed at the bottom of the page are correctly configured.
5. Click Open.
6. Verify that each service is bound to the virtual server by confirming that the Active check box is selected for each service on the Services tab.

Choosing and Configuring Persistence Settings

Sep 04, 2013

You must configure persistence on a virtual server if you want to maintain the states of connections on the servers represented by that virtual server (for example, connections used in e-commerce). The appliance then uses the configured load balancing method for the initial selection of a server, but forwards to that same server all subsequent requests from the same client.

If persistence is configured, it overrides the load balancing methods once the server has been selected. If the configured persistence applies to a service that is down, the appliance uses the load balancing methods to select a new service, and the new service becomes persistent for subsequent requests from the client. If the selected service is in an Out Of Service state, it continues to serve the outstanding requests but does not accept new requests or connections. After the shutdown period elapses, the existing connections are closed. The following table lists the types of persistence that you can configure.

Table 1. Limitations on Number of Simultaneous Persistent Connections

Persistence Type	Persistent Connections
Source IP, SSL Session ID, Rule, DESTIP, SRCIPDESTIP	250K
CookieInsert, URL passive, Custom Server ID	Memory limit. In case of CookieInsert, if time out is not 0, any number of connections is allowed until limited by memory.

If the configured persistence cannot be maintained because of a lack of resources on an appliance, the load balancing methods are used for server selection. Persistence is maintained for a configured period of time, depending on the persistence type. Some persistence types are specific to certain virtual servers. The following table shows the relationship.

Table 2. Persistence Types Available for Each Type of Virtual Server

Persistence TypeHeader 1	HTTP	HTTPS	TCP	UDP/IP	SSL_Bridge
Source IP	YES	YES	YES	YES	YES
CookieInsert	YES	YES	NO	NO	NO
SSL Session ID	NO	YES	NO	NO	YES
URL Passive	YES	YES	NO	NO	NO
Custom Server ID	YES	YES	NO	NO	NO
Rule	YES	YES	NO	NO	NO

SRV_DEST_IP	Persistence Type	Header 1	HTTP	HTTPS	YES	YES	UDP/IP	N/A	SSC_Bridge
DEST_IP			N/A	N/A	YES	YES			N/A

You can also specify persistence for a group of virtual servers. When you enable persistence on the group, the client requests are directed to the same selected server regardless of which virtual server in the group receives the client request. When the configured time for persistence elapses, any virtual server in the group can be selected for incoming client requests.

Two commonly used persistence types are persistence based on cookies and persistence based on server IDs in URLs.

Configuring Persistence Based on Cookies

Updated: 2013-08-23

When you enable persistence based on cookies, the NetScaler adds an HTTP cookie into the Set-Cookie header field of the HTTP response. The cookie contains information about the service to which the HTTP requests must be sent. The client stores the cookie and includes it in all subsequent requests, and the NetScaler uses it to select the service for those requests. You can use this type of persistence on virtual servers of type HTTP or HTTPS.

The NetScaler inserts the cookie `<NSC_XXXX>= <ServiceIP> <ServicePort>`

where:

- `<NSC_XXXX>` is the virtual server ID that is derived from the virtual server name.
- `<ServiceIP>` is the hexadecimal value of the IP address of the service.
- `<ServicePort>` is the hexadecimal value of the port of the service.

The NetScaler encrypts ServiceIP and ServicePort when it inserts a cookie, and decrypts them when it receives a cookie.

Note: If the client is not allowed to store the HTTP cookie, the subsequent requests do not have the HTTP cookie, and persistence is not honored.

By default, the NetScaler sends HTTP cookie version 0, in compliance with the Netscape specification. It can also send version 1, in compliance with RFC 2109.

You can configure a timeout value for persistence that is based on HTTP cookies. Note the following:

- If HTTP cookie version 0 is used, the NetScaler inserts the absolute Coordinated Universal Time (GMT) of the cookie's expiration (the expires attribute of the HTTP cookie), calculated as the sum of the current GMT time on a NetScaler, and the timeout value.
- If an HTTP cookie version 1 is used, the NetScaler inserts a relative expiration time (Max-Age attribute of the HTTP cookie). In this case, the client software calculates the actual expiration time.

Note: Most client software currently installed (Microsoft Internet Explorer and Netscape browsers) understand HTTP cookie version 0; however, some HTTP proxies understand HTTP cookie version 1.

If you set the timeout value to 0, the NetScaler does not specify the expiration time, regardless of the HTTP cookie version used. The expiration time then depends on the client software, and such cookies are not valid if that software is shut down. This persistence type does not consume any system resources. Therefore, it can accommodate an unlimited number of persistent clients.

An administrator can use the procedure in the following table to change the HTTP cookie version.

To change the HTTP cookie version by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, click Change HTTP Parameters.
3. In the Configure HTTP Parameters dialog box, under Cookie, select Version 0 or Version 1.

Note: For information about the parameters, see "[Configuring Persistence Based on Cookies](#)."

To configure persistence based on cookies by using the command line interface

At the command prompt, type the following commands to configure persistence based on cookies and verify the configuration:

- set lb vserver <name> -persistenceType COOKIEINSERT
- show lb vserver <name>

Example

```
> set lb vserver vserver-LB-1 -persistenceType COOKIEINSERT
Done
> show lb vserver vserver-LB-1
vserver-LB-1 (10.102.29.60:80) - HTTP  Type: ADDRESS
.
.
.
Persistence: COOKIEINSERT (version 0) Persistence Timeout: 2 min
.
.
.
Done
>
```

To configure persistence based on cookies by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure persistence (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in the Persistence list, select COOKIEINSERT.
4. In the Time-out (min) text box, type the time-out value (for example, 2).
5. Click OK.
6. Verify that the virtual server for which you configured persistence is correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane.

Configuring Persistence Based on Server IDs in URLs

Updated: 2013-08-23

The NetScaler can maintain persistence based on the server IDs in the URLs. In a technique called URL passive persistence, the NetScaler extracts the server ID from the server response and embeds it in the URL query of the client request. The

server ID is an IP address and port specified as a hexadecimal number. The NetScaler extracts the server ID from subsequent client requests and uses it to select the server.

URL passive persistence requires configuring either a payload expression or a policy infrastructure expression specifying the location of the server ID in the client requests. For more information about expressions, see "[Policy Configuration and Reference](#)."

Note: If the server ID cannot be extracted from the client requests, server selection is based on the load balancing method.

Example: Payload Expression

The expression, URLQUERY contains sid= configures the system to extract the server ID from the URL query of a client request, after matching token sid=. Thus, a request with the URL `http://www.citrix.com/index.asp?&sid=c0a864100050` is directed to the server with the IP address `10.102.29.10` and port `80`.

The timeout value does not affect this type of persistence, which is maintained as long as the server ID can be extracted from the client requests. This persistence type does not consume any system resources, so it can accommodate an unlimited number of persistent clients.

Note: For information about the parameters, see "[Load Balancing](#)."

To configure persistence based on server IDs in URLs by using the command line interface

At the command prompt, type the following commands to configure persistence based on server IDs in URLs and verify the configuration:

- `set lb vserver <name> -persistenceType URLPASSIVE`
- `show lb vserver <name>`

Example

```
> set lb vserver vserver-LB-1 -persistenceType URLPASSIVE
Done
> show lb vserver vserver-LB-1
vserver-LB-1 (10.102.29.60:80) - HTTP  Type: ADDRESS
.
.
.
Persistence: URLPASSIVE Persistence Timeout: 2 min
.
.
.
Done
>
```

To configure persistence based on server IDs in URLs by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure persistence (for example, vserver-LB-1), and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in the Persistence list, select URLPASSIVE.
4. In the Time-out (min) text box, type the time-out value (for example, 2).
5. In the Rule text box, enter a valid expression. Alternatively, click Configure next to the Rule text box and use the Create Expression dialog box to create an expression.
6. Click OK.
7. Verify that the virtual server for which you configured persistence is correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane.

Configuring Features to Protect the Load Balancing Configuration

Jun 24, 2013

You can configure URL redirection to provide notifications of virtual server malfunctions, and you can configure backup virtual servers to take over if a primary virtual server becomes unavailable.

Configuring URL Redirection

Updated: 2013-06-24

You can configure a redirect URL to communicate the status of the appliance in the event that a virtual server of type HTTP or HTTPS is down or disabled. This URL can be a local or remote link. The appliance uses HTTP 302 redirect.

Redirects can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL), the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Note: If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. In this case, a redirect is used when both the primary and backup virtual servers are down.

To configure a virtual server to redirect client requests to a URL by using the command line interface

At the command prompt, type the following commands to configure a virtual server to redirect client requests to a URL and verify the configuration:

- `set lb vserver <name> -redirectURL <URL>`
- `show lb vserver <name>`

Example

```
> set lb vserver vserver-LB-1 -redirectURL http://www.newdomain.com/mysite/maintenance
```

```
Done
```

```
> show lb vserver vserver-LB-1
```

```
vserver-LB-1 (10.102.29.60:80) - HTTP Type: ADDRESS
```

```
State: DOWN
```

```
Last state change was at Wed Jun 17 08:56:34 2009 (+666 ms)
```

```
.
```

```
.
```

```
.
```

```
Redirect URL: http://www.newdomain.com/mysite/maintenance
```

```
.
```

```
.
```

```
.
```

```
Done
```

```
>
```

To configure a virtual server to redirect client requests to a URL by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure URL redirection (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in the Redirect URL text box, type the URL (for example, <http://www.newdomain.com/mysite/maintenance>), and then click OK.
4. Verify that the redirect URL you configured for the server appears in the Details section at the bottom of the pane.

Configuring Backup Virtual Servers

Updated: 2013-06-24

If the primary virtual server is down or disabled, the appliance can direct the connections or client requests to a backup virtual server that forwards the client traffic to the services. The appliance can also send a notification message to the client regarding the site outage or maintenance. The backup virtual server is a proxy and is transparent to the client.

You can configure a backup virtual server when you create a virtual server or when you change the optional parameters of an existing virtual server. You can also configure a backup virtual server for an existing backup virtual server, thus creating a cascaded backup virtual server. The maximum depth of cascading backup virtual servers is 10. The appliance searches for a backup virtual server that is up and accesses that virtual server to deliver the content.

You can configure URL redirection on the primary for use when the primary and the backup virtual servers are down or have reached their thresholds for handling requests.

Note: If no backup virtual server exists, an error message appears, unless the virtual server is configured with a redirect URL. If both a backup virtual server and a redirect URL are configured, the backup virtual server takes precedence.

To configure a backup virtual server by using the command line interface

At the command prompt, type the following commands to configure a backup server and verify the configuration:

- `set lb vserver <name> [-backupVserver <string>]`
- `show lb vserver <name>`

Example

```
> set lb vserver vserver-LB-1 -backupVserver vserver-LB-2
Done
> show lb vserver vserver-LB-1
vserver-LB-1 (10.102.29.60:80) - HTTP  Type: ADDRESS
State: DOWN
Last state change was at Wed Jun 17 08:56:34 2009 (+661 ms)
.
.
.
Backup: vserver-LB-2
.
.
```

Done

>

To set up a backup virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the backup virtual server (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in the Backup Virtual Server list, select the backup virtual server (for example, vserver-LB-2), and then click OK.
4. Verify that the backup virtual server you configured appears in the Details section at the bottom of the pane.
Note: If the primary server goes down and then comes back up, and you want the backup virtual server to function as the primary server until you explicitly reestablish the primary virtual server, select the Disable Primary When Down check box.

A Typical Load Balancing Scenario

Aug 23, 2013

In a load balancing setup, the NetScaler appliances are logically located between the client and the server farm, and they manage traffic flow to the servers.

The following figure shows the topology of a basic load balancing configuration.

Figure 1. Basic Load Balancing Topology

The virtual server selects the service and assigns it to serve client requests. Consider the scenario in the preceding figure, where the services service-HTTP-1 and service-HTTP-2 are created and bound to the virtual server named virtual server-LB-1. Virtual server-LB-1 forwards the client request to either service-HTTP-1 or service-HTTP-2. The system selects the service for each request by using the Least Connections load balancing method. The following table lists the names and values of the basic entities that must be configured on the system.

Table 1. LB Configuration Parameter Values

Entity Type	Required parameters and sample values			
	Name	IP Address	Port	Protocol
Virtual Server	vserver-LB-1	10.102.29.60	80	HTTP
Services	service-HTTP-1	10.102.29.5	8083	HTTP
	service-HTTP-2	10.102.29.6	80	HTTP
Monitors	Default	None	None	None

Entity Type	Required parameters and sample values			
The following figure shows the load balancing sample values and required parameters that are described in the preceding table.	Name	IP Address	Port	Protocol

Figure 2. Load Balancing Entity Model

The following tables list the commands used to configure this load balancing setup by using the command line interface.

Table 2. Initial Configuration Tasks

Task	Command
To enable load balancing	enable feature lb
To create a service named service-HTTP-1	add service service-HTTP-1 10.102.29.5 HTTP 80
To create a service named service-HTTP-2	add service service-HTTP-2 10.102.29.6 HTTP 80
To create a virtual server named vserver-LB-1	add lb vserver vserver-LB-1 HTTP 10.102.29.60 80
To bind a service named service-HTTP-1 to a virtual server named vserver-LB-1	bind lb vserver vserver-LB-1 service-HTTP-1
To bind a service named service-HTTP-2 to a virtual server named vserver-LB-1	bind lb vserver vserver-LB-1 service-HTTP-2

For more information about the initial configuration tasks, see "[Enabling Load Balancing](#)" and "[Configuring Services and a Vserver.](#)"

Table 3. Verification Tasks

Task	Command
To view the properties of a virtual server named vserver-LB-1	show lb vserver vserver-LB-1
To view the statistics of a virtual server named vserver-LB-1	stat lb vserver vserver-LB-1
To view the properties of a service named service-HTTP-1	show service service-HTTP-1
To view the statistics of a service named service-HTTP-1	stat service service-HTTP-1
To view the bindings of a service named service-HTTP-1	show service bindings service-HTTP-1

Table 4. Customization Tasks

Task	Command
To configure persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType SOURCEIP -persistenceMask 255.255.255.255 -timeout 2
To configure COOKIEINSERT persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType COOKIEINSERT
To configure URLPassive persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType URLPASSIVE
To configure a virtual server to redirect the client request to a URL on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -redirectURL http://www.newdomain.com/mysite/maintenance
To set a backup virtual server on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -backupVserver vserver-LB-2

For more information about configuring persistence, see "[Choosing and Configuring Persistence Settings](#)." For information about configuring a virtual server to redirect a client request to a URL and setting up a backup virtual server, see "[Configuring Features to Protect the Load Balancing Configuration](#)."

Accelerating Load Balanced Traffic by Using Compression

Aug 22, 2013

Compression is a popular means of optimizing bandwidth usage, and most web browsers support compressed data. If you enable the compression feature, the NetScaler appliance intercepts requests from clients and determines whether the client can accept compressed content. After receiving the HTTP response from the server, the appliance examines the content to determine whether it is compressible. If the content is compressible, the appliance compresses it, modifies the response header to indicate the type of compression performed, and forwards the compressed content to the client.

NetScaler compression is a policy-based feature. A policy filters requests and responses to identify responses to be compressed, and specifies the type of compression to apply to each response. The appliance provides several built-in policies to compress common MIME types such as text/html, text/plain, text/xml, text/css, text/rtf, application/msword, application/vnd.ms-excel, and application/vnd.ms-powerpoint. You can also create custom policies. The appliance does not compress compressed MIME types such as application/octet-stream, binary, bytes, and compressed image formats such as GIF and JPEG.

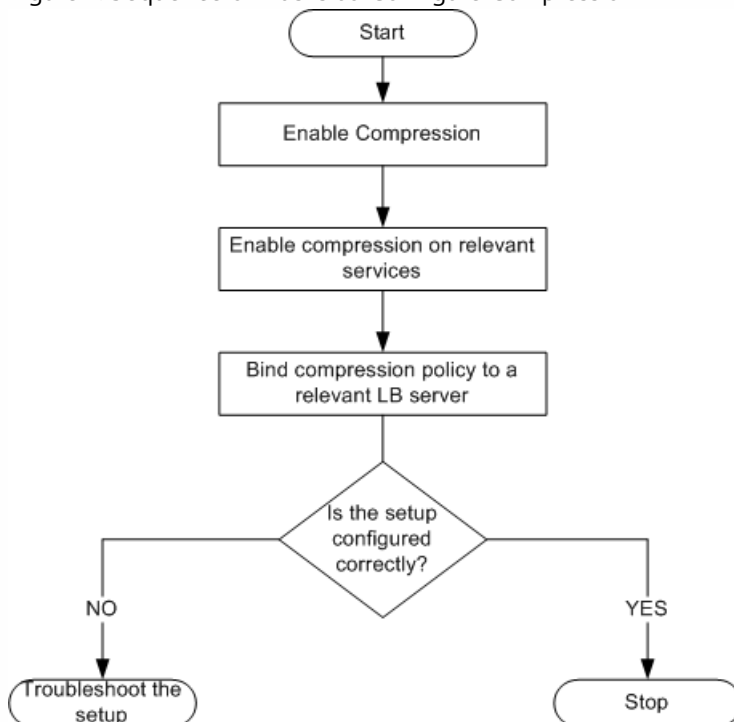

To configure compression, you must enable it globally and on each service that will provide responses that you want compressed. If you have configured virtual servers for load balancing or content switching, you should bind the policies to the virtual servers. Otherwise, the policies apply to all traffic that passes through the appliance.

Compression Configuration Task Sequence

Updated: 2013-08-22

The following flow chart shows the sequence of tasks for configuring basic compression in a load balancing setup.

Figure 1. Sequence of Tasks to Configure Compression

Note: The steps in the above figure assume that load balancing has already been configured.

Enabling Compression

Updated: 2013-06-07

By default, compression is not enabled. You must enable the compression feature to allow compression of HTTP responses that are sent to the client.

To enable compression by using the command line interface

At the command prompt, type the following commands to enable compression and verify the configuration:

- enable ns feature CMP
- show ns feature

Example

```
> enable ns feature CMP
```

```
Done
```

```
> show ns feature
```

	Feature	Acronym	Status
	-----	-----	-----
1)	Web Logging	WL	ON
2)	Surge Protection	SP	OFF
.			
7)	Compression Control	CMP	ON
8)	Priority Queuing	PQ	OFF
.			

```
Done
```

To enable compression by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Compression check box, and then click OK.
4. In the Enable/Disable Feature(s)? dialog box, click Yes.

Configuring Services to Compress Data

Updated: 2013-08-22

In addition to enabling compression globally, you must enable it on each service that will deliver files to be compressed.

To enable compression on a service by using the command line

At the command prompt, type the following commands to enable compression on a service and verify the configuration:

- set service <name> -CMP YES
- show service <name>

Example

```
> show service SVC_HTTP1
SVC_HTTP1 (10.102.29.18:80) - HTTP
State: UP
Last state change was at Tue Jun 16 06:19:14 2009 (+737 ms)
Time since last state change: 0 days, 03:03:37.200
Server Name: 10.102.29.18
Server ID : 0 Monitor Threshold : 0
Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive(CKA): NO
Access Down Service: NO
TCP Buffering(TCPB): NO
HTTP Compression(CMP): YES
Idle timeout: Client: 180 sec Server: 360 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: OFF
Down state flush: ENABLED
```

```
1) Monitor Name: tcp-default
State: DOWN Weight: 1
Probes: 1095 Failed [Total: 1095 Current: 1095]
Last response: Failure - TCP syn sent, reset received.
Response Time: N/A
Done
```

To enable compression on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure compression (for example, service-HTTP-1), and then click Open.
3. On the Advanced tab, under Settings, select the Compression check box, and then click OK.
4. Verify that, when the service is selected, HTTP Compression(CMP): ON appears in the **Details** section at the bottom of the pane.

Binding a Compression Policy to a Virtual Server

Updated: 2013-09-04

If you bind a policy to a virtual server, the policy is evaluated only by the services associated with that virtual server. You can bind compression policies to a virtual server either from the Configure Virtual Server (Load Balancing) dialog box or from the Compression Policy Manager dialog box. This topic includes instructions to bind compression policies to a load balancing virtual server by using the Configure Virtual Server (Load Balancing) dialog box. For information about how you can bind a compression policy to a load balancing virtual server by using the Compression Policy Manager dialog box, see "[Configuring and Binding Policies with the Policy Manager](#)."

To bind or unbind a compression policy to a virtual server by using the command line

At the command prompt, type the following commands to bind or unbind a compression policy to a load balancing virtual server and verify the configuration:

- (bind | unbind) lb vserver <name> -policyName <string>
- show lb vserver <name>

Example

```
> bind lb vserver lbvip -policyName ns_cmp_msapp
Done
> show lb vserver lbvip
lbvip (8.7.6.6:80) - HTTP    Type: ADDRESS
State: UP
Last state change was at Thu May 28 05:37:21 2009 (+685 ms)
Time since last state change: 19 days, 04:26:50.470
Effective State: UP
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Port Rewrite : DISABLED
No. of Bound Services : 1 (Total)    1 (Active)
Configured Method: LEASTCONNECTION
Current Method: Round Robin, Reason: Bound service's state changed to UP
Mode: IP
Persistence: NONE
Vserver IP and Port insertion: OFF
Push: DISABLED Push VServer:
Push Multi Clients: NO
Push Label Rule:

Bound Service Groups:
1)  Group Name: Service-Group-1

1) Service-Group-1 (10.102.29.252: 80) - HTTP State: UP Weight:          1

1) Policy : ns_cmp_msapp Priority:0
Done
```

To bind or unbind a compression policy to a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server to which you want to bind or unbind a compression policy (for example, Vserver-LB-1), and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, on the Policies tab, click Compression.
4. Do one of the following:
 - To bind a compression policy, click Insert Policy, and then select the policy you want to bind to the virtual server.
 - To unbind a compression policy, click the name of the policy you want to unbind from the virtual server, and then click Unbind Policy.
5. Click OK.

Securing Load Balanced Traffic by Using SSL

Jan 31, 2011

The Citrix NetScaler SSL offload feature transparently improves the performance of web sites that conduct SSL transactions. By offloading CPU-intensive SSL encryption and decryption tasks from the local web server to the appliance, SSL offloading ensures secure delivery of web applications without the performance penalty incurred when the server processes the SSL data. Once the SSL traffic is decrypted, it can be processed by all standard services. The SSL protocol works seamlessly with various types of HTTP and TCP data and provides a secure channel for transactions using such data.

To configure SSL, you must first enable it. Then, you configure HTTP or TCP services and an SSL virtual server on the appliance, and bind the services to the virtual server. You must also add a certificate-key pair and bind it to the SSL virtual server. If you use Outlook Web Access servers, you must create an action to enable SSL support and a policy to apply the action. An SSL virtual server intercepts incoming encrypted traffic and decrypts it by using a negotiated algorithm. The SSL virtual server then forwards the decrypted data to the other entities on the appliance for appropriate processing.

This document includes the following:

- [SSL Configuration Task Sequence](#)
- [Enabling SSL Offload](#)
- [Creating HTTP Services](#)
- [Adding an SSL-Based Virtual Server](#)
- [Binding Services to the SSL Virtual Server](#)
- [Adding a Certificate Key Pair](#)
- [Binding an SSL Certificate Key Pair to the Virtual Server](#)
- [Configuring Support for Outlook Web Access](#)

SSL Configuration Task Sequence

To configure SSL, you must first enable it. Then, you must create an SSL virtual server and HTTP or TCP services on the NetScaler. Finally, you must bind a valid SSL certificate and the configured services to the SSL virtual server.

An SSL virtual server intercepts incoming encrypted traffic and decrypts it using a negotiated algorithm. The SSL virtual server then forwards the decrypted data to the other entities on the NetScaler for appropriate processing.

The following flow chart shows the sequence of tasks for configuring a basic SSL offload setup.

Figure 1. Sequence of Tasks to Configure SSL Offloading

Enabling SSL Offload

Updated: 2013-06-05

You should enable the SSL feature before configuring SSL offload. You can configure SSL-based entities on the appliance without enabling the SSL feature, but they will not work until you enable SSL.

To enable SSL by using the command line interface

At the command prompt, type the following commands to enable SSL Offload and verify the configuration:

- enable ns feature SSL
- show ns feature

Example

```
> enable ns feature ssl
Done
> show ns feature
Feature Acronym Status
-----
1) Web Logging WL ON
2) SurgeProtection SP OFF
3) Load Balancing LB ON . . .
9) SSL Offloading SSL ON
10) Global Server Load Balancing GSLB ON . .
Done >
```

To enable SSL by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. Select the SSL Offloading check box, and then click OK.
4. In the Enable/Disable Feature(s)? message box, click Yes.

Creating HTTP Services

Updated: 2013-08-23

A service on the appliance represents an application on a server. Once configured, services are in the disabled state until the appliance can reach the server on the network and monitor its status. This topic covers the steps to create an HTTP service.

Note: For TCP traffic, perform the procedures in this and the following topics, but create TCP services instead of HTTP services.

To add an HTTP service by using the command line interface

At the command prompt, type the following commands to add a HTTP service and verify the configuration:

- add service <name> (<IP> | <serverName>) <serviceType> <port>
- show service <name>

```
> add service SVC_HTTP1 10.102.29.18 HTTP 80
Done
> show service SVC_HTTP1
  SVC_HTTP1 (10.102.29.18:80) - HTTP
  State: UP
  Last state change was at Wed Jul 15 06:13:05 2009
```

```
Time since last state change: 0 days, 00:00:15.350
Server Name: 10.102.29.18
Server ID : 0  Monitor Threshold : 0
Max Conn: 0  Max Req: 0  Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive(CKA): NO
Access Down Service: NO
TCP Buffering(TCPB): NO
HTTP Compression(CMP): YES
Idle timeout: Client: 180 sec  Server: 360 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: OFF
Down state flush: ENABLED
```

- 1) Monitor Name: tcp-default
State: UP Weight: 1
Probes: 4 Failed [Total: 0 Current: 0]
Last response: Success - TCP syn+ack received.
Response Time: N/A

Done

To add an HTTP service by using the configuration utility

1. Navigate to Traffic Management > SSL Offload > Services.
2. In details pane, click Add.
3. In the Create Service dialog box, in the Service Name, Server, and Port text boxes, type the name of the service, IP address, and port (for example, SVC_HTTP1, 10.102.29.18, and 80).
4. In the Protocol list, select the type of the service (for example, HTTP).
5. Click Create, and then click Close. The HTTP service you configured appears in the Services page.
6. Verify that the parameters you configured are correctly configured by selecting the service and viewing the Details section at the bottom of the pane.

Adding an SSL-Based Virtual Server

Updated: 2013-06-05

In a basic SSL offloading setup, the SSL virtual server intercepts encrypted traffic, decrypts it, and sends the clear text messages to the services that are bound to the virtual server. Offloading CPU-intensive SSL processing to the appliance allows the back-end servers to process a greater number of requests.

To add an SSL-based virtual server by using the command line interface

At the command prompt, type the following commands to create an SSL-based virtual server and verify the configuration:

- add lb vserver <name> <serviceType> [<IPAddress> <port>]
- show lb vserver <name>

Example

```
> add lb vserver vserver-SSL-1 SSL 10.102.29.50 443
Done
> show lb vserver vserver-SSL-1
vserver-SSL-1 (10.102.29.50:443) - SSL Type: ADDRESS
State: DOWN[Certkey not bound] Last state change was at Tue Jun 16 06:33:08 2009 (+176 ms)
Time since last state change: 0 days, 00:03:44.120
Effective State: DOWN Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
No. of Bound Services : 0 (Total) 0 (Active)
Configured Method: LEASTCONNECTION Mode: IP
Persistence: NONE
Vserver IP and Port insertion: OFF
Push: DISABLED Push VServer: Push Multi Clients: NO Push Label Rule: Done
```

Caution: To ensure secure connections, you must bind a valid SSL certificate to the SSL-based virtual server before you enable it.

To add an SSL-based virtual server by using the configuration utility

1. Navigate to Traffic Management > SSL Offload > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (SSL Offload) dialog box, in the Name, IP Address, and Port text boxes, type the name of the virtual server, IP address, and port (for example, Vserver-SSL-1, 10.102.29.50, and 443).
4. In the Protocol list, select the type of the virtual server, for example, SSL.
5. Click Create, and then click Close.
6. Verify that the parameters you configured are correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane. The virtual server is marked as DOWN because a certificate-key pair and services have not been bound to it.

Caution: To ensure secure connections, you must bind a valid SSL certificate to the SSL-based virtual server before you enable it.

Binding Services to the SSL Virtual Server

Updated: 2013-08-23

After decrypting the incoming data, the SSL virtual server forwards the data to the services that you have bound to the virtual server.

Data transfer between the appliance and the servers can be encrypted or in clear text. If the data transfer between the appliance and the servers is encrypted, the entire transaction is secure from end to end. For more information about configuring the system for end-to-end security, see "[SSL Offload and Acceleration](#)."

To bind a service to a virtual server by using the command line interface

At the command prompt, type the following commands to bind service to the SSL virtual server and verify the configuration:

- bind lb vserver <name> <serviceName>
- show lb vserver <name>

Example

```
> bind lb vserver vserver-SSL-1 SVC_HTTP1
Done
> show lb vserver vserver-SSL-1 vserver-SSL-1 (10.102.29.50:443) - SSL Type:
ADDRESS State: DOWN[Certkey not bound]
Last state change was at Tue Jun 16 06:33:08 2009 (+174 ms)
Time since last state change: 0 days, 00:31:53.70
Effective State: DOWN Client Idle
Timeout: 180 sec
Down state flush: ENABLED Disable Primary Vserver On Down :
DISABLED No. of Bound Services : 1 (Total) 0 (Active)
Configured Method: LEASTCONNECTION Mode: IP Persistence: NONE Vserver IP and
Port insertion: OFF Push: DISABLED Push VServer: Push Multi Clients: NO Push Label Rule:

1) SVC_HTTP1 (10.102.29.18: 80) - HTTP
State: DOWN Weight: 1
Done
```

To bind a service to a virtual server by using the configuration utility

1. Navigate to Traffic Management > SSL Offload > Virtual Servers.
2. In the details pane, select a virtual server, and then click Open.
3. On the Services tab, in the Active column, select the check boxes next to the services that you want to bind to the selected virtual server.
4. Click OK.
5. Verify that the Number of Bound Services counter in the Details section at the bottom of the pane is incremented by the number of services that you bound to the virtual server.

Adding a Certificate Key Pair

Updated: 2013-06-24

An SSL certificate is an integral element of the SSL Key-Exchange and encryption/decryption process. The certificate is used during SSL handshake to establish the identity of the SSL server. You can use a valid, existing SSL certificate that you have on the NetScaler appliance, or you can create your own SSL certificate. The appliance supports RSA/DSA certificates of up to 4096 bits.

Note: Citrix recommends that you use a valid SSL certificate that has been issued by a trusted certificate authority. Invalid certificates and self-created certificates are not compatible with all SSL clients.

Before a certificate can be used for SSL processing, you must pair it with its corresponding key. The certificate key pair is then bound to the virtual server and used for SSL processing.

To add a certificate key pair by using the command line interface

At the command prompt, type the following commands to create a certificate key pair and verify the configuration:

- add ssl certKey <certkeyName> -cert <string> [-key <string>]
- show sslcertkey <name>

Example

```
> add ssl certKey CertKey-SSL-1 -cert ns-root.cert -key ns-root.key
Done
> show sslcertkey CertKey-SSL-1
Name: CertKey-SSL-1 Status: Valid,
Days to expiration:4811 Version: 3
Serial Number: 00 Signature Algorithm: md5WithRSAEncryption Issuer: C=US,ST=California,L=San
Jose,O=Citrix ANG,OU=NS Internal,CN=default
Validity Not Before: Oct 6 06:52:07 2006 GMT Not After : Aug 17 21:26:47 2022 GMT
Subject: C=US,ST=California,L=San Jose,O=Citrix ANG,OU=NS Internal,CN=default Public Key
Algorithm: rsaEncryption Public Key
size: 1024
Done
```

To add a certificate key pair by using the configuration utility

1. Navigate to Traffic Management > SSL > Certificates.
2. In the details pane, click Add.
3. In the Install Certificate dialog box, in the Certificate-Key Pair Name text box, type a name for the certificate key pair you want to add, for example, Certkey-SSL-1.
4. Under Details, in Certificate File Name, click Browse (Appliance) to locate the certificate. Both the certificate and the key are stored in the /nsconfig/ssl/ folder on the appliance. To use a certificate present on the local system, select Local.
5. Select the certificate you want to use, and then click Select.
6. In Private Key File Name, click Browse (Appliance) to locate the private key file. To use a private key present on the local system, select Local.
7. Select the key you want to use and click Select. To encrypt the key used in the certificate key pair, type the password to be used for encryption in the Password text box.
8. Click Install.
9. Double-click the certificate key pair and, in the Certificate Details window, verify that the parameters have been configured correctly and saved.

Binding an SSL Certificate Key Pair to the Virtual Server

Updated: 2013-06-24

After you have paired an SSL certificate with its corresponding key, you must bind the certificate key pair to the SSL virtual server so that it can be used for SSL processing. Secure sessions require establishing a connection between the client computer and an SSL-based virtual server on the appliance. SSL processing is then carried out on the incoming traffic at the virtual server. Therefore, before enabling the SSL virtual server on the appliance, you need to bind a valid SSL certificate to the SSL virtual server.

To bind an SSL certificate key pair to a virtual server by using the command line

interface

At the command prompt, type the following commands to bind an SSL certificate key pair to a virtual server and verify the configuration:

- bind ssl vserver <vServerName> -certkeyName <string>
- show ssl vserver <name>

Example

```
> bind ssl vserver Vserver-SSL-1 -certkeyName CertKey-SSL-1
Done
> show ssl vserver Vserver-SSL-1
```

Advanced SSL configuration for VServer Vserver-SSL-1:

DH: DISABLED

Ephemeral RSA: ENABLED Refresh Count: 0

Session Reuse: ENABLED Timeout: 120 seconds

Cipher Redirect: ENABLED

SSLv2 Redirect: ENABLED

ClearText Port: 0

Client Auth: DISABLED

SSL Redirect: DISABLED

Non FIPS Ciphers: DISABLED

SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: CertKey-SSL-1 Server Certificate

1) Cipher Name: DEFAULT

Description: Predefined Cipher Alias

Done

To bind an SSL certificate key pair to a virtual server by using the configuration utility

1. Navigate to Traffic Management > SSL Offload > Virtual Servers.
2. Select the virtual server to which you want to bind the certificate key pair, for example, Vserver-SSL-1, and click Open.
3. In the Configure Virtual Server (SSL Offload) dialog box, on the SSL Settings tab, under Available, select the certificate key pair that you want to bind to the virtual server (for example, Certkey-SSL-1), and then click Add.
4. Click OK.
5. Verify that the certificate key pair that you selected appears in the Configured area.

Configuring Support for Outlook Web Access

If you use Outlook Web Access (OWA) servers on your NetScaler appliance, you must configure the appliance to insert a special header field, FRONT-END-HTTPS: ON, in HTTP requests directed to the OWA servers, so that the servers generate URL links as https:// instead of http://.

Note: You can enable OWA support for HTTP-based SSL virtual servers and services only. You cannot apply it for TCP-based SSL virtual servers and services.

To configure OWA support, do the following:

- Create an SSL action to enable OWA support.
- Create an SSL policy.
- Bind the policy to the SSL virtual server.

Creating an SSL Action to Enable OWA Support

Updated: 2013-06-24

Before you can enable Outlook Web Access (OWA) support, you must create an SSL action. SSL actions are bound to SSL policies and triggered when incoming data matches the rule specified by the policy.

To create an SSL action to enable OWA support by using the command line interface

At the command prompt, type the following commands to create an SSL action to enable OWA support and verify the configuration:

- add ssl action <name> -OWASupport ENABLED
- show SSL action <name>

```
> add ssl action Action-SSL-OWA -OWASupport enabled
Done
> show SSL action Action-SSL-OWA
Name: Action-SSL-OWA
Data Insertion Action: OWA
Support: ENABLED
Done
```

To create an SSL action to enable OWA support by using the configuration utility

1. Navigate to Traffic Management > SSL > Policies.
2. In the details pane, on the Actions tab, click Add.
3. In the Create SSL Action dialog box, in the Name text box, type Action-SSL-OWA.
4. Under Outlook Web Access, select Enabled.
5. Click Create, and then click Close.
6. Verify that Action-SSL-OWA appears in the **SSL Actions** page.

Creating SSL Policies

Updated: 2013-09-04

SSL policies are created by using the policy infrastructure. Each SSL policy has an SSL action bound to it, and the action is carried out when incoming traffic matches the rule that has been configured in the policy.

To create an SSL policy by using the command line interface

At the command prompt, type the following commands to configure an SSL policy and verify the configuration:

- add ssl policy <name> -rule <expression> -reqAction <string>
- show ssl policy <name>

Example

```
> add ssl policy Policy-SSL-1 -rule ns_true -reqaction Action-SSL-OWA
Done
> show ssl policy Policy-SSL-1
Name: Policy-SSL-1   Rule: ns_true
Action: Action-SSL-OWA Hits: 0
Policy is bound to following entities
1) PRIORITY : 0
Done
```

To create an SSL policy by using the configuration utility

1. Navigate to Traffic Management > SSL > Policies.
2. In the details pane, click Add.
3. In the Create SSL Policy dialog box, in the Name text box, type the name of the SSL Policy (for example, Policy-SSL-1).
4. In Request Action, select the configured SSL action that you want to associate with this policy (for example, Action-SSL-OWA). The `ns_true` general expression applies the policy to all successful SSL handshake traffic. However, if you need to filter specific responses, you can create policies with a higher level of detail. For more information about configuring granular policy expressions, see "[Understanding Policies and Expressions](#)."
5. In Named Expressions, choose the built-in general expression `ns_true` and click Add Expression. The expression `ns_true` now appears in the Expression text box.
6. Click Create, and then click Close.
7. Verify that the policy is correctly configured by selecting the policy and viewing the Details section at the bottom of the pane.

Binding the SSL Policy to an SSL Virtual Server

Updated: 2013-06-24

After you configure an SSL policy for Outlook Web Access, bind the policy to a virtual server that will intercept incoming Outlook traffic. If the incoming data matches any of the rules configured in the SSL policy, the policy is triggered and the action associated with it is carried out.

To bind an SSL policy to an SSL virtual server by using the command line interface

At the command prompt, type the following commands to bind an SSL policy to an SSL virtual server and verify the configuration:

- `bind ssl vserver <vServerName> -policyName <string>`
- `show ssl vserver <name>`

Example

```
> bind ssl vserver Vserver-SSL-1 -policyName Policy-SSL-1
Done
> show ssl vserver Vserver-SSL-1
Advanced SSL configuration for VServer Vserver-SSL-1:
DH: DISABLED
Ephemeral RSA: ENABLED      Refresh Count: 0
Session Reuse: ENABLED     Timeout: 120 seconds
Cipher Redirect: ENABLED
```

SSLv2 Redirect: ENABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: CertKey-SSL-1 Server Certificate

1) Policy Name: Policy-SSL-1
Priority: 0

1) Cipher Name: DEFAULT
Description: Predefined Cipher Alias

Done

>

To bind an SSL policy to an SSL virtual server by using the configuration utility

1. Navigate to Traffic Management > SSL Offload > Virtual Servers.
2. In the details pane, select the virtual server (for example, Vserver-SSL-1), and then click Open.
3. In the Configure Virtual Server (SSL Offload) dialog box, click Insert Policy, and then select the policy that you want to bind to the SSL virtual server. Optionally, you can double-click the Priority field and type a new priority level.
4. Click OK.

Features at a Glance

Sep 04, 2013

Citrix NetScaler features can be configured independently or in combinations to address specific needs. Although some features fit more than one category, the numerous NetScaler features can generally be categorized as application switching and traffic management features, application acceleration features, and application security and firewall features, and an application visibility feature.

To understand the order in which the features perform their processing, see "[Processing Order of Features.](#)"

This document includes the following:

- [Application Switching and Traffic Management Features](#)
- [Application Acceleration Features](#)
- [Application Security and Firewall Features](#)
- [Application Visibility Feature](#)
- [Cloud Integration Feature](#)

Application Switching and Traffic Management Features

Aug 26, 2016

SSL Offloading

Transparently offloads SSL encryption and decryption from web servers, freeing server resources to service content requests. SSL places a heavy burden on an application's performance and can render many optimization measures ineffective. SSL offload and acceleration allow all the benefits of Citrix Request Switching technology to be applied to SSL traffic, ensuring secure delivery of web applications without degrading end-user performance.

For more information, see "[SSL Offload and Acceleration](#)."

Access Control Lists

Compares incoming packets to Access Control Lists (ACLs). If a packet matches an ACL rule, the action specified in the rule is applied to the packet. Otherwise, the default action (ALLOW) is applied and the packet is processed normally. For the appliance to compare incoming packets to the ACLs, you have to apply the ACLs. All ACLs are enabled by default, but you have to apply them in order for the NetScaler to compare incoming packets against them. If an ACL is not required to be a part of the lookup table, but still needs to be retained in the configuration, it should be disabled before the ACLs are applied. A NetScaler does not compare incoming packets to disabled ACLs.

For more information, see "[Access Control List](#)."

Load Balancing

Load balancing decisions are based on a variety of algorithms, including round robin, least connections, weighted least bandwidth, weighted least packets, minimum response time, and hashing based on URL, domain source IP, or destination IP. Both the TCP and UDP protocols are supported, so the NetScaler can load balance all traffic that uses those protocols as the underlying carrier (for example, HTTP, HTTPS, UDP, DNS, NNTP, and general firewall traffic). In addition, the NetScaler can maintain session persistence based on source IP, cookie, server, group, or SSL session. It allows users to apply custom Extended Content Verification (ECV) to servers, caches, firewalls and other infrastructure devices to ensure that these systems are functioning properly and are providing the right content to users. It can also perform health checks using ping, TCP, or HTTP URL, and the user can create monitors based on Perl scripts. To provide high-scale WAN optimization, the CloudBridge appliances deployed at data centers can be load balanced through NetScaler appliances. The bandwidth and number of concurrent sessions can be improved significantly.

For more information, see "[Load Balancing](#)."

Traffic Domains

Traffic domains provide a way to create logical ADC partitions within a single NetScaler appliance. They enable you to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments whose resources do not interact with each other. An application belonging to a specific traffic domain communicates only with entities, and processes traffic, within that domain. Traffic belonging to one traffic domain cannot cross the boundary of another traffic domain. Therefore, you can use duplicate IP addresses on the appliance as long as an address is not duplicated within the same domain.

For more information, see "[Traffic Domains](#)."

Network Address Translation

Network address translation (NAT) involves modification of the source and/or destination IP addresses, and/or the TCP/UDP port numbers, of IP packets that pass through the NetScaler appliance. Enabling NAT on the appliance enhances

the security of your private network, and protects it from a public network such as the Internet, by modifying your network's source IP addresses when data passes through the NetScaler.

The NetScaler appliance supports the following types of network address translation:

INAT—In Inbound NAT (INAT), an IP address (usually public) configured on the NetScaler appliance listens to connection requests on behalf of a server. For a request packet received by the appliance on a public IP address, the NetScaler replaces the destination IP address with the private IP address of the server. In other words, the appliance acts as a proxy between clients and the server. INAT configuration involves INAT rules, which define a 1:1 relationship between the IP address on the NetScaler appliance and the IP address of the server.

RNAT—In Reverse Network Address Translation (RNAT), for a session initiated by a server, the NetScaler appliance replaces the source IP address in the packets generated by the server with an IP address (type SNIP) configured on the appliance. The appliance thereby prevents exposure of the server's IP address in any of the packets generated by the server. An RNAT configuration involves an RNAT rule, which specifies a condition. The appliance performs RNAT processing on those packets that match the condition.

Stateless NAT46 Translation—Stateless NAT46 enables communication between IPv4 and IPv6 networks, by way of IPv4 to IPv6 packet translation and vice versa, without maintaining any session information on the NetScaler appliance. A stateless NAT46 configuration involves an IPv4-IPv6 INAT rule and an NAT46 IPv6 prefix.

Stateful NAT64 Translation—The stateful NAT64 feature enables communication between IPv4 clients and IPv6 servers through IPv6 to IPv4 packet translation, and vice versa, while maintaining session information on the NetScaler appliance. A stateful NAT64 configuration involves an NAT64 rule and an NAT64 IPv6 prefix.

For more information, see "[Configuring Network Address Translation](#)."

Multipath TCP Support

NetScaler appliances support Multipath TCP (MPTCP). MPTCP is a TCP/IP protocol extension that identifies and uses multiple paths available between hosts to maintain the TCP session. You must enable MPTCP on a TCP profile and bind it to a virtual server. When MPTCP is enabled, the virtual server functions as an MPTCP gateway and converts MPTCP connections with the clients to TCP connections that it maintains with the servers.

For more information, see "[MPTCP \(Multi-Path TCP\)](#)."

Content Switching

Determines the server to which to send the request on the basis of configured content switching policies. Policy rules can be based on the IP address, URL, and HTTP headers. This allows switching decisions to be based on user and device characteristics such as who the user is, what type of agent is being used, and what content the user requested.

For more information, see "[Content Switching](#)."

Global Server Load Balancing (GSLB)

Extends the traffic management capabilities of a NetScaler to include distributed Internet sites and global enterprises. Whether installations are spread across multiple network locations or multiple clusters in a single location, the NetScaler maintains availability and distributes traffic across them. It makes intelligent DNS decisions to prevent users from being sent to a site that is down or overloaded. When the proximity-based GSLB method is enabled, the NetScaler can make load balancing decisions based on the proximity of the client's local DNS server (LDNS) in relation to different sites. The main benefit of the proximity-based GSLB method is faster response time resulting from the selection of the closest available site.

For more information, see "[Global Server Load Balancing](#)."

Dynamic Routing

Enables routers to obtain topology information, routes, and IP addresses from neighboring routers automatically. When dynamic routing is enabled, the corresponding routing process listens to route updates and advertises routes. The routing processes can also be placed in passive mode. Routing protocols enable an upstream router to load balance traffic to identical virtual servers hosted on two standalone NetScaler units using the Equal Cost Multipath technique.

For more information, see "[Configuring Dynamic Routes](#)."

Link Load Balancing

Load balances multiple WAN links and provides link failover, further optimizing network performance and ensuring business continuity. Ensures that network connections remain highly available, by applying intelligent traffic control and health checks to distribute traffic efficiently across upstream routers. Identifies the best WAN link to route both incoming and outbound traffic based on policies and network conditions, and protects applications against WAN or Internet link failure by providing rapid fault detection and failover.

For more information, see "[Link Load Balancing](#)."

TCP Optimization

You can use TCP profiles to optimize TCP traffic. TCP profiles define the way that NetScaler virtual servers process TCP traffic. Administrators can use the built-in TCP profiles or configure custom profiles. After defining a TCP profile, you can bind it to a single virtual server or to multiple virtual servers.

Some of the key optimization features that can be enabled by TCP profiles are:

- TCP keep-alive— Checks the operational status of the peers at specified time intervals to prevent the link from being broken.
- Selective Acknowledgment (SACK)— Improves the performance of data transmission, especially in long fat networks (LFNs).
- TCP window scaling— Allows efficient transfer of data over long fat networks (LFNs).

For more information on TCP Profiles, see "[Configuring TCP Profiles](#)."

Web Interface on NetScaler

Provides access to XenApp and XenDesktop resources, which include applications, content, and desktops. Users access resources through a standard Web browser or by using the Citrix XenApp plug-in. The Web Interface runs as a service on port 8080 on the NetScaler appliance. To create Web Interface sites, Java is executed on Apache Tomcat Web server version 6.0.26 on the NetScaler appliance.

Note: Web Interface is supported only on NetScaler nCore releases.

For more information, see "[Web Interface](#)."

CloudBridge Connector

The Citrix NetScaler CloudBridge Connector feature, a fundamental part of the Citrix OpenCloud framework, is a tool used to build a cloud-extended data center. The OpenCloud Bridge enables you to connect one or more NetScaler appliances or NetScaler virtual appliances on the cloud-to your network without reconfiguring your network. Cloud hosted applications appear as though they are running on one contiguous enterprise network. The primary purpose of the OpenCloud Bridge is to enable companies to move their applications to the cloud while reducing costs and the risk of application failure. In addition, the OpenCloud Bridge increases network security in cloud environments. An OpenCloud Bridge is a Layer-2 network bridge that connects a NetScaler appliance or NetScaler virtual appliance on a cloud instance to a NetScaler appliance or NetScaler virtual appliance on your LAN. The connection is made through a tunnel that uses the Generic Routing Encapsulation (GRE) protocol. The GRE protocol provides a mechanism for encapsulating packets from a wide variety of network protocols to be forwarded over another protocol. Then Internet Protocol security (IPsec) protocol suite is used to secure the communication between the peers in the OpenCloud Bridge.

For more information, see "[CloudBridge](#)."

DataStream

The NetScaler DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests on the basis of the SQL query being sent.

When deployed in front of database servers, a NetScaler ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and on the basis of database names, user names, character sets, and packet size.

You can configure load balancing to switch requests according to load balancing algorithms, or you can elaborate the switching criteria by configuring content switching to make a decision based on SQL query parameters, such as user name, database names, and command parameters. You can further configure monitors to track the states of database servers.

The advanced policy infrastructure on the NetScaler appliance includes expressions that you can use to evaluate and process the requests. The advanced expressions evaluate traffic associated with MySQL database servers. You can use request-based expressions (expressions that begin with `MYSQL.CLIENT` and `MYSQL.REQ`) in advanced policies to make request switching decisions at the content switching virtual server bind point and response-based expressions (expressions that begin with `MYSQL.RES`) to evaluate server responses to user-configured health monitors.

Note: DataStream is supported for MySQL and MS SQL databases.

For more information, see "[DataStream](#)."

Application Acceleration Features

Sep 06, 2013

AppCompress

Uses the gzip compression protocol to provide transparent compression for HTML and text files. The typical 4:1 compression ratio yields up to 50% reduction in bandwidth requirements out of the data center. It also results in significantly improved end-user response time, because it reduces the amount of data that must be delivered to the user's browser.

For more information, see "[Compression](#)."

Cache Redirection

Manages the flow of traffic to a reverse proxy, transparent proxy, or forward proxy cache farm. Inspects all requests, and identifies non-cacheable requests and sends them directly to the origin servers over persistent connections. By intelligently redirecting non-cacheable requests back to the origin web servers, the NetScaler appliance frees cache resources and increases cache hit rates while reducing overall bandwidth consumption and response delays for these requests.

For more information, see "[Cache Redirection](#)."

AppCache

Helps optimize web content and application data delivery by providing a fast in-memory HTTP/1.1 and HTTP/1.0 compliant web caching for both static and dynamic content. This on-board cache stores the results of incoming application requests even when an incoming request is secured or the data compressed, and then reuses the data to fulfill subsequent requests for the same information. By serving data directly from the on-board cache, the appliance can reduce page regeneration times by eliminating the need to funnel static and dynamic content requests to the server.

For more information, see "[Integrated Caching](#)."

TCP Buffering

Buffers the server's response and delivers it to the client at the client's speed, thus offloading the server faster and thereby improving the performance of web sites.

For more information, see "[TCP Buffering](#)."

Application Security and Firewall Features

Oct 30, 2013

Denial of Service Attack (DoS) Defense

Detects and stops malicious distributed denial-of-service (DDoS) attacks and other types of malicious attacks before they reach your servers, preventing them from affecting network and application performance. The NetScaler appliance identifies legitimate clients and elevates their priority, leaving suspect clients unable to consume a disproportionate percentage of resources and cripple your site. The appliance provides application-level protection from the following types of malicious attacks:

- SYN flood attacks
- Pipeline attacks
- Teardrop attacks
- Land attacks
- Fraggle attacks
- Zombie connection attacks

The appliance aggressively defends against these types of attacks by preventing the allocation of server resources for these connections. This insulates servers from the overwhelming flood of packets associated with these events.

The appliance also protects network resources from ICMP based attacks by using ICMP rate limiting and aggressive ICMP packet inspection. It performs strong IP reassembly, drops a variety of suspicious and malformed packets, and applies Access Control Lists (ACLs) to site traffic for further protection.

For more information, see "[HTTP Denial-of-Service Protection](#)."

Content Filtering

Provides protection from malicious attacks for web sites at the Layer 7 level. The appliance inspects each incoming request according to user-configured rules based on HTTP headers, and performs the action the user configured. Actions can include resetting the connection, dropping the request, or sending an error message to the user's browser. This allows the appliance to screen unwanted requests and reduces your servers' exposure to attacks.

This feature can also analyze HTTP GET and POST requests and filter out known bad signatures, allowing it to defend your servers against HTTP-based attacks.

For more information, see "[Content Filtering](#)."

Responder

Functions like an advanced filter and can be used to generate responses from the appliance to the client. Some common uses of this feature are generation of redirect responses, user defined responses, and resets.

For more information, see "[Responder](#)."

Rewrite

Modifies HTTP headers and body text. You can use the rewrite feature to add HTTP headers to an HTTP request or response, make modifications to individual HTTP headers, or delete HTTP headers. It also enables you to modify the HTTP body in requests and responses.

When the appliance receives a request or sends a response, it checks for rewrite rules, and if applicable rules exist, it applies them to the request or response before passing it on to the web server or client computer.

For more information, see "[Rewrite](#)."

Priority Queuing

Prioritizes user requests to ensure that the most important traffic is serviced first during surges in request volume. You can establish priority based on request URLs, cookies, or a variety of other factors. The appliance places requests in a three-tier queue based on their configured priority, enabling business-critical transactions to flow smoothly even during surges or site attacks.

For more information, see "[Priority Queuing](#)."

Surge Protection

Regulates the flow of user requests to servers and controls the number of users that can simultaneously access the resources on the servers, queuing any additional requests once your servers have reached their capacity. By controlling the rate at which connections can be established, the appliance blocks surges in requests from being passed on to your servers, thus preventing site overload.

For more information, see "[Surge Protection](#)."

NetScaler Gateway

NetScaler Gateway is a secure application access solution that provides administrators granular application-level policy and action controls to secure access to applications and data while allowing users to work from anywhere. It gives IT administrators a single point of control and tools to help ensure compliance with regulations and the highest levels of information security across and outside the enterprise. At the same time, it empowers users with a single point of access—optimized for roles, devices, and networks—to the enterprise applications and data they need. This unique combination of capabilities helps maximize the productivity of today's mobile workforce.

For more information, see "[NetScaler Gateway](#)."

Application Firewall

Protects applications from misuse by hackers and malware, such as cross site scripting attacks, buffer overflow attacks, SQL injection attacks, and forceful browsing, by filtering traffic between each protected web server and users that connect to any web site on that web server. The application firewall examines all traffic for evidence of attacks on web server security or misuse of web server resources, and takes the appropriate action to prevent these attacks from succeeding.

For more information, see "[Application Firewall](#)."

Application Visibility Feature

Sep 04, 2013

NetScaler Insight Center

NetScaler Insight Center is a high performance collector that provides end-to-end user experience visibility across Web and HDX (ICA) traffic. It collects HTTP and ICA AppFlow records generated by NetScaler ADC appliances and populates analytical reports covering Layer 3 to Layer 7 statistics. NetScaler Insight Center provides in-depth analysis for the last five minutes of real-time data, and for historical data collected for the last one hour, one day, one week, and one month. HDX (ICA) analytic dashboard enables you to drill down from HDX Users, Applications, Desktops, and even from gateway-level information. Similarly, HTTP analytics provide a bird's eye view of Web Applications, URLs Accessed, Client IP Addresses and Server IP Addresses, and other dashboards. The administrator can drill down and identify the pain points from any of these dashboards, as appropriate for the use case.

EdgeSight for NetScaler

Support for application performance monitoring based on end user experience. This solution leverages the HTML injection feature to obtain various time values, which are used by EdgeSight server for analysis and report generation. EdgeSight for NetScaler provides a way to monitor the performance benefits of a NetScaler and determine potential bottlenecks in a network.

For more information, see "[EdgeSight Monitoring for NetScaler](#)."

Enhanced Application Visibility Using AppFlow

The Citrix NetScaler appliance is a central point of control for all application traffic in the data center. It collects flow and user-session level information valuable for application performance monitoring, analytics, and business intelligence applications. AppFlow transmits this information by using the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. IPFIX (the standardized version of Cisco's NetFlow) is widely used to monitor network flow information. AppFlow defines new Information Elements to represent application-level information.

Using UDP as the transport protocol, AppFlow transmits the collected data, called *flow records*, to one or more IPv4 collectors. The collectors aggregate the flow records and generate real-time or historical reports.

AppFlow provides visibility at the transaction level for HTTP, SSL, TCP, and SSL_TCP flows. You can sample and filter the flow types that you want to monitor.

To limit the types of flows to monitor, by sampling and filtering the application traffic, you can enable AppFlow for a virtual server. AppFlow can also provide statistics for the virtual server.

You can also enable AppFlow for a specific service, representing an application server, and monitor the traffic to that application server.

For more information, see "[AppFlow](#)."

Stream Analytics

The performance of your web site or application depends on how well you optimize the delivery of the most frequently requested content. Techniques such as caching and compression help accelerate the delivery of services to clients, but you need to be able to identify the resources that are requested most frequently, and then cache or compress those resources. You can identify the most frequently used resources by aggregating real-time statistics about website or application traffic. Statistics such as how frequently a resource is accessed relative to other resources and how much bandwidth is consumed

by those resources help you determine whether those resources need to be cached or compressed to improve server performance and network utilization. Statistics such as response times and the number of concurrent connections to the application help you determine whether you must enhance server-side resources.

If the web site or application does not change frequently, you can use products that collect statistical data, and then manually analyze the statistics and optimize the delivery of content. However, if you do not want to perform manual optimizations, or if your web site or application is dynamic in nature, you need infrastructure that can not only collect statistical data but can also automatically optimize the delivery of resources on the basis of the statistics. On the NetScaler appliance, this functionality is provided by the Stream Analytics feature. The feature operates on a single NetScaler appliance and collects run-time statistics on the basis of criteria that you define. When used with NetScaler policies, the feature also provides you with the infrastructure that you need for automatic, real-time traffic optimization.

For more information, see "[Stream Analytics](#)."

Cloud Integration Feature

Aug 23, 2013

AutoScale

All applications have specific usage patterns that comprise peaks and troughs. These load variations can be dynamic in nature and difficult to predict, given that they depend on several factors that are intrinsic to the use case. Cloud users have to constantly monitor the load on their application fleet and make sure that these variations have minimum impact on end users. During periods of peak usage, when the application fleet is overloaded and end users experience significant latency, they have to deploy additional application instances. During trough periods, the expanded fleet is underutilized. So they might have to remove additional instances or bear unnecessary cost overheads. In most cases, they have to perform these tasks manually.

If your organization uses Citrix CloudPlatform to deploy and manage the cloud environment, users can use the *AutoScale* feature in CloudPlatform, in conjunction with a Citrix NetScaler appliance, to automatically scale their applications as needed. The AutoScale feature is part of the elastic load balancing feature in CloudPlatform. A CloudPlatform user can use the AutoScale feature to specify thresholds for various conditions for automatically scaling the application fleet upward and downward. CloudPlatform, in turn, configures the NetScaler appliance (by using the NetScaler NITRO API) to load balance traffic to the application virtual machines (VMs), monitor application thresholds and performance, and trigger scale-up and scale-down actions to add or remove VMs to or from the application fleet.

As the NetScaler administrator, you do not have to perform any tasks for configuring AutoScale on the NetScaler appliance. However, you might have to be aware of certain prerequisites, and you might have to troubleshoot the configuration if issues arise in the AutoScale configuration. To troubleshoot the configuration, you have to be aware of how CloudPlatform works and what configuration CloudPlatform pushes to the NetScaler appliance. You also need a working knowledge of how to troubleshoot issues on a NetScaler appliance.

For more information about AutoScale, see "[AutoScale: Automatic Scaling in the Citrix CloudPlatform Environment.](#)"

Getting Started with Citrix NetScaler VPX

Aug 13, 2014

Intended for system and network administrators who install and configure complex networking equipment, this section of the library describes initial setup and basic configuration of the NetScaler virtual appliance product, including the following topics.

Understanding the NetScaler

Updated: 2013-10-28

The Citrix NetScaler product is an application switch that performs application-specific traffic analysis to intelligently distribute, optimize, and secure Layer 4-Layer 7 (L4–L7) network traffic for web applications. For example, a NetScaler bases load balancing decisions on individual HTTP requests instead of on long-lived TCP connections, so that the failure or slowdown of a server is managed much more quickly and with less disruption to clients. The NetScaler feature set can be broadly categorized as consisting of switching features, security and protection features, and server-farm optimization features.

Switching Features

Updated: 2013-09-06

When deployed in front of application servers, a NetScaler ensures optimal distribution of traffic by the way in which it directs client requests. Administrators can segment application traffic according to information in the body of an HTTP or TCP request, and on the basis of L4–L7 header information such as URL, application data type, or cookie. Numerous load balancing algorithms and extensive server health checks improve application availability by ensuring that client requests are directed to the appropriate servers.

Security and Protection Features

Updated: 2013-10-28

NetScaler security and protection features protect web applications from Application Layer attacks. A NetScaler allows legitimate client requests and can block malicious requests. It provides built-in defenses against denial-of-service (DoS) attacks and supports features that protect against legitimate surges in application traffic that would otherwise overwhelm the servers. An available built-in firewall protects web applications from Application Layer attacks, including buffer overflow exploits, SQL injection attempts, cross-site scripting attacks, and more. In addition, the firewall provides identity theft protection by securing confidential corporate information and sensitive customer data.

Optimization Features

Updated: 2013-09-06

Optimization features offload resource-intensive operations, such as Secure Sockets Layer (SSL) processing, data compression, client keep-alive, TCP buffering, and the caching of static and dynamic content from servers. This improves the performance of the servers in the server farm and therefore speeds up applications. A NetScaler supports several transparent TCP optimizations, which mitigate problems caused by high latency and congested network links, accelerating the delivery of applications while requiring no configuration changes to clients or servers.

Understanding Policies and Expressions

A policy defines specific details of traffic filtering and management on a NetScaler. It consists of two parts: the expression and the action. The expression defines the types of requests that the policy matches. The action tells the NetScaler what to do when a request matches the expression. As an example, the expression might be to match a specific URL pattern to a type of security attack, with the action being to drop or reset the connection. Each policy has a priority, and the priorities determine the order in which the policies are evaluated.

When a NetScaler receives traffic, the appropriate policy list determines how to process the traffic. Each policy on the list contains one or more expressions, which together define the criteria that a connection must meet to match the policy.

For all policy types except Rewrite policies, a NetScaler implements only the first policy that a request matches, not any additional policies that it might also match. For Rewrite policies, the NetScaler evaluates the policies in order and, in the case of multiple matches, performs the associated actions in that order. Policy priority is important for getting the results you want.

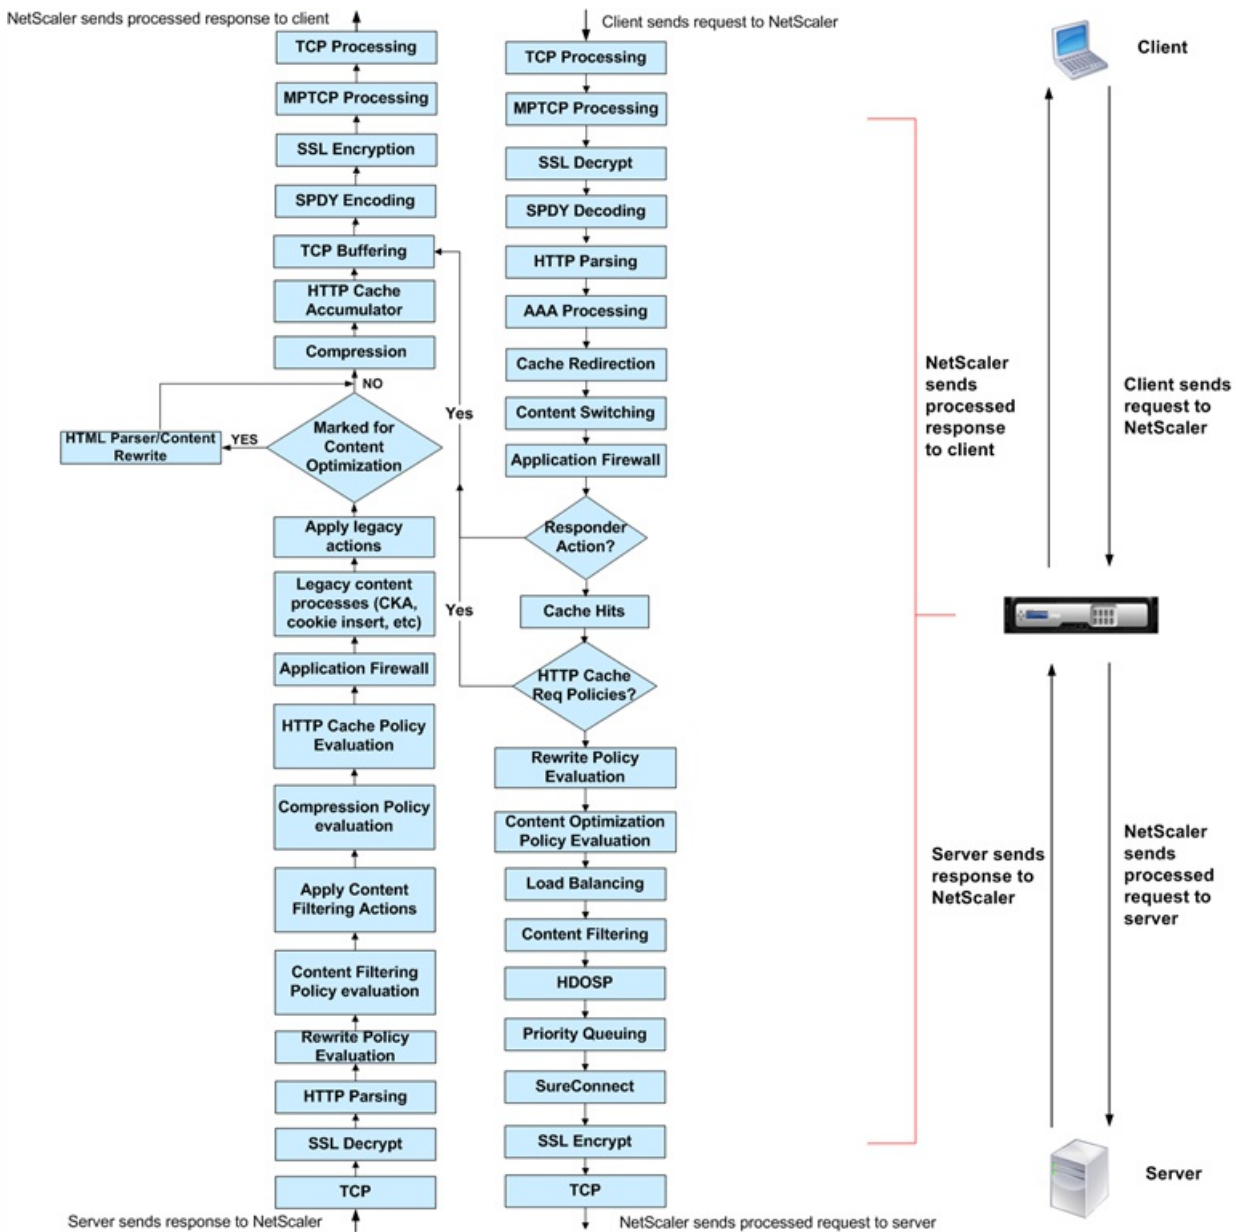

Processing Order of Features

Updated: 2013-08-22

Depending on requirements, you can choose to configure multiple features. For example, you might choose to configure both compression and SSL offload. As a result, an outgoing packet might be compressed and then encrypted before being sent to the client.

The following figure shows the L7 packet flow in the NetScaler.

Figure 1. L7 Packet Flow Diagram

The following figure shows the DataStream packet flow in the NetScaler. DataStream is supported for MySQL and MS SQL databases. For information about the DataStream feature, see "[DataStream](#)."

Citrix NetScaler Virtual Appliance Overview

Oct 06, 2016

The NetScaler virtual appliance product is a virtual NetScaler appliance that can be hosted on Citrix XenServer®, VMware ESX or ESXi, Linux-KVM, and Microsoft Hyper-V virtualization platforms.

A NetScaler virtual appliance supports all the features of a physical NetScaler, except virtual MAC (vMAC) addresses, Layer 2 (L2) mode, and link aggregation control protocol (LACP). VLAN tagging is supported on the NetScaler virtual appliances hosted on the XenServer and on VMware ESX platforms.

For the VLAN tagging feature to work, do one of the following:

- On the Citrix XenServer, configure tagged VLANs on a port on the switch but do NOT configure any VLANs on the XenServer interface attached to that port. The VLAN tags are passed through to the virtual appliance and you can use the tagged VLAN configuration on the virtual appliance.
- On the VMware ESX, set the port group's VLAN ID to 4095 on the vSwitch of VMware ESX server. For more information about setting a VLAN ID on the vSwitch of VMware ESX server, see http://www.vmware.com/pdf/esx3_vlan_wp.pdf.

This overview covers only aspects that are unique to NetScaler virtual appliance.

Note: The terms *NetScaler*, *NetScaler appliance*, and *appliance* are used interchangeably with *NetScaler virtual appliance* unless stated otherwise.

NetScaler Virtual Appliance Setup for the XenServer Platform

Updated: 2013-08-23

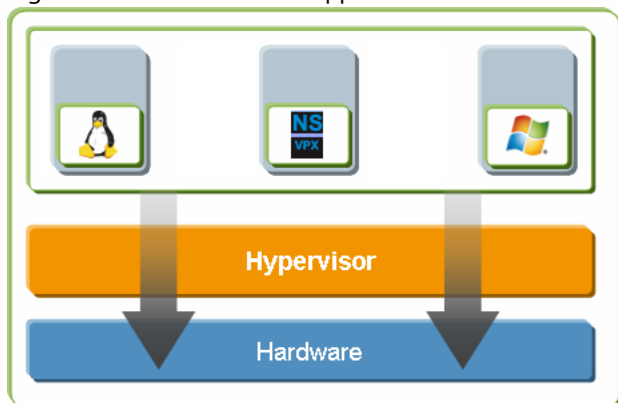

When you set up NetScaler virtual appliance on XenServer, you must use the XenCenter client to install the first NetScaler virtual appliance. Subsequent virtual appliances can be added by using either the XenCenter client or Citrix Command Center.

XenServer

The XenServer® product is a server virtualization platform that offers near bare-metal virtualization performance for virtualized server and client operating systems. XenServer uses the Xen® hypervisor to virtualize each server on which it is installed, enabling each server to host multiple virtual machines simultaneously.

The following figure shows the bare-metal solution architecture of NetScaler virtual appliance on XenServer.

Figure 1. NetScaler Virtual Appliance on XenServer

The bare-metal solution architecture has the following components:

Hardware or physical layer:

Physical hardware components including memory, CPU, network cards, and disk drives.

Xen hypervisor:

Thin layer of software that runs on top of the hardware. The Xen hypervisor gives each virtual machine a dedicated view of the hardware.

Virtual machine:

Operating system hosted on the hypervisor and appearing to the user as a separate physical computer. However, the machine shares physical resources with other virtual machines, and it is portable because the virtual machine is abstracted from physical hardware.

A NetScaler virtual machine, or *virtual appliance*, is installed on the Xen hypervisor and uses paravirtualized drivers to access storage and network resources. It appears to the users as an independent NetScaler appliance with its own network identity, user authorization and authentication capabilities, configuration, applications, and data. The paravirtualization technique enables the virtual machines and the hypervisor to work together to achieve high performance for I/O and for CPU and memory virtualization.

For more information about XenServer, see the XenServer documentation at <http://support.citrix.com/product/xens/>.

XenCenter

XenCenter® is a graphical virtualization-management interface for XenServer®, enabling you to manage servers, resource pools, and shared storage, and to deploy, manage, and monitor virtual machines from your Windows desktop machine.

Use XenCenter to install NetScaler virtual appliance on XenServer.

For more information about XenCenter, see the XenServer documentation at <http://support.citrix.com/product/xens/>.

Command Center

Command Center is a management and monitoring solution for Citrix application networking products that include NetScaler, NetScaler virtual appliance, NetScaler Gateway Enterprise Edition, Citrix® Branch Repeater™, Branch Repeater VPX™, and Citrix Repeater™. Command Center enables network administrators and operations teams to manage, monitor, and troubleshoot the entire global application delivery infrastructure from a single, unified console.

This centralized management solution simplifies operations by providing administrators with enterprise-wide visibility and automating management tasks that need to be executed across multiple devices.

Command Center is available with Citrix NetScaler Enterprise and Platinum editions.

You can use Command Center to provision NetScaler virtual appliance on XenServer, and then you can manage and monitor the virtual appliances from Command Center.

Note: You must use the XenCenter client to manage XenServer. You cannot manage XenServer from Command Center. For more information about Command Center, see the Command Center documentation.

NetScaler Virtual Appliance Setup for the VMware ESX Platform

The NetScaler virtual appliance setup for the VMware ESX platform requires a VMware ESX or ESXi server and the vSphere client.

VMware ESX and ESXi are virtualization products based on bare-metal architecture, offered by VMware, Inc. Citrix NetScaler virtual appliance can be hosted on a VMware ESX or ESXi server.

For more information about VMware ESX, see <http://www.vmware.com/>.

The vSphere client is a graphical interface for managing virtual machines on VMware ESX servers. You use the vSphere client to allocate resources on the ESX server to virtual appliances installed on the server or to deallocate resources. For example, you can allocate virtual network ports to a virtual appliance.

For more information about VMware vSphere client, see <http://www.vmware.com/>.

NetScaler Virtual Appliance Setup for the Microsoft Hyper-V Platform

The NetScaler virtual appliance setup for the Microsoft Hyper-V platform requires Windows Server 2008 R2 or 2012 with the Hyper-V role installed. Like all virtualization systems, Hyper-V enables you to create a virtualized computing environment that results in better utilization of your hardware resources.

Hyper-V is a type 1 hypervisor that comes preinstalled with Windows Server 2008 R2 or 2012. It needs to be enabled as a role on the Windows Server.

For more information about Hyper-V, see [http://technet.microsoft.com/en-us/library/cc816638\(WS.10\).aspx](http://technet.microsoft.com/en-us/library/cc816638(WS.10).aspx).

NetScaler Virtual Appliance Setup for Linux-KVM Platform

The NetScaler® VPX™ is a virtual NetScaler appliance that can be hosted on a kernel based Virtualization Machine(KVM). The host Linux operating system must be installed on suitable hardware by using virtualization tools such as KVM Module and QEMU. NetScaler VPX runs as a virtual appliance on Linux-KVM server. Like all virtualization systems, KVM enables you to create a virtualized computing environment that results in better utilization of your hardware resources.

Hypervisors Supported on a NetScaler Virtual Appliance

The following table lists the details, such as system ID (sysID) and whether support is available for multiple packet engines (multi-PE), for the different hypervisors supported on a NetScaler virtual appliance.

Table 1. Hypervisors Supported on a NetScaler Virtual Appliance

	VPX on XenServer	VPX on VMware ESX	VPX on Microsoft Hyper-V	VPX on generic KVM	VPX on Amazon Web Services
Hypervisor Version	6.0, 6.1, 6.2	4.1, 5.1, 5.5, 6.0 Note: Support for ESX 6.0 is available from NetScaler 10.5 Build 59.x onwards.	2008, 2012	Linux - Fedora 16, Fedora 17, RHEL 6.4	N/A
SysID	450000	450010	450020	450070	450040
Multi-PE Supported	Yes	Yes	Yes	Yes	Yes

Clustering Supported	Yes VPX on XenServer	Yes VPX on VMware ESX	Yes VPX on Microsoft Hyper-V	Yes VPX on generic KVM	No VPX on Amazon Web Services
Licenses	VPX-10, VPX-200, VPX-1000, VPX-3000, VPX-8000	VPX-10, VPX-200, VPX-1000, VPX-3000, VPX-8000	VPX-10, VPX-200, VPX-1000, VPX-3000, VPX-8000	VPX-10, VPX-200, VPX-1000, VPX-3000, VPX-8000	VPX-10, VPX-200, VPX-1000, VPX-3000, VPX-8000, VPX-BYOL

Where Does a NetScaler Appliance Fit in the Network?

Jun 24, 2013

A NetScaler appliance resides between the clients and the servers, so that client requests and server responses pass through it. In a typical installation, virtual servers configured on the appliance provide connection points that clients use to access the applications behind the appliance. In this case, the appliance owns public IP addresses that are associated with its virtual servers, while the real servers are isolated in a private network. It is also possible to operate the appliance in a transparent mode as an L2 bridge or L3 router, or even to combine aspects of these and other modes.

Physical Deployment Modes

Updated: 2013-09-04

A NetScaler appliance logically residing between clients and servers can be deployed in either of two physical modes: inline and one-arm. In inline mode, multiple network interfaces are connected to different Ethernet segments, and the appliance is placed between the clients and the servers. The appliance has a separate network interface to each client network and a separate network interface to each server network. The appliance and the servers can exist on different subnets in this configuration. It is possible for the servers to be in a public network and the clients to directly access the servers through the appliance, with the appliance transparently applying the L4-L7 features. Usually, virtual servers (described later) are configured to provide an abstraction of the real servers. The following figure shows a typical inline deployment.

Figure 1. Inline Deployment

In one-arm mode, only one network interface of the appliance is connected to an Ethernet segment. The appliance in this case does not isolate the client and server sides of the network, but provides access to applications through configured virtual servers. One-arm mode can simplify network changes needed for NetScaler installation in some environments.

For examples of inline (two-arm) and one-arm deployment, see "[Understanding Common Network Topologies](#)."

Citrix NetScaler as an L2 Device

Updated: 2013-09-04

A NetScaler functioning as an L2 device is said to operate in L2 mode. In L2 mode, the NetScaler forwards packets between network interfaces when all of the following conditions are met:

- The packets are destined to another device's media access control (MAC) address.
- The destination MAC address is on a different network interface.
- The network interface is a member of the same virtual LAN (VLAN).

By default, all network interfaces are members of a pre-defined VLAN, VLAN 1. Address Resolution Protocol (ARP) requests and responses are forwarded to all network interfaces that are members of the same VLAN. To avoid bridging loops, L2 mode must be disabled if another L2 device is working in parallel with the NetScaler.

For information about how the L2 and L3 modes interact, see "[Configuring Modes of Packet Forwarding](#)."

For information about configuring L2 mode, see "[Enabling and Disabling Layer 2 Mode](#)."

Citrix NetScaler as a Packet Forwarding Device

Updated: 2014-03-14

A NetScaler appliance can function as a packet forwarding device, and this mode of operation is called L3 mode. With L3 mode enabled, the appliance forwards any received unicast packets that are destined for an IP address that does not belong to the appliance, if there is a route to the destination. The appliance can also route packets between VLANs.

In both modes of operation, L2 and L3, the appliance generally drops packets that are in:

- Multicast frames
- Unknown protocol frames destined for an appliance's MAC address (non-IP and non-ARP)
- Spanning Tree protocol (unless BridgeBPDUs is ON)

For information about how the L2 and L3 modes interact, see "[Configuring Modes of Packet Forwarding](#)."

For information about configuring the L3 mode, see "[Enabling and Disabling Layer 3 Mode](#)."

How a NetScaler Communicates with Clients and Servers

Nov 10, 2016

A NetScaler appliance is usually deployed in front of a server farm and functions as a transparent TCP proxy between clients and servers, without requiring any client-side configuration. This basic mode of operation is called Request Switching technology and is the core of NetScaler functionality. Request Switching enables an appliance to multiplex and offload the TCP connections, maintain persistent connections, and manage traffic at the request (application layer) level. This is possible because the appliance can separate the HTTP request from the TCP connection on which the request is delivered.

Depending on the configuration, an appliance might process the traffic before forwarding the request to a server. For example, if the client attempts to access a secure application on the server, the appliance might perform the necessary SSL processing before sending traffic to the server.

To facilitate efficient and secure access to server resources, an appliance uses a set of IP addresses collectively known as NetScaler-owned IP addresses. To manage your network traffic, you assign NetScaler-owned IP addresses to virtual entities that become the building blocks of your configuration. For example, to configure load balancing, you create virtual servers to receive client requests and distribute them to services, which are entities representing the applications on your servers.

Understanding NetScaler-Owned IP Addresses

To function as a proxy, a NetScaler appliance uses a variety of IP addresses. The key NetScaler-owned IP addresses are:

NetScaler IP (NSIP) address

The NSIP address is the IP address for management and general system access to the appliance itself, and for communication between appliances in a high availability configuration.

Virtual server IP (VIP) address

A VIP address is the IP address associated with a virtual server. It is the public IP address to which clients connect. An appliance managing a wide range of traffic may have many VIPs configured.

Subnet IP (SNIP) address

A SNIP address is used in connection management and server monitoring. You can specify multiple SNIP addresses for each subnet. SNIP addresses can be bound to a VLAN.

IP Set

An IP set is a set of IP addresses, which are configured on the appliance as SNIP. An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it.

Net Profile

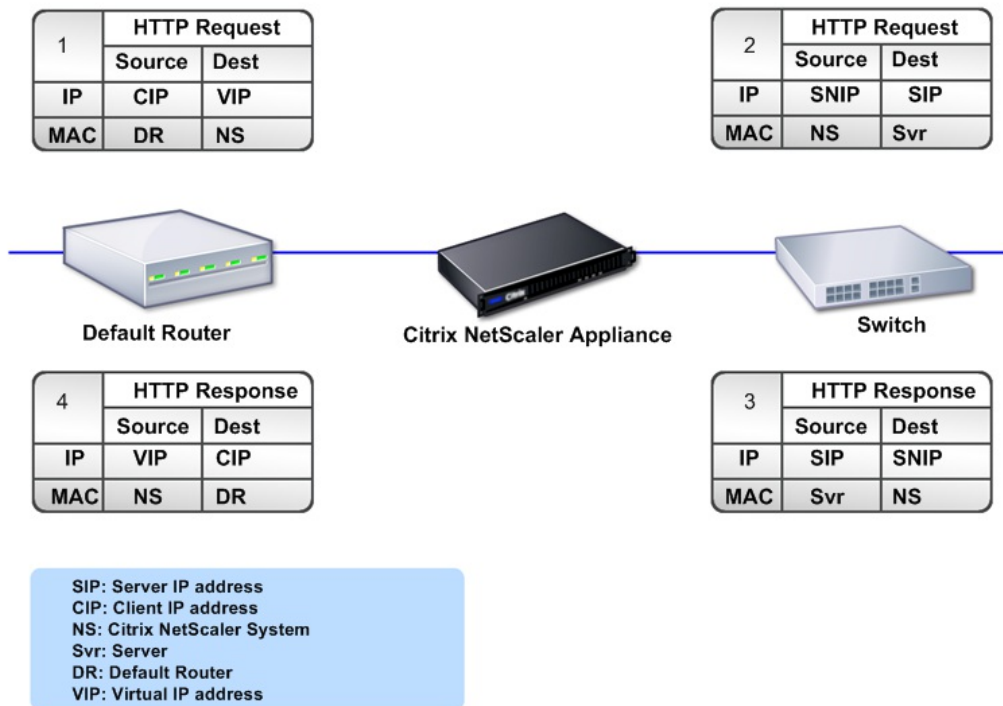

A net profile (or network profile) contains an IP address or an IP set. A net profile can be bound to load balancing or content switching virtual servers, services, service groups, or monitors. During communication with physical servers or peers, the appliance uses the addresses specified in the profile as source IP addresses.

How Traffic Flows Are Managed

Because a NetScaler appliance functions as a TCP proxy, it translates IP addresses before sending packets to a server. When you configure a virtual server, clients connect to a VIP address on the NetScaler instead of directly connecting to a

server. As determined by the settings on the virtual server, the appliance selects an appropriate server and sends the client's request to that server. By default, the appliance uses a SNIP address to establish connections with the server, as shown in the following figure.

Figure 1. Virtual Server Based Connections

In the absence of a virtual server, when an appliance receives a request, it transparently forwards the request to the server. This is called the transparent mode of operation. When operating in transparent mode, an appliance translates the source IP addresses of incoming client requests to the SNIP address but does not change the destination IP address. For this mode to work, L2 or L3 mode has to be configured appropriately.

For cases in which the servers need the actual client IP address, the appliance can be configured to modify the HTTP header by inserting the client IP address as an additional field, or configured to use the client IP address instead of a SNIP address for connections to the servers.

Traffic Management Building Blocks

The configuration of a NetScaler appliance is typically built up with a series of virtual entities that serve as building blocks for traffic management. The building block approach helps separate traffic flows. Virtual entities are abstractions, typically representing IP addresses, ports, and protocol handlers for processing traffic. Clients access applications and resources through these virtual entities. The most commonly used entities are virtual servers and services. Virtual servers represent

groups of servers in a server farm or remote network, and services represent specific applications on each server.

Most features and traffic settings are enabled through virtual entities. For example, you can configure an appliance to compress all server responses to a client that is connected to the server farm through a particular virtual server. To configure the appliance for a particular environment, you need to identify the appropriate features and then choose the right mix of virtual entities to deliver them. Most features are delivered through a cascade of virtual entities that are bound to each other. In this case, the virtual entities are like blocks being assembled into the final structure of a delivered application. You can add, remove, modify, bind, enable, and disable the virtual entities to configure the features. The following figure shows the concepts covered in this section.

Figure 2. How Traffic Management Building Blocks Work

A Simple Load Balancing Configuration

In the example shown in the following figure, the NetScaler appliance is configured to function as a load balancer. For this configuration, you need to configure virtual entities specific to load balancing and bind them in a specific order. As a load balancer, an appliance distributes client requests across several servers and thus optimizes the utilization of resources.

The basic building blocks of a typical load balancing configuration are services and load balancing virtual servers. The services represent the applications on the servers. The virtual servers abstract the servers by providing a single IP address to which the clients connect. To ensure that client requests are sent to a server, you need to bind each service to a virtual server. That is, you must create services for every server and bind the services to a virtual server. Clients use the VIP address to connect to a NetScaler appliance. When the appliance receives client requests sent to the VIP address, it sends them to a server determined by the load balancing algorithm. Load balancing uses a virtual entity called a monitor to track whether a specific configured service (server plus application) is available to receive requests.

Figure 3. Load Balancing Virtual Server, Services, and Monitors

In addition to configuring the load balancing algorithm, you can configure several parameters that affect the behavior and performance of the load balancing configuration. For example, you can configure the virtual server to maintain persistence based on source IP address. The appliance then directs all requests from any specific IP address to the same server.

Understanding Virtual Servers

A virtual server is a named NetScaler entity that external clients can use to access applications hosted on the servers. It is represented by an alphanumeric name, virtual IP (VIP) address, port, and protocol. The name of the virtual server is of only local significance and is designed to make the virtual server easier to identify. When a client attempts to access applications on a server, it sends a request to the VIP instead of the IP address of the physical server. When the appliance receives a request at the VIP address, it terminates the connection at the virtual server and uses its own connection with the server on behalf of the client. The port and protocol settings of the virtual server determine the applications that the virtual server represents. For example, a web server can be represented by a virtual server and a service whose port and protocol are set to 80 and HTTP, respectively. Multiple virtual servers can use the same VIP address but different protocols and ports.

Virtual servers are points for delivering features. Most features, like compression, caching, and SSL offload, are normally enabled on a virtual server. When the appliance receives a request at a VIP address, it chooses the appropriate virtual server by the port on which the request was received and its protocol. The appliance then processes the request as appropriate for the features configured on the virtual server.

In most cases, virtual servers work in tandem with services. You can bind multiple services to a virtual server. These services represent the applications running on physical servers in a server farm. After the appliance processes requests received at a VIP address, it forwards them to the servers as determined by the load balancing algorithm configured on the virtual server. The following figure illustrates these concepts.

Figure 4. Multiple Virtual Servers with a Single VIP Address

The preceding figure shows a configuration consisting of two virtual servers with a common VIP address but different ports and protocols. Each of the virtual servers has two services bound to it. The services s1 and s2 are bound to VS_HTTP and represent the HTTP applications on Server 1 and Server 2. The services s3 and s4 are bound to VS_SSL and represent the SSL applications on Server 2 and Server 3 (Server 2 provides both HTTP and SSL applications). When the appliance receives an HTTP request at the VIP address, it processes the request as specified by the settings of VS_HTTP and sends it to either Server 1 or Server 2. Similarly, when the appliance receives an HTTPS request at the VIP address, it processes it as specified by the settings of VS_SSL and it sends it to either Server 2 or Server 3.

Virtual servers are not always represented by specific IP addresses, port numbers, or protocols. They can be represented by wildcards, in which case they are known as wildcard virtual servers. For example, when you configure a virtual server with a wildcard instead of a VIP, but with a specific port number, the appliance intercepts and processes all traffic conforming to that protocol and destined for the predefined port. For virtual servers with wildcards instead of VIPs and port numbers, the appliance intercepts and processes all traffic conforming to the protocol.

Virtual servers can be grouped into the following categories:

Load balancing virtual server

Receives and redirects requests to an appropriate server. Choice of the appropriate server is based on which of the various load balancing methods the user configures.

Cache redirection virtual server

Redirects client requests for dynamic content to origin servers, and requests for static content to cache servers. Cache redirection virtual servers often work in conjunction with load balancing virtual servers.

Content switching virtual server

Directs traffic to a server on the basis of the content that the client has requested. For example, you can create a content switching virtual server that directs all client requests for images to a server that serves images only. Content switching virtual servers often work in conjunction with load balancing virtual servers.

Virtual private network (VPN) virtual server

Decrypts tunneled traffic and sends it to intranet applications.

SSL virtual server

Receives and decrypts SSL traffic, and then redirects to an appropriate server. Choosing the appropriate server is similar to

choosing a load balancing virtual server.

Understanding Services

Services represent applications on a server. While services are normally combined with virtual servers, in the absence of a virtual server, a service can still manage application-specific traffic. For example, you can create an HTTP service on a NetScaler appliance to represent a web server application. When the client attempts to access a web site hosted on the web server, the appliance intercepts the HTTP requests and creates a transparent connection with the web server.

In service-only mode, an appliance functions as a proxy. It terminates client connections, uses a SNIP address to establish a connection to the server, and translates the source IP addresses of incoming client requests to a SNIP address. Although the clients send requests directly to the IP address of the server, the server sees them as coming from the SNIP address. The appliance translates the IP addresses, port numbers, and sequence numbers.

A service is also a point for applying features. Consider the example of SSL acceleration. To use this feature, you must create an SSL service and bind an SSL certificate to the service. When the appliance receives an HTTPS request, it decrypts the traffic and sends it, in clear text, to the server. Only a limited set of features can be configured in the service-only case.

Services use entities called monitors to track the health of applications. Every service has a default monitor, which is based on the service type, bound to it. As specified by the settings configured on the monitor, the appliance sends probes to the application at regular intervals to determine its state. If the probes fail, the appliance marks the service as down. In such cases, the appliance responds to client requests with an appropriate error message or re-routes the request as determined by the configured load balancing policies.

Installing NetScaler Virtual Appliances on XenServer

Aug 23, 2013

To install NetScaler virtual appliances on Citrix XenServer, you must first install XenServer on a machine with adequate system resources. To perform the NetScaler virtual appliance installation, you use Citrix XenCenter, which must be installed on a remote machine that can connect to the XenServer host through the network.

Note: After the initial configuration of the NetScaler appliance, if you want to upgrade the appliance to the latest software release, see [Upgrading or Downgrading the System Software](#).

Prerequisites for Installing NetScaler Virtual Appliances on XenServer

Updated: 2013-08-23

Before you begin installing a virtual appliance, do the following:

- Install XenServer® version 6.0 or later on hardware that meets the minimum requirements.
- Install XenCenter® on a management workstation that meets the minimum system requirements.
- Obtain virtual appliance license files. For more information about virtual appliance licenses, see the *NetScaler VPX Licensing Guide* at <http://support.citrix.com/article/ctx122426>.

XenServer Hardware Requirements

The following table describes the minimum hardware requirements for a XenServer platform running NetScaler.

Table 1. Minimum System Requirements for XenServer Running NetScaler nCore virtual appliance

Component	Requirement
CPU	2 or more 64-bit x86 CPUs with virtualization assist (Intel-VT or AMD-V) enabled Note: To run NetScaler virtual appliance, hardware support for virtualization must be enabled on the XenServer host. Make sure that the BIOS option for virtualization support is not disabled. Consult your BIOS documentation for more details.
RAM	3 gigabytes (GB)
Disk space	Locally attached storage (PATA, SATA, SCSI) with 40 GB of disk space Note: XenServer installation creates a 4 GB partition for the XenServer host control domain; the remaining space is available for NetScaler virtual appliance and other virtual machines.
Network Interface Card (NIC)	One 1-Gbps NIC Recommended: Two 1-Gbps NICs

For information about installing XenServer, see the XenServer documentation at <http://support.citrix.com/product/xens/>.

The following table lists the virtual computing resources that XenServer must provide for each NetScaler nCore virtual appliance .

Table 2. Minimum Virtual Computing Resources Required for Running NetScaler ncore virtual appliance

Component	Requirement
Memory	2 GB
Virtual CPU (VCPU)	2
Virtual network interfaces	2

Note: For production use of NetScaler virtual appliance, Citrix recommends that CPU priority (in virtual machine properties) be set to the highest level, in order to improve scheduling behavior and network latency.

XenCenter System Requirements

XenCenter® is a Windows client application. It cannot run on the same machine as the XenServer® host. The following table describes the minimum system requirements.

Table 3. Minimum System Requirements for XenCenter Installation

Component	Requirement
Operating system	Windows 7, Windows XP, Windows Server 2003, or Windows Vista
.NET framework	Version 2.0 or later
CPU	750 megahertz (MHz) Recommended: 1 gigahertz (GHz) or faster
RAM	1 GB Recommended: 2 GB
Network Interface Card (NIC)	100 megabits per second (Mbps) or faster NIC

For information about installing XenCenter, see the XenServer documentation at <http://support.citrix.com/product/xens/>.
Installing NetScaler Virtual Appliances on XenServer by Using XenCenter

Updated: 2013-08-23

After you have installed and configured XenServer and XenCenter, you can use XenCenter to install virtual appliances on XenServer. The number of virtual appliances that you can install depends on the amount of memory available on the

hardware that is running XenServer.

After you have used XenCenter to install the initial NetScaler virtual appliance (.xva image) on XenServer, you have the option to use Command Center to provision NetScaler virtual appliance. For more information, see the [Command Center](#) documentation.

To install NetScaler virtual appliances on XenServer by using XenCenter

1. Start XenCenter on your workstation.
2. On the Server menu, click Add.
3. In the Add New Server dialog box, in the Hostname text box, type the IP address or DNS name of the XenServer that you want to connect to.
4. In the User Name and Password text boxes, type the administrator credentials, and then click Connect. The XenServer name appears in the navigation pane with a green circle, which indicates that the XenServer is connected.
5. In the navigation pane, click the name of the XenServer on which you want to install NetScaler virtual appliance.
6. On the VM menu, click Import.
7. In the Import dialog box, in Import file name, browse to the location at which you saved the NetScaler virtual appliance .xva image file. Make sure that the Exported VM option is selected, and then click Next.
8. Select the XenServer on which you want to install the virtual appliance, and then click Next.
9. Select the local storage repository in which to store the virtual appliance, and then click Import to begin the import process.
10. You can add, modify, or delete virtual network interfaces as required. When finished, click Next.
11. Click Finish to complete the import process.
Note: To view the status of the import process, click the **Log** tab.
12. If you want to install another virtual appliance, repeat steps 5 through 11.

Installing NetScaler Virtual Appliances on VMware ESX

Jul 27, 2017

Important: You cannot install standard VMware Tools or upgrade the VMware Tools version available on a NetScaler virtual appliance. VMware Tools for a NetScaler virtual appliance are delivered as part of the NetScaler software release. Before installing NetScaler virtual appliances on VMware ESX, make sure that VMware ESX Server is installed on a machine with adequate system resources. To install NetScaler virtual appliances on VMware ESXi version 4.1 or later, you use VMware vSphere client. The client or tool must be installed on a remote machine that can connect to VMware ESX through the network.

After the installation, you can use vSphere client or vSphere Web Client to manage virtual appliances on VMware ESX 4.1 or later release.

Note:

The VMware vSphere client shows the guest operating system as "Sun Solaris 10" for NetScaler virtual machine. This is by design because VMware ESXi does not recognize FreeBSD.

After the initial configuration of the NetScaler appliance, if you want to upgrade the appliance to the latest software release, see "[Upgrading or Downgrading the System Software](#)."

Prerequisites for Installing NetScaler Virtual Appliances on VMware

Before you begin installing a virtual appliance, do the following:

- Install VMware ESX version 4.1 or later on hardware that meets the minimum requirements.
- Install VMware Client on a management workstation that meets the minimum system requirements.
- Download the NetScaler virtual appliance setup files.
- Label the physical network ports of VMware ESX.
- Obtain NetScaler license files. For more information about NetScaler virtual appliance licenses, see the *NetScaler VPX Licensing Guide* at <http://support.citrix.com/article/ctx131110>.

VMware ESX Hardware Requirements

The following table describes the minimum system requirements for VMware ESX servers running NetScaler nCore virtual appliance.

Table 1. Minimum System Requirements for VMware ESX Servers Running NetScaler nCore virtual appliance

Component	Requirement
CPU	2 or more 64-bit x86 CPUs with virtualization assist (Intel-VT or AMD-V) enabled Note: To run NetScaler virtual appliance, hardware support for virtualization must be enabled on the VMware ESX host. Make sure that the BIOS option for virtualization support is not disabled. For more information, see your BIOS documentation.
RAM	3 GB
Disk space	40 GB of disk space available

Component	Requirement
Network	One 1-Gbps NIC; Two 1-Gbps NICs recommended (The network interfaces must be Intel E1000.)

For information about installing VMware ESX, see <http://www.vmware.com/>.

The following table lists the virtual computing resources that the VMware ESX server must provide for each NetScaler ncore virtual appliance.

Table 2. Minimum Virtual Computing Resources Required for Running NetScaler ncore virtual appliance

Component	Requirement
Memory	2 GB
Virtual CPU (VCPU)	2
Virtual network interfaces	1 Note: With ESX 4.1 or later, you can install a maximum of 10 virtual network interfaces if the VPX hardware is upgraded version to 7 or higher.
Disk space	20 GB Note: This is in addition to any disk requirements for the hypervisor.

Note: For production use of NetScaler virtual appliance, the full memory allocation must be reserved. CPU cycles (in MHz) equal to at least the speed of one CPU core of the ESX should also be reserved.

VMware vSphere Client System Requirements

VMware vSphere is a client application that can run on Windows and Linux operating systems. It cannot run on the same machine as the VMware ESX server. The following table describes the minimum system requirements.

Table 3. Minimum System Requirements for VMware vSphere Client Installation

Component	Requirement
Operating system	For detailed requirements from VMware, search for the "vSphere Compatibility Matrixes" PDF file at http://kb.vmware.com/ .
CPU	750 megahertz (MHz); 1 gigahertz (GHz) or faster recommended
RAM	1 GB; 2 GB recommended
Network Interface	100 Mbps or faster NIC

Card (NIC) Component	Requirement
-------------------------	-------------

OVF Tool 1.0 System Requirements

OVF Tool is a client application that can run on Windows and Linux systems. It cannot run on the same machine as the VMware ESX server. The following table describes the minimum system requirements.

Table 4. Minimum System Requirements for OVF Tool Installation

Component	Requirement
Operating system	For detailed requirements from VMware, search for the "OVF Tool User Guide" PDF file at http://kb.vmware.com/ .
CPU	750 MHz minimum, 1 GHz or faster recommended.
RAM	1 GB Minimum, 2 GB recommended.
Network Interface Card (NIC)	100 Mbps or faster NIC

For information about installing OVF, search for the "OVF Tool User Guide" PDF file at <http://kb.vmware.com/>.

Downloading the NetScaler virtual appliance Setup Files

The NetScaler virtual appliance setup package for VMware ESX follows the Open Virtual Machine (OVF) format standard. You can download the files from MyCitrix.com. You need a My Citrix account to log on. If you do not have a My Citrix account, access the home page at <http://www.mycitrix.com>, click the New Users link, and follow the instructions to create a new My Citrix account.

Once logged on, navigate the following path from the My Citrix home page:

MyCitrix.com > Downloads > NetScaler > Virtual Appliances.

Copy the following files to a workstation on the same network as the ESX server. Copy all three files into the same folder.

- NSVPX-ESX-<release number>-<build number>-disk1.vmdk (for example, NSVPX-ESX-9.3-39.8-disk1.vmdk)
- NSVPX-ESX-<release number>-<build number>.ovf (for example, NSVPX-ESX-9.3-39.8.ovf)
- NSVPX-ESX-<release number>-<build number>.mf (for example, NSVPX-ESX-9.3-39.8.mf)

Labeling the Physical Network Ports of VMware ESX

Before installing a NetScaler virtual appliance, label of all the interfaces that you plan to assign to virtual appliances, in a unique format, for example, NS_NIC_1_1, NS_NIC_1_2, and so on. In large deployments, labeling in a unique format helps in quickly identifying the interfaces that are allocated to the NetScaler virtual appliance among other interfaces used by other virtual machines, such as Windows and Linux. Such labeling is especially important when different types of virtual machines share the same interfaces.

To label the physical network ports of VMware ESX server

1. Log on to the VMware ESX server by using the vSphere client.
2. On the vSphere client, select the Configuration tab, and then click Networking.
3. At the top-right corner, click Add Networking.
4. In the Add Network Wizard, for **Connection Type**, select **Virtual Machine**, and then click Next.
5. Scroll through the list of vSwitch physical adapters, and choose the physical port that will map to interface 1/1 on the virtual appliances.
6. Enter the label of the interface, for example, **NS_NIC_1_1**, as the name of the vSwitch that will be associated with interface 1/1 of the virtual appliances.
7. Click Next to finish the vSwitch creation. Repeat the procedure, beginning with step 2, to add any additional interfaces to be used by your virtual appliances. Label the interfaces sequentially, in the correct format (for example, NS_NIC_1_2).

Installing NetScaler Virtual Appliances on VMware ESX 4.1 or Later

After you have installed and configured VMware ESX 4.1 or later, you can use the VMware vSphere client to install virtual appliances on the VMware ESX. The number of virtual appliances that you can install depends on the amount of memory available on the hardware that is running VMware ESX.

To install NetScaler virtual appliances on VMware ESX 4.1 or later by using VMware vSphere Client

1. Start the VMware vSphere client on your workstation.
2. In the IP address / Name text box, type the IP address of the VMware ESX server that you want to connect to.
3. In the User Name and Password text boxes, type the administrator credentials, and then click Login.
4. On the File menu, click Deploy OVF Template.
5. In the Deploy OVF Template dialog box, in Deploy from file, browse to the location at which you saved the NetScaler virtual appliance setup files, select the .ovf file, and click Next.
6. Map the networks shown in the virtual appliance OVF template to the networks that you configured on the ESX host. Click Next to start installing a virtual appliance on VMware ESX. When installation is complete, a pop-up window informs you of the successful installation.
7. You are now ready to start the NetScaler virtual appliance. In the navigation pane, select the NetScaler virtual appliance that you have just installed and, from the right-click menu, select Power On. Click the Console tab to emulate a console port.
8. If you want to install another virtual appliance, repeat steps 4 through 6.

Installing Citrix NetScaler Virtual Appliances on Microsoft Hyper-V Servers

Feb 09, 2015

Note:

- The NetScaler virtual appliance is supported on Microsoft Hyper-V Server 2008 R2, Microsoft Hyper-V Server 2012 and 2012 R2.
- Intermediate System-to-Intermediate System (ISIS) protocol is not supported on the NetScaler VPX virtual appliance hosted on the HyperV-2012 platform.

To install Citrix NetScaler virtual appliances on Microsoft Windows Server, you must first install Windows Server, with the Hyper-V role enabled, on a machine with adequate system resources. While installing the Hyper-V role, be sure to specify the network interface cards (NICs) on the server that Hyper-V will use to create the virtual networks. You can reserve some NICs for the host. Use Hyper-V Manager to perform the NetScaler virtual appliance installation.

NetScaler virtual appliance for Hyper-V is delivered in virtual hard disk (VHD) format. It includes the default configuration for elements such as CPU, network interfaces, and hard-disk size and format. After you install NetScaler virtual appliance, you can configure the network adapters on virtual appliance, add virtual NICs, and then assign the NetScaler IP address, subnet mask, and gateway, and complete the basic configuration of the virtual appliance.

Note:

After the initial configuration of the NetScaler appliance, if you want to upgrade the appliance to the latest software release, see "[Upgrading or Downgrading the System Software](#)."

Prerequisites for Installing NetScaler Virtual Appliance on Microsoft Servers

Updated: 2014-08-07

Before you begin installing a virtual appliance, do the following:

- Enable the Hyper-V role on Windows Servers . For more information, see [http://technet.microsoft.com/en-us/library/ee344837\(WS.10\).aspx](http://technet.microsoft.com/en-us/library/ee344837(WS.10).aspx).
- Download the virtual appliance setup files.
- Obtain NetScaler virtual appliance license files. For more information about NetScaler virtual appliance licenses, see the *NetScaler VPX Licensing Guide* at <http://support.citrix.com/article/ctx131110>.

Microsoft Server Hardware Requirements

The following table describes the minimum system requirements for Microsoft Servers .

Table 1. Minimum System Requirements for Microsoft Servers

Component	Requirement
CPU	1.4 GHz 64-bit processor
RAM	3 GB

Disk Space Component	32 GB or greater Requirement
--------------------------------	--

The following table lists the virtual computing resources for each NetScaler virtual appliance.

Table 2. Minimum Virtual Computing Resources Required for Running NetScaler Virtual Appliance

Component	Requirement
RAM	2 GB
Virtual CPU	2
Disk Space	20 GB
Virtual Network Interfaces	1

Downloading the NetScaler Virtual Appliance Setup Files

NetScaler virtual appliance for Hyper-V is delivered in virtual hard disk (VHD) format. You can download the files from MyCitrix.com. You will need a My Citrix account to log on. If you do not have a My Citrix account, access the home page at <http://www.mycitrix.com>, click the New Users link, and follow the instructions to create a new My Citrix account.

To download the NetScaler virtual appliance setup files

1. In a Web browser, go to <http://www.citrix.com/> and click My Citrix.
2. Type your user name and password.
3. Click Downloads.
4. In Search Downloads by Product, select NetScaler.
5. Under Virtual Appliances, click NetScaler VPX.
6. Copy the compressed file to your server.

Installing NetScaler Virtual Appliance on Microsoft Servers

Updated: 2014-08-07

After you have enabled the Hyper-V role on Microsoft Server and extracted the virtual appliance files, you can use Hyper-V Manager to install NetScaler virtual appliance. After you import the virtual machine, you need to configure the virtual NICs by associating them to the virtual networks created by Hyper-V.

You can configure a maximum of eight virtual NICs. Even if the physical NIC is DOWN, the virtual appliance assumes that the virtual NIC is UP, because it can still communicate with the other virtual appliances on the same host (server).

Note: You cannot change any settings while the virtual appliance is running. Shut down the virtual appliance and then make changes.

To install NetScaler Virtual Appliance on Microsoft Server by using Hyper-V

Manager

1. To start Hyper-V Manager, click **Start**, point to **Administrative Tools**, and then click **Hyper-V Manager**.
2. In the navigation pane, under Hyper-V Manager, select the server on which you want to install NetScaler virtual appliance.
3. On the **Action** menu, click **Import Virtual Machine**.
4. In the **Import Virtual Machine** dialog box, in **Location**, specify the path of the folder that contains the NetScaler virtual appliance software files, and then select **Copy the virtual machine (create a new unique ID)**. This folder is the parent folder that contains the Snapshots, Virtual Hard Disks, and Virtual Machines folders.
Note: If you received a compressed file, make sure that you extract the files into a folder before you specify the path to the folder.
5. Click **Import**.
6. Verify that the virtual appliance that you imported is listed under **Virtual Machines**.
7. To install another virtual appliance, repeat steps 2 through 6.
Important: Make sure that you extract the files to a different folder in step 4.

To configure virtual NICs on the NetScaler Virtual Appliance

1. Select the virtual appliance that you imported, and then on the **Action** menu, select **Settings**.
2. In the **Settings for <virtual appliance name>** dialog box, click **Add Hardware** in the left pane.
3. In the right pane, from the list of devices, select **Network Adapter**.
4. Click **Add**.
5. Verify that **Network Adapter (not connected)** appears in the left pane.
6. Select the network adapter in the left pane.
7. In the right pane, from the **Network** drop-down list, select the virtual network to connect the adapter to.
8. To select the virtual network for additional network adapters that you want to use, repeat steps 6 and 7.
9. Click **Apply**, and then click **OK**.

To configure NetScaler Virtual Appliance

1. Right-click the virtual appliance that you previously installed, and then select **Start**.
2. Access the console by double-clicking the virtual appliance.
3. Type the NetScaler IP address, subnet mask, and gateway for your virtual appliance.

You have completed the basic configuration of your virtual appliance. Type the IP address in a Web browser to access the virtual appliance.

Installing NetScaler Virtual Appliances on Linux-KVM Platform

Mar 09, 2015

To set up NetScaler VPX for the Linux-KVM platform, you can use the graphical Virtual Machine Manager (Virt-Manager) application. If you prefer the Linux-KVM command line, you can use the `virsh` program.

The host Linux operating system must be installed on suitable hardware by using virtualization tools such as KVM Module and QEMU. The number of virtual machines (VMs) that can be deployed on the hypervisor depends on the application requirement and the chosen hardware.

After you provision a NetScaler virtual appliance, you can add additional interfaces.

Limitations and Usage Guidelines

General Recommendations

To avoid unpredictable behavior, apply the following recommendations:

- Do not change the MTU of the `vnet` interface associated with the NetScaler VM. Shut down the NetScaler VM before modifying any configuration parameters, such as Interface modes or CPU.
- Do not force a shutdown of the NetScaler VM. That is, do not use the **Force off** command.
- Any configurations done on the host Linux might or might not be persistent, depending on your Linux distribution settings. You can choose to make these configurations persistent to ensure consistent behavior across reboots of host Linux operating system.
- The `.raw` file has to be unique for each of the NetScaler VPX instance provisioned.

Limitations

A NetScaler VPX setup on the Linux-KVM platform has the following limitations:

- VLAN tagging is not supported on Netscaler-VPX operating on MacVTap-Bridge, MacVTap-Private, MacVTap-VEPA, or MacVTap-Passthrough interface Mode.
- L2 mode is not supported on Netscaler VPX running on a Linux-KVM host.
- Interface parameter configurations, such as speed, duplex, and auto-negotiation are not supported
- Interface events, such as link UP and DOWN are not supported. Because these events are not reported, the following features are not supported:
 - Static link aggregation
 - Dynamic route advertisement for connected networks
 - Monitored static routes
 - Avoiding split brains in a high availability (HA) setup
 - Partial failure detection in an HA setup
- LACP is not supported on Netscaler VPX operating in Bridge, MacVTap-Bridge, MacVTap-Private, or MacVTap-VEPA interface mode.
- Live Migration of the Netscaler VPX running on KVM is not supported.
- When a VLAN tagged packet destined for a guest VM is received on an Intel IXGBE 10G interface of a KVM host running on Red Hat Enterprise Linux (RHEL) 6.4, the IXGBE driver of this distribution strips the VLAN tag before sending it to the

guest VM (in this case, NetScaler VPX). Because of this host behavior, a NetScaler VPX instance running on RHEL6.4 does not receive the intended VLAN tagged packets.

Prerequisites for Installing NetScaler VPX Virtual Appliances on Linux-KVM Platform

Sep 30, 2015

Hardware Requirements

The following table describes the minimum system requirements for Linux-KVM servers running NetScaler VPX.

Component	Requirement
CPU	<ul style="list-style-type: none">64-bit x86 processors with the hardware virtualization features included in the AMD-V and Intel VT-X processors. To test whether your CPU supports Linux host, enter the following command at the host Linux shell prompt: .egrep'^flags.*(vmx svm)'/proc/cpuinfo If the BIOS settings for the above extension are disabled, you must enable them in BIOS.Provide at least 2 CPU cores to Host Linux.There is no specific recommendation for processor speed, but higher the speed, the better the performance of the VM application.
Memory (RAM)	Minimum 4 GB for the host Linux kernel. Add additional memory as required by the VMs.
Hard Disk	Calculate the space for Host Linux kernel and VM requirements. A single NetScaler VPX VM requires 20 GB of disk space.

Software Requirements

The Host kernel used must be a 64-bit Linux kernel, release 2.6.20 or later, with all virtualization tools. Citrix recommends newer kernels, such as 3.6.11-4 and later.

Many Linux distributions such as Red Hat, Centos, and Fedora, have tested kernel versions and associated virtualization tools.

Guest VM Hardware Requirements

NetScaler VPX supports only IDE hard disk type. The Hard Disk Type has been configured in the XML file which is a part of the NetScaler package.

Networking Requirements

NetScaler VPX supports only virtIO para-virtualized network interfaces.

Source Interface and Modes

The source device type can be either Bridge or MacVTap. In case of MacVTap, four modes are possible - VEPA, Bridge,

Private and Pass-through.

The following tables list the types of interfaces that you can use and the supported traffic types.

For best performance by the NetScaler instance, make sure that the gro and lro capabilities are switched off on the source interfaces

Table 1. Interface Types

Interface Type	Considerations
Source: Bridge	<ul style="list-style-type: none"> • Linux Bridge. • Ebtables and iptables settings on host Linux might filter the traffic on the bridge if you do not choose the correct setting or disable IPTable services.
Source: MacVTap Mode : VEPA	<ul style="list-style-type: none"> • Better performance than a bridge. • Interfaces from the same lower device can be shared across the VMs. • Inter-VM communication using the same lower device is possible only if upstream or downstream switch supports VEPA mode.
Source: MacVTap Mode : Private	<ul style="list-style-type: none"> • Better performance than a bridge. • Interfaces from the same lower device can be shared across the VMs. • Inter-VM communication using the same lower device is not possible.
Source: MacVTap Mode : Bridge	<ul style="list-style-type: none"> • Better as compared to bridge. • Interfaces out of same lower device can be shared across the VMs. • Inter-VM communication using the same lower device is possible, if lower device link is UP.
Source: MacVTap Mode : Pass- through	<ul style="list-style-type: none"> • Better as compared to bridge. • Interfaces out of same lower device cannot be shared across the VMs. • Only one VM can use the lower device.

Table 2. Verified Traffic Types

Test Case	Bridge	MacVTap			
		VEPA	Private	Bridge	Pass-through
Untagged IPv4	S	S	S	S	S
Tagged IPv4	S	NS	NS	NS	NS

IPv4 L3 Forwarding Test Case	Bridge	MacVTap	S	S	S
IPv4 Endpoint Traffic	S	VEPA	Private	Bridge	Pass-through
Broadcast/Multicast Traffic	S	S	S	S	S
Untagged IPv6	S	S	S	S	S
Tagged IPv6	S	NS	NS	NS	NS
IPv6 L3 Forwarding	S	S	S	S	S
IPv6 Endpoint Traffic	S	S	S	S	S

S - Supported.

NS - Not Supported.

Properties Of Source Interfaces

Make sure that you switch off the generic-receive-offload (gro) and large-receive-offload (lro) capabilities of the source interfaces. To switch off the gro and lro capabilities, run the following commands at the host Linux shell prompt.

```
ethtool -K eth6 gro off
```

```
ethtool -K eth6 lro off
```

Example

```
[root@localhost ~]# ethtool -K eth6
Offload parameters for eth6:
 rx-checksumming: on
 tx-checksumming: on
 scatter-gather: on
 tcp-segmentation-offload: on
 udp-fragmentation-offload: off
 generic-segmentation-offload: on
 generic-receive-offload: off
 large-receive-offload: off
 rx-vlan-offload: on
 tx-vlan-offload: on
 ntuple-filters: off
 receive-hashing: on
[root@localhost ~]#
```

Example

If the host Linux bridge is used as a source device, as in the following example, gro and lro capabilities must be switched off

on the vnet interfaces, which are the virtual interfaces connecting the host to the guest VMs.

```
[root@localhost ~]# brctl show eth6_br
bridge name   bridge id     STP enabled  interfaces
eth6_br      8000.00e0ed1861ae  no          eth6
                                     vnet0
                                     vnet2
```

```
[root@localhost ~]#
```

In the above example, the two virtual interfaces are derived from the eth6_br and are represented as vnet0 and vnet2. Run the following commands to switch off gro and lro capabilities on these interfaces.

```
ethtool -K vnet0 gro off
ethtool -K vnet2 gro off
ethtool -K vnet0 lro off
ethtool -K vnet2 lro off
```

Module Required

For better network performance, make sure the vhost_net module is present in the Linux host. To check the existence of vhost_net module, run the following command on the Linux host :

```
lsmod | grep "vhost_net"
```

If vhost_net is not yet running, enter the following command to run it:

```
modprobe vhost_net
```

Provisioning the NetScaler Virtual Appliance by using OpenStack

Oct 09, 2016

You can provision a NetScaler vpx instance in an OpenStack environment either by using the OpenStack command line interface or the OpenStack dashboard or GUI.

Provisioning a NetScaler instance, optionally involves using data from the config drive. Config drive is a special configuration drive that attaches to the instance when it boots. This configuration drive can be used to pass networking configuration like management IP address, network mask, default gateway etc, which the instance can mount and access before you configure the network settings for the instance.

When OpenStack provisions a NetScaler instance, it first detects that the instance is booting in an OpenStack environment by reading a specific BIOS string that indicates OpenStack. This string is 'OpenStack Foundation' and for Redhat Linux distributions, the string is stored in /etc/nova/release. This is a standard mechanism that is available in all OpenStack implementations based on KVM hyper-visor platform. The drive should have a specific OpenStack label.

If the config drive is detected, the instance attempts to read the following information from the file name specified in the nova boot command. In the steps mentioned below, the file is referred as userdata:

- Management IP address
- Network mask
- Default gateway

Once the parameters are successfully read, they are populated in the NetScaler stack. This helps in managing the instance remotely. If the parameters are not read successfully or the config drive is not available, the instance transitions to the default behavior, which is:

- The instance attempts to retrieve the IP address information from DHCP
- If DHCP fails or times-out, the instance comes up with default network configuration (192.168.100.1/16)

Provisioning the NetScaler Virtual Appliance by using OpenStack Using Command Line Interface

Updated: 2015-02-16

You can provision a NetScaler appliance in an OpenStack environment. Provisioning a NetScaler Virtual Appliance on OpenStack involves the following three steps:

1. Extracting the .raw file from the .ova file
2. Building an OpenStack image from the raw image
3. Provisioning a NetScaler instance

To provision a NetScaler instance in an OpenStack environment, complete the following steps:

1. Extract the .raw file from the .ova file.

```
tar xvzf NetScaler1000V-KVM-10.5-49.3_nc.ova
NetScaler1000V-KVM.xml
NetScaler1000V-KVM-10.5-49.3_nc.raw
checksum.txt
```
2. Build an OpenStack image using the .raw file extracted in step 1.

```
glance image-create --name="NS-VPX-10-1-127-1" --property hw_disk_bus=ide --is-public=true
```

```
--container-format=bare --disk-format=raw < NetScaler1000V-KVM-10.1-127.1_nc.raw
```

In the above command, NS-VPX-10-1-127-1 is the name of the OpenStack image that you want to create.

NetScaler1000V-KVM-10.1-127.1_nc.raw is the raw file that was extracted from the ova file. The raw file is the input for creating the OpenStack image.

The following illustration provides a sample output for the glance image-create command.

Property	Value
Property 'hw_disk_bus'	ide
checksum	65b027c72d668abe9941716325731872
container_format	bare
created_at	2014-06-12T06:15:50
deleted	False
deleted_at	None
disk_format	raw
id	102d3621-c6b7-4823-bbf3-2ff47476cdc0
is_public	True
min_disk	0
min_ram	0
name	NS-VPX-10-5-49-3
owner	e6f3a3cc7f764f639370060f1d121a88
protected	False
size	21474836480
status	active
updated_at	2014-06-12T06:21:41
virtual_size	None

3. After an OpenStack image is created, provision the NetScaler virtual appliance instance.

```
nova boot --image NS-VPX-10-1-127-1 --config-drive=true --user-data ./userdata.txt
```

```
--flavor m1.medium --nic net-id=b8c5acee-36b7-4517-af0e-80f8729aa82e vpx10_1_u
```

In the above command, userdata.txt is the file which contains the details like, IP address, netmask, and default gateway for the NetScaler instance. The userdata file is a user customizable file. vpx10_1_u is the name of the virtual appliance that you want to provision.

The following illustration gives a sample output of the nova boot command.

Property	Value
OS-DCF:diskConfig	MANUAL
OS-EXT-AZ:availability_zone	nova
OS-EXT-STS:power_state	0
OS-EXT-STS:task_state	scheduling
OS-EXT-STS:vm_state	building
OS-SRV-USG:launched_at	-
OS-SRV-USG:terminated_at	-
accessIPv4	
accessIPv6

```

Provisioning the NetScaler Virtual Appliance by using OpenStack Dashboard

Updated: 2015-02-26

You can provisioning NetScaler in an OpenStack environment using the OpenStack dashboard.

1. Log in to the OpenStack dashboard.
2. In the Project panel on the left hand side of the dashboard, select Instances.
3. In the Instances panel, click Launch Instance to open the Instance Launching Wizard.

4. In the Launch Instance wizard, fill in the details, like:
 1. Instance Name
 2. Instance Flavor
 3. Instance Count
 4. Instance Boot Source
 5. Image Name

Launch Instance ✕

Details * Access & Security * Networking * Post-Creation Advanced Options

Availability Zone
nova

Instance Name *
NS1000v-Instance 1

Flavor *
m1.medium 2

Instance Count *
1 3

Instance Boot Source *
Boot from image 4

Image Name
NS-VPX-10-5-49-3 (20.0 GB) 5

Specify the details for launching an instance.
The chart below shows the resources used by this project in relation to the project's quotas.

Flavor Details

Name	m1.medium
VCPUs	2
Root Disk	40 GB
Ephemeral Disk	0 GB
Total Disk	40 GB
RAM	4,096 MB

Project Limits

Number of Instances	3 of 10 Used
Number of VCPUs	6 of 20 Used
Total RAM	12,288 of 51,200 MB Used

Cancel **Launch**

5. Click on the Post Creation tab in the wizard. In the Customization Script, add the content of the userdata file. The userdata file contains the IP address, Netmask and Gateway details of the NetScaler instance.
6. Click Launch.

Provisioning the NetScaler Virtual Appliance by using the Virtual Machine Manager

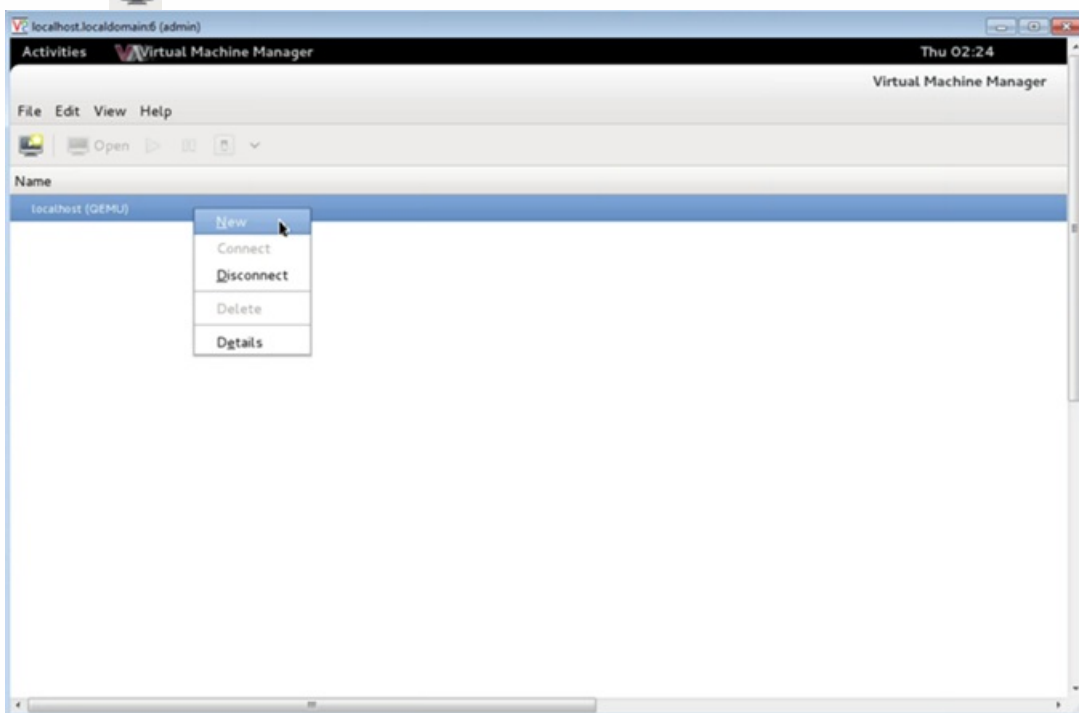

Mar 10, 2015

The Virtual Machine Manager is a desktop tool for managing VM Guests. It enables you to create new VM Guests and various types of storage, and manage virtual networks. You can access the graphical console of VM Guests with the built-in VNC viewer and view performance statistics, either locally or remotely.

After installing your preferred Linux distribution, with KVM virtualization enabled, you can proceed with provisioning virtual machines.

To provision a NetScaler VPX by using Virtual Machine Manager

1. Open the Virtual Machine Manager (**Application > System Tools > Virtual Machine Manager**) and enter the logon credentials in the **Authenticate** window.
2. Click the  icon or right-click **localhost (QEMU)** to create a new NetScaler VPX instance.

3. In the **Name** text box, enter a name for the new VM (for example, NetScaler-VPX).
4. In the **New VM** window, under "Choose how you would like to install the operating system," select **Import existing disk image**, and then and click **Forward**.

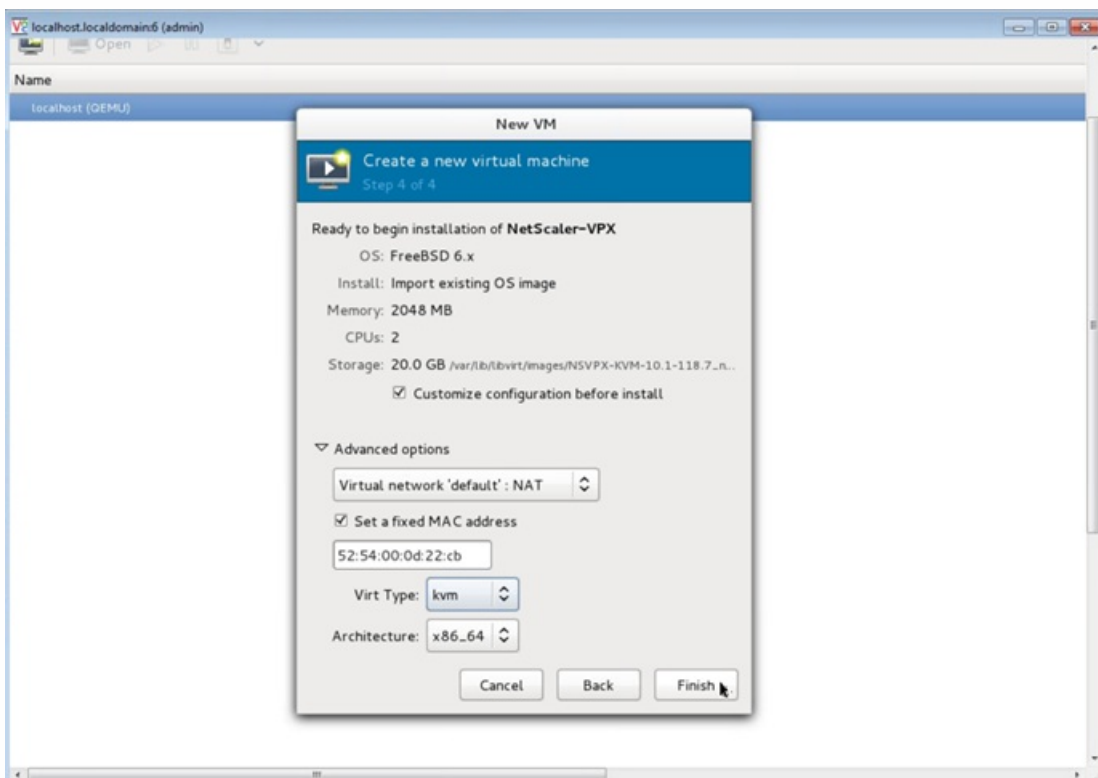

5. In the **Provide the existing storage path** field, navigate the path to the image. Choose the OS type as UNIX and Version as FreeBSD 6.x. Then, click **Forward**.

6. Under "Choose Memory and CPU settings," select the following settings, and then click **Forward**:
- Memory (RAM)— 2048 MB
 - CPUs— 2

7. Select the **Customize configuration before install** check box. Optionally, under "Advanced options," you can customize the MAC address. Make sure the **Virt Type** selected is **kvm** and the Architecture selected is **x86_64**. Click **Finish**.

8. Select a NIC and provide the following configuration:
- Source device— ethX macvtap or Bridge
 - Device model— virtio

- Source mode— Bridge

9. Click **Apply**, and then click **Begin Installation**. After you have provisioned the NetScaler VPX on KVM, you can add additional interfaces

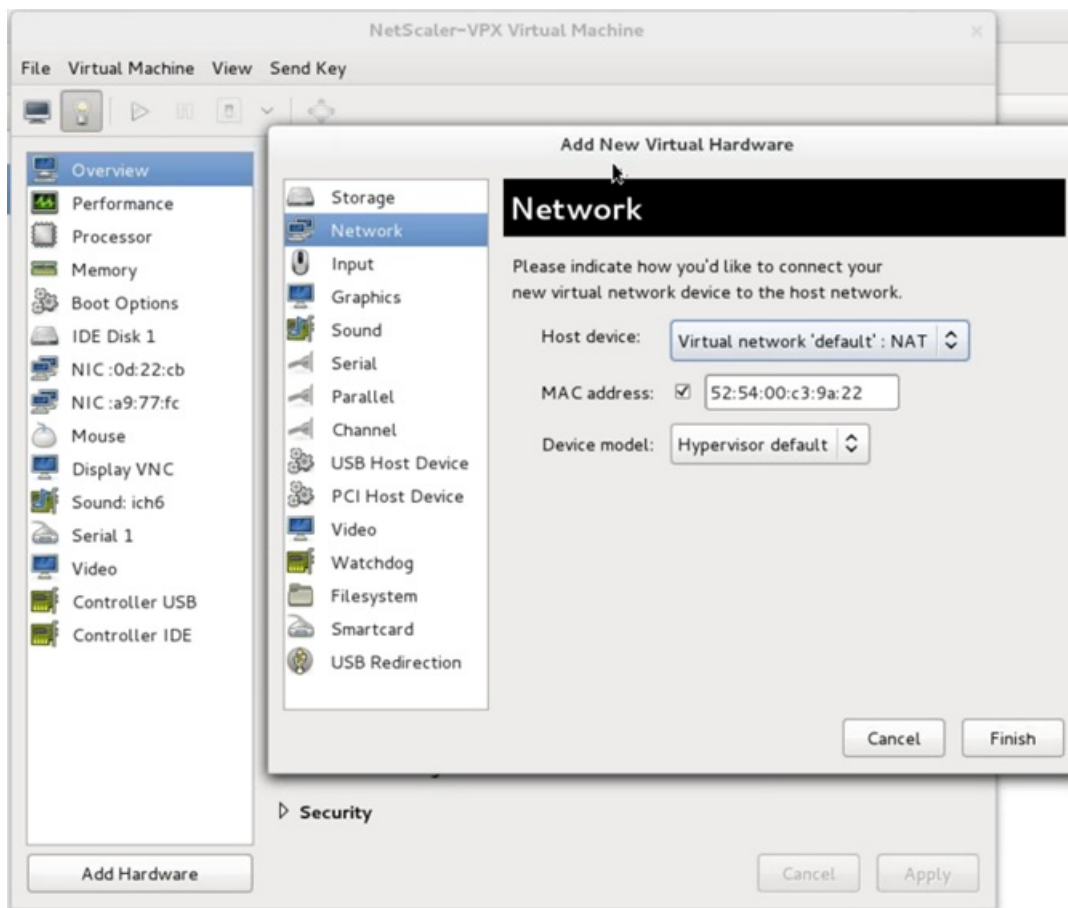

Adding Additional Interfaces to NetScaler VPX by using Virtual Machine Manager

Updated: 2015-03-11

After you have provisioned the NetScaler VPX on KVM, you can add additional interfaces.

To add additional interfaces

1. Shut down the NetScaler VPX instance running on the KVM.
2. Right-click the VPX instance and choose **Open** from the pop-up menu.
3. Click the  icon in the header to view the virtual hardware details.
4. Click **Add Hardware**. In the **Add New Virtual Hardware window**, select **Network** from the navigation menu.

5. In **Host Device** field, select the physical interface type. The host device type can be either Bridge or MacVTap. In case of MacVTap, four modes possible are VEPA, Bridge, Private and Pass-through.

1. For Bridge

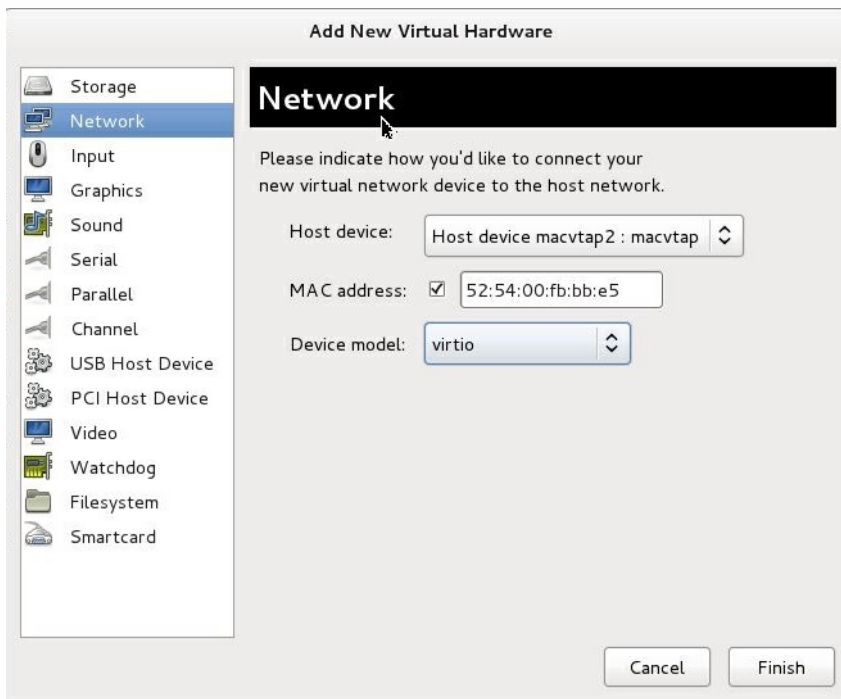

1. Host device— Select the "Specify shared device name" option.

2. Provide the Bridge name that is configured in the KVM host.

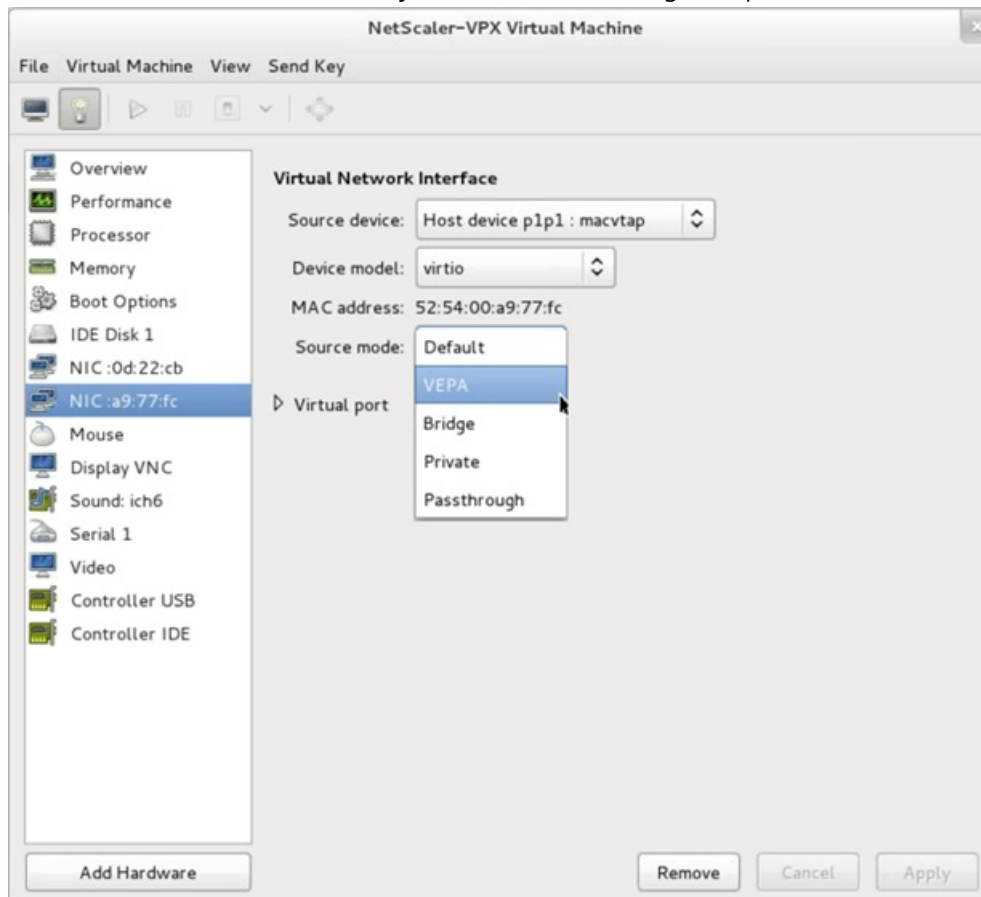

Note: Make sure that you have configured a Linux bridge in the KVM host, bound the physical interface to the bridge, and put the bridge in the UP state.

3. Device model—virtio.
 4. Click Finish.
2. For MacVTap
 1. Host device—Select the physical interface from the menu.
 2. Device model—virtio.

3. Click Finish. You can view the newly added NIC in the navigation pane.

4. Select the newly added NIC and select the Source mode for this NIC. The available modes are VEPA, Bridge, Private, and Passthrough. For more details on the interface and modes, see Source Interface and Modes.

5. Click Apply.

6. Start the NetScaler VPX VM.

Provisioning the NetScaler Virtual Appliance by using the virsh Program

Mar 10, 2015

The virsh program is a command line tool for managing VM Guests. Its functionality is similar to that of Virtual Machine Manager. It enables you to change a VM Guest's status (start, stop, pause, and so on), to set up new Guests and devices, and to edit existing configurations. The virsh program is also useful for scripting VM Guest management operations.

To provision NetScaler VPX by using the virsh program

1. Use the tar command to untar the the NetScaler VPX package. The NSVPX-KVM-*_nc.tgz package contains following components:
 - The Domain XML file specifying VPX attributes [NSVPX-KVM-*_nc.xml]
 - Check sum of NS-VM Disk Image [Checksum.txt]
 - NS-VM Disk Image [NSVPX-KVM-*_nc.raw]

Example:

```
tar -xvzf NSVPX-KVM-10.1-117_nc.tgz
NSVPX-KVM-10.1-117_nc.xml
NSVPX-KVM-10.1-117_nc.raw
checksum.txt
```

2. Copy the NSVPX-KVM-*_nc.xml XML file to a file named <DomainName>-NSVPX-KVM-*_nc.xml. The <DomainName> is also the name of the virtual machine. Example:

```
cp NSVPX-KVM-10.1-117_nc.xml NetScaler-VPX-NSVPX-KVM-10.1-117_nc.xml
```

3. Edit the <DomainName>-NSVPX-KVM-*_nc.xml file to specify the following parameters:

- name— Specify the name.
- mac— Specify the MAC address.
Note: The domain name and the MAC address have to be unique.
- sourcefile— Specify the absolute disk-image source path. The file path has to be absolute. In this example, the disk image is at the following location: /root/NSVPX-KVM-10.1-117_nc.raw.

Example:

```
<name>NetScaler-VPX</name>
  <mac address='52:54:00:29:74:b3'/>
  <source file='/root/NSVPX-KVM-10.1-117_nc.raw'/>
```

4. Edit the <DomainName>-NSVPX-KVM-*_nc.xml file to configure the networking details:

- source dev— specify the interface.
- mode— specify the mode. The default interface is **Macvtap Bridge**.

Example: Mode: MacVTap Bridge Set target interface as ethx and mode as bridge Model type as virtio

```
<interface type='direct'>
  <mac address='52:54:00:29:74:b3'/>
  <source dev='eth0' mode='bridge'/>
  <target dev='macvtap0'/>
  <model type='virtio'/>
  <alias name='net0'/>
  <address type='pci' domain='0x0000' bus='0x00' slot='0x03' function='0x0'/>
</interface>
```

Here, eth0 is the physical interface attached to the VM.

5. Define the VM attributes in the <DomainName>-NSVPX-KVM-*_nc.xml file by using the following command: virsh define <DomainName>-NSVPX-KVM-*_nc.xml Example:
virsh define NS-VPX-NSVPX-KVM-10.1-117_nc.xml
6. Start the VM by entering following command: virsh start [<DomainName> | <DomainUUID>] Example:
virsh start NetScaler-VPX
7. Connect the Guest VM through the console virsh console [<DomainName> | <DomainUUID> |<DomainID>] Example:
virsh console NetScaler-VPX

Adding Additional Interfaces to NetScaler VPX using virsh Program

Updated: 2015-03-09

After you have provisioned the NetScaler VPX on KVM, you can add additional interfaces.

To add additional interfaces

1. Shut down the NetScaler VPX instance running on the KVM.
2. Edit the <DomainName>-NSVPX-KVM-*_nc.xml file using the command: virsh edit [<DomainName> | <DomainUUID>]
3. In the <DomainName>-NSVPX-KVM-*_nc.xml file, append the following parameters:

1. For MacVTap

- Interface type— Specify the interface type as 'direct'.
- Mac address— Specify the Mac address and make sure the MAC address is unique across the interfaces.
- source dev— Specify the interface name.
- mode— Specify the mode; the modes supported are - Bridge, VEPA, Private, and Pass-through
- model type— Specify the model type as virtio

Example:

Mode: MacVTap Pass-through

Set target interface as ethx, Mode as bridge, and model type as virtio

```
<interface type='direct'>
  <mac address='52:54:00:29:74:b3'>
  <source dev='eth1' mode='passthrough'>
  <model type='virtio'>
</interface>
```

Here eth1 is the physical interface attached to the VM.

2. For Bridge Mode

Note: Make sure that you have configured a Linux bridge in the KVM host, bound the physical interface to the bridge, and put the bridge in the UP state.

- Interface type— Specify the interface type as 'bridge'.
- Mac address— Specify the Mac address and make sure the MAC address is unique across the interfaces.
- source bridge— Specify the bridge name.
- model type— Specify the model type as virtio

Example: Bridge Mode

```
<interface type='bridge'>
  <mac address='52:54:00:2d:43:a4'>
  <source bridge='br0'>
```

```
<model type='virtio'/>  
</interface>
```

Managing the NetScaler Guest VMs

Sep 03, 2013

You can use the Virtual Machine Manager and the virsh program to perform management tasks such as starting or stopping a VM Guest, setting up new guests and devices, editing existing configurations, and connecting to the graphical console through Virtual Network Computing (VNC).

Managing the NetScaler Guest VMs using Virtual Machine Manager

Updated: 2013-09-04

Listing the VM Guests

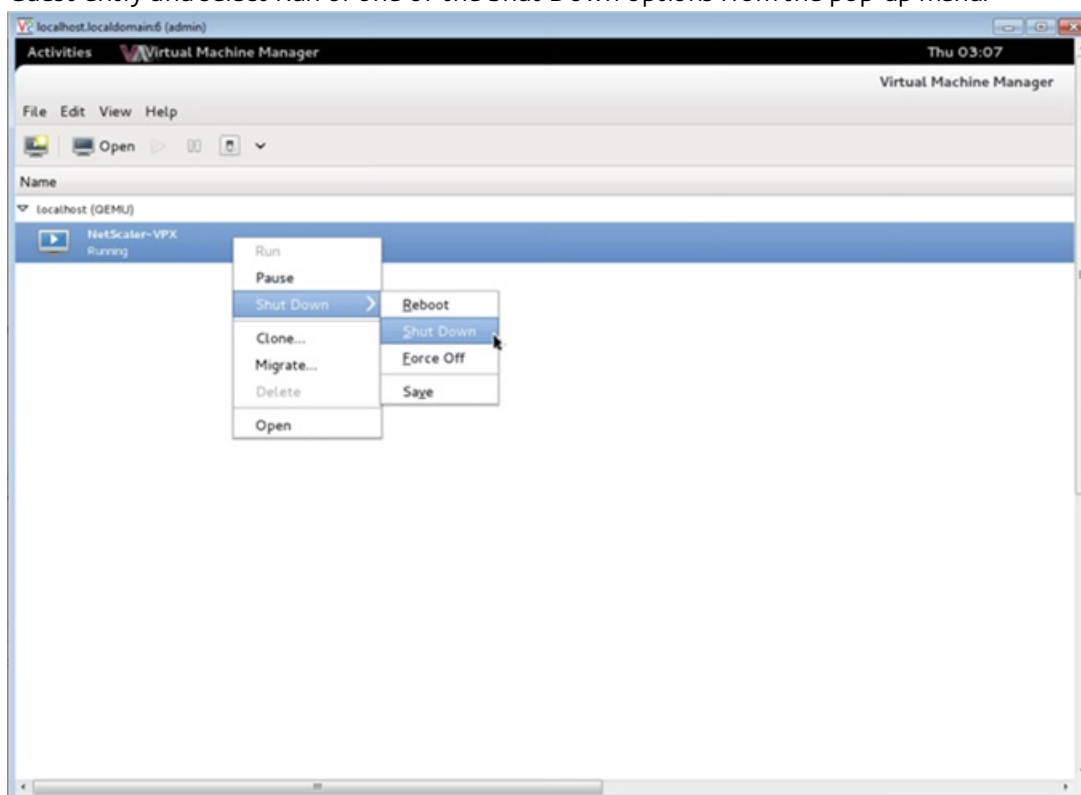

The main Window of the Virtual Machine Manager displays a list of all the VM Guests for each VM host server it is connected to. Each VM Guest entry contains the virtual machine's name, along with its status (Running, Paused, or Shutoff) displayed as icon.

Opening a Graphical Console

Opening a Graphical Console to a VM Guest enables you to interact with the machine like you would with a physical host through a VNC connection. To open the graphical console in the Virtual Machine Manager, right-click the VM Guest entry and select the Open option from the pop-up menu.

Starting and Shutting Down a Guest

You can start or stop a VM Guest from the Virtual Machine Manager. To change the state of the VM, right-click the VM Guest entry and select Run or one of the Shut Down options from the pop-up menu.

Rebooting a Guest

You can reboot a VM Guest from the Virtual Machine Manager. To reboot the VM, right-click the VM Guest entry, and then

select Shut Down > Reboot from the pop-up menu.

Deleting a Guest

Deleting a VM Guest removes its XML configuration by default. You can also delete a guest's storage files. Doing so completely erases the guest.

1. In the Virtual Machine Manager, right-click the VM Guest entry.
2. Select Delete from the pop-up menu. A confirmation window opens.
Note: The Delete option is enabled only when the VM Guest is shut down.
3. Click Delete.
4. To completely erase the guest, delete the associated .raw file by selecting the Delete Associated Storage Files check box.

Managing the NetScaler Guest VMs using the virsh Program

Updated: 2013-09-04

Listing the VM Guests and their current states

To use virsh to display information about the Guests

```
virsh list --all
```

The command output displays all domains with their states.

Example Output:

Id	Name	State
0	Domain-0	running
1	Domain-1	paused
2	Domain-2	inactive
3	Domain-3	crashed

Opening a virsh Console

Connect the Guest VM through the console

```
virsh console [<DomainID> | <DomainName> | <DomainUUID>]
```

Example:

```
virsh console NetScaler-VPX
```

Starting and Shutting Down a Guest

Guests can be started using the DomainName or Domain-UUID.

```
virsh start [<DomainName> | <DomainUUID>]
```

Example

```
virsh start NetScaler-VPX
```

To shut down a guest:

```
virsh shutdown [<DomainID> | <DomainName> | <DomainUUID>]
```

Example:

```
virsh shutdown NetScaler-VPX
```

Rebooting a Guest

```
virsh reboot [<DomainID> | <DomainName> | <DomainUUID>]
```

Example:

```
virsh reboot NetScaler-VPX
```

Deleting a Guest

To delete a Guest VM you need to shut-down the Guest and un-define the <DomainName>-NSVPX-KVM-*_nc.xml before you run the delete command.

```
virsh shutdown [<DomainID> | <DomainName> | <DomainUUID>]
```

```
virsh undefine [<DomainName> | <DomainUUID>]
```

Example:

```
virsh shutdown NetScaler-VPX
```

```
virsh undefine NetScaler-VPX
```

Note: The delete command doesn't remove disk image file which needs to be removed manually.

Installing NetScaler VPX on AWS

Jan 29, 2014

You can now launch an instance of Citrix® NetScaler VPX within Amazon Web Services (AWS). NetScaler VPX is available as an Amazon Machine Image (AMI) in AWS marketplace. NetScaler VPX on AWS enables customers to leverage AWS Cloud computing capabilities and use NetScaler load balancing and traffic management features for their business needs. NetScaler on AWS supports all the traffic management features of a physical NetScaler appliance. NetScaler instances running in AWS can be deployed as standalone instances or in HA pairs.

How NetScaler VPX on AWS Works

Updated: 2014-05-13

AWS offers different types of web services, such as Amazon Simple Storage Services (S3), Amazon Elastic Cloud Compute (EC2), and Amazon Virtual Private Cloud (VPC). Amazon VPC allows you to run AWS resources (for example, EC2 instances) in a private, virtual network. Amazon EC2 instances are available as instance types that map to hardware archetypes on the basis of factors such as number of EC2 Compute Units (ECU), number of virtual cores, and memory size.

The NetScaler VPX AMI is packaged as an EC2 instance that is launched within an AWS VPC. The VPX AMI instance requires a minimum of 2 virtual CPUs and 2 GB of memory. An EC2 instance launched within an AWS VPC can also provide the multiple interfaces, multiple IP addresses per interface, and public and private IP addresses needed for VPX configuration. Currently, on Amazon AWS, VPX can be launched only within a VPC, because each VPX instance requires at least three IP addresses. (Although VPX on AWS can be implemented with one or two elastic network interfaces, Citrix recommends three network interfaces for a standard VPX on AWS installation.) AWS currently makes multi-IP functionality available only to instances running within an AWS VPC. A VPX instance in a VPC can be used to load balance servers running in EC2 instances.

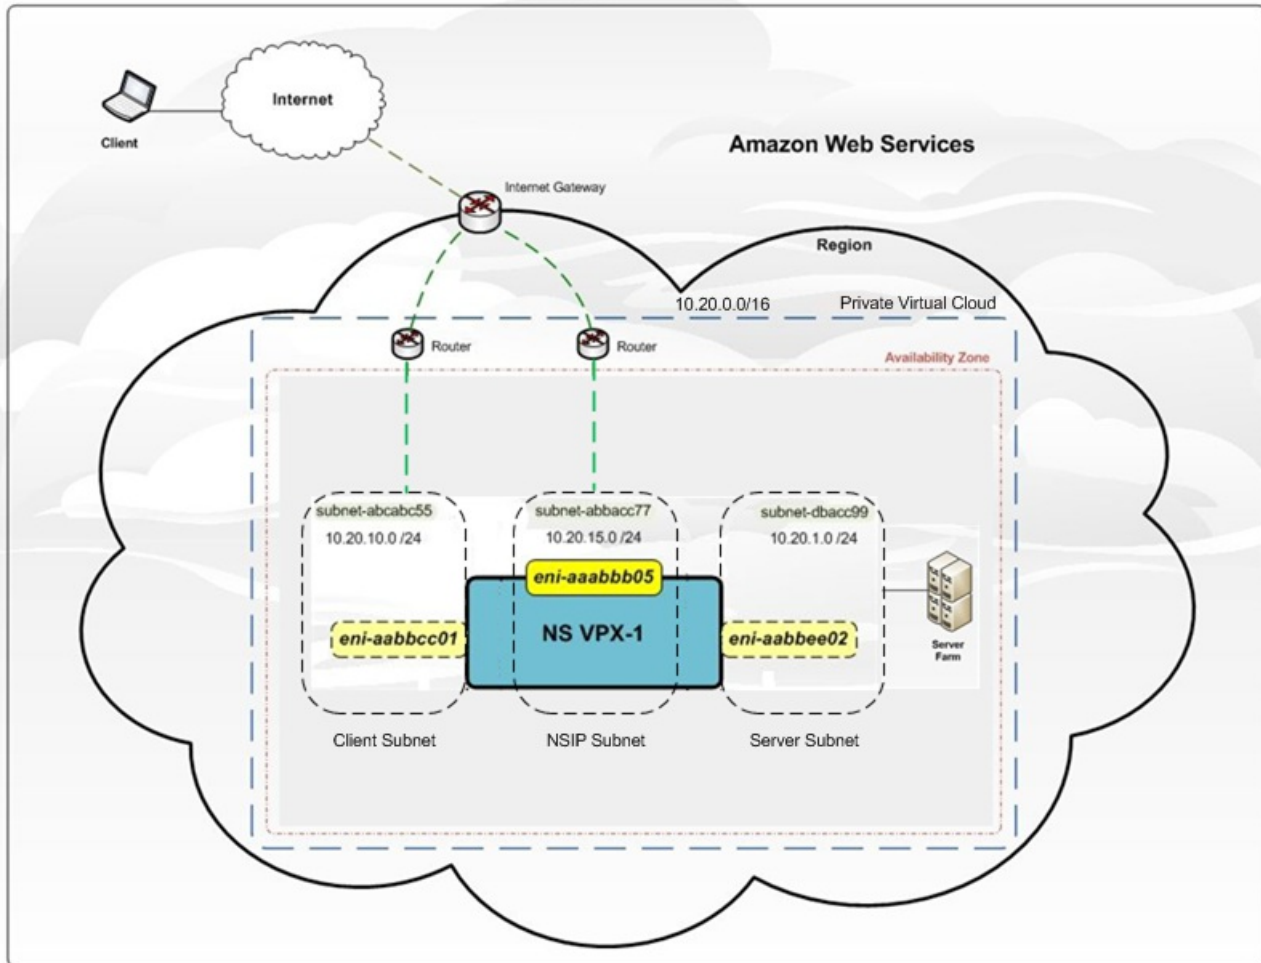

An Amazon VPC allows you to create and control a virtual networking environment, including your own IP address range, subnets, route tables, and network gateways.

Note: By default, you can create up to 5 VPC instances per AWS region for each AWS account. You can request higher VPC limits by submitting Amazon's request form (<http://aws.amazon.com/contact-us/vpc-request/>).

VPX on AWS Architecture

An EC2 instance of NetScaler VPX (AMI image) is launched within the AWS VPC. The following figure shows a typical VPX on AWS deployment.

Figure 1. VPX on AWS Architecture

The figure shows a simple topology of an AWS VPC with a NetScalerVPX deployment. The AWS VPC has:

1. A single Internet gateway to route traffic in and out of the VPC.
2. Network connectivity between the Internet gateway and the Internet.
3. Three subnets, one each for management, client, and server.
4. Network connectivity between the Internet gateway and the two subnets (management and client).
5. A single NetScaler VPX deployed within the VPC. The VPX instance has three Elastic Network Interfaces (ENIs), one attached to each subnet.

Supported EC2 instances

The NetScaler AMI can be launched on any of the following EC2 instance types:

- m3.large
- m3.xlarge
- m3.2xlarge

For more information about Amazon EC2 instances, see:

<http://docs.amazonwebservices.com/AWSEC2/latest/UserGuide/instance-types.html>

ENI Support

Updated: 2014-05-13

The following table lists the EC2 instance types and corresponding number of supported ENIs and number of private IP addresses per ENI.

Table 1. EC2 Support for ENIs and IP Addresses

Instance Name	Number of ENIs	Private IP Addresses per ENI
m3.large	3	10
m3.xlarge	4	15
m3.2xlarge	4	30

Limitations and Usage Guidelines

May 13, 2014

- The clustering feature is not supported for VPX.
- For HA to work as expected, associate a dedicated NATing device to management Interface or associate EIP to NSIP. For more information on NAT, in the AWS documentation, see [NAT Instances](#).
- Data traffic and management traffic should be segregated by using ENIs belonging to different subnets.
- Only the NSIP address should be present on the management ENI.
- If a NAT instance is used for security instead of assigning an EIP to the NSIP, appropriate VPC level routing changes are required. For instructions on making VPC level routing changes, in the AWS documentation, see "[Scenario 2: VPC with Public and Private Subnets](#)."
- A VPX instance can be moved from one EC2 instance type to another (for example, from m3.large to an m3.xlarge).
- For storage options for VPX on AWS, Citrix recommends EBS, because it is durable and the data is available even after it is detached from instance.
- Dynamic addition of ENIs to VPX is not supported. You have to restart the VPX instance to apply the update. Citrix recommends you to stop the standalone or HA instance, attach the new ENI, and then restart the instance.
- You can assign multiple IP addresses to an ENI. The maximum number of IP addresses per ENI is determined by the EC2 instance type, see [EC2 Support for ENIs and IP Addresses](#).
- Citrix recommends that you avoid using the enable and disable interface commands on NetScaler VPX interfaces.
- Due to Amazon AWS limitations, these features are not supported:
 - IPV6
 - Gratuitous ARP(GARP)
 - L2 mode
 - Tagged VLAN
 - Dynamic Routing
 - Virtual MAC (VMAC)

Launching the NetScaler VPX for AWS AMI

May 21, 2017

You can launch a Citrix NetScaler VPX AMI within an Amazon Web Services (AWS) Virtual Private Cloud (VPC) in one of two ways:

1. Using the Amazon GUI and CLI toolkit.
2. Using a Citrix authored CloudFormation template.
3. Using the Amazon 1-Click launch.

Note: The following are the default administrator credentials to access a NetScaler VPX instance:

- Username—nsroot
- Password—The default password for the nsroot account is set to the AWS instance-ID of the NetScaler VPX instance. For a high availability configuration between two NetScaler VPX instances, the nsroot password of the secondary node is set to that of the primary node after the HA configuration synchronization.

Launching NetScaler VPX for AWS by Using the Amazon GUI and CLI toolkit

To launch a NetScaler VPX AMI within an Amazon Web Services (AWS) Virtual Private Cloud (VPC) by using the Amazon GUI and CLI toolkit, you need:

- An AWS account
- An AWS Virtual Private cloud (VPC)
- The AWS API toolkit (if creating a VPX instance with three or more ENIs).
- An IAM account

Creating an AWS Account

To launch a NetScaler VPX AMI in an Amazon Web Services (AWS) Virtual Private Cloud (VPC), you need an AWS account. You can create an AWS account for free at www.aws.amazon.com.

Creating an AWS Virtual Private Cloud (VPC)

Citrix recommends at least three IP addresses for a NetScaler instance. Currently, the only support that AWS provides for instances with multiple IP addresses is for instances within an AWS VPC.

To create an AWS VPC, first launch the AWS GUI console. For instructions for using the AWS GUI console, see <http://docs.amazonwebservices.com/AmazonVPC/latest/GettingStartedGuide/GetStarted.html?r=2900>.

To create an AWS VPC

1. Use the VPC with a Single Public Subnet Only option to create a new AWS VPC in an AWS availability zone.
2. Create additional subnets within the AWS VPC. Citrix recommends that you create at least three subnets, of the following types:
 - One subnet for NetScaler management traffic. You place the NetScaler management IP(NSIP) on this subnet.
 - One or more subnets for client-access (user-to-NetScaler) traffic, through which clients connect to one or more virtual IP (VIP) addresses assigned to NetScaler load balancing virtual servers.
 - One or more subnets for the server-access (NetScaler-to-server) traffic, through which your servers connect to NetScaler-owned subnet IP (SNIP) addresses.

For more information about NetScaler load balancing and virtual servers, virtual IP addresses (VIPs), and subnet IP addresses (SNIPs), see: [Getting Started with Citrix NetScaler](#).

Note:

- All subnets should be in the same availability zone.
- You can launch a NetScaler AMI in an AWS VPC with a single subnet. In this configuration, the management traffic, client-side traffic, and server-side traffic all use the same subnet, and high availability (HA) cannot be configured.
- You can launch the NetScaler AMI into an AWS VPC with two subnets. In this configuration, one subnet is used for management traffic, and the other subnet is used for both client-side and server-side traffic. This topology supports NetScaler HA.

3. Create an Internet gateway and attach it to the VPC instance.
4. Create routing tables for all traffic flowing into or out of the VPC. You need routes for access to the NSIP and to any client-facing VIP addresses. Traffic leaving the VPC must be routed through the Internet Gateway of the AWS VPC.

Note:

- Make sure that you associate management and client subnets with the routing table.
- Add a default route to the routing table for the traffic flowing out of the VPC. Set the Destination to 0.0.0.0/0, and the Target as the Internet gateway address.

5. Create a security group and open the required ports.

Setting-up the AWS API Toolkit

The AWS GUI console does not allow you to launch instances with more than two ENIs. For a standard deployment, you have to create at least three ENIs for a VPC instance (though it is possible to launch a NetScaler AMI with one or two ENIs). To create three or more ENIs for a NetScaler instance, you must use the AWS CLI. To use the AWS CLI, you must install the AWS API toolkit.

The AWS API toolkit is available for download at <http://aws.amazon.com/developertools/351/>. To install the AWS API toolkit, complete the following tasks on a Windows or Linux machine:

1. Download the AWS API Toolkit.
2. Download X.509 certificate files and X.509 private key file.
3. Download the private key.
4. Convert the downloaded private key (.pem file) for SSH connectivity.
5. Configure the AWS API Toolkit environment on your Windows or Linux computer.

To download the AWS API toolkit

1. In a web browser, open the following website: <http://aws.amazon.com/developertools/351/>.
2. On the Amazon EC2 API Tools page, in the Download section, click Download the Amazon EC2 API Tools.
3. Save the file, ec2-api-tools.zip, to a local disk and use a file compression utility (for example, WinZip) to extract the files.

To download the X.509 certificate file and X.509 private key file

1. In your browser, open the following website: <http://aws.amazon.com/>.
2. Click My Account/Console, and then click Security Credentials.
3. On the Amazon Web Services Sign in page, use your Amazon account credentials to sign in.
4. On the Security Credentials page, in the Access Credentials section, on the X.509 Certificates tab, click Create a New Certificate.
5. In the X.509 Certificate Created dialog box, Click Download Private Key File and save the private key file to a secure folder on your local drive.
6. Click Download X.509 Certificate and save the certificate to a secure folder on your local drive.
7. Click Close.

Note: The Private Key File can be downloaded only at the time of creating a certificate. However, you can download the

certificate at any time after creating it.

To download private key for SSH connectivity

1. In your browser, open the following website: <http://aws.amazon.com/> .
2. Click **My Account/Console**.
3. On the **Amazon Web Services Sign in** page, use your Amazon account credentials to sign in.
4. In the **Service** pane, in **Amazon Web Services**, click **EC2**.
5. In the **Navigation** section, in **Network and Security**, click **Key Pairs**.
6. In the **Key Pairs** pane, click **Create Key Pair**.
7. In the **Create Key Pair** dialog box, type the name for key pair and click **Create**.
8. Download the Key Pair to the local disk and click **Close**.

To convert the downloaded private key for SSH connectivity

For SSH connections from a management machine using Putty, you must convert the .pem file (Private Key) into .ppk file. The .ppk file is the private key for SSH connections to the NetScaler VPX instance hosted in the AWS environment. To convert the .pem file to a .ppk file, use the Putty application's PuttyGen utility. Make sure that the key pairs and certificate files are stored in an unshared and secured directory. After the conversion, you can use SSH to securely connect to the management address of the VPX on AWS instance.

To configure the AWS API Toolkit environment on a Windows machine

1. Move the certificate files to an unshared folder (for example, aws-ec2-api-tools).
2. Move the extracted AWS API toolkit folder to the unshared folder (for example, the aws-ec2-api-tools folder created in example in Step 1).
3. Create a batch file to configure the specific AWS environment in the unshared folder (aws-ec2-api-tools if you used the example in the preceding two steps). Following is an example of the batch file. The file location used in this example is C:\aws-vpc-config\ and the file name is set-aws-environment.bat.

```
rem Setup Amazon EC2 Command-Line Tools
```

```
set JAVA_HOME="C:\Program Files\Java\jre7\"
```

```
set EC2_HOME="C:\aws-ec2-api-tools\"
```

```
set PATH=%PATH%;%EC2_HOME%\bin
```

```
set EC2_PRIVATE_KEY=C:\aws-ec2-security-files\pk-3T6ACCLBEDGD3O3SMAM7YDI76VP5HXSU.pem
```

```
set EC2_CERT=C:\aws-ec2-security-files\cert-3T6ACCLBEDGD3O3SMAM7YDI76VP5HXSU.pem
```

```
set EC2_URL=https://<aws-region>.ec2.amazonaws.com
```

4. Open the command prompt and run the batch file. For the file in the above example, type:

```
C:\aws-vpc-config> set-aws-environment.bat
```

5. Run the ec2ver command to verify that the AWS toolkit is installed properly. For example:

```
C:\aws-vpc-config>ec2ver 1.5.6.1 2012-06-15
```

To configure the AWS API Toolkit on a Linux machine

1. Move the certificate files to an unshared folder (for example, aws-ec2-api-tools).
2. Move the extracted AWS API toolkit folder to the unshared folder (for example, the aws-ec2-api-tools folder created in example in Step 1).

3. Create a shell script to configure the specific AWS environment in the unshared folder (aws-ec2-api-tools if you used the example in the preceding two steps). Following is an example of the batch file. In this example, the file location used is C:\aws-vpc-config\ and the file name used is set-aws-environment.bat.

```
# Setup Amazon EC2 Command-Line Tools
```

```
export EC2_HOME=~/.ec2-api-tools-1.5.6.0
```

```
export EC2_URL= https://us-east-1.ec2.amazonaws.com
```

```
export PATH=$EC2_HOME/bin:/usr/bin:~/usr/sbin:/usr/local/sbin:/sbin
```

```
export EC2_PRIVATE_KEY=~/.pk-XOX3NS2UPZL6BGLFO7PM5OGLYBDPUCB.pem
```

```
export EC2_CERT=~/.cert-XOX3NS2UPZL6BGLFO7PM5OGLYBDPUCB.pem
```

```
export JAVA_HOME=/usr
```

```
export PS1="AWS PROMPT >"
```

4. Run the ec2ver command to verify that the AWS toolkit is installed properly. For example:

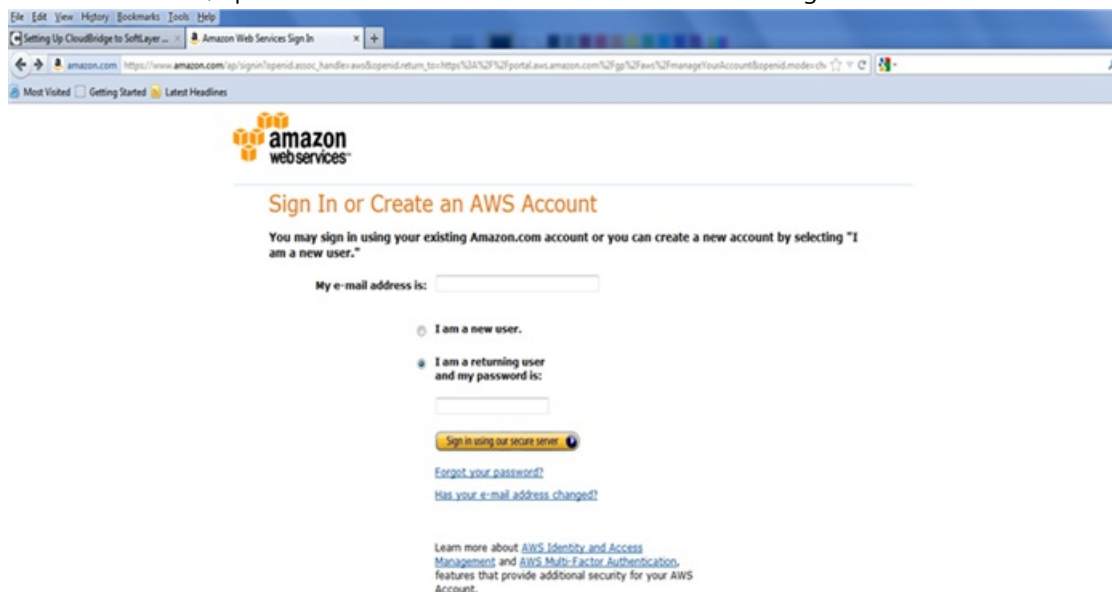

```
AWS PROMPT >ec2ver
```

```
1.5.6.1 2012-06-15
```

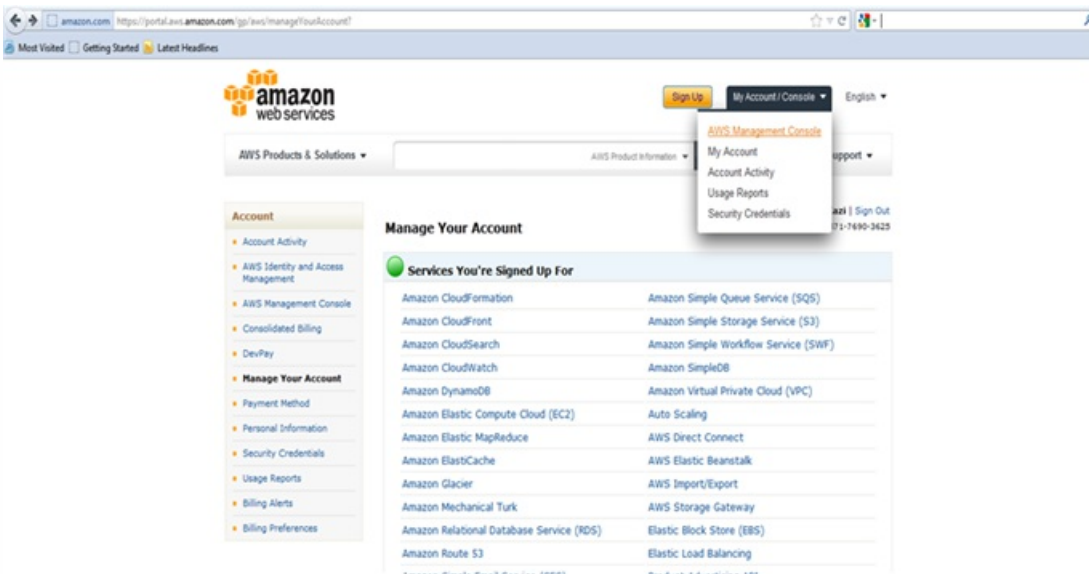

Creating an IAM Account

Before you launch the VPX AMI instance, you have to create a new IAM user account with the Access and Secret keys. The Access and Secret key credentials from the new IAM user are required for launching the NetScaler AMI instance. To create a new IAM user for NetScaler, complete the following steps.

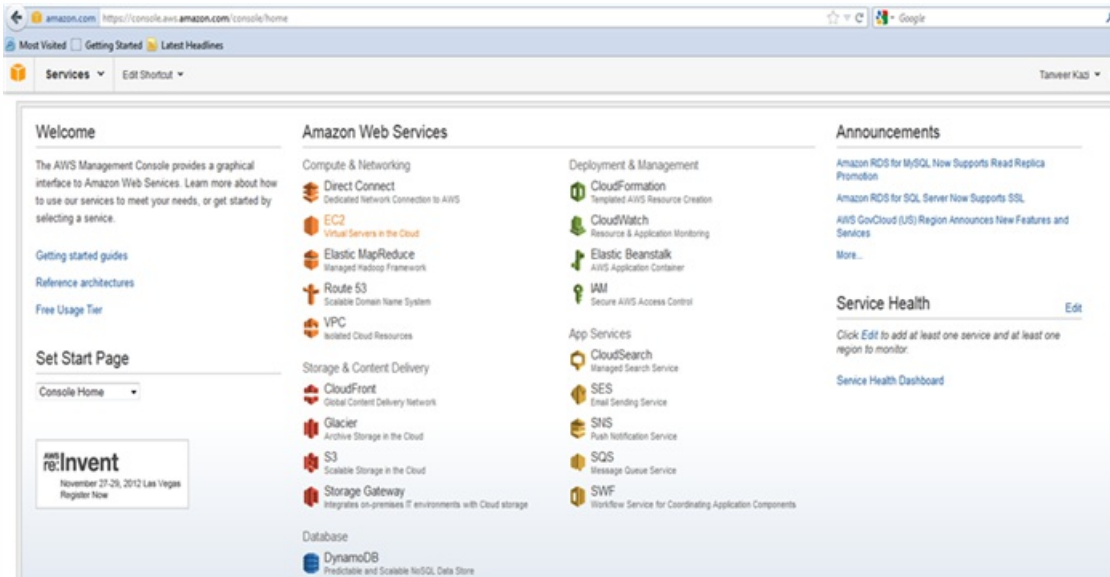

1. In a web browser, open the website at www.aws.amazon.com and log on with AWS credentials.

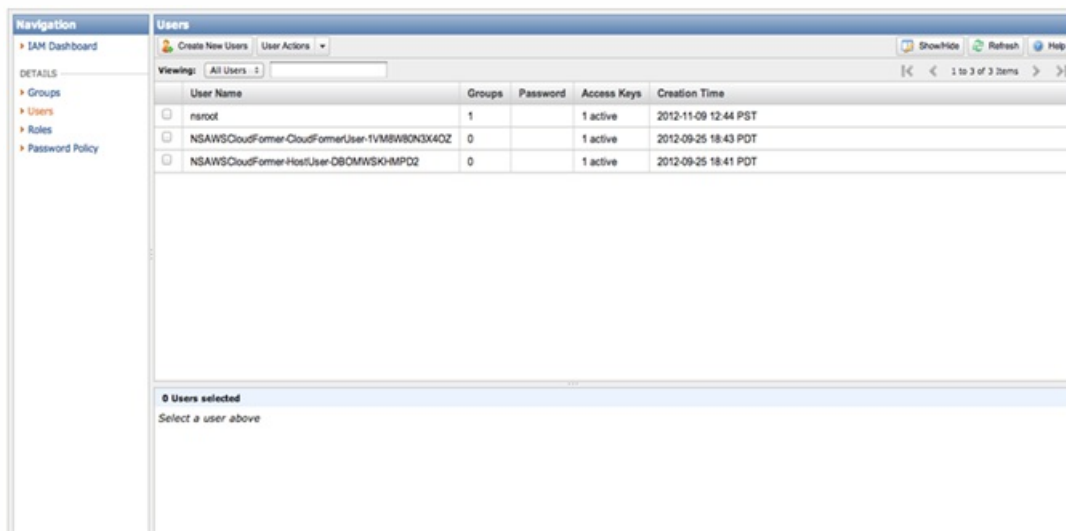

2. Click My Account/Console, and then click AWS Management Console.

3. On the Amazon Web Services page, click IAM.

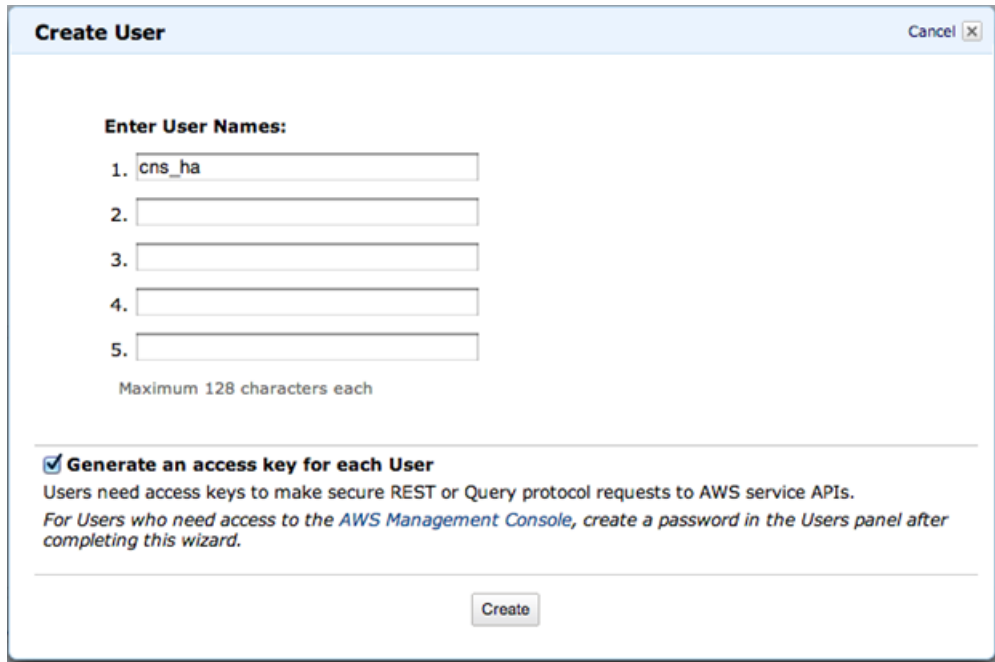

4. In the Navigation pane, click Users, and then click Create New Users.

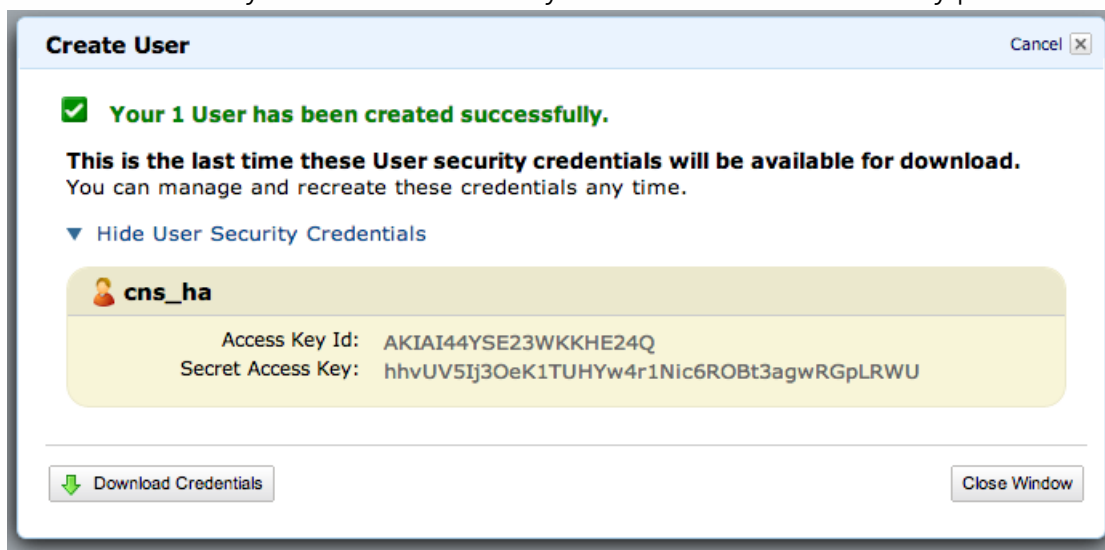

5. In the Create User dialog box, in one of the Enter User Names text boxes, type a user name (for example, cns_ha). Also

select the Generate an access key for each User check box, and then click Create.

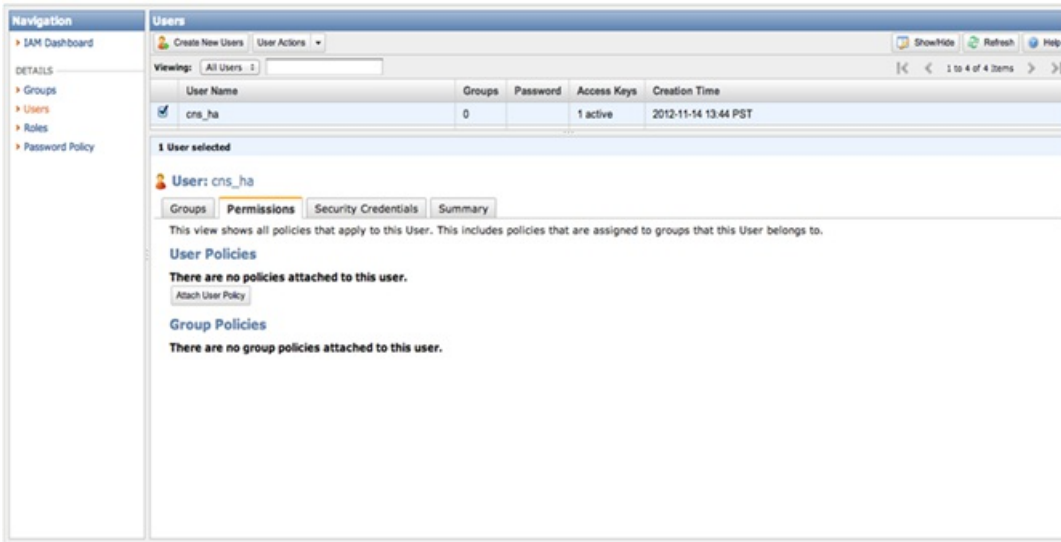

6. After a new IAM user is created, click Download Credentials to download the Access and Secret Keys to a safe location. These keys are required for launching NetScaler AMI. Click Close.

Note: The Access Key ID and Secret Access Key values are used to create the key-pair file and to launch an instance.

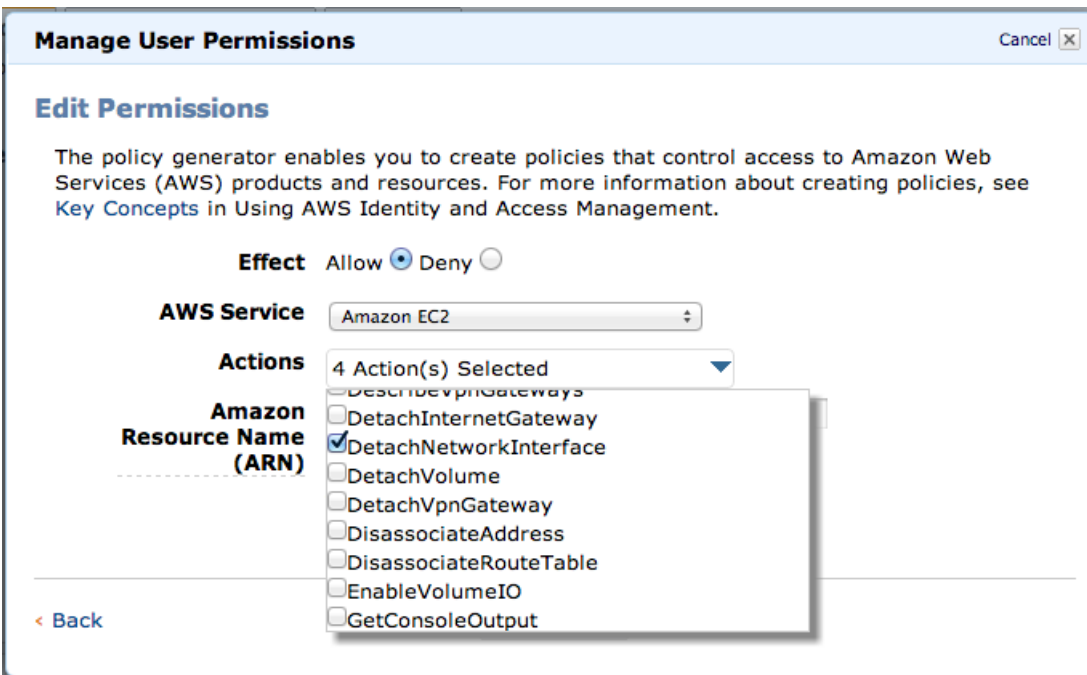

7. In the Users pane, select the newly created IAM user and click the Permissions tab. Then, click Attach User Policy to set policies for the user.

8. In the Manage User Permissions dialog box, next to Effect, select the Allow option. For AWS Service, select Amazon EC2. From the Actions drop-down list, select the following four actions:

- AttachNetworkInterface
- DescribeInstances
- DescribeNetworkInterfaces
- DetachNetworkInterface

9. Click Add Statement.

11. Click Apply Policy to set the new permissions for the selected user.

Launching the NetScaler AMI

Use the AWS CLI to launch the NetScaler AMI in an AWS VPC. Use the `ec2-run-instances` command. For information about the `ec2-run-instances` command, see

<http://docs.amazonwebservices.com/AWSEC2/latest/CommandLineReference/ApiReference-cmd-RunInstances.html>.

Following are Windows and Linux examples of running the command to launch a single NetScaler instance. The EC2 instance type is `m3.large`. It is configured with the following entities:

- NetScaler AMI named `ami-bd2986d4`.
- Three ENIs (named `NSIP`, `CLIENT-SIDE`, and `SERVER-SIDE`) associated with the three subnets (`15fa057e`, `1547ba7e`, and `1547ba7e`) within the VPC.
- A single IP address for the `NSIP` ENI.
- Multiple private IP addresses (for multiple VIPs) on the `CLIENT-SIDE` ENI.
- Multiple private IPs (for multiple SNIPs) on the `SERVER-SIDE` ENI.

On a Windows platform:

```
C:\aws-vpc-config>ec2-run-instances ami-bd2986d4 -n 1 -t m1.large -k keyPairName -f access-secret-key-file -a :0:subnet-15fa057e:"NSIP":10.20.15.21 -a :1:subnet-1547ba7e:"CLIENT-SIDE":10.20.10.21:::"10.20.10.22,10.20.10.23,10.20.10.24,10.20.10.25,10.20.10.26,10.20.10.27,10.20.10.28,10.20.10.29,10.20.10.30" -a :2:subnet-cc47baa7:"SERVER-SIDE":10.20.1.21:::"10.20.1.22,10.20.1.23,10.20.1.24,10.20.1.25,10.20.1.26,10.20.1.27,10.20.1.28,10.20.1.29,10.20.1.30"
```

Note: The `access-secret-key-file` file contains the access and secret keys.

On a Linux platform:

```
AWS PROMPT > ec2-run-instances ami-bd2986d4 -n 1 -t m1.large -k keyPairName -f access-secret-key-file -a :0:subnet-15fa057e:"NSIP":10.20.15.21 -a :1:subnet-1547ba7e:"CLIENT-SIDE":10.20.10.21:::10.20.10.22,10.20.10.23,10.20.10.24,10.20.10.25,10.20.10.26,10.20.10.27,10.20.10.28,10.20.10.29,10.20.10.30 -a :2:subnet-cc47baa7:"SERVER-SIDE":10.20.1.21:::10.20.1.22,10.20.1.23,10.20.1.24,10.20.1.25,10.20.1.26,10.20.1.27,10.20.1.28,10.20.1.29,10.20.1.30
```

Note: The access-secret-key-file file contains the access and secret keys.

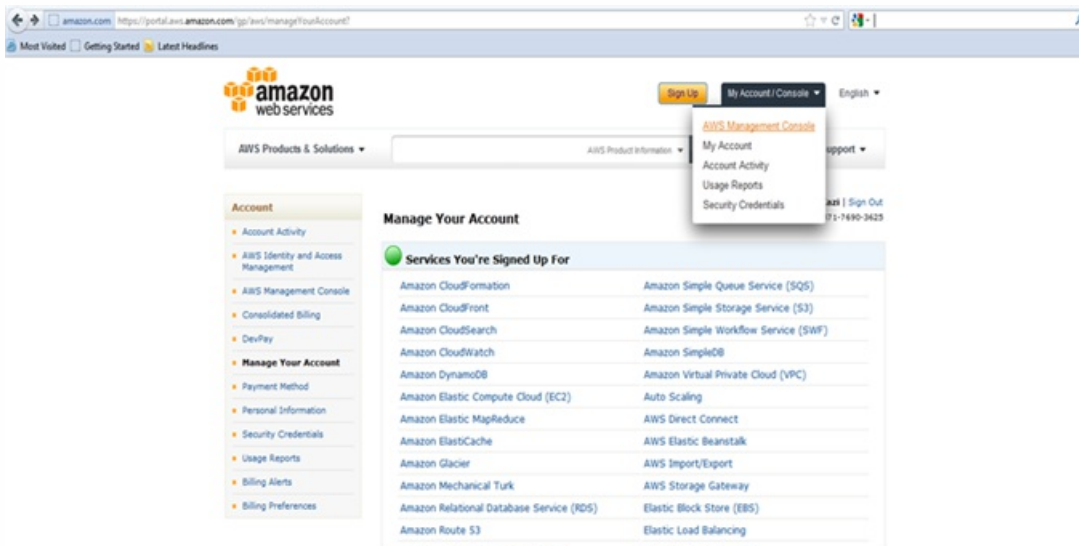

The command returns the instance ID and the associated information. You can see the instance running within your AWS GUI Console.

Note: Make sure that the environment variable EC2_URL points to the region where you want to launch the VPX instance.
To access the EC2 instance

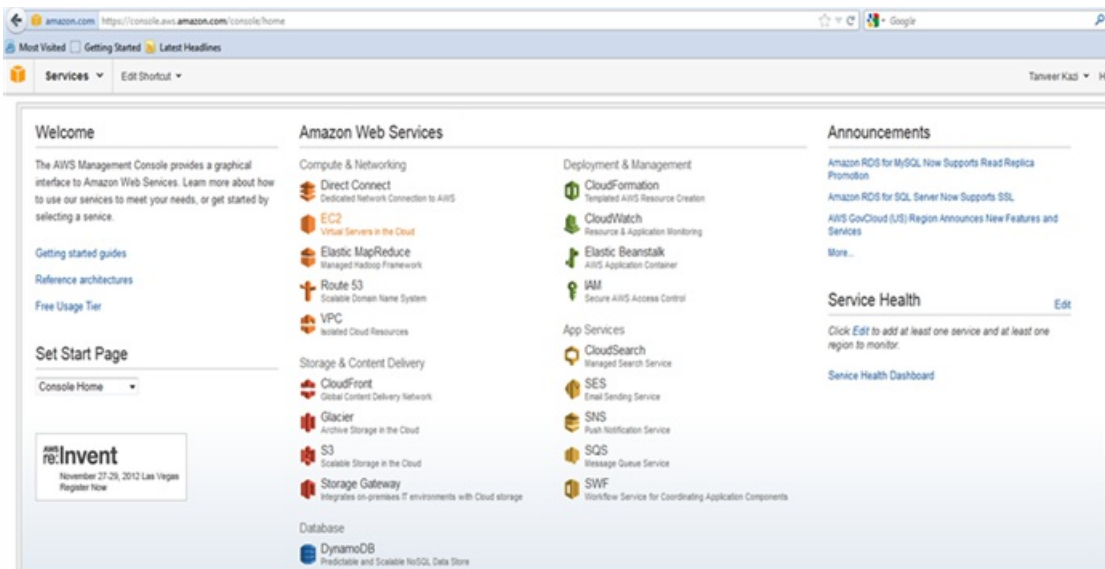

1. In a web browser, open the website at www.aws.amazon.com and log on with AWS credentials.

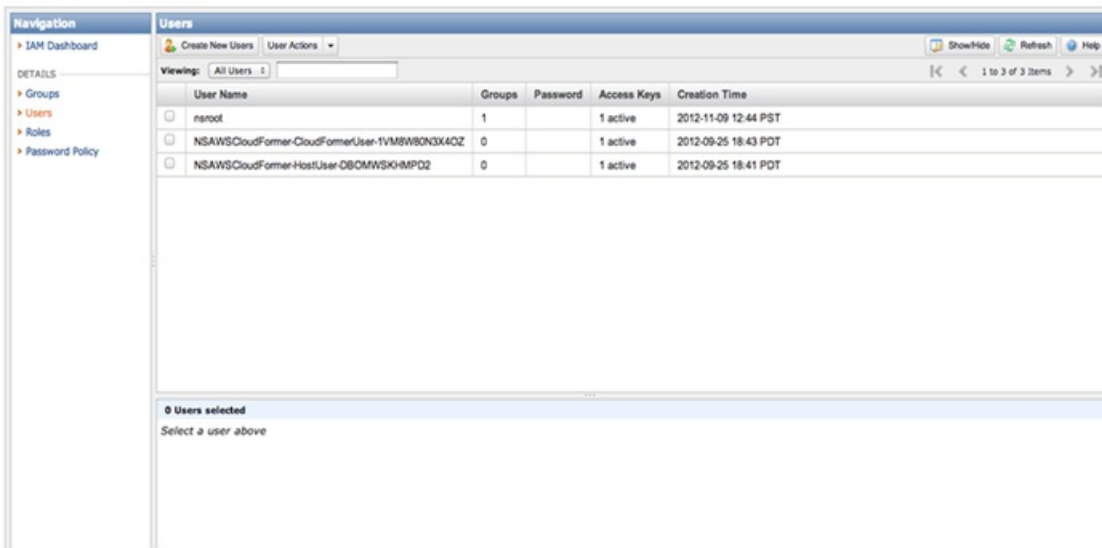

2. Click My Account/Console, and then click AWS Management Console.

3. On the Amazon Web Services page, click EC2.

- On the Amazon EC2 Console Dashboard page, in the Navigation pane, click Instances and verify that all of the NetScaler VPX instances are configured with the IP addresses that you specified when you used the `ec2-run-instances` command. Note: The VPX instance or instances can take from five to ten minutes to start running.

The `ec2-run-instances` command does not allow associating AWS elastic IP with an ENI. To associate one or more EIPs with an ENI in the Navigation pane, in the NETWORK & SECURITY area, click Elastic IPs and associate EIPs with Private IP addresses for any of the VIPs that need to be externally routable.

You must also associate the instance ENIs with appropriate security groups. Go to the Network Interfaces section, right-click on the individual ENI, and select the Change Security Groups option. You can then associate a proper VPC security group.

Using the Citrix CloudFormation Template to launch NetScaler VPX for AWS

Citrix also provides a CloudFormation template that can be used to automate NetScaler instance launch. The tool requires an existing VPC environment. It launches a NetScaler instance with three ENIs. Therefore, to use the CloudFormation template, make sure that you have the following:

- AWS account
- AWS VPC

3. Three subnets within the VPC
4. A security group to use for the NetScaler instances ENIs

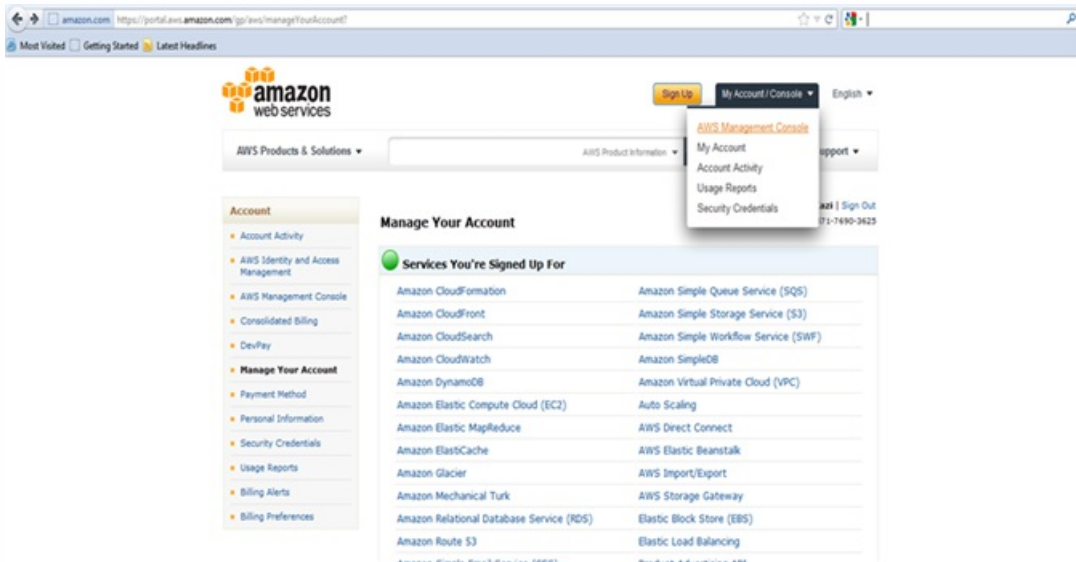

Refer to [Creating an AWS Virtual Private Cloud \(VPC\)](#) for information about how to configure subnets and security groups within a VPC. After configuring the required subnets and security groups, you can launch the NetScaler VPX AMI in AWS VPC. The CloudFormation tool provides functionality to launch a single NetScaler VPX instance or, to create a high availability environment, a pair of NetScaler VPX instances.

Launching a single NetScaler VPX instance in AWS

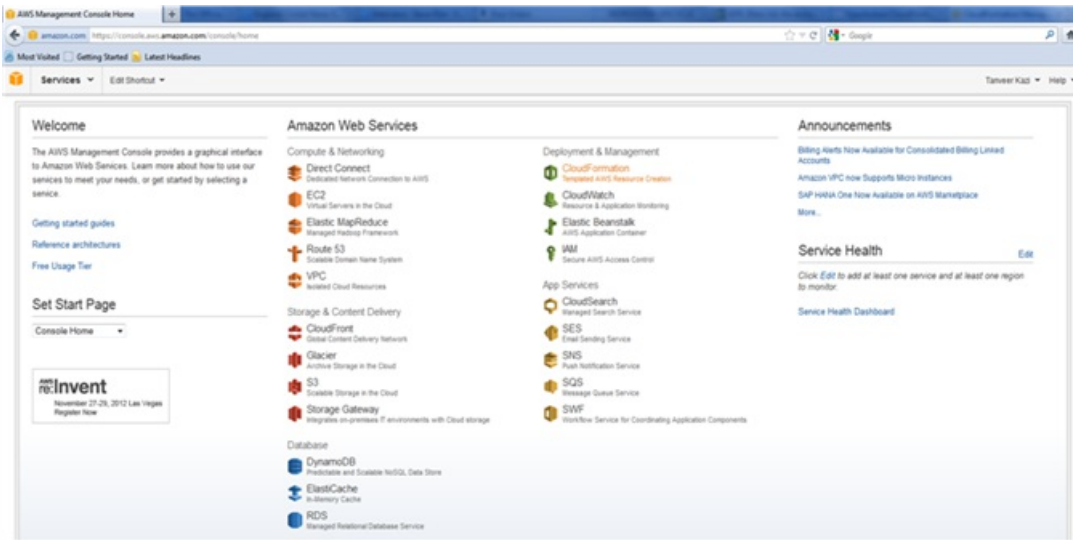

1. In a web browser, open the website at www.aws.amazon.com and log on with AWS credentials.

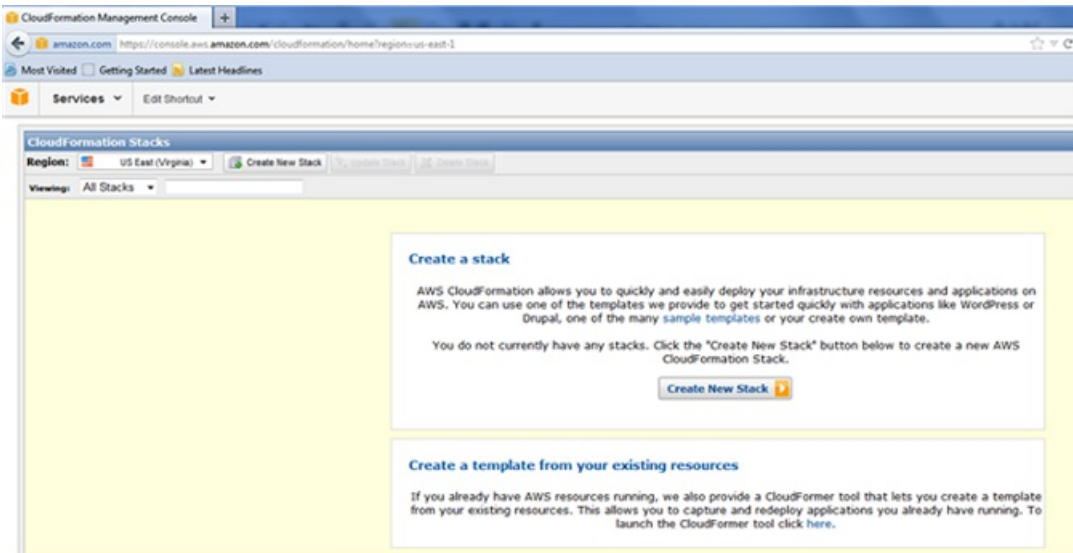

2. Click My Account/Console, and then click AWS Management Console.

3. On the Amazon Web Services page, click Cloud Formation in the Deployment & Management section.

4. On the CloudFormation Stacks page, select the Region in which you plan to deploy the NetScaler VPX instance, and then click Create New Stack.

5. In the Create Stack dialog box, specify a value for Stack Name, select the Upload a Template File option, and then click Browse. Select the template for a standalone NetScaler VPX from the local drive, and then click Continue.

Note:

6. In the next pane, specify values for:

- **VpcID** : An identifier to assign to the Virtual Private Cloud (VPC).
- **NsipSubnet** : Subnet in which the NSIP is configured in the VPC
- **ServerSubnet**: Subnet in which the server farm is configured in the VPC
- **ClientSubnet**: SubnetId in which the client side is configured in the VPC
- **SecurityGroup**: VPC Security group ID
- **VPXPrimary**: Name of the primary VPX instance type
- **AccessKey**: Access Key for IAM user account
- **SecretKey**: Secret Key for IAM user account
- **TenancyType**: Instance tenancy type, can be default or dedicated
- **NSIP**: Private IP assigned to the NSIP ENI. The last octet of NSIP should be between 5 and 254.
- **ServerIP**: Private IP assigned to the Server ENI. The last octet should be between 5 and 254.
- **ClientIP**: Private IP assigned to the Client ENI. The last octet should be between 5 and 254.
- **KeyName**: Name of an existing EC2 KeyPair to enable SSH access to the instances.

Note: Make sure that the VPC, subnets, security groups, routes and gateway associations are already configured.

9. Click Continue to create a Stack.

10. Click Close to close the Create Stack dialog box.
11. The new stack that you created appears on the CloudFormation Stacks page.

Note:

- Currently, the CloudFormation utility does not provide the functionality to add secondary IP addresses. Use the AWS console, after deploying a NetScaler VPX instance, to add the secondary IP addresses to the ENIs.
- The CloudFormation scripts for the standalone and HA pair VPX instances have the latest AMIs for the five supported regions. You have to update the scripts to synchronize with the latest AMIs.
- The script automatically selects the correct AMI for the region in which the VPX instance is being deployed.
- By default, all the ENIs are attached to one security group, use the AWS console to attach an ENI to a different security group.
- EIPs are automatically allocated and assigned to an instance. If the EIP limit exceeds the threshold for the region, the CloudFormation script fails and displays an error message.

Collaborating to Deliver High-Quality Products and Content Launching NetScaler VPX by using the AWS 1-Click

1-Click helps you to launch an instance of NetScaler VPX on AWS, quickly as compared to other launching methods, with the default options. After the instance is launched on AWS, you can modify these options by using either the AWS CLI or

the AWS GUI.

The default options include the following elastic network interfaces (ENIs) for the NetScaler instance:

- **Management Interface**—Associates a subnet for management related traffic. You add the NetScaler management IP (NSIP) address to this subnet.
- **Public Interface**—Associates a subnet for the client-access (user-to-NetScaler) traffic. You add one or more virtual IP (VIP) addresses on this subnet.
- **Private Interface**—Associates a subnet for server-access (NetScaler-to-server) traffic. You add subnet IP (SNIP) addresses on this subnet.

Before you begin launching an instance of NetScaler VPX on AWS, consider the following points :

- For security reasons, none of the elastic IP addresses are attached to the ENIs of the NetScaler VPX instance launched by using 1-Click. This means that the NetScaler VPX instance (including the management IP address) is not reachable from outside the AWS Virtual Private Cloud (VPC). If your VPC uses a Virtual Gateway or other method to provide a VPN access to the VPC, you can administer the instance by using the IP address of the network interface in the management subnet. If you do not have VPN access to your VPC, Citrix recommends that you set up a jump box instance within the VPC, and then use this as the source for accessing or managing other instances within the VPC. For instructions to create an SSH jump box, see https://s3.amazonaws.com/awssmp-usagelnsstructions/Creating_and_using_VPC.txt.
- Three default security policies are created. A policy each is attached to the management, public and private interfaces, respectively.
 - The security policy for the management interface allows traffic from a set of ports.
 - The security policies for the public and private interfaces block all the traffic to or from these interfaces. You can later modify these security groups to filter the desired traffic.
- High Availability configuration is not supported for a NetScaler VPX instance launched by using AWS 1-click.

Before you begin launching an instance of NetScaler VPX on AWS, make sure that you have the following:

- An AWS account
- An AWS Virtual Private Cloud (VPC)
- Three subnets within the AWS VPC (one each for management interface, public interface, and private interface of the NetScaler instance)
- An IAM key pair

For information about creating an AWS account, a VPC, subnets in a VPC, and an IAM key pair, see [Launching NetScaler VPX for AWS by Using the Amazon GUI and CLI toolkit](#).

To launch an instance of NetScaler VPX on AWS by using 1-Click

1. Log on to the AWS marketplace (<https://aws.amazon.com/marketplace>) by using your Amazon AWS credentials.
2. In the search field, type NetScaler VPX to search for the NetScaler AMI, and click Go.
3. On the search result page, click the desired Citrix NetScaler VPX offering.

Learn about instance types

After few minutes, the NetScaler instance is launched with three ENIs. You can now connect to the NSIP address (the IP address on the management ENI) of the instance by using the NetScaler CLI or NetScaler GUI and start configuring the NetScaler features, for example, load balancing.

Verifying the NetScaler VPX on AWS Installation

May 14, 2014

When the NetScaler instance is running, you can access the instance through the NetScaler GUI or the NetScaler CLI by connecting to the EIP associated with the management ENI (NSIP). For example, use the following addressing notation in a web browser:

http://<Elastic_IP> (unsecured access)

or

https://<Elastic_IP> (secured access)

Note:

- To access a NetScaler instance through SSH, provide the .pem file.
- You can use the AWS GUI console to manually add the private IP addresses for SNIPs on server subnets and VIPs on client subnets.
- If you want to access the NSIP from the Internet, you must assign an EIP to the NSIP address of each NetScaler instance. Also, make sure that the NSIP subnet is associated with a routing table that has a default route set to the Internet gateway.
- If you want VIP addresses to be accessible through the Internet, you must associate an EIP with each VIP address that is defined in the configuration.
- The following are the default administrator credentials to access a NetScaler VPX instance:
 - Username—nsroot
 - Password—The default password for the nsroot account is set to the AWS instance-ID of the NetScaler VPX instance. For a high availability configuration between two NetScaler VPX instances, the nsroot password of the secondary node is set to that of the primary node after the HA configuration synchronization.
- You can find the private key file from the AWS console. To view the private key file:
 1. Log on to the AWS marketplace (<https://aws.amazon.com/marketplace>) by using your Amazon AWS credentials.
 2. Click **Amazon Web Services Home**.
 3. Click **My Account/Console**, and then click **Security Credentials**.

Attaching Additional IP Addresses to an Instance

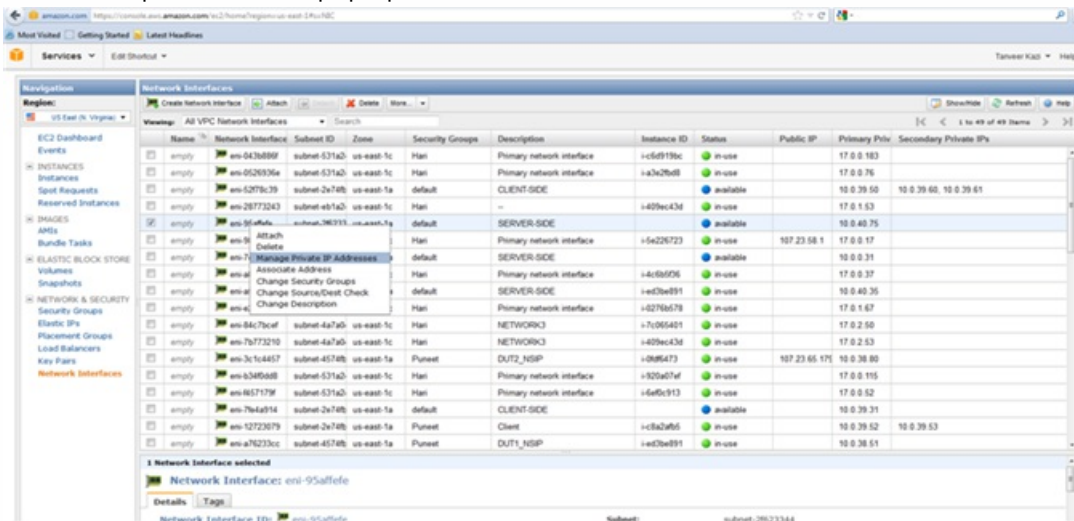

Aug 23, 2013

You can attach additional IP addresses to an instance as follows:

1. Add a secondary IP address to an ENI.
2. Associate an EIP with the secondary IP address that you created.

To add a secondary IP address to the ENI

1. In a web browser, open the website at www.aws.amazon.com and log on with AWS credentials.
2. Click My Account/Console, and then click AWS Management Console.
3. On the Amazon Web Services page, click EC2.
4. On the Amazon EC2 Console's Dashboard page, in the Navigation pane, in NETWORK & SECURITY, click Network Interfaces.
5. In the Network Interfaces pane, right-click the ENI attached to the subnet, and then select the Manage Private IP Addresses option from the pop-up menu.

6. In the Manage Private IP Addresses dialog box, click Assign a secondary private IP address and either let AWS automatically assign an IP address or type an IP address in the auto-assign text-field. Click Yes, Update.

Associating an EIP with the secondary IP

Complete the following steps to associate an EIP with a secondary IP address:

1. On the Amazon EC2 Console Dashboard page, in the Navigation pane, in NETWORK & SECURITY, click Elastic IPs.
2. In the Addresses pane, click Allocate New Address.
3. In the Allocate New Address dialog box, select VPC from the EIP used in drop-down list and click Yes, Allocate.
4. Select the newly allocated EIP, and click Associate Address.
5. In the Associate Address dialog box, select, from the **Instance** and the **Private IP address** drop-down lists, the instance and private address that you want to associate with the EIP. Then, click Yes, Associate.

Downloading a NetScaler VPX License

Jan 31, 2011

After the initial instance launch, NetScaler VPX for AWS requires a license. If you are bringing your own license (BYOL), see the *VPX Licensing Guide* at <http://support.citrix.com/article/CTX122426>

You have to:

1. Use the licensing portal within MyCitrix to generate a valid license.
2. Upload the license to the instance.

If this is a **paid** marketplace instance, then you do not need to install a license. The correct feature set and performance will activate automatically.

Load Balancing Servers in different Availability Zones

Nov 27, 2012

A NetScaler instance can be used to load balance servers running in the same availability zone, or in:

- A different availability zone (AZ) in the same AWS VPC
- A different AWS region
- AWS EC2 in a VPC

To enable NetScaler to load balance servers running outside the AWS VPC that the NetScaler instance is in, configure the NetScaler to use EIPs to route traffic through the Internet gateway, as follows:

1. Configure a SNIP on the NetScaler by using the NetScaler CLI or the NetScaler GUI
2. Enable traffic to be routed out of the AZ, by creating a public facing subnet for the server-side traffic.
3. Add an Internet gateway route to the routing table, using the AWS GUI console.
4. Associate the routing table you just updated with the server-side subnet.
5. Associate an EIP with the server-side private IP address that is mapped to a NetScaler SNIP address.

High Availability

May 13, 2014

Two Citrix® NetScaler® VPX™ instances in AWS can be configured as a high availability (HA) pair. With one instance configured as the primary node and the other as the secondary node, the primary node accepts connections and manages servers while the secondary node monitors the primary. If, for any reason, the primary node is unable to accept connections, the secondary node takes over.

The following figure shows an example of the HA deployment architecture for NetScaler VPX on AWS.
Figure 1. NetScaler VPX on AWS - HA Deployment

To deploy HA for VPX on AWS, you must configure at least two ENIs on the primary instance and a single ENI on the secondary instance. On each instance, configure the NetScaler IP (NSIP) address (the management address) on the default ENI. On the primary instance, use the additional ENIs for client and server connections.

For instructions on obtaining access and secret keys, in the AWS documentation, see "[How Do I Get Security Credentials?](#)" and "[Creating, Modifying, and Viewing User Access Keys \(AWS Management Console\)](#)." For instructions to create an IAM user and set permissions, see "[Creating an IAM Account](#)."

Example format for a key file is:

ACCESS_KEY="AKIAJPBBBBBBBVA2PR2OHJNA"

SECRET_KEY="d75KxU7ukd44444NNNNtrrAOgynwBdJoSiooP"

Note: For HA failover to work:

1. The NSIP addresses for each NetScaler instance in an HA pair must be configured on the default ENI of the instance.
2. Both the primary and secondary instances must have EIPs associated with the NSIP or NAT configured to handle outgoing traffic in order to have access to the AWS API servers.
3. Client and server traffic (data-plane traffic) must not be configured on the default ENI.

4. Access and secret keys associated with the user's AWS Identity and Access Management (IAM) account. If the correct key information is not used when creating VPX instances, the HA deployment will fail. The access and secret keys are required for sending Query APIs to the AWS server.
5. Nameservers/DNS servers are configured at VPC level using DHCP options.

Notes on HA:

- Because Amazon does not allow any broadcast/multicast packets in AWS, HA is implemented by migrating data-plane ENIs from the primary to the secondary (new primary) VPX instance when the primary VPX instance fails.
- To deploy HA for VPX on AWS, you must configure at least two ENIs on the primary instance and a single ENI on the secondary instance.
- Because the default ENI cannot be moved to another VPX instance, you should not use the default ENI for data.
- The message `AWSCONFIG_IOCTL_NSAPI_HOTPLUG_INTF` success output 0 indicates that the two data ENI's have successfully attached to the secondary instance (the new primary).
- Failover might take up to 20 seconds due to the AWS detach/attach ENI mechanism.
- Upon failover, the failed instance always restarts.
- The secondary node always has one ENI interface (for management) and the primary node can have up to four ENIs.
- The heartbeat packets are received only on the management interface.
- The configuration file of the primary and secondary NetScaler appliances is synchronized, including the nsroot password. The nsroot password of the secondary node is set to that of the primary node after the HA configuration synchronization.
- **The AWS debug messages are available in the log file, `/var/log/ns.log`, on the VPX instance.**

Configuring High Availability for VPX on AWS

To deploy HA for two VPX instances on AWS, you must create the primary NetScaler VPX instances with three ENIs and the secondary NetScaler VPX with a single ENI.

Following is an example of launching a primary VPX instance with three ENIs:

```
C:\aws-vpc-config>ec2-run-instances ami-bd2986d4 -n 1 -t m1.large -k keyPairName -f ./access-secret-key-file -a :0:subnet-15fa057e:"NSIP":10.20.15.21 -a :1:subnet-1547ba7e:"CLIENT-SIDE":10.20.10.21:::"10.20.10.22,10.20.10.23,10.20.10.24,10.20.10.25,10.20.10.26,10.20.10.27,10.20.10.28,10.20.10.29,10.20.10.30" -a :2:subnet-cc47baa7:"SERVER-SIDE":10.20.1.21:::"10.20.1.22,10.20.1.23,10.20.1.24,10.20.1.25,10.20.1.26,10.20.1.27,10.20.1.28,10.20.1.29,10.20.1.30"
```

Following is an example of launching a secondary VPX instance with a single ENI:

```
C:\aws-vpc-config>ec2-run-instances ami-bd2986d4 -n 1 -t m1.large -k keyPairName -f access-secret-key-file -a :0:subnet-15fa057e:"NSIP":10.20.15.31
```

Note: The `access-secret-key-file` argument contains the access and secret key. (You cannot change the `access-secret-key-file` associated with a VPC instance after it is created.)

After the two NetScaler instances are UP, configure the HA pairing on both the instances. You have to configure the instance with two or more ENIs before configuring HA on the instance with one ENI. Use the `add HA node` command, from within the NetScaler CLI, or from the NetScaler GUI. For example:

On the VPX instance with two or more ENIs:

```
add HA node 1 10.20.15.31
```

On the VPX instance with one ENI:

add HA node 1 10.20.15.21

After you enter add HA node commands, the two nodes form an HA pair, and configuration information is synchronized between the two VPX instances.

To remove HA from NetScaler VPX pair

You can remove HA configuration from the NetScaler VPX pair by using the remove ha node command. You have to remove the HA configuration from the secondary NetScaler VPX before removing the HA configuration from the primary NetScaler VPX.

For example, on the Secondary NetScaler VPX instance, at the NetScaler command line, type:

```
remove ha node
```

```
save config
```

On the Primary NetScaler VPX instance, at the NetScaler command line, type:

```
remove ha node
```

```
save config
```

Launching NetScaler VPX pairs for HA by using Citrix CloudFormation

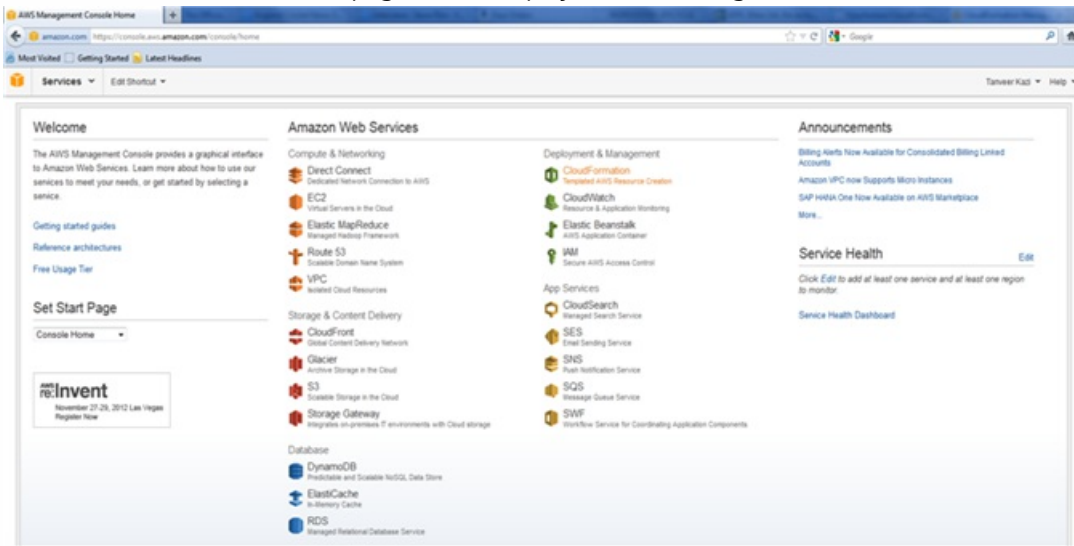

1. In a web browser, open the website at www.aws.amazon.com and log on with AWS credentials.

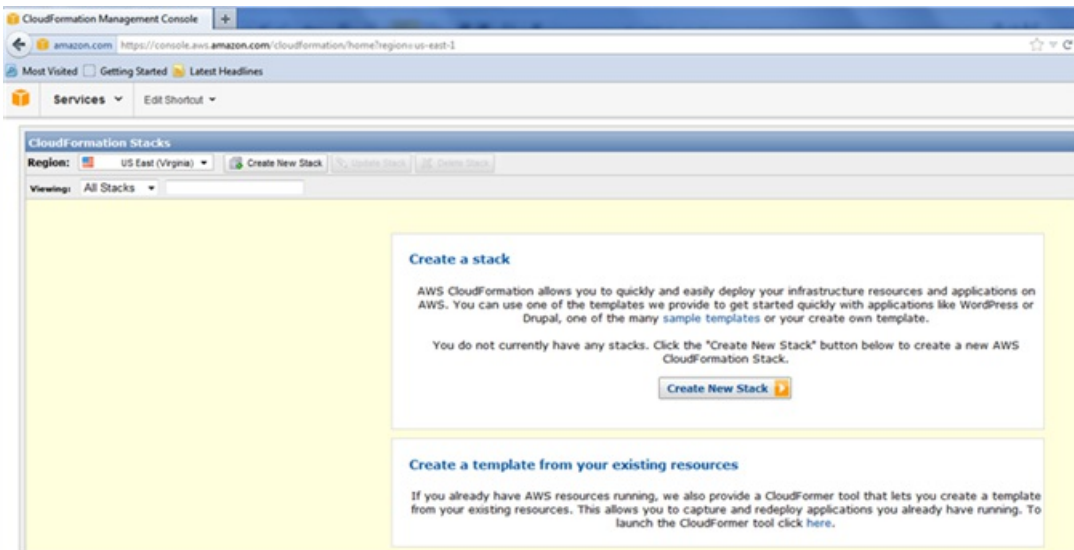

2. Click My Account/Console, and then click AWS Management Console.

3. On the Amazon Web Services page, in the Deployment & Management section, click Cloud Formation.

4. On the CloudFormation Stacks page, select the Region in which you plan to deploy the NetScaler VPX instance, and then click Create New Stack.

5. In the Create Stack dialog box, specify value for Stack Name, select the Upload a Template File option, and then click Browse. Select the template for HA NetScaler VPX from the local drive, and then click **Continue**.

Create Stack Cancel X

SELECT TEMPLATE SPECIFY PARAMETERS REVIEW

AWS CloudFormation gives you an easier way to create a collection of related AWS resources (a stack) by describing your requirements in a template. To create a stack, fill in the name for your stack and select a template. You may chose one of the sample templates to get started quickly, or one of you own templates stored in S3 or on your local hard drive.

Stack Name:
test-stack

Stack Template Source:

Show Advanced Options

6. In the next pane, specify values for:
- **VpcID**: An identifier to assign to the Virtual Private Cloud (VPC).
 - **NsipSubnet**: Subnet in which the NSIP is configured in VPC.
 - **ServerSubnet**: Subnet in which the server farm is configured in VPC.
 - **ClientSubnet**: SubnetId in which the client side is configured in VPC.
 - **SecurityGroup**: VPC Security group id.
 - **VPXPrimary**: Name of Primary VPX instance type.
 - **AccessKey**: Access Key for IAM user account.
 - **SecretKey**: Secret Key for IAM user account.
 - **TenancyType**: Instance tenancy type, can be default or dedicated.
 - **NSIP**: Private IP assigned to the NSIP ENI. The last octet of NSIP should be between 5 and 254.
 - **NSIPSec**: Private IP assigned to the NSIP ENI of Secondary. last octet has to be between 5 and 254.
 - **ServerIP**: Private IP assigned to the Server ENI. The last octet should be between 5 and 254.
 - **ClientIP**: Private IP assigned to the Client ENI. The last octet should be between 5 and 254.
 - **KeyName**: Name of an existing EC2 KeyPair to enable SSH access to the instances.

Note: Make sure that the VPC, subnets, security groups, routes associations, gateway associations are already configured.

SPECIFY PARAMETERS
REVIEW

Template Description: Netscaler AWS-VPX template creates a single instance of VPX with 3 ENIs associated to 3 VPC subnets (NSIP, Client, Server). The ENIs are associated with Private IPs and security group defined in VPC. EIP is assigned and associated with the NSIP.

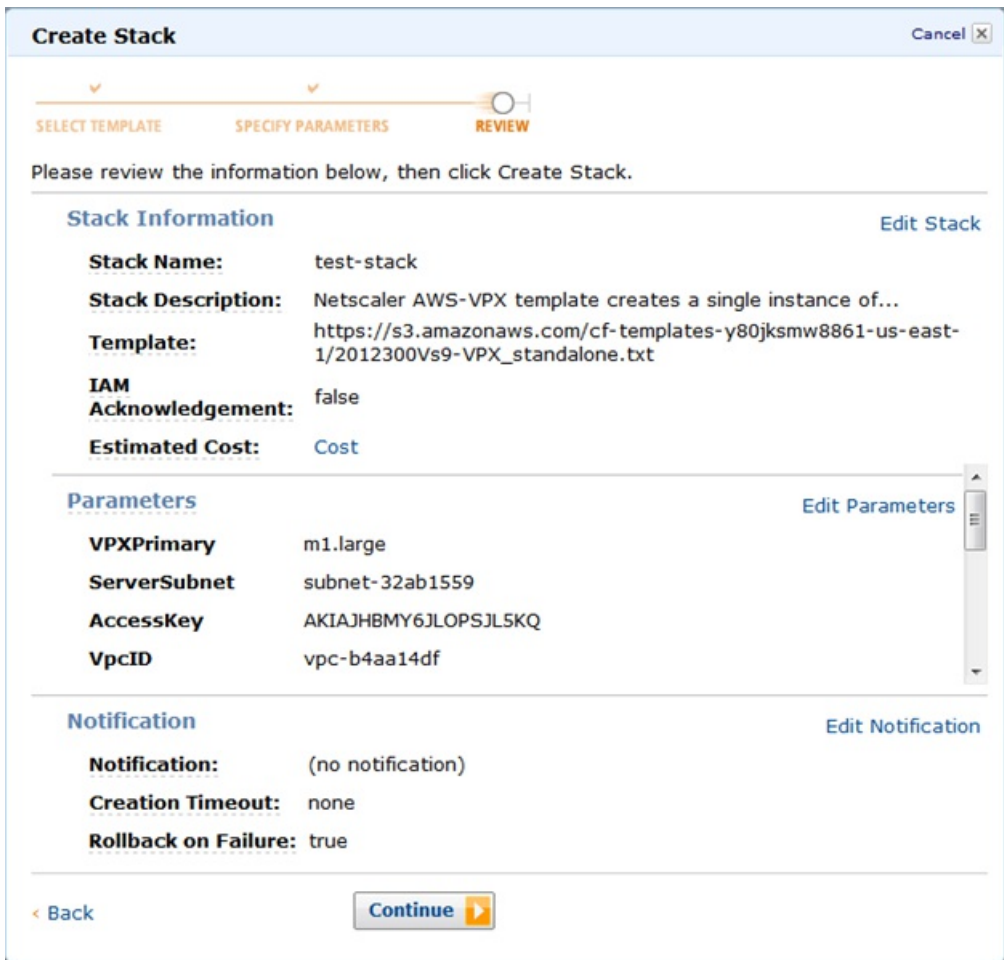

Specify Parameters

Below are the parameters associated with your CloudFormation template. You may review and proceed with the default parameters or make customizations as needed below.

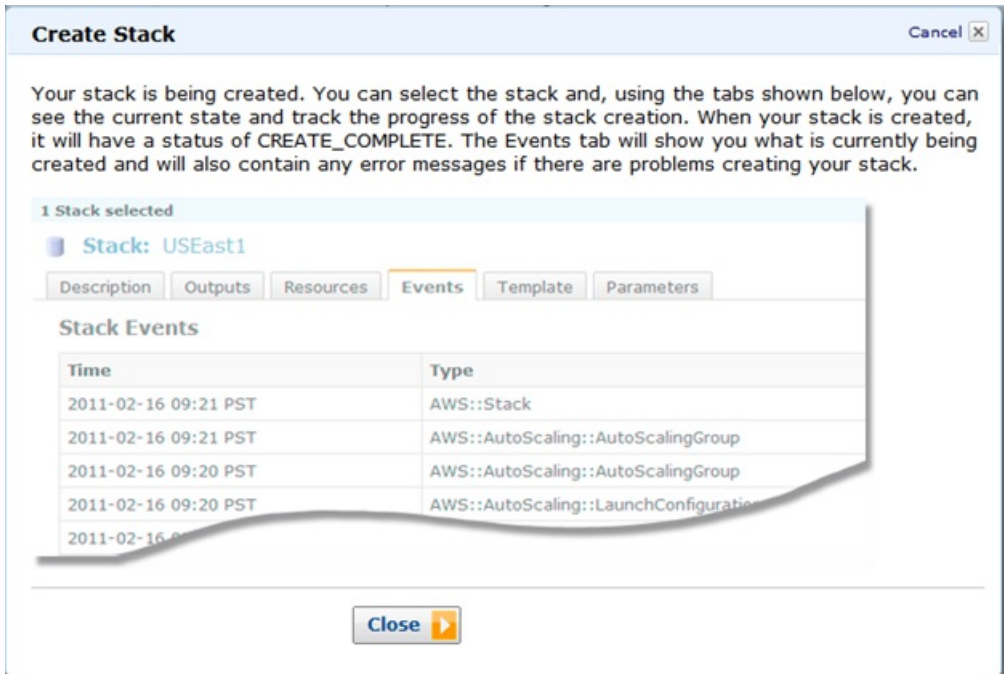

VPXPrimary	<input type="text" value="m1.large"/>
Primary VPX instance	
ServerSubnet	<input type="text" value="subnet-32ab1559"/>
SubnetId of an existing subnet in your Virtual Private Cloud (VPC) dedicated for Server side	
AccessKey	<input type="text" value="AKIAJHBMY6JLOPSJL5KQ"/>
Access Key for AWS account	
VpcID	<input type="text" value="vpc-b4aa14df"/>
VpcId of your existing Virtual Private Cloud (VPC)	
NsipSubnet	<input type="text" value="subnet-4bab1520"/>
SubnetId of an existing subnet in your Virtual Private Cloud (VPC) dedicated for NSIP	
SecurityGroup	<input type="text" value="sg-e479998b"/>
VPC Security group id	
ServerIP	<input type="text" value="172.16.20.5"/>

< Back
Continue

7. Click Continue.
8. Review the specified values in the Create Stack dialog box.

9. Click Continue to create a Stack.

10. Click Close to close the Create Stack dialog box.

11. The new stack that you created appears on the CloudFormation Stacks page.

Upgrading a NetScaler VPX instance on AWS

Apr 22, 2014

You can upgrade the EC2 instance type, throughput, software edition, and the system software of a NetScaler VPX running on AWS. For certain types of upgrades, Citrix recommends using the High Availability Configuration method to minimize downtime.

Note:

- NetScaler software release 10.1.e-124.1308.e or later for a NetScaler VPX AMI (including both utility license and customer license) does not support the M1 and M2 instance families.
- Because of changes in NetScaler instance support, downgrading from 10.1.e-124 or a later release to 10.1.123.x or an earlier release is not supported.
- Most of the upgrades do not require the launch of a new AMI, and the upgrade can be done on the current NetScaler AMI instance. If you do want to upgrade to a new NetScaler AMI instance, use the high availability configuration method.

Changing the EC2 Instance Type of a NetScaler VPX Instance on AWS

Updated: 2014-04-22

If your NetScaler VPX instances are running release 10.1.e-124.1308.e or later, you can change the EC2 instance type from the AWS console as follows:

1. Stop the VPX instance.
2. Change the EC2 instance type from the AWS console.
3. Start the instance.

You can also use the above procedure to change the EC2 instance type for a release, earlier than 10.1.e-124.1308.e, unless you want to change the instance type to M3. In that case, you must first follow the standard NetScaler upgrade procedure, at [Upgrading or Downgrading the System Software](#), to upgrade the NetScaler software to 10.1.e-124 or a later release, and then follow the above steps.

Upgrading the Throughput or Software Edition for a NetScaler VPX Instance on AWS

Updated: 2014-04-22

To upgrade the software edition (for example, to upgrade from standard to platinum edition) or throughput (for example, to upgrade from 200 mbps to 1000mbps), the method depends on the instance's license.

Using a customer license (Bring-Your-Own-License)

If you are using a customer license, you can purchase and download the new license from the Citrix Licensing portal (MyCitrix), and then install the license on the VPX instance. For more information about downloading and installing a license from the MyCitrix portal, see the VPX Licensing Guide.

Using a utility license (Utility license with hourly fee)

AWS does not support direct upgrades for fee-based instances. To upgrade the software edition or throughput of a fee based NetScaler VPX instance, launch a new AMI with the desired license and capacity and migrate the older instance configuration to the new instance. This can be achieved by using a NetScaler high availability configuration as described in ["Upgrading to a New NetScaler AMI Instance by Using a NetScaler High Availability Configuration."](#)

Upgrading the System Software of a NetScaler VPX Instance on AWS

Updated: 2014-04-22

If you need to upgrade a NetScaler instance running 10.1.e-124.1308.e or a later release, follow the standard NetScaler upgrade procedure at [Upgrading or Downgrading the System Software](#).

If you need to upgrade a NetScaler instance running a release older than 10.1.e-124.1308.e to 10.1.e-124.1308.e or a later release, first upgrade the system software, and then change the instance type to M3 as follows:

1. Stop the VPX instance.
2. Change the EC2 instance type from the AWS console.
3. Start the instance.

Upgrading to a New NetScaler AMI Instance by Using a NetScaler High Availability Configuration

Updated: 2014-04-22

To use the high availability method of upgrading to a new NetScaler AMI instance, perform the following tasks:

- Create a new instance with the desired EC2 instance type, software edition, throughput, or software release from the AWS marketplace.
- Configure high availability between the old instance (to be upgraded) and the new instance. After high availability is configured between the old and the new instance, configuration from the old instance is synchronized to the new instance.
- Force an HA failover from the old instance to the new instance. As a result, the new instance becomes primary and starts receiving traffic.
- Stop, and reconfigure or remove the old instance from AWS.

Prerequisites and Points to Consider

- Make sure you understand how high availability works between two NetScaler VPX instances on AWS. For more information about high availability configuration between two NetScaler VPX instances on AWS, see [High Availability](#).
- You must create the new instance in the same availability zone as the old instance, having the exact same security group and subnet.
- High availability setup requires access and secret keys associated with the user's AWS Identity and Access Management (IAM) account for both instances. If the correct key information is not used when creating VPX instances, the HA setup fails. For more information about creating an IAM account for a VPX instance, see [Creating an IAM Account](#).
- You must use the EC2 console to create the new instance. You cannot use the AWS 1-click launch, because it does not accept the access and secret keys as the input.
- The new instance should have only one ENI interface.

To upgrade a NetScaler VPX Instance by using a high availability configuration

1. Configure high availability between the old and the new instance. To configure high availability between two NetScaler VPX instances, at the NetScaler command prompt of each instance, type:
 - add ha node <nodeID> <IPaddress of the node to be added>
 - save config

Example

At the NetScaler command prompt of the old instance, type:

```
> add ha node 30 192.0.2.30
```

```
Done
```

At the NetScaler command prompt of the new instance, type:

```
> add ha node 10 192.0.2.10
```

Done

Note the following:

- In the HA setup, the old instance is the primary node and the new instance is the secondary node.
- The NSIP IP address is not copied from the old instance to the new instance. Therefore, after the upgrade, your new instance has a different management IP address from the previous one.
- The nsroot account password of the new instance is set to that of the old instance after HA synchronization.

For more information about high availability configuration between two NetScaler VPX instances on AWS, see [High Availability](#).

2. Force an HA failover. To force a failover in a high availability configuration, at the NetScaler command prompt of either of the instances, type:

- force HA failover

As the result of forcing a failover, the ENIs of the old instance are migrated to the new instance and traffic flows through the new instance (the new primary node). The old instance (the new secondary node) restarts.

If the following warning message appears, type N to abort the operation:

```
WARNING]:Force Failover may cause configuration loss, peer health not optimum. Reason(s):
```

```
HA version mismatch
```

```
HA heartbeats not seen on some interfaces
```

```
Please confirm whether you want force-failover (Y/N)?
```

The warning message appears because the system software of the two VPX instances is not HA compatible. As a result, the configuration of the old instance cannot be automatically synced to the new instance during a forced failover.

Following is the workaround for this issue:

1. At the NetScaler shell prompt of the old instance, type the following command to create a backup of the configuration file (ns.conf):

- copy /nsconfig/ns.conf to /nsconfig/ns.conf.bkp

2. Remove the following line from the backup configuration file (ns.conf.bkp):

- set ns config -IPAddress <IP> -netmask <MASK>

For example, set ns config -IPAddress 192.0.2.10 -netmask 255.255.255.0

3. Copy the old instance's backup configuration file (ns.conf.bkp) to the /nsconfig directory of the the new instance.
4. At the NetScaler shell prompt of the new instance, type the following command to load the old instance's configuration file (ns.conf.bkp) on the new instance:
 - batch -f /nsconfig/ns.conf.bkp
5. Save the configuration on the new instance.
 - Save conifg
6. At the NetScaler command prompt of either of the nodes, type the following command to force a failover, and then type Y for the warning message to confirm the force failover operation:
 - force ha failover

Example

```
> force ha failover
```

```
WARNING]:Force Failover may cause configuration loss, peer health not optimum.
```

```
Reason(s):
```

HA version mismatch

HA heartbeats not seen on some interfaces

Please confirm whether you want force-failover (Y/N)? Y

3. Remove the HA configuration, so that the two instances are no longer in an HA configuration. First remove the HA configuration from the secondary node and then remove the HA configuration from the primary node.

To remove an HA configuration between two NetScaler VPX instances, at the command prompt of each instance, type:

- remove ha node <nodeID>
- save config

For more information about high availability configuration between two NetScaler instances on AWS, see [High Availability](#).

Example

At the NetScaler command prompt of the old instance (new secondary node), type:

```
> remove ha node 30
```

```
Done
```

```
> save config
```

```
Done
```

At the NetScaler command prompt of the new instance (new primary node), type:

```
> remove ha node 10
```

```
Done
```

```
> save config
```

```
Done
```

Troubleshooting the NetScaler VPX on AWS

Apr 28, 2014

Amazon does not provide console access to a NetScaler VPX virtual instance. To troubleshoot, you have to use the AWS GUI to view the activity log. You can debug only if the network is connected. To view an instance's system log, right-click the instance and select system log.

Citrix provides support for fee based NetScaler VPX instances (utility license with hourly fee) on AWS. To file a support case, find your AWS account number and support PIN code, and call Citrix support. You will also be asked for your name and email address. To find the support PIN, log on to the NetScaler configuration utility and navigate to the System page.

Here is an example of a system page showing the support PIN.

The screenshot displays the NetScaler configuration utility interface. The top navigation bar includes 'Dashboard', 'Configuration', and 'Reporting'. The main content area is titled 'System Information' and contains a table of system details. A red box highlights the 'Technical Support PIN' field, which is currently obscured by a greyed-out value. Below the system information is a 'Hardware Information' section with a table of device specifications.

System Information	
System IP	10.102.10.105
Netmask	255.255.255.0
Number of Mapped IP(s)	
Node	Standalone
Technical Support PIN	[REDACTED]
Time Zone	Coordinated Universal Time
System Time	Mon, 21 Apr 2014 22:27:25 UTC
Last Config Changed Time	Mon, 21 Apr 2014 22:26:37 UTC
Last Config Saved Time	Mon, 21 Apr 2014 22:26:20 UTC

Hardware Information	
Platform	NetScaler Virtual Appliance 450040
Manufactured on	2/17/2009
CPU	1800 MHZ
Host Id	0a0eea87dda7
Serial no	HE2H91SC26
Encoded serial no	98310000cb254307ee78

Deploying Citrix NetScaler VPX on Microsoft Azure

Jul 14, 2015

You can now deploy Citrix NetScaler VPX virtual appliance in a Microsoft Azure cloud. The NetScaler VPX virtual appliances are available as an image in the Azure Marketplace. NetScaler VPX on Azure enables customers to leverage Azure cloud computing capabilities and use NetScaler load balancing and traffic management features for their business needs. You can deploy NetScaler VPX instances in Azure either as standalone instances or as high availability pairs in active-active or active-standby modes.

This document assumes that you are familiar with Microsoft Azure terminology and network details. For information about Microsoft Azure, see the Microsoft Azure documentation at <http://azure.microsoft.com/en-us/documentation/>

This document also assumes that you have basic knowledge of a NetScaler appliance. For detailed information about NetScaler appliances, see

- <http://support.citrix.com/proddocs/topic/netscaler/ns-gen-netscaler-wrapper-con.html>
- <http://support.citrix.com/proddocs/topic/netscaler-gateway-105/ng-deployment-wrapper-con.html>

This document provides information about:

- [Release Notes: NetScaler VPX on Azure](#)
- [Limitations and Usage Guidelines](#)
- [Network Architecture](#)
- [How NetScaler VPX Works on Azure](#)
- [Port Usage Guidelines](#)
- [Configuring NetScaler VPX in the Azure Cloud](#)
- [Configuring Multiple Azure VIPs for a NetScaler VPX in the Azure Cloud](#)
- [Configuring NetScaler VPX in a High Availability Mode in Azure](#)
- [Appendix](#)

For information about NetScaler Gateway configuration for Citrix XenApp and XenDesktop in Azure cloud, see https://www.citrix.com/content/dam/citrix/en_us/documents/products-solutions/netscaler-vpx-deployment-with-xendesktop-and-xenapp-on-microsoft-azure.pdf.

Limitations and Usage Guidelines

Design characteristics of the Azure Cloud impose the following limitations on the NetScaler VPX solution for Azure:

1. Although you can provision a NetScaler VPX instance in Azure with multiple NICs, the multiple NIC feature has a few constraints as documented in the following Microsoft article: <http://azure.microsoft.com/blog/2014/10/30/multiple-vm-nics-and-network-virtual-appliances-in-azure/>. Because of one of the limitations – “The order of the NICs inside the VM will be random”, if you provision a NetScaler VPX instance with multiple NICs, the instance might become unresponsive if Azure processes or your use of Azure tools shuts down and restarts the virtual machine.
To avoid this issue, Citrix recommends that you deploy NetScaler VPX instances in single IP mode, which is available only in Azure deployments. For more information about the single IP mode and the traffic flow in a NetScaler VPX on Azure deployment, see [How NetScaler VPX Works on Azure](#).

2. The Azure architecture does not accommodate support for the following NetScaler features:

Clustering

IPv6

Gratuitous ARP (GARP)

L2 Mode

Tagged VLAN

Dynamic Routing

Virtual MAC (VMAC)

USIP

GSLB

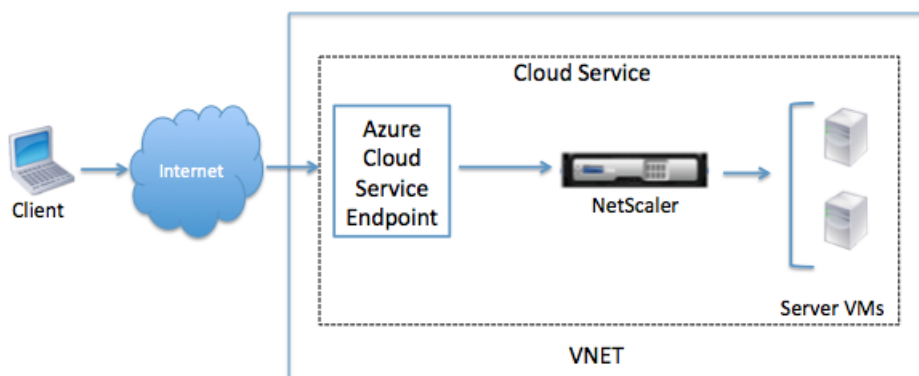

CloudBridge Connector

3. The Intranet IP (IIP) feature is not supported, because Azure does not provide the pool of IP addresses required for this feature. IIP is frequently used in VOIP, SIP, or server-initiated-connection deployment.
4. If you expect that you might have to shut down and temporarily deallocate the NetScaler VPX virtual machine at any time, assign a static Internal IP address while creating the virtual machine. If you do not assign a static internal IP address, Azure might assign the virtual machine a different IP address each time it restarts, and the virtual machine might become inaccessible. For more information, see [Provisioning NetScaler VPX on Azure with Static IIP](#).
5. In an Azure deployment, only the following NetScaler VPX models are supported: VPX 10, VPX 200, and VPX 1000. These virtual appliances can be deployed on any instance type that has two or more cores and more than 2 GB memory. See the NetScaler VPX datasheet: https://www.citrix.com/content/dam/citrix/en_us/documents/products-solutions/citrix-netscaler-vpx-data-sheet.pdf

Network Architecture

In a Microsoft Azure cloud, a NetScaler VPX instance resides between the Azure cloud service endpoint and the backend servers. The NetScaler instance does not receive client requests directly. They are received on the endpoint, which forwards the requests to the NetScaler VPX instance, and the instance sends them to the servers. The response from a server follows the same path in reverse.

The following figure shows how traffic flows from a client to the server through a NetScaler VPX instance provisioned in the Azure cloud.

How NetScaler VPX Works on Azure

A regular NetScaler VPX appliance requires at least three IP addresses to function:

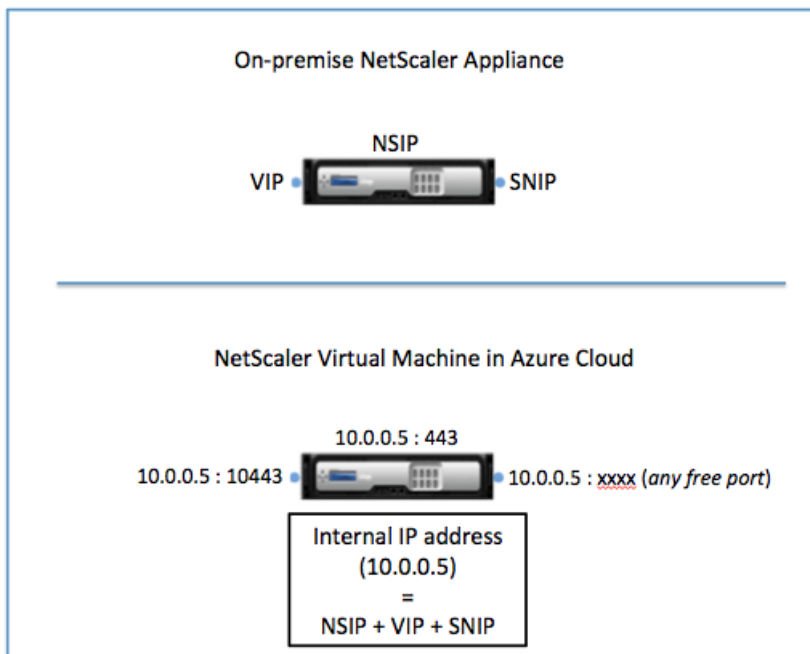

- Management IP address called the NetScaler IP (NSIP) address
- Subnet IP (SNIP) address for communicating with the server farm
- Virtual server IP (VIP) address for accepting client requests

In the Azure network architecture, only one private IP address (internal IP address) is assigned to an instance during provisioning through DHCP.

Although you can provision a NetScaler VPX instance in Azure with multiple NICs, the multiple NIC feature has a few constraints that might make the instance unresponsive. For details about this constraint, see [Limitations and Usage Guidelines](#).

To prevent this limitation, you can deploy NetScaler VPX instance in Azure with single IP architecture, where the three IP functions of a NetScaler appliance are multiplexed onto one IP address. This single IP address uses different port numbers to function as the NSIP, SNIP, and VIP.

The following image illustrates how a single IP address is used to perform the functions of NSIP, SNIP, and VIP.

Note: The single IP mode is available only in Azure deployments. This mode is not available in the on-premise NetScaler VPX, NetScaler VPX on AWS, and NetScaler VPX instances running in other deployments.

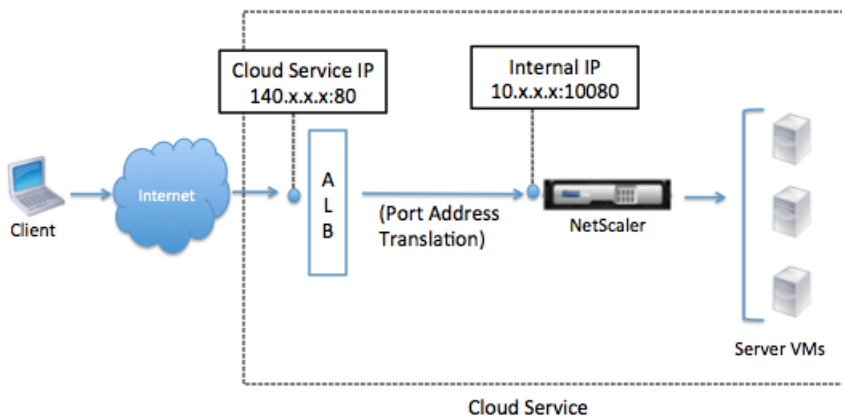

Traffic Flow Through Port Address Translation

Note: This document refers to the Azure public virtual IP (VIP) address as the cloud service IP address to avoid confusion with the NetScaler virtual IP (VIP) address.

In an Azure deployment, when you provision the NetScaler VPX instance as a virtual machine (VM), Azure assigns a cloud service IP address and an internal IP address (non-routable) to the NetScaler virtual machine. Endpoints are defined for the NetScaler instance and each endpoint is assigned a public port and a private port. The NetScaler instance listens on the internal IP address and private port.

The client request that originates from the Internet is received by the Azure cloud service endpoint on the cloud service public IP address and public port. This endpoint performs port address translation (PAT) to map the public IP address and port to the internal IP address and private port of the NetScaler virtual machine, and forwards the traffic to the virtual machine.

The following figure shows how Azure performs port address translation to direct traffic to the NetScaler internal IP address and private port.

In this example, the cloud service IP address assigned to the VM is 140.x.x.x, and the internal IP address is 10.x.x.x. When the endpoints are defined, public HTTP port 80 is defined as the port on which the client requests are received, and a corresponding private port, 10080, is defined as the port on which the NetScaler virtual machine listens. The client request is received on IP address 140.x.x.x at port 80. Azure performs port address translation to map this address and port to internal IP address 10.x.x.x on private port 10080 and forwards the client request.

For information about port usage guidelines while defining endpoints, see [Port Usage Guidelines](#).

For information about endpoints, see <http://azure.microsoft.com/en-in/documentation/articles/virtual-machines-set-up-endpoints/>

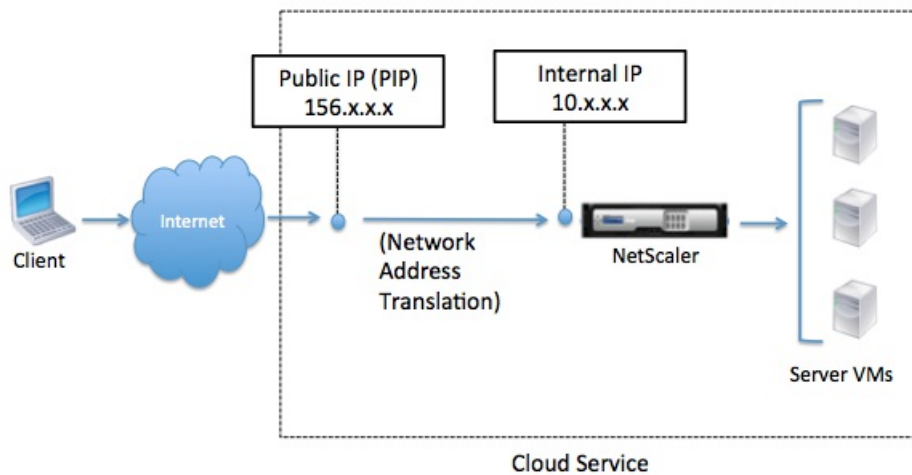

Note: You can also configure multiple cloud service IP addresses for multiple virtual servers with unique FQDNs configured on the NetScaler VPX VM. For more information, see [Configuring Multiple Azure VIPs for a NetScaler VPX in the Azure Cloud](#).

Traffic Flow Through Network Address Translation

You can also request an instance-level public IP address (PIP) for your NetScaler virtual machine. If you use a PIP, you need not define an endpoint to receive traffic. The incoming request from the Internet is received on the PIP. Azure performs network address translation (NAT) and forwards the traffic to the internal IP address of the NetScaler instance.

Note that you can create a PIP only through Windows PowerShell or REST APIs. For more information about PIP, see <https://msdn.microsoft.com/en-us/library/azure/dn690118.aspx>.

The following figure shows how Azure performs network address translation to map the NetScaler internal IP address.

In this example, the PIP assigned to the NetScaler virtual machines is 156.x.x.x and the internal IP address is 10.x.x.x. No endpoints are defined. The client request is received on PIP 156.x.x.x. Azure performs network address translation to map the PIP to the internal IP address 10.x.x.x, and forwards the client request.

Note: Citrix recommends that you use the cloud service IP address to receive traffic from the Internet, and use either the cloud service public IP address or the PIP to access the NetScaler instance for management purposes. Also, note that NetScaler high availability does not work if you use PIP to receive client traffic from the Internet.

Port Usage Guidelines

You can configure additional endpoints while creating the NetScaler virtual machine or after the virtual machine is provisioned. Each endpoint has a public port and a private port.

Before adding endpoints, note the following guidelines regarding the port numbers you can use:

1. The following ports are reserved by the NetScaler virtual machine. You cannot define these as private ports when using the cloud service IP address for requests from the Internet.

Ports 21, 22, 80, 443, 8080, 67, 161, 179, 500, 520, 3003, 3008, 3009, 3010, 3011, 4001, 5061, 9000, 7000.

However, if you want Internet-facing services such as the VIP to use a standard port (for example, port 443) you have to create port mapping by using the Azure endpoint. The standard port is then mapped to a different port that is configured on the NetScaler for this VIP service.

For example, a VIP service might be running on port 8443 on the NetScaler instance but be mapped to public port 443. So, when the user accesses port 443 through the cloud service IP, the request is actually directed to private port 8443.

2. Cloud service IP does not support protocols in which port mapping is opened dynamically, such as passive FTP or ALG.
3. Azure load balancer does not work with PIP. Therefore, in the current NetScaler high availability (HA) design, a PIP cannot be used as a VIP, that is, as an Internet-facing interface. For more information about configuring NetScaler VPX HA in the Azure cloud, see [Configuring NetScaler VPX in High Availability Mode in Azure](#).
4. In a NetScaler Gateway deployment, you need not configure a SNIP address because the NSIP can be used as a SNIP when no SNIP is configured.
5. You must configure the VIP address by using the NSIP address and some nonstandard port number. For call-back configuration on the backend server, the VIP port number has to be specified along with the VIP URL (for example, url:port).

Example:

If the VPN virtual server FQDN is vip.test.com, and the VPN virtual server is running on port 8443 then, the call-back URL will be: <https://vip.test.com:8443>

Configuring NetScaler VPX in the Azure Cloud

Jul 14, 2015

Provisioning a NetScaler VPX instance in the Azure cloud involves obtaining the NetScaler VPX image either from the Azure [marketplace](#) or from the Citrix [download page](#), creating the virtual machine instance in Azure, and defining endpoints.

You can create a NetScaler VPX instance in Azure either by using the new Azure Preview portal or by using the classic Azure Management portal.

Before you start provisioning the VM, review the [Before You Begin](#) section.

This document includes the following information:

- [Before You Begin](#)
- [Creating a NetScaler VPX Instance on Microsoft Azure by Using the Azure Preview Portal](#)
- [Creating a NetScaler VPX Instance on Microsoft Azure by Using the Classic Azure Management Portal](#)
- [Accessing the NetScaler VPX Virtual Machine](#)

Before You Begin

Make sure that you have the following:

- A Microsoft Azure user account
- Access to Microsoft Azure Preview Management portal
- Access to the Microsoft Azure Classic Management portal
- Microsoft Azure SDK
- Microsoft Azure PowerShell

Before you begin creating the NetScaler VPX instance, make sure that you have created a virtual network with required subnets in which the VPX will reside. You can create virtual networks during VM provisioning but you will not have the flexibility to set different subnets. For information about creating virtual networks, see <http://azure.microsoft.com/en-us/documentation/articles/create-virtual-network/>

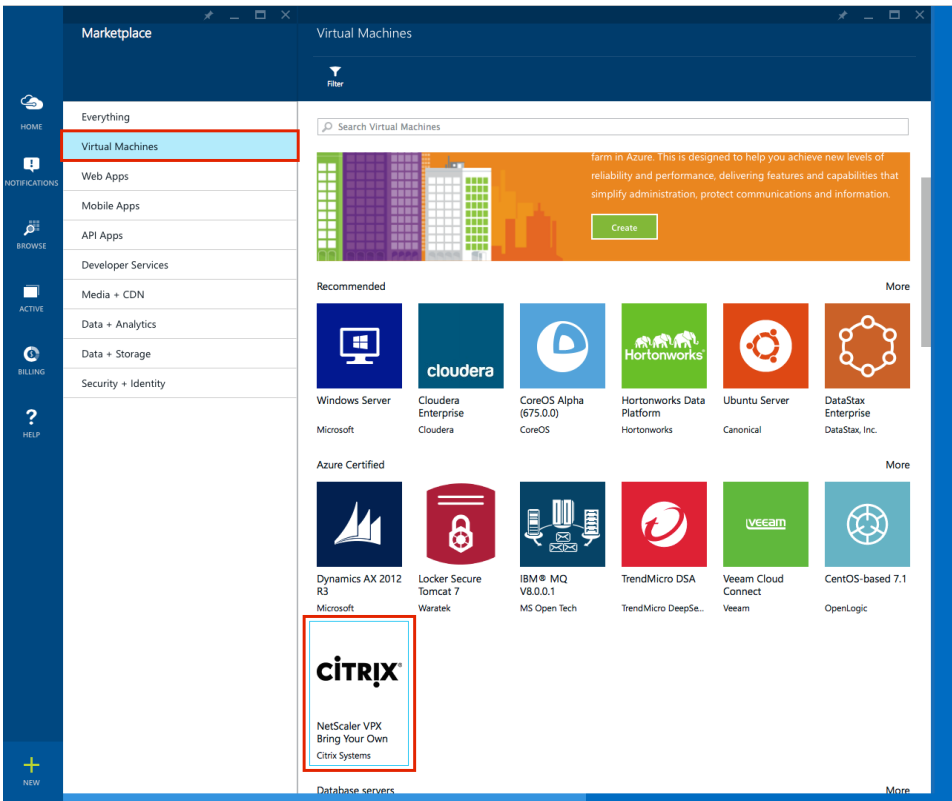

Optionally, configure DNS server and VPN connectivity that allows a virtual machine to access Internet resources.

Creating a NetScaler VPX Instance on Microsoft Azure by Using the Azure Preview Portal

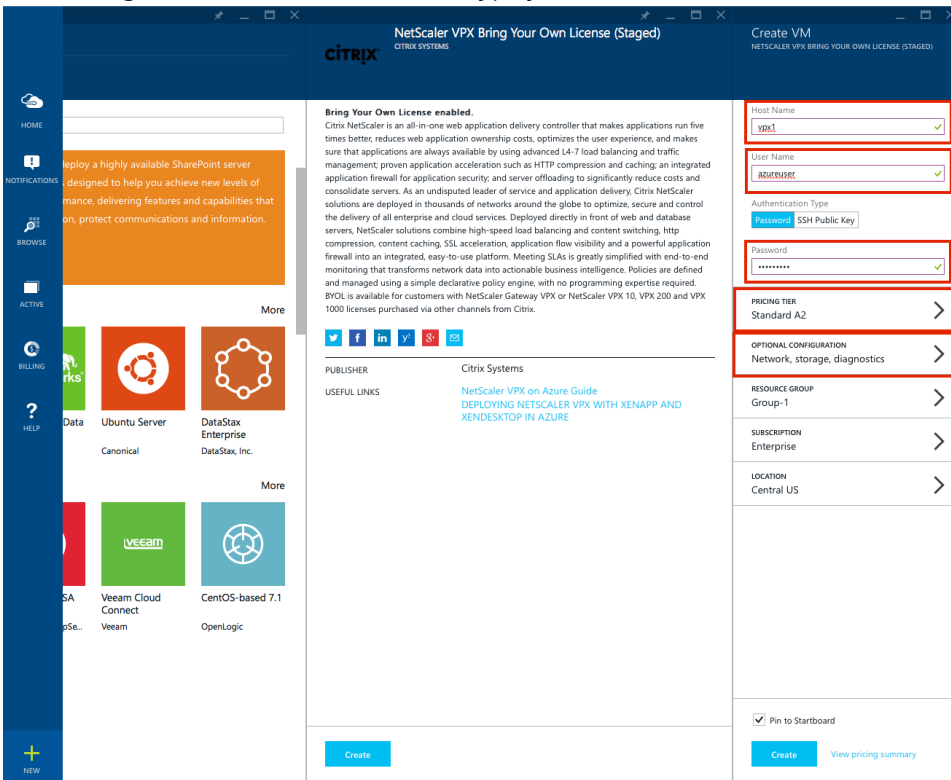

Obtain the NetScaler VPX image from the Azure [MarketPlace](#), and then use the Azure MarketPlace Preview portal to create a NetScaler VPX instance.

To create a NetScaler VPX instance on Microsoft Azure by using the Azure Marketplace Preview Portal

1. On the Microsoft Azure Portal page (<https://portal.azure.com>), click Marketplace.
2. On the Marketplace page, click Virtual Machine and select Citrix NetScaler VPX Bring Your Own.

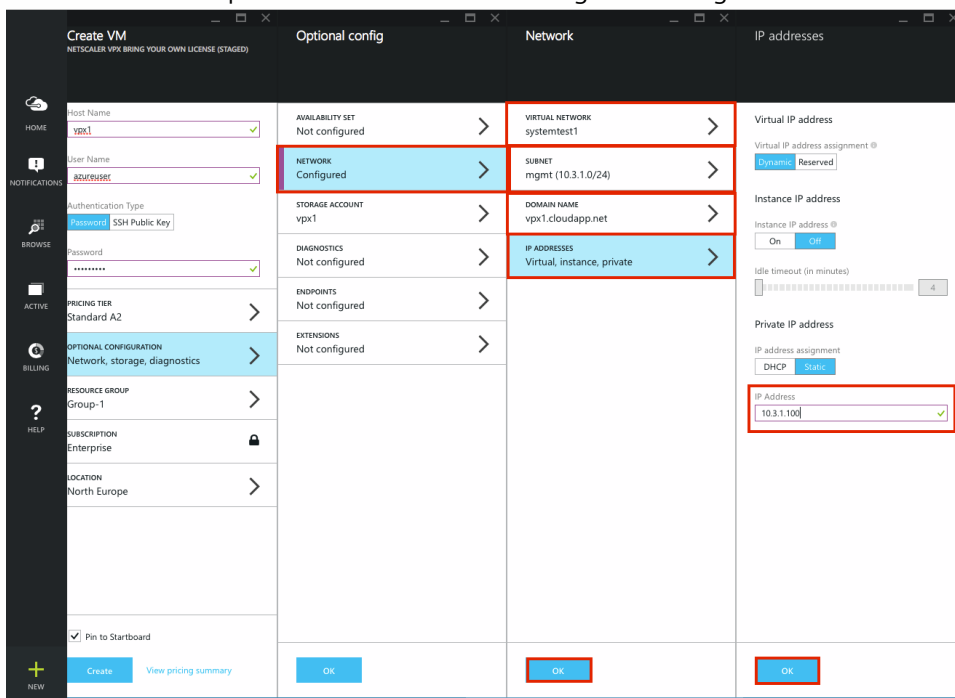

3. On the NetScaler VPX Bring Your Own License page, click Create.
4. On the Create VM page:
 1. Specify values for Host Name and User Name.
 2. Under Authentication Type, select SSH Public Key or Password.
 3. Click Pricing Tier and select the instance type you want to use.

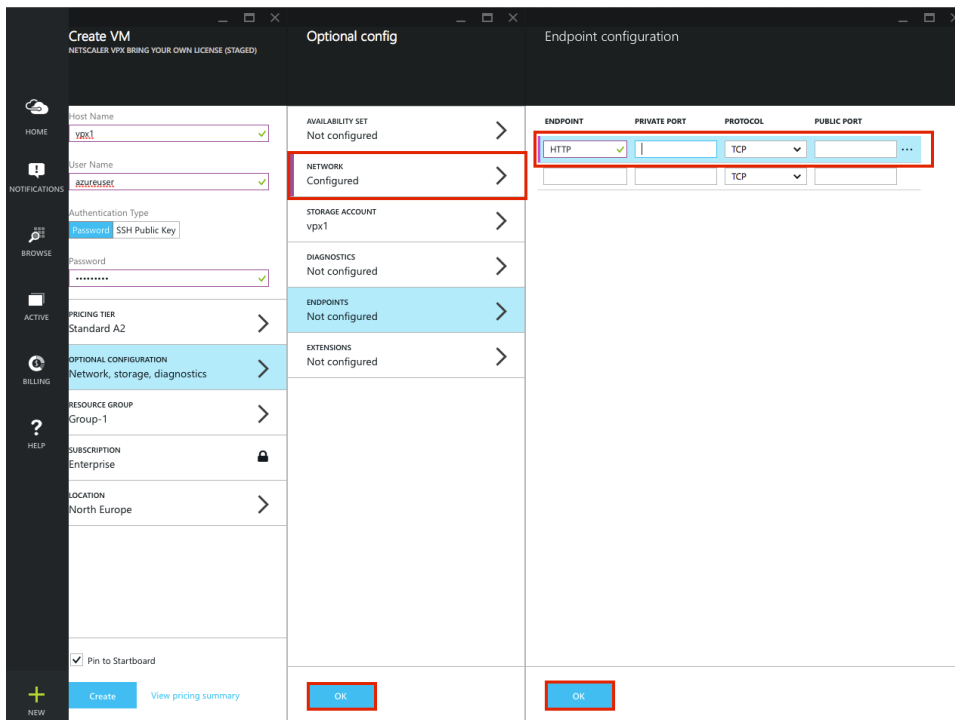

4. In Optional Configuration, do the following:
 1. Configure Availability Set as required.

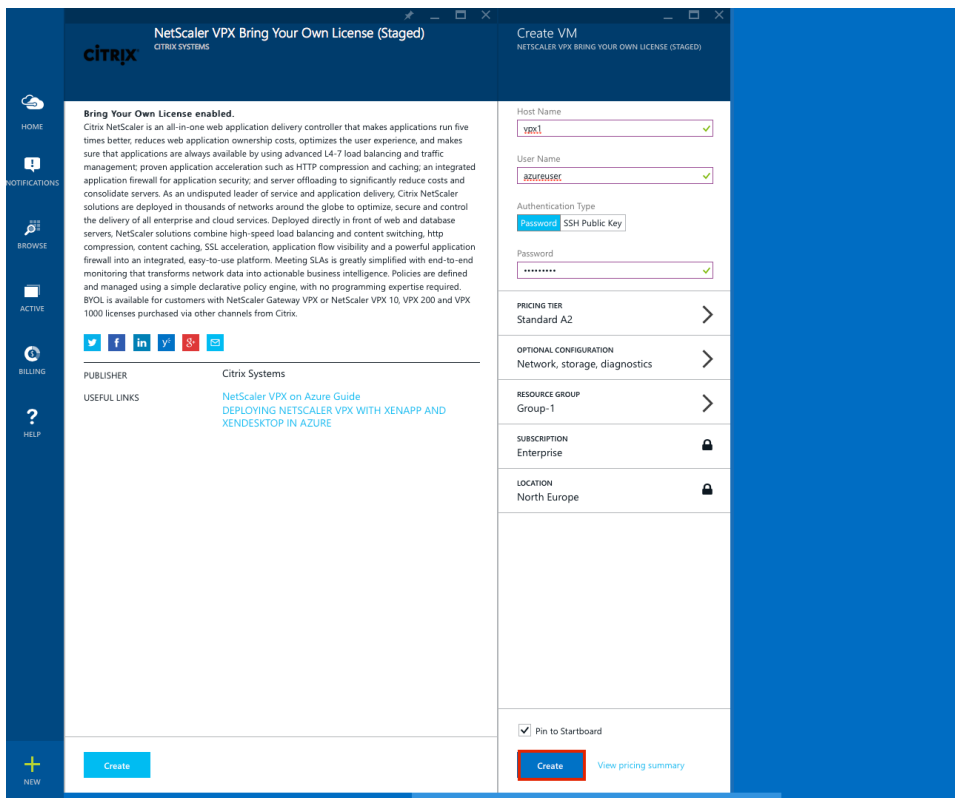

- Click Virtual Network and select the virtual network you have created.
Note: It is recommended that you create network settings before you begin provisioning the VM so that the network information is available during provisioning. If you create a virtual network during VM provisioning, you will not be able to set different subnets.
- Click Subnet to select the specific subnet.
- Click Domain Name to select an existing cloud service or to create a new one.
- In IP Addresses, specify a static IP address.
Note: If you expect that you might have to shut down and temporarily de-allocate the NetScaler VPX virtual machine at any time, assign a static Internal IP address. If you do not assign a static internal IP address, Azure might assign the virtual machine a different IP address each time it restarts, and the virtual machine might become inaccessible.
- Click OK for each option to make sure each configured setting is saved.

- Click Endpoints and add the public and private endpoints you want to use. Note that SSH endpoint is automatically set by Azure with a random public port and a private port as 22. Therefore, provisioning will fail if you add SSH. Click OK to save the endpoints.

8. Click Create.

9. Review the offer details and legal terms on the Create VM page and click Create.

On the Portal page you can view the progress of the NetScaler VPX virtual machine provisioning.

After the virtual machine is provisioned, a “deployment ID” is generated for use as the password to log on to the NetScaler virtual machine the first time. To view this deployment ID, double-click the virtual machine instance.

Notes:

- The default username to log on to the NetScaler virtual machine is nsroot. However, the default password is set

to the “deployment ID” that is generated after the virtual machine is provisioned. You can change the password after you log on to the instance.

- The password for the user that is created during the virtual machine provisioning remains the same as the one you had provided. Make sure that you do not provide nsroot as this user ID.

Creating a NetScaler VPX Instance on Microsoft Azure by Using the Classic Azure Management Portal

Obtain the NetScaler VPX image from the Citrix [download page](#) and upload it to Azure. Then, use the classic Azure management portal to create a NetScaler VPX instance.

To create a NetScaler VPX instance on Microsoft Azure by using the classic Azure management portal

1. On the **Virtual Machines** page, click **New**.
2. Navigate to **Compute > Virtual Machine > From Gallery > My Images**, select the VPX image that you have uploaded, and click the arrow at the right bottom corner.
3. On the **Virtual machine configuration** page, specify values for the required fields.
4. On the next screen, create a new cloud service. You can either configure the endpoints here, or at a later stage after the virtual machine is provisioned.
5. On the next screen, be sure to clear the **The VM agent that supports extensions is already installed** checkbox. The agent brings up the NetScaler virtual machine with the specified parameters by exchanging heartbeats and status with the Azure Fabric Controller.

For instructions on how to create a NetScaler VPX instance on Azure by using the Azure PowerShell, see [Provisioning NetScaler VPX with Single NIC by Using Azure PowerShell](#).

After the virtual machine is provisioned, a “deployment ID” is generated for use as the password to log on to the NetScaler virtual machine the first time. To view this deployment ID, double-click the virtual machine instance.

Note

- The default username to log on to the NetScaler virtual machine is nsroot. However, the default password is set to the “deployment ID” that is generated after the virtual machine is provisioned. You can change the password after you log on to the instance.
- The password for the user that is created during the virtual machine provisioning remains the same as that you had provided. Make sure that you do not provide nsroot as this user ID.

If you expect that you might have to shut down and temporarily deallocate the NetScaler VPX virtual machine at any time, assign a static Internal IP address while creating the virtual machine. If you do not assign a static internal IP address, Azure might assign the virtual machine a different IP address each time it restarts, and the virtual machine might become inaccessible. You can assign static internal IP address only when you provision the virtual machine through Azure PowerShell. For information about creating a virtual machine with a static internal IP address, see [Provisioning NetScaler VPX on Azure with a Static IIP by Using Azure PowerShell](#).

Accessing the NetScaler VPX Virtual Machine

You can access the NetScaler instance either through its graphical user interface (GUI) or through the command line interface (CLI). You can use either the cloud service IP address or the PIP to access the NetScaler virtual machine instance.

To log on to the virtual machine, use either of the following credentials:

- The username and password specified while creating the virtual machine.
- nsroot as the username and the “deployment ID” that was generated by Azure during virtual machine provisioning.

You can change the password after you log on to the instance.

To access the NetScaler instance through the GUI

In a browser's address field, type the cloud service public IP address provided by Azure during virtual machine provisioning, or type the PIP address.

Note: Make sure you have created an endpoint to allow access to the private port 80 or 443 when accessing the GUI by using the cloud service IP.

To access the NetScaler instance through the CLI

Use any command line access tool (for example, Putty). Specify either the cloud service public IP address provided by Azure during NetScaler VPX provisioning, or specify the PIP address. Use SSH protocol with port 22.

Note: Make sure that you have created an endpoint to allow access to the private port 22 when accessing the CLI by using the cloud service IP.

For information about getting started with a NetScaler appliance, see <http://support.citrix.com/proddocs/topic/netscaler-10-5/ns-gen-getting-started-wrapper-10-con.html>

Configuring Multiple Azure VIPs for a NetScaler VPX in the Azure Cloud

Aug 26, 2015

Note

This document refers to the Azure public virtual IP (VIP) address as the cloud service IP address to avoid confusion with the NetScaler virtual IP (VIP) address.

Microsoft Azure now allows you to configure multiple cloud service IP addresses (Azure public virtual IP addresses (VIPs)) to access Azure cloud services. This enables you to host multiple NetScaler virtual servers with unique FQDNs.

For example, you have four virtual servers with unique FQDNs configured on your NetScaler VPX VM. In the Azure architecture, these virtual servers are represented by the internal single IP assigned to your VM and a private port. However, you want different public cloud service IP addresses for each of these virtual servers. To achieve this, you can configure four public cloud service IP addresses to access the Azure load balancer. Then, map each public cloud service IP address and port to a virtual server represented by the internal IP of your VM and the private port.

The following image illustrates how you can configure multiple cloud service IP addresses (Azure public VIPs) for NetScaler virtual servers with unique FQDNs.

In this example, there are two SSL virtual servers and two HTTP virtual servers configured on the NetScaler VPX VM. Each virtual server is represented by the VPX VM internal IP address and a unique private port. Four cloud service IP addresses (Azure public VIPs) are configured that are used by the clients to access the Azure load balancer. Each cloud service IP:public port is mapped to an internal IP:unique port. For example, VIP1 IP:443 is mapped to VPX IP:10443. So, all traffic from the client to this SSL virtual server is accessed through public VIP1 IP:443.

For more information about multiple VIPs per cloud service, see <https://azure.microsoft.com/en-us/documentation/articles/load-balancer-multivip/>

Configuration Steps

You can configure multiple cloud service IP addresses by using Azure PowerShell. You have to first add a cloud service IP address (Azure VIP) to a cloud service and then associate this IP address to an endpoint. For information about the commands to configure this, see <https://azure.microsoft.com/en-us/documentation/articles/load-balancer-multivip/>

You can also associate one cloud service IP address with two NetScaler VPX virtual machines in an HA mode. For example, you have configured multiple cloud service IP addresses to access the Azure load balancer and you want to configure two virtual machines named VPX1 and VPX2 in an HA mode. You can associate only one cloud service IP (say, VIP1) to both the VPX VMs. For information about the configuration steps, see <https://azure.microsoft.com/en-us/documentation/articles/load-balancer-multivip/#how-to-enable-load-balancing-on-a-specific-vip>

Configuring NetScaler VPX in High Availability Mode in Azure

Jan 28, 2011

You can set up two NetScaler VPX instances for high availability in either active-active or active-passive mode.

When two NetScaler VPX instances are configured in active-active mode, both instances must have the same configuration. The client traffic is distributed across the virtual servers in both the instances by the Azure load balancer. The VIP addresses in both the instances are different and should match the NSIP of that VPX instance.

The active-passive mode provides failover capability. In this mode, the VPX instances synchronize their configuration states. When the primary instance fails, the secondary instance takes over.

For information about high availability in NetScaler appliance, see <http://support.citrix.com/proddocs/topic/ns-system-10-5-map/ns-nw-ha-intro-wrppr-con.html>

In a Microsoft Azure deployment, a high availability configuration of two NetScaler virtual machines is achieved by using the Azure load balancer, which distributes the client traffic across the virtual servers configured on both the NetScaler instances. Two types of Azure load balancers are available for high availability:

- **Azure external load balancer:** If the client traffic originates from the Internet, you have to deploy the external load balancer between the Internet and the NetScaler VPX instances to distribute client traffic.
- **Azure internal load balancer:** If the client traffic originates from within the cloud service, or is forwarded by a gateway or firewall within the cloud service, you have to deploy the internal load balancer to distribute client traffic.

To achieve high availability on Azure, you must add the two NetScaler VMs as a load balanced set and configure the endpoints.

Points to Consider Before You Begin Configuration

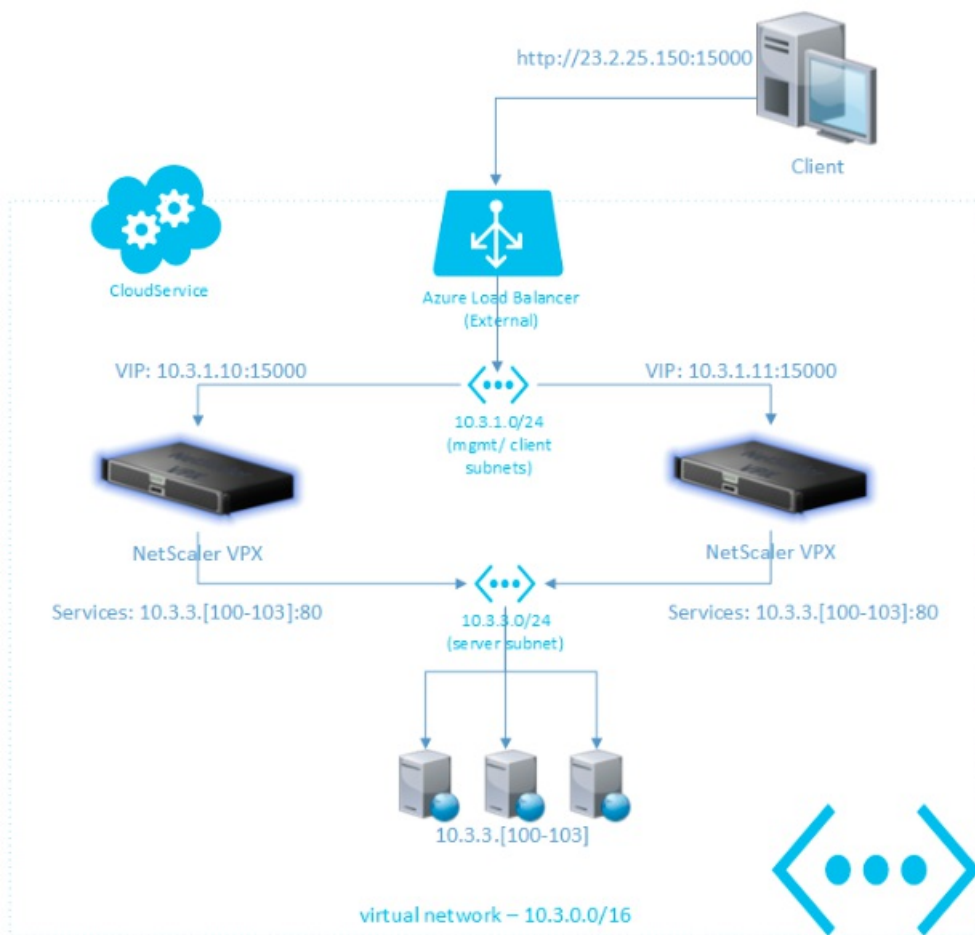

Note the following before you begin configuring the NetScaler instances in high availability mode in the Azure cloud.

- The two NetScaler virtual machines that you want to add to a load balanced set should be provisioned in the same cloud service.
- A load balanced set applies only to a VM's default NIC. Therefore the VIP has to be configured on the VPX's default NIC.
- The endpoints are configured on both the NetScaler VMs and are bound to the Azure load balancer.
- In an active-passive deployment, the Azure load balancer monitors both the primary and the secondary NetScaler VM by sending them TCP probes. These TCP probes are sent on port 9000.

Configuring NetScaler High Availability with the Azure External Load Balancer

If your client traffic originates from the Internet, you have to deploy the external load balancer to create a high availability configuration of NetScaler virtual machines in a load-balanced set.

The following figure shows how high availability is achieved in active-active mode by using the external load balancer. The two NetScaler VMs are in a load-balanced set sharing an endpoint that accepts client traffic from the Internet over port 15000. The Azure external load balancer load balances these client requests between the two virtual machines.

Before you begin configuring the load-balanced set through the Azure portal, do one of the following:

- For an active-active deployment, configure the required services on the two NetScaler virtual machines.
- For an active-passive deployment, configure the NetScaler virtual machines as primary and secondary nodes by using the following command: `add ha node <ID> <IP address>`.

To configure the load-balanced set by using the Azure management portal

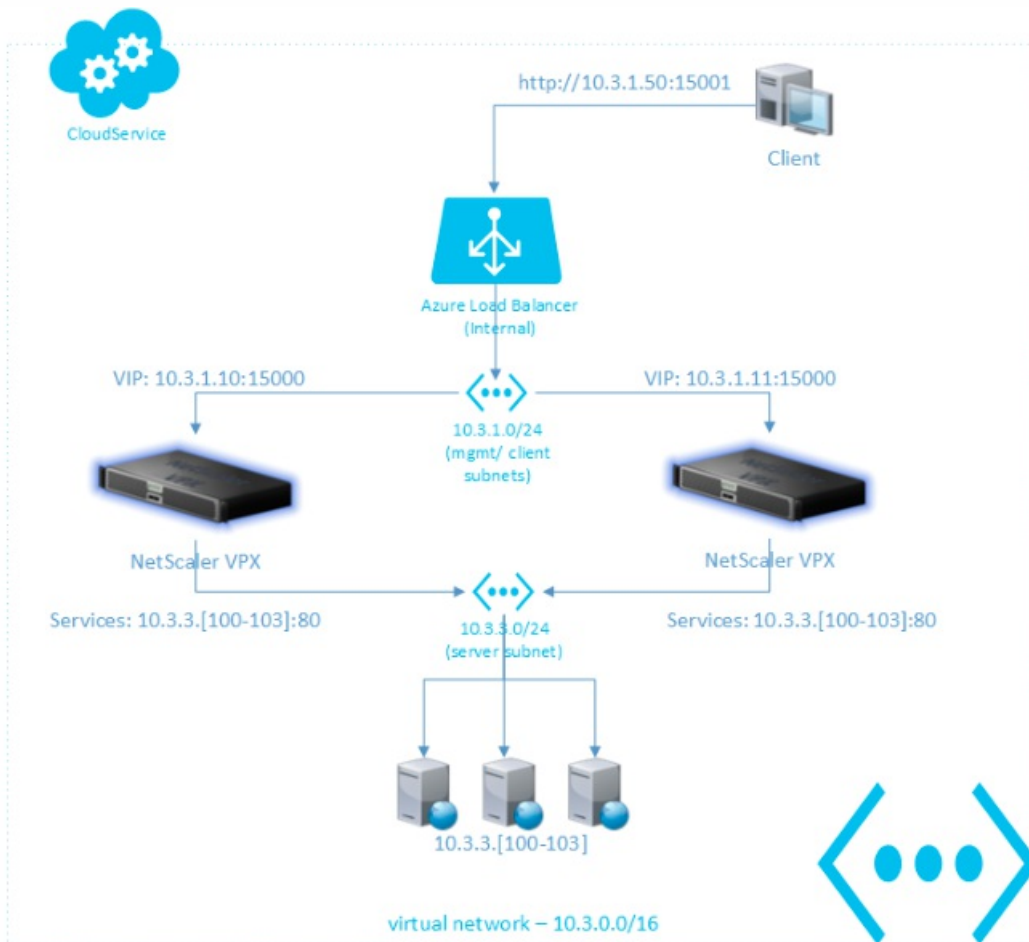

1. Select the first virtual machine that you want to make part of HA pair, click Endpoint, and then click Add.
2. Select Add a stand-alone endpoint, specify values for name, protocol, public and private ports, and select Create a load-balanced set.
3. Set the parameters as follows:
 - Probe protocol – TCP
 - Probe port – 9000
 - Probe interval – 5 seconds
 - Number of probes - 2
4. Select the second virtual machine of the HA pair, and add an endpoint.
5. Select Add an endpoint to an existing load-balanced set, and then specify values for name, protocol, public ports, and private ports. Click the tick mark to complete the configuration.

Configuring NetScaler High Availability with the Azure Internal Load Balancer

If your client traffic originates from within the cloud service or a virtual network with a regional scope, you have to deploy the internal load balancer to achieve high availability of NetScaler virtual machines added to a load-balanced set.

Note: You can configure an internal load balancer only by using Azure PowerShell.

The following figure shows how high availability is achieved in an active-active mode by using the internal load balancer. The two NetScaler virtual machines are in a load-balanced set sharing an endpoint that accepts client traffic from the Internet at port 15001. The Azure internal load balancer load balances these client requests between the two virtual machines.

Before you begin configuring the load-balanced set by using Azure PowerShell, do one of the following:

- For an active-active deployment, configure the required services on the two NetScaler virtual machines.
- For an active-passive deployment, configure the NetScaler virtual machines as primary and secondary nodes by using the following command: `add ha node <ID> <IP address>`.

You can configure the load-balanced set only by using Azure PowerShell. For information about the cmdlet that you need to run, see [Configuring NetScaler VPX HA with Azure Internal Load Balancer by Using Azure PowerShell](#).

Appendix

Jan 28, 2011

This appendix provides cmdlets with which you can do the following in Azure PowerShell:

- Provision NetScaler virtual machines in the Azure cloud
- Configure NetScaler VPX HA with Azure External Load Balancer
- Configure NetScaler VPX HA with Azure Internal Load Balancer
- Provision NetScaler VPX in Azure with Static IP

Provisioning NetScaler VPX with Single NIC by Using Azure PowerShell

```
$image = Get-AzureVMImage -ImageName "vpx_105_51_1040"
$vm = New-AzureVMConfig -Name "vpx_bwc_105" -InstanceSize "Medium" -Image $image.ImageName
Add-AzureProvisioningConfig -VM $vm -Linux -Linuxuser "user" -Password "Citrix123"
Set-AzureSubnet -SubnetNames "mgmt.-1" -VM $vm
Set-AzureStaticVNetIP -IPAddress "10.3.1.10" -VM $vm
New-AzureService -ServiceName "vpx105" -Location "North Europe"
Set-AzureEndpoint -Name "SSH" -LocalPort 22 -PublicPort 22 -Protocol tcp -VM $vm
Add-AzureEndpoint -Name "HTTP" -LocalPort 80 -PublicPort 80 -Protocol tcp -VM $vm
Add-AzureEndpoint -Name "SSL" -LocalPort 443 -PublicPort 443 -Protocol tcp -VM $vm
New-AzureVM -ServiceName "vpx105" -VNetName "systemtestazure" -VM $vm
Configuring NetScaler VPX HA with Azure External Load Balancer by Using Azure PowerShell
```

```
$vm1 = "vpxne1"
$vm2 = "vpxne2"
$svc = "vpxne"
$lbsetname = "azurelb"
$epname = "vip"
```

```
Get-AzureVM -Name $vm1 -ServiceName $svc | Add-AzureEndpoint -LBSetName $lbsetname -Name
$epname -Protocol "tcp" -LocalPort 15000 -PublicPort 15000 -ProbeProtocol TCP -ProbePort
9000 -ProbeIntervalInSeconds 5 | Update-AzureVM
```

```
Get-AzureVM -Name $vm1 -ServiceName $svc | Add-AzureEndpoint -LBSetName $lbsetname -Name
$epname -Protocol "tcp" -LocalPort 15000 -PublicPort 15000 -ProbeProtocol TCP -ProbePort
9000 -ProbeIntervalInSeconds 5 | Update-AzureVM
```

Configuring NetScaler VPX HA with Azure Internal Load Balancer by Using Azure PowerShell

```
$svc = "vpxne" [Cloud service name]
$ilb = "vpx-ilb" [Name of the internal load balancer] $subnet = "mgmtsub"
[Management subnet where the default NIC exists]
$IP = "10.3.1.50" [IP address from the management subnet]
```

```
Add-AzureInternalLoadBalancer -ServiceName $svc -InternalLoadBalancerName $ilb
-SubnetName $subnet -StaticVNetIPAddress $IP
```

```
$vm1 = "vpxne1"
$vm2 = "vpxne2"
```

```
$epname = "vip2"
$prot = "TCP"
$locport = 1500
$pubport = 1500
$lbsetname = "azure_ilb"
```

```
Get-AzureVM -ServiceName $svc -Name $vm1 | Add-AzureEndpoint -Name $epname -Protocol
$prot -LocalPort $locport -PublicPort $pubport -LBSetName $lbsetname -InternalLoadBalancerName
$ilb -ProbeProtocol TCP -ProbePort 9000 -ProbeIntervalInSeconds 5 | Update-AzureVM
```

```
Get-AzureVM -ServiceName $svc -Name $vm2 | Add-AzureEndpoint -Name $epname -Protocol
$prot -LocalPort $locport -PublicPort $pubport -LBSetName $lbsetname -InternalLoadBalancerName
$ilb -ProbeProtocol TCP -ProbePort 9000 -ProbeIntervalInSeconds 5 | Update-AzureVM
```

Provisioning NetScaler VPX on Azure with a Static IIP by Using Azure PowerShell

Before you begin provisioning the virtual machine with a static internal IP address, make sure that

- Azure virtual network is configured
- You have downloaded Azure PowerShell

Run the following commands on Azure PowerShell to provision NetScaler VPX on Azure with static IIP.

```
$image = Get-AzureVMImage -ImageName "image1045"
```

```
$vm = New-AzureVMConfig -Name "vpx3" -InstanceSize "Medium" -Image $image.ImageName
```

```
Add-AzureProvisioningConfig -VM $vm -Linux -Linuxuser "user" -Password "Citrix123"
```

```
Set-AzureSubnet
```

```
-SubnetNames
```

```
"mgmt-1" -VM $vm
```

```
Set-AzureStaticVNetIP -IPAddress "1.10.1.5" -VM $vm
```

```
New-AzureService -ServiceName "singlevpx" -Location "North Europe" <To add new cloud service>
```

```
Set-AzureEndpoint -Name "SSH" -LocalPort 22 -PublicPort 1322 -Protocol tcp -VM $vm
```

```
New-AzureVM -ServiceName "singlevpx" -VNetName "pcwestus" -VM $vm
```

Release Notes: NetScaler VPX on Azure

Jan 28, 2011

These release notes describe the known issues in NetScaler release 10.5 build 51.1048.e. This release is based on the main release [NetScaler 10.5 build 51.10](#).

Release history:

- Build 51.1048.e (2015-05-01) (Current build)

Related links

[Download Package](#) | [Documentation](#) | [Citrix services and support](#)

Known Issues

Following are the known issues in NetScaler VPX on Azure release 10.5

Configuration Utility

- The configuration utility displays an incorrect status message after you create virtual servers, actions, and policies for content switching, load balancing, auditing, and AppFlow entities.

[# 558648]

- A user who launches the XenApp/XenDesktop wizard and creates a VPN virtual server is shown a check box for redirecting requests from HTTP to HTTPS. When the user selects the checkbox and enters the FQDN, VPN virtual server creation fails.

Workaround: Do not select the check box. Use the CLI to add a load balancing virtual server on a nonstandard port, and set the redirect URL (add lb vserver <NameOfVserver> HTTP <NSIP/ VIP IP> <NonStandardPort> -redirectURL "https://FQDN")

```
add lb vserver <NameOfVserver> HTTP <NSIP/ VIP IP> <NonStandardPort> -redirectURL
```

[# 547226]

- The configuration utility's Welcome page prompts you to enter a SNIP address, but you do not have to configure a SNIP for NetScaler VPX on Azure. You can skip this step.

[# 559971]

Load Balancing

- Azure's DNS server is marked DOWN when added as a UDP server. The problem does not occur if you specify TCP when adding the DNS server.

[# 544030]

System

- Launching an application through CVPN mode with Receiver for HTML5 fails or takes a long time during some launches, and an attempt to launch through ICA proxy mode from an Internet Explorer browser fails.

[# 559212]

- The /var/core directory might not be available for core dumps in some circumstances.

[# 554865]

- When you create an LDAP action on the LDAP policy page, the GUI does not immediately include the action's name in the drop-down list.

[# 540563]

- A VPN client does not receive a clean-up prompt when logging off.

[# 541859]

- This release does not support Web Interface on NetScaler (WIonNS).

[# 544257]

- High availability session propagation is not supported in Azure. The NetScaler HA nodes can't maintain sessions across failover, because Azure disallows promiscuous mode. A NetScaler node can send or receive packets at only the original assigned IP address.

[# 542196]

- In full VPN mode, user logon through a Chrome browser generates an error page after the logon process, before app enumeration.

[# 539815]

- The VIP address added when a virtual server is created is not removed when the virtual server is removed. The address continues to appear in the "show ip" command output. The same issue occurs with the "clear config extended" command.

[# 539598]

- The /var/core directory might not be available for core dumps in some circumstances.

[# 523943]

- The showtechsupport command reports permission errors while collecting debug information. The error messages can be ignored.

[# 524176]

- The MAC address of a VPX interface might change when a VPX instance in Azure Cloud is shut down and then restarted. Be sure to use the license utilities to obtain a Host ID when generating a license for VPX in Azure, rather than directly using the MAC address.

[# 527117]

- In rare circumstances, a VPX instance can dump packet engine core after a warm restart.

[# 559529]

- In rare circumstances, the VPX instance can dump kernel core after a warm restart.

[# 559176]

Tools

- The Azure Portal reports a VPX instance remaining in the "installing extensions" stage if you leave the VM Extensions checkbox selected. The VPX instance is not affected. You can clear the VM extensions checkbox during provisioning.

[# 559525]

Changes and Fixes

The following bugs have been fixed in NetScaler VPX on Azure release 10.5

Bug ID	Description
BUG0558656	When you open a content switching policy in the configuration utility (Traffic Management > Content Switching > Policies), an editing window appears unexpectedly.
BUG0558893	The configuration utility does not display a No Policy button in the binding section of policy label configuration at System > AppFlow > Policy Labels.
BUG0539743	In a double hop deployment, STA server status on hop 1 does not go down when double hop is disabled in hop2, and the user still launches ICA apps.
BUG0542245	If you enable and then disable the double hop option, a SOCKS mode ICA application fails to launch.
ENH0529959	The Waagent folder, in /var and /var/log, is not collected in the showtechsupport bundle.

Configuring the Basic System Settings

Aug 23, 2013

After installing a Citrix NetScaler virtual appliance, you need to access it to configure the basic settings. Initially, you must access the NetScaler command line through the respective management application of the virtualization host (either Citrix XenCenter for Citrix XenServer or VMware vSphere client for VMware ESX) to specify a NetScaler IP (NSIP) address, subnet mask, and default gateway. The NSIP is the management address at which you can then access the NetScaler command line, through an SSH client, or access the configuration utility. You can use either of these access methods, or the console, to continue with basic configuration.

To access the configuration utility, type the NSIP into the address field of any browser (for example, `http://<NSIP_address>`). You need Java RunTime Environment (JRE) version 1.6 or later.

Setting Up the Initial Configuration by Using the NetScaler Virtual Appliance Console

Updated: 2013-08-23

Your first task after installing a NetScaler virtual appliance on a virtualization host is to use the NetScaler virtual appliance console in the XenCenter client or vSphere client to configure the following initial settings.

Note: If you have installed a virtual appliance on XenServer by using Command Center, you do not have to configure these settings. Command Center implicitly configures the settings during installation. For more information about provisioning virtual appliance from Command Center, see the " Command Center" documentation.

NetScaler IP address (NSIP):

The IP address at which you access a NetScaler or a NetScaler virtual appliance for management purposes. A physical NetScaler or virtual appliance can have only one NSIP. You must specify this IP address when you configure the virtual appliance for the first time. You cannot remove an NSIP address.

Netmask:

The subnet mask associated with the NSIP address.

Default Gateway:

You must add a default gateway on the virtual appliance if you want access it through SSH or the configuration utility from an administrative workstation or laptop that is on a different network.

To configure the initial settings on the virtual appliance through the virtual appliance Console by using the management application

1. Connect to the XenServer or VMware ESX server on which the virtual appliance is installed by using XenCenter or vSphere client, respectively.
2. In the details pane, on the Console tab, log on to the virtual appliance by using the administrator credentials.
3. At the prompts, enter the NSIP address, subnet mask, and default gateway, and then save the configuration.

After you have set up an initial configuration through the NetScaler virtual appliance Console in the management application, you can use either the NetScaler command-line interface or the configuration utility to complete the configuration or to change the initial settings.

Configuring NetScaler Virtual Appliance by Using the Command Line Interface

Updated: 2013-08-23

You can use the command line interface to set up the NSIP, Mapped IP (MIP), Subnet IP (SNIP), and hostname. You can also configure advanced network settings and change the time zone.

To complete initial configuration by using the command line interface

1. Use either the SSH client or the NetScaler virtual appliance Console in XenCenter to access the command line interface.
2. Log on to the virtual appliance, using the administrator credentials.
3. At the command prompt, type `config ns` to run the configuration script.
4. To complete the initial configuration, follow the prompts.

You have now completed the basic configuration of the virtual appliance. To continue the configuration process, choose one of the following options:

Citrix NetScaler Load Balancing Switch

If you are configuring the virtual appliance as a standard NetScaler load balancing switch with other licensed features, see "[Traffic Management](#)."

Citrix NetScaler Application Firewall

If you are configuring the virtual appliance as a standalone application firewall, see "[Application Firewall](#)."

For more information about the various features supported on the NetScaler virtual appliance, see [Features at a Glance](#).

Configuring NetScaler Virtual Appliance by Using the Configuration Utility

Updated: 2013-08-23

To use the Setup Wizard to set up the NetScaler virtual appliance, you must access the configuration utility from your Web browser. You can use the Setup Wizard to configure the NSIP, MIP, SNIP, hostname, and default gateway. You can also configure settings for a Web application by using an application template. You can also configure the appliance as a load balancer for Citrix XenDesktop or Citrix XenApp.

For information about application templates, see "[AppExpert](#)."

For information about the load balancing feature of a virtual appliance, see "[Traffic Management](#)."

To configure initial settings by using the configuration utility

1. In the address field of a Web browser, type: `http://<NSIP address>`
2. In User Name and Password, type the administrator credentials.
3. In Deployment Type, select NetScaler ADC.
4. In Start in, select Configuration, and then click Login.
5. In the Setup Wizard, click Next and follow the instructions.

You have now completed the basic configuration of the virtual appliance. To continue the configuration process, choose one of the following options:

Citrix NetScaler Load Balancing Switch

If you are configuring the virtual appliance as a standard NetScaler load balancing switch with other licensed features, see "[Traffic Management](#)."

Citrix NetScaler Application Firewall

If you are configuring the virtual appliance as a standalone application firewall, see "[Application Firewall](#)."

For more information about the various features supported on the NetScaler virtual appliance, see [Features at a Glance](#).

Understanding Common Network Topologies

Sep 04, 2013

As described in "[Physical Deployment Modes](#)," you can deploy the Citrix NetScaler appliance either inline between the clients and servers or in one-arm mode. Inline mode uses a two-arm topology, which is the most common type of deployment.

This document includes the following:

- [Setting Up Common Two-Arm Topologies](#)
- [Setting Up Common One-Arm Topologies](#)

Setting Up Common Two-Arm Topologies

Updated: 2013-06-24

In a two-arm topology, one network interface is connected to the client network and another network interface is connected to the server network, ensuring that all traffic flows through the appliance. This topology might require you to reconnect your hardware and also might result in a momentary downtime. The basic variations of two-arm topology are multiple subnets, typically with the appliance on a public subnet and the servers on a private subnet, and transparent mode, with both the appliance and the servers on the public network.

Setting Up a Simple Two-Arm Multiple Subnet Topology

Updated: 2013-10-01

One of the most commonly used topologies has the NetScaler appliance inline between the clients and the servers, with a virtual server configured to handle the client requests. This configuration is used when the clients and servers reside on different subnets. In most cases, the clients and servers reside on public and private subnets, respectively.

For example, consider an appliance deployed in two-arm mode for managing servers S1, S2, and S3, with a virtual server of type HTTP configured on the appliance, and with HTTP services running on the servers. The servers are on a private subnet and a SNIP is configured on the appliance to communicate with the servers. The Use SNIP (USNIP) option must be enabled on the appliance so that it uses the SNIP instead of the MIP.

As shown in the following figure, the VIP is on public subnet 217.60.10.0, and the NSIP, the servers, and the SNIP are on private subnet 192.168.100.0/24.

Figure 1. Topology Diagram for Two-Arm Mode, Multiple Subnets

Task overview: To deploy a NetScaler appliance in two-arm mode with multiple subnets

1. Configure the NSIP and default gateway, as described in "[Configuring the NetScaler IP Address \(NSIP\)](#)."
2. Configure the SNIP, as described in "[Configuring Subnet IP Addresses](#)."
3. Enable the USNIP option, as described in "[To enable or disable USNIP mode](#)."
4. Configure the virtual server and the services, as described in "[Creating a Virtual Server](#)" and "[Configuring Services](#)."
5. Connect one of the network interfaces to a private subnet and the other interface to a public subnet.

Setting Up a Simple Two-Arm Transparent Topology

Updated: 2013-09-16

Use transparent mode if the clients need to access the servers directly, with no intervening virtual server. The server IP addresses must be public because the clients need to be able to access them. In the example shown in the following figure, a NetScaler appliance is placed between the client and the server, so the traffic must pass through the appliance. You must enable L2 mode for bridging the packets. The NSIP and MIP are on the same public subnet, 217.60.10.0/24.

Figure 2. Topology Diagram for Two-Arm, Transparent Mode

Task overview: To deploy a NetScaler in two-arm, transparent mode

1. Configure the NSIP, MIP, and default gateway, as described in "[Configuring a NetScaler by Using the Command Line Interface](#)."
2. Enable L2 mode, as described in "[Enabling and Disabling Layer 2 Mode](#)."
3. Configure the default gateway of the managed servers as the MIP.
4. Connect the network interfaces to the appropriate ports on the switch.

Setting Up Common One-Arm Topologies

The two basic variations of one-arm topology are with a single subnet and with multiple subnets.

Setting Up a Simple One-Arm Single Subnet Topology

Updated: 2013-08-23

You can use a one-arm topology with a single subnet when the clients and servers reside on the same subnet. For example, consider a NetScaler deployed in one-arm mode for managing servers S1, S2, and S3. A virtual server of type HTTP is configured on a NetScaler, and HTTP services are running on the servers. As shown in the following figure, the NetScaler IP address (NSIP), the Mapped IP address (MIP), and the server IP addresses are on the same public subnet, 217.60.10.0/24.

Figure 3. Topology Diagram for One-Arm Mode, Single Subnet

Task overview: To deploy a NetScaler in one-arm mode with a single subnet

1. Configure the NSIP, MIP, and the default gateway, as described in "[Configuring the NetScaler IP Address \(NSIP\)](#)".
2. Configure the virtual server and the services, as described in "[Creating a Virtual Server](#)" and "[Configuring Services](#)".
3. Connect one of the network interfaces to the switch.

Setting Up a Simple One-Arm Multiple Subnet Topology

Updated: 2013-08-23

You can use a one-arm topology with multiple subnets when the clients and servers reside on the different subnets. For example, consider a NetScaler appliance deployed in one-arm mode for managing servers S1, S2, and S3, with the servers connected to switch SW1 on the network. A virtual server of type HTTP is configured on the appliance, and HTTP services are running on the servers. These three servers are on the private subnet, so a subnet IP address (SNIP) is configured to communicate with them. The Use Subnet IP address (USNIP) option must be enabled so that the appliance uses the SNIP instead of a MIP. As shown in the following figure, the virtual IP address (VIP) is on public subnet 217.60.10.0/24; the NSIP, SNIP, and the server IP addresses are on private subnet 192.168.100.0/24.

Figure 4. Topology Diagram for One-Arm Mode, Multiple Subnets

Task overview: To deploy a NetScaler appliance in one-arm mode with multiple subnets

1. Configure the NSIP and the default gateway, as described in "[Configuring the NetScaler IP Address \(NSIP\)](#)".
2. Configure the SNIP and enable the USNIP option, as described in "[Configuring Subnet IP Addresses](#)".
3. Configure the virtual server and the services, as described in "[Creating a Virtual Server](#)" and "[Configuring Services](#)".
4. Connect one of the network interfaces to the switch.

Configuring System Management Settings

Sep 04, 2013

Once your initial configuration is in place, you can configure settings to define the behavior of the Citrix NetScaler appliance and facilitate connection management. You have a number of options for handling HTTP requests and responses. Routing, bridging, and MAC based forwarding modes are available for handling packets not addressed to the NetScaler. You can define the characteristics of your network interfaces and can aggregate the interfaces. To prevent timing problems, you can synchronize the NetScaler clock with a Network Time Protocol (NTP) server. The NetScaler can operate in various DNS modes, including as an authoritative domain name server (ADNS). You can set up SNMP for system management and customize syslog logging of system events. Before deployment, verify that your configuration is complete and correct.

This document includes the following:

- [Configuring System Settings](#)
- [Configuring Modes of Packet Forwarding](#)
- [Configuring Network Interfaces](#)
- [Configuring Clock Synchronization](#)
- [Configuring DNS](#)
- [Configuring SNMP](#)
- [Verifying the Configuration](#)

Note: In addition to the tasks listed above, you can configure Syslog logging. For instructions, see “[Audit Logging](#).”

Configuring System Settings

Sep 04, 2013

Configuration of system settings includes basic tasks such as configuring HTTP ports to enable connection keep-alive and server offload, setting the maximum number of connections for each server, and setting the maximum number of requests per connection. You can enable client IP address insertion for situations in which a proxy IP address is not suitable, and you can change the HTTP cookie version.

You can also configure a NetScaler appliance to open FTP connections on a controlled range of ports instead of ephemeral ports for data connections. This improves security, because opening all ports on the firewall is insecure. You can set the range anywhere from 1,024 to 64,000.

Before deployment, go through the verification checklists to verify your configuration. To configure HTTP parameters and the FTP port range, use the NetScaler configuration utility.

You can modify the types of HTTP parameters described in the following table.

Table 1. HTTP Parameters

Parameter Type	Specifies
HTTP Port Information	<p>The web server HTTP ports used by your managed servers. If you specify the ports, the appliance performs request switching for any client request that has a destination port matching a specified port.</p> <p>Note: If an incoming client request is not destined for a service or a virtual server that is specifically configured on the appliance, the destination port in the request must match one of the globally configured HTTP ports. This allows the appliance to perform connection keep-alive and server off-load.</p>
Limits	<p>The maximum number of connections to each managed server, and the maximum number of requests sent over each connection. For example, if you set Max Connections to 500, and the appliance is managing three servers, it can open a maximum of 500 connections to each of the three servers. By default, the appliance can create an unlimited number of connections to any of the servers it manages. To specify an unlimited number of requests per connection, set Max Requests to 0.</p> <p>Note: If you are using the Apache HTTP server, you must set Max Connections equal to the value of the MaxClients parameter in the Apache httpd.conf file. Setting this parameter is optional for other web servers.</p>
Client IP Insertion	<p>Enable/disable insertion of the client's IP address into the HTTP request header. You can specify a name for the header field in the adjacent text box. When a web server managed by an appliance receives a mapped IP address or a subnet IP address, the server identifies it as the client's IP address. Some applications need the client's IP address for logging purposes or to dynamically determine the content to be served by the web server.</p> <p>You can enable insertion of the actual client IP address into the HTTP header request sent from the client to one, some, or all servers managed by the appliance. You can then access the</p>

Parameter Type	Specifies inserted address through a minor modification to the server (using an Apache module, ISAPI interface, or NSAPI interface).
Cookie Version	The HTTP cookie version to use when COOKIEINSERT persistence is configured on a virtual server. The default, version 0, is the most common type on the Internet. Alternatively, you can specify version 1.
Requests/Responses	Options for handling certain types of requests, and enable/disable logging of HTTP error responses.
Server Header Insertion	Insert a server header in NetScaler-generated HTTP responses.

To configure HTTP parameters by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Settings, click Change HTTP parameters.
3. In the Configure HTTP parameters dialog box, specify values for some or all of the parameters that appear under the headings listed in the table above.
4. Click OK.

To set the FTP port range by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Settings, click Change global system settings.
3. Under FTP Port Range, in the Start Port and End Port text boxes, type the lowest and highest port numbers, respectively, for the range you want to specify (for example, 5000 and 6000).
4. Click OK.

Configuring Modes of Packet Forwarding

Jun 24, 2013

The NetScaler appliance can either route or bridge packets that are not destined for an IP address owned by the appliance (that is, the IP address is not the NSIP, a MIP, a SNIP, a configured service, or a configured virtual server). By default, L3 mode (routing) is enabled and L2 mode (bridging) is disabled, but you can change the configuration. The following flow chart shows how the appliance evaluates packets and either processes, routes, bridges, or drops them.

Figure 1. Interaction between Layer 2 and Layer 3 Modes

An appliance can use the following modes to forward the packets it receives:

- Layer 2 (L2) Mode
- Layer 3 (L3) Mode
- MAC-Based Forwarding Mode

Enabling and Disabling Layer 2 Mode

Updated: 2013-09-13

Layer 2 mode controls the Layer 2 forwarding (bridging) function. You can use this mode to configure a NetScaler appliance to behave as a Layer 2 device and bridge the packets that are not destined for it. When this mode is enabled, packets are not forwarded to any of the MAC addresses, because the packets can arrive on any interface of the appliance and each interface has its own MAC address.

With Layer 2 mode disabled (which is the default), the appliance drops packets that are not destined for one of its MAC address. If another Layer 2 device is installed in parallel with the appliance, Layer 2 mode must be disabled to prevent

bridging (Layer 2) loops. You can use the configuration utility or the command line to enable Layer 2 mode.

Note: The appliance does not support spanning tree protocol. To avoid loops, if you enable L2 mode, do not connect two interfaces on the appliance to the same broadcast domain.

To enable or disable Layer 2 mode by using the command line interface

At the command prompt, type the following commands to enable/disable Layer 2 mode and verify that it has been enabled/disabled:

- enable ns mode <Mode>
- disable ns mode <Mode>
- show ns mode

Examples

```
> enable ns mode l2
Done
> show ns mode
```

Mode	Acronym	Status
1) Fast Ramp	FR	ON
2) Layer 2 mode	L2	ON
.		
.		
.		

```
Done
>
```

```
> disable ns mode l2
Done
> show ns mode
```

Mode	Acronym	Status
1) Fast Ramp	FR	ON
2) Layer 2 mode	L2	OFF
.		
.		
.		

```
Done
>
```

To enable or disable Layer 2 mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In the Configure Modes dialog box, to enable Layer 2 mode, select the Layer 2 Mode check box. To disable Layer 2 mode, clear the check box.

4. Click OK. The Enable/Disable Mode(s)? message appears in the details pane.
5. Click Yes.

Enabling and Disabling Layer 3 Mode

Updated: 2013-09-13

Layer 3 mode controls the Layer 3 forwarding function. You can use this mode to configure a NetScaler appliance to look at its routing table and forward packets that are not destined for it. With Layer 3 mode enabled (which is the default), the appliance performs route table lookups and forwards all packets that are not destined for any appliance-owned IP address. If you disable Layer 3 mode, the appliance drops these packets.

To enable or disable Layer 3 mode by using the command line interface

At the command prompt, type the following commands to enable/disable Layer 3 mode and verify that it has been enabled/disabled:

- enable ns mode <Mode>
- disable ns mode <Mode>
- show ns mode

Examples

```
> enable ns mode l3
```

```
Done
```

```
> show ns mode
```

Mode	Acronym	Status
-----	-----	-----
1) Fast Ramp	FR	ON
2) Layer 2 mode	L2	OFF
.		
.		
.		
9) Layer 3 mode (ip forwarding)	L3	ON
.		
.		
.		

```
Done
```

```
>
```

```
> disable ns mode l3
```

```
Done
```

```
> show ns mode
```

Mode	Acronym	Status
-----	-----	-----
1) Fast Ramp	FR	ON
2) Layer 2 mode	L2	OFF

9) Layer 3 mode (ip forwarding) L3 OFF

Done

>

To enable or disable Layer 3 mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In the Configure Modes dialog box, to enable Layer 3 mode, select the Layer 3 Mode (IP Forwarding) check box. To disable Layer 3 mode, clear the check box.
4. Click OK. The Enable/Disable Mode(s)? message appears in the details pane.
5. Click Yes.

Enabling and Disabling MAC-Based Forwarding Mode

Updated: 2013-09-13

You can use MAC-based forwarding to process traffic more efficiently and avoid multiple-route or ARP lookups when forwarding packets, because the NetScaler appliance remembers the MAC address of the source. To avoid multiple lookups, the appliance caches the source MAC address of every connection for which it performs an ARP lookup, and it returns the data to the same MAC address.

MAC-based forwarding is useful when you use VPN devices because the appliance ensures that all traffic flowing through a particular VPN passes through the same VPN device.

The following figure shows the process of MAC-based forwarding.

Figure 2. MAC-Based Forwarding Process

When MAC-based forwarding is enabled, the appliance caches the MAC address of:

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server responds through an appliance, the appliance sets the destination MAC address of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when an appliance initiates a connection, it uses the route and ARP tables for the lookup function. To enable MAC-based forwarding, use the configuration utility or the command line.

Some deployments require the incoming and outgoing paths to flow through different routers. In these situations, MAC-based forwarding breaks the topology design. For a global server load balancing (GSLB) site that requires the incoming and outgoing paths to flow through different routers, you must disable MAC-based forwarding and use the appliance's default router as the outgoing router.

With MAC-based forwarding disabled and Layer 2 or Layer 3 connectivity enabled, a route table can specify separate routers for outgoing and incoming connections. To disable MAC-based forwarding, use the configuration utility or the command line.

To enable or disable MAC-based forwarding by using the command line interface

At the command prompt, type the following commands to enable/disable MAC-based forwarding mode and verify that it has been enabled/disabled:

- `enable ns mode <Mode>`
- `disable ns mode <Mode>`
- `show ns mode`

Example

```
> enable ns mode mbf
```

```
Done
```

```
> show ns mode
```

Mode	Acronym	Status
-----	-----	-----
1) Fast Ramp	FR	ON
2) Layer 2 mode	L2	OFF
.		
.		
.		
6) MAC-based forwarding	MBF	ON
.		
.		
.		

```
Done
```

```
>
```

```
> disable ns mode mbf
```

Done

> show ns mode

Mode	Acronym	Status
-----	-----	-----
1) Fast Ramp	FR	ON
2) Layer 2 mode	L2	OFF
.		
.		
.		
6) MAC-based forwarding	MBF	OFF
.		
.		
.		

Done

>

To enable or disable MAC-based forwarding by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features group, click Configure modes.
3. In the Configure Modes dialog box, to enable MAC-based forwarding mode, select the MAC Based Forwarding check box. To disable MAC-based forwarding mode, clear the check box.
4. Click OK. The Enable/Disable Mode(s)? message appears in the details pane.
5. Click Yes.

Configuring Network Interfaces

Aug 23, 2013

NetScaler interfaces are numbered in slot/port notation. In addition to modifying the characteristics of individual interfaces, you can configure virtual LANs to restrict traffic to specific groups of hosts. You can also aggregate links into high-speed channels.

Virtual LANs

The NetScaler supports (Layer 2) port and IEEE802.1Q tagged virtual LANs (VLANs). VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface to belong to multiple VLANs by using IEEE 802.1q tagging.

You can bind your configured VLANs to IP subnets. The NetScaler (if it is configured as the default router for the hosts on the subnets) then performs IP forwarding between these VLANs. A NetScaler supports the following types of VLANs.

Default VLAN

By default, the network interfaces on a NetScaler are included in a single, port-based VLAN as untagged network interfaces. This default VLAN has a VID of 1 and exists permanently. It cannot be deleted, and its VID cannot be changed.

Port-Based VLANs

A set of network interfaces that share a common, exclusive, Layer 2 broadcast domain define the membership of a port-based VLAN. You can configure multiple port-based VLANs. When you add an interface to a new VLAN as an untagged member, it is automatically removed from the default VLAN.

Tagged VLAN

A network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of only one VLAN (its native VLAN). The untagged network interface forwards the frames for the native VLAN as untagged frames. A tagged network interface can be a part of more than one VLAN. When you configure tagging, be sure that both ends of the link have matching VLAN settings. You can use the configuration utility to define a tagged VLAN (nsvlan) that can have any ports bound as tagged members of the VLAN. Configuring this VLAN requires a reboot of the NetScaler and therefore must be done during initial network configuration.

Link Aggregate Channels

Link aggregation combines incoming data from multiple ports into a single high speed link. Configuring the link aggregate channel increases the capacity and availability of the communication channel between a NetScaler and other connected devices. An aggregated link is also referred to as a channel.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. A network interface can be bound to only one channel. Binding a network interface to a link aggregate channel changes the VLAN configuration. That is, binding network interfaces to a channel removes them from the VLANs that they originally belonged to and adds them to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you have bound network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then you bind them to link aggregate channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them to VLAN 2.

Note: You can also use Link Aggregation Control Protocol (LACP) to configure link aggregation. For more information, see ""Configuring Link Aggregation by Using the Link Aggregation Control Protocol."

Configuring Clock Synchronization

Aug 23, 2013

You can configure your NetScaler appliance to synchronize its local clock with a Network Time Protocol (NTP) server. This ensures that its clock has the same date and time settings as the other servers on your network. NTP uses User Datagram Protocol (UDP) port 123 as its transport layer. You have to add NTP servers in the NTP configuration file so that the appliance periodically gets updates from these servers.

If you do not have a local NTP server, you can find a list of public, open access, NTP servers at the official NTP site at <http://www.ntp.org>.

To configure clock synchronization on your appliance

1. Log on to the command line and enter the shell command.
2. At the shell prompt, copy the `ntp.conf` file from the `/etc` directory to the `/nsconfig` directory. If the file already exists in the `/nsconfig` directory, make sure that you remove the following entries from the `ntp.conf` file:

```
restrict localhost
```

```
restrict 127.0.0.2
```

These entries are required only if you want to run the device as a time server. However, this feature is not supported on the NetScaler.

3. Edit `/nsconfig/ntp.conf` by typing the IP address for the desired NTP server under the file's `server` and `restrict` entries.
4. Create a file named `rc.netscaler` in the `/nsconfig` directory, if the file does not already exist in the directory.
5. Edit `/nsconfig/rc.netscaler` by adding the following entry: `/usr/sbin/ntpd -c /nsconfig/ntp.conf -l /var/log/ntpd.log &`
This entry starts the `ntpd` service, checks the `ntp.conf` file, and logs messages in the `/var/log` directory.

Note: If the time difference between the NetScaler and the time server is more than 1000 sec, the `ntpd` service terminates with a message to the NetScaler log. To avoid this, you need to start `ntpd` with the `-g` option, which forcibly syncs the time. Add the following entry in `/nsconfig/rc.netscaler`:

```
/usr/sbin/ntpd -g -c /nsconfig/ntp.conf -l /var/log/ntpd.log &
```

If you do not want to forcibly sync the time when there is a large difference, you can set the date manually and then start `ntpd` again. You can check the time difference between the appliance and the time server by running the following command in the shell:

```
ntpdate -q <IP address or domain name of the NTP server>
```

6. Reboot the appliance to enable clock synchronization.

Note: If you want to start time synchronization before you restart the appliance, enter the following command (which you added to the `rc.netscaler` file in step 5) at the shell prompt:

```
/usr/sbin/ntpd -c /nsconfig/ntp.conf -l /var/log/ntpd.log &
```

Configuring DNS

Sep 04, 2013

You can configure a NetScaler appliance to function as an Authoritative Domain Name Server (ADNS), DNS proxy server, End Resolver, or Forwarder. You can add DNS resource records such as SRV Records, AAAA Records, A Records, MX Records, NS Records, CNAME Records, PTR Records, and SOA Records. Also, the appliance can balance the load on external DNS servers.

A common practice is to configure an appliance as a forwarder. For this configuration, you need to add external name servers. After you have added the external servers, you should verify that your configuration is correct.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

When adding name servers, you can specify IP addresses or virtual IP addresses (VIPs). If you use IP addresses, the appliance load balances requests to the configured name servers in a round robin manner. If you use VIPs, you can specify any load balancing method.

To add a name server by using the command line interface

At the command prompt, type the following commands to add a name server and verify the configuration:

- add dns nameServer <IP>
- show dns nameServer <IP>

Example

```
> add dns nameServer 10.102.29.10
Done
> show dns nameServer 10.102.29.10
1) 10.102.29.10 - State: DOWN
Done
>
```

To add a name server by using the configuration utility

1. Navigate to Traffic Management > DNS > Name Servers.
2. In the details pane, click Add.
3. In the Create Name Server dialog box, select IP Address.
4. In the IP Address text box, type the IP address of the name server (for example, 10.102.29.10). If you are adding an external name server, clear the Local check box.
5. Click Create, and then click Close.
6. Verify that the name server you added appears in the Name Servers pane.

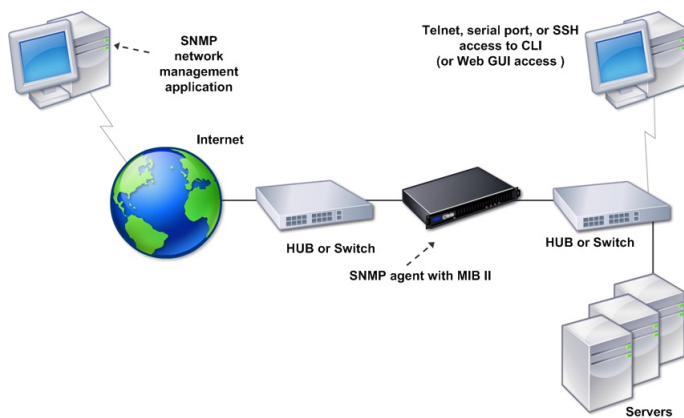

Configuring SNMP

May 14, 2012

The Simple Network Management Protocol (SNMP) network management application, running on an external computer, queries the SNMP agent on the NetScaler. The agent searches the management information base (MIB) for data requested by the network management application and sends the data to the application.

SNMP monitoring uses traps messages and alarms. SNMP traps messages are asynchronous events that the agent generates to signal abnormal conditions, which are indicated by alarms. For example, if you want to be informed when CPU utilization is above 90 percent, you can set up an alarm for that condition. The following figure shows a network with a NetScaler that has SNMP enabled and configured.

Figure 1. SNMP on the NetScaler

The SNMP agent on a NetScaler supports SNMP version 1 (SNMPv1), SNMP version 2 (SNMPv2), and SNMP version 3 (SNMPv3). Because it operates in bilingual mode, the agent can handle SNMPv2 queries, such as Get-Bulk, and SNMPv1 queries. The SNMP agent also sends traps compliant with SNMPv2 and supports SNMPv2 data types, such as counter64. SNMPv1 managers (programs on other servers that request SNMP information from the NetScaler) use the NS-MIB-smiv1.mib file when processing SNMP queries. SNMPv2 managers use the NS-MIB-smiv2.mib file.

The NetScaler supports the following enterprise-specific MIBs:

A subset of standard MIB-2 groups

Provides MIB-2 groups SYSTEM, IF, ICMP, UDP, and SNMP.

A system enterprise MIB

Provides system-specific configuration and statistics.

To configure SNMP, you specify which managers can query the SNMP agent, add SNMP trap listeners that will receive the SNMP trap messages, and configure SNMP Alarms.

Adding SNMP Managers

You can configure a workstation running a management application that complies with SNMP version 1, 2, or 3 to access an

appliance. Such a workstation is called an SNMP manager. If you do not specify an SNMP manager on the appliance, the appliance accepts and responds to SNMP queries from all IP addresses on the network. If you configure one or more SNMP managers, the appliance accepts and responds to SNMP queries from only those specific IP addresses. When specifying the IP address of an SNMP manager, you can use the netmask parameter to grant access from entire subnets. You can add a maximum of 100 SNMP managers or networks.

To add an SNMP manager by using the command line interface

At the command prompt, type the following commands to add an SNMP manager and verify the configuration:

- add snmp manager <IPAddress> ... [-netmask <netmask>]
- show snmp manager <IPAddress>

Example

```
> add snmp manager 10.102.29.5 -netmask 255.255.255.255
Done
> show snmp manager 10.102.29.5
1) 10.102.29.5    255.255.255.255
Done
>
```

To add an SNMP manager by using the configuration utility

1. In the navigation pane, expand System, expand SNMP, and then click Managers.
2. In the details pane, click Add.
3. In the Add SNMP Manager dialog box, in the IP Address text box, type the IP address of the workstation running the management application (for example, 10.102.29.5).
4. Click Create, and then click Close.
5. Verify that the SNMP manager you added appears in the Details section at the bottom of the pane.

Adding SNMP Traps Listeners

Updated: 2013-09-13

After configuring the alarms, you need to specify the trap listener to which the appliance will send the trap messages. Apart from specifying parameters like IP address and the destination port of the trap listener, you can specify the type of trap (either generic or specific) and the SNMP version.

You can configure a maximum of 20 trap listeners for receiving either generic or specific traps.

To add an SNMP trap listener by using the command line interface

At the command prompt, type the following command to add an SNMP trap and verify that it has been added:

- add snmp trap specific <IP>
- show snmp trap

Example

```
> add snmp trap specific 10.102.29.3
Done
```

```

> show snmp trap
Type   DestinationIP DestinationPort Version SourceIP   Min-Severity Community
-----
generic 10.102.29.9   162          V2    NetScaler IP N/A    public
generic 10.102.29.5   162          V2    NetScaler IP N/A    public
generic 10.102.120.101 162          V2    NetScaler IP N/A    public
.
.
.
specific 10.102.29.3   162          V2    NetScaler IP -    public
Done
>

```

To add an SNMP trap listener by using the configuration utility

1. In the navigation pane, expand System, expand SNMP, and then click Traps.
2. In the details pane, click Add.
3. In the Create SNMP Trap Destination dialog box, in the Destination IP Address text box, type the IP address (for example, 10.102.29.3).
4. Click Create and then click Close.
5. Verify that the SNMP trap you added appears in the Details section at the bottom of the pane.

Configuring SNMP Alarms

Updated: 2013-09-13

You configure alarms so that the appliance generates a trap message when an event corresponding to one of the alarms occurs. Configuring an alarm consists of enabling the alarm and setting the severity level at which a trap is generated. There are five severity levels: Critical, Major, Minor, Warning, and Informational. A trap is sent only when the severity of the alarm matches the severity specified for the trap.

Some alarms are enabled by default. If you disable an SNMP alarm, the appliance will not generate trap messages when corresponding events occur. For example, if you disable the Login-Failure SNMP alarm, the appliance will not generate a trap message when a login failure occurs.

To enable or disable an alarm by using the command line interface

At the command prompt, type the following commands to enable or disable an alarm and verify that it has been enabled or disabled:

- set snmp alarm <trapName> [-state ENABLED | DISABLED]
- show snmp alarm <trapName>

Example

```

> set snmp alarm LOGIN-FAILURE -state ENABLED
Done
> show snmp alarm LOGIN-FAILURE
Alarm      Alarm Threshold Normal Threshold Time State   Severity Logging
-----

```

```
1) LOGIN-FAILURE N/A      N/A      N/A  ENABLED -  ENABLED
Done
>
```

To set the severity of the alarm by using the command line interface

At the command prompt, type the following commands to set the severity of the alarm and verify that the severity has been set correctly:

- set snmp alarm <trapName> [-severity <severity>]
- show snmp alarm <trapName>

Example

```
> set snmp alarm LOGIN-FAILURE -severity Major
Done
> show snmp alarm LOGIN-FAILURE
Alarm      Alarm Threshold Normal Threshold Time State  Severity Logging
-----  -
1) LOGIN-FAILURE N/A      N/A      N/A  ENABLED Major  ENABLED
Done
>
```

To configure alarms by using the configuration utility

1. In the navigation pane, expand System, expand SNMP, and then click Alarms.
2. In the details pane, select an alarm (for example, LOGIN-FAILURE), and then click Open.
3. In the Configure SNMP Alarm dialog box, to enable the alarm, select Enabled in the State drop-down list. To disable the alarm, select Disabled.
4. In the Severity drop-down list, select a severity option (for example, Major).
5. Click OK, and then click Close.
6. Verify that the parameters for the SNMP alarm you configured are correctly configured by viewing the Details section at the bottom of the pane.

Verifying the Configuration

Nov 08, 2013

After you finish configuring your system, complete the following checklists to verify your configuration.

Configuration Checklist

- The build running is:
- There are no incompatibility issues. (Incompatibility issues are documented in the build's release notes.)
- The port settings (speed, duplex, flow control, monitoring) are the same as the switch's port.
- Enough mapped IP addresses have been configured to support all server-side connections during peak times.
 - The number of configured mapped IP addresses is: _____
 - The expected number of simultaneous server connections is:
[] 62,000 [] 124,000 [] Other_____

Topology Configuration Checklist

- The routes have been used to resolve servers on other subnets.

The routes entered are:

- If the NetScaler is in a public-private topology, reverse NAT has been configured.
- The failover (high availability) settings configured on the NetScaler resolve in a one arm or two-arm configuration. All unused network interfaces have been disabled:

- If the NetScaler is placed behind an external load balancer, then the load balancing policy on the external load balancer is not "least connection."

The load balancing policy configured on the external load balancer is:

- If the NetScaler is placed in front of a firewall, the session time-out on the firewall is set to a value greater than or equal to 300 seconds.

Note: The TCP idle connection timeout on a NetScaler appliance is 360 seconds. If the timeout on the firewall is also set to 300 seconds or more, then the appliance can perform TCP connection multiplexing effectively because connections will not be closed earlier.

The value configured for the session time-out is: _____

Server Configuration Checklist

- "Keep-alive" has been enabled on all the servers.
The value configured for the keep-alive time-out is: _____
- The default gateway has been set to the correct value. (The default gateway should either be a NetScaler or upstream router.) The default gateway is:

- The server port settings (speed, duplex, flow control, monitoring) are the same as the switch port settings.
-

- If the Microsoft® Internet Information Server is used, buffering is enabled on the server.
- If an Apache Server is used, the MaxConn (maximum number of connections) parameter is configured on the server and on the NetScaler.

The MaxConn (maximum number of connections) value that has been set is:

- If a Netscape® Enterprise Server™ is used, the maximum requests per connection parameter is set on the NetScaler. The maximum requests per connection value that has been set is:
-

Software Features Configuration Checklist

- Does the Layer 2 mode feature need to be disabled? (Disable if another Layer 2 device is working in parallel with a NetScaler.)

Reason for enabling or disabling:

- Does the MAC-based forwarding feature need to be disabled? (If the MAC address used by return traffic is different, it should be disabled.)

Reason for enabling or disabling:

- Does host-based reuse need to be disabled? (Is there virtual hosting on the servers?)

Reason for enabling or disabling:

- Do the default settings of the surge protection feature need to be changed?

Reason for changing or not changing:

Access Checklist

- The system IPs can be pinged from the client-side network.
- The system IPs can be pinged from the server-side network.
- The managed server(s) can be pinged through the NetScaler.
- Internet hosts can be pinged from the managed servers.
- The managed server(s) can be accessed through the browser.
- The Internet can be accessed from managed server(s) using the browser.
- The system can be accessed using SSH.
- Admin access to all managed server(s) is working.

Note: When you are using the ping utility, ensure that the pinged server has ICMP ECHO enabled, or your ping will not succeed.

Firewall Checklist

The following firewall requirements have been met:

- UDP 161 (SNMP)
- UDP 162 (SNMP trap)
- TCP/UDP 3010 (GUI)
- HTTP 80 (GUI)
- TCP 22 (SSH)

Load Balancing Traffic on a NetScaler Appliance

Jun 24, 2013

The load balancing feature distributes client requests across multiple servers to optimize resource utilization. In a real-world scenario with a limited number of servers providing service to a large number of clients, a server can become overloaded and degrade the performance of the server farm. A Citrix NetScaler appliance uses load balancing criteria to prevent bottlenecks by forwarding each client request to the server best suited to handle the request when it arrives.

To configure load balancing, you define a virtual server to proxy multiple servers in a server farm and balance the load among them.

When a client initiates a connection to the server, a virtual server terminates the client connection and initiates a new connection with the selected server, or reuses an existing connection with the server, to perform load balancing. The load balancing feature provides traffic management from Layer 4 (TCP and UDP) through Layer 7 (FTP, HTTP, and HTTPS).

The NetScaler appliance uses a number of algorithms, called load balancing methods, to determine how to distribute the load among the servers. The default load balancing method is the Least Connections method.

A typical load balancing deployment consists of the entities described in the following figure.

Figure 1. Load Balancing Architecture

The entities function as follows:

- **Virtual server.** An entity that is represented by an IP address, a port, and a protocol. The virtual server IP address (VIP) is usually a public IP address. The client sends connection requests to this IP address. The virtual server represents a bank of servers.
- **Service.** A logical representation of a server or an application running on a server. Identifies the server's IP address, a port, and a protocol. The services are bound to the virtual servers.
- **Server object.** An entity that is represented by an IP address. The server object is created when you create a service. The IP address of the service is taken as the name of the server object. You can also create a server object and then create

services by using the server object.

- **Monitor.** An entity that tracks the health of the services. The appliance periodically probes the servers using the monitor bound to each service. If a server does not respond within a specified response timeout, and the specified number of probes fails, the service is marked DOWN. The appliance then performs load balancing among the remaining services.

Configuring Load Balancing

Jun 24, 2013

To configure load balancing, you must first create services. Then, you create virtual servers and bind the services to the virtual servers. By default, the NetScaler appliance binds a monitor to each service. After binding the services, verify your configuration by making sure that all of the settings are correct.

Note: After you deploy the configuration, you can display statistics that show how the entities in the configuration are performing. Use the statistical utility or the `stat lb vserver <vserverName>` command.

Optionally, you can assign weights to a service. The load balancing method then uses the assigned weight to select a service. For getting started, however, you can limit optional tasks to configuring some basic persistence settings, for sessions that must maintain a connection to a particular server, and some basic configuration-protection settings.

The following flow chart illustrates the sequence of the configuration tasks.

Figure 1. Sequence of Tasks to Configure Load Balancing

Enabling Load Balancing

Before configuring load balancing, make sure that the load balancing feature is enabled.

To enable load balancing by using the command line interface

At the command prompt, type the following commands to enable load balancing and verify that it is enabled:

- enable feature lb
- show feature

Example

```
> enable feature lb
Done
> show feature
```

Feature	Acronym	Status
-----	-----	-----
1) Web Logging	WL	OFF
2) Surge Protection	SP	OFF
3) Load Balancing	LB	ON
.		
.		
.		
9) SSL Offloading	SSL	ON
.		
.		
.		

Done

To enable load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click OK.
4. In the Enable/Disable Feature(s)? message, click Yes.

Configuring Services and a Virtual Server

Updated: 2013-06-24

When you have identified the services you want to load balance, you can implement your initial load balancing configuration by creating the service objects, creating a load balancing virtual server, and binding the service objects to the virtual server.

To implement the initial load balancing configuration by using the command line interface

At the command prompt, type the following commands to implement and verify the initial configuration:

- add service <name> <IPaddress> <serviceType> <port>
- add lb vserver <vServerName> <serviceType> [<IPaddress> <port>]
- bind lb vserver <name> <serviceName>
- show service bindings <serviceName>

Example

```
> add service service-HTTP-1 10.102.29.5 HTTP 80
Done
> add lb vserver vserver-LB-1 HTTP 10.102.29.60 80
Done
> bind lb vserver vserver-LB-1 service-HTTP-1
Done
> show service bindings service-HTTP-1
  service-HTTP-1 (10.102.29.5:80) - State : DOWN

  1)  vserver-LB-1 (10.102.29.60:80) - State : DOWN
Done
```

To implement the initial load balancing configuration by using the configuration utility

1. Navigate to Traffic Management > Load Balancing.
2. In the details pane, under Getting Started, click Load Balancing wizard, and follow the instructions to create a basic load balancing setup.
3. Return to the navigation pane, expand Load Balancing, and then click Virtual Servers.
4. Select the virtual server that you configured and verify that the parameters displayed at the bottom of the page are correctly configured.
5. Click Open.
6. Verify that each service is bound to the virtual server by confirming that the Active check box is selected for each service on the Services tab.

Choosing and Configuring Persistence Settings

Sep 04, 2013

You must configure persistence on a virtual server if you want to maintain the states of connections on the servers represented by that virtual server (for example, connections used in e-commerce). The appliance then uses the configured load balancing method for the initial selection of a server, but forwards to that same server all subsequent requests from the same client.

If persistence is configured, it overrides the load balancing methods once the server has been selected. If the configured persistence applies to a service that is down, the appliance uses the load balancing methods to select a new service, and the new service becomes persistent for subsequent requests from the client. If the selected service is in an Out Of Service state, it continues to serve the outstanding requests but does not accept new requests or connections. After the shutdown period elapses, the existing connections are closed. The following table lists the types of persistence that you can configure.

Table 1. Limitations on Number of Simultaneous Persistent Connections

Persistence Type	Persistent Connections
Source IP, SSL Session ID, Rule, DESTIP, SRCIPDESTIP	250K
CookieInsert, URL passive, Custom Server ID	Memory limit. In case of CookieInsert, if time out is not 0, any number of connections is allowed until limited by memory.

If the configured persistence cannot be maintained because of a lack of resources on an appliance, the load balancing methods are used for server selection. Persistence is maintained for a configured period of time, depending on the persistence type. Some persistence types are specific to certain virtual servers. The following table shows the relationship.

Table 2. Persistence Types Available for Each Type of Virtual Server

Persistence TypeHeader 1	HTTP	HTTPS	TCP	UDP/IP	SSL_Bridge
Source IP	YES	YES	YES	YES	YES
CookieInsert	YES	YES	NO	NO	NO
SSL Session ID	NO	YES	NO	NO	YES
URL Passive	YES	YES	NO	NO	NO
Custom Server ID	YES	YES	NO	NO	NO
Rule	YES	YES	NO	NO	NO

SRV_ID	DEST_IP	Persistence Type	Header 1	HTTP	HTTPS	YES	YES	UDP/IP	N/A	SSL_Bridge
	DEST_IP			N/A	N/A	YES	YES	YES		N/A

You can also specify persistence for a group of virtual servers. When you enable persistence on the group, the client requests are directed to the same selected server regardless of which virtual server in the group receives the client request. When the configured time for persistence elapses, any virtual server in the group can be selected for incoming client requests.

Two commonly used persistence types are persistence based on cookies and persistence based on server IDs in URLs.

Configuring Persistence Based on Cookies

Updated: 2013-08-23

When you enable persistence based on cookies, the NetScaler adds an HTTP cookie into the Set-Cookie header field of the HTTP response. The cookie contains information about the service to which the HTTP requests must be sent. The client stores the cookie and includes it in all subsequent requests, and the NetScaler uses it to select the service for those requests. You can use this type of persistence on virtual servers of type HTTP or HTTPS.

The NetScaler inserts the cookie `<NSC_XXXX>= <ServiceIP> <ServicePort>`

where:

- `<NSC_XXXX>` is the virtual server ID that is derived from the virtual server name.
- `<ServiceIP>` is the hexadecimal value of the IP address of the service.
- `<ServicePort>` is the hexadecimal value of the port of the service.

The NetScaler encrypts ServiceIP and ServicePort when it inserts a cookie, and decrypts them when it receives a cookie.

Note: If the client is not allowed to store the HTTP cookie, the subsequent requests do not have the HTTP cookie, and persistence is not honored.

By default, the NetScaler sends HTTP cookie version 0, in compliance with the Netscape specification. It can also send version 1, in compliance with RFC 2109.

You can configure a timeout value for persistence that is based on HTTP cookies. Note the following:

- If HTTP cookie version 0 is used, the NetScaler inserts the absolute Coordinated Universal Time (GMT) of the cookie's expiration (the expires attribute of the HTTP cookie), calculated as the sum of the current GMT time on a NetScaler, and the timeout value.
- If an HTTP cookie version 1 is used, the NetScaler inserts a relative expiration time (Max-Age attribute of the HTTP cookie). In this case, the client software calculates the actual expiration time.

Note: Most client software currently installed (Microsoft Internet Explorer and Netscape browsers) understand HTTP cookie version 0; however, some HTTP proxies understand HTTP cookie version 1.

If you set the timeout value to 0, the NetScaler does not specify the expiration time, regardless of the HTTP cookie version used. The expiration time then depends on the client software, and such cookies are not valid if that software is shut down. This persistence type does not consume any system resources. Therefore, it can accommodate an unlimited number of persistent clients.

An administrator can use the procedure in the following table to change the HTTP cookie version.

To change the HTTP cookie version by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, click Change HTTP Parameters.
3. In the Configure HTTP Parameters dialog box, under Cookie, select Version 0 or Version 1.

Note: For information about the parameters, see "[Configuring Persistence Based on Cookies](#)."

To configure persistence based on cookies by using the command line interface

At the command prompt, type the following commands to configure persistence based on cookies and verify the configuration:

- set lb vserver <name> -persistenceType COOKIEINSERT
- show lb vserver <name>

Example

```
> set lb vserver vserver-LB-1 -persistenceType COOKIEINSERT
Done
> show lb vserver vserver-LB-1
vserver-LB-1 (10.102.29.60:80) - HTTP  Type: ADDRESS
.
.
.
Persistence: COOKIEINSERT (version 0) Persistence Timeout: 2 min
.
.
.
Done
>
```

To configure persistence based on cookies by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure persistence (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in the Persistence list, select COOKIEINSERT.
4. In the Time-out (min) text box, type the time-out value (for example, 2).
5. Click OK.
6. Verify that the virtual server for which you configured persistence is correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane.

Configuring Persistence Based on Server IDs in URLs

Updated: 2013-08-23

The NetScaler can maintain persistence based on the server IDs in the URLs. In a technique called URL passive persistence, the NetScaler extracts the server ID from the server response and embeds it in the URL query of the client request. The

server ID is an IP address and port specified as a hexadecimal number. The NetScaler extracts the server ID from subsequent client requests and uses it to select the server.

URL passive persistence requires configuring either a payload expression or a policy infrastructure expression specifying the location of the server ID in the client requests. For more information about expressions, see "[Policy Configuration and Reference](#)."

Note: If the server ID cannot be extracted from the client requests, server selection is based on the load balancing method.

Example: Payload Expression

The expression, URLQUERY contains sid= configures the system to extract the server ID from the URL query of a client request, after matching token sid=. Thus, a request with the URL `http://www.citrix.com/index.asp?&sid=c0a864100050` is directed to the server with the IP address `10.102.29.10` and port `80`.

The timeout value does not affect this type of persistence, which is maintained as long as the server ID can be extracted from the client requests. This persistence type does not consume any system resources, so it can accommodate an unlimited number of persistent clients.

Note: For information about the parameters, see "[Load Balancing](#)."

To configure persistence based on server IDs in URLs by using the command line interface

At the command prompt, type the following commands to configure persistence based on server IDs in URLs and verify the configuration:

- `set lb vserver <name> -persistenceType URLPASSIVE`
- `show lb vserver <name>`

Example

```
> set lb vserver vserver-LB-1 -persistenceType URLPASSIVE
Done
> show lb vserver vserver-LB-1
vserver-LB-1 (10.102.29.60:80) - HTTP  Type: ADDRESS
.
.
.
Persistence: URLPASSIVE Persistence Timeout: 2 min
.
.
.
Done
>
```

To configure persistence based on server IDs in URLs by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure persistence (for example, vserver-LB-1), and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in the Persistence list, select URLPASSIVE.
4. In the Time-out (min) text box, type the time-out value (for example, 2).
5. In the Rule text box, enter a valid expression. Alternatively, click Configure next to the Rule text box and use the Create Expression dialog box to create an expression.
6. Click OK.
7. Verify that the virtual server for which you configured persistence is correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane.

Configuring Features to Protect the Load Balancing Configuration

Jun 24, 2013

You can configure URL redirection to provide notifications of virtual server malfunctions, and you can configure backup virtual servers to take over if a primary virtual server becomes unavailable.

Configuring URL Redirection

Updated: 2013-06-24

You can configure a redirect URL to communicate the status of the appliance in the event that a virtual server of type HTTP or HTTPS is down or disabled. This URL can be a local or remote link. The appliance uses HTTP 302 redirect.

Redirects can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL), the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Note: If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. In this case, a redirect is used when both the primary and backup virtual servers are down.

To configure a virtual server to redirect client requests to a URL by using the command line interface

At the command prompt, type the following commands to configure a virtual server to redirect client requests to a URL and verify the configuration:

- `set lb vserver <name> -redirectURL <URL>`
- `show lb vserver <name>`

Example

```
> set lb vserver vserver-LB-1 -redirectURL http://www.newdomain.com/mysite/maintenance
```

```
Done
```

```
> show lb vserver vserver-LB-1
```

```
vserver-LB-1 (10.102.29.60:80) - HTTP Type: ADDRESS
```

```
State: DOWN
```

```
Last state change was at Wed Jun 17 08:56:34 2009 (+666 ms)
```

```
.
```

```
.
```

```
.
```

```
Redirect URL: http://www.newdomain.com/mysite/maintenance
```

```
.
```

```
.
```

```
.
```

```
Done
```

```
>
```

To configure a virtual server to redirect client requests to a URL by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure URL redirection (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in the Redirect URL text box, type the URL (for example, <http://www.newdomain.com/mysite/maintenance>), and then click OK.
4. Verify that the redirect URL you configured for the server appears in the Details section at the bottom of the pane.

Configuring Backup Virtual Servers

Updated: 2013-06-24

If the primary virtual server is down or disabled, the appliance can direct the connections or client requests to a backup virtual server that forwards the client traffic to the services. The appliance can also send a notification message to the client regarding the site outage or maintenance. The backup virtual server is a proxy and is transparent to the client.

You can configure a backup virtual server when you create a virtual server or when you change the optional parameters of an existing virtual server. You can also configure a backup virtual server for an existing backup virtual server, thus creating a cascaded backup virtual server. The maximum depth of cascading backup virtual servers is 10. The appliance searches for a backup virtual server that is up and accesses that virtual server to deliver the content.

You can configure URL redirection on the primary for use when the primary and the backup virtual servers are down or have reached their thresholds for handling requests.

Note: If no backup virtual server exists, an error message appears, unless the virtual server is configured with a redirect URL. If both a backup virtual server and a redirect URL are configured, the backup virtual server takes precedence.

To configure a backup virtual server by using the command line interface

At the command prompt, type the following commands to configure a backup server and verify the configuration:

- `set lb vserver <name> [-backupVserver <string>]`
- `show lb vserver <name>`

Example

```
> set lb vserver vserver-LB-1 -backupVserver vserver-LB-2
Done
> show lb vserver vserver-LB-1
vserver-LB-1 (10.102.29.60:80) - HTTP  Type: ADDRESS
State: DOWN
Last state change was at Wed Jun 17 08:56:34 2009 (+661 ms)
.
.
.
Backup: vserver-LB-2
.
.
```

Done

>

To set up a backup virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the backup virtual server (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in the Backup Virtual Server list, select the backup virtual server (for example, vserver-LB-2, and then click OK.
4. Verify that the backup virtual server you configured appears in the Details section at the bottom of the pane.
Note: If the primary server goes down and then comes back up, and you want the backup virtual server to function as the primary server until you explicitly reestablish the primary virtual server, select the Disable Primary When Down check box.

A Typical Load Balancing Scenario

Aug 23, 2013

In a load balancing setup, the NetScaler appliances are logically located between the client and the server farm, and they manage traffic flow to the servers.

The following figure shows the topology of a basic load balancing configuration.

Figure 1. Basic Load Balancing Topology

The virtual server selects the service and assigns it to serve client requests. Consider the scenario in the preceding figure, where the services service-HTTP-1 and service-HTTP-2 are created and bound to the virtual server named virtual server-LB-1. Virtual server-LB-1 forwards the client request to either service-HTTP-1 or service-HTTP-2. The system selects the service for each request by using the Least Connections load balancing method. The following table lists the names and values of the basic entities that must be configured on the system.

Table 1. LB Configuration Parameter Values

Entity Type	Required parameters and sample values			
	Name	IP Address	Port	Protocol
Virtual Server	vserver-LB-1	10.102.29.60	80	HTTP
Services	service-HTTP-1	10.102.29.5	8083	HTTP
	service-HTTP-2	10.102.29.6	80	HTTP
Monitors	Default	None	None	None

Entity Type	Required parameters and sample values			
The following figure shows the load balancing sample values and required parameters that are described in the preceding table.	Name	IP Address	Port	Protocol

Figure 2. Load Balancing Entity Model

The following tables list the commands used to configure this load balancing setup by using the command line interface.

Table 2. Initial Configuration Tasks

Task	Command
To enable load balancing	<code>enable feature lb</code>
To create a service named service-HTTP-1	<code>add service service-HTTP-1 10.102.29.5 HTTP 80</code>
To create a service named service-HTTP-2	<code>add service service-HTTP-2 10.102.29.6 HTTP 80</code>
To create a virtual server named vserver-LB-1	<code>add lb vserver vserver-LB-1 HTTP 10.102.29.60 80</code>
To bind a service named service-HTTP-1 to a virtual server named vserver-LB-1	<code>bind lb vserver vserver-LB-1 service-HTTP-1</code>
To bind a service named service-HTTP-2 to a virtual server named vserver-LB-1	<code>bind lb vserver vserver-LB-1 service-HTTP-2</code>

For more information about the initial configuration tasks, see "[Enabling Load Balancing](#)" and "[Configuring Services and a Vserver.](#)"

Table 3. Verification Tasks

Task	Command
To view the properties of a virtual server named vserver-LB-1	show lb vserver vserver-LB-1
To view the statistics of a virtual server named vserver-LB-1	stat lb vserver vserver-LB-1
To view the properties of a service named service-HTTP-1	show service service-HTTP-1
To view the statistics of a service named service-HTTP-1	stat service service-HTTP-1
To view the bindings of a service named service-HTTP-1	show service bindings service-HTTP-1

Table 4. Customization Tasks

Task	Command
To configure persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType SOURCEIP -persistenceMask 255.255.255.255 -timeout 2
To configure COOKIEINSERT persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType COOKIEINSERT
To configure URLPassive persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType URLPASSIVE
To configure a virtual server to redirect the client request to a URL on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -redirectURL http://www.newdomain.com/mysite/maintenance
To set a backup virtual server on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -backupVserver vserver-LB-2

For more information about configuring persistence, see "[Choosing and Configuring Persistence Settings](#)." For information about configuring a virtual server to redirect a client request to a URL and setting up a backup virtual server, see "[Configuring Features to Protect the Load Balancing Configuration](#)."

Accelerating Load Balanced Traffic by Using Compression

Aug 22, 2013

Compression is a popular means of optimizing bandwidth usage, and most web browsers support compressed data. If you enable the compression feature, the NetScaler appliance intercepts requests from clients and determines whether the client can accept compressed content. After receiving the HTTP response from the server, the appliance examines the content to determine whether it is compressible. If the content is compressible, the appliance compresses it, modifies the response header to indicate the type of compression performed, and forwards the compressed content to the client.

NetScaler compression is a policy-based feature. A policy filters requests and responses to identify responses to be compressed, and specifies the type of compression to apply to each response. The appliance provides several built-in policies to compress common MIME types such as text/html, text/plain, text/xml, text/css, text/rtf, application/msword, application/vnd.ms-excel, and application/vnd.ms-powerpoint. You can also create custom policies. The appliance does not compress compressed MIME types such as application/octet-stream, binary, bytes, and compressed image formats such as GIF and JPEG.

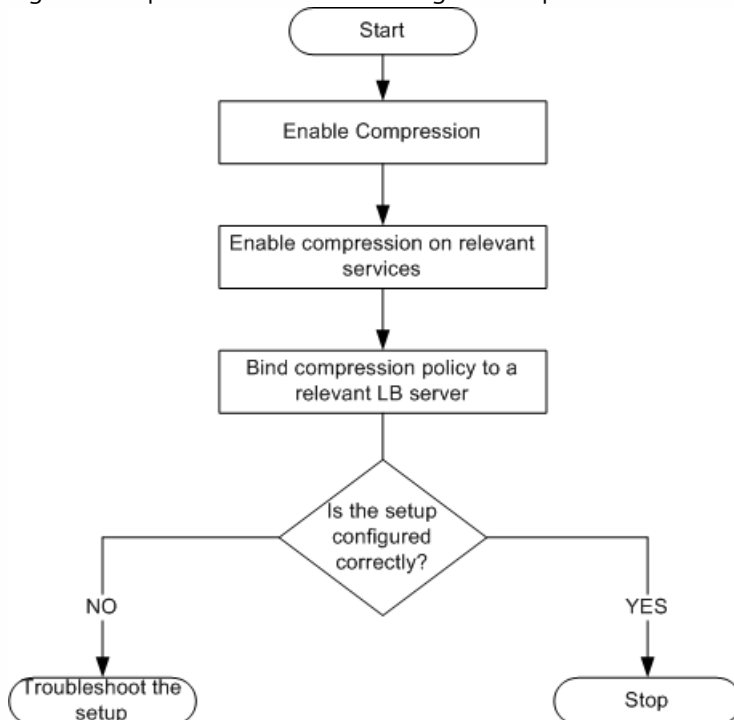

To configure compression, you must enable it globally and on each service that will provide responses that you want compressed. If you have configured virtual servers for load balancing or content switching, you should bind the policies to the virtual servers. Otherwise, the policies apply to all traffic that passes through the appliance.

Compression Configuration Task Sequence

Updated: 2013-08-22

The following flow chart shows the sequence of tasks for configuring basic compression in a load balancing setup.

Figure 1. Sequence of Tasks to Configure Compression

Note: The steps in the above figure assume that load balancing has already been configured.

Enabling Compression

By default, compression is not enabled. You must enable the compression feature to allow compression of HTTP responses that are sent to the client.

To enable compression by using the command line interface

At the command prompt, type the following commands to enable compression and verify the configuration:

- enable ns feature CMP
- show ns feature

Example

```
> enable ns feature CMP
Done
> show ns feature
```

	Feature	Acronym	Status
	-----	-----	-----
1)	Web Logging	WL	ON
2)	Surge Protection	SP	OFF
.			
7)	Compression Control	CMP	ON
8)	Priority Queuing	PQ	OFF
.			

```
Done
```

To enable compression by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Compression check box, and then click OK.
4. In the Enable/Disable Feature(s)? dialog box, click Yes.

Configuring Services to Compress Data

Updated: 2013-08-22

In addition to enabling compression globally, you must enable it on each service that will deliver files to be compressed.

To enable compression on a service by using the command line

At the command prompt, type the following commands to enable compression on a service and verify the configuration:

- set service <name> -CMP YES
- show service <name>

Example

```
> show service SVC_HTTP1
```

SVC_HTTP1 (10.102.29.18:80) - HTTP
State: UP
Last state change was at Tue Jun 16 06:19:14 2009 (+737 ms)
Time since last state change: 0 days, 03:03:37.200
Server Name: 10.102.29.18
Server ID : 0 Monitor Threshold : 0
Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive(CKA): NO
Access Down Service: NO
TCP Buffering(TCPB): NO
HTTP Compression(CMP): YES
Idle timeout: Client: 180 sec Server: 360 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: OFF
Down state flush: ENABLED

1) Monitor Name: tcp-default
State: DOWN Weight: 1
Probes: 1095 Failed [Total: 1095 Current: 1095]
Last response: Failure - TCP syn sent, reset received.
Response Time: N/A
Done

To enable compression on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure compression (for example, service-HTTP-1), and then click Open.
3. On the Advanced tab, under Settings, select the Compression check box, and then click OK.
4. Verify that, when the service is selected, HTTP Compression(CMP): ON appears in the **Details** section at the bottom of the pane.

Binding a Compression Policy to a Virtual Server

Updated: 2013-09-04

If you bind a policy to a virtual server, the policy is evaluated only by the services associated with that virtual server. You can bind compression policies to a virtual server either from the Configure Virtual Server (Load Balancing) dialog box or from the Compression Policy Manager dialog box. This topic includes instructions to bind compression policies to a load balancing virtual server by using the Configure Virtual Server (Load Balancing) dialog box. For information about how you can bind a compression policy to a load balancing virtual server by using the Compression Policy Manager dialog box, see "[Configuring and Binding Policies with the Policy Manager](#)."

To bind or unbind a compression policy to a virtual server by using the command line

At the command prompt, type the following commands to bind or unbind a compression policy to a load balancing virtual server and verify the configuration:

- (bind | unbind) lb vserver <name> -policyName <string>
- show lb vserver <name>

Example

```
> bind lb vserver lbvip -policyName ns_cmp_msapp
Done
> show lb vserver lbvip
lbvip (8.7.6.6:80) - HTTP    Type: ADDRESS
State: UP
Last state change was at Thu May 28 05:37:21 2009 (+685 ms)
Time since last state change: 19 days, 04:26:50.470
Effective State: UP
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Port Rewrite : DISABLED
No. of Bound Services : 1 (Total)    1 (Active)
Configured Method: LEASTCONNECTION
Current Method: Round Robin, Reason: Bound service's state changed to UP
Mode: IP
Persistence: NONE
Vserver IP and Port insertion: OFF
Push: DISABLED Push VServer:
Push Multi Clients: NO
Push Label Rule:

Bound Service Groups:
1)  Group Name: Service-Group-1

1) Service-Group-1 (10.102.29.252: 80) - HTTP State: UP Weight:          1

1) Policy : ns_cmp_msapp Priority:0
Done
```

To bind or unbind a compression policy to a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server to which you want to bind or unbind a compression policy (for example, Vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Policies tab, click Compression.
4. Do one of the following:

- To bind a compression policy, click Insert Policy, and then select the policy you want to bind to the virtual server.
- To unbind a compression policy, click the name of the policy you want to unbind from the virtual server, and then click Unbind Policy.

5. Click OK.

Securing Load Balanced Traffic by Using SSL

Jan 31, 2011

The Citrix NetScaler SSL offload feature transparently improves the performance of web sites that conduct SSL transactions. By offloading CPU-intensive SSL encryption and decryption tasks from the local web server to the appliance, SSL offloading ensures secure delivery of web applications without the performance penalty incurred when the server processes the SSL data. Once the SSL traffic is decrypted, it can be processed by all standard services. The SSL protocol works seamlessly with various types of HTTP and TCP data and provides a secure channel for transactions using such data.

To configure SSL, you must first enable it. Then, you configure HTTP or TCP services and an SSL virtual server on the appliance, and bind the services to the virtual server. You must also add a certificate-key pair and bind it to the SSL virtual server. If you use Outlook Web Access servers, you must create an action to enable SSL support and a policy to apply the action. An SSL virtual server intercepts incoming encrypted traffic and decrypts it by using a negotiated algorithm. The SSL virtual server then forwards the decrypted data to the other entities on the appliance for appropriate processing.

This document includes the following:

- [SSL Configuration Task Sequence](#)
- [Enabling SSL Offload](#)
- [Creating HTTP Services](#)
- [Adding an SSL-Based Virtual Server](#)
- [Binding Services to the SSL Virtual Server](#)
- [Adding a Certificate Key Pair](#)
- [Binding an SSL Certificate Key Pair to the Virtual Server](#)
- [Configuring Support for Outlook Web Access](#)

SSL Configuration Task Sequence

To configure SSL, you must first enable it. Then, you must create an SSL virtual server and HTTP or TCP services on the NetScaler. Finally, you must bind a valid SSL certificate and the configured services to the SSL virtual server.

An SSL virtual server intercepts incoming encrypted traffic and decrypts it using a negotiated algorithm. The SSL virtual server then forwards the decrypted data to the other entities on the NetScaler for appropriate processing.

The following flow chart shows the sequence of tasks for configuring a basic SSL offload setup.

Figure 1. Sequence of Tasks to Configure SSL Offloading

Enabling SSL Offload

You should enable the SSL feature before configuring SSL offload. You can configure SSL-based entities on the appliance without enabling the SSL feature, but they will not work until you enable SSL.

To enable SSL by using the command line interface

At the command prompt, type the following commands to enable SSL Offload and verify the configuration:

- enable ns feature SSL
- show ns feature

Example

```
> enable ns feature ssl
Done
> show ns feature
Feature Acronym Status
-----
1) Web Logging WL ON
2) SurgeProtection SP OFF
3) Load Balancing LB ON . . .
9) SSL Offloading SSL ON
10) Global Server Load Balancing GSLB ON . .
Done >
```

To enable SSL by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. Select the SSL Offloading check box, and then click OK.
4. In the Enable/Disable Feature(s)? message box, click Yes.

Creating HTTP Services

Updated: 2013-08-23

A service on the appliance represents an application on a server. Once configured, services are in the disabled state until the appliance can reach the server on the network and monitor its status. This topic covers the steps to create an HTTP service.

Note: For TCP traffic, perform the procedures in this and the following topics, but create TCP services instead of HTTP services.

To add an HTTP service by using the command line interface

At the command prompt, type the following commands to add a HTTP service and verify the configuration:

- add service <name> (<IP> | <serverName>) <serviceType> <port>
- show service <name>

```
> add service SVC_HTTP1 10.102.29.18 HTTP 80
Done
> show service SVC_HTTP1
SVC_HTTP1 (10.102.29.18:80) - HTTP
State: UP
Last state change was at Wed Jul 15 06:13:05 2009
Time since last state change: 0 days, 00:00:15.350
Server Name: 10.102.29.18
```

```
Server ID : 0 Monitor Threshold : 0
Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive(CKA): NO
Access Down Service: NO
TCP Buffering(TCPB): NO
HTTP Compression(CMP): YES
Idle timeout: Client: 180 sec Server: 360 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: OFF
Down state flush: ENABLED
```

```
1) Monitor Name: tcp-default
    State: UP Weight: 1
    Probes: 4 Failed [Total: 0 Current: 0]
    Last response: Success - TCP syn+ack received.
    Response Time: N/A
Done
```

To add an HTTP service by using the configuration utility

1. Navigate to Traffic Management > SSL Offload > Services.
2. In details pane, click Add.
3. In the Create Service dialog box, in the Service Name, Server, and Port text boxes, type the name of the service, IP address, and port (for example, SVC_HTTP1, 10.102.29.18, and 80).
4. In the Protocol list, select the type of the service (for example, HTTP).
5. Click Create, and then click Close. The HTTP service you configured appears in the Services page.
6. Verify that the parameters you configured are correctly configured by selecting the service and viewing the Details section at the bottom of the pane.

Adding an SSL-Based Virtual Server

In a basic SSL offloading setup, the SSL virtual server intercepts encrypted traffic, decrypts it, and sends the clear text messages to the services that are bound to the virtual server. Offloading CPU-intensive SSL processing to the appliance allows the back-end servers to process a greater number of requests.

To add an SSL-based virtual server by using the command line interface

At the command prompt, type the following commands to create an SSL-based virtual server and verify the configuration:

- add lb vserver <name> <serviceType> [<IPAddress> <port>]
- show lb vserver <name>

Example

```
> add lb vserver vserver-SSL-1 SSL 10.102.29.50 443
```

Done

```
> show lb vserver vserver-SSL-1
```

```
vserver-SSL-1 (10.102.29.50:443) - SSL Type: ADDRESS
```

```
State: DOWN[Certkey not bound] Last state change was at Tue Jun 16 06:33:08 2009 (+176 ms)
```

```
Time since last state change: 0 days, 00:03:44.120
```

```
Effective State: DOWN Client Idle Timeout: 180 sec
```

```
Down state flush: ENABLED
```

```
Disable Primary Vserver On Down : DISABLED
```

```
No. of Bound Services : 0 (Total) 0 (Active)
```

```
Configured Method: LEASTCONNECTION Mode: IP
```

```
Persistence: NONE
```

```
Vserver IP and Port insertion: OFF
```

```
Push: DISABLED Push VServer: Push Multi Clients: NO Push Label Rule: Done
```

Caution: To ensure secure connections, you must bind a valid SSL certificate to the SSL-based virtual server before you enable it.

To add an SSL-based virtual server by using the configuration utility

1. Navigate to Traffic Management > SSL Offload > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (SSL Offload) dialog box, in the Name, IP Address, and Port text boxes, type the name of the virtual server, IP address, and port (for example, Vserver-SSL-1, 10.102.29.50, and 443).
4. In the Protocol list, select the type of the virtual server, for example, SSL.
5. Click Create, and then click Close.
6. Verify that the parameters you configured are correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane. The virtual server is marked as DOWN because a certificate-key pair and services have not been bound to it.

Caution: To ensure secure connections, you must bind a valid SSL certificate to the SSL-based virtual server before you enable it.

Binding Services to the SSL Virtual Server

Updated: 2013-08-23

After decrypting the incoming data, the SSL virtual server forwards the data to the services that you have bound to the virtual server.

Data transfer between the appliance and the servers can be encrypted or in clear text. If the data transfer between the appliance and the servers is encrypted, the entire transaction is secure from end to end. For more information about configuring the system for end-to-end security, see "[SSL Offload and Acceleration](#)."

To bind a service to a virtual server by using the command line interface

At the command prompt, type the following commands to bind service to the SSL virtual server and verify the configuration:

- bind lb vserver <name> <serviceName>
- show lb vserver <name>

Example

```

> bind lb vserver vserver-SSL-1 SVC_HTTP1
Done
> show lb vserver vserver-SSL-1 vserver-SSL-1 (10.102.29.50:443) - SSL Type:
ADDRESS State: DOWN[Certkey not bound]
Last state change was at Tue Jun 16 06:33:08 2009 (+174 ms)
Time since last state change: 0 days, 00:31:53.70
Effective State: DOWN Client Idle
Timeout: 180 sec
Down state flush: ENABLED Disable Primary Vserver On Down :
DISABLED No. of Bound Services : 1 (Total) 0 (Active)
Configured Method: LEASTCONNECTION Mode: IP Persistence: NONE Vserver IP and
Port insertion: OFF Push: DISABLED Push VServer: Push Multi Clients: NO Push Label Rule:

1) SVC_HTTP1 (10.102.29.18: 80) - HTTP
State: DOWN Weight: 1
Done

```

To bind a service to a virtual server by using the configuration utility

1. Navigate to Traffic Management > SSL Offload > Virtual Servers.
2. In the details pane, select a virtual server, and then click Open.
3. On the Services tab, in the Active column, select the check boxes next to the services that you want to bind to the selected virtual server.
4. Click OK.
5. Verify that the Number of Bound Services counter in the Details section at the bottom of the pane is incremented by the number of services that you bound to the virtual server.

Adding a Certificate Key Pair

Updated: 2013-06-24

An SSL certificate is an integral element of the SSL Key-Exchange and encryption/decryption process. The certificate is used during SSL handshake to establish the identity of the SSL server. You can use a valid, existing SSL certificate that you have on the NetScaler appliance, or you can create your own SSL certificate. The appliance supports RSA/DSA certificates of up to 4096 bits.

Note: Citrix recommends that you use a valid SSL certificate that has been issued by a trusted certificate authority. Invalid certificates and self-created certificates are not compatible with all SSL clients.

Before a certificate can be used for SSL processing, you must pair it with its corresponding key. The certificate key pair is then bound to the virtual server and used for SSL processing.

To add a certificate key pair by using the command line interface

At the command prompt, type the following commands to create a certificate key pair and verify the configuration:

- add ssl certKey <certkeyName> -cert <string> [-key <string>]
- show sslcertkey <name>

Example

```
> add ssl certKey CertKey-SSL-1 -cert ns-root.cert -key ns-root.key
Done
> show sslcertkey CertKey-SSL-1
Name: CertKey-SSL-1 Status: Valid,
Days to expiration:4811 Version: 3
Serial Number: 00 Signature Algorithm: md5WithRSAEncryption Issuer: C=US,ST=California,L=San
Jose,O=Citrix ANG,OU=NS Internal,CN=de fault
Validity Not Before: Oct 6 06:52:07 2006 GMT Not After : Aug 17 21:26:47 2022 GMT
Subject: C=US,ST=California,L=San Jose,O=Citrix ANG,OU=NS Internal,CN=d efault Public Key
Algorithm: rsaEncryption Public Key
size: 1024
Done
```

To add a certificate key pair by using the configuration utility

1. Navigate to Traffic Management > SSL > Certificates.
2. In the details pane, click Add.
3. In the Install Certificate dialog box, in the Certificate-Key Pair Name text box, type a name for the certificate key pair you want to add, for example, Certkey-SSL-1.
4. Under Details, in Certificate File Name, click Browse (Appliance) to locate the certificate. Both the certificate and the key are stored in the /nsconfig/ssl/ folder on the appliance. To use a certificate present on the local system, select Local.
5. Select the certificate you want to use, and then click Select.
6. In Private Key File Name, click Browse (Appliance) to locate the private key file. To use a private key present on the local system, select Local.
7. Select the key you want to use and click Select. To encrypt the key used in the certificate key pair, type the password to be used for encryption in the Password text box.
8. Click Install.
9. Double-click the certificate key pair and, in the Certificate Details window, verify that the parameters have been configured correctly and saved.

Binding an SSL Certificate Key Pair to the Virtual Server

Updated: 2013-06-24

After you have paired an SSL certificate with its corresponding key, you must bind the certificate key pair to the SSL virtual server so that it can be used for SSL processing. Secure sessions require establishing a connection between the client computer and an SSL-based virtual server on the appliance. SSL processing is then carried out on the incoming traffic at the virtual server. Therefore, before enabling the SSL virtual server on the appliance, you need to bind a valid SSL certificate to the SSL virtual server.

To bind an SSL certificate key pair to a virtual server by using the command line interface

At the command prompt, type the following commands to bind an SSL certificate key pair to a virtual server and verify the configuration:

- bind ssl vserver <vServerName> -certkeyName <string>
- show ssl vserver <name>

Example

```
> bind ssl vserver Vserver-SSL-1 -certkeyName CertKey-SSL-1
Done
> show ssl vserver Vserver-SSL-1
```

Advanced SSL configuration for VServer Vserver-SSL-1:

DH: DISABLED

Ephemeral RSA: ENABLED Refresh Count: 0

Session Reuse: ENABLED Timeout: 120 seconds

Cipher Redirect: ENABLED

SSLv2 Redirect: ENABLED

ClearText Port: 0

Client Auth: DISABLED

SSL Redirect: DISABLED

Non FIPS Ciphers: DISABLED

SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: CertKey-SSL-1 Server Certificate

1) Cipher Name: DEFAULT

Description: Predefined Cipher Alias

Done

To bind an SSL certificate key pair to a virtual server by using the configuration utility

1. Navigate to Traffic Management > SSL Offload > Virtual Servers.
2. Select the virtual server to which you want to bind the certificate key pair, for example, Vserver-SSL-1, and click Open.
3. In the Configure Virtual Server (SSL Offload) dialog box, on the SSL Settings tab, under Available, select the certificate key pair that you want to bind to the virtual server (for example, Certkey-SSL-1), and then click Add.
4. Click OK.
5. Verify that the certificate key pair that you selected appears in the Configured area.

Configuring Support for Outlook Web Access

If you use Outlook Web Access (OWA) servers on your NetScaler appliance, you must configure the appliance to insert a special header field, FRONT-END-HTTPS: ON, in HTTP requests directed to the OWA servers, so that the servers generate URL links as https:// instead of http://.

Note: You can enable OWA support for HTTP-based SSL virtual servers and services only. You cannot apply it for TCP-based SSL virtual servers and services.

To configure OWA support, do the following:

- Create an SSL action to enable OWA support.
- Create an SSL policy.
- Bind the policy to the SSL virtual server.

Creating an SSL Action to Enable OWA Support

Updated: 2013-06-24

Before you can enable Outlook Web Access (OWA) support, you must create an SSL action. SSL actions are bound to SSL policies and triggered when incoming data matches the rule specified by the policy.

To create an SSL action to enable OWA support by using the command line interface

At the command prompt, type the following commands to create an SSL action to enable OWA support and verify the configuration:

- add ssl action <name> -OWASupport ENABLED
- show SSL action <name>
> add ssl action Action-SSL-OWA -OWASupport enabled
Done
> show SSL action Action-SSL-OWA
Name: Action-SSL-OWA
Data Insertion Action: OWA
Support: ENABLED
Done

To create an SSL action to enable OWA support by using the configuration utility

1. Navigate to Traffic Management > SSL > Policies.
2. In the details pane, on the Actions tab, click Add.
3. In the Create SSL Action dialog box, in the Name text box, type Action-SSL-OWA.
4. Under Outlook Web Access, select Enabled.
5. Click Create, and then click Close.
6. Verify that Action-SSL-OWA appears in the **SSL Actions** page.

Creating SSL Policies

Updated: 2013-09-04

SSL policies are created by using the policy infrastructure. Each SSL policy has an SSL action bound to it, and the action is carried out when incoming traffic matches the rule that has been configured in the policy.

To create an SSL policy by using the command line interface

At the command prompt, type the following commands to configure an SSL policy and verify the configuration:

- add ssl policy <name> -rule <expression> -reqAction <string>
- show ssl policy <name>

Example

```
> add ssl policy Policy-SSL-1 -rule ns_true -reqaction Action-SSL-OWA  
Done  
> show ssl policy Policy-SSL-1  
Name: Policy-SSL-1 Rule: ns_true
```

```
Action: Action-SSL-OWA Hits: 0
Policy is bound to following entities
1) PRIORITY : 0
Done
```

To create an SSL policy by using the configuration utility

1. Navigate to Traffic Management > SSL > Policies.
2. In the details pane, click Add.
3. In the Create SSL Policy dialog box, in the Name text box, type the name of the SSL Policy (for example, Policy-SSL-1).
4. In Request Action, select the configured SSL action that you want to associate with this policy (for example, Action-SSL-OWA). The `ns_true` general expression applies the policy to all successful SSL handshake traffic. However, if you need to filter specific responses, you can create policies with a higher level of detail. For more information about configuring granular policy expressions, see "[Understanding Policies and Expressions](#)."
5. In Named Expressions, choose the built-in general expression `ns_true` and click Add Expression. The expression `ns_true` now appears in the Expression text box.
6. Click Create, and then click Close.
7. Verify that the policy is correctly configured by selecting the policy and viewing the Details section at the bottom of the pane.

Binding the SSL Policy to an SSL Virtual Server

Updated: 2013-06-24

After you configure an SSL policy for Outlook Web Access, bind the policy to a virtual server that will intercept incoming Outlook traffic. If the incoming data matches any of the rules configured in the SSL policy, the policy is triggered and the action associated with it is carried out.

To bind an SSL policy to an SSL virtual server by using the command line interface

At the command prompt, type the following commands to bind an SSL policy to an SSL virtual server and verify the configuration:

- `bind ssl vserver <vServerName> -policyName <string>`
- `show ssl vserver <name>`

Example

```
> bind ssl vserver Vserver-SSL-1 -policyName Policy-SSL-1
Done
> show ssl vserver Vserver-SSL-1
Advanced SSL configuration for VServer Vserver-SSL-1:
DH: DISABLED
Ephemeral RSA: ENABLED      Refresh Count: 0
Session Reuse: ENABLED     Timeout: 120 seconds
Cipher Redirect: ENABLED
SSLv2 Redirect: ENABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
```

Non FIPS Ciphers: DISABLED

SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: CertKey-SSL-1 Server Certificate

1) Policy Name: Policy-SSL-1

Priority: 0

1) Cipher Name: DEFAULT

Description: Predefined Cipher Alias

Done

>

To bind an SSL policy to an SSL virtual server by using the configuration utility

1. Navigate to Traffic Management > SSL Offload > Virtual Servers.
2. In the details pane, select the virtual server (for example, Vserver-SSL-1), and then click Open.
3. In the Configure Virtual Server (SSL Offload) dialog box, click Insert Policy, and then select the policy that you want to bind to the SSL virtual server. Optionally, you can double-click the Priority field and type a new priority level.
4. Click OK.

Setting Up vPath on NetScaler VPX

Jul 05, 2016

After installing the NetScaler virtual appliance, you must set it up to communicate with the servers.

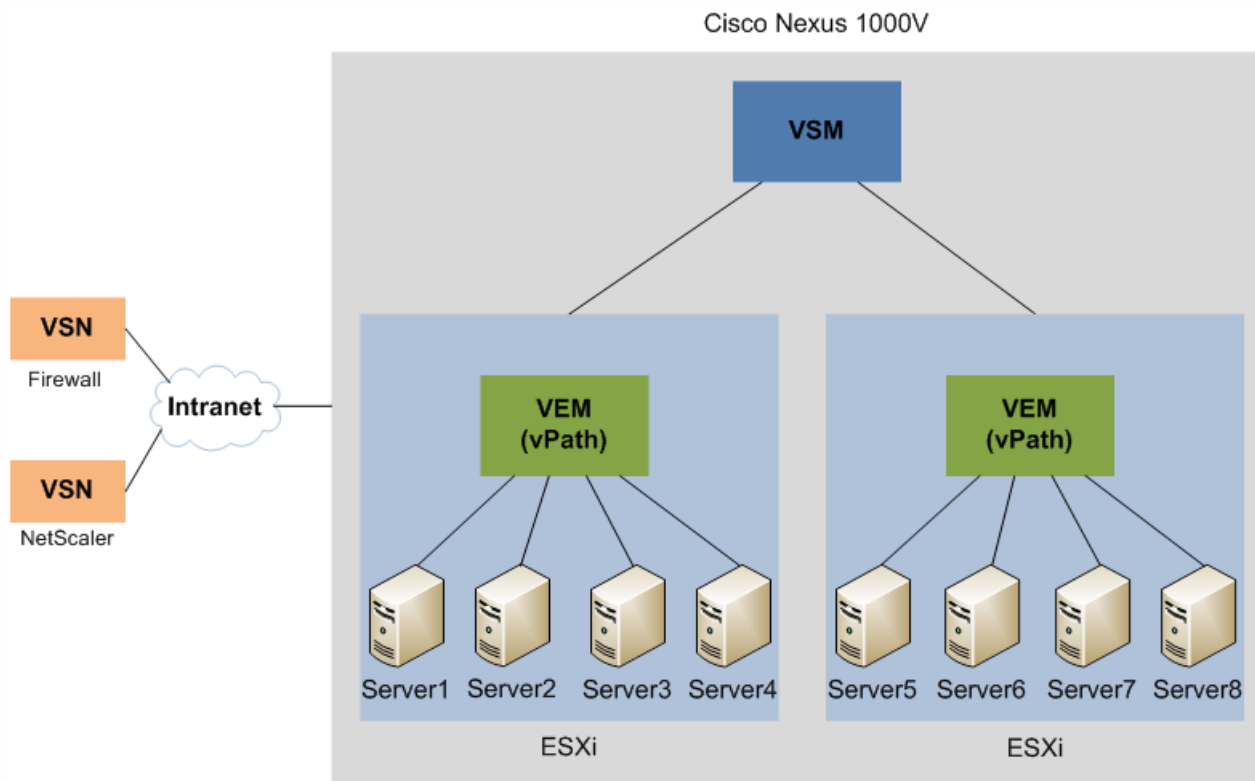

In a NetScaler deployment, the virtual appliance communicates with servers through the Virtual Ethernet Modules (VEMs). A VEM can only interpret packets that are encapsulated with vPath service intelligence. Therefore, you must set up the virtual appliance to apply vPath encapsulation to all packets that are being sent to the server.

Note

The vPath feature is no longer available in NetScaler version 11.1.

vPath uses overlay tunnels to steer traffic to a VSN (for example, a NetScaler virtual appliance), which can be either Layer 2 or Layer 3 adjacent. For detailed information on vPath, see "[Cisco vPath and vServices Reference Guide for VMware vSphere.](#)"

Figure 1. NetScaler 1000V with Nexus 1000V

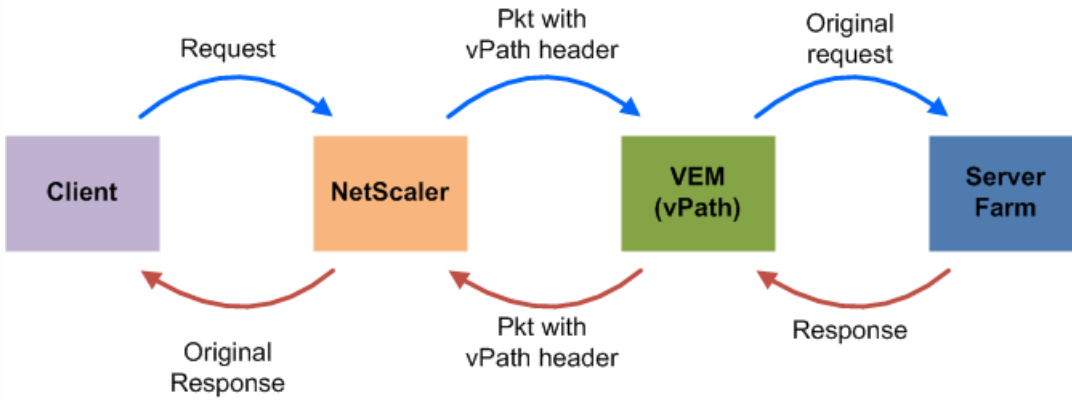

VSM – Virtual Supervisor Module, VEM – Virtual Ethernet Module, VSN – Virtual Service Node

How vPath Works

Oct 06, 2014

Figure 1. Packet Flow Using vPath

The above figure illustrates the flow of traffic using vPath:

1. Client sends request to the NetScaler virtual appliance.
2. The NetScaler virtual appliance encapsulates the client request with a vPath header and sends the updated packet to the server that is selected by the load balancing algorithm.
3. The VEM (in which the vPath module is embedded) intercepts and decapsulates the packet and forwards it to the server.
4. Server responds with the required information.
5. The VEM encapsulates the server response with a vPath header and forwards the packet to the NetScaler virtual appliance.
6. The NetScaler virtual appliance decapsulates the packet and sends the response to the client.

Step 1: Configuring vPath on a NetScaler

Oct 06, 2014

All data transmitted between the NetScaler virtual appliance and the server is vPath encapsulated. By default, vPath is disabled on the NetScaler virtual appliance. Therefore, to configure vPath on a NetScaler, you must first enable vPath, and then configure a SNIP address as the source of the vPath packet when the packet is forwarded to the switch.

If, in the return flow, the vPath packet is received at an IP address other than the specified SNIP address, the appliance drops the packet.

To configure vPath on a NetScaler by using the command line interface

At the command prompt, do the following:

1. Enable vPath on the NetScaler virtual appliance.
`enable ns feature vPath`
2. Specify the SNIP address to be used as the source IP address of the vPath packet. You can also specify whether the NetScaler must offload to the VEM, sessions for which the NetScaler has no matching configurations and hence not interested in.
`set vPathParam -srcIP <ip_addr> -offload <ENABLED | DISABLED>`

Note:

- When the offload parameter is enabled, the NetScaler adds an extra 24 bytes to the vPath header.
 - By default, the NetScaler IP (NSIP) address is configured as the vPath source IP address. However, the `show vPathParam` command shows the source IP address as 0.0.0.0.
3. If you have a server that is not configured as a service on the NetScaler, you must explicitly enable vPath encapsulation as follows:
`add vpath <name> (<destIP> [<netmask>] [<gateway>]) -encapMode L3`
 4. Save the configurations.
`save ns config`

To configure vPath on a NetScaler by using the graphical user interface

1. Navigate to Configuration > System > Settings.
2. In the details pane, under Modes and Features, click Configure advanced features and select the vPath checkbox.
3. Navigate to Configuration > System > Network.
4. In the details pane, under Settings, click Configure VPath Parameters and select the appropriate SNIP address as the source address.
5. To enable vPath encapsulation on a server that is not configured on the NetScaler, navigate to Configuration > System > Network > vPath.
6. In the details pane, click Add and provide the required details.

Step 2: Configuring Load Balancing of Backend Servers

Oct 06, 2014

When deployed in front of application servers, NetScaler ensures optimal distribution of traffic by the way in which it directs client requests. Administrators can segment application traffic according to information in the body of an HTTP or TCP request, and on the basis of L4-L7 header information such as URL, application data type, or cookie.

Numerous load balancing algorithms and extensive server health checks improve application availability by ensuring that client requests are directed to the appropriate servers.

To configure load balancing of servers, do the following:

1. Enable the load balancing feature and the use source IP (USIP) mode of the NetScaler.

Navigate to Configuration > System > Settings and under Modes and Features do the following:

1. Click Configure basic features and select the Load Balancing checkbox.
2. Click Configure modes and select the Use Source IP checkbox.

Note: With vPath integration, Source NAT is not required and server return traffic is redirected to NetScaler by vPath service attached to the server VM port. The original source IP is preserved for all connections.

2. Add the required servers as services on the NetScaler .

Navigate to Configuration > Traffic Management > Load Balancing > Services, click Add and configure the details (IP address, port, protocol) of each of the servers as services on the NetScaler .

Note: NetScaler is tightly integrated with the vPath architecture, and will not work without a vPath port-profile attached to the servers. Therefore, till the port profile configuration (provided in [step 3](#)) is done, the service state may appear as **Down**.

3. Create a virtual server that will bind these services to the virtual server IP address.

Navigate to Configuration > Traffic Management > Load Balancing > Virtual Servers, click Add and configure the name, virtual IP address (VIP), protocol, load balancing method, and the services to be bound to the virtual server.

4. Save the configurations. Click Save in the upper right hand corner of the interface.

Step 3: Binding Backend Servers to a Port Profile

Oct 06, 2014

After performing the vPath configurations on the NetScaler and then configuring the load balancing virtual server, you must define the NetScaler as a Virtual Service Node (VSN) and associate it with a port profile. The port profile, which is defined on the Virtual Supervisor Module (VSM), specifies that all traffic reaching the virtual port of the server must be redirected to the NetScaler virtual appliance. On the vCenter Server, you must then bind the port profile to the virtual port that is associated with the virtual machine.

Note: Every virtual NIC of a virtual machine has a corresponding virtual port on the Nexus virtual switch. Each virtual port must be associated with a port profile that specifies the properties of the device.

On the Nexus Virtual Supervisor Module (VSM), do the following

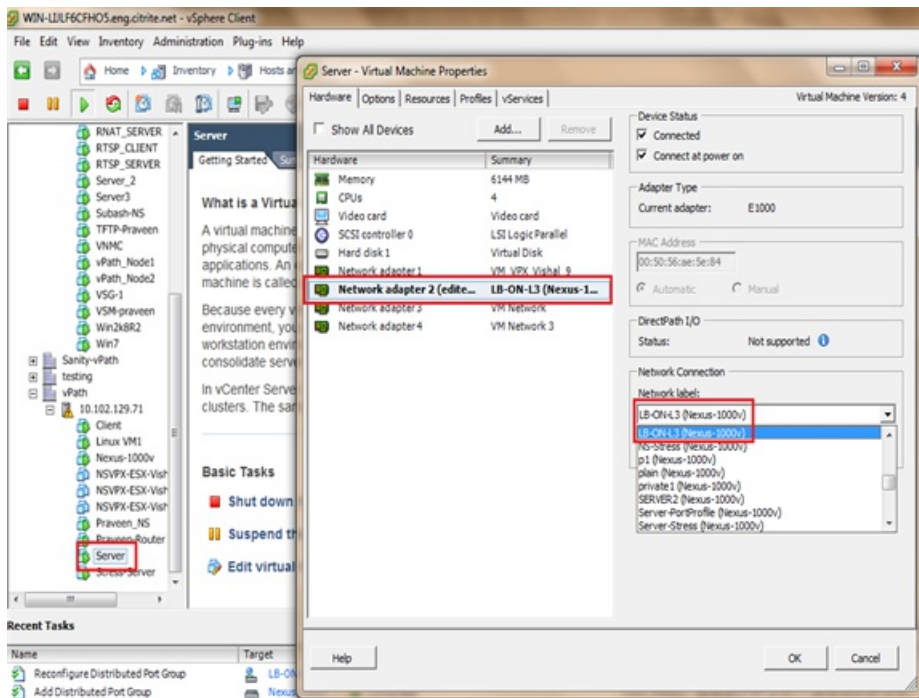

1. Configure the NetScaler virtual appliance as a VSN. **Example:** Create a VSN named "NS1" for a NetScaler with IP address 10.102.38.220.

```
# vservice node NS1 type adc
  ip address 10.102.38.220
  adjacency I3
  fail-mode open
```

2. Create a port profile for the NetScaler virtual appliance. **Example:** Create a port profile named "LB-ON-L3" to be used for the NetScaler services.

```
# port-profile type vethernet LB-ON-L3
  vmware port-group
  switchport mode access
  switchport access vlan 1
  vservice node NS1
  no shutdown
  system vlan 1
  state enabled
```

3. On the vCenter Server, bind the port profile to the virtual machine as shown in the following image:

Note: Repeat this step to bind the required servers to the port profile.

Behavioral Aspects of NetScaler with vPath

Oct 06, 2014

Some points to note in a NetScaler deployment with vPath configured:

- The maximum value for the Maximum Segment Size (MSS) of the default TCP profile (nstcp_default_profile) is 1380.
- The MSS used by services and virtual servers is determined as follows:
 - A service uses the MSS configured for the default TCP profile (nstcp_default_profile) regardless of the MSS of the TCP profile that is bound to the service.
 - A virtual server uses the MSS that is the lower of the MSS defined for the default TCP profile (nstcp_default_profile) and the TCP profile that is bound to the virtual server.
- Supports pre-fragmentation of vPath encapsulated packets. Even packets with Do not Fragment (DF) bit set are pre-fragmented.
- When encapsulating a full-size packet with vPath information, if the packet exceeds the MTU, then, if the icmpErrGenerate parameter is set to ENABLED, the NetScaler generates an ICMP (Type 3,code 4) fragment needed error message.

Features at a Glance

Sep 04, 2013

Citrix NetScaler features can be configured independently or in combinations to address specific needs. Although some features fit more than one category, the numerous NetScaler features can generally be categorized as application switching and traffic management features, application acceleration features, and application security and firewall features, and an application visibility feature.

To understand the order in which the features perform their processing, see "[Processing Order of Features.](#)"

This document includes the following:

- [Application Switching and Traffic Management Features](#)
- [Application Acceleration Features](#)
- [Application Security and Firewall Features](#)
- [Application Visibility Feature](#)
- [Cloud Integration Feature](#)

Application Switching and Traffic Management Features

Aug 30, 2016

SSL Offloading

Transparently offloads SSL encryption and decryption from web servers, freeing server resources to service content requests. SSL places a heavy burden on an application's performance and can render many optimization measures ineffective. SSL offload and acceleration allow all the benefits of Citrix Request Switching technology to be applied to SSL traffic, ensuring secure delivery of web applications without degrading end-user performance.

For more information, see "[SSL Offload and Acceleration](#)."

Access Control Lists

Compares incoming packets to Access Control Lists (ACLs). If a packet matches an ACL rule, the action specified in the rule is applied to the packet. Otherwise, the default action (ALLOW) is applied and the packet is processed normally. For the appliance to compare incoming packets to the ACLs, you have to apply the ACLs. All ACLs are enabled by default, but you have to apply them in order for the NetScaler to compare incoming packets against them. If an ACL is not required to be a part of the lookup table, but still needs to be retained in the configuration, it should be disabled before the ACLs are applied. A NetScaler does not compare incoming packets to disabled ACLs.

For more information, see "[Access Control List](#)."

Load Balancing

Load balancing decisions are based on a variety of algorithms, including round robin, least connections, weighted least bandwidth, weighted least packets, minimum response time, and hashing based on URL, domain source IP, or destination IP. Both the TCP and UDP protocols are supported, so the NetScaler can load balance all traffic that uses those protocols as the underlying carrier (for example, HTTP, HTTPS, UDP, DNS, NNTP, and general firewall traffic). In addition, the NetScaler can maintain session persistence based on source IP, cookie, server, group, or SSL session. It allows users to apply custom Extended Content Verification (ECV) to servers, caches, firewalls and other infrastructure devices to ensure that these systems are functioning properly and are providing the right content to users. It can also perform health checks using ping, TCP, or HTTP URL, and the user can create monitors based on Perl scripts. To provide high-scale WAN optimization, the CloudBridge appliances deployed at data centers can be load balanced through NetScaler appliances. The bandwidth and number of concurrent sessions can be improved significantly.

For more information, see "[Load Balancing](#)."

Traffic Domains

Traffic domains provide a way to create logical ADC partitions within a single NetScaler appliance. They enable you to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments whose resources do not interact with each other. An application belonging to a specific traffic domain communicates only with entities, and processes traffic, within that domain. Traffic belonging to one traffic domain cannot cross the boundary of another traffic domain. Therefore, you can use duplicate IP addresses on the appliance as long as an address is not duplicated within the same domain.

For more information, see "[Traffic Domains](#)."

Network Address Translation

Network address translation (NAT) involves modification of the source and/or destination IP addresses, and/or the TCP/UDP port numbers, of IP packets that pass through the NetScaler appliance. Enabling NAT on the appliance enhances

the security of your private network, and protects it from a public network such as the Internet, by modifying your network's source IP addresses when data passes through the NetScaler.

The NetScaler appliance supports the following types of network address translation:

INAT — In Inbound NAT (INAT), an IP address (usually public) configured on the NetScaler appliance listens to connection requests on behalf of a server. For a request packet received by the appliance on a public IP address, the NetScaler replaces the destination IP address with the private IP address of the server. In other words, the appliance acts as a proxy between clients and the server. INAT configuration involves INAT rules, which define a 1:1 relationship between the IP address on the NetScaler appliance and the IP address of the server.

RNAT — In Reverse Network Address Translation (RNAT), for a session initiated by a server, the NetScaler appliance replaces the source IP address in the packets generated by the server with an IP address (type SNIP) configured on the appliance. The appliance thereby prevents exposure of the server's IP address in any of the packets generated by the server. An RNAT configuration involves an RNAT rule, which specifies a condition. The appliance performs RNAT processing on those packets that match the condition.

Stateless NAT46 Translation—Stateless NAT46 enables communication between IPv4 and IPv6 networks, by way of IPv4 to IPv6 packet translation and vice versa, without maintaining any session information on the NetScaler appliance. A stateless NAT46 configuration involves an IPv4-IPv6 INAT rule and an NAT46 IPv6 prefix.

Stateful NAT64 Translation—The stateful NAT64 feature enables communication between IPv4 clients and IPv6 servers through IPv6 to IPv4 packet translation, and vice versa, while maintaining session information on the NetScaler appliance. A stateful NAT64 configuration involves an NAT64 rule and an NAT64 IPv6 prefix.

For more information, see "[Configuring Network Address Translation](#)."

Multipath TCP Support

NetScaler appliances support Multipath TCP (MPTCP). MPTCP is a TCP/IP protocol extension that identifies and uses multiple paths available between hosts to maintain the TCP session. You must enable MPTCP on a TCP profile and bind it to a virtual server. When MPTCP is enabled, the virtual server functions as an MPTCP gateway and converts MPTCP connections with the clients to TCP connections that it maintains with the servers.

For more information, see "[MPTCP \(Multi-Path TCP\)](#)."

Content Switching

Determines the server to which to send the request on the basis of configured content switching policies. Policy rules can be based on the IP address, URL, and HTTP headers. This allows switching decisions to be based on user and device characteristics such as who the user is, what type of agent is being used, and what content the user requested.

For more information, see "[Content Switching](#)."

Global Server Load Balancing (GSLB)

Extends the traffic management capabilities of a NetScaler to include distributed Internet sites and global enterprises. Whether installations are spread across multiple network locations or multiple clusters in a single location, the NetScaler maintains availability and distributes traffic across them. It makes intelligent DNS decisions to prevent users from being sent to a site that is down or overloaded. When the proximity-based GSLB method is enabled, the NetScaler can make load balancing decisions based on the proximity of the client's local DNS server (LDNS) in relation to different sites. The main benefit of the proximity-based GSLB method is faster response time resulting from the selection of the closest available site.

For more information, see "[Global Server Load Balancing](#)."

Dynamic Routing

Enables routers to obtain topology information, routes, and IP addresses from neighboring routers automatically. When dynamic routing is enabled, the corresponding routing process listens to route updates and advertises routes. The routing processes can also be placed in passive mode. Routing protocols enable an upstream router to load balance traffic to identical virtual servers hosted on two standalone NetScaler units using the Equal Cost Multipath technique.

For more information, see "[Configuring Dynamic Routes](#)."

Link Load Balancing

Load balances multiple WAN links and provides link failover, further optimizing network performance and ensuring business continuity. Ensures that network connections remain highly available, by applying intelligent traffic control and health checks to distribute traffic efficiently across upstream routers. Identifies the best WAN link to route both incoming and outbound traffic based on policies and network conditions, and protects applications against WAN or Internet link failure by providing rapid fault detection and failover.

For more information, see "[Link Load Balancing](#)."

TCP Optimization

You can use TCP profiles to optimize TCP traffic. TCP profiles define the way that NetScaler virtual servers process TCP traffic. Administrators can use the built-in TCP profiles or configure custom profiles. After defining a TCP profile, you can bind it to a single virtual server or to multiple virtual servers.

Some of the key optimization features that can be enabled by TCP profiles are:

- TCP keep-alive— Checks the operational status of the peers at specified time intervals to prevent the link from being broken.
- Selective Acknowledgment (SACK)— Improves the performance of data transmission, especially in long fat networks (LFNs).
- TCP window scaling— Allows efficient transfer of data over long fat networks (LFNs).

For more information on TCP Profiles, see "[Configuring TCP Profiles](#)."

Web Interface on NetScaler

Provides access to XenApp and XenDesktop resources, which include applications, content, and desktops. Users access resources through a standard Web browser or by using the Citrix XenApp plug-in. The Web Interface runs as a service on port 8080 on the NetScaler appliance. To create Web Interface sites, Java is executed on Apache Tomcat Web server version 6.0.26 on the NetScaler appliance.

Note: Web Interface is supported only on NetScaler nCore releases.

For more information, see "[Web Interface](#)."

CloudBridge Connector

The Citrix NetScaler CloudBridge Connector feature, a fundamental part of the Citrix OpenCloud framework, is a tool used to build a cloud-extended data center. The OpenCloud Bridge enables you to connect one or more NetScaler appliances or NetScaler virtual appliances on the cloud-to your network without reconfiguring your network. Cloud hosted applications appear as though they are running on one contiguous enterprise network. The primary purpose of the OpenCloud Bridge is to enable companies to move their applications to the cloud while reducing costs and the risk of application failure. In addition, the OpenCloud Bridge increases network security in cloud environments. An OpenCloud Bridge is a Layer-2 network bridge that connects a NetScaler appliance or NetScaler virtual appliance on a cloud instance to a NetScaler appliance or NetScaler virtual appliance on your LAN. The connection is made through a tunnel that uses the Generic Routing Encapsulation (GRE) protocol. The GRE protocol provides a mechanism for encapsulating packets from a wide variety of network protocols to be forwarded over another protocol. Then Internet Protocol security (IPsec) protocol suite is used to secure the communication between the peers in the OpenCloud Bridge.

For more information, see "[CloudBridge](#)."

DataStream

The NetScaler DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests on the basis of the SQL query being sent.

When deployed in front of database servers, a NetScaler ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and on the basis of database names, user names, character sets, and packet size.

You can configure load balancing to switch requests according to load balancing algorithms, or you can elaborate the switching criteria by configuring content switching to make a decision based on SQL query parameters, such as user name, database names, and command parameters. You can further configure monitors to track the states of database servers.

The advanced policy infrastructure on the NetScaler appliance includes expressions that you can use to evaluate and process the requests. The advanced expressions evaluate traffic associated with MySQL database servers. You can use request-based expressions (expressions that begin with `MYSQL.CLIENT` and `MYSQL.REQ`) in advanced policies to make request switching decisions at the content switching virtual server bind point and response-based expressions (expressions that begin with `MYSQL.RES`) to evaluate server responses to user-configured health monitors.

Note: DataStream is supported for MySQL and MS SQL databases.

For more information, see "[DataStream](#)."

Application Acceleration Features

Sep 06, 2013

AppCompress

Uses the gzip compression protocol to provide transparent compression for HTML and text files. The typical 4:1 compression ratio yields up to 50% reduction in bandwidth requirements out of the data center. It also results in significantly improved end-user response time, because it reduces the amount of data that must be delivered to the user's browser.

For more information, see "[Compression](#)."

Cache Redirection

Manages the flow of traffic to a reverse proxy, transparent proxy, or forward proxy cache farm. Inspects all requests, and identifies non-cacheable requests and sends them directly to the origin servers over persistent connections. By intelligently redirecting non-cacheable requests back to the origin web servers, the NetScaler appliance frees cache resources and increases cache hit rates while reducing overall bandwidth consumption and response delays for these requests.

For more information, see "[Cache Redirection](#)."

AppCache

Helps optimize web content and application data delivery by providing a fast in-memory HTTP/1.1 and HTTP/1.0 compliant web caching for both static and dynamic content. This on-board cache stores the results of incoming application requests even when an incoming request is secured or the data compressed, and then reuses the data to fulfill subsequent requests for the same information. By serving data directly from the on-board cache, the appliance can reduce page regeneration times by eliminating the need to funnel static and dynamic content requests to the server.

For more information, see "[Integrated Caching](#)."

TCP Buffering

Buffers the server's response and delivers it to the client at the client's speed, thus offloading the server faster and thereby improving the performance of web sites.

For more information, see "[TCP Buffering](#)."

Application Security and Firewall Features

Oct 30, 2013

Denial of Service Attack (DoS) Defense

Detects and stops malicious distributed denial-of-service (DDoS) attacks and other types of malicious attacks before they reach your servers, preventing them from affecting network and application performance. The NetScaler appliance identifies legitimate clients and elevates their priority, leaving suspect clients unable to consume a disproportionate percentage of resources and cripple your site. The appliance provides application-level protection from the following types of malicious attacks:

- SYN flood attacks
- Pipeline attacks
- Teardrop attacks
- Land attacks
- Fraggle attacks
- Zombie connection attacks

The appliance aggressively defends against these types of attacks by preventing the allocation of server resources for these connections. This insulates servers from the overwhelming flood of packets associated with these events.

The appliance also protects network resources from ICMP based attacks by using ICMP rate limiting and aggressive ICMP packet inspection. It performs strong IP reassembly, drops a variety of suspicious and malformed packets, and applies Access Control Lists (ACLs) to site traffic for further protection.

For more information, see "[HTTP Denial-of-Service Protection](#)."

Content Filtering

Provides protection from malicious attacks for web sites at the Layer 7 level. The appliance inspects each incoming request according to user-configured rules based on HTTP headers, and performs the action the user configured. Actions can include resetting the connection, dropping the request, or sending an error message to the user's browser. This allows the appliance to screen unwanted requests and reduces your servers' exposure to attacks.

This feature can also analyze HTTP GET and POST requests and filter out known bad signatures, allowing it to defend your servers against HTTP-based attacks.

For more information, see "[Content Filtering](#)."

Responder

Functions like an advanced filter and can be used to generate responses from the appliance to the client. Some common uses of this feature are generation of redirect responses, user defined responses, and resets.

For more information, see "[Responder](#)."

Rewrite

Modifies HTTP headers and body text. You can use the rewrite feature to add HTTP headers to an HTTP request or response, make modifications to individual HTTP headers, or delete HTTP headers. It also enables you to modify the HTTP body in requests and responses.

When the appliance receives a request or sends a response, it checks for rewrite rules, and if applicable rules exist, it applies them to the request or response before passing it on to the web server or client computer.

For more information, see "[Rewrite](#)."

Priority Queuing

Prioritizes user requests to ensure that the most important traffic is serviced first during surges in request volume. You can establish priority based on request URLs, cookies, or a variety of other factors. The appliance places requests in a three-tier queue based on their configured priority, enabling business-critical transactions to flow smoothly even during surges or site attacks.

For more information, see "[Priority Queuing](#)."

Surge Protection

Regulates the flow of user requests to servers and controls the number of users that can simultaneously access the resources on the servers, queuing any additional requests once your servers have reached their capacity. By controlling the rate at which connections can be established, the appliance blocks surges in requests from being passed on to your servers, thus preventing site overload.

For more information, see "[Surge Protection](#)."

NetScaler Gateway

NetScaler Gateway is a secure application access solution that provides administrators granular application-level policy and action controls to secure access to applications and data while allowing users to work from anywhere. It gives IT administrators a single point of control and tools to help ensure compliance with regulations and the highest levels of information security across and outside the enterprise. At the same time, it empowers users with a single point of access—optimized for roles, devices, and networks—to the enterprise applications and data they need. This unique combination of capabilities helps maximize the productivity of today's mobile workforce.

For more information, see "[NetScaler Gateway](#)."

Application Firewall

Protects applications from misuse by hackers and malware, such as cross site scripting attacks, buffer overflow attacks, SQL injection attacks, and forceful browsing, by filtering traffic between each protected web server and users that connect to any web site on that web server. The application firewall examines all traffic for evidence of attacks on web server security or misuse of web server resources, and takes the appropriate action to prevent these attacks from succeeding.

For more information, see "[Application Firewall](#)."

Application Visibility Feature

Sep 04, 2013

NetScaler Insight Center

NetScaler Insight Center is a high performance collector that provides end-to-end user experience visibility across Web and HDX (ICA) traffic. It collects HTTP and ICA AppFlow records generated by NetScaler ADC appliances and populates analytical reports covering Layer 3 to Layer 7 statistics. NetScaler Insight Center provides in-depth analysis for the last five minutes of real-time data, and for historical data collected for the last one hour, one day, one week, and one month. HDX (ICA) analytic dashboard enables you to drill down from HDX Users, Applications, Desktops, and even from gateway-level information. Similarly, HTTP analytics provide a bird's eye view of Web Applications, URLs Accessed, Client IP Addresses and Server IP Addresses, and other dashboards. The administrator can drill down and identify the pain points from any of these dashboards, as appropriate for the use case.

EdgeSight for NetScaler

Support for application performance monitoring based on end user experience. This solution leverages the HTML injection feature to obtain various time values, which are used by EdgeSight server for analysis and report generation. EdgeSight for NetScaler provides a way to monitor the performance benefits of a NetScaler and determine potential bottlenecks in a network.

For more information, see "[EdgeSight Monitoring for NetScaler](#)."

Enhanced Application Visibility Using AppFlow

The Citrix NetScaler appliance is a central point of control for all application traffic in the data center. It collects flow and user-session level information valuable for application performance monitoring, analytics, and business intelligence applications. AppFlow transmits this information by using the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. IPFIX (the standardized version of Cisco's NetFlow) is widely used to monitor network flow information. AppFlow defines new Information Elements to represent application-level information.

Using UDP as the transport protocol, AppFlow transmits the collected data, called *flow records*, to one or more IPv4 collectors. The collectors aggregate the flow records and generate real-time or historical reports.

AppFlow provides visibility at the transaction level for HTTP, SSL, TCP, and SSL_TCP flows. You can sample and filter the flow types that you want to monitor.

To limit the types of flows to monitor, by sampling and filtering the application traffic, you can enable AppFlow for a virtual server. AppFlow can also provide statistics for the virtual server.

You can also enable AppFlow for a specific service, representing an application server, and monitor the traffic to that application server.

For more information, see "[AppFlow](#)."

Stream Analytics

The performance of your web site or application depends on how well you optimize the delivery of the most frequently requested content. Techniques such as caching and compression help accelerate the delivery of services to clients, but you need to be able to identify the resources that are requested most frequently, and then cache or compress those resources. You can identify the most frequently used resources by aggregating real-time statistics about website or application traffic. Statistics such as how frequently a resource is accessed relative to other resources and how much bandwidth is consumed

by those resources help you determine whether those resources need to be cached or compressed to improve server performance and network utilization. Statistics such as response times and the number of concurrent connections to the application help you determine whether you must enhance server-side resources.

If the web site or application does not change frequently, you can use products that collect statistical data, and then manually analyze the statistics and optimize the delivery of content. However, if you do not want to perform manual optimizations, or if your web site or application is dynamic in nature, you need infrastructure that can not only collect statistical data but can also automatically optimize the delivery of resources on the basis of the statistics. On the NetScaler appliance, this functionality is provided by the Stream Analytics feature. The feature operates on a single NetScaler appliance and collects run-time statistics on the basis of criteria that you define. When used with NetScaler policies, the feature also provides you with the infrastructure that you need for automatic, real-time traffic optimization.

For more information, see "[Stream Analytics](#)."

Cloud Integration Feature

Aug 23, 2013

AutoScale

All applications have specific usage patterns that comprise peaks and troughs. These load variations can be dynamic in nature and difficult to predict, given that they depend on several factors that are intrinsic to the use case. Cloud users have to constantly monitor the load on their application fleet and make sure that these variations have minimum impact on end users. During periods of peak usage, when the application fleet is overloaded and end users experience significant latency, they have to deploy additional application instances. During trough periods, the expanded fleet is underutilized. So they might have to remove additional instances or bear unnecessary cost overheads. In most cases, they have to perform these tasks manually.

If your organization uses Citrix CloudPlatform to deploy and manage the cloud environment, users can use the *AutoScale* feature in CloudPlatform, in conjunction with a Citrix NetScaler appliance, to automatically scale their applications as needed. The AutoScale feature is part of the elastic load balancing feature in CloudPlatform. A CloudPlatform user can use the AutoScale feature to specify thresholds for various conditions for automatically scaling the application fleet upward and downward. CloudPlatform, in turn, configures the NetScaler appliance (by using the NetScaler NITRO API) to load balance traffic to the application virtual machines (VMs), monitor application thresholds and performance, and trigger scale-up and scale-down actions to add or remove VMs to or from the application fleet.

As the NetScaler administrator, you do not have to perform any tasks for configuring AutoScale on the NetScaler appliance. However, you might have to be aware of certain prerequisites, and you might have to troubleshoot the configuration if issues arise in the AutoScale configuration. To troubleshoot the configuration, you have to be aware of how CloudPlatform works and what configuration CloudPlatform pushes to the NetScaler appliance. You also need a working knowledge of how to troubleshoot issues on a NetScaler appliance.

For more information about AutoScale, see "[AutoScale: Automatic Scaling in the Citrix CloudPlatform Environment.](#)"

Hardware Installation

Aug 06, 2017

Note

For the latest content, see [NetScaler MPX](#).

The following sections describe the hardware installation and initial configuration for all NetScaler hardware platforms.

Hardware Platforms	Describes the NetScaler hardware platforms and provides detailed information about each platform and its components.
Preparing for Installation	Describes how to unpack the NetScaler appliance and prepare the site and rack for installing the appliance. Lists the cautions and warnings that you should review before you install the appliance.
Installing the Hardware	Describes the steps to install the rails, mount the hardware, connect the cables, and turn on the appliance.
Initial Configuration	Describes how to perform initial configuration of your NetScaler appliance and assign management and network IP addresses.
Lights Out Management Port of the NetScaler Appliance	Describes the different operations you can perform on your NetScaler appliance by using the Lights Out Management Port.

For information about NetScaler hardware and software compatibility and the supported upgrade and downgrade paths, see <http://support.citrix.com/article/CTX113357>.

Licensing, Upgrading, and Downgrading

Mar 17, 2012

The following topics describe the migration instructions for setting up a new version of a NetScaler with a list of all new and deprecated commands, parameters, and SNMP OIDs.

This document includes the following information:

- [Changes in Release 10.5](#)
- [Deprecated Commands, Parameters, and SNMP OIDs](#)
- [NetScaler Licensing Overview](#)
- [NetScaler Gateway Universal License](#)
- [Upgrading or Downgrading the System Software](#)
- [Troubleshooting](#)

- **SSL Renegotiation**

Issue ID 0462681: SSL renegotiation is now blocked by default. In earlier releases, the default setting was to allow SSL renegotiation.

The following commands are deprecated in release 10.5:

- add vpn epaprofile
- rm vpn epaprofile
- show vpn epaprofile

The following parameters are deprecated in release 10.5:

- unset aaa kcdAccount -keytab
- show aaa kcdAccount -principle
- show protocol httpBand -AvgBandSize
- show protocol httpBand -BandData
- show protocol httpBand -AccessRatio
- add vpn vserver -advancedEpa
- add vpn vserver -deploymentType
- set vpn vserver -advancedEpa
- bind vpn vserver -epaprofile
- unbind vpn vserver -epaprofile
- show vpn vserver -advancedEpa
- show vpn vserver -deploymentType
- show vpn vserver -epaprofile
- show vpn vserver -epaprofileoptional
- add vpn intranetApplication -clientApplication
- show vpn intranetApplication -clientApplication
- show vpn intranetApplication -spoofIIP

The following SNMP OIDs are deprecated in release 10.5:

- spdy2TotStreams,1.3.6.1.4.1.5951.4.1.1.48.72

- spdy2TotStreams,1.3.6.1.4.1.5951.4.1.1.48.72

NetScaler Licensing Overview

Jan 25, 2016

The process of allocating your NetScaler licenses has been greatly simplified. The new licensing framework allows you to focus on getting maximum value from Citrix products.

In the NetScaler configuration utility (GUI), you can use your hardware serial number (HSN) or your license activation code (LAC) to allocate your licenses. Alternatively, if a license is already present on your local computer, you can upload it to the appliance.

For all other functionality, such as returning or reallocating your license, you must use the licensing portal. Optionally, you can still use the licensing portal for license allocation. For more information about the licensing portal, see "<http://support.citrix.com/article/CTX131110>".

Note: You must purchase separate licenses for each appliance in a high availability (HA) pair. Make sure that the same type of licenses are installed on both the appliances. For example, if you purchase a platinum license for one appliance, you must purchase another platinum license for the other appliance.

This document includes the following information:

- [Prerequisites](#)
- [Allocating your License by using the Configuration Utility](#)
- [Installing the License](#)
- [Verifying the Licensed Features](#)
- [Enabling or Disabling a Feature](#)

Updated: 2014-06-24

To use the hardware serial number or license activation code to allocate your licenses:

- You must be able to access public domains through the appliance. For example, the appliance should be able to access www.citrix.com. The license allocation software internally accesses the Citrix licensing portal for your license. To access a public domain, you can either use a proxy server or set up a DNS server and, on your NetScaler appliance, configure a NetScaler IP (NSIP) address or a subnet IP (SNIP) address.
- Your license must be linked to your hardware, or you must have a valid license activation code (LAC). Citrix sends your LAC by email when you purchase a license.

Updated: 2014-06-25

If your license is already linked to your hardware, the license allocation process can use the hardware serial number. Otherwise, you must type the license activation code (LAC).

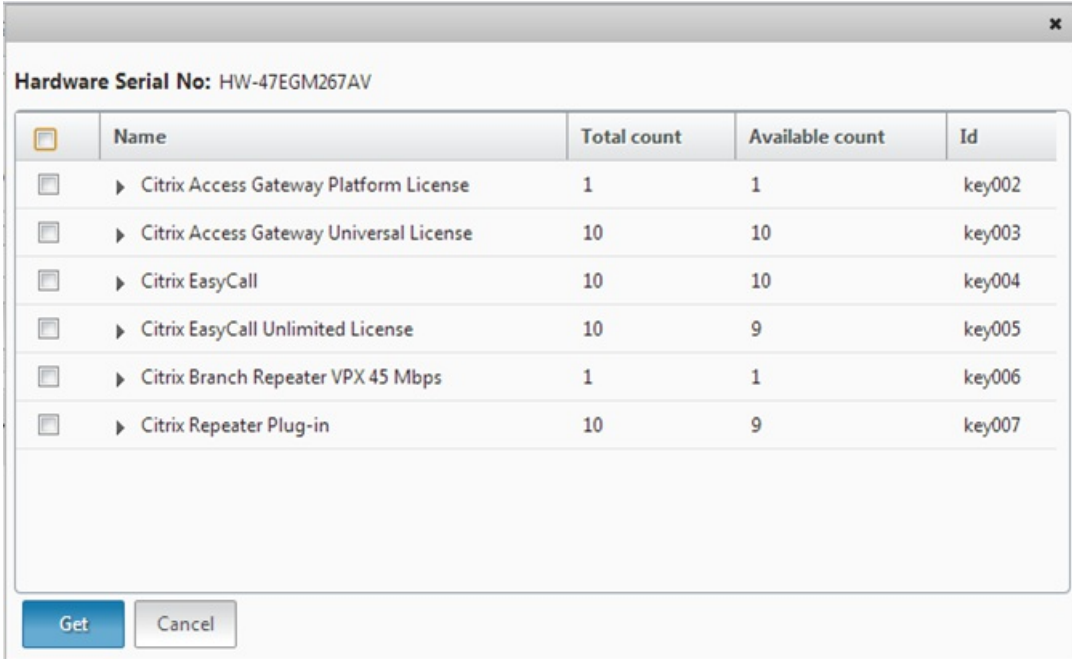

To allocate your license

1. In a web browser, type the IP address of the NetScaler (for example, <http://192.168.100.1>).
2. In User Name and Password, type the administrator credentials.
3. On the Configuration tab, navigate to System > Licenses.
4. In the details pane, click Manage Licenses, click Add New License, and then select one of the following options:

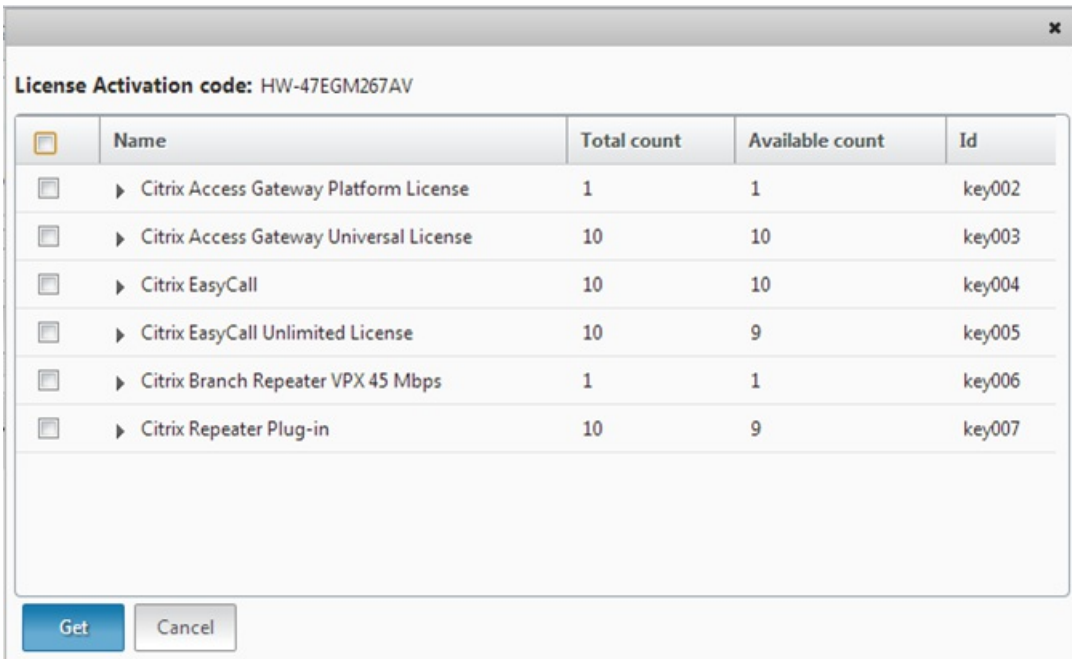

- **Use Serial Number.** The software internally fetches the serial number of your appliance and uses this number to display your license(s).
- **Use License Activation Code.** Citrix emails the LAC for the license that you purchased. Enter the LAC in the text box.
If you do not want to configure internet connectivity on the NetScaler appliance, you can use a proxy server. Select the **Connect through Proxy Server** check box and specify the IP address and port of your proxy server.

5. Click Get Licenses. Depending on the option that you selected, one of the following dialog boxes appears.

- The following dialog box appears if you selected Hardware Serial Number.

- The following dialog box appears if you selected License Activation Code.

6. Select the license that you want to allocate, and then click Get.
7. Click Reboot for the license to take effect.

8. In the Reboot dialog box, click OK to proceed with the changes, or click Close to cancel the changes.

Updated: 2014-06-24

If you downloaded your license file to your local computer by accessing the licensing portal, you must upload the license to the appliance.

To install a license file by using the configuration utility

1. In a web browser, type the IP address of the NetScaler (for example, <http://192.168.100.1>).
2. In User Name and Password, type the administrator credentials.
3. On the Configuration tab, navigate to System > Licenses .
4. In the details pane, click Manage Licenses.
5. Click Add New License, then select **Upload license files from a local computer**.
6. Click Browse. Navigate to the location of the license files, select the license file, and then click Open.
7. Click Reboot to apply the license.
8. In the Reboot dialog box, click OK to proceed with the changes, or click Close to cancel the changes.

See also

To install the licenses by using the command line interface

1. Open an SSH connection to the NetScaler by using an SSH client, such as PuTTY.
2. Log on to the NetScaler by using the administrator credentials.
3. Switch to the shell prompt, create a license subdirectory in the nsconfig directory, if it does not exist, and copy the new license file(s) to this directory.

Example

login: nsroot

Password: nsroot

```
Last login: Mon Aug 4 03:37:27 2008 from 10.102.29.9
```

```
Done
```

```
> shell
```

```
Last login: Mon Aug 4 03:51:42 from 10.103.25.64
```

```
root@ns# mkdir /nsconfig/license
```

```
root@ns# cd /nsconfig/license
```

Copy the new license file(s) to this directory.

Note: The NetScaler appliance does not prompt for a reboot option when you use the command line interface to install the licenses. Run the `reboot -w` command to warm reboot the system, or run the `reboot` command to reboot the system normally.

Updated: 2014-06-24

Before using a feature, make sure that your license supports the feature.

To verify the licensed features by using the command line interface

1. Open an SSH connection to the NetScaler by using an SSH client, such as PuTTY.
2. Log on to the NetScaler by using the administrator credentials.
3. At the command prompt, enter the `sh ns license` command to display the features supported by the license.

Example

```
sh ns license
```

```
License status:
```

```
Web Logging: YES
```

```
Surge Protection: YES
```

```
.....
```

```
HTML Injection: YES
```

```
Done
```

To verify the licensed features by using the configuration utility

1. In a Web browser, type the IP address of the NetScaler, such as `http://192.168.100.1`.
2. In User Name and Password, type the administrator credentials.
3. Provide the User name and Password and click Login.
4. In the navigation pane, expand System, and then click Licenses. You will see a green check mark next to the licensed features.

Updated: 2014-07-01

When you use the NetScaler appliance for the first time, you need to enable a feature before you can use its functionality. If you configure a feature before it is enabled, a warning message appears. The configuration is saved but it will apply only after the feature is enabled.

To enable a feature by using the command line interface

At the NetScaler command prompt, type the following commands to enable a feature and verify the configuration:

- enable feature <FeatureName>
- show feature

Example

```
enable feature lb cs
done
>show feature
```

	Feature	Acronym	Status
	-----	-----	-----
1)	Web Logging	WL	OFF
2)	Surge Protection	SP	ON
3)	Load Balancing	LB	ON
4)	Content Switching	CS	ON
5)	Cache Redirection	CR	ON
.			
.			
.			
24)	NetScaler Push	push	OFF

Done

The example shows how to enable load balancing (lb) and content switching (cs).

If the license key is not available for a particular feature, the following error message appears for that feature:

ERROR: feature(s) not licensed

Note: To enable an optional feature, you need a feature-specific license. For example, if you have purchased and installed the Citrix NetScaler Enterprise Edition license and need to enable the Integrated Caching feature, you first need to purchase and install the AppCache license.

To disable a feature by using the command line interface

At the NetScaler command prompt, type the following commands to disable a feature and verify the configuration:

- disable feature <FeatureName>
- show feature

Example

The following example shows how to disable load balancing (LB).

```
> disable feature lb
Done
> show feature
```

	Feature	Acronym	Status
	-----	-----	-----
1)	Web Logging	WL	OFF
2)	Surge Protection	SP	ON
3)	Load Balancing	LB	OFF
4)	Content Switching	CS	ON

```
.  
.   
.   
24) NetScaler Push      push      OFF  
Done  
>
```

NetScaler Gateway Universal License

Jul 30, 2017

The NetScaler Gateway universal license limits the number of concurrent user sessions to the number of licenses purchased. If you purchase 100 licenses, you can have 100 concurrent sessions at any time. When a user ends a session, that license is released for the next user. A user who logs on to the NetScaler Gateway from more than one computer occupies a license for each session.

If all licenses are occupied, no additional connections can be opened until a user ends a session or the administrator terminates the session using the configuration utility. When a connection is closed, the license is released and can be used for a new user.

This document includes the following information:

- [Obtaining the Universal License](#)
- [Installing the Universal License](#)
- [Verifying Installation of the Universal License](#)

You need the following information before going to the Citrix Web site for the universal license.

Your user ID and password for My Citrix

Register at My Citrix (www.mycitrix.com) to receive your user ID and password.

Note: If you cannot locate either the license code or your user ID and password, contact Citrix Customer Service.

The host name of the NetScaler Gateway

The entry field for this name on My Citrix is case-sensitive, so make sure that you copy the host name exactly as it is configured on the NetScaler.

The number of licenses you want to include in the license file

You do not have to download all of the licenses you are entitled to at once. For example, if your company purchased 100 licenses, you can choose to download 50. You can allocate the rest in another license file at a later time. Multiple license files can be installed on the NetScaler Gateway.

Note: Before obtaining your licenses, make sure you configure the host name of the NetScaler using the Setup Wizard and then restart the NetScaler.

To obtain your universal license

1. In a Web browser, go to <http://www.citrix.com/> and click My Citrix.
2. Enter your user name and password. If this is the first time you are logging on to the site, you are asked for additional background information.
3. Under My Tools, point to Choose a toolbox, and click Activation System/Manage Assets.
4. In the Current Tool drop-down menu, select Activate/Allocate and follow the directions to obtain your license file.

To install the license, see "[Installing the License](#)". After installation, verify that the license was installed correctly.

Before proceeding, verify that your universal license is installed correctly.

To verify installation of the universal license by using the command line interface

1. Open an SSH connection to the NetScaler appliance by using an SSH client, such as PuTTY.
2. Log on to the NetScaler appliance by using the administrator credentials.
3. Use the show license command to verify that “SSL VPN = YES” and that Maximum Users has increased from 5 to the expected number of concurrent users.

To verify installation of the universal license by using the configuration utility

1. In a Web browser, type the IP address of the NetScaler appliance, such as <http://192.168.100.1>.
2. In User Name and Password, type the administrator credentials.
3. In the navigation pane, expand System, and then click Licenses.
4. In the Licenses pane, you will see a green check mark next to **NetScaler** Gateway. The field Maximum NetScaler Gateway Users Allowed displays the number of concurrent user sessions licensed on the NetScaler appliance.

Upgrading or Downgrading the System Software

May 17, 2017

NetScaler 10.5 offers new and updated features with increased functionality. A comprehensive list of enhancements is listed in the release notes accompanying the release announcement. Take a moment to read this document before you upgrade your software.

It is important to understand the licensing framework and types of licenses before you upgrade your software. A software edition upgrade may require new licenses, such as upgrading from the standard edition to the enterprise edition, the standard edition to the platinum edition, or the enterprise edition to the platinum edition.

Note: For upgrading or downgrading the nodes in a cluster setup, see "[Upgrading or Downgrading the Cluster Software](#)". Upgrading from release 10.1 build 121.10 or any earlier releases to release 10.1 build 122.17 and later involves some location changes of user monitor script files. For details, see [Directory Locations of Script Files for User Monitors](#).

This document includes the following information:

- [Upgrading to Release 10.5](#)
- [Downgrading from Release 10.5](#)

In release 10.1 build 122.17, the script files for user monitors are at a new location. If you upgrade an appliance or virtual appliance to release 10.1 build 122.17 or later, the changes are as follows:

- A new directory named `conflicts` is created in `/nsconfig/monitors/` and all the built-in scripts of the previous builds are moved to this directory.
- All new built-in scripts are available in the `/netscaler/monitors/` directory. All custom scripts are available in the `/nsconfig/monitors/` directory.
- You must save a new custom script in the `/nsconfig/monitors/` directory.
- After the upgrade is completed, if a custom script is created and saved in the `/nsconfig/monitors/` directory with the same name as that of a built-in script, the script in the `/netscaler/monitors/` directory takes priority. That is, the custom script is not run.

If you provision a virtual appliance running release 10.1 build 122.17 or later, the changes are as follows:

- All built-in scripts are available in the `/netscaler/monitors/` directory
- The directory `/nsconfig/monitors/` is empty.
- If you create a new custom script, you must save it in the `/nsconfig/monitors/` directory.

For more information about user monitors, see "[Understanding User Monitors](#)."

Before You Begin

May 28, 2017

Before you start the upgrade or downgrade process, make sure you check the guidelines given at this [link](#).

Upgrading to Release 10.5

May 17, 2017

You can use the configuration utility to upgrade most older releases to 10.5. For others, you must use the command line interface. You follow the same basic procedure to upgrade either a standalone appliance or each appliance in a high availability pair, although additional considerations apply to upgrading a high availability pair.

This document includes the following information:

- [Upgrading a Standalone NetScaler](#)
- [Upgrading a High Availability Pair](#)

Before upgrading the system software, make sure that you have the required licenses. For more information, see "[NetScaler Licensing Overview](#)." You do not need a new license for the following upgrades:

- 8.x to 9.x
- 8.x or 9.x to 10.x
- 8.x, 9.x, or 10.x to 10.y

Note: When upgrading from release 8.0, 8.1, 9.0, 9.1, 9.2, 9.3, 10, or 10.1, you have the option to use the configuration utility or the command line interface. Citrix recommends to perform the upgrade by using the command line interface. When using the upgrade wizard in the configuration utility to upgrade from release 8.0, do not use the Device option to upload your software.

In the following procedure, <release> and <releasenameumber> represent the release version you are upgrading to, and <targetbuildnumber> represents the build number that you are upgrading to. The procedure includes optional steps to avoid losing any updates that are pushed to the /etc directory during the upgrade.

To upgrade a standalone NetScaler appliance running release 8.0, 8.1, 9.0, 9.1, 9.2, 9.3, 10, or 10.1 by using the command line interface

1. Use an SSH client, such as PuTTY, to open an SSH connection to the appliance.
2. Log on to the appliance by using the administrator credentials. Save the running configuration. At the prompt, type:
save
config
3. Create a copy of the ns.conf file. At the shell prompt, type:
 1. cd /nsconfig
 2. cp ns.conf ns.conf.NS<currentreleasenameumber><currentbuildnumber>You should backup the configuration file to another computer.
4. (Optional) If you have modified some of the following files in the /etc directory, and copied them to /nsconfig to maintain persistency, any updates that are pushed to the /etc directory during the upgrade might be lost:
 - ttys
 - resolv.conf
 - sshd_config
 - host.conf
 - newsyslog.conf
 - host.conf
 - httpd.conf
 - rc.conf

- syslog.conf
- crontab
- monitrc

To avoid losing these updates, create a `/var/nsconfig_backup` directory, and move the customized files to this directory. That is, move any files that you modified in `/etc` directory and copied to `/nsconfig` by running the following command:

```
cp /nsconfig/<filename> /var/nsconfig_backup
```

Example:

```
cp /nsconfig/syslog.conf /var/nsconfig_backup
```

5. Create a location for the installation package. At the shell prompt type
 1. `cd/var/nsinstall`
 2. `mkdir <releasenum>nsinstall`
 3. `cd <releasenum>nsinstall`
 4. `mkdir build_<targetbuildnum>`
 5. `cd build_<targetbuildnum>`
6. Download or copy the installation package (`build-<release>-<targetbuildnum>_nc.tgz`) to the directory that you created for it. To download the installation package from the Citrix Web site, do the following:
 1. Go to MyCitrix.com, log on with your credentials, and click Downloads.
 2. In Select a Product, select NetScaler ADC.
 3. Under Firmware, click the release and build number to download.
 4. Click Get Firmware.

Note: Documentation is not available as part of the build in NetScaler release 10.1, build 118.7 or later. See [Citrix NetScaler](#) for the documentation.
7. Extract the contents of the installation package. Example:

```
tar -xvzf build_10.1-49.3_nc.tgz
```
8. Run the `installns` script to install the new version of the system software. The script updates the `/etc` directory. Example:

```
./installns
```

Note:

To install a FIPS appliance, run the `installns` script with the `-F` option.

Warning: When upgrading to the NetScaler nCore build, the installation script prompts you to delete the `/var` directory if the swap partition is smaller than 32 gigabytes (GB). If this prompt appears, type N, save any important files located in `/var` to a backup location, and then re-run the installation script.

If the free space available on the flash drive is insufficient to install the new build, the appliance prompts you to clean up the flash drive.
9. When prompted, restart the NetScaler.
10. (Optional) If you performed [step 4](#), do the following:
 1. Manually compare the files in `/var/nsconfig_backup` and `/etc` and make appropriate changes in `/etc`.
 2. To maintain persistency, move the updated files in `/etc` to `/nsconfig`.
 3. Restart the appliance to put the changes into effect.

```
login: nsroot
```

```
Password: nsroot
```

```
Last login: Mon Apr 19 03:37:27 2014 from 10.102.29.9
```

```
Done
```

```

> save config
> shell
Last login: Mon Apr 10 03:51:42 from 10.103.25.64
root@NSnnn# cd /var/nsinstall
root@NSnnn# cd 10_5nsinstall
root@NSnnn# mkdir build_49
root@NSnnn# cd build_49
root@NSnnn# ftp ... get build-10.5-49_nc.tgz
root@NSnnn# tar xzvf build-10.5-49_nc.tgz
root@NSnnn# ./installns
installns version (10.5-49) kernel (ns-10.5-49_nc.gz)
...
...
...
Copying ns-10.5-49_nc.gz to /flash/ns-10.5-49_nc.gz ...

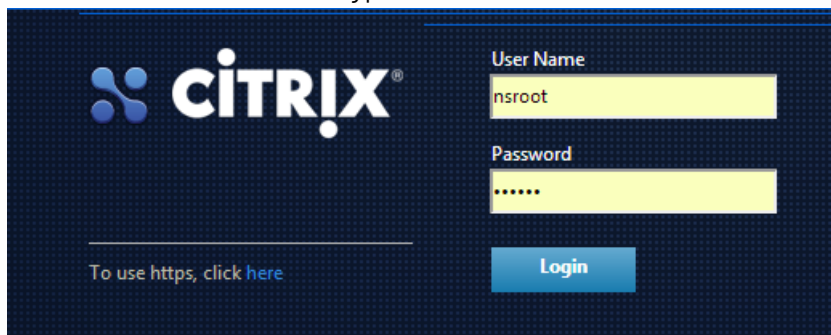

...
Installation has completed.

```

Reboot NOW? [Y/N] Y

To upgrade a standalone NetScaler running release 8.0, 8.1, 9.0, 9.1, 9.2, 9.3, 10, or 10.1 by using the configuration utility

1. In a Web browser, type the IP address of the NetScaler, such as <http://10.102.29.50>.
2. In User Name and Password, type the administrator credentials and then click **Login**, as shown in the following figure.

3. In the configuration utility, in the navigation pane, click System.
4. In the System Overview page, click System Upgrade.
5. Follow the instructions to upgrade the software.
6. When prompted, select Reboot.

Note: After the upgrade, close all browser instances and clear your computer's cache before accessing the appliance.

Updated: 2015-04-1

To upgrade the system software on NetScaler units in a high availability (HA) pair, first upgrade the secondary node, and then the primary node.

Points to Note

1. If the two nodes in an HA configuration are running different NetScaler software releases, the following information

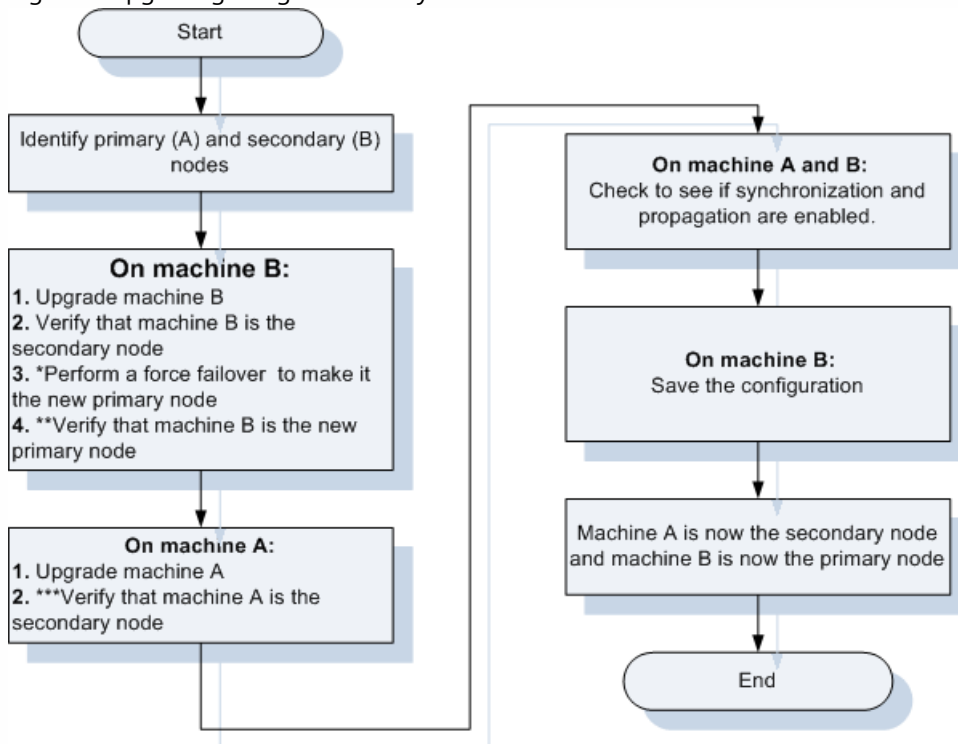

does not get synchronized on the primary and secondary nodes:

- Configuration propagation and synchronization
- States of the services
- Connection failover sessions
- Persistence sessions

The above information might not get synchronized on the primary and secondary nodes if the two nodes are running different builds of the same release. Refer to the [Known Issues](#) section of the release notes to check if your NetScaler build has this issue.

2. Synchronization of the files in the All mode of the Sync HA files command works successfully if the two nodes in an HA configuration are running different NetScaler software releases, or the two nodes are running different builds of the same release. For more information, see [Synchronising Configuration Files in High Availability Setup](#).

Figure 1. Upgrading a High Availability Pair

*After upgrading machine B, it becomes the primary node. If machine B does not function as expected, enter the force failover command on the new primary node (machine B) forcing it to again become the secondary node, and contact Citrix Customer Service before proceeding. After you test that machine B properly functions as the new primary node, proceed with upgrading the former primary node (machine A).

**After machine B is upgraded successfully, both synchronization and propagation are automatically disabled until you upgrade machine A.

***After both the nodes are upgraded successfully, synchronization and propagation are automatically enabled.

In the following procedure, machine A is the primary node and machine B is the secondary node before the upgrade.

To upgrade NetScaler units in a high availability pair running release 8.0, 8.1, 9.0, 9.1, 9.2, 9.3, 10, or 10.1 by using the command line interface

On machine B (original secondary node)

1. Follow the procedure for upgrading a standalone node as described in "[Upgrading a Standalone NetScaler Appliance](#)". The procedure includes optional steps to avoid losing any updates that are pushed to the /etc directory during the upgrade.
2. After the appliance restarts, log on with the administrator credentials and enter the show ha node command to verify that the appliance is a secondary node.
3. Test the new build by entering the force failover command on the secondary node (machine B). At the command prompt type force failover.
When you do so, machine B becomes the primary node. If machine B does not function as expected, enter the force failover command on the new primary node (machine B) forcing it to again become the secondary node, and contact Citrix Customer Service before proceeding.
4. Enter the show ha node command to verify that machine B is the new primary node.

Example

```
login: nsroot
Password: nsroot
Last login: Mon Mar 26 08:37:26 2008 from 10.102.29.9
Done
```

```
show ha node
  2 nodes:
1)  Node ID:  0
    IP:  10.0.4.2
    Node State: UP
    Master State: Primary
    ...
    Sync State: AUTO DISABLED
    Propagation: AUTO DISABLED
    ...
```

Done

Note: After machine B is upgraded successfully, both synchronization and propagation are automatically disabled until you upgrade machine A.

On machine A (original primary node)

5. Follow the procedure for upgrading a standalone node as described in "[Upgrading a Standalone NetScaler Appliance](#)." The procedure includes optional steps to avoid losing any updates that are pushed to the /etc directory during the upgrade.
6. After the appliance restarts, log on by using the administrator credentials, and enter the show ha node command to verify that the appliance is a secondary node and that synchronization is disabled.

Note: After both nodes are upgraded successfully, synchronization and propagation are automatically enabled.

On machine A and machine B

7. After successfully upgrading both the nodes, run the show ha node command to verify that synchronization and propagation are enabled on the primary node and synchronization is successful and propagation is enabled on the secondary node.

Example

On Primary node (Machine B)

```
show ha node
  Node ID: 0
  IP: 10.0.4.2
  Node State: UP
  Master State: Primary
...
...
  INC State: DISABLED
  Sync State: ENABLED
  Propagation: ENABLED
  Enabled Interfaces : 1/1
  Disabled Interfaces : None
  HA MON ON Interfaces : 1/1
...
...
  Local node information
  Critical Interfaces: 1/1
Done
```

On Secondary node (Machine A)

```
Show ha node
  Node ID: 0
  IP: 10.0.4.11
  Node State: UP
  Master State: Secondary
..
..
  INC State: DISABLED
  Sync State: SUCCESS
  Propagation: ENABLED
  Enabled Interfaces : 1/1
  Disabled Interfaces : None
  HA MON ON Interfaces : 1/1
...
...
  Local node information:
  Critical Interfaces: 1/1
Done
```

On machine B (new primary node)

8. Enter the save ns config command to save the configuration.

Machine B (original secondary node) is now the primary node and machine A (original primary node) is now the secondary node.

Note: You can enter the force failover command again to make machine A (original primary node) as the primary node and machine B (original secondary node) as the secondary node.

To upgrade NetScaler units in a high availability pair running release 8.0, 8.1, 9.0, 9.1,

9.2, 9.3, or 10 by using the configuration utility

1. Log on to the secondary node and perform the upgrade as described in "[To upgrade a standalone NetScaler running release 8.0, 8.1, 9.0, 9.1, 9.2, or 9.3 by using the configuration utility](#)".

Note: Before upgrading the primary node (machine A), you have the option to test the new release by entering the force failover command at the command line interface on the secondary node (machine B). When you do so, machine B becomes the primary node. If machine B does not function as expected, enter the force failover command at the command line interface on the new primary node (machine B) forcing it to again become the secondary node, and contact Citrix Customer Service before proceeding. If machine B properly assumes the role of primary node, proceed with upgrading the former primary node (machine A).

2. Log on to the primary node and perform the upgrade as described in "[To upgrade a standalone NetScaler running release 8.0, 8.1, 9.0, 9.1, 9.2, or 9.3 by using the configuration utility](#)".

Downgrading from Release 10.5

May 17, 2017

You can downgrade to any release on a standalone NetScaler or a high availability pair by using the command line interface.

Caution: Loss in configuration may occur when downgrading. You should compare the configurations before and after the downgrade, and then manually reenter any missing entries.

This procedure provides steps to downgrade from release 10.5 to an earlier release.

Note: Downgrading using the configuration utility is not supported.

This document includes the following information:

- [Downgrading a Standalone NetScaler](#)
- [Downgrading a High Availability Pair](#)

In the following procedure, <release> and <releasenum> represent the release version you are downgrading to, and <targetbuildnumber> represents the build number that you are downgrading to. Refer to the table below for specific values.

Table 1. Release Version Values

Release Version	<release>	<releasenum>
10.1	10.1	10.1
10	10	10
9.3	9.3	9.3
9.2	9.2	9.2
9.1	9.1	9.1
8.1	8.1	8.1
8.0	8.0	8.0
7.0	7.0	7.0

To downgrade a standalone NetScaler

1. Open an SSH connection to the NetScaler by using an SSH client, such as PuTTY.
2. Log on to the NetScaler by using the administrator credentials. Save the running configuration. At the prompt, type:

save config

3. Create a copy of the ns.conf file. At the shell prompt, type:

1. `cd /nsconfig`
2. `cp ns.conf ns.conf.NS10.5<currentbuildnumber>`

You should backup a copy of the configuration file on another computer.

4. Copy the <releasenum> configuration file (ns.conf.NS<releasenum>) to ns.conf. At the shell prompt, type:

1. `cp ns.conf.NS<releasenum> ns.conf`

Note: ns.conf.NS<releasenum> is the backup configuration file that is automatically created when the system software is upgraded from release version <releasenum> to the current release version. There may be some loss in configuration when downgrading. After the appliance restarts, compare the configuration saved in step 3 with the running configuration, and make any adjustments for features and entities configured before the downgrade. Save the running configuration after making the changes.

Important: If routing is enabled, perform step 5. Otherwise, skip to step 6.

5. If routing is enabled, the ZebOS.conf file will contain the configuration. At the shell prompt, type:

1. `cd /nsconfig`
2. `cp ZebOS.conf ZebOS.conf.NS`
3. `cp ZebOS.conf.NS<targetreleasenum> ZebOS.conf`

6. Change directory to /var/nsinstall/<releasenum>nsinstall, or create one if it does not exist.

7. Change directory to build_<targetbuildnumber>, or create one if it does not exist.

8. Download or copy the installation package (build-<release>-<targetbuildnumber>.tgz) and the documentation bundle (ns-<releasenum>-<targetbuildnumber>-doc.tgz) to this directory and extract the contents of the installation package.

9. Run the installns script to install the new version of the system software. The script updates the /etc directory.

If the configuration file for the build that you are downgrading to exists on the appliance, you are prompted to load that configuration, as shown in the following figure.

Figure 1. Downgrade menu if configuration file exists

version	build	size	last modified	file name
Copied to ns.conf		72545	Jun 18 04:42	ns.conf.NS10.1-112.13
NS10.1	112.13	72545	Jun 18 04:42	ns.conf.NS10.1
NS10.1	112.13	72545	Jun 18 04:42	ns.conf.4
NS10.1	109.1	87219	Jun 18 04:42	ns.conf.NS10.1-109.1
NS10.1	93.051	74443	Jun 18 04:42	ns.conf.NS10.1-93.051
NS10.0	29.1.	62849	Jun 18 04:42	ns.conf.NS10.0-29.1.

Listed above are 5 configuration files, found in /nsconfig, that are appropriate for use with build 112.13.

Use the arrow keys to select an item in the menu above, then type:

```
'c' - copy file over ns.conf
'v' - view file (with vi; type ':q!' to exit vi)
'>' - more files
'<' - fewer files
'd' - done
```

If the free space available on the flash drive is insufficient to install the new build, the NetScaler prompts you to clean up of the flash drive.

10. When prompted, restart the NetScaler.

```
login: nsroot
Password: nsroot
Last login: Tue Mar 27 01:38:25 2014 from 10.102.29.9
Done
> save config
> shell
Last login: Tue Mar 27 02:07:06 from 10.103.25.64
```

```
root@NSnnn# cp ns.conf.NS10.1 ns.conf
root@NSnnn# cd /var/nsinstall
root@NSnnn# mkdir 10.1nsinstall
root@NSnnn# cd 10.1nsinstall
root@NSnnn# mkdir build_125
root@NSnnn# cd build_125
root@NSnnn# ftp 10.102.1.1
ftp> mget build-10.1-125_nc.tgz
ftp> mget get ns-10.1-125-doc.tgz
ftp> bye
root@NSnnn# tar xzvf build-10.1-125_nc.tgz
root@NSnnn# ./installns
installns version (10.1-125) kernel (ns-10.1-125.gz)
...
...
...
Copying ns-10.1-125.gz to /flash/ns-10.1-125_nc.gz ...
Changing /flash/boot/loader.conf for ns-10.1-125 ...
Installing documentation...
```

Installation has completed.

Reboot NOW? [Y/N] Y

To downgrade the system software on NetScaler units in a high availability pair, you need to downgrade the software first on the secondary node and then on the primary node. For instructions on downgrading each node separately, see "[Downgrading a Standalone NetScaler](#)".

Troubleshooting

Aug 13, 2013

If the appliance does not work as expected after you complete the installation, upgrade, or downgrade process, the first thing to do is to check for the most common causes of the problem.

This document includes the following information:

- [Resources for Troubleshooting](#)
- [Troubleshooting Issues Related to the Installation, Upgrade, and Downgrade processes](#)

Updated: 2013-08-13

For best results, use the following resources to troubleshoot an issue related to installing, upgrading, or downgrading a NetScaler appliance:

- The configuration files from the appliance. In case of a High Availability pair, the configuration files from both appliances.
- The following files from the appliance(s):
 - The relevant newnslog files.
 - The ns.log file.
 - The messages file.
- A network topology diagram.

Updated: 2013-11-22

Following are the most common installation, upgrade, and downgrade issues, and tips for resolving them:

- **Issue**
The NetScaler appliance is not accessible after the software downgrade

Cause

During the software downgrade process, if the configuration file of the existing release and build does not match the configuration file of the earlier release and build, the appliance cannot load the configuration, and the default IP address is assigned to the appliance.

Resolution

- Verify that the appliance is accessible from the console.
- Verify the NSIP address and the routes on the appliance.
 - If the IP address has changed to the default 192.168.100.1 IP address, change the IP address as required.
 - Verify that the appliance is accessible.
- **Issue**
Configuration of the appliance is lost after you upgrade the software across multiple releases.

Cause

Some migration commands are built in for upgrading to the next release. Such commands might not be available across releases.

Resolution

- Verify the path of the upgrade process. Citrix recommends upgrading by one release at a time. For example, if the softer needs to be upgraded from NetScaler release 9.2 to NetScaler release 10.1, the following is the recommended path for the upgrade:
 - NetScaler release 9.2 to NetScaler release 9.3
 - NetScaler release 9.3 to NetScaler release 10
 - NetScaler release 10 to NetScaler release 10.1
- Verify that the appliance has appropriate license files.
- Verifying the configuration at each step of the upgrade process can give you pointers to the issue.

• Issue

During an upgrade, if I run the command for synchronizing, the following message appears:

Command failed on the secondary node but succeeded on the primary node.

Resolution

Do not run any dependent commands (set /unset /bind /unbind) when High Availability (HA) synchronization is in progress.

• Issue

During an upgrade process, traffic does not pass through the new primary node when you run the force failover command.

Resolution

- Check for problems with the network topology and the switch configurations.
 - Run the set L2param -garpreply ENABLED command to enable the GARP reply.
 - Try using VMAC if not already used.
 - Run the sendarp -a command from the primary node.
- **Issue**
In an HA pair, after you run the force HA failover command the devices keep rebooting. The secondary device does not come up after an upgrade.

Resolution

Check to see if the /var directory is full. If so, remove the old installation files. Run the df -h command to show the available disk space.

• Issue

After upgrading an HA pair, one of the nodes is listed as state UNKNOWN.

Resolution

- Check to see if both nodes are running the same build. If the builds are not same and HA nodes have a version mismatch, some of the fields are shown as UNKNOWN when you run the show ha node command.
 - Check to see if the secondary appliance is reachable.
- **Issue**
After you upgrade the NetScaler appliance, the interface shows most of the load balancing virtual servers and services are DOWN.

Resolution

Verify that the SNIP address is active on the secondary appliance. Also, type the show service command to see if the service is running.

- **Issue**

After performing an upgrade, all virtual servers are down on the secondary appliance.

Resolution

Enable the HA state and HA synchronization by running the following commands:

- set node hastate enable
- set node hasync enable

Disabling HA is not recommended.

- **Issue**

After performing a downgrade, the NetScaler appliance does not boot up properly.

Resolution

Check to see if the correct license has been installed.

- **Issue**

In an HA pair, some features do not get synchronized after an upgrade is performed.

Resolution

Run the sync ha file misc command to synchronize the configurations files from the primary node to secondary node.

- **Issue**

During reboot, the following error message appears:

One or more commands in ns.conf failedWhat should I do?

Resolution

Make sure that no command in the ns.conf file exceeds the 255 byte limit. In commands that create policies that are too long for the 255-byte limit, you can use pattern sets to shorten the policies.

Example:

```
add cs policy p11 -rule 'HTTP.REQ.URL.ENDSWITH_ANY("ctx_file_extensions")'
```

Done

ctx_file_extensions is a default patset that covers a large number of extensions. In addition to the default pattern sets, you can create user-defined pattern sets. Add a patset by running the following command:

```
add patset <name>
```

Note: Patsets are supported only in release 9.3 or later.

- **Issue**

When upgrading a NetScaler VPX appliance, I am told to free up space in /var. What files do I remove?

Resolution

Remove the old installation files from /var/tmp/ directory. Also remove unwanted files from /flash.

- **Issue**

There is no connectivity to the graphical user interface (GUI) when you run the force HA failover command on the

secondary appliance.

Resolution

Log on to the secondary appliance using the command line interface and enable the access to GUI by running the set ns ip <IP> -gui enabled command.

- **Issue**

After performing an upgrade, and when I click on any link on the GUI that has to load a java applet (Upgrade Wizard or license Wizard), the following error message appears: **GUI version does not match with the kernel version. Please close this instance, clear java plug-in cache and reopen.**

Resolution

- Log on to the NetScaler appliance using the GUI.
- Navigate to NetScaler Gateway > Global Settings.
- Click Change Global Settings under Settings.
- In the details pane, under Client Experience, select Default from the UI theme list.
- Click OK.

Note: These troubleshooting steps also apply to issues with configuration loss when downgrading the software across multiple releases.

For any other issue, see the release notes, Knowledge Center articles, and FAQs.

System

Sep 05, 2013

The following topics provide information of the NetScaler system.

Administration	Manages and monitors the NetScaler appliance by using built-in features such as authentication and authorization, SNMP management, audit logging, web server logging, NTP management, and Reporting tool.
AppFlow	Provides information about the reporting capabilities of AppFlow feature of the NetScaler.
AutoScale	Describes how users of Citrix CloudPlatform can use the AutoScale feature on the NetScaler appliance to enable automatic scaling of their applications.
CloudBridge Connector	Provides help in reducing the cost of moving your applications to the cloud, reduce the risk of application failure, and increase network efficiency in your cloud environment.
Clustering	A setup of multiple nCore NetScaler appliances that ensure high availability, high throughput, and scalability of a deployment of NetScaler appliances.
EdgeSight Monitoring for NetScaler	Monitors the end-user experience with web applications that are served in a NetScaler environment.
Flex Tenancy	A methodology that allows you to tune a group of NetScaler virtual appliance instances to the unique characteristics and needs of individual applications in a complex Web 2.0 setup.
High Availability	A setup of two NetScaler appliances that ensure the high availability of NetScaler appliances.
Web Interface	Provides access to Citrix XenApp and Citrix XenDesktop applications.

Basic Operations

Jul 24, 2015

Any changes you make to the configuration of a NetScaler appliance are not saved automatically. You have to save the settings manually. When an appliance is restarted, it loads the latest saved configuration.

This document includes the following details:

- [Viewing and Saving Configurations](#)
- [Clearing the NetScaler Configuration](#)

Configurations are stored in the /nsconfig/ns.conf directory. For configurations to be available across sessions, you must save the configuration after every configuration change.

To view the running configuration by using the command line interface

At the command prompt, type:

```
show ns runningConfig
```

To view the running configuration by using the configuration utility

- Navigate to System > Diagnostics and, in the View Configuration group, click Running Configuration.

To find the difference between two configuration files by using the command line interface

At the command prompt, type:

```
diff ns config <configfile1> <configfile2>
```

To find the difference between two configuration files by using the configuration utility

- Navigate to System > Diagnostics and, in the View Configuration group, click Configuration difference.

To save configurations by using the command line interface

At the command prompt, type:

```
save ns config
```

To save configurations by using the configuration utility

On the Configuration tab, in the top-right corner, click the Save icon.

To view the saved configurations by using the command line interface

At the command prompt, type:

```
show ns ns.conf
```

To view the saved configurations by using the configuration utility

Navigate to System > Diagnostics and, in the View Configuration group, click Saved Configuration.

You have the following three options for clearing the NetScaler configuration.

Basic level. Clearing your configuration at the basic level clears all settings except the following:

- NSIP, MIP(s), and SNIP(s)
- Network settings (Default Gateway, VLAN, RHI, NTP, and DNS settings)
- HA node definitions
- Feature and mode settings
- Default administrator password (nsroot)

Extended level. Clearing your configuration at the extended level clears all settings except the following:

- NSIP, MIP(s), and SNIP(s)
- Network settings (Default Gateway, VLAN, RHI, NTP, and DNS settings)
- HA node definitions

Feature and mode settings revert to their default values.

Full level. Clearing your configuration at the full level returns all settings to their factory default values. However, the NSIP and default gateway are not changed, because changing them could cause the appliance to lose network connectivity.

To clear the configuration by using the command line interface

At the command prompt, type:

```
clear ns config -force <level>
```

Example: To forcefully clear the basic configurations on an appliance.

```
clear ns config -force basic
```

To clear the configuration by using the configuration utility

- Navigate to System > Diagnostics and, in the Maintenance group, click Clear Configuration and select the configuration level to be cleared from the appliance.

Configuring Clock Synchronization

Jul 24, 2015

You can configure your NetScaler appliance to synchronize its local clock with a Network Time Protocol (NTP) server. This ensures that its clock has the same date and time settings as the other servers on your network.

You can configure clock synchronization on your appliance by adding NTP server entries to the `ntp.conf` file from either the configuration utility or the command line interface, or by manually modifying the `ntp.conf` file and then starting the NTP daemon (NTPD). The clock synchronization configuration does not change if the appliance is restarted, upgraded, or downgraded. However, the configuration does not get propagated to the secondary NetScaler in a high availability setup.

Note: If you do not have a local NTP server, you can find a list of public, open access, NTP servers at the official NTP site, <http://www.ntp.org>, under Public Time Servers List. Before configuring your NetScaler to use a public NTP server, be sure to read the Rules of Engagement page (link included on all Public Time Servers pages).

This document includes the following details:

- [Setting Up Clock Synchronization](#)
- [Starting the NTP Daemon](#)
- [Configuring Clock Synchronization Manually](#)

Setting Up Clock Synchronization

Updated: 2014-08-18

To configure clock synchronization, you must add NTP servers and then enable NTP synchronization.

To add an NTP server by using the command line interface

At the command prompt, type the following commands to add an NTP server and verify the configuration:

- `add ntp server (<serverIP> | <serverName>) [-minpoll <positive_integer>] [-maxpoll <positive_integer>]`
- `show ntp server`

Example

```
> add ntp server 10.102.29.30 -minpoll 6 -maxpoll 11
```

To configure an NTP server by using the configuration utility

Navigate to System > NTP Servers, and create the NTP server.

Starting the NTP Daemon

Updated: 2014-08-08

When you enable NTP synchronization, the NetScaler starts the NTP daemon and uses the NTP server entries in the `ntp.conf` file to synchronize its local time setting. If you do not want to synchronize the appliance time with the other servers in the network, you can disable NTP synchronization, which stops the NTP daemon (NTPD).

To enable NTP synchronization by using the command line interface

At the command prompt, type one of the following commands:

```
enable ntp sync
```

To enable NTP synchronization by using the configuration utility

Navigate to System > NTP Servers, click Action and select NTP Synchronization.

Configuring Clock Synchronization Manually

Updated: 2013-08-23

You can configure clock synchronization manually by logging on to the NetScaler and editing the ntp.conf file.

To enable clock synchronization on your NetScaler by modifying the ntp.conf file

1. Log on to the command line interface.
2. Switch to the shell prompt.
3. Copy the /etc/ntp.conf file to /nsconfig/ntp.conf, unless the /nsconfig directory already contains an ntp.conf file.
4. Check the /nsconfig/ntp.conf file for the following entries and, if they are present, remove them:
restrict localhost

restrict 127.0.0.2
5. Add the IP address for the desired NTP server to the /nsconfig/ntp.conf file, beneath the file's server and restrict entries.
Note: For security reasons, there should be a corresponding restrict entry for each server entry.
6. If the /nsconfig directory does not contain a file named rc.netscaler, create the file.
7. Add the following entry to /nsconfig/rc.netscaler: /usr/sbin/ntpd -c /nsconfig/ntp.conf -l /var/log/ntpd.log &
This entry starts the ntpd service, checks the ntp.conf file, and logs messages in the /var/log directory.

This process runs every time the NetScaler is restarted.

8. Reboot the NetScaler to enable clock synchronization.

Note:

If you want to start the time synchronization process without restarting the NetScaler, run the following command from the shell prompt:

```
/usr/sbin/ntpd -c /nsconfig/ntp.conf -l /var/log/ntpd.log &
```

Configuring System Session Timeout

Sep 12, 2014

A session timeout interval is provided to restrict the time duration for which a session (GUI, CLI, or API) remains active when not in use. For the NetScaler, the system session timeout can be configured at the following levels:

- **User level timeout.** Applicable to the specific user.

GUI	Navigate to System > User Administration > Users, select a user, and edit the user's timeout setting.
CLI	At the command prompt, enter the following command: set system user <name> -timeout <secs>

- **User group level timeout.** Applicable to all users in the group.

GUI	Navigate to System > User Administration > Groups, select a group, and edit the group's timeout setting.
CLI	At the command prompt, enter the following command: set system group <groupName> -timeout <secs>

- **Global system timeout.** Applicable to all users and users from groups who do not have a timeout configured.

GUI	Navigate to System > Settings, click Change global system settings, and update the timeout value as required.
CLI	At the command prompt, enter the following command: set system parameter -timeout <secs>

The timeout value specified for a user has the highest priority. If timeout is not configured for the user, the timeout configured for a member group is considered. If timeout is not specified for a group (or the user does not belong to a group), the globally configured timeout value is considered. If timeout is not configured at any level, the default value of 900 seconds is set as the system session timeout.

Additionally, you can specify timeout durations for each of the interfaces you are accessing. However, the timeout value specified for a specific interface is restricted to the timeout value configured for the user that is accessing the interface. For example, let us consider an user "publicadmin" who has a timeout value of 20 minutes. Now, when accessing an interface, the user must specify a timeout value that is within 20 minutes.

Note: You can choose to keep a check on the minimum and maximum timeout values by specifying the timeout as restricted (in CLI by specifying the restrictedTimeout parameter). This parameter is provided to account for previous NetScaler versions where the timeout value was not restricted.

- When enabled, the minimum configurable timeout value is 5 minutes (300 secs) and the maximum value is 1 day (86400 secs). If the timeout value is already configured to a value larger than 1 day, when this parameter is enabled, you are prompted to change it. If you do not change the value, the timeout value will automatically be reconfigured to the default timeout duration of 15 minutes (900 secs) on next reboot. The same will happen if the configured timeout value is less than 5 minutes.

- When disabled, the configured timeout durations are considered.

To configure the timeout duration at each interface:

NetScaler user interface	Timeout configuration
CLI	Specify the timeout value on the command prompt by using the following command: set cli mode -timeout <secs>
API	Specify the timeout value in the login payload.

Viewing the System Date and Time

Aug 08, 2014

To change the system date and time, you must use the shell interface to the underlying FreeBSD OS. However, to view the system date and time, you can use the command line interface or the configuration utility.

To view the system date and time by using the command line interface

At the command prompt, type:

```
show ns config
```

To view the system date and time by using the configuration utility

Navigate to System and select the System Information tab to view the system date.

Backing up and Restoring the NetScaler Appliance

Nov 21, 2016

You can back up the current state of a NetScaler appliance, and later use the backed up files to restore the appliance to the same state. You must use this feature before performing an upgrade or for precautionary reasons. A backup of a stable system enables you to restore the system to a stable point in the event that it becomes unstable.

Points to remember

- Sysid and Interfaces should be same.
- Network configuration should be supported on New Platform.
- New Platform build should be either same of backup file or higher version than it.

This document includes the following details:

- [Backing up a NetScaler Appliance](#)
- [Restoring the NetScaler Appliance](#)

Backing up a NetScaler Appliance

Updated: 2015-03-11

Depending on the type of data to be backed up and the frequency at which you will create a backup, you can take a basic backup or a full backup.

- **Basic backup.** Backs up only configuration files. You might want to perform this type of backup frequently, because the files it backs up change constantly. The files that are backed up are:

Directory	Sub-Directory or Files
/nsconfig/	<ul style="list-style-type: none">• ns.conf• ZebOS.conf• rc.netscaler• snmpd.conf• nsbefore.sh• nsafter.sh• inetd.conf• ntp.conf• syslog.conf• newsyslog.conf• crontab• host.conf• hosts• ttys• sshd_config• httpd.conf• monitrc• rc.conf• ssh_config

Directory	Sub-Directory or Files
	<ul style="list-style-type: none"> • localtime • issue • issue.net
/var/	<ul style="list-style-type: none"> • download/* • log/wicmd.log • wi/tomcat/webapps/* • wi/tomcat/logs/* • wi/tomcat/conf/catalina/localhost/* • nslw.bin/etc/krb.conf • nslw.bin/etc/krb.keytab • netscaler/locdb/* • lib/likewise/db/* • vpn/bookmark/* • netscaler/crl • nstemplates/* • learnt_data/*
/netscaler/	<ul style="list-style-type: none"> • custom.html • vsr.htm

- **Full backup.** In addition to the files that are backed up by a basic backup, a full backup backs up some less frequently updated files. The files that are backed up when using the full backup option are:

Directory	Sub-Directory or Files
/nsconfig/	<ul style="list-style-type: none"> • ssl/* • license/* • fips/*
/var/	<ul style="list-style-type: none"> • netscaler/ssl/* • wi/java_home/jre/lib/security/cacerts/* • wi/java_home/lib/security/cacerts/*

The backup is stored as a compressed TAR file in the `/var/ns_sys_backup/` directory. To avoid issues due to non-availability of disk space, you can store a maximum of 50 backup files in this directory. You can use the `rm` system backup command to delete existing backup files so that you can create more backups.

Note:

- While the backup operation is in progress, do not execute commands that affect the configuration.
- If a file that is required to be backed up is not available, the operation skips that file.

To backup the NetScaler by using the NetScaler command line interface

At the command prompt, do the following:

1. Save the NetScaler configurations.

```
save ns config
```

2. Create the backup file.

```
create system backup [<fileName>] -level <basic | full> -comment <string>
```

Note: If the file name is not specified, the appliance creates a TAR file with the following naming convention:
backup_<level>_<nsip_address>_<date-timestamp>.tgz.

Example: To backup the full appliance using the default naming convention for the backup file.

```
> create system backup -level full
```

3. Verify that the backup file was created.

```
show system backup
```

You can view properties of a specific backup file by using the fileName parameter.

To backup the NetScaler by using the configuration utility

Navigate to System > Backup and Restore, click Backup and then specify the details of the backup.

Restoring the NetScaler Appliance

When you restore the appliance from a backup file, the restore operation untars the backup file into the /var/ns_sys_backup/ directory. Once the untar operation is complete, the files are copied to their respective directories.

Attention: The restore operation does not succeed if the backup file is renamed or if the contents of the file are modified.

To restore the NetScaler by using the command line interface

At the command prompt, do the following:

1. Obtain a list of the backup files available on the appliance.

```
show system backup
```
2. Restore the appliance by specifying one of the backup files.

```
restore system backup <filename>
```

Example: To restore by using a full backup of an appliance.

```
> restore system backup backup_full_<nsip_address>_<date-timestamp>.tgz
```

3. Reboot the appliance.

```
reboot
```

To restore the NetScaler by using the configuration utility

Navigate to System > Backup and Restore, right-click the backup file to be restored and click Restore.

Restarting or Shutting down the Appliance

Sep 16, 2014

The NetScaler appliance can be remotely restarted or shut down from the available user interfaces. When a standalone NetScaler appliance is restarted or shut down, the unsaved configurations (configurations performed since the last `save ns config` command was issued) are lost.

In a high availability setup, when the primary appliance is rebooted/shut down, the secondary appliance takes over and becomes the primary. The unsaved configurations from the old primary are available on the new primary appliance.

You can also restart the appliance by only rebooting the NetScaler software and not rebooting the underlying operating system. This is called a warm reboot. For example, when you add a new license or change the NetScaler IP address, you can warm reboot the NetScaler appliance for these changes to take place.

Note: Warm reboot can be performed only on nCore appliances.

To restart the NetScaler by using the command line interface

At the command prompt, type:

```
reboot [-warm]
```

To restart the NetScaler by using the configuration utility

1. In the configuration utility, click Reboot on the home page of the Configuration tab.
2. When prompted to reboot, select Save configuration to make sure that you do not lose any configurations.

Note: You can perform a warm reboot by selecting Warm reboot.

To shut down the NetScaler by using the command line interface

At the command prompt, type:

- `shutdown -p now`: Shuts down the software and switches off the NetScaler. To restart NetScaler MPX, press the AC power switch. To Restart NetScaler VPX, restart the VPX instance.
- `shutdown -h now`: Shuts down the software and leaves the NetScaler switched on. Press any key to restart the NetScaler. This command does not switch off the NetScaler. Therefore, do not switch off the AC power or remove the AC power cables.

Note: The appliance cannot be shut down from the configuration utility.

Admin Partitioning

Nov 16, 2015

Click [here](#) for the Admin Partitioning documentation for NetScaler versions 11.0 and 10.5.

About the Admin Partitions Release

Nov 20, 2014

Review the release notes for the NetScaler 10.5 Enhancement (Admin Partitions) Build 52.1155.e release. This release is based on main release NetScaler 10.5 Build 52.11.

Release history:

- Build 52.1155.e (2014-11-18) (Current build)

This release notes includes information of all enhancement (Admin Partitions) builds of NetScaler 10.5 .

Note:

- This release notes does not document security fixes. To check if this build fixed any security issues, please refer to the security bulletin that is provided by the NetScaler security team.
- You can find the build in which the issue was provided by viewing the **[From Build xxxx]** label that is provided below each issue.

Points to Note

Some important aspects to keep in mind while using Build 52.1155.e.

- For large configurations, Citrix advises that you change the maximum memory limit from the default value of 10 MB.

[From Build 52.1155.e] [#504366]

- After adding an admin partition, make sure you save the configurations on the default partition. Otherwise, the partition setup configurations will be lost on system reboot.

[From Build 52.1155.e] [#493668]

- While creating an admin partition make sure that you first bind the user to the partition and then bind the required command policy to that user.

[From Build 52.1155.e] [#500821]

Fixed Issues

The issues addressed in Build 52.1155.e.

- In admin partitions, details of interfaces are not displayed correctly.

[From Build 52.1155.e] [#511015, #512639]

- For all users, besides nsroot, failure in the execution of the "import responder htmlpage" command results in the "Done" message being displayed. This behavior is exhibited in default and non-default partitions.

[From Build 52.1155.e] [#506340]

- The NetScaler configuration utility incorrectly displays VLAN1, which cannot be bound to a partition. If you try to bind this VLAN, the following error is displayed: "Operation not permitted".

[From Build 52.1155.e] [#507394]

- Traffic domains can not be added by using the configuration utility.

[From Build 52.1155.e] [#512627]

- An invalid error message is being displayed when trying to add a VLAN.

[From Build 52.1155.e] [#513222, #512642, #512655]

- The configuration utility throws an error when the values for minimum bandwidth, maximum bandwidth, and maximum connections are either set greater than the maximum supported value or lesser than the minimum supported value. Instead, the default value should have been set.

[From Build 52.1155.e] [#510293]

- When deleting an admin partition, the NetScaler appliance can crash in some rarely occurring scenario.

[From Build 52.1155.e] [#504911, #505396]

- Logging in to a NetScaler VPX too quickly after it has boot-up can cause the appliance to become unavailable.

[From Build 52.1155.e] [#510294]

- When using the audit log feature, when deleting a partition, assert in hit when the NetScaler tries to transmit an NSB which is already freed. This issue is observed in the following scenarios:

- When force failover is done on the primary node of HA setup.

- When "clear config -f extended+" command was issued in default partition with 6 interfaces in a VPX and 2 user partitions configured with basic configs in it.

[From Build 52.1155.e] [#504101, #505766, #507193]

Known Issues

The known issues present in Build 52.1155.e.

- In a NetScaler VPX with a large number of partitions, there can be lack of available disk space as newnslog files are created frequently due to rollover. This may result in the GUI and CLI becoming inaccessible.

[From Build 52.1155.e] [#515419]

- RPCSVR services cannot be configured in admin partitions.

[From Build 52.1155.e] [#498477]

- The GSLB configurations applied in the default partition can be viewed in admin partitions. This is not expected as user must not be able to view configurations that are defined in other partitions.

[From Build 52.1155.e] [#489512]

- In a high availability (HA) deployment of NetScaler that has a high number of partitions (approximately 500) configured, the configuration synchronization might take more than 5 minutes.

[From Build 52.1155.e] [#515322]

- Even though a partition operator cannot perform the add/rm/set/unset /bind/unbind/show operation for lb vserver, service, servicegroup, app flow collector, and cs policy, the configuration utility displays these operations.

[From Build 52.1155.e] [#507995]

- The Surge protection feature cannot be configured in an admin partition. Since, surge protection parameters are part of the Change Global System Settings (System > Settings) dialog, when you try to update the global settings, the "Operation not supported" message is displayed.

[From Build 52.1155.e] [#498004]

- When configuring an admin partition, in the list of channels (Network > Channels), the state of the LACP channel is incorrectly displayed. This issue is not present in the default partition.

[From Build 52.1155.e] [#517606, #518444]

- When a partition admin tries to perform the Download, Create, or Create Directory operation on the "Manage Certificate" screen, the operation not permitted error is displayed. The expected behavior is that the buttons must be disabled.

[From Build 52.1155.e] [#491353]

- In a high availability (HA) deployment of the NetScaler, if there have been more than two failovers, the load balancing persistency of previous sessions in admin partitions is not honored.

[From Build 52.1155.e] [#517023]

- When displaying the results of the "show lb monitor" command, the numbering of the user-defined monitors restarts from 1 instead of continuing the numbering from the list of built-in monitors.

[From Build 52.1155.e] [#511222]

- In both, default or admin partitions, when trying to import a password-protected key file, you get an error indicating that the key file is invalid. This error occurs because the NetScaler cannot import such key files.

[From Build 52.1155.e] [#512334]

- The maximum memory that can be configured for an admin partition is 2048 MB. Setting a value greater than this means that the value is automatically truncated to 2048 MB. This memory limit is per packet engine of the NetScaler.

[From Build 52.1155.e] [#504426]

- The Path MTU (PMTU) details are maintained at the global level instead of being maintained for each admin partition. This may cause NetScaler to use smaller segment size (MSS) to some hosts from all partitions even when some partitions may have routes which allow larger MSS.

[From Build 52.1155.e] [#502352]

- For a weblog client that is deployed on Linux, if there are more than 100 admin partitions, the partition names are not displayed properly.

[From Build 52.1155.e] [#518461]

- NetScaler might bypass TCP buffering for connections in non-default partitions since the memory pool is not initialized properly.

[From Build 52.1155.e] [#496522]

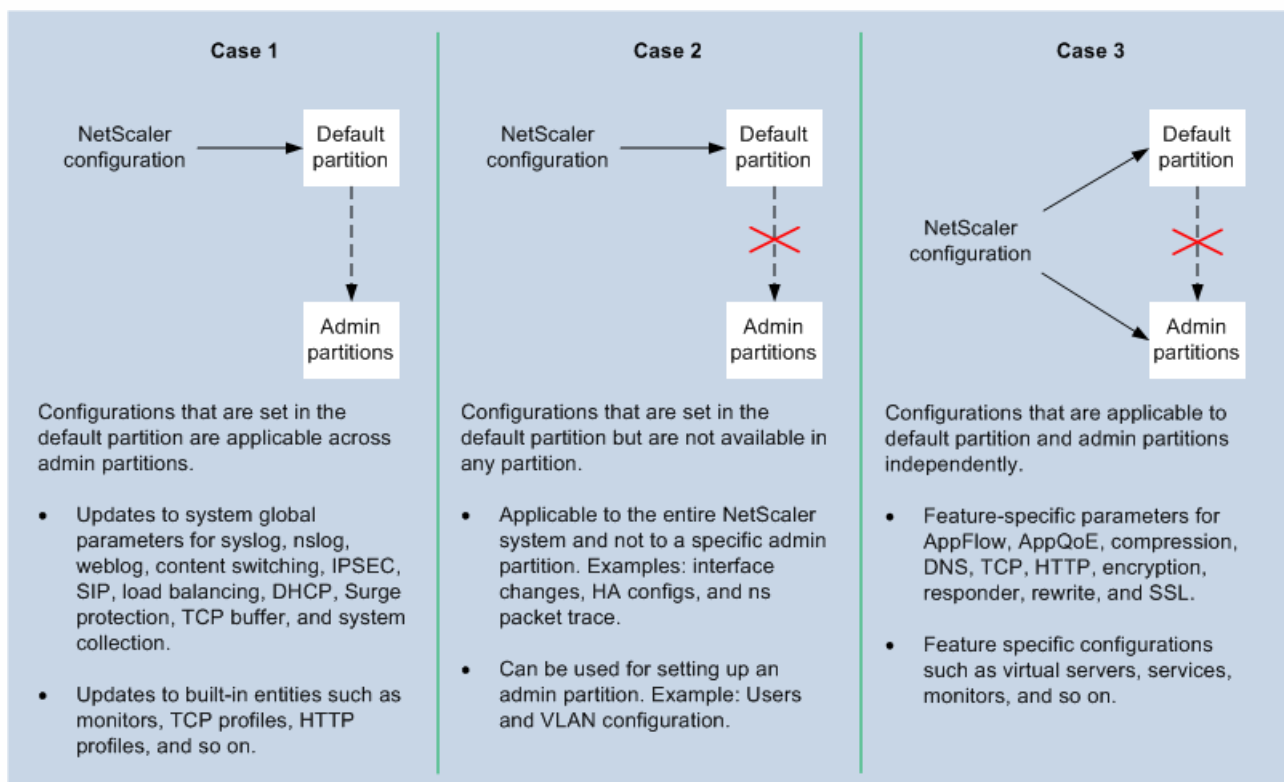

Types of Partitions

Apr 07, 2015

The NetScaler ADC ships with a single partition that is called the default partition. When the NetScaler is partitioned (when required to isolate the configurations or traffic), then, in addition to the default partition, the NetScaler can have one or more (maximum of 512) admin partitions. For details on default and admin partitions, see [table](#) that is provided below.

In a partitioned NetScaler, NetScaler configurations can be defined as follows:

- **Global NetScaler configurations.** NetScaler configurations that are globally available (not restricted to specific partitions) must be defined in the default partition. Check Case 1 and Case 2 in the graphical illustration provided below.
- **Partition-specific configurations.** NetScaler configurations that must be available on specific admin partitions can be defined on that admin partition. Check Case 3 in the graphical illustration provided below.

The following table provides details of default and admin partitions.

	Default partition	Admin partitions
Users	By default, the following users have access to the default partition: <ul style="list-style-type: none"> • NetScaler superusers (including nsroot) • NetScaler users who are not associated with a command policy that starts with partition-. 	NetScaler superuser and other users who have been associated with that partition. Note: Partition users do not have shell access.

File structure	<p>Default partition</p> <p>Uses the default file structure.</p> <p>For example, the NetScaler configuration files for default partition are stored in the /nsconfig directory. Similarly, log files are stored in the /var/log/ directory.</p> <p>The same logic applies for SSL certificates for the default partition.</p>	<p>Admin partitions</p> <p>NetScaler configurations for an admin partition are stored in the /nsconfig/partitions/<partitionName>/ns.conf file.</p> <p>Other partition-specific files are stored in the /var/partitions/<partitionName> directory.</p> <p>For example:</p> <ul style="list-style-type: none"> • /var/partitions/<partitionName>/download/ - To store downloaded files • /var/partitions/<partitionName>/log - To store partition specific log files. Currently, however, logging is not supported at partition-level. Therefore, this directory is empty and all logs are stored in the /var/log/ directory. • /var/partitions/<partitionName>/netscaler/ssl - To store SSL CRL certificate related files
Resources available	All NetScaler resources.	NetScaler resources that are explicitly assigned to the partition.

Benefits and Uses of Admin Partitions

Nov 14, 2014

Admin partitions provide the following benefits:

- Allows delegation of administrative ownership of an application to the customer.
- Reduces the cost of ADC ownership without compromising on performance and ease-of-use.
- Safeguards from unwarranted configuration changes. In a non-partitioned NetScaler, authorized users of other application could intentionally or unintentionally change configurations that are required for your application. This could lead to undesirable behavior. This possibility is reduced in a partitioned NetScaler.
- Accelerates and allows to scale application deployments.
- Allows application-level or localized management and reporting.

Let us analyze a couple of scenarios and see how admin partitioning provides some of the benefits listed above.

Case 1 : To understand how an enterprise can benefit from this feature, consider a scenario faced by a company named Foo.com:

- Foo.com has a single NetScaler ADC.
- There are five departments and each department has one application that requires to be deployed with the NetScaler.
- Each application must be managed independently by a different set of users or administrators. Other users must be restricted from accessing the configurations.
- The application or back-end must be able to share resources like IP addresses.
- The global IT department must be able to control NetScaler-level settings which must be common to all partitions.
- Applications must be independent of one another. An error in configuration of one application must not affect the other.

A non-partitioned NetScaler would not be able to satisfy these requirements. However, you can achieve all these requirements by partitioning a NetScaler.

Simply create a partition for each of the applications, assign the required users to the partitions, specify the VLAN for each partition, and define global settings on the default partition.

Case 2 : To understand how a service provider can benefit from this feature, consider a scenario faced by a service provider named BigProvider:

- BigProvider has 5 customers: 3 small enterprises and 2 large enterprises.
- SmallBiz, SmallerBiz, and StartupBiz need only the most basic NetScaler functionality.
- BigBiz and LargeBiz are larger enterprises and have applications that attract a lot of traffic. They would like to use some of the more complex NetScaler functionality.

In a non-partitioned approach, the NetScaler administrator would typically use a NetScaler SDX appliance and provision a NetScaler instance for each customer. This solution would suit BigBiz and LargeBiz, because their applications need the undiminished power of the entire non-partitioned NetScaler. However, this solution might not be cost effective for servicing SmallBiz, SmallerBiz, and StartupBiz.

Therefore, BigProvider decides that admin partitioning is the way forward. They use NetScaler SDX appliance to bring up dedicated NetScaler instances for BigBiz and LargeBiz. They use a single NetScaler which is partitioned into three partitions, one each for SmallBiz, SmallerBiz, and StartupBiz.

The NetScaler administrator (superuser) then creates an admin partition for each of the small customers, specifies the users for the partitions, specifies the NetScaler resources for the partitions, and specifies the VLAN to be used by the traffic that is destined for each of the partitions.

NetScaler Feature-level Support in Admin Partitions

Sep 16, 2016

As described in [types of partitions](#), NetScaler configurations that are defined for individual admin partitions are called partition-specific configurations. There are some NetScaler features that cannot be defined in admin partitions, while being configurable in the default partition. The following table lists the configurations that are currently not partition-specific, that is, cannot be configured in admin partitions.

Note:

- Admin partitions cannot be set up in a NetScaler cluster.
- Subsequent release of the NetScaler appliance will provide support for these features.

	Group	Feature	NetSCALER 10.5
	Policy	Extensibility	No
	LB	DBS AutoScale	No
	LB	DNSSEC	No
	LB	Diameter	No
	LB	RTSP	No

Policies	OCSP Responder	No
SSL	SSL-FIPS	No

Partitioning a NetScaler

Dec 10, 2014

Note: Only superusers are authorized to partition a NetScaler.

Setting up an admin partition requires the following operations:

1. Create an admin partition and allocate the required NetScaler resources to that partition.
2. Specify the users that can access this partition.
3. Specify the level of authorization (using command policies) each user has in the partition.
4. Specify the configurations to isolate traffic across partitions.

After partitioning the NetScaler, make sure the users are made aware that their NetScaler configurations are now isolated from users who are not members of the partition.

Note:

- All configurations to set up an admin partition must be done from the default partition.
- Make sure the relevant users, command policies, VLANs, and bridgegroups are available on the NetScaler appliance.

To partition a NetScaler by using the command line interface

On the command prompt, do the following:

1. Create a partition and configure the NetScaler resources for that partition.
`add ns partition <partitionName> [-maxBandwidth <positive_integer>] [-minBandwidth <positive_integer>] [-maxConn <positive_integer>] [-maxMemLimit <positive_integer>]`

Note:

- For deployments that have large size of NetScaler configuration and large quantum of traffic, Citrix advises that you change the maximum memory limit from the default value of 10 MB.
 - Use the `set ns partition` command if you want to modify any configuration settings.
2. Associate the appropriate users with the partition.
`bind system user <name> -partitionName <string>`
 3. Associate one of the following command policies with the user: `partition-operator`, `partition-read-only`, `partition-network`, and `partition-admin`.
`bind system user <name> <policyName> <priority>`
 4. Configure the VLAN through which traffic for this partition must be routed. You can use bridgegroups instead of VLANs to route the traffic.
 - Add the VLAN and bind the required interfaces to it.
`add vlan <id>`

`bind vlan <id> -ifnum <interface>`

OR

- Add the bridgegroup and bind the required VLANs to it.
`add bridgegroup <id>`

`bind bridgegroup <id> -vlan <id>`

5. Bind the VLAN or bridgegroup to the partition.

```
bind ns partition <partitionName> -vlan <positive_ integer>
```

OR

```
bind ns partition <partitionName> -bridgegroup <positive_ integer>
```

Note: Use the show vlan or the show bridgegroup command to view the partitions associated with that VLAN or bridgegroup.

6. Verify the configurations of the partition.

```
show ns partition <partitionName>
```

Note: You can also use the stat ns partition command to view partition configurations.

7. Save the configuration.

```
save ns config
```

To partition a NetScaler by using the configuration utility

On the Configuration tab of the graphical user interface:

1. Navigate to System > Partition Administration, click Add and do the following:

1. Create and configure the resources for the admin partition.
2. Specify the VLANs or bridgegroups to be associated with the partition.
3. Associate user(s) with the partition.

Note: Make sure you bind users who are not yet associated with partition type command policies.

2. Navigate to System > User Administration, and to the partition user, bind the appropriate command policy. The command policy must be one of the partition- entries. The choice depends on the level of authorization you intend the user to have.
3. Save the configuration.

Configuring in a NetScaler Partition

Dec 10, 2014

Accessing a partitioned NetScaler is the same as accessing a non-partitioned NetScaler: through the NetScaler IP (NSIP) address or any other management IP address. As a user, after you provide your valid logon credentials, you are taken to the partition to which you are bound. Any configurations that you create are saved to that partition. If you are associated with more than one partition, you are taken to the first partition with which you were associated. If you want to configure entities on one of your other partitions, you must explicitly switch to that partition.

Note:

- NetScaler superusers and other non-partition users are taken to the default partition.
- Users of all the 512 partitions can log in simultaneously.

After accessing the appropriate partition, configurations that you perform are saved to that partition and are specific to that partition.

To configure in a NetScaler partition by using the command line interface

1. Log on to the NetScaler.
2. Check if you are in the correct partition. The command prompt displays the name of the currently selected partition.
 - If yes, skip to the next step.
 - If no, get a list of the partitions with which you are associated and switch over to the appropriate partition.
 1. `show system user <username>`
 2. `switch ns partition <partitionName>`
3. Now, you can perform the required configurations on the NetScaler just as you would do on a non-partitioned NetScaler.

To configure in a NetScaler partition by using the configuration utility

1. Log on to the NetScaler.
2. Check if you are in the correct partition. The top bar of the graphical user interface displays the name of the currently selected partition.
 - If yes, skip to the next step.
 - If no, navigate to System > Administrative Partitions > Partitions, right-click the partition to which you want to switch, and select Switch.
3. Now, you can perform the required configurations on the NetScaler just as you would do on a non-partitioned NetScaler.

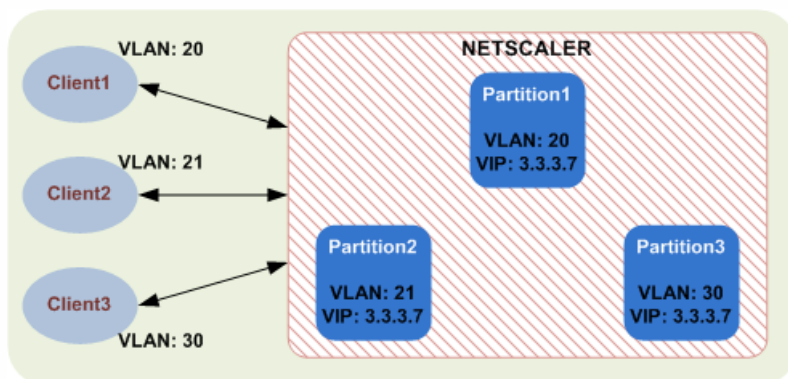

Use Case: Resource Sharing Across Admin Partitions

Dec 10, 2014

By using admin partitions, resources such as IP addresses and entity names can be shared across different partitions. This means that you can now use an IP address (for example, 3.3.3.7) as the virtual server IP address across partitions or use the same name (for example, lbvserver1) for multiple virtual servers across partitions.

This is possible as each partition is associated with a different VLAN (or bridgegroup) and therefore traffic destined for different applications is segregated.

As shown in the following image, the virtual server IP address 3.3.3.7 is used in Partition1, Partition2, and Partition3.

Let us understand how the configurations must be performed.

Creating and configuring partitions that share the same IP address among virtual servers

1. **On default partition:** Log on to the NetScaler appliance as a super user and configure the three partitions as follows:

```
shell> ssh 10.102.29.60 -l nsroot
password: *****
```

```
> add ns partition Partition1
Done
```

```
> add ns partition Partition2
Done
```

```
> add ns partition Partition3
Done
```

```
> bind system user user1 -partitionName Partition1
Done
```

```
> bind system user user2 -partitionName Partition2
Done
```

```
> bind system user user3 -partitionName Partition3
Done
```

```
> bind system user user1 partition-admin 10
```

```
Done
```

```
> bind system user user2 partition-admin 20
```

```
Done
```

```
> bind system user user3 partition-admin 20
```

```
Done
```

```
> add vlan 20
```

```
Done
```

```
> bind vlan 20 -ifnum 2/1
```

```
Done
```

```
> add vlan 21
```

```
Done
```

```
> bind vlan 21 -ifnum 3/1
```

```
Done
```

```
> add vlan 30
```

```
Done
```

```
> bind vlan 30 -ifnum 4/1
```

```
Done
```

```
> bind ns partition Partition1 -vlan 20
```

```
Done
```

```
> bind ns partition Partition2 -vlan 21
```

```
Done
```

```
> bind ns partition Partition3 -vlan 30
```

```
Done
```

2. **On Partition1:** Log on to the NetScaler appliance as user1 and configure on Partition1.

```
shell> ssh 10.102.29.60 -l user1
```

```
password: *****
```

```
Partition1> add ns ip 3.3.3.2 255.255.255.0 -vServer DISABLED -type SNIP
```

```
Done
```

```
Partition1> add service s1 3.3.3.5 HTTP 80
```

```
Done
```

```
Partition1> add lb vserver lbvserver1 HTTP 3.3.3.7 80 -persistenceType NONE
```

Done

```
Partition1> bind lb vserver lbvserver1 s1
```

Done

```
Partition1> bind vlan 20 -IPAddress 3.3.3.2 255.255.255.0
```

Done

3. **On Partition2:** Log on to the NetScaler appliance as user2 and configure on Partition2.

```
shell> ssh 10.102.29.60 -l user2
```

```
password: ****
```

```
Partition2> add ns ip 5.5.5.3 255.255.255.0 -vServer DISABLED -type SNIP
```

Done

```
Partition2> add service s1 5.5.5.5 HTTP 80
```

Done

```
Partition2> add lb vserver lbvserver1 HTTP 3.3.3.7 80 -persistenceType NONE
```

Done

```
Partition2> bind lb vserver lbvserver1 s1
```

Done

```
Partition2> bind vlan 21 -IPAddress 5.5.5.3 255.255.255.0
```

Done

4. **On Partition3:** Log on to the NetScaler appliance as user3 and configure on Partition3.

```
shell> ssh 10.102.29.60 -l user3
```

```
password: ****
```

```
Partition3> add ns ip 6.6.6.3 255.255.255.0 -vServer DISABLED -type SNIP
```

Done

```
Partition3> add service s1 6.6.6.6 HTTP 80
```

Done

```
Partition3> add lb vserver lbvserver1 HTTP 3.3.3.7 80 -persistenceType NONE
```

Done

```
Partition3> bind lb vserver lbvserver1 s1
```

Done

```
Partition3> bind vlan 30 -IPAddress 6.6.6.3 255.255.255.0
```

Done

Admin Partitions FAQs

Jun 03, 2015

How can I get auditlogs for an admin partition?

In a partitioned NetScaler, you cannot have specific log servers for a specific partition. The servers that are defined at the default partition are applicable across all admin partitions. Therefore, to view the audit logs for a specific partition, you will have to use the "show audit messages" command.

Note: The users of an admin partition do not have access to the shell and therefore are not able to access the log files.

How can I get web logs for an admin partition?

You can get the web logs for an admin partition as follows:

- For NetScaler 11 and later versions
The web logging feature must be enabled on each of the partitions that require web logging. Using the NetScaler Web Logging (NSWL) client, the NetScaler retrieves the web logs for all the partitions with which the user is associated.
- For versions prior to NetScaler 11
Web logs can be obtained only by nsroot and other superusers. Also, even though web logging is enabled on the default partition, the NetScaler Web Logging (NSWL) client fetches web logs for all the partitions.

To view the partition for each log entry, customize the log format to include the %P option. You can then filter the logs to view the logs for a specific partition.

How can I get the trace for an admin partition?

You can get the trace for an admin partition as follows:

- For NetScaler 11 and later versions
In a partitioned NetScaler appliance, the nstrace operation can be performed on individual admin partitions. The trace files are stored in the /var/partitions/<partitionName>/nstrace/directory.
- For versions prior to NetScaler 11
The nstrace operation can only be performed on the default partition. Therefore, packet captures are available for the entire NetScaler system. To get partition-specific packet captures, use VLAN-ID based filters.

How can I configure integrated caching in a partitioned NetScaler appliance?

Note: Integrated caching in admin partitions is supported from NetScaler 11 onwards.

To configure integrated caching (IC) on a partitioned NetScaler, after defining the IC memory on the default partition, the superuser can configure the IC memory on each admin partition such that the total IC memory allocated to all admin partitions does not exceed the IC memory defined on the default partition. The memory that is not configured for the admin partitions remains available for the default partition.

For example, if a NetScaler appliance with two admin partitions has 10 GB of IC memory allocated to the default partition, and IC memory allocation for the two admin partitions is as follows:

- Partition1: 4 GB
- Partition2: 3 GB

Then, the default partition has $10 - (4 + 3) = 3$ GB of IC memory available for use.

Note: If all IC memory is used by the admin partitions, no IC memory is available for the default partition.

Where can I find the logs for a partition?

NetScaler logs are not partition-specific. Log entries for all partitions must be stored in the /var/log/ directory.

Where can I get the NetScaler configuration file for a partition?

The configuration file (ns.conf) for the default partition is available in the /nsconfig directory. For admin partitions, the file is available in the /nsconfig/partitions/<partitionName> directory.

How can I get the technical support bundle specific to an admin partition?

To get the tech support bundle for a specific partition, you must execute the show techsupport -scope partition -partitionname <string> command from the default partition.

Note: This command also gives system-specific information.

What is the scope for L2 and L3 parameters in admin partitions?

Note: Applicable from NetScaler 11 onwards.

On a partitioned NetScaler appliance, the scope of updating the L2 and L3 parameters is as follows:

- For L2 parameters that are set by using the "set L2Param" command, the following parameters can be updated only from the default partition, and their values are applicable to all the admin partitions:
maxBridgeCollision, bdgSetting, garpOnVridIntf, garpReply, proxyArp, resetInterfaceOnHAfailover, and skip_proxying_bsd_traffic

The other L2 parameters can be updated in specific admin partitions, and their values are local to those partitions.

- For L3 parameters that are set by using the "set L3Param" command, all parameters can be updated in specific admin partitions, and their values are local to those partitions. Similarly, the values that are updated in the default partition are applicable only to the default partition.

How to enable dynamic routing in an admin partition?

Note: Dynamic routing in admin partitions is supported from NetScaler 11 onwards.

While dynamic routing (OSPF, RIP, BGP, ISIS, BGP+) is by default enabled on the default partition, in an admin partition, it must be enabled by using the following command:

```
set L3Param -dynamicRouting ENABLED
```

Note: A maximum of 63 partitions can run dynamic routing (62 admin partitions and 1 default partition).

On enabling dynamic routing on an admin partition, a virtual router (VR) is created.

- Each VR maintains its own vlan0 which will be displayed as vlan0_<partition-name>.
- All unbound IP addresses that are exposed to ZebOS are bound to vlan0.
- The default VR (of the default partition) shows all the VRs that are configured.
- The default VR shows the VLANs that are bound to these VRs (except default vlans).

Authentication and Authorization

Mar 17, 2014

To configure NetScaler authentication and authorization, you must first define the users who have access to the NetScaler appliance, and then you can organize these users into groups. After configuring users and groups, you need to configure command policies to define types of access, and assign the policies to users and/or groups.

You must log on as an administrator to configure users, groups, and command policies. The default NetScaler administrator user name is *nsroot*. After logging on as the default administrator, you should change the password for the nsroot account. Once you have changed the password, no user can access the NetScaler appliance until you create an account for that user. If you forget the administrator password after changing it from the default, you can reset it to nsroot.

Note: Local users can authenticate to the NetScaler even if external authentication servers are configured. You can restrict this by disabling the localAuth parameter of the set system parameter command.

Configuring Users, User Groups, and Command Policies

Oct 06, 2016

You must define your users by configuring accounts for them. To simplify the management of user accounts, you can organize them into groups. You can create command policies, or use built-in command policies, to regulate user access to commands.

You can also customize the command-line prompt for a user. Prompts can be defined in a user's configuration, in a user-group configuration, and in the global system configuration settings. The prompt displayed for a given user is determined by the following order of precedence:

1. Display the prompt as defined in the user's configuration.
2. Display the prompt as defined in the group configuration for the user's group.
3. Display the prompt as defined in the system global configuration settings.

You can now specify a timeout value for inactive CLI sessions for a system user. If a user's CLI session is idle for a time that exceeds the timeout value, the NetScaler appliance terminates the connection. The timeout can be defined in a user's configuration, in a user-group configuration, and in the global system configuration settings. The timeout for inactive CLI sessions for a user is determined by the following order of precedence:

1. Timeout value as defined in the user's configuration.
2. Timeout value as defined in the group configuration for the user's group.
3. Timeout value as defined in the global system configuration settings.

This document includes the following details:

- [Configuring User Accounts](#)
- [Configuring User Groups](#)
- [Configuring Command Policies](#)

Configuring User Accounts

Updated: 2014-08-07

To configure user accounts, you simply specify user names and passwords. You can change passwords and remove user accounts at any time.

To create a user account by using the command line interface

At the command prompt, type the following commands to create a user account and verify the configuration:

- `add system user <userName> [-promptString <string>] [-timeout <secs>]`
- `show system user <userName>`

Example

```
> add system user johnd -promptString user-%u-at-%T
```

Enter password:

Confirm password:

To configure a user account by using the configuration utility

Navigate to System > User Administration > Users, and create the user.

Configuring User Groups

Updated: 2014-08-07

After configuring a user group, you can easily grant the same access rights to everyone in the group. To configure a group, you create the group and bind users to the group. You can bind each user account to more than one group. Binding user accounts to multiple groups may allow more flexibility when applying command policies.

To create a user group by using the command line interface

At the command prompt, type the following commands to create a user group and verify the configuration:

- add system group <groupName> [-promptString <string>] [-timeout <secs>]
- show system group <groupName>

Example

```
> add system group Managers -promptString Group-Managers-at-%h
```

To bind a user to a group by using the command line interface

At the command prompt, type the following commands to bind a user account to a group and verify the configuration:

- bind system group <groupName> -userName <userName>
- show system group <groupName>

Example

```
> bind system group Managers -userName user1
```

To configure a user group by using the configuration utility

Navigate to System > User Administration > Groups, and create the user group.

Note: To add members to the group, in the Members section, click Add. Select users from the Available list and add them to the Configured list.

Configuring Command Policies

Command policies regulate which commands, command groups, virtual servers, and other entities that users and user groups are permitted to use.

The appliance provides a set of built-in command policies, and you can configure custom policies. To apply the policies, you bind them to users and/or groups.

Here are the key points to keep in mind when defining and applying command policies.

- You cannot create global command policies. Command policies must be bound directly to the users and groups on the appliance.
- Users or groups with no associated command policies are subject to the default (DENY-ALL) command policy, and are therefore unable to execute any configuration commands until the proper command policies are bound to their accounts.
- All users inherit the policies of the groups to which they belong.
- You must assign a priority to a command policy when you bind it to a user account or group account. This enables the appliance to determine which policy has priority when two or more conflicting policies apply to the same user or group.

- The following commands are available by default to any user and are unaffected by any command you specify: help, show cli attribute, set cli prompt, clear cli prompt, show cli prompt, alias, unalias, history, quit, exit,whoami, config, set cli mode, unset cli mode, and show cli mode.

Built-in Command Policies

Updated: 2015-06-15

The following table describes the built-in policies.

Table 1. Built-in Command Policies

Policy name	Allows
read-only	Read-only access to all show commands except show ns runningConfig, show ns ns.conf, and the show commands for the NetScaler command group.
operator	Read-only access and access to commands to enable and disable services and servers.
network	Full access, except to the set and unset SSL commands, show ns ns.conf, show ns runningConfig, and show gslb runningConfig commands.
sysadmin	[From NetScaler 11 onwards] A sysadmin is lower than a superuser is terms of access allowed on the appliance. A sysadmin user can perform all NetScaler operations with the following exceptions: no access to the NetScaler shell, cannot perform user configurations, cannot perform partition configurations, and some other configurations as stated in the sysadmin command policy.
superuser	Full access. Same privileges as the nsroot user.

Creating Custom Command Policies

Updated: 2015-06-15

Regular expression support is offered for users with the resources to maintain more customized expressions, and for those deployments that require the flexibility that regular expressions offer. For most users, the built-in command policies are sufficient. Users who need additional levels of control but are unfamiliar with regular expressions may want to use only simple expressions, such as those in the examples provided in this section, to maintain policy readability.

When you use a regular expression to create a command policy, keep the following in mind.

- When you use regular expressions to define commands that will be affected by a command policy, you must enclose the commands in double quotation marks. For example, to create a command policy that includes all commands that begin with show, type:

```
"^show .*$"
```

To create a command policy that includes all commands that begin with rm, type:

```
"^rm .*$"
```

- Regular expressions used in command policies are not case sensitive.

The following table lists examples of regular expressions:

Table 2. Examples of Regular Expressions for Command Policies

Command specification	Matches these commands
"^rm\s+.*\$"	All remove actions, because all remove actions begin with the rm string, followed by a space and additional parameters such as command groups, command object types and arguments.
"^show\s+.*\$"	All show commands, because all show actions begin with the show string, followed by a space and additional parameters such as command groups, command object types and arguments..
"^shell\$"	The shell command alone, but not combined with additional parameters such as command groups, command object types and arguments.
"^add\s+vserver\s+.*\$"	All create virtual server actions, which consist of the add vserver command followed by a space and additional parameters such as command groups, command object types and arguments.
"^add\s+(lb\s+vserver)\s+.*"	All create lb virtual server actions, which consist of the add lb vserver command followed by a space and additional parameters such as command groups, command object types and arguments.

The following table shows the command specifications for each of the built-in command policies.

Table 3. Expressions Used in the Built-in Command Policies

Policy name	Command specification regular expression
read-only	(^man.*)(^show\s+(?!system)(?!configstatus)(?!ns ns\.conf)(?!ns savedconfig)(?!ns runningConfig)(?!lgs lb runningConfig)(?!audit messages)(?!techsupport).*)(^stat.*)
operator	(^man.*)(^show\s+(?!system)(?!configstatus)(?!ns ns\.conf)(?!ns savedconfig)(?!ns runningConfig)(?!lgs lb runningConfig)(?!audit messages)

	(?!techsupport.*)(^stat.*)(^(enable disable) (server service).*)
network	^(?!clear ns config.*)(?!scp.*)(?!set ssl fips)(?!reset ssl fips)(?!diff ns config)(?!shell)(?!reboot)(?!batch)\S+\s+(?!system)(?!configstatus)(?!ns ns\.conf)(?!ns savedconfig)(?!ns runningConfig)(?!slb runningConfig)(?!techsupport).*
sysadmin	[From NetScaler 11 onwards] ^(?!shell)(?!sftp)(?!scp)(?!batch)(?!source)(?!.*superuser)(?!.*nsroot)(?!show\s+system\s+(user cmdPolicy))(?!(set add rm create export kill)\s+system)(?!(unbind bind)\s+system\s+(user group))(?!diff\s+ns\s+config)(?!S+\s+ns\s+partition).*
superuser	.*

To create a command policy by using the command line interface

At the command prompt, type the following commands to create a command policy and verify the configuration:

- add system cmdPolicy <policyname> <action> <cmdspec>
- show system cmdPolicy <policyName>

Example

```
> add system cmdPolicy read_all ALLOW (^show\s+(\!system)(\!ns ns.conf)(\!ns runningConfig).*)(^stat.*)
```

To configure a command policy by using the configuration utility

Navigate to System > User Administration > Command Policies, and create the command policy.

Binding Command Policies to Users and Groups

Updated: 2014-08-07

Once you have defined your command policies, you must bind them to the appropriate user accounts and groups. When you bind a policy, you must assign it a priority so that the appliance can determine which command policy to follow when two or more applicable command policies are in conflict.

Command policies are evaluated in the following order:

- Command policies bound directly to users and the corresponding groups are evaluated according to priority number. A command policy with a lower priority number is evaluated before one with a higher priority number. Therefore, any privileges the lower-numbered command policy explicitly grants or denies are not overridden by a higher-numbered command policy.
- When two command policies, one bound to a user account and other to a group, have the same priority number, the command policy bound directly to the user account is evaluated first.

To bind command policies to a user by using the command line interface

At the command prompt, type the following commands to bind a command policy to a user and verify the configuration:

- `bind system user <userName> -policyName <policyName> <priority>`
- `show system user <userName>`

Example

```
> bind system user user1 -policyName read_all 1
```

To bind command policies to a user by using the configuration utility

Navigate to System > User Administration > Users, select the user and bind command policies.

Optionally, you can modify the default priority to ensure that the policy is evaluated in the proper order.

To bind command policies to a group by using the command line interface

At the command prompt, type the following commands to bind a command policy to a group, and verify the configuration:

- `bind system group <groupName> -policyName <policyName> <priority>`
- `show system group <groupName>`

Example

```
> bind system group Managers -policyName read_all 1
```

To bind command policies to a group by using the configuration utility

Navigate to System > User Administration > Groups, select the group, and bind command policies.

Optionally, you can modify the default priority to ensure that the policy is evaluated in the proper order.

Resetting the Default Administrator (nsroot) Password

Nov 24, 2014

The nsroot account provides complete access to all features of the appliance. Therefore, to preserve security, the nsroot account should be used only when necessary, and only individuals whose duties require full access should know the password for the nsroot account. Frequently changing the nsroot password is advisable. If you lose the password, you can reset it to the default and then change it.

To reset the nsroot password, you must boot the appliance into single user mode, mount the file systems in read/write mode, and remove the set NetScaler user nsroot entry from the ns.conf file. You can then reboot, log on with the default password, and choose a new password.

To reset the nsroot password

1. Connect a computer to the console port of the NetScaler ADC and log on.
Note: You cannot log on by using SSH to perform this procedure; you must connect directly to the appliance.
2. Reboot the NetScaler ADC.
3. Press CTRL+C when the following message appears:
Press [Ctrl-C] for command prompt, or any other key to boot immediately.

Booting [kernel] in # seconds.

4. Run the following command to start the NetScaler in a single user mode:
boot -s

Note: If boot -s does not work, then try reboot -- -s and appliance will reboot in single user mode.
After the appliance boots, it displays the following message:

Enter full path name of shell or RETURN for /bin/sh:

5. Press ENTER key to display the # prompt, and type the following commands to mount the file systems:
 1. Run the following command to check the disk consistency:
fsck /dev/ad0s1a

Note: Your flash drive will have a specific device name depending on your NetScaler; hence, you have to replace ad0s1a in the preceding command with the appropriate device name.

2. Run the following command to display the mounted partitions:
df

If the flash partition is not listed, you need to mount it manually.

3. Run the following command to mount the flash drive:
mount /dev/ad0s1a /flash

6. Run the following command to change to the nsconfig directory:
cd /flash/nsconfig

7. Run the following commands to rewrite the ns.conf file and remove the set of system commands defaulting to the nsroot user:
 1. Run the following command to create a new configuration file that does not have commands defaulting to the

nsroot user:

```
grep -v "set system user nsroot" ns.conf > new.conf
```

2. Run the following command to make a backup of the existing configuration file:
mv ns.conf old.ns.conf
3. Run the following command to rename the new.conf file to ns.conf:
mv new.conf ns.conf
8. Run the following command to reboot the NetScaler:
reboot
9. Log on using the default nsroot user credentials.
10. Run the following command to reset the nsroot user password:
set system user nsroot <New_Password>

Note: To use the "?" character in a password string, precede this character with the "\" character.

For example, yourexamplepasswd\? is set for the nsroot account after you perform the following operation:

```
> set system user nsroot yourexamplepasswd\?
```

Example of a User Scenario

Sep 06, 2013

The following example shows how to create a complete set of user accounts, groups, and command policies and bind each policy to the appropriate groups and users. The company, Example Manufacturing, Inc., has three users who can access the NetScaler appliance:

- **John Doe.** The IT manager. John needs to be able to see all parts of the NetScaler configuration but does not need to modify anything.
- **Maria Ramiez.** The lead IT administrator. Maria needs to be able to see and modify all parts of the NetScaler configuration except for NetScaler commands (which local policy dictates must be performed while logged on as nsroot).
- **Michael Baldrock.** The IT administrator in charge of load balancing. Michael needs to be able to see all parts of the NetScaler configuration, but needs to modify only the load balancing functions.

The following table shows the breakdown of network information, user account names, group names, and command policies for the sample company.

Table 1. Sample Values for Creating Entities

Field	Value	Note
NetScaler host name	ns01.example.net	N/A
User accounts	johnd, mariar, and michaelb	John Doe, IT manager, Maria Ramirez, IT administrator and Michael Baldrock, IT administrator.
Groups	Managers and SysOps	All managers and all IT administrators.
Command Policies	read_all, modify_lb, and modify_all	Allow complete read-only access, Allow modify access to load balancing, and Allow complete modify access.

The following description walks you through the process of creating a complete set of user accounts, groups, and command policies on the NetScaler appliance named ns01.example.net.

The description includes procedures for binding the appropriate user accounts and groups to one another, and binding appropriate command policies to the user accounts and groups.

This example illustrates how you can use prioritization to grant precise access and privileges to each user in the IT department.

The example assumes that initial installation and configuration have already been performed on the NetScaler.

Configuration steps

1. Use the procedure described in "[Configuring User Accounts](#)" to create user accounts **johnd**, **mariar**, and **michaelb**.
2. Use the procedure described in "[Configuring User Groups](#)" to create user groups **Managers** and **SysOps**, and then bind the users **mariar** and **michaelb** to the **SysOps** group and the user **johnd** to the **Managers** group.

3. Use the procedure described in "[Creating Custom Command Policies](#)" to create the following command policies:
 - **read_all** with action **Allow** and command spec "(^show\s+(?!system)(?!ns ns.conf)(?!ns runningConfig).*)|(^stat.*)"
 - **modify_lb** with action as **Allow** and the command spec "^set\s+lb\s+.*\$"
 - **modify_all** with action as **Allow** and the command spec "^\S+\s+(?!system).*"
4. Use the procedure described in "[Binding Command Policies to Users and Groups](#)" to bind the **read_all** command policy to the **SysOps** group, with priority value **1**.
5. Use the procedure described in "[Binding Command Policies to Users and Groups](#)" to bind the **modify_lb** command policy to user **michaelb**, with priority value **5**.

The configuration you just created results in the following:

- John Doe, the IT manager, has read-only access to the entire NetScaler configuration, but he cannot make modifications.
- Maria Ramirez, the IT lead, has near-complete access to all areas of the NetScaler configuration, having to log on only to perform NetScaler-level commands.
- Michael Baldrock, the IT administrator responsible for load balancing, has read-only access to the NetScaler configuration, and can modify the configuration options for load balancing.

The set of command policies that applies to a specific user is a combination of command policies applied directly to the user's account and command policies applied to the group(s) of which the user is a member.

Each time a user enters a command, the operating system searches the command policies for that user until it finds a policy with an ALLOW or DENY action that matches the command. When it finds a match, the operating system stops its command policy search and allows or denies access to the command.

If the operating system finds no matching command policy, it denies the user access to the command, in accordance with the NetScaler appliance's default deny policy.

Note: When placing a user into multiple groups, take care not to cause unintended user command restrictions or privileges. To avoid these conflicts, when organizing your users in groups, bear in mind the NetScaler command policy search procedure and policy ordering rules.

Configuring External User Authentication

Jun 01, 2015

External user authentication is the process of authenticating the users of the Citrix NetScaler appliance by using an external authentication server. The NetScaler supports LDAP, RADIUS, and TACACS+ authentication servers. To configure external user authentication, you must create authentication policies. You can configure one or many authentication policies, depending on your authentication needs. An authentication policy consists of an expression and an action. Authentication policies use NetScaler classic expressions, which are described in detail in "[Policy Configuration and Reference](#)."

After creating an authentication policy, you bind it to the system global entity and assign a priority to it. You can create simple server configurations by binding a single authentication policy to the system global entity. Or you can configure a cascade of authentication servers by binding multiple policies to the system global entity. If no authentication policies are bound to the system, users are authenticated by the onboard system.

This document includes the following details:

- [Configuring LDAP Authentication](#)
- [Configuring RADIUS Authentication](#)
- [Configuring TACACS+ Authentication](#)
- [Binding the Authentication Policies to the System Global Entity](#)

Configuring LDAP Authentication

Updated: 2014-12-29

You can configure the NetScaler appliance to authenticate user access with one or more LDAP servers. LDAP authorization requires identical group names in Active Directory, on the LDAP server, and on the appliance. The characters and case must also be the same.

By default, LDAP authentication is secured by using SSL/TLS protocol. There are two types of secure LDAP connections. In the first type, the LDAP server accepts the SSL/TLS connection on a port separate from the port used to accept clear LDAP connections. After users establish the SSL/TLS connection, LDAP traffic can be sent over the connection. The second type allows both unsecured and secure LDAP connections and is handled by a single port on the server. In this scenario, to create a secure connection, the client first establishes a clear LDAP connection. Then the LDAP command StartTLS is sent to the server over the connection. If the LDAP server supports StartTLS, the connection is converted to a secure LDAP connection by using TLS.

The port numbers for LDAP connections are:

- 389 for unsecured LDAP connections
- 636 for secure LDAP connections
- 3268 for Microsoft unsecure LDAP connections
- 3269 for Microsoft secure LDAP connections

LDAP connections that use the StartTLS command use port number 389. If port numbers 389 or 3268 are configured on the appliance, it tries to use StartTLS to make the connection. If any other port number is used, connection attempts use SSL/TLS. If StartTLS or SSL/TLS cannot be used, the connection fails.

When configuring the LDAP server, the case of the alphabetic characters must match that on the server and on the appliance. If the root directory of the LDAP server is specified, all of the subdirectories are also searched to find the user attribute. In large directories, this can affect performance. For this reason, Citrix recommends that you use a specific organizational unit (OU).

The following table lists examples of user attribute fields for LDAP servers.

Table 1. User Attribute Fields for LDAP Servers

LDAP server	User attribute	Case sensitive?
Microsoft Active Directory	Server sAMAccountName	No
Novell eDirectory	cn	Yes
IBM Directory Server	uid	Yes
Lotus Domino	CN	Yes
Sun ONE directory (formerly iPlanet)	uid or cn	Yes

The following table lists examples of the base distinguished name (DN).

Table 2. Examples of Base Distinguished Name

LDAP server	Base DN
Microsoft Active Directory	DC=citrix, DC=local
Novell eDirectory	dc=citrix, dc=net
IBM Directory Server	cn=users
Lotus Domino	OU=City, O=Citrix, C=US

Sun ONE directory (formerly iPlanet) LDAP server	ou=People, dc=citrix, dc=com Base DN
---	---

The following table lists examples of the bind distinguished name (DN).

Table 3. Examples of Bind Distinguished Name

LDAP server	Bind DN
Microsoft Active Directory	CN=Administrator, CN=Users, DC=citrix, DC=local
Novell eDirectory	cn=admin, dc=citrix, dc=net
IBM Directory Server	LDAP_dn
Lotus Domino	CN=Notes Administrator, O=Citrix, C=US
Sun ONE directory (formerly iPlanet)	uid=admin, ou=Administrators, ou=TopologyManagement, o=NetscapeRoot

To configure LDAP authentication by using the command line interface

At the command prompt, do the following:

1. Create an LDAP action.

```
add authentication ldapAction <name> {-serverIP <ip_addr|ipv6_addr|*> | {-serverName <string>}} > [-authTimeout <positive_integer>] [-ldapBase <string>] [-ldapBindDn <string>]
{-ldapBindDnPassword } [-ldapLoginName <string>] [-groupName <string>] [-subAttributeName <string>]
```

Example:

```
add authentication ldapAction ldap70 -serverIP <IP> -authTimeout 30 -ldapBase "CN=xxxxx,DC=xxxx,DC=xxx" -ldapBindDn "CN=xxxxx,CN=xxxxx,DC=xxxx,DC=xxx" -ldapBindDnPassword abcd -lde
```

2. Create an LDAP policy.

```
add authentication ldapPolicy <name> <rule> [<reqAction>]
```

Example:

```
add authentication ldappolicy ldap_pol ns_true ldap70
```

3. Bind the LDAP policy to the following bind points at which the policy will be evaluated.

- **System Global:** bind system global <policyName> [-priority <positive_integer>]
- **VPN Global:** bind vpn global <policyName> [-priority <positive_integer>]
- **Authentication Server:** bind authentication vserver <name> [-policy <string>] [-priority <positive_integer>]
- **VPN Server:** bind vpn vserver <name> [-policy <string>] [-priority <positive_integer>]

To configure LDAP authentication by using the configuration utility

Navigate to System > Authentication > LDAP, and create the LDAP authentication policy.

Determining attributes in the LDAP directory

If you need help determining your LDAP directory attributes, you can easily look them up with the free LDAP browser from Softerra.

You can download the LDAP browser from the Softerra LDAP Administrator Web site at <http://www.ldapbrowser.com>. After the browser is installed, set the following attributes:

- The host name or IP address of your LDAP server.
- The port of your LDAP server. The default is 389.
- The base DN field can be left blank.
- The information provided by the LDAP browser can help you determine the base DN needed for the Authentication tab.
- The Anonymous Bind check determines whether the LDAP server requires user credentials for the browser to connect to it. If the LDAP server requires credentials, leave the check box cleared.

After completing the settings, the LDAP browser displays the profile name in the left pane and connects to the LDAP server.

Configuring RADIUS Authentication

Updated: 2014-08-08

You can configure the NetScaler appliance to authenticate user access with one or more RADIUS servers. If you are using RSA SecurID, SafeWord, or Gemalto Protiva products, use a RADIUS server.

Your configuration might require using a network access server IP address (NAS IP) or a network access server identifier (NAS ID). When configuring the appliance to use a RADIUS authentication server, use the following guidelines:

- If you enable use of the NAS IP, the appliance sends its configured IP address to the RADIUS server, rather than the source IP address used in establishing the RADIUS connection.
- If you configure the NAS ID, the appliance sends the identifier to the RADIUS server. If you do not configure the NAS ID, the appliance sends its host name to the RADIUS server.
- When the NAS IP is enabled, the appliance ignores any NAS ID that was configured by using the NAS IP to communicate with the RADIUS server.

To configure RADIUS authentication by using the configuration utility

Navigate to System > Authentication > Radius, and create the RADIUS authentication policy.

Choosing RADIUS authentication protocols

The NetScaler appliance supports implementations of RADIUS that are configured to use any of several protocols for user authentication, including:

- Password Authentication Protocol
- Challenge-Handshake Authentication Protocol (CHAP)

- Microsoft Challenge-Handshake Authentication Protocol (MS-CHAP Version 1 and Version 2)

If your deployment of the appliance is configured to use RADIUS authentication and your RADIUS server is configured to use Password Authentication Protocol, you can strengthen user authentication by assigning a strong shared secret to the RADIUS server. Strong RADIUS shared secrets consist of random sequences of uppercase and lowercase letters, numbers, and punctuation, and are at least 22 characters long. If possible, use a random character generation program to determine RADIUS shared secrets.

To further protect RADIUS traffic, assign a different shared secret to each appliance or virtual server. When you define clients on the RADIUS server, you can also assign a separate shared secret to each client. If you do this, you must configure separately each policy that uses RADIUS authentication.

Shared secrets are configured on the appliance when a RADIUS policy is created.

Configuring IP address extraction

You can configure the appliance to extract the IP address from a RADIUS server. When a user authenticates with the RADIUS server, the server returns a framed IP address that is assigned to the user. The following are attributes for IP address extraction:

- Allows a remote RADIUS server to supply an IP address from the internal network for a user logged on to the appliance.
- Allows configuration for any RADIUS attribute using the type `ipaddress`, including those that are vendor encoded.

When configuring the RADIUS server for IP address extraction, you configure the vendor identifier and the attribute type.

The vendor identifier enables the RADIUS server to assign an IP address to the client from a pool of IP addresses that are configured on the RADIUS server. The vendor ID and attributes are used to make the association between the RADIUS client and the RADIUS server. The vendor ID is the attribute in the RADIUS response that provides the IP address of the internal network. A value of zero indicates that the attribute is not vendor encoded. The attribute type is the remote IP address attribute in a RADIUS response. The minimum value is one and the maximum value is 255.

A common configuration is to extract the RADIUS attribute *framed IP address*. The vendor ID is set to zero or is not specified. The attribute type is set to eight.

To configure IP address extraction by using the configuration utility

1. Navigate to System > Authentication > Radius, and select a policy.
2. Modify the server parameters and set relevant values in Group Vendor Identifier and Group Attribute Type fields.

Configuring TACACS+ Authentication

Updated: 2014-08-07

You can configure a TACACS+ server for authentication. Similar to RADIUS authentication, TACACS+ uses a secret key, an IP address, and the port number. The default port number is 49. To configure the appliance to use a TACACS+ server, provide the server IP address and the TACACS+ secret. The port needs to be specified only when the server port number in use is something other than the default port number of 49.

To configure TACACS+ authentication by using the configuration utility

Navigate to System > Authentication > TACACS, and create the TACACS authentication policy.

After the TACACS+ server settings are configured on the appliance, bind the policy to the system global entity. For more information about binding authentication policies globally, see "[Binding the Authentication Policies to the System Global Entity](#)."

Binding the Authentication Policies to the System Global Entity

Updated: 2014-12-30

When the authentication policies are configured, bind the policies to the system global entity.

To bind an authentication policy to system global using the command line interface

At the command line prompt, do the following:

```
bind system global <policyName> [-priority <positive_integer>]
```

Example:

```
bind system global ldappol1 -priority 10
```

To bind an authentication policy to system global using the configuration utility

1. Navigate to System > Authentication, and select the authentication type.
2. On the Policies tab, click Global Bindings and bind the authentication policies.

TCP Configurations

Sep 28, 2016

TCP configurations for a NetScaler appliance can be specified in an entity called a TCP profile, which is a collection of TCP settings. The TCP profile can then be associated with services or virtual servers that want to use these TCP configurations.

A default TCP profile can be configured to set the TCP configurations that will be applied by default, globally to all services and virtual servers.

Note: When a TCP parameter has different values for service, virtual server, and globally, the value of the most-specific entity (the service) is given the highest precedence. The NetScaler appliance also provides other approaches for configuring TCP. Read on for more information.

The NetScaler appliance supports the following TCP capabilities:

- Defending TCP against spoofing attacks. The NetScaler implementation of window attenuation is RFC 4953 compliant.
- Explicit Congestion Notification (ECN), which sends notification of the network congestion status to the sender of the data and takes corrective measures for data congestion or data corruption. The NetScaler implementation of ECN is RFC 3168 compliant.
- Round Trip Time Measurement (RTTM) using the TimeStamp option. For the TimeStamp option to work, at least one side of the connection (client or server) must support it. The NetScaler implementation of TimeStamp option is RFC 1323 compliant.
- Detection of spurious retransmissions can be done using TCP duplicate selective acknowledgement (D-SACK) and forward RTO-Recovery (F-RTO). In case of spurious retransmissions, the congestion control configurations are reverted to their original state. The NetScaler implementation of D-SACK is RFC 2883 compliant, and F-RTO is RFC 5682 compliant.
- Congestion control using New-Reno, BIC, CUBIC, and TCP Westwood algorithms.
- Window scaling to increase the TCP receive window size beyond its maximum value of 65,535 bytes.
Note: Before configuring window scaling, make sure that:
 - You do not set a high value for the scale factor, because this could have adverse effects on the appliance and the network.
 - You do not configure window scaling unless you clearly know why you want to change the window size.
 - Both hosts in the TCP connection send a window scale option during connection establishment. If only one side of a connection sets this option, window scaling is not used for the connection.
 - Each connection for same session is an independent window scaling session. For example, when a client's request and the server's response flow through the appliance, it is possible to have window scaling between the client and the appliance without window scaling between the appliance and the server.
- TCP maximum congestion window size that is user configurable. The default value is 8190 bytes.
- Selective acknowledgment (SACK), using which the data receiver (either a NetScaler appliance or a client) notifies the sender about all the segments that have been received successfully.
- Forward acknowledgment (FACK) avoids TCP congestion by explicitly measuring the total number of data bytes outstanding in the network, and helping the sender (either a NetScaler ADC or a client) control the amount of data injected into the network during retransmission timeouts.
- TCP connection multiplexing enables reuse of existing TCP connections. The NetScaler appliance stores established TCP connections to the reuse pool. Whenever a client request is received, appliance checks for an available connection in the reuse pool and serves the new client if the connection is available. If it is unavailable, the appliance creates a new connection for the client request and stores the connection to the reuse pool.
NetScaler supports connection multiplexing for HTTP, SSL, and DataStream connection types.
- Dynamic receive buffering allows the receive buffer to be adjusted dynamically based on memory and network conditions.
- MPTCP connections between client and NetScaler. MPTCP connections are not supported between NetScaler and the backend server.
The NetScaler implementation of MPTCP is RFC 6824 compliant.

Note:

- For MPTCP to work, both sides of the connection (client and server) must support it. If you use the NetScaler appliance as an MPTCP gateway for your servers, the servers do not have to support MPTCP.
- The NetScaler appliance does not initiate subflows (MP_JOIN's). The appliance expects the client to initiate subflows.
- TCP keep-alive to monitor the TCP connections to verify if the peers are up.
- Extracting the TCP/IP path overlay option and inserting client-IP HTTP header. Extracting TCP/IP path overlay and inserting client-IP HTTP header. Data transport through overlay networks often uses connection termination or Network Address Translation (NAT), in which the IP address of the source client is lost. To avoid this, the Netscaler appliance extracts the TCP/IP path overlay option and inserts the source client's IP address into the HTTP header. With the IP address in the header, the web server can identify the source client that made the connection. The extracted data is valid for lifetime of the TCP connection and therefore, this prevents the next hop host from having to interpret the option again. This option is applicable only for web services that have the client-IP insertion option enabled.

Additionally, NetScaler provides configuration support for the following:

- TCP segmentation offload.
- Synchronizing cookie for TCP handshake with clients. Disabling this capability prevents SYN attack protection on the NetScaler appliance.
- Learning MSS to enable MSS learning for all the virtual servers configured on the appliance.

This document includes the following details:

- [Setting Global TCP Parameters](#)
- [Setting Service or Virtual Server Specific TCP Parameters](#)
- [Built-in TCP Profiles](#)
- [Sample TCP Configurations](#)

Setting Global TCP Parameters

Updated: 2014-08-08

The NetScaler appliance allows you to specify values for TCP parameters that are applicable to all NetScaler services and virtual servers. This can be done using:

- Default TCP profile
- [Global TCP command](#)
- [TCP buffering feature](#)

Note: The `recvBuffSize` parameter of the `set ns tcpParam` command is deprecated from release 9.2 onwards. In later releases, set the buffer size by using the `bufferSize` parameter of the `set ns tcpProfile` command. If you upgrade to a release where the `recvBuffSize` parameter is deprecated, the `bufferSize` parameter is set to its default value.

Default TCP Profile

A TCP profile, named as `nstcp_default_profile`, is used to specify TCP configurations that will be used if no TCP configurations are provided at the service or virtual server level.

Note:

- Not all TCP parameters can be configured through the default TCP profile. Some settings have to be performed by using the global TCP command (see section below).
- The default profile does not have to be explicitly bound to a service or virtual server.

To configure the default TCP profile

- Using the command line interface, at the command prompt enter:

```
set ns tcpProfile nstcp_default_profile ...
```

- On the configuration utility, navigate to System > Profiles, click TCP Profiles and update `nstcp_default_profile`.

Global TCP command

Another approach you can use to configure global TCP parameters is the global TCP command. In addition to some unique parameters, this command duplicates some parameters that can be set by using a TCP profile. Any update made to these duplicate parameters is reflected in the corresponding parameter in the default TCP profile.

For example, if the SACK parameter is updated using this approach, the value is reflected in the SACK parameter of the default TCP profile (`nstcp_default_profile`).

Note: Citrix recommends that you use this approach only for TCP parameters that are not available in the default TCP profile.

To configure the global TCP command

- Using the command line interface, at the command prompt enter:

```
set ns tcpParam ...
```

- On the configuration utility, navigate to System > Settings, click Change TCP parameters and update the required TCP parameters.

TCP buffering feature

NetScaler provides a feature called TCP buffering that you can use to specify the TCP buffer size. The feature can be enabled globally or at service level.

Note: The buffer size can also be configured in the default TCP profile. If the buffer size has different values in the TCP buffering feature and the default TCP profile, the greater value is applied. To configure the TCP buffering feature globally

- At the command prompt enter:

```
enable ns mode TCPB
```

```
set ns tcpbufParam -size <positiveInteger> -memLimit <positiveInteger>
```

- On the configuration utility, navigate to System > Settings, click Configure Modes and select TCP Buffering. And, navigate to System > Settings, click Change TCP parameters and specify the values for Buffer size and Memory usage limit.

Setting Service or Virtual Server Specific TCP Parameters

Updated: 2014-08-08

Using TCP profiles, you can specify TCP parameters for services and virtual servers. You must define a TCP profile (or use a built-in TCP profile) and associate the profile with the appropriate service and virtual server.

Note:

- You can also modify the TCP parameters of default profiles as per your requirements. For more information on built-in TCP profiles, see [Built-in TCP Profiles](#).
- You can specify the TCP buffer size at service level using the parameters specified by the TCP buffering feature. For more information, see [TCP buffering feature](#).

To specify service or virtual server level TCP configurations by using the command line interface

At the command prompt, perform the following:

1. Configure the TCP profile.

```
set ns tcpProfile <profile-name>...
```

2. Bind the TCP profile to the service or virtual server.

To bind the TCP profile to the service:

```
set service <name> ....
```

Example:

```
> set service service1 -tcpProfileName profile1
```

To bind the TCP profile to the virtual server:

```
set lb vserver <name> ....
```

Example:

```
> set lb vserver lbvserver1 -tcpProfileName profile1
```

To specify service or virtual server level TCP configurations by using the configuration utility

At the configuration utility, perform the following:

1. Configure the TCP profile.

Navigate to System > Profiles > TCP Profiles, and create the TCP profile.

2. Bind the TCP profile to the service or virtual server.

Navigate to Traffic Management > Load Balancing > Services/Virtual Servers, and create the TCP profile, which should be bound to the service or virtual server.

Built-in TCP Profiles

Updated: 2014-04-07

For convenience of configuration, the NetScaler provides some built-in TCP profiles. Review the built-in profiles listed below and select a profile and use it as it is or modify it to meet your requirements. You can bind these profiles to your required services or virtual servers.

Table 1. Built-in TCP Profiles

Built-in profile	Description
nstcp_default_profile	Represents the default global TCP settings on the appliance.
nstcp_default_tcp_lan	Useful for back-end server connections, where these servers reside on the same LAN as the appliance.
nstcp_default_tcp_lan_thin_stream	Similar to the nstcp_default_tcp_lan profile; however, the settings are tuned to small size packet flows.
nstcp_default_tcp_interactive_stream	Similar to the nstcp_default_tcp_lan profile; however, it has a reduced delayed ACK timer and ACK on PUSH packet settings.
nstcp_default_tcp_lfp	Useful for long fat pipe networks (WAN) on the client side. Long fat pipe networks have long delay, high bandwidth lines with minimal packet drops.
nstcp_default_tcp_lfp_thin_stream	Similar to the nstcp_default_tcp_lfp profile; however, the settings are tuned for small size packet flows.
nstcp_default_tcp_lnp	Useful for long narrow pipe networks (WAN) on the client side. Long narrow pipe networks have considerable packet loss once in a while.
nstcp_default_tcp_lnp_thin_stream	Similar to the nstcp_default_tcp_lnp profile; however, the settings are tuned for small size packet flows.
nstcp_internal_apps	Useful for internal applications on the appliance (for example, GSLB sitesyncing). This contains tuned window scaling and SACK options for the desired applications. This profile should not be bound to applications other than internal applications.
nstcp_default_Mobile_profile	Useful for mobile devices.
nstcp_default_XA_XD_profile	Useful for a XenApp or XenDesktop deployment.

Sample TCP Configurations

Updated: 2015-04-28

Sample command line interface examples for configuring the following:

- [Defending TCP against spoofing attacks](#)
- [Explicit Congestion Notification \(ECN\)](#)
- [Selective ACKnowledgment \(SACK\)](#)
- [Window Scaling \(WS\)](#)
- [Maximum Segment Size \(MSS\)](#)
- [NetScaler to learn the MSS of a virtual server](#)
- [TCP keep-alive](#)
- [Buffer size - using TCP profile](#)
- [Buffer size - using TCP buffering feature](#)
- [MPTCP](#)
- [Congestion control](#)
- [Dynamic receive buffering](#)

Defending TCP against spoofing attacks

Enable the NetScaler to defend TCP against spoof attacks. By default the "rstWindowAttenuation" parameter is disabled. This parameter is enabled to protect the appliance against spoofing. If you enable, it will reply with corrective acknowledgement (ACK) for an invalid sequence number. Possible values are Enabled, Disabled.

```
> set ns tcpProfile profile1 -rstWindowAttenuate ENABLED - By default the "rstWindowAttenuation" parameter is disabled. This parameter is enabled to protect the appliance against spoofing. If you enable
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

Explicit Congestion Notification (ECN)

Enable ECN on the required TCP profile.

```
> set ns tcpProfile profile1 -ECN ENABLED
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

Selective ACKnowledgment (SACK)

Enable SACK on the required TCP profile.

```
> set ns tcpProfile profile1 -SACK ENABLED
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

Window Scaling (WS)

Enable window scaling and set the window scaling factor on the required TCP profile.

```
> set ns tcpProfile profile1 -WS ENABLED -WSVal 9
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

Maximum Segment Size (MSS)

Update the MSS related configurations.

```
> set ns tcpProfile profile1 -mss 1460 -maxPktPerMss 512
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

NetScaler to learn the MSS of a virtual server

Enable the NetScaler to learn the VSS and update other related configurations.

```
> set ns tcpParam -learnVsvrMSS ENABLED -mssLearnInterval 180 -mssLearnDelay 3600
Done
```

TCP keep-alive

Enable TCP keep-alive and update other related configurations.

```
> set ns tcpProfile profile1 -KA ENABLED -KaprobeUpdateLastactivity ENABLED -KAconnIdleTime 900 -KAmaxProbes 3 -KaprobeInterval 75
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

Buffer size - using TCP profile

Specify the buffer size.

```
> set ns tcpProfile profile1 -bufferSize 8190
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

Buffer size - using TCP buffering feature

Enable the TCP buffering feature (globally or for a service) and then specify the buffer size and the memory limit.

```
> enable ns feature TCPB
Done
> set ns tcpbufParam -size 64 -memLimit 64
Done
```

MPTCP

Enable MPTCP and then set the optional MPTCP configurations.

```
> set ns tcpProfile profile1 -mptcp ENABLED
Done
> set ns tcpProfile profile1 -mptcpDropDataOnPreEstSF ENABLED -mptcpFastOpen ENABLED -mptcpSessionTimeout 7200
Done
> set ns tcpParam -mptcpConCloseOnPassiveSF ENABLED -mptcpChecksum ENABLED -mptcpSFtimeout 0 -mptcpSFReplaceTimeout 10
-mptcpMaxSF 4 -mptcpMaxPendingSF 4 -mptcpPendingJoinThreshold 0 -mptcpRTOsToSwitchSF 2 -mptcpUseBackupOnDSS ENABLED
Done
```

Congestion control

Set the required TCP congestion control algorithm.

```
> set ns tcpProfile profile1 -flavor Westwood
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

Dynamic receive buffering

Enable dynamic receive buffering on the required TCP profile.

```
> set ns tcpProfile profile1 -dynamicReceiveBuffering ENABLED
Done
```

```
> set lb vserver lbserver1 -tcpProfileName profile1  
Done
```

HTTP Configurations

Sep 30, 2016

HTTP configurations for a NetScaler appliance can be specified in an entity called an HTTP profile, which is a collection of HTTP settings. The HTTP profile can then be associated with services or virtual servers that want to use these HTTP configurations.

A default HTTP profile can be configured to set the HTTP configurations that will be applied by default, globally to all services and virtual servers.

Note: When a HTTP parameter has different values for service, virtual server, and globally, the value of the most-specific entity (the service) is given the highest precedence.

The NetScaler appliance also provides other approaches for configuring HTTP. Read on for more information.

The NetScaler supports the following HTTP capabilities:

- WebSocket protocol which allows browsers and other clients to create a bi-directional, full duplex TCP connection to the servers. The NetScaler implementation of WebSocket is RFC [6455](#) compliant.
- SPDY (Speedy). For more information, see [SPDY](#).

This document includes the following details:

- [Setting Global HTTP Parameters](#)
- [Setting Service or Virtual Server Specific HTTP Parameters](#)
- [Built-in HTTP Profiles](#)
- [Sample HTTP Configurations](#)

Setting Global HTTP Parameters

Updated: 2014-08-06

The NetScaler appliance allows you to specify values for HTTP parameters that are applicable to all NetScaler services and virtual servers. This can be done using:

- [Default HTTP profile](#)
- [Global HTTP command](#)

Default HTTP profile

A HTTP profile, named as `nshttp_default_profile`, is used to specify HTTP configurations that will be used if no HTTP configurations are provided at the service or virtual server level.

Note:

- Not all HTTP parameters can be configured through the default HTTP profile. Some settings have to be performed by using the global HTTP command (see section below).
- The default profile does not have to be explicitly bound to a service or virtual server.

To configure the default HTTP profile

- Using the command line interface, at the command prompt enter:

```
set ns httpProfile nshttp_default_profile ...
```

- On the configuration utility, navigate to System > Profiles, click HTTP Profiles and update nshttp_default_profile.

Global HTTP command

Another approach you can use to configure global HTTP parameters is the global HTTP command. In addition to some unique parameters, this command duplicates some parameters that can be set by using a HTTP profile. Any update made to these duplicate parameters is reflected in the corresponding parameter in the default HTTP profile.

For example, if the maxReusePool parameter is updated using this approach, the value is reflected in the maxReusePool parameter of the default HTTP profile (nshttp_default_profile).

Note: Citrix recommends that you use this approach only for HTTP parameters that are not available in the default HTTP profile.

To configure the global HTTP command

- Using the command line interface, at the command prompt enter:

```
set ns httpParam ...
```

- On the configuration utility, navigate to System > Settings, click Change HTTP parameters and update the required HTTP parameters.

Setting Service or Virtual Server Specific HTTP Parameters

Updated: 2014-08-07

Using HTTP profiles, you can specify HTTP parameters for services and virtual servers. You must define a HTTP profile (or use a built-in HTTP profile) and associate the profile with the appropriate service and virtual server.

Note: You can also modify the HTTP parameters of default profiles as per your requirements. For more information on built-in HTTP profiles, see [Built-in HTTP Profiles](#).

To specify service or virtual server level HTTP configurations by using the command line interface

At the command prompt, perform the following:

1. Configure the HTTP profile.

```
set ns httpProfile <profile-name>...
```

2. Bind the HTTP profile to the service or virtual server.

To bind the HTTP profile to the service:

```
set service <name> .....
```

Example:

```
> set service service1 -httpProfileName profile1
```

To bind the HTTP profile to the virtual server:

```
set lb vserver <name> .....
```

Example:

```
> set lb vserver lbvserver1 -httpProfileName profile1
```

To specify service or virtual server level HTTP configurations by using the configuration utility

At the configuration utility, perform the following:

1. Configure the HTTP profile.
Navigate to System > Profiles > HTTP Profiles, and create the HTTP profile.
2. Bind the HTTP profile to the service or virtual server.
Navigate to Traffic Management > Load Balancing > Services/Virtual Servers, and create the HTTP profile, which should be bound to the service/virtual server.

Built-in HTTP Profiles

Updated: 2014-04-25

For convenience of configuration, the NetScaler provides some built-in HTTP profiles. Review the profiles listed below and use it as it is or modify it to meet your requirements. You can bind these profiles to the required services or virtual servers.

Table 1. Built-in HTTP Profiles

Built-in profile	Description
nshttp_default_profile	Represents the default global HTTP settings on the appliance.
nshttp_default_strict_validation	Settings for deployments that require strict validation of HTTP requests and responses.

Sample HTTP Configurations

Updated: 2014-04-25

Sample command line interface examples to configure the following:

- [HTTP band statistics](#)
- [WebSocket connections](#)

HTTP band statistics

Specify the band size for HTTP requests and responses.

```
> set protocol httpBand reqBandSize 300 respBandSize 2048
Done
> show protocol httpband -type REQUEST
```

WebSocket connections

Enable webSocket on the required HTTP profile.

```
> set ns httpProfile http_profile1 -webSocket ENABLED
```

```
Done  
> set lb vserver lbvserver1 -httpProfileName profile1  
Done
```

SNMP

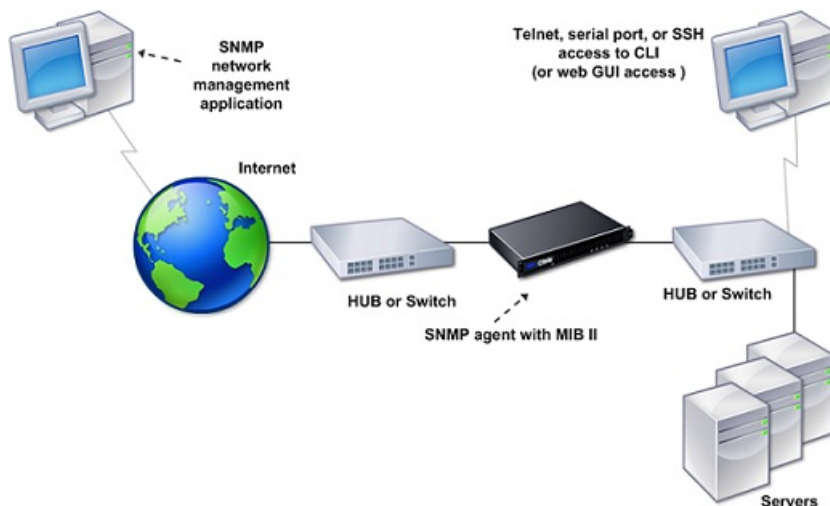

Jun 01, 2015

You can use Simple Network Management Protocol (SNMP) to configure the SNMP agent on the Citrix NetScaler appliance to generate asynchronous events, which are called *traps*. The traps are generated whenever there are abnormal conditions on the NetScaler. The traps are then sent to a remote device called a *trap listener*, which signals the abnormal condition on the NetScaler appliance. Or, you can query the SNMP agent for System-specific information from a remote device called an *SNMP manager*. The agent then searches the management information base (MIB) for the data requested and sends the data to the SNMP manager.

The SNMP agent on the NetScaler can generate traps compliant with SNMPv1, SNMPv2, and SNMPv3. For querying, the SNMP agent supports SNMP version 1 (SNMPv1), SNMP version 2 (SNMPv2), and SNMP version 3 (SNMPv3).

The following figure illustrates a network with a NetScaler that has SNMP enabled and configured. In the figure, each SNMP network management application uses SNMP to communicate with the SNMP agent on the NetScaler. The SNMP agent searches its management information base (MIB) to collect the data requested by the SNMP Manager and provides the information to the application.

Figure 1. *NetScaler Supporting SNMP*

Importing MIB Files to the SNMP Manager and Trap Listener

To monitor a NetScaler appliance, you must download the MIB object definition files. The MIB files include the following:

- MIB-2 groups SYSTEM, IF, ICMP, UDP, and SNMP.
- NetScaler-specific configuration and statistics.

You can obtain the MIB object definition files from the `/netscaler/snmp` directory or from the Downloads tab of the NetScaler GUI.

If the SNMP management application is other than WhatsUpGold, download the following files to the SNMP management application:

- NS-MIB-smiv1.mib. Used by SNMPv1 managers and trap listeners.

- NS-MIB-smiv2.mib. Used by SNMPv2 and SNMPv3 managers and SNMPv2 trap listeners.

If the SNMP management application is WhatsUpGold, download the following files to the SNMP management application:

- mib.txt
- traps.txt

Configuring the NetScaler to Generate SNMP Traps

Jun 01, 2015

You can configure the NetScaler appliance to generate asynchronous events, which are called *traps*. The traps are generated whenever there are abnormal conditions on the appliance. The traps are sent to a remote device called a *trap listener*. This helps administrators monitor the appliance and respond promptly to any issues.

The NetScaler appliance provides a set of condition entities called *SNMP alarms*. When the condition in any SNMP alarm is met, the appliance generates SNMP trap messages that are sent to the configured trap listeners. For example, when the LOGIN-FAILURE alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a login failure on the appliance.

To configure the NetScaler appliance to generate traps, you need to enable and configure alarms. Then, you specify trap listeners to which the appliance will send the generated trap messages.

This document includes the following details:

- [Enabling an SNMP Alarm](#)
- [Configuring Alarms](#)
- [Configuring SNMPv1 or SNMPv2 Traps](#)
- [Configuring SNMPv3 Traps](#)
- [Enabling Unconditional SNMP Trap Logging](#)

Enabling an SNMP Alarm

Updated: 2014-08-08

The NetScaler appliance generates traps only for SNMP alarms that are enabled. Some alarms are enabled by default, but you can disable them.

When you enable an SNMP alarm, the appliance generates corresponding trap messages when some events occur. Some alarms are enabled by default.

To enable an SNMP alarm by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `enable snmp alarm <trapName>`
- `show snmp alarm <trapName>`

To enable an SNMP alarm by using the configuration utility

1. Navigate to System > SNMP > Alarms, and select the alarm.
2. Click Actions and select Enable.

Configuring Alarms

Updated: 2014-08-06

The NetScaler appliance provides a set of condition entities called *SNMP alarms*. When the condition set for an SNMP alarm is met, the appliance generates SNMP traps messages that are sent to the configured trap listeners. For example,

when the LOGIN-FAILURE alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a login failure on the appliance.

You can assign an SNMP alarm with a severity level. When you do this, the corresponding trap messages are assigned that severity level.

The following are the severity levels, defined on the appliance, in decreasing order of severity.

- Critical
- Major
- Minor
- Warning
- Informational

For example, if you set a warning severity level for the SNMP alarm named LOGIN-FAILURE, the trap messages generated when there is a login failure will be assigned with the warning severity level.

You can also configure an SNMP alarm to log the corresponding trap messages generated whenever the condition on that alarm is met.

To configure an SNMP alarm by using the command line interface

At the command prompt, type the following commands to configure an SNMP alarm and verify the configuration:

- `set snmp alarm <trapName> [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-time <secs>] [-state (ENABLED | DISABLED)] [-severity <severity>] [-logging (ENABLED | DISABLED)]`
- `show snmp alarm <trapName>`

To configure SNMP alarms by using the configuration utility

Navigate to System > SNMP > Alarms, select an alarm and configure the alarm parameters.

Configuring SNMPv1 or SNMPv2 Traps

Updated: 2014-08-06

After configuring the alarms, you need to specify the trap listener to which the appliance sends the trap messages. Apart from specifying parameters such as IP or IPv6 address and the destination port of the trap listener, you can specify the type of trap (either generic or specific) and the SNMP version.

You can configure a maximum of 20 trap listeners for receiving either generic or specific traps.

You can also configure the appliance to send SNMP trap messages with a source IP address other than the NetScaler IP (NSIP or NSIP6) address to a particular trap listener. For a trap listener that has an IPv4 address, you can set the source IP to either a mapped IP (MIP) address or a subnet IP (SNIP) address configured on the appliance. For a trap listener that has an IPv6 address, you can set the source IP to subnet IPv6 (SNIP6) address configured on the appliance.

You can also configure the appliance to send trap messages to a trap listener on the basis of a severity level. For example, if you set the severity level as Minor for a trap listener, all trap messages of the severity level equal to or greater than Minor (Minor, Major, and Critical) are sent to the trap listener.

If you have defined a community string for the trap listener, you must also specify a community string for each trap that is

to be sent to the listener. A trap listener for which a community string has been defined accepts only trap messages that include a community string matching the community string defined in the trap listener. Other trap messages are dropped.

To add an SNMP trap by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp trap <trapClass> <trapDestination> -version (V1 | V2) -destPort <port> -communityName <string> -srcIP <ip_addr> -severity <severity>`
- `show snmp trap`

Example

```
> add snmp trap specific 10.102.29.3 -version V2 -destPort 80 -communityName com1 -severity Major
```

To configure SNMP Traps by using the configuration utility

Navigate to `System > SNMP > Traps`, and create the SNMP trap.

Configuring SNMPv3 Traps

Updated: 2014-08-08

SNMPv3 provides security capabilities such as authentication and encryption by using the credentials of SNMP users. An SNMP manager can receive SNMPv3 trap messages only if its configuration includes the password assigned to the SNMP user.

The trap destination can now receive SNMPv1, SNMPv2, and SNMPv3 trap messages.

To configure an SNMPv3 trap by using the command line interface

At the command prompt, do the following:

1. Add an SNMPv3 trap.

```
add snmp trap <trapClass> <trapDestination> -version ( V1 | V2 | V3 ) -destPort <port> -communityName <string> -srcIP <ip_addr> -severity <severity>
```

Note: Once set, the SNMP trap version cannot not be modified.

Example

```
> add snmp trap specific 10.102.29.3 -version V3 -destPort 80 -communityName com1 -severity Major
```

2. Add an SNMP user.

```
add snmp user <name> -group <string> [ -authType ( MD5 | SHA ) { -authPasswd } [-privType ( DES | AES ) { -privPasswd }]]
```

Example

```
> add snmp user edocs_user -group edocs_group
```

3. Bind the SNMPv3 trap to the SNMP user.

```
bind snmp trap <trapClass> <trapDestination> [-version <version>] (-userName <string> [-securityLevel <securityLevel>])
```

Example

```
> bind snmp trap specific 10.102.29.3 -version V3 -userName edocs_user -securityLevel authPriv
```

To configure an SNMPv3 trap by using the configuration utility

1. Add an SNMPv3 trap.
Navigate to System > SNMP > Traps, and create the SNMP trap by selecting V3 as the SNMP version.
2. Add an SNMP user.
Navigate to System > SNMP > Users, and create the SNMP user.
3. Bind the SNMPv3 trap to the SNMP user.
 - Navigate to System > SNMP > Traps, and select the SNMP version 3 trap.
 - Select the user to which the trap should be bound and define the appropriate Security Level.

Enabling Unconditional SNMP Trap Logging

Updated: 2014-08-08

By default, the NetScaler appliance logs any SNMP trap messages (for SNMP alarms in which logging is enabled) when at least one trap listener is specified on the appliance. However, you can specify that SNMP trap messages be logged even when no trap listeners are configured.

To enable unconditional SNMP trap logging by using the command line interface

At the command prompt, type the following commands to configure unconditional SNMP trap logging and verify the configuration:

- set snmp option -snmpTrapLogging (ENABLED | DISABLED)
- show snmp option

To enable unconditional SNMP trap logging by using the configuration utility

Navigate to System > SNMP, click Change SNMP Options and select SNMP Trap Logging.

Configuring the NetScaler for SNMP v1 and v2 Queries

Jun 01, 2015

You can query the NetScaler SNMP agent for system-specific information from a remote device called *SNMP managers*. The agent then searches the management information base (MIB) for the data requested and sends the data to the SNMP manager.

The following types of SNMP v1 and v2 queries are supported by the SNMP agent:

- GET
- GET NEXT
- ALL
- GET BULK

You can create strings called community strings and associate each of these to query types. You can associate one or more community strings to each query type. Community strings are passwords and used to authenticate SNMP queries from SNMP managers.

For example, if you associate two community strings, such as **abc** and **bcd**, to the query type GET NEXT, the SNMP agent on the NetScaler appliance considers only those GET NEXT SNMP query packets that contain **abc** or **bcd** as the community string.

This document includes the following details:

- [Specifying an SNMP Manager](#)
- [Specifying an SNMP Community](#)

Specifying an SNMP Manager

Updated: 2014-08-06

You must configure the NetScaler appliance to allow the appropriate SNMP managers to query it. You must also provide the SNMP manager with the required NetScaler-specific information. You can add up to a maximum of 100 SNMP managers or networks.

For an IPv4 SNMP manager you can specify a host name instead of the manager's IP address. If you do so, you must add a DNS name server that resolves the host name of the SNMP manager to its IP address. You can add up to a maximum of five host-name based SNMP managers.

Note: The appliance does not support use of host names for SNMP managers that have IPv6 addresses. You must specify the IPv6 address.

If you do not configure at least one SNMP manager, the appliance accepts and responds to SNMP queries from all IP addresses on the network. If you configure one or more SNMP managers, the appliance accepts and responds only to SNMP queries from those specific IP addresses.

If you remove an SNMP manager from the configuration, that manager can no longer query the appliance.

To add SNMP managers by specifying IP addresses by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp manager <IPAddress> ... [-netmask <netmask>]
- show snmp manager

Example

```
> add snmp manager 10.102.29.10 10.102.29.15 10.102.29.30
```

To add an SNMP manager by specifying its host name by using the command line interface

Important: If you specify the SNMP manager's host name instead of its IP address, you must configure a DNS name server to resolve the host name to the SNMP manager's IP address. For more information, see "[Adding a Name Server.](#)"

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp manager <IPAddress> [-domainResolveRetry <integer>]
- show snmp manager

Example

```
> add nameserver 10.103.128.15
```

```
> add snmp manager engwiki.eng.example.net -domainResolveRetry 10
```

To add an SNMP manager by using the configuration utility

1. Navigate to System > SNMP > Managers, and create the SNMP manager.

Important: If you specify the SNMP manager's host name instead of its IPv4 address, you must configure a DNS name server to resolve the host name to the SNMP manager's IP address. For more information, see "[Adding a Name Server.](#)"

Note: The appliance does not support host names for SNMP managers that have IPv6 addresses.

Specifying an SNMP Community

Updated: 2014-08-06

You can create strings called community strings and associate them with the following SNMP query types on the appliance:

- GET
- GET NEXT
- ALL
- GET BULK

You can associate one or more community strings to each query types. For example, when you associate two community strings, such as **abc** and **bcd**, to the query type GET NEXT, the SNMP agent on the appliance considers only those GET NEXT SNMP query packets that contain **abc** or **bcd** as the community string.

If you do not associate any community string to a query type then the SNMP agent responds to all SNMP queries of that type.

To specify an SNMP community by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp community <communityName> <permissions>
- show snmp community

Example

```
> add snmp community com all
```

To configure an SNMP community string by using the configuration utility

Navigate to System > SNMP > Community, and create the SNMP community.

Configuring the NetScaler for SNMPv3 Queries

Oct 09, 2016

Simple Network Management Protocol Version 3 (SNMPv3) is based on the basic structure and architecture of SNMPv1 and SNMPv2. However, SNMPv3 enhances the basic architecture to incorporate administration and security capabilities, such as authentication, access control, data integrity check, data origin verification, message timeliness check, and data confidentiality.

To implement message level security and access control, SNMPv3 introduces the user-based security model (USM) and the view-based access control model (VACM).

- **User-Based Security Model.** The user-based security model (USM) provides message-level security. It enables you to configure users and security parameters for the SNMP agent and the SNMP manager. USM offers the following features:
 - **Data integrity:** To protect messages from being modified during transmission through the network.
 - **Data origin verification:** To authenticate the user who sent the message request.
 - **Message timeliness:** To protect against message delays or replays.
 - **Data confidentiality:** To protect the content of messages from being disclosed to unauthorized entities or individuals.
- **View-Based Access Control Model.** The view-based access control model (VACM) enables you to configure access rights to a specific subtree of the MIB based on various parameters, such as security level, security model, user name, and view type. It enables you to configure agents to provide different levels of access to the MIB to different managers.

The Citrix NetScaler supports the following entities that enable you to implement the security features of SNMPv3:

- SNMP Engines
- SNMP Views
- SNMP Groups
- SNMP Users

These entities function together to implement the SNMPv3 security features. Views are created to allow access to subtrees of the MIB. Then, groups are created with the required security level and access to the defined views. Finally, users are created and assigned to the groups.

Note: The view, group, and user configuration are synchronized and propagated to the secondary node in a high availability (HA) pair. However, the engine ID is neither propagated nor synchronized as it is unique to each NetScaler appliance.

To implement message authentication and access control, you need to:

- Set the Engine ID
- Configure Views
- Configure Groups
- Configure Users

This document includes the following details:

- [Setting the Engine ID](#)
- [Configuring a View](#)
- [Configuring a Group](#)
- [Configuring a User](#)

Setting the Engine ID

Updated: 2014-08-06

SNMP engines are service providers that reside in the SNMP agent. They provide services such as sending, receiving, and authenticating messages. SNMP engines are uniquely identified using engine IDs.

The NetScaler appliance has a unique engineID based on the MAC address of one of its interfaces. It is not necessary to override the engineID. However, if you want to change the engine ID, you can reset it.

To set the engine ID by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- set snmp engineId <engineID>
- show snmp engineId

Example

```
> set snmp engineId 8000173f0300c095f80c68
```

To set the engine ID by using configuration utility

Navigate to System > SNMP > Users, click Configure Engine ID and type an engine ID.

Configuring a View

Updated: 2014-08-06

SNMP views restrict user access to specific portions of the MIB. SNMP views are used to implement access control.

To add an SNMP view by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp view <name> <subtree> -type (included | excluded)
- show snmp view <name>

Example

```
> add snmp view View1 1.3.6.1.4.1.5951 -type included
```

To configure an SNMP view by using the configuration utility

Navigate to System > SNMP > Views, and create the SNMP view.

Configuring a Group

Updated: 2014-08-06

SNMP groups are logical aggregations of SNMP users. They are used to implement access control and to define the security levels. You can configure an SNMP group to set access rights for users assigned to that group, thereby restricting the users to specific views.

You need to configure an SNMP group to set access rights for users assigned to that group.

To add an SNMP group by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp group <name> <securityLevel> -readViewName <string>
- show snmp group <name> <securityLevel>

Example

```
> add snmp group edocs_group2 authPriv -readViewName edocs_read_view
```

To configure an SNMP group by using the configuration utility

Navigate to System > SNMP > Groups, and create the SNMP group.

Configuring a User

Updated: 2014-08-06

SNMP users are the SNMP managers that the agents allow to access the MIBs. Each SNMP user is assigned to an SNMP group.

You need to configure users at the agent and assign each user to a group.

To configure a user by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp user <name> -group <string> [-authType (MD5 | SHA) {-authPasswd } [-privType (DES | AES) {-privPasswd }]]`
- `show snmp user <name>`

authType is the authentication option available while configuring an user. There are two authentication types such as MD5 and SHA. privType is the encryption option available while configuring an user. There are two types of encryption such as DES of key size 128 bit, and AES of key size 128 bit.

Example

```
> add snmp user edocs_user -group edocs_group
```

To configure an SNMP user by using the configuration utility

Navigate to System > SNMP > Users, and create the SNMP user.

Configuring SNMP Alarms for Rate Limiting

Aug 24, 2016

Citrix NetScaler appliances such as the NetScaler MPX 10500, 12500, and 15500 are rate limited. The maximum throughput (Mbps) and packets per second (PPS) are determined by the license purchased for the appliance. For rate-limited platforms, you can configure SNMP traps to send notifications when throughput and PPS approach their limits and when they return to normal.

Throughput and PPS are monitored every seven seconds. You can configure traps with high-threshold and normal-threshold values, which are expressed as a percentage of the licensed limits. The appliance then generates a trap when throughput or PPS exceeds the high threshold, and a second trap when the monitored parameter falls to the normal threshold. In addition to sending the traps to the configured destination device, the NetScaler logs the events associated with the traps in the `/var/log/ns.log` file as `EVENT ALERTSTARTED` and `EVENT ALERTENDED`.

Exceeding the throughput limit can result in packet loss. You can configure SNMP alarms to report packet loss.

For more information about SNMP alarms and traps, see "[Configuring the NetScaler to generate SNMP v1 and v2 Traps.](#)"

This document includes the following details:

- [Configuring an SNMP Alarm for Throughput or PPS](#)
- [Configuring SNMP Alarm for Dropped Packets](#)

Configuring an SNMP Alarm for Throughput or PPS

Updated: 2014-08-12

To monitor both throughput and PPS, you must configure separate alarms and set threshold pps value in Mbps.

To configure an SNMP alarm for the throughput rate by using the command line interface

At the command prompt, type the following commands to configure the SNMP alarm and verify the configuration:

- `set snmp alarm PF-RL-RATE-THRESHOLD [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-state (ENABLED | DISABLED)] [-severity <severity>] [-logging (ENABLED | DISABLED)]`
- `show snmp alarm PF-RL-RATE-THRESHOLD`

Example

```
> set snmp alarm PF-RL-RATE-THRESHOLD -thresholdValue 70 -normalValue 50
```

To configure an SNMP alarm for PPS by using the command line interface

At the command prompt, type the following commands to configure the SNMP alarm for PPS and verify the configuration:

- `set snmp alarm PF-RL-PPS-THRESHOLD [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-state (ENABLED | DISABLED)] [-severity <severity>] [-logging (ENABLED | DISABLED)]`
- `show snmp alarm PF-RL-PPS-THRESHOLD`

Example

```
> set snmp alarm PF-RL-PPS-THRESHOLD -thresholdValue 70 -normalValue 50
```

To configure an SNMP alarm for throughput or PPS by using the configuration utility

1. Navigate to `System > SNMP > Alarms`, and select `PF-RL-RATE-THRESHOLD` (for throughput rate) or `PF-RL-PPS-THRESHOLD` (for packets per second).

2. Set the alarm parameters and enable the selected SNMP alarm.

Configuring SNMP Alarm for Dropped Packets

Updated: 2014-08-12

You can configure an alarm for packets dropped as a result of exceeding the throughput limit and an alarm for packets dropped as a result of exceeding the PPS limit.

To configure an SNMP alarm for packets dropped because of excessive throughput, by using the command line interface

At the command prompt, type:

```
set snmp alarm PF-RL-RATE-PKTS-DROPPED [-state (ENABLED | DISABLED)] [-severity <severity>] [-logging ( ENABLED | DISABLED )]
```

To configure an SNMP alarm for packets dropped because of excessive PPS, by using the command line interface

At the command prompt, type:

```
set snmp alarm PF-RL-PPS-PKTS-DROPPED [-state (ENABLED | DISABLED)] [-severity <severity>] [-logging ( ENABLED | DISABLED )]
```

To configure an SNMP alarm for dropped packets by using the configuration utility

1. Navigate to System > SNMP > Alarms, and select PF-RL-RATE-PKTS-DROPPED (for packets dropped because of excessive throughput) or PF-RL-PPS-PKTS-DROPPED (for packets dropped because of excessive PPS).
2. Set the alarm parameters and enable the selected SNMP alarm.

Audit Logging

Jun 03, 2015

Auditing is a methodical examination or review of a condition or situation. The Audit Logging feature enables you to log the NetScaler states and status information collected by various modules in the kernel and in the user-level daemons. For audit logging, you can use the SYSLOG protocol, the native NSLOG protocol, or both.

SYSLOG is a standard protocol for logging. It has two components: the SYSLOG auditing module, which runs on the NetScaler appliance, and the SYSLOG server, which can run on the underlying FreeBSD operating system (OS) of the NetScaler appliance or on a remote system. SYSLOG uses user data protocol (UDP) for data transfer.

Similarly, the native NSLOG protocol has two components— the NSLOG auditing module, which runs on the NetScaler appliance, and the NSLOG server, which can run on the underlying FreeBSD OS of the NetScaler appliance or on a remote system. NSLOG uses transmission control protocol (TCP) for data transfer.

When you run a SYSLOG or NSLOG server, it connects to the NetScaler appliance. The NetScaler appliance then starts sending all the log information to the SYSLOG or NSLOG server, and the server can filter the log entries before storing them in a log file. An NSLOG or SYSLOG server can receive log information from more than one NetScaler appliance, and a NetScaler appliance can send log information to more than one SYSLOG server or NSLOG server.

The log information that a SYSLOG or NSLOG server collects from a NetScaler appliance is stored in a log file in the form of messages. These messages typically contain the following information:

- The IP address of a NetScaler appliance that generated the log message
- A time stamp
- The message type
- The predefined log levels (Critical, Error, Notice, Warning, Informational, Debug, Alert, and Emergency)
- The message information

To configure audit logging, you first configure the audit modules on the NetScaler appliance. That involves creating audit policies and specifying the NSLOG server or SYSLOG server information. You then install and configure the SYSLOG or the NSLOG server on the underlying FreeBSD OS of the NetScaler appliance or on a remote system.

Note: Because SYSLOG is an industry standard for logging program messages, and various vendors provide support, this documentation does not include SYSLOG server configuration information.

The NSLOG server has its own configuration file (auditlog.conf). You can customize logging on the NSLOG server system by making additional modifications to the configuration file (auditlog.conf).

Configuring the NetScaler Appliance for Audit Logging

Jun 01, 2015

On the NetScaler appliance, you configure SYSLOG and/or NSLOG policies. Each policy includes a rule, which is an expression identifying the messages to be logged, and a SYSLOG or NSLOG (depending on the type of policy) action. The action specifies the server to which to send the log message, the level of the messages to be logged, and the data format of the logged messages. You can bind the policies globally or to individual virtual servers.

The appliance logs the following information related to TCP connections:

- Source port
- Destination port
- Source IP
- Destination IP
- Number of bytes transmitted and received
- Time period for which the connection is open

Note:

- You can enable TCP logging on individual load balancing virtual servers. You must bind the audit log policy to a specific load balancing virtual server that you want to log.
- When using the NetScaler as the audit log server, by default, the ns.log file is rotated (new file is created) when the file size reaches 100K and the last 25 copies of the ns.log are archived and compressed with gzip. To accommodate more archived files after 25 files, the oldest archive is deleted. You can modify the 100K limit or the 25 file limit by updating the following entry in the /etc/newsyslog.conf file:

```
/var/log/ns.log 600 25 100 * Z
```

where, 25 is the number of archived files to be maintained and 100K is the size of the ns.log file after which the file will be archived.

This document includes the following details:

- [Configuring SYSLOG and NSLOG Actions](#)
- [Configuring Audit Policies](#)

Configuring SYSLOG and NSLOG Actions

Updated: 2015-06-03

You can configure audit server actions for different servers and for different log levels.

To configure a SYSLOG server action by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> [-dateFormat (MMDDYYYY | DDMMYYYY)]
- show audit syslogAction [<name>]

Example

```
> add audit syslogaction audit-action1 10.102.1.1 -loglevel INFORMATIONAL -dateformat MMDDYYYY
```

To configure an NSLOG server action by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add audit nslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> [-dateFormat (MMDDYYYY | DDMMYYYY)]
- show audit nslogAction [<name>]

Example

```
> add audit nslogAction nslog-action1 10.102.1.3 -serverport 520 -loglevel INFORMATIONAL -dateFormat MMDDYYYY
```

To configure an auditing server action by using the configuration utility

Navigate to System > Auditing > Syslog or Nslog, click Servers tab and create the auditing server.

Configuring Audit Policies

Updated: 2015-04-29

Configure SYSLOG policies to log messages to a SYSLOG server, and/or NSLOG policy to log messages to an NSLOG server. Each policy includes a rule identifying the messages to be logged, and a SYSLOG or NS LOG (depending on the type of policy) action.

To configure a SYSLOG policy by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add audit syslogPolicy <name> <rule> <action>
- show audit syslogPolicy [<name>]

Example

```
> add audit syslogpolicy syslog-pol1 ns_true audit-action1
```

To configure an NSLOG policy by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add audit nslogPolicy <name> <rule> <action>
- show audit nslogPolicy [<name>]

Example

```
> add audit nslogPolicy nslog-pol1 ns_true nslog-action1
```

To configure an audit server policy by using the configuration utility

Navigate to System > Auditing > Syslog or Nslog, click Policies tab and create the auditing policy.

Binding the Audit Policies Globally

Updated: 2015-06-02

You must globally bind the audit log policies to enable logging of all NetScaler system events. By defining the priority level, you can set the evaluation order of the audit server logging. Priority 0 is the highest and is evaluated first. The higher the priority number, the lower is the priority of evaluation.

To configure a SYSLOG policy by using the command line interface

At the command prompt, type:

- bind system global [<policyName> [-priority <positive_integer>]]
- show system global

Example

```
> bind system global nslog-pol1 -priority 20
```

To globally bind the audit policy by using the configuration utility

1. Navigate to System > Auditing > Syslog or Nslog.
2. On Policies tab, click Action, and select Global Bindings to bind the audit global policies.

Configuring Policy-Based Logging

Updated: 2014-08-07

You can configure policy-based logging for rewrite and responder policies. Audit messages are then logged in a defined format when the rule in a policy evaluates to TRUE. To configure policy-based logging, you configure an audit-message action that uses default syntax expressions to specify the format of the audit messages, and associate the action with a policy. The policy can be bound either globally or to a load balancing or content switching virtual server. You can use audit-message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats.

Pre Requisites

- User Configurable Log Messages (userDefinedAuditlog) option is enabled for when configuring the audit action server to which you want to send the logs in a defined format. For more information about enabling policy-based logging on an audit action server, see "[Binding the Audit Policies Globally](#)."
- The related audit policy is bound to system global. For more information about binding audit policies to system global, see "[Binding the Audit Policies Globally](#)."

Configuring an Audit Message Action

You can configure audit message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats. Audit-message actions use expressions to specify the format of the audit messages.

To create an audit message action by using the command line interface

At the command prompt, type:

```
add audit messageaction <name> <logLevel> <stringBuilderExp> [-logtoNewnslog (YES | NO)] [-bypassSafetyCheck (YES | NO)]
```

Example

```
> add audit messageaction log-act1 CRITICAL "'Client:'+CLIENT.IP.SRC+' accessed '+HTTP.REQ.URL' -bypassSafetyCheck YES
```

To configure an audit message action by using the configuration utility

Navigate to System > Auditing > Message Actions, and create the audit message action.

Binding Audit Message Action to a Policy

After you have created an audit message action, you must bind it to a rewrite or responder policy. For more information about binding log message actions to a rewrite or responder policy, see "[Rewrite](#)" or "[Responder](#)".

Installing and Configuring the NSLOG Server

Jul 24, 2015

During installation, the NSLOG server executable file (auditserver) is installed along with other files. The auditserver executable file includes options for performing several actions on the NSLOG server, including running and stopping the NSLOG server. In addition, you use the auditserver executable to configure the NSLOG server with the IP addresses of the NetScaler appliances from which the NSLOG server will start collecting logs. Configuration settings are applied in the NSLOG server configuration file (auditlog.conf).

Then, you start the NSLOG server by executing the auditserver executable. The NSLOG server configuration is based on the settings in the configuration file. You can further customize logging on the NSLOG server system by making additional modifications to the NSLOG server configuration file (auditlog.conf).

Attention: The version of the NSLOG server package must be the same as that of the NetScaler. For example, if the version of the NetScaler is 10.1 Build 125.9, the NSLOG server must also be of the same version. The following table lists the operating systems on which the NSLOG server is supported.

Table 1. Supported Platforms for the NSLOG Server

Operating system	Software requirements	Remarks
Windows	<ul style="list-style-type: none">• Windows XP Professional• Windows Server 2003• Windows 2000/NT• Windows Server 2008• Windows Server 2008 R2	
Linux	<ul style="list-style-type: none">• RedHat Linux 4 or later• SUSE Linux Enterprise 9.3 or later	
FreeBSD	FreeBSD 6.3 or later	For NetScaler 10.5, use only FreeBSD 8.4.
Mac OS	Mac OS 8.6 or later	Not supported on NetScaler 10.1 and later releases.

The minimum hardware specifications for the platform running the NSLOG server are as follows:

- Processor- Intel x86 ~501 megahertz (MHz)
- RAM - 512 megabytes (MB)
- Controller - SCSI

This document includes the following details:

- [Installing NSLOG Server on the Linux Operating System](#)
- [Installing NSLOG Server on the FreeBSD Operating System](#)
- [Installing NSLOG Server Files on the Windows Operating System](#)
- [NSLOG Server Command Options](#)
- [Adding the NetScaler Appliance IP Addresses on the NSLOG Server](#)
- [Verifying the NSLOG Server Configuration File](#)

Installing NSLOG Server on the Linux Operating System

Updated: 2013-06-20

Log on to the Linux system as an administrator. Use the following procedure to install the NSLOG server executable files on the system.

To install the NSLOG server package on a Linux operating system

1. At a Linux command prompt, type the following command to copy the NSauditserver.rpm file to a temporary directory:
`cp <path_to_cd>/Utilities/auditserver/Linux/NSauditserver.rpm /tmp`
2. Type the following command to install the NSauditserver.rpm file:
`rpm -i NSauditserver.rpm`

This command extracts the files and installs them in the following directories:

- /usr/local/netscaler/etc
- /usr/local/netscaler/bin
- /usr/local/netscaler/samples

To uninstall the NSLOG server package on a Linux operating system

1. At a command prompt, type the following command to uninstall the audit server logging feature:
`rpm -e NSauditserver`
2. For more information about the NSauditserver RPM file, use the following command:
`rpm -qpi *.rpm`
3. To view the installed audit server files use the following command:
`rpm -qpl *.rpm`

*.rpm: Specifies the file name.

Installing NSLOG Server on the FreeBSD Operating System

Before you can install the NSLOG server, you have to copy the NSLOG package from the NetScaler product CD or download it from www.citrix.com. The NSLOG package has the following name format:

AuditServer_<release number>-<build number>.zip

For example: AuditServer_10.5-58.11.zip

This package contains files for all supported platforms: Linux, Windows, and FreeBSD. On a FreeBSD operating system, install the NSLOG package that has the following name format:

audserver_bsd-<release number>-<build number>.tgz

For example: audserver_bsd-10.5-58.11.tgz

To download NSLOG package from www.citrix.com

1. In a web browser, go to www.citrix.com.
2. In the menu bar, click Log In.
3. Enter your login credentials, and then click Log In.
4. In the menu bar, click Downloads.
5. From the **Select a product** list, select **NetScaler ADC**.
6. On the **NetScaler ADC** page, select the release for which you want to download the NSLOG package (for example, Release 10.5), and then select **Firmware**.
7. Under **Firmware**, select the NetScaler firmware for the build number for which you want to download the NSLOG package.
8. On the page that appears, scroll down, select **Audit Servers**, and click **Download File** next to the package that you want to download.

To install the NSLOG server package on a FreeBSD operating system

1. On the system to which you have downloaded the NSLOG package AuditServer_<release number>-<build number>.zip (for example, AuditServer_9.3-51.5.zip), extract the FreeBSD NSLOG server package audserver_bsd-<release number>-<build number>.tgz (for example, audserver_bsd-9.3-51.5.tgz) from the package.
2. Copy the FreeBSD NSLOG server package audserver_bsd-<release number>-<build number>.tgz (for example, audserver_bsd-9.3-51.5.tgz) to a directory on a system running FreeBSD OS.
3. At a command prompt for the directory into which the FreeBSD NSLOG server package was copied, run the following command to install the package:

```
pkg_add audserver_bsd-<release number>-<build number>.tgz
```

Example

```
pkg_add audserver_bsd-9.3-51.5.tgz
```

The following directories are extracted:

- <root directory extracted from the FreeBSD NSLOG server package tgz file>\netscaler\bin (for example, /var/auditserver/netscaler/bin)
 - <root directory extracted from the FreeBSD NSLOG server package tgz file>\netscaler\etc (for example, /var/auditserver/netscaler/etc)
 - <root directory extracted from the FreeBSD NSLOG server package tgz file>\netscaler\samples (for example, /var/auditserver/samples)
4. At a command prompt, type the following command to verify that the package is installed:
pkg_info | grep NSaudserver

To uninstall the NSLOG server package on a FreeBSD operating system

At a command prompt, type:

```
pkg_delete NSaudserver
```

Installing NSLOG Server Files on the Windows Operating System

Updated: 2013-06-20

Before you can install the NSLOG server, you have to copy the NSLOG package from the NetScaler product CD or download it from www.citrix.com. The NSLOG package has the following name format AuditServer_<release number>-<build number>.zip (for example, AuditServer_9.3-51.5.zip). This package contains NSLOG installation packages for all supported platforms.

To download NSLOG package from www.Citrix.com

1. In a web browser, go to www.citrix.com.
2. In the menu bar, click Log In.
3. Enter your login credentials, and then click Log In.
4. In the menu bar, click Downloads.
5. Search to find the page that provides the appropriate release number and build.
6. On that page, under Audit Servers, click Download to download the NSLOG package, having the format AuditServer_<release number>-<build number>.zip , to your local system (for example, AuditServer_9.3-51.5.zip).

To install NSLOG server on a Windows operating system

1. On the system, where you have downloaded the NSLOG package AuditServer_<release number>-<build number>.zip (for example, AuditServer_9.3-51.5.zip), extract audserver_win-<release number>-<build number>.zip (for example, audserver_win-9.3-51.5.zip) from the package.
2. Copy the extracted file audserver_<release number>-<build number>.zip (for example, audserver_win-9.3-51.5.zip) to a Windows system on which you want to install the NSLOG server.
3. Unzip the audserver_<release number>-<build number>.zip file (for example, audserver_win-9.3-51.5.zip).
4. The following directories are extracted:
 1. <root directory extracted from the Windows NSLOG server package zip file>\bin (for example, C:\audserver_win-9.3-51.5\bin)
 2. <root directory extracted from the Windows NSLOG server package zip file>\etc (for example, C:\audserver_win-9.3-51.5\ etc)
 3. < root directory extracted from the Windows NSLOG server package zip file >\samples (for example, C:\audserver_win-9.3-51.5\ samples)
5. At a command prompt, run the following command from the <root directory extracted from the Windows NSLOG server package zip file>\bin path:
audserver -install -f <directorypath>\auditlog.conf

<directorypath>: Specifies the path to the configuration file (auditlog.conf). By default, log.conf is under <root directory extracted from Windows NSLOG server package zip file>\samples directory. But you can copy auditlog.conf to your desired directory.

To uninstall the NSLOG server on a Windows operating system

At a command prompt, run the following from the <root directory extracted from Windows NSLOG server package zip file>\bin path:

```
audserver -remove
```

NSLOG Server Command Options

The following table describes the commands that you can use to configure audit server options.

Table 2. Audit Server Options

Audit server commands	Specifies
audserver -help	The available Audit Server options.
audserver -addns -f <path to configuration file>	<p>The system that gathers the log transaction data.</p> <p>You are prompted to enter the IP address of the NetScaler appliance.</p> <p>Enter the valid user name and password.</p>
audserver -verify -f <path to configuration file>	Check for syntax or semantic errors in the configuration file (for example, auditlog.conf).
audserver -start -f <path to configuration file>	<p>Start audit server logging based on the settings in the configuration file (auditlog.conf).</p> <p>Linux only: To start the audit server as a background process, type the ampersand sign (&) at the end of the command.</p>
audserver -stop (Linux only)	Stops audit server logging when audit server is started as a background process. Alternatively, use the Ctrl+C key to stop audit server logging.
audserver -install -f <path to configuration file> (Windows only)	Installs the audit server logging client as a service on Windows.
audserver -startservice (Windows Only)	<p>Start the audit server logging service, when you enter this command at a command prompt.</p> <p>You can also start audit server logging from Start > Control Panel > Services.</p> <p>Note: Audit server logging starts by using the configuration settings in the configuration file, for example, auditlog.conf file specified in the audit server install option.</p>
audserver -stopservice (Windows Only)	Stop audit server logging.
audserver -remove	Removes the audit server logging service from the registry.

Audit server commands	Specifies
Run the <code>audserver</code> command	from the directory in which the audit server executable is present:

- On Windows: `\ns\bin`
- On Solaris and Linux: `\usr\local\netscaler\bin`

The audit server configuration files are present in the following directories:

- On Windows: `\ns\etc`
- On Linux: `\usr\local\netscaler\etc`

The audit server executable is started as `./auditserver` in Linux and FreeBSD.

Adding the NetScaler Appliance IP Addresses on the NSLOG Server

In the configuration file (`auditlog.conf`), add the IP addresses of the NetScaler appliances whose events must be logged.

To add the IP addresses of the NetScaler appliance

At a command prompt, type the following command:

```
audserver -addns -f <directorypath>\auditlog.conf
```

`<directorypath>`: Specifies the path to the configuration file (`auditlog.conf`).

You are prompted to enter the information for the following parameters:

NSIP: Specifies the IP address of the NetScaler appliance, for example, `10.102.29.1`.

Userid: Specifies the user name, for example, `nsroot`.

Password: Specifies the password, for example, `nsroot`.

If you add multiple NetScaler IP addresses (NSIP), and later you do not want to log all of the NetScaler appliance event details, you can delete the NSIPs manually by removing the NSIP statement at the end of the `auditlog.conf` file. For a high availability (HA) setup, you must add both primary and secondary NetScaler IP addresses to `auditlog.conf` by using the `audserver` command. Before adding the IP address, make sure the user name and password exist on the system.

Verifying the NSLOG Server Configuration File

Check the configuration file (`audit log.conf`) for syntax correctness to enable logging to start and function correctly.

To verify configuration, at a command prompt, type the following command:

```
audserver -verify -f <directorypath>\auditlog.conf
```

`<directorypath>`: Specifies the path to the configuration file (`audit log.conf`).

Running the NSLOG Server

Jun 20, 2013

To start audit server logging

Type the following command at a command prompt:

```
audserver -start -f <directorypath>\auditlog.conf
```

<directorypath>: Specifies the path to the configuration file (audit log.conf).

To stop audit server logging that starts as a background process in FreeBSD or Linux

Type the following command:

```
audserver -stop
```

To stop audit server logging that starts as a service in Windows

Type the following command:

```
audserver -stopservice
```

Customizing Logging on the NSLOG Server

Jul 24, 2015

You can customize logging on the NSLOG server by making additional modifications to the NSLOG server configuration file (log.conf). Use a text editor to modify the log.conf configuration file on the server system.

To customize logging, use the configuration file to define filters and log properties.

- **Log filters.** Filter log information from a NetScaler appliance or a set of NetScaler appliances.
- **Log properties.** Each filter has an associated set of log properties. Log properties define how to store the filtered log information.

This document includes the following details:

- [Creating Filters](#)
- [Specifying Log Properties](#)

Creating Filters

Updated: 2013-11-14

You can use the default filter definition located in the configuration file (audit log.conf), or you can modify the filter or create a new filter. You can create more than one log filter.

Note: For consolidated logging, if a log transaction occurs for which there is no filter definition, the default filter is used (if it is enabled.) The only way you can configure consolidated logging of all the NetScaler appliances is by defining the default filter.

To create a filter

At the command prompt, type the following command in the configuration file (auditlog.conf):

```
filter <filterName> [IP <ip>] [NETMASK <mask>] [ON | OFF]
```

<filterName>: Specify the name of the filter (maximum of 64 alphanumeric characters).

<ip>: Specify the IP addresses.

<mask>: Specify the subnet mask to be used on a subnet.

Specify ON to enable the filter to log transactions, or specify OFF to disable the filter. If no argument is specified, the filter is ON

Examples

```
filter F1 IP 192.168.100.151 ON
```

To apply the filter F2 to IP addresses 192.250.100.1 to 192.250.100.254:

```
filter F2 IP 192.250.100.0 NETMASK 255.255.255.0 ON
```

filterName is a required parameter if you are defining a filter with other optional parameters, such as IP address, or the combination of IP address and Netmask.

Specifying Log Properties

Updated: 2013-11-13

Log properties associated with the filter are applied to all the log entries present in the filter. The log property definition starts with the key word BEGIN and ends with END as illustrated in the following example:

```
BEGIN <filtername>
logFileNameFormat ...
logDirectory ...
logInterval ...
logFileSizeLimit ....
END
```

Entries in the definition can include the following:

- **LogFileNameFormat** specifies the file name format of the log file. The name of the file can be of the following types:
 - Static: A constant string that specifies the absolute path and the file name.
 - Dynamic: An expression that includes the following format specifiers:
 - Date (%{format}t)
 - % creates file name with NSIP

Example

```
LogFileNameFormat Ex%{%m%d%y}t.log
```

This creates the first file name as Exmmdyy.log. New files are named: Exmmdyy.log.0, Exmmdyy.log.1, and so on. In the following example, the new files are created when the file size reaches 100MB.

Example

```
LogInterval size
```

```
LogFileSize 100
```

```
LogFileNameFormat Ex%{%m%d%y}t
```

Caution: The date format %t specified in the LogFileNameFormat parameter overrides the log interval property for that filter. To prevent a new file being created every day instead of when the specified log file size is reached, do not use %t in the LogFileNameFormat parameter.

- **logDirectory** specifies the directory name format of the log file. The name of the file can be either of the following:
 - Static: Is a constant string that specifies the absolute path and file name.
 - Dynamic: Is an expression containing the following format specifiers:
 - Date (%{format}t)
 - % creates directory with NSIP

The directory separator depends on the operating system. In Windows, use the directory separator \.

Example:

```
LogDirectory dir1\dir2\dir3
```

In the other operating systems (Linux, FreeBSD, etc.), use the directory separator /.

- **LogInterval** specifies the interval at which new log files are created. Use one of the following values:
 - Hourly: A file is created every hour. Default value.
 - Daily: A file is created every day at midnight.
 - Weekly: A file is created every Sunday at midnight.

- Monthly : A file is created on the first day of the month at midnight.
- None: A file is created only once, when audit server logging starts.
- Size: A file is created only when the log file size limit is reached.

Example

LogInterval Hourly

- **LogFileSizeLimit** specifies the maximum size (in MB) of the log file. A new file is created when the limit is reached.

Note that you can override the loginterval property by assigning size as its value.

The default LogFileSizeLimit is 10 MB.

Example

LogFileSizeLimit 35

Default Settings for the Log Properties

Mar 28, 2012

The following is an example of the default filter with default settings for the log properties:

```
begin default
logInterval Hourly
logFileSizeLimit 10
logFilenameFormat auditlog%{%y%m%d}.log
end default
```

Following are two examples of defining the default filters:

Example 1

```
Filter f1 IP 192.168.10.1
```

This creates a log file for NSI 192.168.10.1 with the default values of the log in effect.

Example 2

```
Filter f1 IP 192.168.10.1
```

```
begin f1
logFilenameFormat logfiles.log
end f1
```

This creates a log file for NSIP 192.168.10.1. Since the log file name format is specified, the default values of the other log properties are in effect.

Sample Configuration File (audit.conf)

Mar 28, 2012

Following is a sample configuration file:

```
#####  
# This is the Auditserver configuration file  
# Only the default filter is active  
# Remove leading # to activate other filters  
#####  
MYIP <NSAuditserverIP>  
MYPORT 3023  
# Filter filter_nsis IP <Specify the NetScaler IP address to filter on > ON  
# begin filter_nsis  
# logInterval Hourly  
# logFileSizeLimit 10  
# logDirectory logdir^%A\  
# logFilenameFormat nsip%{d%m%Y}t.log  
# end filter_nsis  
Filter default  
begin default  
logInterval Hourly  
logFileSizeLimit 10  
logFilenameFormat auditlog%{y%m%d}t.log  
end default
```

Web Server Logging

Jun 25, 2014

You can use the Web server logging feature to send logs of HTTP and HTTPS requests to a client system for storage and retrieval. This feature has two components:

- The Web log server, which runs on the NetScaler.
- The NetScaler Web Logging (NSWL) client, which runs on the client system.

When you run the NetScaler Web Logging (NSWL) client:

1. It connects to the NetScaler.
2. The NetScaler buffers the HTTP and HTTPS request log entries before sending them to the client.
3. The client can filter the entries before storing them.

To configure Web server logging, you first enable the Web logging feature on the NetScaler and configure the size of the buffer for temporarily storing the log entries. Then, you install NSWL on the client system. You then add the NetScaler IP address (NSIP) to the NSWL configuration file. You are now ready to start the NSWL client to begin logging. You can customize Web server logging by making additional modifications to the NSWL configuration file (log.conf).

Configuring the NetScaler for Web Server Logging

Oct 09, 2016

To configure the NetScaler for web server logging you are required to only enable the Web Server Logging feature. Optionally, you can perform the following configurations:

- Modify the size of the buffer (default size is 16 MB) that stores the logged information before it is sent to the NetScaler Web Logging (NSWL) client.
- Specify the custom HTTP headers that you want to export to the NSWL client. You can configure a maximum of two HTTP request and two HTTP response header names.

To configure web server logging by using the command line interface

At the command prompt, perform the following operations:

- Enable the web server logging feature.
`enable ns feature WL`
- [Optional] Modify the buffer size for storing the logged information.
`set ns weblogparam -bufferSizeMB <size>`

Note: To activate your modification, you must disable and then re-enable the Web server logging feature.

- [Optional] Specify the custom HTTP header names that you want to export.
`set ns weblogparam [-customReqHdrs <string> ...] [-customRspHdrs <string> ...]`

Example

COPY

```
> enable ns feature WL
```

```
Done
```

```
> set ns weblogparam -bufferSizeMB 60
```

```
Done
```

```
> show ns weblogparam
```

```
Web Logging parameters:
```

```
Log buffer size: 60MB
```

```
Custom HTTP request headers: (none)
```

```
Custom HTTP response headers: (none)
```

```
Done
```

```
> set ns weblogparam -customReqHdrs req1 req2 -customRspHdrs res1 res2
```

```
Done
```

```
> show ns weblogparam
```

```
Web Logging parameters:
```

```
Log buffer size: 60MB
```

```
Custom HTTP request headers: req1, req2
```

```
Custom HTTP response headers: res1, res2
```

```
Done
```

To configure web server logging by using the configuration utility

Navigate to System > Settings and perform the following operations:

- To enable the web server logging feature, click Change Advanced Features and select Web Logging.
- To modify the buffer size, click Change Global System Settings and under Web Logging, enter the buffer size.
- To specify the custom HTTP headers to be exported, click Change Global System Settings and under Web Logging, specify the header values.

Installing the NetScaler Web Logging (NSWL) Client

Jun 01, 2015

During installation, the NSWL client executable file (nswl) is installed along with other files. The nswl executable file provides a list of options that you can use. For details, see [Configuring the NSWL Client](#).

Attention: The version of the NSWL client must be the same as that of the NetScaler. For example, if the version of the NetScaler is 10.1 Build 125.9, the NSWL client must also be of the same version.

The following table lists the operating systems on which the NSWL client can be installed.

Table 1. Supported Platforms for the NSWL Client with hardware requirements

Operating system	Version	Hardware requirements	Remarks
Windows	<ul style="list-style-type: none">Windows XP ProfessionalWindows Server 2003Windows 2000/NTWindows Server 2008Windows Server 2008 R2	Processor - Intel x86 ~501 MHz RAM - 512 MB Controller - SCSI	
Mac OS	Mac OS 8.6 or later	-	Not supported on NetScaler 10.1 and later releases.
Linux	<ul style="list-style-type: none">RedHat Linux 4 or laterSUSE Linux Enterprise 9.3 or later	Processor - Intel x86 ~501 MHz RAM - 512 MB Controller - SCSI	
Solaris	Solaris Sun OS 5.6 or later	Processor - UltraSPARC-IIi 400 MHz RAM - 512 MB Controller - SCSI	Not supported on NetScaler 10.5 and later releases.
FreeBSD	FreeBSD 6.3 or later	Processor - Intel x86 ~501 MHz RAM - 512 MB Controller - SCSI	For NetScaler 10.5, use only FreeBSD 8.4.

Operating system	Version	Hardware requirements	Remarks
	AIX 6.1		Not supported on NetScaler 10.5 and later releases.

If the NSWL client system cannot process the log transaction because of a CPU limitation, the Web log buffer overruns and the logging process reinitiates.

Caution: Reinitiation of logging can result in loss of log transactions.

To temporarily solve a NSWL client system bottleneck caused by a CPU limitation, you can tune the Web server logging buffer size on the NetScaler appliance. To solve the problem, you need a client system that can handle the site's throughput.

This document includes the following details:

- [Downloading the NSWL Client](#)

Downloading the NSWL Client

Updated: 2014-06-25

You can obtain the NSWL client package from either the NetScaler product CD or the Citrix downloads site. Within the package there are separate installation packages for each supported platforms.

To download the NSWL client package from the Citrix site

1. Open the URL: <https://www.citrix.com/downloads.html>.
2. Log in to the site using your credentials.
3. Open the page for the required release number and build.
4. In the page, under Weblog Clients, click Download. The package has the name format as follows: Weblog-<release number>-<build number>.zip.

Installing the NSWL Client on a Solaris System

Updated: 2014-06-25

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_solaris-<release number>-<build number>.tar` file from the package.
2. Copy the extracted file to a Solaris system on which you want to install the NSWL client.
3. Extract the files from the tar file with the following command:

```
tar xvf nswl_solaris-9.3-51.5.tar
```

A directory NSweblog is created in the temporary directory, and the files are extracted to the NSweblog directory.
4. Install the package with the following command:

```
pkgadd -d
```

The list of available packages appears. In the following example, one NSweblog package is shown:

1 NSweblog NetScaler Weblogging (SunOS,sparc) 7.0

5. You are prompted to select the packages. Select the package number of the NSweblog to be installed.
After you select the package number and press Enter, the files are extracted and installed in the following directories:
 - /usr/local/netscaler/etc
 - /usr/local/netscaler/bin
 - /usr/local/netscaler/samples
6. To check whether the NSWL package is installed, execute the following command:
`pkginfo | grep NSweblog`
Note: To uninstall the NSWL package, execute the following command:
`pkgrm NSweblog`

Installing the NSWL Client on a Linux System

Updated: 2014-06-25

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_linux-<release number>-<build number>.rpm` file from the package.
2. Copy the extracted file to a system, running Linux OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

```
rpm -i nswl_linux-9.3-51.5.rpm
```

This command extracts the files and installs them in the following directories.

- /usr/local/netscaler/etc
- /usr/local/netscaler/bin
- /usr/local/netscaler/samples

Note: To uninstall the NSWL package, execute the following command:

```
rpm -e NSweblog
```

Note: To get more information about the NSweblog RPM file, execute the following command:

```
rpm -qpi *.rpm
```

Note: To view the installed Web server logging files, execute the following command:

```
rpm -qpl *.rpm
```

Installing the NSWL Client on a FreeBSD System

Updated: 2014-06-25

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_bsd-<release number>-<build number>.tgz` file from the package.
2. Copy the extracted file to a system, running FreeBSD OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

```
pkg_add nswl_bsd-9.3-51.5.tgz
```

This command extracts the files and installs them in the following directories.

- /usr/local/netscaler/etc
- /usr/local/netscaler/bin
- /usr/local/netscaler/samples

Note: To uninstall the NSWL package, execute the following command:

```
pkg_delete NSweblog
```

4. To verify that the package is installed, execute the following command:

```
pkg_info | grep NSweblog
```

Installing the NSWL Client on a Mac System

Updated: 2014-06-25

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_macos-<release number>-<build number>.tgz` file from the package.
2. Copy the extracted file to a system, running Mac OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

```
pkg_add nswl_macos-9.3-51.5.tgz
```

This command extracts the files and installs them in the following directories:

- /usr/local/netscaler/etc
- /usr/local/netscaler/bin
- /usr/local/netscaler/samples

Note: To uninstall the NSWL package, execute the following command:

```
pkg_delete NSweblog
```

4. To verify that the package is installed, execute the following command:

```
pkg_info | grep NSweblog
```

Installing the NSWL Client on a Windows System

Updated: 2014-09-18

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_win-<release number>-<build number>.zip` file from the package.
2. Copy the extracted file to a Windows system on which you want to install the NSWL client.
3. On the Windows system, unzip the file in a directory (referred as <NSWL-HOME>). The following directories are extracted: bin, etc, and samples.
4. At the command prompt, run the following command from the <NSWL-HOME>\bin directory:

```
nswl -install -f <directorypath>\log.conf
```

where,

<directorypath> refers to the path of the configuration file (log.conf). By default, the file is in the <NSWL-HOME>\etc directory. However, you can copy the configuration file to any other directory.

Note: To uninstall the NSWL client, at the command prompt, run the following command from the <NSWL-HOME>\bin directory:

```
> nswl -remove
```

Installing the NSWL Client on a AIX System

Updated: 2014-06-25

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_aix-<release number>-<build number>.rpm` file from the package.
2. Copy the extracted file to a system, running AIX OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

```
rpm -i nswl_aix-9.3-51.5.rpm
```

This command extracts the files and installs them in the following directories.

- /usr/local/netscaler/etc
- /usr/local/netscaler/bin
- /usr/local/netscaler/samples

Note: To uninstall the NSWL package, execute the following command:

```
rpm -e NSweblog
```

Note: To get more information about the NSweblog RPM file, execute the following command:

```
rpm -qpi *.rpm
```

Note: To view the installed Web server logging files, execute the following command:

```
rpm -qpl *.rpm
```

Configuring the NSWL Client

Jun 01, 2015

After installing the NSWL client, you can configure the NSWL client using the `nswl` executable. These configurations are then stored in the NSWL client configuration file (`log.conf`).

Note: You can further customize logging on the NSWL client system by making additional modifications to the NSWL configuration file (`log.conf`). For details, see [Customizing Logging on the NSWL Client System](#).

The following table describes the commands that you can use to configure the NSWL client.

NSWL command	Specifies
<code>nswl -help</code>	The available NSWL help options.
<code>nswl -addns -f <path-to-configuration-file></code>	The system that gathers the log transaction data. You are prompted to enter the IP address of the NetScaler appliance. Enter a valid user name and password.
<code>nswl -verify -f <path-to-configuration-file></code>	Check for syntax or semantic errors in the configuration file.
<code>nswl -start -f <path-to-configuration-file></code>	Start the NSWL client based on the settings in the configuration file. Note: For Solaris and Linux: To start Web server logging as a background process, type the ampersand sign (&) at the end of the command.
<code>nswl -stop</code> (Solaris and Linux only)	Stop the NSWL client if it was started as a background process; otherwise, use CTRL+C to stop Web server logging.
<code>nswl -install -f <path-to-configuration-file></code> (Windows only)	Install the NSWL client as a service in Windows.
<code>nswl -startservice</code> (Windows only)	Start the NSWL client by using the settings in the configuration file specified in the <code>nswl install</code> option. You can also start NSWL client from Start > Control Panel > Services.
<code>nswl -stopservice</code> (Windows only)	Stops the NSWL client.
<code>nswl -remove</code>	Remove the NSWL client service from the registry.

Run the following commands from the directory in which the NSWL executable is located:

- Windows: `\ns\bin`
- Solaris and Linux: `\usr\local\netscaler\bin`

The Web server logging configuration files are located in the following directory path:

- Windows: `\ns\etc`
- Solaris and Linux: `\usr\local\netscaler\etc`

The NSWL executable is started as `.nswl` in Linux and Solaris.

This document includes the following details:

- [Adding the IP Addresses of the NetScaler Appliance](#)
- [Verifying the NSWL Configuration File](#)
- [Running the NSWL Client](#)

Adding the IP Addresses of the NetScaler Appliance

Updated: 2013-07-17

In the NSWL client configuration file (`log.conf`), add the NetScaler IP address (NSIP) from which the NSWL client will start collecting logs.

To add the NSIP address of the NetScaler appliance

1. At the client system command prompt, type:

```
nswl -addns -f <directorypath> \log.conf
```

<directorypath>: Specifies the path to the configuration file (`log.conf`).

2. At the next prompt, enter the following information:

- **NSIP:** Specify the IP address of the NetScaler appliance.
- **Username and Password:** Specify the `nsroot` user credentials of the NetScaler appliance.

Note: If you add multiple NetScaler IP addresses (NSIP), and later you do not want to log all of NetScaler system log details, you can delete the NSIPs manually by removing the NSIP statement at the end of the `log.conf` file. During a failover setup, you must add both primary and secondary NetScaler IP addresses to the `log.conf` by using the command. Before adding the IP address, make sure the user name and password exist on the NetScaler appliances.

Verifying the NSWL Configuration File

Updated: 2013-06-20

To make sure that logging works correctly, check the NSWL configuration file (`log.conf`) on the client system for syntax errors.

To verify the configuration in the NSWL configuration file

At the client system command prompt, type:

```
nswl -verify -f <directorypath>\log.conf
```

<directorypath>: Specifies the path to the configuration file (`log.conf`).

Running the NSWL Client

Updated: 2013-06-20

To start Web server logging

At the client system command prompt, type:

```
nswl -start -f <directorypath>\log.conf
```

<directorypath>: Specifies the path to the configuration file (log.conf).

To stop Web server logging started as a background process on the Solaris or Linux operating systems

At the command prompt, type:

```
nswl -stop
```

To stop Web server logging started as a service on the Windows operating system

At the command prompt, type:

```
nswl -stopservice
```

Customizing Logging on the NSWL Client System

Jun 01, 2015

You can customize logging on the NSWL client system by making additional modifications to the NSWL client configuration file (log.conf). Use a text editor to modify the log.conf configuration file on the client system.

To customize logging, use the configuration file to define filters and log properties.

- **Log filters.** Filter log information based on the host IP address, domain name, and host name of the Web servers.
- **Log properties.** Each filter has an associated set of log properties. Log properties define how to store the filtered log information.

This document includes the following details:

- [Creating Filters](#)
- [Specifying Log Properties](#)
- [Understanding the NCSA and W3C Log Formats](#)
- [Creating a Custom Log Format](#)
- [Arguments for Defining a Custom Log Format](#)
- [Time Format Definition](#)
- [Sample Configuration File](#)

Sample Configuration File

Following is a sample configuration file:

```
#####
# This is the NSWL configuration file
# Only the default filter is active
# Remove leading # to activate other filters
#####
#####
# Default filter (default on)
# W3C Format logging, new file is created every hour or on reaching 10MB file size,
# and the file name is Exymmdd.log
#####
Filter default
begin default
    logFormat      W3C
    logInterval    Hourly
    logFileSizeLimit 10
    logFilenameFormat Ex%{%y%m%d}t.log
end default
#####
# netscaler caches example
# CACHE_F filter covers all the transaction with HOST name www.netscaler.com and the listed server ip's
#####
#Filter CACHE_F HOST www.netscaler.com IP 192.168.100.89 192.168.100.95 192.168.100.52 192.168.100.53 ON
#####
# netscaler origin server example
# Not interested in Origin server to Cache traffic transaction logging
#####
#Filter ORIGIN_SERVERS IP 192.168.100.64 192.168.100.65 192.168.100.66 192.168.100.67 192.168.100.225 192.168.100.226 192.168.
100.227 192.168.100.228 OFF
#####
# netscaler image server example
```

```

# all the image server logging.
#####
#Filter IMAGE_SERVER HOST www.netscaler.images.com IP 192.168.100.71 192.168.100.72 192.168.100.169 192.168.100.170 192.168.10
0.171 ON
#####
# NCSA Format logging, new file is created every day midnight or on reaching 20MB file size,
# and the file name is /datadisk5/netscaler/log/NS<hostname>/Nsmmdyy.log.
# Exclude objects that ends with .gif .jpg .jar.
#####
#begin ORIGIN_SERVERS
# logFormat      NCSA
# logInterval    Daily
# logFileSizeLimit 40
# logFilenameFormat /datadisk5/ORGIN/log/%v/NS%{%m%d%y}t.log
# logExclude     .gif .jpg .jar
#end ORIGIN_SERVERS

#####
# NCSA Format logging, new file is created every day midnight or on reaching 20MB file size,
# and the file name is /datadisk5/netscaler/log/NS<hostname>/Nsmmdyy.log with log record timestamp as GMT.
#####
#begin CACHE_F
# logFormat      NCSA
# logInterval    Daily
# logFileSizeLimit 20
# logFilenameFormat /datadisk5/netscaler/log/%v/NS%{%m%d%y}t.log
# logtime        GMT
#end CACHE_F

#####
# W3C Format logging, new file on reaching 20MB and the log file path name is
# atadisk6/netscaler/log/server's ip/Exmmydd.log with log record timestamp as LOCAL.
#####
#begin IMAGE_SERVER
# logFormat      W3C
# logInterval    Size
# logFileSizeLimit 20
# logFilenameFormat /datadisk6/netscaler/log/%AEx%{%m%d%y}t
# logtime        LOCAL
#end IMAGE_SERVER

#####
# Virtual Host by Name firm, can filter out the logging based on the host name by,
#####

#Filter VHOST_F IP 10.101.2.151 NETMASK 255.255.255.0
#begin VHOST_F
# logFormat      W3C
# logInterval    Daily
# logFileSizeLimit 10
logFilenameFormat /ns/prod/vhost/%v/Ex%{%m%d%y}t
#end VHOST_F

##### END FILTER CONFIGURATION #####
Creating Filters

```

Updated: 2014-01-06

You can use the default filter definition located in the configuration file (log.conf), or you can modify the filter or create a new filter. You can create more than one log filter.

Note: Consolidated logging, which logs transactions for which no filter is defined, uses the default filter if it is enabled. Consolidated logging of all servers can be done by defining only the default filter.

If the server hosts multiple Web sites and each Web site has its own domain name, and each domain is associated with a virtual server, you can configure Web server logging to create a separate log directory for each Web site. The following table displays the parameters for creating a filter.

Table 1. Parameters for Creating a Filter

Parameter	Specifies
filterName	Name of the filter. The filter name can include alphanumeric characters and cannot be longer than 59 characters. Filter names longer than 59 characters are truncated to 59 characters.
HOST name	Host name of the server for which the transactions are being logged.
IP ip	IP address of the server for which transactions are to be logged (for example, if the server has multiple domains that have one IP address).
IP ip 2...ip n:	Multiple IP addresses (for example, if the server domain has multiple IP addresses).
ip6 ip	IPv6 address of the server for which transactions are to be logged.
IP ip NETMASK mask	IP addresses and netmask combination to be used on a subnet.
ON OFF	Enable or disable the filter to log transactions. If no argument is selected, the filter is enabled (ON).

To create a filter

To create a filter, enter the following command in the log.conf file:

- filter <filterName> <HOST name> | [IP<ip>] | [IP<ip 2...ip n>] | <IP ip NETMASK mask> [ON | OFF]
- filter <filterName> <HOST name> | [IP6 ip/<prefix length>][ON | OFF]

To create a filter for a virtual server

To create a filter for a virtual server, enter the following command in the log.conf file:

```
filter <filterName> <VirtualServer IP address>
```

Example

In the following example, you specify an IP address of 192.168.100.0 and netmask of 255.255.255.0. The filter applies to IP addresses 192.168.100.1 through 192.168.100.254.

```
Filter F1 HOST www.netscaler.com ON
```

```
Filter F2 HOST www.netscaler.com IP 192.168.100.151 ON
```

```
Filter F3 HOST www.netscaler.com IP 192.168.100.151 192.165.100.152 ON
```

```
Filter F4 IP 192.168.100.151
```

Filter F5 IP 192.168.100.151 HOST www.netscaler.com OFF
Filter F6 HOST www.netscaler.com HOST www.xyz.com HOST www.abcxyz.com IP 192.168.100.200 ON
Filter F7 IP 192.250.100.0 NETMASK 255.255.255.0
Filter F8 HOST www.xyz.com IP 192.250.100.0 NETMASK 255.255.255.0 OFF
For creating filters for servers having IPv6 addresses.
Filter F9 2002::8/112 ON
Filter F10 HOST www.abcd.com IP6 2002::8 ON

Specifying Log Properties

Log properties are applied to all log entries associated with the filter. The log property definition begins with the keyword BEGIN and ends with END as illustrated in the following example:

```
BEGIN <filename>  
logFormat ...  
logFilenameFormat ...  
logInterval ...  
logFileSize ....  
logExclude ....  
logTime ....  
END
```

Entries in the definition can include the following:

- **LogFormat** specifies the Web server logging feature that supports NCSA, W3C Extended, and custom log file formats.

By default, the logformat property is w3c. To override, enter custom or NCSA in the configuration file, for example:

```
LogFormat NCSA
```

Note: For the NCSA and custom log formats, local time is used to time stamp transactions and for file rotation.

- **LogInterval** specifies the intervals at which new log files are created. Use one of the following values:

- Hourly: A file is created every hour.
- Daily: A file is created every day at midnight. Default value.
- Weekly: A file is created every Sunday at midnight.
- Monthly: A file is created on the first day of the month at midnight.
- None: A file is created only once, when Web server logging starts.

Example

```
LogInterval Daily
```

- **LogFileSizeLimit** specifies the maximum size of the log file in MB. It can be used with any log interval (weekly, monthly, and so on.) A file is created when the maximum file size limit is reached or when the defined log interval time elapses.

To override this behavior, specify the size as the loginterval property so that a file is created only when the log file size limit is reached.

The default LogFileSizeLimit is 10 MB.

Example

```
LogFileSizeLimit 35
```

- **LogFilenameFormat** specifies the file name format of the log file. The name of the file can be of the following types:

- Static: Specifies a constant string that contains the absolute path and file name.
- Dynamic: Specifies an expression containing the following format:
 - Server IP address (%A)
 - Date (%{format}t)
 - URL suffix (%x)
 - Host name (%v)

Example

LogFileNameFormat Ex%{%m%d%y}t.log

This command creates the first file name as Exmmdyy.log, then every hour creates a file with file name: Exmmdyy.log.0, Exmmdyy.log.1,..., Exmmdyy.log.n.

Example

LogInterval size

LogFileSize 100

LogFileNameFormat Ex%{%m%d%y}t

Caution: The date format %t specified in the LogFileNameFormat command overrides the log interval property for that filter. To prevent a new file being created every day instead of when the specified log file size is reached, do not use %t in the LogFileNameFormat.

- **LogExclude** prevents logging of transactions with the specified file extensions.

Example

LogExclude .html

This command creates a log file that excludes log transactions for *.html files.

- **LogTime** specifies log time as either GMT or LOCAL.

The defaults are:

- NCSA log file format: LOCAL
- W3C log file format: GMT.

Understanding the NCSA and W3C Log Formats

Updated: 2013-09-30

The NetScaler supports the following standard log file formats:

- NCSA Common Log Format
- W3C Extended Log Format

NCSA Common Log Format

If the log file format is NCSA, the log file displays log information in the following format:

Client_IP_address -User_Name [Date:Time -TimeZone] "Method Object HTTP_version"

HTTP_StatusCode BytesSent

To use the NCSA Common log format, enter NCSA in the LogFormat argument in the log.conf file.

The following table describes the NCSA Common log format.

Table 2. NCSA Common Log Format

Argument	Specifies
Client_IP_address	The IP address of the client computer.
User Name	The user name.
Date	The date of the transaction.
Time	The time when the transaction was completed.

Argument	Specifies
Time Zone	The time zone (Greenwich Mean Time or local time).
Method	The request method (for example; GET, POST).
Object	The URL.
HTTP_version	The version of HTTP used by the client.
HTTP_StatusCode	The status code in the response.
Bytes Sent	The number of bytes sent from the server.

W3C Extended Log Format

An extended log file contains a sequence of lines containing ASCII characters terminated by either a Line Feed (LF) or the sequence Carriage Return Line Feed (CRLF.) Log file generators must follow the line termination convention for the platform on which they are run.

Log analyzers must accept either LF or CRLF form. Each line may contain either a directive or an entry. If you want to use the W3C Extended log format, enter W3C as the Log-Format argument in the log.conf file.

By default, the standard W3C log format is defined internally as the custom log format, shown as follows:

```
%{%Y-%m-%d%H:%M:%S}t %a %u %S %A %p %m %U %q %s %j %J %T %H %+{user-agent}i %+{cookie} i%+{referer}i
```

For a description of the meaning of this each custom format, see "[Appendix A: Arguments for Defining a Custom Log Format](#)." You can also change the order or remove some fields in this W3C log format. For example:

```
logFormat W3C {%Y-%m-%d%H:%M:%S}t %m %U
```

W3C log entries are created with the following format:

```
#Version: 1.0
#Fields: date time cs-method cs-uri
#Date: 12-Jun-2001 12:34
2001-06-12 12:34:23 GET /sports/football.html
2001-06-12 12:34:30 GET /sports/football.html
```

Entries

Entries consist of a sequence of fields relating to a single HTTP transaction. Fields are separated by white space; Citrix recommends the use of tab characters. If a field in a particular entry is not used, a dash (-) marks the omitted field.

Directives

Directives record information about the logging process. Lines beginning with the pound sign (#) contain directives.

The following table describes the directives.

Table 3. Directive Descriptions

Directive	Description
Version: <integer>.<integer>	Displays the version of the extended log file format used. This document defines version 1.0.

Directive	Description
Fields: [<specifier>...]	Identifies the fields recorded in the log.
Software: <string>	Identifies the software that generated the log.
Start-Date: <date> <time>	Displays the date and time at which the log was started.
End-Date: <date> <time>	Displays the date and time at which logging finished.
Date: <date> <time>	Displays the date and time when the entry was added.
Remark: <text>	Displays comments. Analysis tools ignore data recorded in this field.

Note: The Version and Fields directives are required. They precede all other entries in the log file.

Example

The following sample log file shows the log entries in W3C Extended log format:

```
#Version: 1.0
#Fields: time cs-method cs-uri
#Date: 12-Jan-1996 00:00:00
00:34:23 GET /sports/football.html
12:21:16 GET /sports/football.html
12:45:52 GET /sports/football.html
12:57:34 GET /sports/football.html
```

Fields

The Fields directive lists a sequence of field identifiers that specify the information recorded in each entry. Field identifiers may have one of the following forms:

- **identifier:** Relates to the transaction as a whole.
- **prefix-identifier:** Relates to information transfer between parties defined by the value prefix.
- **prefix (header):** Specifies the value of the HTTP header field header for transfer between parties defined by the value prefix. Fields specified in this manner always have the type <string>.

The following table describes defined prefixes.

Table 4. Prefix Descriptions

Prefix	Specifies
c	Client
s	Server
r	Remote
cs	Client to server
sc	Server to client

Prefix	Specifies
	Server to remote server (prefix used by proxies)
rs	Remote server to server (prefix used by proxies)
x	Application-specific identifier

Examples

The following examples are defined identifiers that use prefixes:

cs-method: The method in the request sent by the client to the server.

sc(Referer): The Referer field in the reply.

c-ip: The IP address of the client.

Identifiers

The following table describes the W3C Extended log format identifiers that do not require a prefix.

Table 5. W3C Extended Log Format Identifiers (No Prefix Required)

Identifier	Description
date	The date on which the transaction was done.
time	The time when the transaction is done.
time-taken	The time taken (in seconds) for the transaction to complete.
bytes	The number of bytes transferred.
cached	Records whether a cache hit has occurred. A zero indicates a cache miss.

The following table describes the W3C Extended log format identifiers that require a prefix.

Table 6. W3C Extended Log Format Identifiers (Requires a Prefix)

Identifier	Description
IP	The IP address and the port number.
dns	The DNS name.
status	The status code.
comment	The comment returned with status code.
method	The method.

Identifier	Description
url-stem	The stem portion of the URL.
url-query	The query portion of the URL.

The W3C Extended Log file format allows you to choose log fields. These fields are shown in the following table.

Table 7. W3C Extended Log File Format (Allows Log Fields)

Field	Description
Date	The date on which the transaction is done.
Time	The time when the transaction is done.
Client IP	The IP address of the client.
User Name	The user name.
Service Name	The service name, which is always HTTP.
Server IP	The server IP address.
Server Port	The server port number
Method	The request method (for example; GET , POST).
Url Stem	The URL stem.
Url Query	The query portion of the URL.
Http Status	The status code in the response.
Bytes Sent	The number of bytes sent to the server (request size, including HTTP headers).
Bytes Received	The number of bytes received from the server (response size, including HTTP headers).
Time Taken	The time taken for transaction to complete, in seconds.
Protocol Version	The version number of HTTP being used by the client.
User Agent	The User-Agent field in the HTTP protocol.
Cookie	The Cookie field of the HTTP protocol.

Field	Description
Referer	The Réferer field of the HTTP protocol.

Creating a Custom Log Format

Updated: 2013-09-30

You can customize the display format of the log file data manually or by using the NSWL library. By using the custom log format, you can derive most of the log formats that Apache currently supports.

Creating a Custom Log Format by Using the NSWL Library

Use one of the following NSWL libraries depending on whether the NSWL executable has been installed on a Windows or Solaris host computer:

- **Windows:** The nswl.lib library located in \ns\bin directory on the system manager host computer.
- **Solaris:** The libnswl.a library located in /usr/local/netScaler/bin.

To create the custom log format by using the NSWL Library

1. Add the following two C functions defined by the system in a C source file:

ns_userDefFieldName() : This function returns the string that must be added as a custom field name in the log record.

ns_userDefFieldVal() : This function implements the custom field value, then returns it as a string that must be added at the end of the log record.

2. Compile the file into an object file.
3. Link the object file with the NSWL library (and optionally, with third party libraries) to form a new NSWL executable.
4. Add a %d string at the end of the logFormat string in the configuration file (log.conf).

Example

```
#####
# A new file is created every midnight or on reaching 20MB file size,
# and the file name is /datadisk5/netScaler/log/NS<hostname>/Nsmmdyy.log and create digital
#signature field for each record.
BEGIN CACHE_F
logFormat custom "%a - %{user-agent}i [%d/%B/%Y %T -%g] "%x" %s %b%{referrer}i "%{user-agent}i "%{cookie}i" %d "
logInterval Daily
logFileSizeLimit 20
logFilenameFormat /datadisk5/netScaler/log/%v/NS%{m%Y}t.log
END CACHE_F
```

Creating a Custom Log Format Manually

To customize the format in which log file data should appear, specify a character string as the argument of the LogFormat log property definition. For more information, see "[Appendix A: Arguments for Defining a Custom Log Format](#)." The following is an example where character strings are used to create a log format:

```
LogFormat Custom ""%a - %{user-agent}i "[%d/%m/%Y]t %U %s %b %T"
```

- The string can contain the "c" type control characters \n and \t to represent new lines and tabs.
- Use the <Esc> key with literal quotes and backslashes.

The characteristics of the request are logged by placing % directives in the format string, which are replaced in the log file by the values.

If the %v (Host name) or %x (URL suffix) format specifier is present in a log file name format string, the following characters in the file name are replaced by an underscore symbol in the log configuration file name:

" * ./ : < > ? \ |

Characters whose ASCII values lie in the range of 0-31 are replaced by the following:

%<ASCII value of character in hexadecimal>.

For example, the character with ASCII value 22 is replaced by %16.

Caution: If the %v format specifier is present in a log file name format string, a separate file is opened for each virtual host. To ensure continuous logging, the maximum number of files that a process can have open should be sufficiently large. See your operating system documentation for a procedure to change the number of files that can be opened.

Creating Apache Log Formats

You can derive from the custom logs most of the log formats that Apache currently supports. The custom log formats that match Apache log formats are:

NCSA/combined: LogFormat custom %h %l %u [%t] "%r" %s %B "%{referer}i" "%{user-agent}i"

NCSA/Common: LogFormat custom %h %l %u [%t] "%r" %s %B

Referer Log: LogFormat custom "%{referer}i" -> %U

Useragent: LogFormat custom %{user-agent}i

Similarly, you can derive the other server log formats from the custom formats.

Arguments for Defining a Custom Log Format

Updated: 2015-04-02

The following table describes the data that you can use as the Log Format argument string:

Table 8. Custom Log Format

Argument	Specifies
%a	Remote IPv4 address.
%A	Local IPv4 address.
%a6	Remote IPv6 address.
%A6	Local IPv6 address.
%B	Bytes sent, excluding the HTTP headers (response size).
%b	Bytes received, excluding the HTTP headers (request size).
%d	User-defined field.
%e1	Value of the first custom HTTP request header.
%e2	Value of the second custom HTTP request header.

Argument	Specifies
%E1	Value of the first custom HTTP response header.
%E2	Value of the second custom HTTP response header.
Note: For instructions on how to export custom HTTP headers, see " Configuring the NetScaler for Web Server Logging ."	
%g	Greenwich Mean Time offset (for example, -0800 for Pacific Standard Time).
%h	Remote host.
%H	Request protocol.
{Foobar}i	Contents of the Foobar: header line(s) in the request sent to the server. The system supports the User-Agent, Referer and cookie headers. The + after the % in this format informs the logging client to use the + as a word separator.
%j	Bytes received, including headers (request size)
%J	Bytes sent, including headers (response size)
%l	Remote log name (from identd, if supplied).
%m	Request method.
%M	Time taken to serve the request (in microseconds)
{Foobar}o	Contents of Foobar: header line(s) in the reply. USER-AGENT, Referer, and cookie headers (including set cookie headers) are supported.
%p	Canonical port of the server serving the request.
%q	Query string (prefixed with a question mark (?) if a query string exists).
%r	First line of the request.
%s	Requests that were redirected internally, this is the status of the original request.
%t	Time, in common log format (standard English time format).
{format}t	Time, in the form given by format, must be in the strftime(3) format. For format descriptions, see " Appendix B: Time Format Definition ."
%T	Time taken to serve the request, in seconds.
%u	Remote user (from auth; may be bogus if return status (%s) is 401).

Argument	Specifies
%U	URL path requested.
%v	Canonical name of the server serving the request.
%V	Virtual server IPv4 address in the system, if load balancing, content switching, and/or cache redirection is used.
%V6	Virtual server IPv6 address in the system, if load balancing, content switching, and/or cache redirection is used.

For example, if you define the log format as `%+{user-agent}i`, and if the user agent value is Citrix NetScaler system Web Client, then the information is logged as `NetScaler system+Web+Client`. An alternative is to use double quotation marks. For example, `"%{user-agent}i"` logs it as `"Citrix NetScaler system Web Client."` Do not use the <Esc> key on strings from `%..r`, `%..i` and, `%..o`. This complies with the requirements of the Common Log Format. Note that clients can insert control characters into the log. Therefore, you should take care when working with raw log files.

Time Format Definition

Updated: 2015-04-28

The following table lists the characters that you can enter as the format part of the `%{format}t` string described in the Custom Log Format table of "[Arguments for Defining a Custom Log Format](#)." Values within brackets ([]) show the range of values that appear. For example, [1,31] in the %d description in the following table shows %d ranges from 1 to 31.

Table 9. Time Format Definition

Argument	Specifies
%%	The same as %.
%a	The abbreviated name of the week day for the locale.
%A	The full name of the week day for the locale.
%b	The abbreviated name of the month for the locale.
%B	The full name of the month for the locale.
%C	The century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by a 0.
%d	The day of month [1,31]; single digits are preceded by 0.
%e	The day of month [1,31]; single digits are preceded by a blank.
%h	The abbreviated name of the month for the locale.
%H	The hour (24-hour clock) [0,23]; single digits are preceded by a 0.
%I	The hour (12-hour clock) [1,12]; single digits are preceded by a 0.

Argument	Specifies
%j	The number of the day in the year [1,366]; single digits are preceded by 0.
%k	The hour (24-hour clock) [0,23]; single digits are preceded by a blank.
%l	The hour (12-hour clock) [1,12]; single digits are preceded by a blank.
%m	The number of the month in the year [1,12]; single digits are preceded by a 0.
%M	The minute [00,59]; leading 0 is permitted but not required.
%n	Inserts a new line.
%p	The equivalent of either a.m. or p.m. for the locale.
%r	The appropriate time representation in 12-hour clock format with %p.
%S	The seconds [00,61]; the range of values is [00,61] rather than [00,59] to allow for the occasional leap second and for the double leap second.
%t	Inserts a tab.
%u	The day of the week as a decimal number [1,7]. 1 represents Sunday, 2 represents Tuesday and so on.
%U	The number of the week in the year as a decimal number [00,53], with Sunday as the first day of week 1.
%w	The day of the week as a decimal number [0,6]. 0 represents Sunday.
%W	Specifies the number of the week in the year as a decimal number [00,53]. Monday is the first day of week 1.
%y	The number of the year within the century [00,99]. For example, 5 would be the fifth year of that century.
%Y	The year, including the century (for example, 1993).

Note: If you specify a conversion that does not correspond to any of the ones described in the preceding table, or to any of the modified conversion specifications listed in the next paragraph, the behavior is undefined and returns 0.

The difference between %U and %W (and also between modified conversions %OU and %OW) is the day considered to be the first day of the week. Week number 1 is the first week in January (starting with a Sunday for %U, or a Monday for %W). Week number 0 contains the days before the first Sunday or Monday in January for %U and %W.

Configuring Call Home

Jun 14, 2016

The Call Home feature monitors your NetScaler appliance for critical error conditions. Call Home registers your appliance with the Citrix Technical Support server. If your appliance is successfully registered with the Support server, Call Home automatically uploads system data to that server in the event that one of the conditions occurs. The NetScaler Appliance keeps a full log of all upload events. If you are unable to correct the problem after reviewing the appliance's log, you can contact the Citrix Technical Support team and open a service request. The team can analyze the uploaded system data and recommend possible solutions.

The Call Home feature is supported on all three platforms of NetScaler ADC.

- In NetScaler MPX, Call Home feature is supported on all MPX models.
- In NetScaler SDX, Call Home feature is supported on all VPX instances running on a SDX box 002E

Following is a typical set up for Call Home.

Step 1: Appliance Registration

Step 2: Trigger Based Upload

The process flow for using Call Home can be categorized as follows:

- Registration of the NetScaler appliance to the Citrix Technical Support server.
- Uploading of the appliance's data to the Citrix Technical Support server. The support server has the following URL: <https://callhome.citrix.com/>.
- Opening a Technical Support case (Optional).

By default, the Citrix Call Home service is disabled on the appliance. You must first enable the service to register the appliance for critical error conditions.

Registration of the NetScaler appliance. The appliance has to be registered to the Citrix Technical Support server before Call Home can upload the system data to the server when predefined error conditions occur on the appliance. Enabling the Call Home feature on the NetScaler appliance initiates the registration process. The process flow is as follows:

1. The Call Home process sends the following details to the Citrix Technical Support server:

- Hardware serial number is shared for NetScaler MPX and SDX models
 - License serial number is shared for NetScaler VPX models.
2. The server checks its database for an active technical support service contract for the appliance.
 3. If there is an active technical support service contract, the support server registers the NetScaler appliance for Call Home and sends a successful-registration response to the appliance stating that the feature is successfully enabled. If there is no active technical support service contract, the server sends a registration-failure response to the NetScaler appliance.

The following table lists the error conditions that Call Home currently monitors on a NetScaler Appliance:

Table 1. List of error conditions monitored by Call Home

Error Condition	Indicates	Call Home Monitoring Interval	Corresponding SNMP Alarm Name
Compact flash drive errors	The compact flash drive on the appliance that encountered read or write errors.	24 hours	COMPACT-FLASH-ERRORS
Hard disk drive errors	The hard drives on the appliance that encountered read or write errors.	24 hours	HARD-DISK-DRIVE-ERRORS
Power supply unit failure	One of the power supply units on the NetScaler appliance has failed.	7 seconds	POWER-SUPPLY-FAILURE
SSL card failure	One of the SSL cards on the NetScaler appliance has failed.	7 seconds	SSL-CARD-FAILED
Warm restart	The appliance has warm restarted due to a failure of a system process.	After every restart of the NetScaler appliance.	WARM-RESTART-EVENT

Note: The Call Home feature do not monitor the power supply unit (PSU) status for VPX models and VPX instances.

Uploading of appliance's data to the Support server. An error condition triggers the following sequence of events:

1. The Call Home process checks the registration status. If the status indicates successful registration, the process advances to the next step.
2. The Call Home process runs a showtech support script that collects all of the system related data in a tar file. The data in the tar file includes configurations, logs, and statistics. Call Home locally saves the tar file at `/var/tmp/support/callhome`.
3. Call Home uploads a copy of the tar file to the Citrix Technical Support server. The Appliance logs the uploading of the tar file in a log file named `callhome.log` located at `/var/log`. You can also configure the CALLHOME-UPLOAD-EVENT SNMP alarm to generate an SNMP alert whenever Call Home uploads happen.
4. If the SNMP alarm related to the error condition is enabled, the SNMP agent on the appliance generates an SNMP trap message and sends it to all of the configured SNMP trap destinations. For more information about configuring SNMP alarms and trap destinations, see "[Configuring the NetScaler to Generate SNMPv1 and SNMPv2 Traps.](#)"

Note:

- Call Home creates the Call Home tar file and uploads it to the CITRIX tech support server for only the first occurrence of a particular error condition since the appliance was last restarted. If you want the NetScaler appliance to send you alerts each time a particular error condition occurs, configure the corresponding SNMP alarm for the error condition.
- For the warm restart error condition, the Call Home tar file is uploaded to the server again only if the result of the failure

is different from the result of the previous failure.

The Call Home tar file has the following name format:

collector_callhome_<NSIP of the appliance>_<P for Primary or standalone, or S for Secondary>_<date>_<hours, in 24 hr format, according to the local time zone>_<minutes>.tar.gz. For example, collector_callhome_10.105.13.100_P_2Feb2012_20_30.tar.gz.

Opening a Technical Support Service Request . After you review the logs and SNMP trap messages for Call Home upload events, you have the option of contacting the Citrix Technical Support team and opening a service request. For more information about contacting the team and opening a service request, see <http://support.citrix.com/article/CTX132307>.

The Support team can then analyze the system data in the uploaded Call Home tar files and sends recommendations for possible solutions to the administrator's email address.

Before you begin configuring Call Home, do the following:

- Make sure that the NetScaler appliance is connected to the Internet or to a proxy server that has internet connectivity.
- Make sure that you have an active Citrix Technical Support service contract for the appliance.

Configuring Call Home on the NetScaler appliance consists of the following tasks:

1. **Enable the Call Home feature.** When you enable the Call Home feature, the Call Home process registers the appliance with the Citrix Technical Support server. The registration takes some time to complete. During that time, the appliance displays the status as IN PROGRESS. When the registration is complete, the appliance displays the status as SUCCESSFUL.
Note: While upgrading the NetScaler appliance from an older release to release 10.1 or later, the NetScaler appliance prompts you to enable the Call Home feature, if:
 - The Call Home feature is not supported in the older release.
 - The Call Home feature is disabled in the older release.
2. **(Optional) Specify the administrator's email address.** The Call Home process sends the email address to the Support server, where it is stored for future correspondence regarding Call Home uploads.
3. **(Optional) Specify Proxy server settings.** NetScaler appliance needs internet connectivity to upload the collector archive to the Citrix Technical Support server. If the appliance does not have internet connectivity, then a proxy server (having internet connectivity) can be configured to upload the data.
4. **(Optional) Enable the CALLHOME-UPLOAD-EVENT SNMP alarm.** The SNMP agent on the NetScaler appliance generates a trap message and sends to all the configured SNMP trap destinations. The message includes the status of uploading of the Call Home tar file by the Call Home process. For more information about configuring SNMP alarms and trap destinations, see "[Configuring the NetScaler to Generate SNMPv1 and SNMPv2 Traps.](#)"
5. **(Optional) Enable all of the corresponding SNMP alarms.** Call Home creates and uploads a Call Home tar file for the first occurrence of a monitored error condition since the appliance was last restarted. If you want to be alerted of these error conditions, you can configure the corresponding SNMP alarm. Table 1 lists all the corresponding SNMP alarms. For more information about configuring SNMP alarms and trap destinations, see "[Configuring the NetScaler to Generate SNMPv1 and SNMPv2 Traps.](#)"

To enable Call Home by using the command line interface

At the command prompt, type any of the following:

- enable ns feature ch
- enable ns feature callhome

To check the status of the appliance's registration to the Support server by using the command line interface

At the command prompt, type:

```
show callhome
```

Example

```
> enable ns feature ch
```

```
Done
```

```
> show callhome
```

```
Callhome feature: ENABLED
```

```
Registration with Citrix upload server IN PROGRESS
```

```
E-mail address configured:
```

```
Proxy mode:NO  laddress:  Port:0
```

```
Trigger event      State  First occurrence  Latest occurrence
```

```
-----
```

Trigger event	State	First occurrence	Latest occurrence
1) Compact flash errors	Enabled
2) Hard disk drive errors	Enabled
3) Power supply unit failure	Enabled
4) SSL card failure	Enabled
5) Warm restart	Enabled	N/A	..

```
Done
```

```
> show callhome
```

```
Callhome feature: ENABLED
```

```
Registration with Citrix upload server SUCCESSFUL
```

```
E-mail address configured:
```

```
Proxy mode:NO  laddress:  Port:0
```

```
Trigger event      State  First occurrence  Latest occurrence
```

```
-----
```

Trigger event	State	First occurrence	Latest occurrence
1) Compact flash errors	Enabled
2) Hard disk drive errors	Enabled
3) Power supply unit failure	Enabled
4) SSL card failure	Enabled
5) Warm restart	Enabled	N/A	..

```
Done
```

To specify the administrator's email address and proxy server settings by using the command line interface

At the command prompt, type:

- set callhome -emailAddress <string>
- set callhome -proxyMode (YES | NO) [-IPAddress <ip_addr|ipv6_addr|*>] [-port <port|*>]

- show callhome

Example

```
> set callhome -emailAddress exampleadmin@example.com
Done
```

```
> set callhome -proxyMode Yes -IPAddress 10.102.167.33 -port 80
Done
```

```
> show callhome
E-mail address configured: exampleadmin@example.com
Proxy mode:YES  Ipaddress: 10.102.167.33  Port:80
```

Trigger event	State	First occurrence	Latest occurrence
1) Compact flash errors	Enabled
2) Hard disk drive errors	Enabled
3) Power supply unit failure	Enabled
4) SSL card failure	Enabled
5) Warm restart	Enabled	N/A	..

Done

To enable Call Home proxy mode by using the command line interface

At the command prompt, type:

- set callhome -ipAddress <ipaddress> -port <port> -proxyMode [yes | no]
- show callhome

Note: Proxy mode is enabled only when the -proxymode parameter is set to YES. If it is set to NO, the proxy functionality does not work, even if the IP address and port are configured. The port number should be for an HTTP service on the proxy server, not for an HTTPS service.

Example

```
> set callhome ipAddress 10.0.0.1 -port 80 -proxyMode yes
Done
```

To enable Call Home by using the configuration utility

Navigate to System > Settings, click Configure Advanced Features and select the Call Home option.

To check the status of the appliance's registration with the Support server by using the configuration utility

Navigation to System > Diagnostics and, in the Technical Support Tools group, select Call Home option to view the status of registration.

To specify the administrator's email address by using the configuration utility

Navigation to System > Diagnostics and, in the Technical Support Tools group, select Call Home option to specify the administrator's email address.

To enable Call Home proxy mode by using the configuration utility

Navigation to System > Diagnostics and, in the Technical Support Tools group, select Call Home option to specify the proxy server's IP address and the port number.

Reporting Tool

Jun 01, 2015

Use the Citrix® NetScaler® Reporting tool to view NetScaler performance statistics data as reports. Statistics data are collected by the nscollect utility and are stored in a database. When you want to view certain performance data over a period of time, the Reporting tool pulls out specified data from the database and displays them in charts.

Reports are a collection of charts. The Reporting tool provides built-in reports as well as the option to create custom reports. In a report, you can modify the charts and add new charts. You can also modify the operation of the data collection utility, nscollect, and stop or start its operation.

This document includes the following details:

- [Using the Reporting Tool](#)
- [Working with Reports](#)
- [Working with Charts](#)
- [Examples](#)
- [Stopping and Starting the Data Collection Utility](#)

Using the Reporting Tool

The Reporting tool is a Web-based interface accessed from the Citrix® NetScaler® appliance. Use the Reporting tool to display the performance statistics data as reports containing graphs. In addition to using the built-in reports, you can create custom reports, which you can modify at any time. Reports can have between one and four charts. You can create up to 256 custom reports.

To invoke the Reporting tool

1. Use the Web browser of your choice to connect to the IP address of the NetScaler (for example, <http://10.102.29.170/>). The Web Logon screen appears.
2. In the User Name text box, type the user name assigned to the NetScaler.
3. In the Password text box, type the password.
4. In the Start in drop-down box, select Reporting.
5. Click Login.

The following screen shots show the report toolbar and the chart toolbar, which are frequently referenced in this documentation.

Figure 1. *Report Toolbar*

Figure 2. *Chart Toolbar*

Working with Reports

Updated: 2013-09-27

You can plot and monitor statistics for the various functional groups configured on the NetScaler over a specified time interval. Reports enable you to troubleshoot or analyze the behavior of your appliance. There are two types of reports: built-in reports and custom reports. Report content for built-in or custom reports can be viewed in a graphical format or a

tabular format. The graphical view consists of line, area, and bar charts that can display up to 32 sets of data (counters). The tabular view displays the data in columns and rows. This view is useful for debugging error counters.

The default report that is displayed in the Reporting tool is CPU vs. Memory Usage and HTTP Requests Rate. You can change the default report view by displaying the report you want as your default view, and then clicking Default Report.

Reports can be generated for the last hour, last day, last week, last month, last year, or you can customize the duration.

You can do the following with reports:

- Toggle between a tabular view of data and a graphical view of data.
- Change the graphical display type, such as bar chart or line chart.
- Customize charts in a report.
- Export the chart as an Excel comma-separated value (CSV) file.
- View the charts in detail by zooming in, zooming out, or using a drag-and-drop operation (scrolling).
- Set a report as the default report for viewing whenever you log on.
- Add or remove counters.
- Print reports.
- Refresh reports to view the latest performance data.

Using Built-in Reports

The Reporting tool provides built-in reports for frequently viewed data. Built-in reports are available for the following functional groups: System, Network, SSL, Compression, Integrated Cache, NetScaler Gateway, and Citrix NetScaler Application Firewall. By default, the built-in reports are displayed for the last day. However, you can view the reports for the last hour, last week, last month, or last year.

Note: You cannot save changes to built-in reports, but you can save a modified built-in report as a custom report. To display a built-in report

1. In the left pane of the Reporting tool, under Built-in Reports, expand a group (for example, SSL).
2. Click a report (for example, SSL > All Backend Ciphers).

Creating and Deleting Reports

You can create your own custom reports and save them with user-defined names for reuse. You can plot different counters for different groups based on your requirements. You can create up to 256 custom reports.

You can either create a new report or save a built-in report as a custom report. By default, a newly created custom report contains one chart named System Overview, which displays the CPU Usage counter plotted for the last day. You can customize the interval and set the data source and time zone from the report toolbar. Within a report, you can use the chart toolbars to add, modify, or delete charts, as described in "[Working with Charts](#)."

By default, newly created custom reports contain one chart named System Overview that displays a CPU Usage counter plotted for the last day.

To create a custom report

1. In the Reporting tool, on the report toolbar, click Create, or if you want to create a new custom report based on an existing report, open the existing report, and then click Save As.
2. In Report Name box, type a name for the custom report.
3. Do one of the following:

- To add the report to an existing folder, in Create in or Save in, click the down arrow to choose an existing folder, and then click OK.
- To create a new folder to store the report, click the Click to add folder icon, in Folder Name, type the name of the folder, and in Create in, specify where you want the new folder to reside in the hierarchy, and then click OK.

Note: You can create up to 128 folders.

To delete a custom report

1. In the left pane of the Reporting tool, next to Custom Reports, click the Click to manage custom reports icon.
2. Select the check box that corresponds with the report you want to delete, and then click Delete.

Note: When you delete a folder, all the contents of that folder are deleted.

Modifying the Time Interval

By default, built-in reports display data for the last day. However, if you want to change the time interval for a built-in report, you can save the report as a custom report. The new interval applies to all charts in the report. The following table describes the time-interval options.

Table 1. Time Intervals

Time interval	Displays
 Last Hour	Statistics data collected for the last hour.
 Last Day	Statistics data collected for the last day (24 hours).
 Last Week	Statistics data collected for the last week (7 days).
 Last Month	Statistics data collected for the last month (31 days).
 Last Year	Statistics data collected for the last year (365 days).
 Custom	Statistics data collected for a time period that you are prompted to specify.

To modify the time interval

1. In the left pane of the Reporting tool, click a report.
2. On the report toolbar, click Duration, and then click a time interval.

Setting the Data Source and Time Zone

You can retrieve data from different data sources to display them in the reports. You can also define the time zone for the reports and apply the currently displayed report's time selection to all the reports, including the built-in reports.

To set the data source and time zone

1. In the Reporting tool, on the report toolbar, click Settings.
2. In the Settings dialog box, in Data Source, select the data source from which you want to retrieve the counter information.
3. Do one or both of the following:
 - If you want the tool to remember the time period for which a chart is plotted, select the Remember time selection for charts check box.
 - If you want the reports to use the time settings of your NetScaler appliance, select the Use Appliance's time zone check box.

Exporting and Importing Custom Reports

You can share reports with other NetScaler administrators by exporting reports. You can also import reports.

To export or import custom reports

1. In the left pane of the Reporting tool, next to Custom Reports, click the Click to manage custom reports icon.
2. Select the check box that corresponds with the report you want to export or import, and then click Export or Import.
Note: When you export the file, it is exported in a .gz file format.

Working with Charts

Updated: 2013-09-06

Use charts to plot and monitor counters or groups of counters. You can include up to four charts in one report. In each chart, you can plot up to 32 counters. The charts can use different graphical formats (for example, area and bar). You can move the charts up or down within the report, customize the colors and visual display for each counter in a chart, and delete a chart when you do not want to monitor it.

In all report charts, the horizontal axis represents time and the vertical axis represents the value of the counter.

Adding a Chart

When you add a chart to a report, the System Overview chart appears with the CPU Usage counter plotted for the last one day. To plot a different group of statistics or select a different counter, see "[Modifying a Chart](#)."

Note: If you add charts to a built-in report, and you want to retain the report, you must save the report as a custom report. Use the following procedure to add a chart to a report.

To add a chart to a report

1. In the left pane of the Reporting tool, click a report.
2. Under the chart where you want to add the new chart, click the Add icon.

Modifying a Chart

You can modify a chart by changing the functional group for which the statistics are displayed and by selecting different counters.

To modify a chart

1. In the left pane of the Reporting tool, click a report.
2. Under the chart that you want to modify, click Counters.
3. In the dialog box that appears, in the Title box, type a name for the chart.
4. Next to Plot chart for, do one of the following:
 - To plot counters for global counters, such as Integrated Cache and Compression, click System global statistics.
 - To plot entity counters for entity types, such as Load Balancing and GSLB, click System entities statistics.
5. In Select group, click the desired entity.
6. Under Counters, in Available, click the counter name(s) that you want to plot, and then click the > button.
7. If you selected System entities statistics in step 4, on the Entities tab, under Available, click the entity instance name(s) you want to plot, and then click the > button.
8. Click OK.

Viewing a Chart

You can specify the graphical formats of the plotted counters in a chart. Charts can be viewed as line charts, spline charts, step-line charts, scatter charts, area charts, bar charts, stacked area charts, and stacked bar charts. You can also zoom in, zoom out, or scroll inside the plot area of a chart. You can zoom in or out for all data sources for 1 hour, 1 day, 1 week, 1 month, 1 year, and 3 years.

Other options for customizing the view of a chart include customizing the axes of the charts, changing the background and edge color of the plot area, customizing the color and size of the grids, and customizing the display of each data set (counter) in a chart.

Data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.

Whenever you modify a built-in report, you need to save the report as a custom report to retain your changes.

To change the graph type of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart you want to view, on the chart toolbar, click Customize.
3. On the Chart tab, under Category, click Plot type, and then click the graph type you want to display for the chart. If you want to display the graph is 3D, select the Use 3D check box.

To refocus a chart with detailed data

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Zoom In, and do one or both of the following:
 - To refocus the chart to display data for a specific time window, drag and drop the cursor from the start time to the end time. For example, you can view data for a one-hour period on a certain day.
 - To refocus the chart to display data for a data point, simply click once on chart where you want to zoom in and get more detailed information.
3. Once you have the desired range of time for which you want to view detailed data, on the report toolbar, click Tabular

View. Tabular view displays the data in numeric form in rows and columns.

To view numeric data for a graph

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Tabular View. To return to the graphical view, click Graphical View.

Note: You can also view the numeric data in the graphical view by hovering your cursor over the notches in the gridlines.

To scroll through time in a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Scroll, and then click inside the chart and drag the cursor in the direction for which you want to see data for a new time period. For example, if you want to view data in the past, click and drag to the left.

To change the background color and text color of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the axes, click Customize.
3. On the Chart tab, under Category, click one or more of the following:
 - To change the background color, click Background Color, and then select the options for color, transparency, and effects.
 - To change the text color, click Text Color, and then select the options for color, transparency, and effects.

To customize the axes of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the axes, click Customize.
3. On the Chart tab, under Category, click one or more of the following:
 - To change the scale of the left y-axis, click Left Y-Axis, and then select the scale you want.
 - To change the scale of the right y-axis, click Right Y-Axis, in Data set to plot, select the data set, and then select the scale you want.

Note: The data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.

 - To plot each data set in its own hidden y-axis, click Multiple Axes, and then click Enable.

To change the background color, edge color, and gridlines for a plot area of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the plot area, click Customize.
3. On the Plot Area tab, under Category, click one or more of the following:
 - To change the background color and edge color of the chart, click Background Color and Edge Color, and then select the options for color, transparency, and effects.
 - To change the horizontal or vertical grids of the chart, click Horizontal Grids or Vertical Grids, and then select the options for displaying the grids, grid width, grid color, transparency, and effects.

To change the color and graph type of a data set

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the display of the data set (counters), click Customize.

3. On the Data Set tab, in Select Data Set, select the data set (counter) for which you want to customize the graphical display.

Note: The data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.

4. Under Category, do one of more of the following:
 - To change the background color, click Color, and then select the options for color, transparency, and effects.
 - To change the graph type, click Plot type, and then select the graph type you want to display for the data set. If you want to display the graph as 3D, select the Use 3D check box.

Exporting Chart Data to Excel

For further data analysis, you can export charts to Excel in a comma-separated value (CSV) format.

To export chart data to Excel

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart with the data you want to export to Excel, click Export.

Deleting a Chart

If you do not want to use a chart, you can remove it from the report. You can permanently remove charts from custom reports only. If you delete a chart from a built-in report and want to retain the changes, you need to save the report as a custom report.

To delete a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart that you want to delete, click the Delete icon.

Examples

To display the trend report for CPU usage and memory usage for the last week

1. In the left pane of the Reporting tool, under Built-in Reports, expand System.
2. Click the report CPU vs. Memory Usage and HTTP Requests Rate.
3. In the right pane, on the report toolbar, click Duration, and then click Last Week.

To compare the bytes received rate and the bytes transmitted rate between two interfaces for the last week

1. In the right pane, on the report toolbar, click Create.
2. In the Report Name box, type a name for the custom report (for example, Custom_Interfaces), and then click OK. The report is created with the default System Overview chart, which displays the CPU Usage counter plotted for the last hour.
3. Under System Overview, on the chart toolbar, click Counters.
4. In the counter selection pane, in Title, type a name for the chart (for example, Interfaces bytes data).
5. In Plot chart for, click System entities statistics, and then in Select Group, select Interface.
6. On the Entities tab, click the interface name(s) you want to plot (for example, 1/1 and 1/2), and then click the > button.
7. On the Counters tab, click Bytes received (Rate) and Bytes transmitted (Rate) and then click the > button.

8. Click OK.
9. On the report toolbar, click Duration, and then click Last Week.

Stopping and Starting the Data Collection Utility

Updated: 2014-09-24

The data collection utility, `nscollect`, runs automatically when you start the NetScaler ADC. This utility retrieves the application performance data and stores it in the form of data sources on the ADC. You can create up to 32 data sources. The default data source is `/var/log/db/default`.

The data collection utility creates databases for global counters and entity-specific counters, and uses this data to generate reports. Global-counter databases are created at `/var/log/db/<DataSourceName>`. The entity-specific databases are created based on the entities configured on the NetScaler, and a separate folder is created for each entity type in `/var/log/db/<DataSourceName/EntityNameDB>`.

`Nscollect` retrieves data once every 5 minutes. It retains data in 5-minute granularity for one day, hourly for the last 30 days, and daily for three years.

You might have to stop and restart the data collection utility if data is not updated accurately or the reports display corrupted data.

To stop `nscollect`

At the command prompt, type:

```
/netScaler/nscollect stop
```

To start `nscollect` on the current SSH session to the NetScaler:

At the command prompt, type:

```
/netScaler/nscollect start
```

To start `nscollect` on the local system:

At the command prompt, type:

```
/netScaler/nscollect start &
```

AppFlow

May 29, 2015

The Citrix NetScaler appliance is a central point of control for all application traffic in the data center. It collects flow and user-session level information valuable for application performance monitoring, analytics, and business intelligence applications. It also collects web page performance data and database information. AppFlow transmits the information by using the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. IPFIX (the standardized version of Cisco's NetFlow) is widely used to monitor network flow information. AppFlow defines new Information Elements to represent application-level information, web page performance data, and database information.

Using UDP as the transport protocol, AppFlow transmits the collected data, called *flow records*, to one or more IPv4 collectors. The collectors aggregate the flow records and generate real-time or historical reports.

AppFlow provides visibility at the transaction level for HTTP, SSL, TCP, and SSL_TCP flows. You can sample and filter the flow types that you want to monitor.

AppFlow use actions and policies to send records for a selected flow to specific set of collectors. An AppFlow action specifies which set of collectors will receive the AppFlow records. Policies, which are based on Advanced expressions can be configured to select flows for which flow records will be sent to the collectors specified by the associated AppFlow action.

To limit the types of flows, you can enable AppFlow for a virtual server. AppFlow can also provide statistics for the virtual server.

You can also enable AppFlow for a specific service, representing an application server, and monitor the traffic to that application server.

Note: This feature is supported only on NetScaler nCore builds.

This topic includes the following details:

- [How AppFlow Works](#)
- [Configuring the AppFlow Feature](#)
- [Exporting Performance Data of Web Pages to AppFlow Collector](#)

How AppFlow Works

Updated: 2015-05-28

In the most common deployment scenario, inbound traffic flows to a Virtual IP address (VIP) on the NetScaler appliance and is load balanced to a server. Outbound traffic flows from the server to a mapped or subnet IP address on the NetScaler and from the VIP to the client. A flow is a unidirectional collection of IP packets identified by the following five tuples: sourceIP, sourcePort, destIP, destPort, and protocol.

The following figure describes how the AppFlow feature works.

Figure 1. NetScaler Flow Sequence

Application-specific flow information captured by AppFlow

As shown in the figure, the network flow identifiers for each leg of a transaction depend on the direction of the traffic.

The different flows that form a flow record are:

Flow1: <Client-IP, Client-Port, VIP-IP, VIP-port, Protocol>

Flow2: <NS-MIP/SNIP, NS-port, Server-IP, Server-Port, Protocol>

Flow3: <Server-IP, Server-Port, NS-MIP/SNIP, NS-Port, Protocol>

Flow4: <VIP-IP, VIP-port, Client-IP, Client-Port, Protocol>

To help the collector link all four flows in a transaction, AppFlow adds a custom transactionID element to each flow. For application-level content switching, such as HTTP, it is possible for a single client TCP connection to be load balanced to different backend TCP connections for each request. AppFlow provides a set of records for each transaction.

This topic includes the following details:

- [Flow Records](#)
- [Templates](#)

Flow Records

Updated: 2013-08-20

AppFlow records contain standard NetFlow or IPFIX information, such as time stamps for the beginning and end of a flow, packet count, and byte count. AppFlow records also contain application-level information (such as HTTP URLs, HTTP request methods and response status codes, server response time, and latency), web page performance data (such as page load time, page render time, and time spent on the page), and database information (such as database protocol, database response status and database response size). IPFIX flow records are based on templates that need to be sent before sending flow records.

Templates

AppFlow defines a set of templates, one for each type of flow. Each template contains a set of standard Information Elements (IEs) and Enterprise-specific Information Elements (EIEs). IPFIX templates define the order and sizes of the Information Elements (IE) in the flow record. The templates are sent to the collectors at regular intervals, as described in RFC 5101.

A template can include the following EIEs:

transactionID

An unsigned 32-bit number identifying an application-level transaction. For HTTP, this corresponds to a request and response pair. All flow records that correspond to this request and response pair have the same transaction ID. In the most common case, there are four uniflow records that correspond to this transaction. If the NetScaler generates the response by itself (served from the integrated cache or by a security policy), there may be only two flow records for this transaction.

connectionID

An unsigned 32-bit number identifying a layer-4 connection (TCP or UDP). The NetScaler flows are usually bidirectional, with two separate flow records for each direction of the flow. This information element can be used to link the two flows. For the NetScaler, connectionID is an identifier for the connection data structure to track the progress of a connection. In an HTTP transaction, for instance, a given connectionID may have multiple transactionID elements corresponding to multiple requests that were made on that connection.

tcpRTT

The round trip time, in milliseconds, as measured on the TCP connection. This can be used as a metric to determine the client or server latency on the network.

httpRequestMethod

An 8-bit number indicating the HTTP method used in the transaction. An options template with the number-to-method mapping is sent along with the template.

httpRequestSize

An unsigned 32-bit number indicating the request payload size.

httpRequestURL

The HTTP URL requested by the client.

httpUserAgent

The source of incoming requests to the Web server.

httpResponseStatus

An unsigned 32-bit number indicating the response status code.

httpResponseSize

An unsigned 32-bit number indicating the response size.

httpResponseTimeToFirstByte

An unsigned 32-bit number indicating the time taken to receive the first byte of the response.

httpResponseTimeToLastByte

An unsigned 32-bit number indicating the time taken to receive the last byte of the response.

flowFlags

An unsigned 64-bit flag used to indicate different flow conditions.

EIEs for web page performance data

clientInteractionStartTime

Time at which the browser receives the first byte of the response to load any objects of the page such as images, scripts, and stylesheets.

clientInteractionEndTime

Time at which the browser received the last byte of response to load all the objects of the page such as images, scripts, and stylesheets.

clientRenderStartTime

Time at which the browser starts to render the page.

clientRenderEndTime

Time at which browser finished rendering the entire page, including the embedded objects.

EIEs for database information

dbProtocolName

An unsigned 8-bit number indicating the database protocol. Valid values are 1 for MS SQL and 2 for MySQL.

dbReqType

An unsigned 8-bit number indicating the database request method used in the transaction. For MS SQL, valid values are 1 is for QUERY, 2 is for TRANSACTION, and 3 is for RPC. For valid values for MySQL, see the MySQL documentation.

dbReqString

Indicates the database request string without the header.

dbRespStatus

An unsigned 64-bit number indicating the status of the database response received from the web server.

dbRespLength

An unsigned 64-bit number indicating the response size.

dbRespStatString

The response status string received from the web server.

Configuring the AppFlow Feature

Jul 02, 2017

You configure AppFlow in the same manner as most other policy-based features. First, you enable the AppFlow feature. Then you specify the collectors to which the flow records are sent. After that, you define actions, which are sets of configured collectors. Then you configure one or more policies and associate an action to each policy. The policy tells the NetScaler appliance to select requests the flow records of which are sent to the associated action. Finally, you bind each policy either globally or to specific vservers to put it into effect.

You can further set AppFlow parameters to specify the template refresh interval and to enable the exporting of httpURL, httpCookie, and httpReferer information. On each collector, you must specify the NetScaler IP address as the address of the exporter.

Note: For information about configuring the NetScaler as an exporter on the collector, see the documentation for the specific collector.

The configuration utility provides tools that help users define the policies and actions that determine exactly how the NetScaler appliance export records for a particular flow to a set of collectors(action.) The command line interface provides a corresponding set of CLI-based commands for experienced users who prefer a command line.

This topic includes the following details:

- [Enabling AppFlow](#)
- [Specifying a Collector](#)
- [Configuring an AppFlow Action](#)
- [Configuring an AppFlow Policy](#)
- [Binding an AppFlow Policy](#)
- [Enabling AppFlow for Virtual Servers](#)
- [Enabling AppFlow for a Service](#)
- [Setting the AppFlow Parameters](#)
- [Example: Configuring AppFlow for DataStream](#)

Enabling AppFlow

Updated: 2014-08-07

To be able to use the AppFlow feature, you must first enable it.

Note: AppFlow can be enabled only on nCore NetScaler appliances.

To enable the AppFlow feature by using the command line interface

At the command prompt, type one of the following commands:

```
enable ns feature AppFlow
```

To enable the AppFlow feature by using the configuration utility

Navigate to System > Settings, click Configure Advanced Features and select the AppFlow option.

Specifying a Collector

Updated: 2014-08-07

A collector receives flow records generated by the NetScaler appliance. To be able to send flow records, you must specify

at least one collector. You can specify up to four. However, you cannot export the same data to multiple collectors. You can remove unused collectors. By default, the collector listens to IPFIX messages on UDP port 4739. You can change the default port, when configuring the collector. Similarly, by default, NSIP is used as the source IP for appflow traffic. You can change this default source IP to a SNIP or MIP address when configuring a collector.

To specify a collector by using the command line interface

At the command prompt, type the following commands to add a collector and verify the configuration:

- add appflow collector <name> -IPAddress <ipaddress> -port <port_number> -netprofile <netprofile_name>
- show appflow collector <name>

Example

```
> add appflow collector col1 -IPAddress 10.102.29.251 -port 8000 -netprofile n2
```

To specify a collector by using the configuration utility

Navigate to System > AppFlow > Collectors, and create the AppFlow collector.

Configuring an AppFlow Action

Updated: 2014-08-07

An AppFlow action is a set collectors, to which the flow records are sent if the associated AppFlow policy matches.

To configure an AppFlow action by using the command line interface

At the command prompt, type the following commands to configure an Appflow action and verify the configuration:

- add appflow action <name> --collectors <string> ... [-clientSideMeasurements (Enabled | Disabled)] [-comment <string>]
- show appflow action

Example

```
> add appflow action apfl-act-collector-1-and-3 -collectors collector-1 collector-3
```

To configure an AppFlow action by using the configuration utility

Navigate to System > AppFlow > Actions, and create the AppFlow action.

Configuring an AppFlow Policy

Updated: 2014-08-07

After you configure an AppFlow action, you must next configure an AppFlow policy. An AppFlow policy is based on a rule, which consists of one or more expressions.

Note: For creating and managing AppFlow policies, the configuration utility provides assistance that is not available at the command line interface.

To configure an AppFlow policy by using the command line interface

At the command prompt, type the following command to add an AppFlow policy and verify the configuration:

- add appflow policy <name> <rule> <action>
- show appflow policy <name>

Example

```
> add appflow policy apfl-pol-tcp-dsprt client.TCP.DSTPORT.EQ(22) apfl-act-collector-1-and-3
```

To configure an AppFlow policy by using the configuration utility

Navigate to System > AppFlow > Policies, and create the AppFlow policy.

To add an expression by using the Add Expression dialog box

1. In the Add Expression dialog box, in the first list box choose the first term for your expression.

HTTP

The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.

SSL

The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

CLIENT

The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.

2. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.
3. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

Binding an AppFlow Policy

Updated: 2014-08-07

To put a policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the NetScaler, or to a specific virtual server, so that the policy applies only to the traffic related to that virtual server.

When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

In the NetScaler operating system, policy priorities work in reverse order—the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is performed first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you globally bind it. You can then add additional policies at any time without having to change the priority of an existing policy.

To globally bind an AppFlow policy by using the command line interface

At the command prompt, type the following command to globally bind an AppFlow policy and verify the configuration:

- `bind appflow global <policyName> <priority> [<gotoPriorityExpression [-type <type>] [-invoke (<labelType> <labelName>)]`
- `show appflow global`

Example

```
bind appflow global af_policy_lb1_10.102.71.190 1 NEXT -type REQ_OVERRIDE -invoke vserver google
```

To bind an AppFlow policy to a specific virtual server by using the command line interface

At the command prompt, type the following command to bind an appflow policy to a specific virtual server and verify the configuration:

```
bind lb vserver <name> -policyname <policy_name> -priority <priority>
```

Example

```
bind lb vserver google -policyname af_policy_google_10.102.19.179 -priority 251
```

To globally bind an AppFlow policy by using the configuration utility

Navigate to System > AppFlow, click AppFlow policy Manager and select the relevant Bind Point (Default Global) and Connection Type, and then bind the AppFlow policy.

To bind an AppFlow policy to a specific virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, select the virtual server, and click Policies, and bind the AppFlow policy.

Enabling AppFlow for Virtual Servers

Updated: 2014-08-12

If you want to monitor only the traffic through certain virtual servers, enable AppFlow specifically for those virtual servers. You can enable AppFlow for load balancing, content switching, cache redirection, SSL VPN, GSLB, and authentication virtual servers.

To enable AppFlow for a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> <protocol> <IPAddress> <port> -appflowLog ENABLED
```

Example

```
> set cs vserver Vserver-CS-1 HTTP 10.102.29.161 80 -appflowLog ENABLED
```

To enable AppFlow for a virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select the virtual server, and enable AppFlow Logging option.

Enabling AppFlow for a Service

Updated: 2014-08-07

You can enable AppFlow for services that are to be bound to the load balancing virtual servers.

To enable AppFlow for a service by using the command line interface

At the command prompt, type:

```
set service <name> -appflowLog ENABLED
```

Example

```
set service ser -appflowLog ENABLED
```

To enable AppFlow for a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, select the service, and enable AppFlow Logging option.

Setting the AppFlow Parameters

Updated: 2014-08-08

You can set AppFlow parameters to customize the exporting of data to the collectors.

To set the AppFlow Parameters by using the command line interface

At the command prompt, type the following commands to set the AppFlow parameters and verify the settings:

- set appflow param [-templateRefresh <secs>] [-appnameRefresh <secs>] [-flowRecordInterval <secs>] [-udpPmtu <positive_integer>] [-httpUrl (**ENABLED** | **DISABLED**)] [-httpCookie (**ENABLED** | **DISABLED**)] [-httpReferer (**ENABLED** | **DISABLED**)] [-httpMethod (**ENABLED** | **DISABLED**)] [-httpHost (**ENABLED** | **DISABLED**)] [-httpUserAgent (**ENABLED** | **DISABLED**)] [-httpXForwardedFor (**ENABLED** | **DISABLED**)] [-clientTrafficOnly (**YES** | **NO**)]
- show appflow Param

Example

```
> set appflow Param -templateRefresh 240 -udpPmtu 128 -httpUrl enabled
```

To set the AppFlow parameters by using the configuration utility

Navigate to System > AppFlow, click Change AppFlow Settings, and specify relevant AppFlow parameters.

Example: Configuring AppFlow for DataStream

Updated: 2013-08-20

The following example illustrates the procedure for configuring AppFlow for DataStream using the command line interface.

```
> enable feature appflow
> add db user sa password freebsd
> add lbvserver lb0 MSSQL 10.102.147.97 1433 -appflowLog ENABLED
> add service sv0 10.103.24.132 MSSQL 1433 -appflowLog ENABLED
> bind lbvserver lb0 sv0
> add appflow collector col0 -IPAddress 10.102.147.90
> add appflow action act0 -collectors col0
> add appflow policy pol0 "mssql.req.query.text.contains(\"select\")" act0
> bind lbvserver lb0 -policyName pol0 -priority 10
```

When the Netscaler appliance receives a database request, the appliance evaluates the request against a configured policy. If a match is found, the details are sent to the AppFlow collector configured in the policy.

Exporting Performance Data of Web Pages to AppFlow Collector

May 28, 2015

The EdgeSight Monitoring application provides web page monitoring data with which you can monitor the performance of various Web applications served in a Netscaler environment. You can now export this data to AppFlow collectors to get an in-depth analysis of the web page applications. AppFlow, which is based on IPFIX standard, provides more specific information about web application performance than does EdgeSight monitoring alone.

You can configure both load balancing and content switching virtual servers to export EdgeSight Monitoring data to AppFlow collectors. Before configuring a virtual server for AppFlow export, associate an Appflow action with the EdgeSight Monitoring responder policy.

The following web page performance data is exported to AppFlow:

- **Page Load Time.** Elapsed time, in milliseconds, from when the browser starts to receive the first byte of a response until the user starts to interact with the page. At this stage, all the page content might not be loaded.
- **Page Render Time.** Elapsed time, in milliseconds, from when the browser receives the first byte of response until either all page content has been rendered or the page load action has timed out.
- **Time Spent on the Page.** Time spent by users on a page. Represents the period of time from one page request to the next one.

AppFlow transmits the performance data by using the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. The AppFlow templates use the following enterprise-specific Information Elements (IEs) to export the information:

- **Client Load End Time.** Time at which the browser received the last byte of a response to load all the objects of the page such as images, scripts, and stylesheets.
- **Client Load Start Time.** Time at which the browser receives the first byte of the response to load any objects of the page such as images, scripts, and stylesheets.
- **Client Render End Time.** Time at which browser finished rendering the entire page, including the embedded objects.
- **Client Render Start Time.** Time at which the browser started rendering the page.

- [Associating an AppFlow Action with the EdgeSight Monitoring Responder Policy](#)

Prerequisites for Exporting Performance Data of Web Pages to AppFlow Collectors

Updated: 2013-09-13

Before associating the AppFlow action with the AppFlow policy, verify that the following prerequisites have been met:

- The AppFlow feature has been enabled and configured. For instructions, see "[Configuring the AppFlow feature](#)".
- The Responder feature has been enabled. For instructions, see "[Enabling a Responder Feature](#)".
- The EdgeSight Monitoring feature has been enabled. For instructions, see "[Enabling an Application for EdgeSight Monitoring](#)".
- EdgeSight Monitoring has been enabled on the load balancing or content switching virtual servers bound to the services of applications for which you want to collect the performance data. For instructions, see "[Enabling an Application for](#)

Associating an AppFlow Action with the EdgeSight Monitoring Responder Policy

Updated: 2013-10-31

To export the web page performance data to the AppFlow collector, you must associate an AppFlow action with the EdgeSight Monitoring responder policy. An AppFlow action specifies which set of collectors receive the traffic.

To associate an AppFlow action with the EdgeSight Monitoring Responder policy by using the command line interface

At the command prompt, type:

```
set responder policy <name> -appflowAction <action_Name>
```

Example

```
set responder policy pol -appflowAction actn
```

To associate an AppFlow action with the EdgeSight Monitoring Responder policy by using the configuration utility

1. Navigate to AppExpert > Responder > Policies.
2. In the details pane, select an EdgeSight Monitoring responder policy, and then click **Open**.
3. In the **Configure Responder Policy** dialog box, in the **AppFlow Action** drop-down list, select the AppFlow action associated with the collectors to which you want to send the web-page performance data.
4. Click **OK**.

Configuring a Virtual Server to Export EdgeSight Statistics to Appflow Collectors

To export EdgeSight statistics information from a virtual server to the AppFlow collector, you must associate an AppFlow action with the virtual server.

To associate an AppFlow action with a Load Balancing or Content Switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers or Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select a virtual server, or multiple virtual servers, and then click Enable EdgeSight Monitoring.
3. In the Enable EdgeSight Monitoring dialog box, select the Export EdgeSight statistics to Appflow check box.
4. From the Appflow Action drop-down list, select the AppFlow action. The AppFlow action defines the list of AppFlow collectors to which it exports EdgeSight Monitoring statistics. If you have selected multiple load balancing virtual servers, the same AppFlow Action will be associated with the responder policies bound to them. You can later change the AppFlow Action configured for each of the selected Load Balancing virtual server individually, if required.
5. Click OK.

AutoScale

Aug 26, 2013

Efficient hosting of applications in a cloud requires continuous optimization of application availability. To meet increasing demand, you have to scale network resources upward. When demand subsides, you need to scale down to avoid the unnecessary cost of idle resources. To minimize the cost of running the application by deploying only as many instances as are necessary during any given period of time, you have to constantly monitor traffic. However, monitoring traffic manually is not a feasible option. For the application environment to be able to scale up or down rapidly, you need to automate the processes of monitoring traffic and of scaling resources up and down whenever necessary.

If your organization uses Citrix CloudPlatform to deploy and manage the cloud environment, a Citrix NetScaler appliance can automatically scale users' applications as needed. The CloudPlatform elastic load balancing feature includes a feature called *AutoScale*. A CloudPlatform user can use the AutoScale feature to specify thresholds for various conditions for automatically scaling the application fleet upward and downward. The scale-up and scale-down conditions can vary from simple use cases, such as a server's CPU usage, to complex use cases, such as a combination of a server's CPU usage and responsiveness. CloudPlatform, in turn, configures the NetScaler appliance to load balance traffic to the application virtual machines (VMs), monitor application thresholds and performance, and trigger scale-up and scale-down actions to add or remove VMs to or from the application fleet.

The CloudPlatform user performs all AutoScale configuration tasks by using the CloudPlatform user interface or APIs. The CloudPlatform user:

1. Creates a load balancing rule, with the necessary load balancing algorithm and stickiness.
2. Configures AutoScale parameters by specifying the application instance template, the minimum number of instances to maintain, the maximum number of instances permitted, scale-up and scale-down policies, and other information necessary for the functioning of the feature.
3. Submits the configuration.

For information about configuring a load balancing rule and AutoScale, see *Citrix CloudPlatform 3.0.5 (powered by Apache CloudStack) Administrator's Guide*, at <http://support.citrix.com/article/CTX134823>.

When the CloudPlatform user completes the AutoScale configuration, CloudPlatform uses the NetScaler NITRO API to push all the necessary configuration commands to the NetScaler appliance. As the NetScaler administrator, you do not have to perform any tasks for configuring AutoScale on the NetScaler appliance. However, you might have to be aware of certain prerequisites, and you might have to troubleshoot the configuration if issues arise in the AutoScale configuration. To troubleshoot the configuration, you have to be aware of how CloudPlatform works and what configuration CloudPlatform pushes to the NetScaler appliance. You also need a working knowledge of how to troubleshoot issues on a NetScaler appliance.

How AutoScale Works

Sep 06, 2013

When the CloudPlatform user completes the AutoScale configuration, CloudPlatform uses the NetScaler NITRO API to create an AutoScale-related configuration on the NetScaler appliance. For information about the configuration commands that CloudPlatform uses to configure the NetScaler appliance, see "[NetScaler Configuration Details](#)."

The following diagram shows the sequence of operations, beginning with CloudPlatform pushing the AutoScale configuration to the NetScaler appliance. The events are numbered in the order in which they occur, and are described below.

Figure 1. AutoScale Architecture

When the CloudPlatform user submits the AutoScale configuration, the following events occur:

1. CloudPlatform uses the NetScaler NITRO API to push the AutoScale configuration to the NetScaler appliance, creating AutoScale-related entities on the appliance. The entities include a load balancing virtual server, a service group, and monitors.
2. The AutoScale engine on the NetScaler appliance sends API requests to CloudPlatform to initially deploy the minimum number of virtual machines required.
3. CloudPlatform provisions the minimum number of instances (VMs) on the hypervisors (virtualization hosts) that it manages.
4. The NetScaler appliance discovers the IP addresses assigned by CloudPlatform to the newly created VMs and binds them, as services, to the service group representing them. The NetScaler appliance can then load balance traffic to the VMs.
5. NetScaler monitors bound to the service group start monitoring the load by collecting SNMP metrics from the instances.
6. The AutoScale engine on the NetScaler appliance monitors the metrics collected from the VMs and triggers scale-up and scale-down events whenever the metrics breach the configured threshold for the specified period. As part of the scale-up trigger, the NetScaler AutoScale engine sends an API request to CloudPlatform to deploy a new VM. After the virtual machine is deployed, the AutoScale engine binds the service representing the VM (IP address and port) to the service group and, after the configured quiet time, starts forwarding load balanced traffic to the new virtual machine. Likewise, as part of the scale-down trigger, the NetScaler AutoScale engine selects a VM, stops forwarding new requests to that

instance, and waits for the configured quiet time (to allow for the processing of current requests to complete) before it sends an API request to CloudPlatform to destroy the chosen instance.

In this way, the NetScaler appliance monitors the application and triggers scale-up and scale-down events on the basis of application load and/or performance.

Supported Environment

Sep 30, 2013

AutoScale is supported in the following environment:

- Citrix CloudPlatform 3.0.5.
- Citrix NetScaler MPX/SDX/virtual appliance running Citrix NetScaler release 10.e and later.
- SNMP v1/v2.

Prerequisites

Sep 06, 2013

Before you set up AutoScale, do the following:

- Make sure that CloudPlatform is reachable from the NetScaler appliance. You can do so by logging on to the NetScaler appliance and sending ping requests to the CloudPlatform server's IP address.
- Make sure that the network service offering used in CloudPlatform includes the NetScaler appliance as an external load balancing device.
- Use a CloudPlatform and NetScaler release that supports AutoScale. For information about NetScaler releases that support AutoScale, see "[Supported Environment](#)."

If you have to troubleshoot an AutoScale setup, you also have to know the prerequisites for setting up AutoScale in CloudPlatform. See the "Prerequisites" section of "Configuring AutoScale" in the *Citrix CloudPlatform 3.0.5 (powered by Apache CloudStack) Administrator's Guide*, at <http://support.citrix.com/article/CTX134823>.

NetScaler Configuration Details

Mar 19, 2012

The following table describes the AutoScale configuration commands that are used by Citrix CloudPlatform to configure a NetScaler appliance.

Table 1. NetScaler Configuration for AutoScale

AutoScale configuration command(s)	Description
<pre>add lb vserver Cloud-VirtualServer-192.0.2.116-22 TCP 192.0.2.116 22 -persistenceType NONE -lbMethod ROUNDROBIN -cltTimeout 9000 -minAutoscaleMembers 2 -maxAutoscaleMembers 5</pre>	<p>Creates a load balancing virtual server to evenly distribute the load on the application instances (ROUNDROBIN method). The virtual server also specifies the limits for the number of instances to which the application can scale up or down (maxAutoscaleMembers and minAutoscaleMembers, respectively).</p>
<pre>add serviceGroup Clouda35a6b6b76614006b97476e841b80f79 TCP -maxClient 0 -maxReq 0 -cip DISABLED -usip NO -useproxyport YES -cltTimeout 9000 -svrTimeout 9000 -CKA NO -TCPB NO -CMP NO -autoScale POLICY -memberPort 22</pre> <pre>bind lb vserver Cloud-VirtualServer-192.0.2.116-22 Clouda35a6b6b76614006b97476e841b80f79</pre>	<p>Creates an AutoScale service group for the application instances, with the service group's autoScale parameter set to POLICY. Also specifies the port on which the service group members must receive traffic.</p> <p>The second command binds the service group to the load balancing virtual server.</p>
<pre>add server autoscale-internal_server_Clouda35a6b6b76614006b97476e841b80f79 autoscale-internal_server_Clouda35a6b6b76614006b97476e841b80f79</pre> <pre>bind serviceGroup Clouda35a6b6b76614006b97476e841b80f79 autoscale-internal_server_Clouda35a6b6b76614006b97476e841b80f79 22</pre>	<p>Creates a server entry to represent the application instances.</p> <p>Binds the server entry to the service group.</p>
<pre>add lb metricTable Cloud-MTb1-192.0.2.116-22</pre> <pre>bind lb metricTable Cloud-MTb1-192.0.2.116-22 Linux_User_CPU_-_percentage 1.3.6.1.4.1.2021.11.9.0</pre>	<p>Configures a new SNMP monitor to retrieve the specified</p>

AutoScale configuration command(s)	metrics Description
<pre>add lb monitor Cloud-Mon-192.0.2.116-22 LOAD -interval 24 -destPort 161 -snmpCommunity public -metricTable Cloud-MTb1-192.0.2.116-22 bind lb monitor Cloud-Mon-192.0.2.116-22 -metric Linux_User_CPU_-_percentage -metricThreshold 2147483647 bind serviceGroup Clouda35a6b6b76614006b97476e841b80f79 -monitorName Cloud-Mon-192.0.2.116-22 -passive</pre>	
<pre>add autoscale profile Cloud-AutoScale-Profile-192.0.2.116-22 -type CLOUDSTACK -url "http://10.102.31.107:8080/client/api" -apiKey t0fEWPtk_ncQYbofjAm1jjlgGTR7UNZrKZ3sdEpLREBNzBPLSNpNz8qNSbc439xNtYnEYdWn_MsUC_CUazalKg -sharedSecret -PrE5h3DP7swHAN12TGBIX-xSTRlHsob9116O0VO1FMxvE1UOI7uoD6_Z0bkkLaVtK5Y10oBkTzgbTwp3u5ICQ</pre>	Creates an AutoScale profile to specify the details required by NetScaler for making API requests to CloudPlatform (URL, API key, and shared secret).
<pre>add autoscale action Cloud-AutoScale-ScaleUpAction-192.0.2.116-22 -type SCALE_UP -profileName Cloud-AutoScale-Profile-192.0.2.116-22 -parameters "command=deployVirtualMachine&zoneid=2ab23590-78cb-4106-8d85-4412a2f2435f&serviceofferingid=b9503e47-0d8f-4c89-a88d-04d8b17fe8e9&templateid=1a4a5084-208c-47a8-9c16-d582550cf759&displayname=AutoScale-LB-lb&networkids=a3c97129-b729-4c72-994f-7b918f20ce4d&lbruleid=f96b7f3b-19ec-4123-891c-604f05b032b3" -quietTime 90 -vServer Cloud-VirtualServer-192.0.2.116-22</pre>	Creates a scale-up action, which enables the NetScaler appliance to add virtual machines (instances) to the application fleet.
<pre>add autoscale action Cloud-AutoScale-ScaleDownAction-192.0.2.116-22 -type SCALE_DOWN -profileName Cloud-AutoScale-Profile-192.0.2.116-22 -parameters "command=destroyVirtualMachine&lbruleid=f96b7f3b-19ec-4123-891c-604f05b032b3" -vmDestroyGracePeriod 30 -quietTime 90 -vServer Cloud-VirtualServer-192.0.2.116-22</pre>	Creates a scale-down action, which enables the NetScaler appliance to remove virtual machines (instances) from the application fleet.
<pre>add autoscale policy Cloud-AutoScale-Policy-Min-192.0.2.116-22 -rule "SYS.VSERVER("Cloud-VirtualServer-192.0.2.116-22").ACTIVESERVICES.LT(SYS.VSERVER("Cloud-VirtualServer-192.0.2.116-22").MINAUTOSCALEMEMBERS)" -action Cloud-AutoScale-ScaleUpAction-192.0.2.116-22</pre>	Creates an AutoScale policy to initially create the specified minimum number of VMs and, later, to ensure that the number of VMs in the fleet does not fall below the required minimum.
<pre>add autoscale policy Cloud-AutoScale-Policy-Max-192.0.2.116-22 -rule "SYS.VSERVER("Cloud-VirtualServer-192.0.2.116-22").ACTIVESERVICES.GT(SYS.VSERVER("Cloud-VirtualServer-192.0.2.116-22").MAXAUTOSCALEMEMBERS)" -action Cloud-AutoScale-ScaleDownAction-192.0.2.116-22</pre>	Creates an AutoScale policy to prevent the number of VMs in the fleet from exceeding the specified maximum.
<pre>add autoscale policy Cloud-AutoScale-Policy-192.0.2.116-22-35 -rule "SYS.VSERVER("Cloud-VirtualServer-192.0.2.116-22").ACTIVESERVICES.LT(SYS.VSERVER("Cloud-VirtualServer-192.0.2.116-22").MAXAUTOSCALEMEMBERS) && (SYS.VSERVER("Cloud-VirtualServer-192.0.2.116-22").SNMP_TABLE(0).AVERAGE_VALUE.GT(90))" -action Cloud-AutoScale-ScaleUpAction-192.0.2.116-22</pre>	Creates an AutoScale policy to evaluate the metrics that are collected and trigger a

AutoScale configuration command(s)	Description
	<p>scale-up action when the metric value breaches the threshold specified for the scale-up policy.</p>
<pre>add autoscale policy Cloud-AutoScale-Policy-192.0.2.116-22-36 -rule "SYS.VSERVER("Cloud-VirtualServer-192.0.2.116-22").ACTIVESERVICES.GT(SYS.VSERVER("Cloud-VirtualServer-192.0.2.116-22").MINAUTOSCALEMEMBERS) && (SYS.VSERVER("Cloud-VirtualServer-192.0.2.116-22").SNMP_TABLE(0).AVERAGE_VALUE.LT(30))" -action Cloud-AutoScale-ScaleDownAction-192.0.2.116-22</pre>	<p>Creates an AutoScale policy to evaluate the collected metrics and trigger a scale-down action when the metric value breaches the threshold specified by the scale-down policy.</p>
<pre>add ns timer Cloud-AutoScale-Timer-192.0.2.116-22 -interval 30 bind ns timer Cloud-AutoScale-Timer-192.0.2.116-22 -policyName Cloud-AutoScale-Policy-Min-192.0.2.116-22 -priority 1 -gotoPriorityExpression END -sampleSize 1 -threshold 1 bind ns timer Cloud-AutoScale-Timer-192.0.2.116-22 -policyName Cloud-AutoScale-Policy-Max-192.0.2.116-22 -priority 2 -gotoPriorityExpression END -sampleSize 1 -threshold 1 bind ns timer Cloud-AutoScale-Timer-192.0.2.116-22 -policyName Cloud-AutoScale-Policy-192.0.2.116-22-35 -priority 3 -gotoPriorityExpression END -sampleSize 2 -threshold 2 bind ns timer Cloud-AutoScale-Timer-192.0.2.116-22 -policyName Cloud-AutoScale-Policy-192.0.2.116-22-36 -priority 4 -gotoPriorityExpression END -sampleSize 2 -threshold 2</pre>	<p>Creates a timer that enables evaluation of the AutoScale policies at the configured sampling intervals.</p>

Troubleshooting

Sep 06, 2013

Before you attempt to resolve an AutoScale issue, make sure that the prerequisites have been adhered to, on both the CloudPlatform server and the NetScaler appliance, as described in "[Prerequisites](#)." If that does not resolve the issue, your problem could be one of the following.

The AutoScale configuration was successfully configured in CloudPlatform. Yet, the minimum number of VMs has not been created.

- Recommend that the CloudPlatform user deploy one VM manually in the network before configuring AutoScale. Ask the user to remove the AutoScale configuration from the NetScaler appliance or the load balancer from the network, manually deploy one VM (preferably using the template created for the AutoScale configuration), and then create the AutoScale configuration.
- Verify that the CloudPlatform user has configured the VM template in such a way that the VMs that are created from the template can accept traffic without manual intervention. If a provisioned VM cannot accept traffic automatically, the metric remains above the threshold, and the AutoScale configuration continues to provision additional VMs, as designed. To remedy the issue, disable AutoScale from CloudPlatform, fix the template, and then enable AutoScale.
- Verify that the CloudPlatform user has not exceeded the limit for the number of VMs imposed by the user's account.
- Verify that the CloudPlatform server is up and is reachable from the NetScaler appliance.
- Verify that the CloudPlatform log file, management-server.log, has reported the successful creation of the AutoScale configuration in CloudPlatform.
- Verify that the scale-up policy that is responsible for initial scale up (the policy name is prefixed with Cloud-AutoScale-Policy-Min) is receiving hits.

The AutoScale configuration is rapidly spawning a large number of VMs

- Verify that the CloudPlatform user has configured the VM template in such a way that the VMs that are created from the template can accept traffic without manual intervention. If a provisioned VM cannot accept traffic automatically, the metric remains above the threshold, and the AutoScale configuration continues to provision additional VMs, as designed. To remedy the issue, disable AutoScale from CloudPlatform, fix the template, and then enable AutoScale.
- Verify that the quiet time that the CloudPlatform user has configured in the AutoScale configuration is sufficient to ensure even traffic distribution to all the VMs, including the new VM. If the quiet time is too low, and traffic distribution has not stabilized, the metrics might remain above the threshold, and additional VMs might be spawned.

When I ran the top command on my VM, I noticed that the CPU usage on my VM had breached the threshold that was configured for the scale-up action in AutoScale. Yet, the application is not scaling up.

- Verify that the CloudPlatform user has installed an SNMP agent in the VM template, and that the SNMP agent is up and running on every VM.
- Verify that the CloudPlatform user has not exceeded the limit for the number of VMs imposed by the user's account.
- Verify that the CloudPlatform user has correctly configured the SNMP parameters to collect metrics from the VM (for example, the community string and the port).
- Verify that the scale-up or scale-down policy is receiving hits.
- Verify that the CloudPlatform server is up, and that the CloudPlatform server is reachable from the NetScaler appliance.

One or more additional VMs have been created, but they are not accepting traffic (that is, VMs have been created, but the average value of the metrics is still above the threshold)

- Verify that the user has configured the templates in such a way that the VMs created from the templates can start serving traffic without any manual intervention.
- Verify that the service is running on the VMs, on the configured member port.
- Send a ping request to the gateway (virtual router), from the VM that is not accepting traffic.

The AutoScale configuration has been deleted, but the VMs continue to exist

- The VMs might not be deleted immediately after the AutoScale configuration is deleted. Wait for about 5 minutes after you have deleted the AutoScale configuration, and then check again.
- If the destruction of VMs has not commenced after 5 minutes, you might have to delete the VMs manually.

Clustering

Dec 07, 2016

A NetScaler cluster is a group of nCore appliances working together as a single system image. Each appliance of the cluster is called a node. The cluster can have one appliance or as many as 32 NetScaler nCore hardware or virtual appliances as nodes.

The client traffic is distributed between the nodes to provide high availability, high throughput, and scalability.

To create a cluster, you must add the appliances as cluster nodes, set up communication between the nodes, set up links to the client and server networks, configure the appliances, and configure the distribution of client and server traffic.

NetScaler Feature-level Support in a Cluster

Oct 14, 2016

The following table lists the features that are not supported in the NetScaler 10 release and also states the support for the feature in subsequent NetScaler releases.

Note:

- Unless stated otherwise in this table, all NetScaler features are supported in a cluster.
- The entry "Node-level" in the table indicates that the feature is supported only on individual cluster nodes.

Cluster Configuration	10	10.1	10.5
SSL (classic policies) Note: SSL - advanced policies are supported from NetScaler 10 onwards.	No	No	No
SSL FIPS	No	No	No
SSL Certificate Bundle	No	No	No
Content switching actions Note: The content switching feature is supported from NetScaler 10.1 onwards.	No	Yes	Yes
Policy-based logging for content switching policies	No	Yes	Yes
Rate limiting	No	Yes	Yes
Action analytics	No	Yes	Yes
Branch Repeater load balancing	No	Yes	Yes
GSLB	No	No	Yes
RTSP	No	No	No
DNSSEC	No	No	No
DNS64	No	No	No
FTP	No	No	No
TFTP	No	No	No
Connection mirroring	No	No	No
Integrated caching	Node-Level	Node-level	Node-level
Large shared cache	No	Node-level	Node-level
Application firewall	No	No	Node-level
HTTP Denial-of-Service Protection (HDOSP)	Node-level	Node-level	Node-level
Priority queuing (PQ)	Node-level	Node-level	Node-level
Sure connect (SC)	Node-level	Node-level	Node-level
AppQoE	NA	Node-level	Yes
Surge protection	Node-level	Node-level	Node-level
MPTCP	No	No	Yes

Striped SNIPs	Yes	Yes	Yes
MSR	Yes	Yes	Yes
IS-IS (IPv4 and IPv6)	No	Yes	Yes
Jumbo Frames	No	No	Yes
IP-IP tunneling	No	Yes	Yes
Link load balancing	No	No	Yes
FIS (Failover Interface Set)	No	No	Yes
Link redundancy (LR)	No	No	Yes
NAT46	No	No	No
NAT64	No	No	No
RNAT6	No	No	No
LSN/CGNAT	No	No	No
IPv6 ReadyLogo	No	No	No
Traffic domains	No	No	Yes
Route monitor	No	No	No
GRE tunneling (CB)	No	No	No
Layer 2 mode	No	No	Yes
Net profiles	No	No	Yes
HTTPS callout	No	Yes	Yes
AAA-TM	No	Node-level	Node-level
AppFlow	No	Node-level	Node-level
Web Insight	No	No	No
HDX Insight	No	No	No
VMAC/VRRP	No	No	Yes
NetScaler Push	No	No	No
Stateful Connection Failover	No	No	No
Graceful Shutdown	No	No	No
DBS AutoScale	No	No	No
DSR using TOS	No	No	No

Prerequisites for Cluster Nodes

Jan 28, 2016

NetScaler appliances that are to be added to a cluster must satisfy the following criteria:

- A NetScaler cluster can only include NetScaler nCore appliances. Clustering of NetScaler Classic appliances is not supported.
- All appliances must have the same software version and build.
- All appliances must be of the same platform type. This means that a cluster must have either all hardware appliances (MPX) or virtual appliances (VPX) or SDX NetScaler instances.

Note:

- For a cluster of hardware appliances (MPX), all appliances must be of the same model type.
- For a cluster of virtual appliances (VPX), the appliances must be deployed on the following hypervisors: XenServer, Hyper-V, VMware ESX, and KVM.
- Clusters of SDX NetScaler instances are supported in NetScaler 10.1 and later releases. To create a cluster of SDX NetScaler instances, see "[Setting up a Cluster of NetScaler Instances](#)".
- Jumbo frames are not supported on a NetScaler cluster that is made up of NetScaler SDX instances.
- All appliances must be on the same network.
- All appliances must have the same licenses. Also, depending on the NetScaler version, there are some additional aspects to address:
 - For releases prior to NetScaler 10.5 Build 52.x:
 - A separate cluster license file is required. This file must be copied to the `/nsconfig/license/` directory of the configuration coordinator.
 - Because of the separate cluster license file, the cluster feature is available irrespective of the NetScaler license.
 - For releases after NetScaler 10.5 Build 52.x:
 - No separate cluster license is required.
 - Cluster is licensed with the Enterprise and Platinum licenses. Cluster is not available for Standard license.
- Be initially configured and connected to a common client-side and server-side network.

Note: For a cluster of virtual appliances, that has large configurations, it is recommended to use 6 GB RAM for each node of the cluster.

Cluster Overview

Jun 15, 2015

A NetScaler cluster is formed by grouping NetScaler appliances together. Based on the network location of the NetScaler appliances that you intend adding to the cluster, you must be aware of the following cluster setups:

Note: Unless specified otherwise, cluster features and configurations are the same for L2 and L3 clusters.

- **L2 cluster:** In this cluster deployment, all cluster nodes belong to the same network.

- **L3 cluster:** In this cluster deployment, cluster nodes can belong to different networks.

Note: Not yet supported. Likely to be supported in future NetScaler versions.

Synchronization Across Cluster Nodes

May 25, 2015

All configurations on a NetScaler cluster are performed on the cluster IP address, which is the management address of the cluster. This cluster IP address is owned by a cluster node that is referred to as the cluster configuration coordinator or as shown in the following figure:

The configurations that are available on the configuration coordinator are automatically propagated to the other cluster nodes and therefore all cluster nodes have the same configurations.

Note:

- NetScaler allows only a few configurations to be performed on individual cluster nodes through their NetScaler IP (NSIP) address. In these cases, you must ensure configuration consistency manually across all nodes in the cluster. These configurations are not propagated across the other cluster nodes. For more information on operations supported on each cluster nodes, see "[Operations Supported on Individual Cluster Nodes](#)".
- The following commands when executed on the cluster IP address are not propagated to other cluster nodes:
 - shutdown: Shuts down only the configuration coordinator.
 - reboot: Reboots only the configuration coordinator.
 - rm cluster instance: Removes the cluster instance from the node that you are executing the command on.
- For a command to propagate to other cluster nodes:
 - The quorum must be configured on cluster instance.
 - The majority of the cluster quorum with $(n/2 + 1)$ of the cluster nodes must be active for the cluster to be operational.
 - A cluster can run with a minimum number of nodes when majority rule $(n/2 + 1)$ is relaxed.

When a node is added to a cluster, the configurations and the files (SSL certificates, licenses, DNS, and so on) that are available on the cluster configuration coordinator are synchronized to the newly added cluster node. When an existing cluster node, that was intentionally disabled or that had failed, is once again added, the cluster compares the configurations available on the node with the configurations available on the configuration coordinator. If there is a mismatch in configurations, the node is synchronized by using one of the following:

- **Full synchronization.** If the difference between configurations exceeds 255 commands, all the configurations of the configuration coordinator are applied to the node that is rejoining the cluster. The node remains operationally unavailable for the duration of the synchronization.
- **Incremental Synchronization.** If the difference between configurations is less than or equal to 255 commands, only the configurations that are not available are applied to the node that is rejoining the cluster. The operational state of the node remains unaffected.

Note: You can also manually synchronize the configurations and files. For more information, see "[Synchronizing Cluster Configurations](#)" and "[Synchronizing Cluster Files](#)".

Striped, Partially Striped, and Spotted Configurations

May 25, 2015

By virtue of command propagation, all nodes in a cluster have the same configurations. However, you may want some configurations to be available only on certain cluster nodes. While you cannot restrict the nodes on which the configurations are available, you can specify the nodes on which the configurations are active.

For example, you can define a SNIP address to be active on only one node, or define a SNIP address to be active on all nodes, or define a VIP address to be active on only one node, or define a VIP address to be active on all nodes, or define a VIP address to be active only on two nodes of a 3-node cluster.

Depending on the number of nodes the configurations are active on, cluster configurations are referred to as striped, partially striped, or spotted configurations.

Figure 1. Three-node cluster with striped, partially striped, and spotted configurations

The following table provides more details on the types of configurations:

Configuration Type	Active on...	Applicable to...	Configurations...
Striped configuration	All the cluster nodes	All entities	No specific configuration required to make an entity striped. By default, all entities defined on a cluster IP address are striped on all the cluster nodes.
Partially striped configuration	A subset of cluster nodes	Refer "Node Groups"	Bind the entities that you want to be partially striped, to a node group. The configuration will be active only on the cluster nodes that belong to the node group.
Spotted configuration	Single cluster node	<ul style="list-style-type: none"> SNIP address SNMP Engine ID Hostname of cluster 	A spotted configuration can be defined using one of two approaches. <ul style="list-style-type: none"> SNIP address. When creating the SNIP address, specify the node on which you want the SNIP address to be active, as the owner node. Example: <pre>add ns ip 10.102.29.106 255.255.255.0 -type SNIP -ownerNode 2</pre>

Configuration Type	Active on...	Applicable to... nodes Entities that can be	Configurations... (assuming node NS2 ID is 2)
		bound to a node group	<p>Note: You cannot change the ownership of a spotted SNIP address at run time. To change the ownership, you must first delete the SNIP address and add it again by specifying the new owner.</p> <ul style="list-style-type: none"> • Entities that can be bound to a node group. By binding the entity to a single-member node group.

Note: Citrix recommends that you use spotted SNIP addresses. You can use striped SNIP addresses only if there is a shortage of IP addresses. The use of striped IP addresses can result in ARP flux issues.

Communication in a Cluster Setup

May 25, 2015

The interfaces of NetScaler appliances that are added to a cluster, are prefixed with a node ID. This helps identify the cluster node to which the interface belongs. Therefore, the interface identifier c/u , where c is the controller number and u is the unit number, now becomes $n/c/u$, where n is the node ID. For example, in the following figure, interface 1/2 of node n1 is represented as 0/1/2, interface 1/1 of node n2 is represented as 1/1/1, and interface 1/4 of node n3 is represented as 2/1/4.

Figure 1. Interface naming convention in a cluster

Server communication

The cluster communicates with the server through the physical connections between the cluster node and the server-side connecting device. The logical grouping of these physical connections is called the server data plane.

Client communication

The cluster communicates with the client through the physical connections between the cluster node and the client-side connecting device. The logical grouping of these physical connections is called the client data plane.

Inter-node communication

The cluster nodes can also communicate with each other. The manner in which they communicate depends on whether the node exists on the same network or across networks.

- Cluster nodes within the same network communicate with each other by using the cluster backplane. The backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch. The different types of traffic that goes through backplane, which is used by internode communication are:
 - Node to Node Messaging (NNM)
 - Steered traffic
 - Configuration propagation and synchronization
- Each node of the cluster uses a special MAC cluster backplane switch address to communicate with other nodes through the backplane. The cluster special MAC is of the form: **0x02 0x00 0x6F <cluster_id> <node_id> <reserved>**, where <cluster_id> is the cluster instance ID, <node_id> is the node number of the NetScaler appliance that are added to a cluster
- Across networks, steering of packets is done through a GRE tunnel and other node-to-node communication is routed across nodes as required.

The following figures shows the communication interfaces in L2 clusters and L3 clusters.

Figure 2. Cluster communication interfaces - L2 cluster

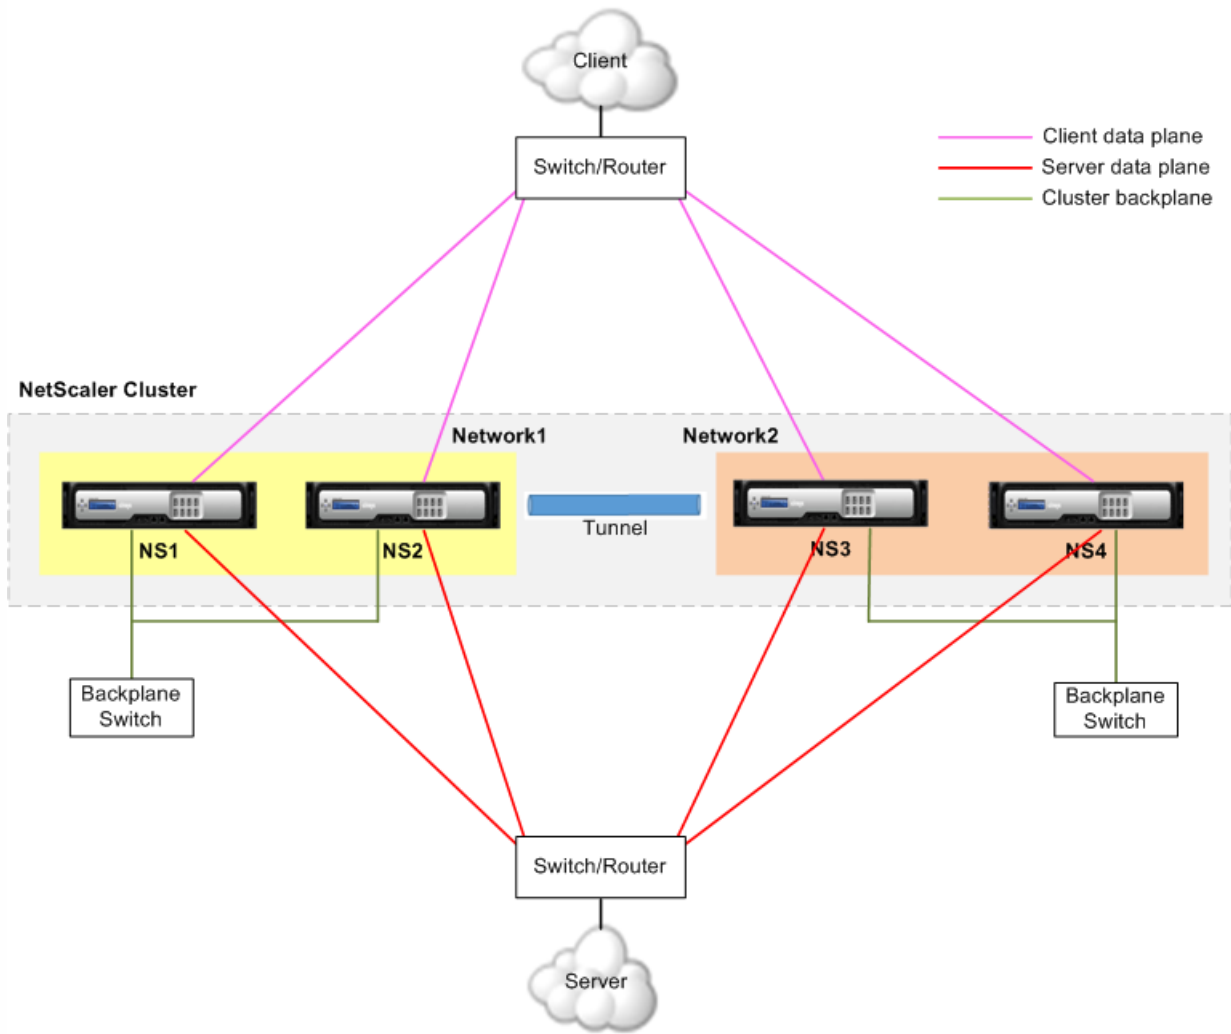

Figure 3. Cluster communication interfaces - L3 cluster

Traffic Distribution in a Cluster Setup

May 25, 2015

In a cluster setup, external networks view the collection of NetScaler appliances as a single entity. So, the cluster must select a single node that must receive the traffic. The cluster does this selection by using Equal Cost Multiple Path (ECMP) or cluster link aggregation traffic distribution mechanism. The selected node is called the flow receiver.

The flow receiver gets the traffic and then, using internal cluster logic determines the node that must process the traffic. This node is called the flow processor. The flow receiver steers the traffic to the flow processor over the backplane.

Note:

- The flow receiver and flow processor must be nodes capable of serving traffic.

Figure 1. Traffic distribution in a cluster

The above figure shows a client request flowing through the cluster. The client sends a request to a virtual IP (VIP) address. A traffic distribution mechanism configured on the client data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the node that must process the traffic, and steers the request to that node (unless the flow receiver selects itself as the flow processor).

The flow processor establishes a connection with the server. The server processes the request and sends the response to the subnet IP (SNIP) address that sent the request to the server.

- If the SNIP address is a striped or partially striped IP address, the traffic distribution mechanism configured on the server data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the flow processor, and steers the request to the flow processor through the cluster backplane.
- If the SNIP address is a spotted IP address, the node that owns the SNIP address receives the response from the server.

In an asymmetric cluster topology (all cluster nodes are not connected to the external switch), you must use linksets either exclusively or combined with ECMP or cluster link aggregation. For more information, see "[Using Linksets](#)".

Cluster Nodegroups

May 25, 2015

Note: Nodegroups are supported from NetScaler 10.1 onwards.

As the name indicates, a cluster nodegroup is a group of cluster nodes.

Figure 1. NetScaler cluster with nodegroups

The above figure shows a cluster which has nodegroups NG1 and NG2 that include 3 cluster nodes each. The cluster also has 3 nodes that are not part of any nodegroup.

A nodegroup can be configured for the following:

- To define spotted and partially striped configurations. For more information, see "[Nodegroups for Spotted and Partially-Striped Configurations](#)".
- To configure redundancy of nodegroups. For more information, see "[Configuring Redundancy for Nodegroups](#)".
Note: Supported from NetScaler 10.5 Build 52.1115.e onwards.

Note: The above functions of a nodegroup are mutually exclusive. This means that a nodegroup can provide only one of the above mentioned functionality.

Cluster and Node States

Sep 23, 2015

For a cluster to be functional, a majority of the nodes ($n/2 + 1$) must be operationally active (operational state is ACTIVE). Check table below.

Important

From NetScaler release 10.5, you can configure the cluster to be functional even when the majority criteria is not satisfied. This configuration must be performed when creating a cluster.

The following table describes the states of a cluster node:

Type	Possible values	Description
Admin state	PASSIVE, ACTIVE, SPARE	<p>Specifies the responsibility of the node within the cluster setup. You can set the admin state to be one of the following:</p> <ul style="list-style-type: none">• PASSIVE (default state). These nodes are in sync with the cluster, but do not serve any traffic. You must explicitly change its state to one of the other admin states, to make it ready to play a more active role.• ACTIVE. These nodes are in sync with the cluster and serve traffic that reaches the cluster. Check operational state for information on when this node can serve traffic.• SPARE. These nodes act as backup nodes for the cluster. Spare nodes are always in sync with the cluster, but do not serve any traffic till one of the ACTIVE (admin state) nodes becomes unavailable. When this happens, the admin state of this node continues to be SPARE, but its operational state changes to ACTIVE. <p>Note: The preemption parameter that is specified on a cluster instance, indicates whether the SPARE node remains operationally active even when a ACTIVE (admin state) node becomes available.</p> <ul style="list-style-type: none">• If preemption is disabled, the spare node continues to serve traffic even if a node in ACTIVE admin state comes back online.• If preemption is enabled, when a node in ACTIVE admin state comes back online, it preempts the spare node and starts serving traffic. The spare node goes back to inactive state.
Health	UP, NOT UP, UNKNOWN	<p>Indicates whether the cluster node can successfully handle traffic by checking for the following criteria for the node:</p> <ul style="list-style-type: none">• The interfaces are up and enabled.• The SSL cards are available.• The cluster synchronization operation is enabled and completed.• The backplane interface is up and enabled.• The CLAG member(s) are up. <p>Based on the above criteria, the health of a node can be:</p> <ul style="list-style-type: none">• UP. When all the criteria are satisfied.

Type	Possible values	Description
Operational state	ACTIVE, INACTIVE, UNKNOWN	<ul style="list-style-type: none"> • UNKNOWN. When the node cannot receive heartbeats from other nodes. <p>Indicates that the node can serve traffic. The operational state of a node is determined by a combination of the admin state and the health of the node.</p> <ul style="list-style-type: none"> • ACTIVE. When the health of the node is UP and one of the following is true: <ul style="list-style-type: none"> • Node in ACTIVE admin state. • Node in SPARE admin state and node is being used as backup. • INACTIVE. In the following cases: <ul style="list-style-type: none"> • Node in PASSIVE admin state, regardless of the health. • Node in ACTIVE admin state and health is NOT UP. • Node in SPARE admin state and node is not being used as backup. • UNKNOWN. When the node cannot receive heartbeats from other nodes. <p>Review the <i>ns.log</i> file, error counters, and the output of the "show cluster node" command, to help determine the exact reason for a node to be in INACTIVE and UNKNOWN state.</p>

Routing in a Cluster

Apr 12, 2013

Routing in a cluster works in much the same way as routing in a standalone system. A few points to note:

- Routing runs only on spotted SNIP addresses and NSIP addresses.
- All routing configurations must be performed from the cluster IP address and the configurations are propagated to the other cluster nodes.
- Node-specific routing configurations must be performed by using the owner-node argument as follows:

```
!  
interface vlan97  
!  
router ospf  
owner-node 0  
ospf router-id 97.131.0.1  
exit-owner-node  
owner-node 1  
ospf router-id 97.131.0.2  
exit-owner-node  
owner-node 2  
ospf router-id 97.131.0.3  
exit-owner-node  
redistribute kernel  
network 97.0.0.0/8 area 0  
!
```

- Retrieve node-specific routing configurations by specifying the node(s) in the owner-node argument as follows:

```
> vtysh  
ns# owner-node 0 1  
ns(node-0 1)# show cluster state  
ns(node-0 1)# exit-owner-node
```

- Clear node-specific routing configurations by specifying the node(s) in the owner-node argument as follows:

```
> vtysh  
ns# owner-node 0 1  
ns(node-0 1)# clear config  
ns(node-0 1)# exit-owner-node
```

- Routing protocol daemons can run and adjacencies can be formed on active and inactive nodes of a cluster.
- Only active nodes advertise host routes to VIP addresses.
- Active and inactive nodes can learn dynamic routes and install them into the routing table.
- Routes learnt on a node are propagated to other nodes in the cluster only if route propagation is configured. This is mostly needed in asymmetric topologies where the unconnected nodes may not be able to form adjacencies.

```
ns(config)# ns route-install propagate
```

Note: Make sure that route propagation is not configured in a symmetric cluster topology as it can result in making the node unavailable to the cluster.

Setting up a NetScaler Cluster

Jun 15, 2015

NetScaler appliances that you want to add to the cluster must satisfy the criteria specified in "[Prerequisites for Cluster Nodes](#)". Before actually setting up a cluster, you must be aware of cluster basics. For information, see "[Cluster Overview](#)".

Forming a cluster requires you to set up inter-node communication, create the cluster (by adding the first NetScaler appliance), and then add the other cluster nodes. Each of these steps is explained with relevant details in subsequent topics.

Setting up Inter-Node Communication

Feb 04, 2016

The nodes in a cluster communicate with each other through the cluster backplane.

1. Identify the network interface that you want to use for the backplane.
2. Connect an Ethernet or optical cable from the selected network interface to the cluster backplane switch.

For example, to use interface 1/2 as the backplane interface for node 4, connect a cable from the 1/2 interface of node 4 to the backplane switch.

Important points to note when setting up the cluster backplane

- Do not use the appliance's management interface (0/1) as the backplane interface.
- Backplane interfaces must not be used for the client or server data planes.
- Configure a link aggregate (LA) channel to optimize the throughput of the cluster backplane.
- Citrix recommends that you dedicate a separate switch for the backplane, so that large amounts of traffic can be handled seamlessly.
- Backplane interfaces of all nodes of a cluster must be connected to the same switch and bound to the same L2 VLAN.
- If you have multiple clusters with the same cluster instance ID, make sure that the backplane interfaces of each cluster are bound to a different VLAN.
- The backplane interface is always monitored, regardless of the HA monitoring settings of that interface.
- The state of MAC spoofing on the different virtualization platforms can affect the steering mechanism on the cluster backplane. Therefore, make sure the appropriate state is configured:
 - XenServer - Disable MAC spoofing
 - HyperV - Enable MAC spoofing
 - ESX - Enable MAC spoofing (also make sure "Forged Transmits" is enabled)
- The Maximum Transmission Unit (MTU) for interfaces of the backplane switch must be greater than or equal to 1578 bytes, if features like MBF, L2 policies, ACLs, routing in CLAG deployments are configured. The MTU on the cluster backplane is automatically updated.

Creating a NetScaler Cluster

Apr 03, 2015

To create a cluster, start by taking one of the NetScaler appliances that you want to add to the cluster. On this node, you must create the cluster instance and define the cluster IP address. This node is the first cluster node and is called the cluster configuration coordinator. All configurations that are performed on the cluster IP address are stored on this node and then propagated to the other cluster nodes.

The responsibility of configuration coordination in a cluster is not fixed to a specific node. It can change over time depending on the following factors:

- The priority of the node. The node with the highest priority (lowest priority number) is made the configuration coordinator. Therefore, if a node with a priority number lower than that of the existing configuration coordinator is added, the new node takes over as the configuration coordinator.
Note: Node priority can be configured from NetScaler 10.1 onwards.
- If the current configuration coordinator goes down. The node with the next lowest priority number takes over as the configuration coordinator. If the priority is not set or if there are multiple nodes with the lowest priority number, the configuration coordinator is selected from one of the available nodes.

Note: The configurations of the appliance (including SNIP addresses and VLANs) are cleared by implicitly executing the `clear ns config` extended command. However, the default VLAN and NSVLAN are not cleared from the appliance. Therefore, if you want the NSVLAN on the cluster, make sure it is created before the appliance is added to the cluster.

1. Log on to an appliance (for example, appliance with NSIP address 10.102.29.60) that you want to add to the cluster.
2. Add a cluster instance.
`add cluster instance <clId> -quorumType <NONE | MAJORITY>`

Note:

- The cluster instance ID must be unique within a LAN.

3. Add the NetScaler appliance to the cluster.
`add cluster node <nodeId> <IPAddress> -state <state> -backplane <interface_name>`

Example

Adding a node for an L2 cluster (all cluster nodes are in the same network).

```
> add cluster node 0 10.102.29.60 -state PASSIVE -backplane 0/1/1
```

4. Add the cluster IP address (for example, 10.102.29.61) on this node.
`add ns ip <IPAddress> <netmask> -type clip`

Example

```
> add ns ip 10.102.29.61 255.255.255.255 -type clip
```

5. Enable the cluster instance.
`enable cluster instance <clId>`
6. Save the configuration.
`save ns config`
7. Warm reboot the appliance.

reboot -warm

Verify the cluster configurations by using the show cluster instance command. Verify that the output of the command displays the NSIP address of the appliance as a node of the cluster.

1. Log on to an appliance (for example, an appliance with NSIP address 10.102.29.60) that you intend to add to the cluster.
2. Navigate to System > Cluster.
3. In the details pane, click the Manage Cluster link.
4. In the Cluster Configuration dialog box, set the parameters required to create a cluster. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click Create.
6. In the Configure cluster instance dialog box, make sure that the Enable cluster instance check box is selected.
7. In the Cluster Nodes pane, select the node and click Open.
8. In the Configure Cluster Node dialog box, set the State.
9. Click OK, and then click Save.
10. Warm reboot the appliance.

Adding a Node to the Cluster

Apr 03, 2015

You can seamlessly scale the size of a cluster to include a maximum of 32 nodes. When a NetScaler appliance is added to the cluster, the configurations from that appliance are cleared and cluster configurations are synchronized on this node. There can be an intermittent drop in traffic while the synchronization is in progress.

Note:

- The licenses of the appliance are checked against the licenses available on the configuration coordinator. The appliance is added if the licenses match.
- If you use the NetScaler CLI to add a node, the new node does not become a functional part of the cluster until it is explicitly joined to the cluster. Therefore, after adding the node, log on to that node and join the node to the cluster. Alternatively, you can add the node from the command line and use the configuration utility to join the node to the cluster. If you use the configuration utility, you need only log on to the cluster IP address and add the node. The newly added node is automatically joined to the cluster.

Important: Before you add a NetScaler appliance to a cluster:

- Set up the backplane interface for the node.
- If you want the NSVLAN on the cluster, make sure that the NSVLAN is created on the appliance before it is added to the cluster.
- Citrix recommends that you add the node as a passive node. Then, after joining the node to the cluster, complete the node specific configuration from the cluster IP address. Run the force cluster sync command if the cluster has only spotted IP addresses, has L3 VLAN binding, or has static routes.
- When an appliance with a preconfigured link aggregate (LA) channel is added to a cluster, the LA channel continues to exist in the cluster environment. The LA channel is renamed from LA/x to nodeId/LA/x, where LA/x is the LA channel identifier.

1. Log on to the cluster IP address and, at the command prompt, do the following:

1. Add the appliance (for example, 10.102.29.70) to the cluster.

```
add cluster node <nodeId> <IPAddress> -state <state> -backplane <interface_name>
```

Example

```
> add cluster node 1 10.102.29.70 -state PASSIVE -backplane 1/1/1
```

2. Save the configuration.

```
save ns config
```

2. Log on to the newly added node (for example, 10.102.29.70) and do the following:

1. Join the node to the cluster.

```
join cluster -clip <ip_addr> -password <password>
```

Example

```
> join cluster -clip 10.102.29.61 -password nsroot
```

2. Save the configuration.

```
save ns config
```

3. Warm reboot the appliance.

reboot -warm

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, click Add to add the new node (for example, 10.102.29.70).
4. In the Create Cluster Node dialog box, configure the new node. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click Create. When prompted to perform a warm reboot, click Yes.

If you have used the command line to add a node to the cluster, but have not joined the node to the cluster, you can use the following procedure.

Note: When a node joins the cluster, it takes over its share of traffic from the cluster and hence an existing connection can get terminated.

1. Log on to the node that you want to join to the cluster (for example, 10.102.29.70).
2. Navigate to System > Cluster.
3. In the details pane, under Get Started, click the Join Cluster link.
4. In the Join to existing cluster dialog box, set the cluster IP address and the nsroot password of the configuration coordinator. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click OK.

Viewing the Details of a Cluster

Feb 13, 2015

You can view the details of the cluster instance and the cluster nodes by logging on to the cluster IP address.

Log on to the cluster IP address and, at the command prompt, type:

```
show cluster instance <clld>
```

Note: When executed from the NSIP address of a cluster node that is not the configuration coordinator, this command displays the status of the cluster on this node.

Log on to the cluster IP address and, at the command prompt, type:

```
show cluster node <nodeId>
```

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, under Get Started, click the Manage Cluster link to view the details of the cluster.

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, click the node for which you want to view the details.

Distributing Traffic Across Cluster Nodes

Feb 13, 2015

After you have created the NetScaler cluster and performed the required configurations, you must deploy Equal Cost Multiple Path (ECMP) or cluster Link Aggregation (LA) on the client data plane (for client traffic) or server data plane (for server traffic). These mechanisms distribute external traffic across the cluster nodes.

Using Equal Cost Multiple Path (ECMP)

Feb 13, 2015

With the Equal Cost Multiple Path (ECMP) mechanism, the router has equal-cost routes to VIP addresses with the next hops as the active nodes of the cluster. The router uses a stateless hash-based mechanism to distribute traffic across the routes.

Note: Routes are limited to the maximum number of ECMP routes supported by the upstream router.

To use ECMP, you must first enable the required routing protocol (OSPF, RIP, BGP, or ISIS) on the cluster IP address. You must bind the interfaces and the spotted IP address (with dynamic routing enabled) to a VLAN. Configure the selected routing protocol and redistribute the kernel routes on the ZebOS by using the vtysh shell.

You must perform similar configurations on the cluster IP address and on the external connecting device.

Note:

- All routing configurations must be done through the cluster IP address. No configurations must be performed on individual cluster nodes.
- Make sure that the licenses on the cluster support dynamic routing, otherwise ECMP does not work.
- ECMP is not supported for wildcard virtual servers since RHI needs a VIP address to advertise to a router and wildcard virtual servers do not have associated VIP addresses.

You must have detailed knowledge of routing protocols to use ECMP. For more information, see "Configuring Dynamic Routes". For more information on routing in a cluster, see "Routing in a Cluster".

Figure 1. ECMP topology

As seen in the above figure, the ECMP router can reach the VIP address via SNIP0, SNIP1, or SNIP2.

1. Log on to the cluster IP address.
2. Enable the routing protocol.
enable ns feature <feature>

Example: To enable the OSPF routing protocol.

```
> enable ns feature ospf
```

3. Add a VLAN.
add vlan <id>

Example

```
> add vlan 97
```

4. Bind the interfaces of the cluster nodes to the VLAN.
bind vlan <id> -ifnum <interface_name>

Example

```
> bind vlan 97 -ifnum 0/1/2 1/1/2 2/1/2
```

5. Add a spotted SNIP address for each node and enable dynamic routing on it.
add ns ip <SNIP> <netmask> -ownerNode <positive_integer> -dynamicRouting ENABLED

Example

```
> add ns ip 97.131.0.1 255.0.0.0 -ownerNode 0 -dynamicRouting ENABLED -type SNIP > add ns ip 97.131.0.2 255.0.0.0 -ownerNode 1 -dynamicRouting ENABLED -type SNIP > add ns ip 97.131.0.3 255.0.0.0 -ownerNode 2 -dynamicRouting ENABLED -type SNIP
```

6. Bind one of the spotted SNIP addresses to the VLAN. When you bind one spotted SNIP address to a VLAN, all other spotted SNIP addresses defined on the cluster in that subnet are automatically bound to the VLAN.
bind vlan <id> -IPAddress <SNIP> <netmask>

Example

```
> bind vlan 97 -ipAddress 97.131.0.1 255.0.0.0
```

Note: You can use NSIP addresses of the cluster nodes instead of adding SNIP addresses. If so, you do not have to perform steps 3 - 6.

7. Configure the routing protocol on ZebOS using vtysh shell.

Example: To configure OSPF routing protocol on node IDs 0, 1, and 2.

```
> vtysh ! interface vlan97 ! router ospf owner-node 0 ospf router-id 97.131.0.1 exit-owner-node owner-node 1 ospf router-id 97.131.0.2 exit-owner-node owner-node 2 ospf router-id 97.131.0.3 exit-owner-node
```

Note: For VIP addresses to be advertised, RHI setting must be done by using the vserverRHILevel parameter as follows:

```
add ns ip <IPAddress> <netmask> -type VIP -vserverRHILevel <vserverRHILevel>
```

For OSPF specific RHI settings, there are additional settings that can be done as follows:

```
add ns ip <IPAddress> <netmask> -type VIP -ospfLSAType ( TYPE1 | TYPE5 ) -ospfArea <positive_integer>
```

Use the add ns ip6 command to perform the above commands on IPv6 addresses.

8. Configure ECMP on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

```
//For OSPF (IPv4 addresses) Global config: Configure terminal feature ospf Interface config: Configure terminal interface Vlan10 no shutdown ip address 97.131.0.5/8 Configure terminal ro
```

Use Case: ECMP with BGP Routing

Aug 06, 2013

To configure ECMP with BGP routing protocol, perform the following steps:

1. Log on to the cluster IP address.
2. Enable BGP routing protocol.
> enable ns feature bgp
3. Add VLAN and bind the required interfaces.
> add vlan 985
> bind vlan 985 -ifnum 0/0/1 1/0/1
4. Add the spotted IP address and bind them to the VLAN.
> add ns ip 10.100.26.14 255.255.255.0 -ownerNode 1 -dynamicRouting ENABLED
> add ns ip 10.100.26.15 255.255.255.0 -ownerNode 2 -dynamicRouting ENABLED
> bind vlan 985 -ipAddress 10.100.26.10 255.255.255.0
5. Configure BGP routing protocol on ZebOS using vtysh shell.
> vtysh
conf t
router bgp 65535
neighbor 10.100.26.1 remote-as 65535
6. Configure BGP on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.
router bgp 65535
no synchronization
bgp log-neighbor-changes

Using Cluster Link Aggregation

Feb 08, 2016

Cluster link aggregation, as the name suggests, is a group of interfaces of cluster nodes. It is an extension of NetScaler link aggregation. The only difference is that, while link aggregation requires the interfaces to be from the same device, in cluster link aggregation, the interfaces are from different nodes of the cluster. For more information about link aggregation, see "[Configuring Link Aggregation](#)".

Important

- Cluster link aggregation is supported for a cluster of hardware (MPX) appliances.
- Cluster link aggregation is supported for a cluster of virtual (VPX) appliances that are deployed on ESX and KVM hypervisors, with the following restrictions:
 - Dedicated interfaces need to be used. This means that the interfaces must not be shared with other virtual machines.
 - If the cluster link aggregation member interfaces are manually disabled or if cluster link aggregation itself is manually disabled, then interface power down capability is achieved only by LACP timeout mechanism.
 - Jumbo MTU is not supported on LACP cluster link aggregation.

Note: Cluster link aggregation is not supported on VPX appliances that are deployed on XenServer, AWS, and Hyper-V.

- Cluster link aggregation is not supported on NetScaler SDX appliances.
- The number of interfaces that can be bound to cluster LA is 16 (from each node), and the maximum number of interfaces in cluster LA can be $(16 * n)$, where n is the number of nodes in a cluster. The total number of interfaces in cluster LA depends on the number of interfaces for every port channel on upstream switch.

For example, consider a three-node cluster where all three nodes are connected to the upstream switch. A cluster LA channel (CLA/1) is formed by binding interfaces 0/1/2, 1/1/2, and 2/1/2.

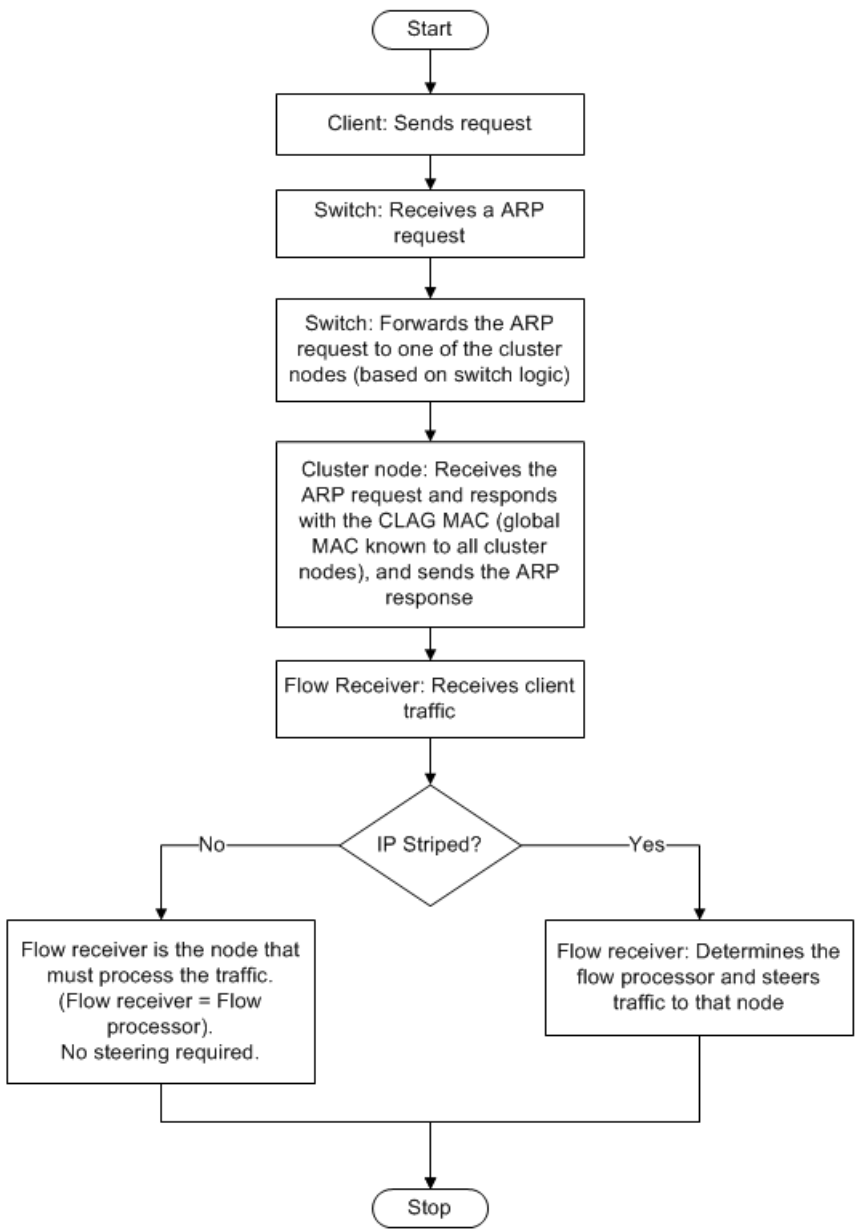

Figure 1. Cluster Link Aggregation topology

A cluster LA channel has the following attributes:

- Each channel has a unique MAC agreed upon by cluster nodes.
- The channel can bind both local and remote nodes' interfaces.
- A maximum of four cluster LA channels are supported in a cluster.
- Backplane interfaces cannot be part of a cluster LA channel.
- When an interface is bound to a cluster LA channel, the channel parameters have precedence over the network interface parameters. A network interface can be bound to one channel only.
- Management access to a cluster node, must not be configured on a cluster LA channel (for example, CLA/1) or its member interfaces. This is because when the node is INACTIVE, the corresponding cluster LA interface is marked as power down and therefore loses management access.

Figure 2. Traffic distribution flow using cluster LA

Static Cluster Link Aggregation

Feb 13, 2015

You must configure a static cluster LA channel on the cluster IP address and on the external connecting device. If possible, configure the upstream switch to distribute traffic based on IP address or port instead of MAC address.

For more information about configuring a static LA channel, see "[Configuring Link Aggregation Manually](#)".

1. Log on to the cluster IP address.

Note: Make sure that you configure the cluster LA channel on the cluster IP address before configuring link aggregation on the external switch. Otherwise, the switch will forward traffic to the cluster even though the cluster LA channel is not configured. This can lead to loss of traffic.

2. Create a cluster LA channel.

```
add channel <id> -speed <speed>
```

Example

```
> add channel CLA/1 -speed 1000
```

Note: You must not specify the speed as AUTO. Rather, you must explicitly specify the speed as 10, 100, 1000, or 10000. Only interfaces that have the speed matching the <speed> attribute in the cluster LA channel are added to the active distribution list.

3. Bind the required interfaces to the cluster LA channel. Make sure that the interfaces are not used for the cluster backplane.

```
bind channel <id> <if num>
```

Example

```
> bind channel CLA/1 0/1/2 1/1/2 2/1/2
```

4. Verify the configurations.

```
show channel <id>
```

Example

```
> show channel CLA/1
```

Note: You can bind the cluster LA channel to a VLAN by using the bind vlan command. The interfaces of the channel are automatically bound to the VLAN.

5. Configure static LA on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1). Similar configurations must be performed on other switches.

Global config:

```
Configure terminal
```

Interface level config:

```
interface Ethernet2/47
  switchport
  switchport access vlan 10
  channel-group 7 mode on
  no shutdown
```

```
interface Ethernet2/48
  switchport
  switchport access vlan 10
  channel-group 7 mode on
  no shutdown
```

Dynamic Cluster Link Aggregation

Apr 29, 2015

Dynamic cluster LA channel uses Link Aggregation Control Protocol (LACP). For more information about configuring a dynamic LA channel, see "[Configuring Link Aggregation by Using the Link Aggregation Control Protocol](#)".

You must perform similar configurations on the cluster IP address and on the external connecting device. If possible, configure the upstream switch to distribute traffic based on IP address or port instead of MAC address.

Points to remember:

- Enable LACP (by specifying the LACP mode as either ACTIVE or PASSIVE).

Note: Make sure the LACP mode is not set as PASSIVE on both the NetScaler cluster and the external connecting device.

- Specify the same LACP key on each interface that you want to be the part of the channel. For creating a cluster LA channel, the LACP key can have a value from 5 through 8. For example, if you set the LACP key on interfaces 0/1/2, 1/1/2, and 2/1/2 to 5, CLA/1 is created. The interfaces 0/1/2, 1/1/2, and 2/1/2 are automatically bound to CLA/1. Similarly, if you set the LACP key to 6, CLA/2 channel is created.
- Specify the LAG type as Cluster.

On the cluster IP address, for each interface that you want to add to the cluster LA channel, type:

```
set interface <id> -lACPmode <lACPmode> -lACPkey <positive_integer> -lagType CLUSTER
```

Example: To configure a cluster LA channel CLA/1 of 3 interfaces.

```
> set interface 0/1/2 -lACPmode active -lACPkey 5 -lagType Cluster
> set interface 1/1/2 -lACPmode active -lACPkey 5 -lagType Cluster
> set interface 2/1/2 -lACPmode active -lACPkey 5 -lagType Cluster
```

Note: Optionally, you can enable [Link Redundancy in a Cluster with LACP](#).

Similarly, configure dynamic LA on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1). Similar configurations must be performed on other switches.

Global config:

```
Configure terminal
```

```
feature lACP
```

Interface level config:

```
interface Ethernet2/47
  switchport
  switchport access vlan 10
  channel-group 7 mode active
  no shutdown
```

```
interface Ethernet2/48
  switchport
```

```
switchport access vlan 10  
channel-group 7 mode active  
no shutdown
```

Link Redundancy in a Cluster with LACP

May 05, 2015

A NetScaler cluster provides link redundancy for LACP to ensure that all nodes have the same partner key.

To understand the need for link redundancy, let us consider the example of the following cluster setup along with the accompanying cases (with attention to case 3):

In this setup, interfaces I1, I2, I3 and I4 are bound to LACP channel with KEY 5. On the partner side, I1 and I2 are connected to Switch 1 to form a single LA channel with KEY 1. Similarly, I3 and I4 are connected to Switch 2 to form a single LA channel with KEY 2.

Now let us consider the following cases to understand the need for link redundancy:

Case 1: Switch 1 is up and Switch 2 is down

In this case, cluster LA on both the nodes would stop receiving LACPDUs from Key2 and would start receiving LACPDUs from Key1. On both the nodes, cluster LA is connected to KEY 1 and I1 and I2 will be UP and channel on both the nodes would be UP.

Case 2: Switch1 goes down and Switch2 becomes UP

In this case, cluster LA on both the nodes would stop receiving LACPDUs from Key1 and would start receiving LACPDUs from Key2. On both the nodes, cluster LA is connected to Key2 and I3 and I4 will be UP and channel on both the nodes would be UP.

Case 3: Both Switch1 and Switch2 are UP

In this case, it is possible that cluster LA on node1 chooses Key1 as its partner and cluster LA on node2 chooses Key2 as its partner. This means that I1 on node1 and I4 on node2 are receiving traffic which is undesirable. This can happen because the LACP state machine is node-level and chooses its partners on first-come first-serve basis.

To solve these concerns, link redundancy of dynamic cluster LA is supported. To configure link redundancy on a channel or interface, you must enable it as follows:

```
set channel CLA/1 -linkRedundancy ON
```

Using Linksets

Feb 27, 2015

Linksets must be used when some cluster nodes are not physically connected to the external network. In such a cluster topology, the unconnected cluster nodes use the interfaces specified in the linkset to communicate with the external network through the cluster backplane. Linksets are typically used in scenarios when the connecting devices have insufficient ports to connect the cluster nodes.

Note: Linksets are a mandatory configuration in the following scenarios:

- For deployments that require MAC-Based Forwarding (MBF).
- To improve manageability of ACL and L2 policies involving interfaces. You must define a linkset of the interfaces and add ACL and L2 policies based on linksets.

Linksets must be configured only through the cluster IP address.

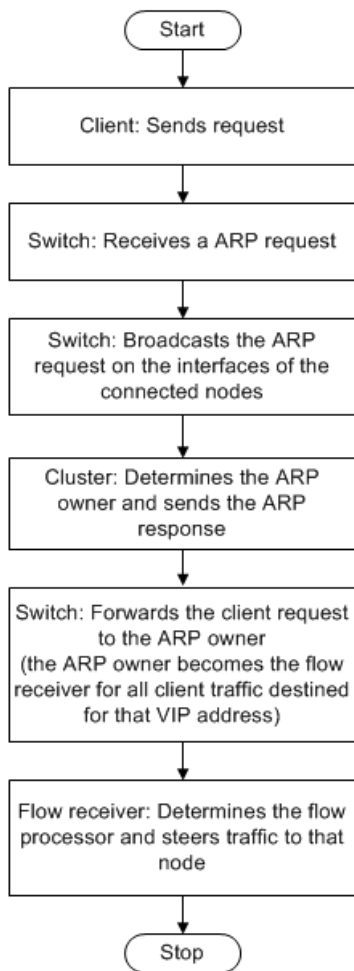

For example, consider a three node cluster where the upstream switch has only two ports available. Using linksets, you can connect two nodes to the switch and leave the third node unconnected. In the following figure, a linkset (LS/1) is formed by binding the interfaces 0/1/2 and 1/1/2. NS2 is the unconnected node of the cluster.

Figure 1. Linksets topology

The linkset informs NS2 that it can use interfaces 0/1/2 and 1/1/2 to communicate with the network devices. All traffic to and from NS2 is now routed through interfaces 0/1/2 or 1/1/2.

Figure 2. Traffic distribution flow using linksets

1. Log on to the cluster IP address.
2. Create a linkset.
add linkset <id>

Example

```
> add linkset LS/1
```

3. Bind the required interfaces to the linkset. Make sure the interfaces are not used for the cluster backplane.
bind linkset <id> -ifnum <interface_name> ...

Example

```
> bind linkset LS/1 -ifnum 0/1/2 1/1/2
```

4. Verify the linkset configurations.
show linkset <id>

Example

```
> show linkset LS/1
```

Note: You can bind the linkset to a VLAN by using the bind vlan command. The interfaces of the linkset are automatically bound to the VLAN.

1. Log on to the cluster IP address.

2. Navigate to System > Network > Linksets.
3. In the details pane, click Add.
4. In the Create Linkset dialog box:
 1. Specify the name of the linkset by setting the Linkset parameter.
 2. Specify the Interfaces to be added to the linkset and click Add. Repeat this step for each interface you want to add to the linkset.
5. Click Create, and then click Close.

Managing the NetScaler Cluster

Nov 17, 2014

After you have created a cluster and configured the required traffic distribution mechanism, the cluster is able to serve traffic. During the lifetime of the cluster, you can perform cluster tasks such as configuring nodegroups, disabling nodes of a cluster, discovering NetScaler appliances, viewing statistics, synchronizing cluster configurations, cluster files, and the time across the nodes, and upgrading or downgrading the software of cluster nodes.

Nodegroups for Spotted and Partially-Striped Configurations

May 25, 2015

By virtue of the default cluster behavior, all configurations performed on the cluster IP address are available on all nodes of the cluster. However, there might be cases where you need some configurations to be available only on specific cluster nodes.

You can achieve this requirement by defining a nodegroup that includes the specific cluster nodes, and then binding the configuration to that nodegroup. This ensures that the configuration is active only on those cluster nodes. These configurations are called partially-striped or spotted (if active only on a single node). For more information, see [Striped, Partially Striped, and Spotted Configurations](#).

For example, consider a cluster with three nodes. You create a nodegroup NG0 that includes node n1 and another nodegroup NG1 that includes n2 and n3. Bind load balancing virtual server .77 to NG0 and load balancing virtual server .69 to NG1.

This means that virtual server .77 will be active only on n1 and consequently only n1 will receive traffic that is directed to .77. Similarly, virtual server .69 will be active only on nodes n2 and n3 and consequently only n2 and n3 will receive traffic that is directed to .69.

Figure 1. NetScaler cluster with nodegroups configured for spotted and partial-striped configurations

The entities or configurations that you can bind to a nodegroup are:

- Load balancing, content switching, cache redirection, authentication (AAA) virtual servers
Note: FTP load balancing virtual servers cannot be bound to nodegroups.
- VPN virtual server (Supported from NetScaler 10.5 Build 50.10 onwards)
- Global Server Load Balancing (GSLB) sites and other GSLB entities (Supported from NetScaler 10.5 Build 52.11 onwards)
- Limit identifiers and stream identifiers

Behavior of Nodegroups

Mar 18, 2015

Due to the interoperability of nodegroups with different NetScaler features and entities, there are some behavioral aspects to be noted. Nodes in a nodegroup can also be backed up. Read on for more information.

- A nodegroup that has entities bound to it cannot be removed.
- A cluster node that belongs to a nodegroup with entities bound to it, cannot be removed.
- A cluster instance that has nodegroups with entities bound to it, cannot be removed.
- You cannot add an entity that has a dependency on another entity that is not part of the nodegroup. If you need to do so, first remove the dependency. Then, add both the entities to the nodegroup and reassociate the entities.

Examples:

- Assume you have a virtual server, VS1, whose backup is virtual server VS2. To add VS1 to a nodegroup, first make sure that VS2 is removed as the backup server of VS1. Then, bind each server individually to the nodegroup, and then configure VS2 as the backup for VS1.
- Assume you have a content switching virtual server, CSVS1, whose target load balancing virtual server is LBVS1. To add CSVS1 to a nodegroup, first remove LBVS1 as the target. Then, bind each server individually to the nodegroup, and then configure LBVS1 as the target.
- Assume you have a load balancing virtual server, LBVS1, that has a policy which invokes another load balancing virtual server, LBVS2. To add either one of the virtual servers, first remove the association. Then, bind each server individually to the nodegroup, and then reassociate the virtual servers.
- You cannot bind an entity to a nodegroup that has no nodes and that has the strict option enabled. Consequently, you cannot unbind the last node of a nodegroup that has entities bound to it and that has the strict option enabled
- The strict option cannot be modified for a nodegroup that has no nodes but has entities bound to it.

By default, a nodegroup is designed to provide back up nodes for members of a nodegroup. If a nodegroup member goes down, a cluster node that is not a member of the nodegroup dynamically replaces the failed node. This node is called the replacement node.

Note: For a single-member nodegroup, a backup node is automatically preselected when an entity is bound to the nodegroup.

When the original member of the nodegroup comes up, the replacement node, by default, is replaced by the original member node.

From NetScaler 10.5 Build 50.10 onwards, however, the NetScaler allows you to change this replacement behavior. When you enable the sticky option, the replacement node is retained even after the original member node comes up. The original node takes over only when the replacement node goes down.

You can also disable the backup functionality. To do this, you must enable the strict option. In this scenario, when a nodegroup member goes down, no other cluster node is picked up as a backup node. The original node continues being part of the nodegroup when it comes up. This option ensures that entities bound to a nodegroup are active only on nodegroup members.

Note: The strict and sticky option can be set only when creating a nodegroup.

Configuring Nodegroups for Spotted and Partially-Striped Configurations

Mar 31, 2015

To configure a nodegroup for spotted and partially-striped configurations you must first create a nodegroup and then bind the required nodes to the nodegroup. You must then associate the required entities to that nodegroup. The entities that are bound to the nodegroup will be:

- Spotted - If bound to a nodegroup that has a single node.
- Partially striped - If bound to a nodegroup that has more than one node.

Some points to remember:

- GSLB is supported on a cluster only when GSLB sites are bound to nodegroups that have a single cluster node. For more information, see [Setting Up GSLB in a Cluster](#).
- NetScaler Gateway is supported on a cluster only when the VPN virtual servers are bound to nodegroups that have a single cluster node. The sticky option must be enabled on the nodegroup.
- Application firewall is supported on a cluster only when application firewall profiles are associated with virtual servers that are bound to nodegroups that have a single cluster node. You are not allowed to do the following:
 - Bind application firewall profiles to striped or partially striped virtual servers.
 - Bind the policy to a global bind point or to user-defined policy labels.
 - Unbind, from a nodegroup, a virtual server that has application firewall profiles.

Check [NetScaler Features Supported in a Cluster](#) to see the NetScaler versions from which GSLB, NetScaler Gateway, and application firewall are supported in a cluster.

1. Log on to the cluster IP address.
2. Create a nodegroup. Type:
`add cluster nodegroup <name> -strict (YES | NO)`

Example

```
> add cluster nodegroup NG0 -strict YES
```

3. Bind the required nodes to the nodegroup. Type the following command for each member of the nodegroup:
`bind cluster nodegroup <name> -node <nodeId>`

Example: To bind nodes with IDs 1, 5, and 6.

```
> bind cluster nodegroup NG0 -node 1
> bind cluster nodegroup NG0 -node 5
> bind cluster nodegroup NG0 -node 6
```

4. Bind the entity to the nodegroup. Type the following command once for every entity that you want to bind:
`bind cluster nodegroup <name> (-vServer <string> | -identifierName <string> | -gslbSite <string> -service <string>)`

Note: The `gslbSite` and `service` parameters are available from NetScaler 10.5 onwards.

Example: To bind virtual servers VS1 and VS2 and rate limit identifier named identifier1.

```
> bind cluster nodegroup NG0 -vServer VS1
> bind cluster nodegroup NG0 -vServer VS2
> bind cluster nodegroup NG0 -identifierName identifier1
```

5. Verify the configurations by viewing the details of the nodegroup. Type:
show cluster nodegroup <name>

Example

```
> show cluster nodegroup NG0
```

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Node Groups.
3. In the details pane, click Add.
4. In the Create Node Group dialog box, configure the nodegroup:
 1. Under Cluster Nodes, click the Add button.
 - The Available list displays the nodes that you can bind to the nodegroup and the Configured list displays the nodes that are bound to the nodegroup.
 - Click the + sign in the Available list to bind the node. Similarly, click the - sign in the Configured list to unbind the node.
 2. Under Virtual Servers, select the tab corresponding to the type of virtual server that you want to bind to the nodegroup. Click the Add button.
 - The Available list displays the virtual servers that you can bind to the nodegroup and the Configured list displays the virtual servers that are bound to the nodegroup.
 - Click the + sign in the Available list to bind the virtual server. Similarly, click the - sign in the Configured list to unbind the virtual server.

Configuring Redundancy for Nodegroups

Mar 18, 2015

Note: Supported from NetScaler 10.5 Build 52.1115.e onwards.

Nodegroups can be configured such that when one nodegroup goes down, another nodegroup can take over and process traffic. For example, when a nodegroup NG1 goes down, NG2 takes over.

Note: This functionality can be used to configure datacenter redundancy where each nodegroup is configured as a datacenter.

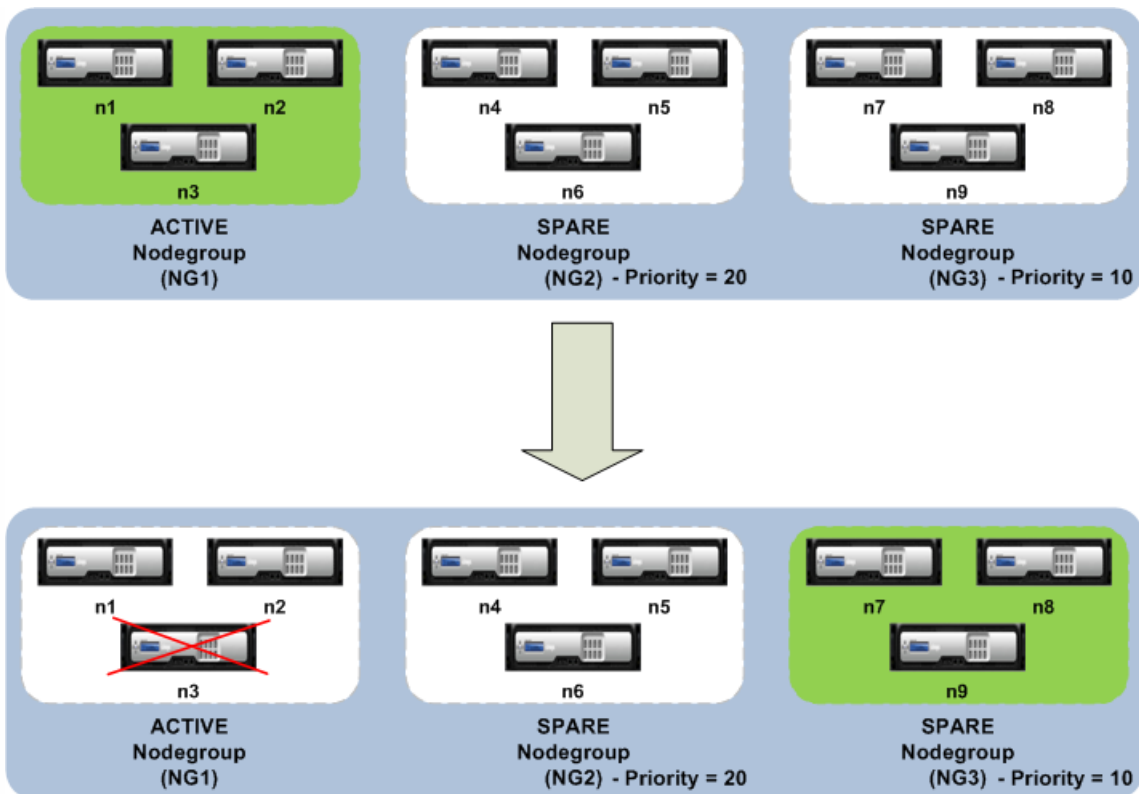

To achieve this use case, cluster nodes must be logically grouped into nodegroups, where some nodegroups must be configured as ACTIVE and others as SPARE. The active nodegroup with the highest priority (that is, the lowest priority number) is made operationally active and therefore serves traffic. When a node from this operationally active nodegroup goes down, the node count of this nodegroup is compared with the node count of the other active nodegroups in order of their priority. If a nodegroup has a higher or equal node count, that nodegroup is made operationally active. Else, the spare nodegroups are checked.

Note:

- Only one state-specific nodegroup can be active at a given point in time.
- A cluster node inherits the state of the nodegroup. So, if a node with "SPARE" state is added to nodegroup with state as "ACTIVE", the node automatically behaves as an active node.
- The preemption parameter that is defined for the cluster instance decides whether the initial active nodegroup will take control when the it comes up again.
- A spare node group can take up a node group and host active traffic when an active node group goes down.

The following figure shows a nodegroup setup that has nodegroup redundancy defined. NG1 is initially the active nodegroup. When it loses one of the nodes, the spare nodegroup (NG3) with the highest priority starts serving traffic.

Figure 1. NetScaler cluster with nodegroup redundancy configured

Configuring redundancy for nodegroups

1. Log on to the cluster IP address.
2. Create the active nodegroup and bind the required cluster nodes.

```
add cluster nodegroup NG1 -state ACTIVE
```

```
bind cluster nodegroup NG1 -node n1
```

```
bind cluster nodegroup NG1 -node n2
```

```
bind cluster nodegroup NG1 -node n3
```
3. Create the spare nodegroup and bind the requisite nodes.

```
add cluster nodegroup NG2 -state SPARE -priority 20
```

```
bind cluster nodegroup NG2 -node n4
```

```
bind cluster nodegroup NG2 -node n5
```

```
bind cluster nodegroup NG2 -node n6
```
4. Create another spare nodegroup and bind the requisite nodes.

```
add cluster nodegroup NG3 -state SPARE -priority 10
```

```
bind cluster nodegroup NG3 -node n7
```

```
bind cluster nodegroup NG3 -node n8
```

```
bind cluster nodegroup NG3 -node n9
```

Synchronizing Cluster Configurations

Feb 13, 2015

NetScaler configurations that are available on the configuration coordinator are synchronized to the other nodes of the cluster when:

- A node joins the cluster
- A node rejoins the cluster
- A new command is executed through the cluster IP address.

Additionally, you can forcefully synchronize the configurations that are available on the configuration coordinator (full synchronization) to a specific cluster node. Make sure you synchronize one cluster node at a time, otherwise the cluster can get affected.

At the command prompt of the appliance on which you want to synchronize the configurations, type:

```
force cluster sync
```

1. Log on to the appliance on which you want to synchronize the configurations.
2. Navigate to System > Cluster.
3. In the details pane, under Utilities, click Force cluster sync.
4. Click OK.

Synchronizing Time Across Cluster Nodes

Mar 31, 2015

The cluster uses Precision Time Protocol (PTP) to synchronize the time across cluster nodes. PTP uses multicast packets to synchronize the time. If there are some issues in time synchronization, you must disable PTP and configure Network Time Protocol (NTP) on the cluster.

At the command prompt of the cluster IP address, type:

```
set ptp -state disable
```

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, under Utilities, click Configure PTP Settings.
4. In the Enable/Disable PTP dialog box, select whether you want to enable or disable PTP.
5. Click OK.

Synchronizing Cluster Files

Feb 26, 2016

The files available on the configuration coordinator are called cluster files. These files are automatically synchronized on the other cluster nodes when the node is added to the cluster and periodically, during the lifetime of the cluster. Additionally, you can manually synchronize the cluster files.

The directories and files from the configuration coordinator that are synchronized are:

- /nsconfig/ssl/
- /var/netScaler/ssl/
- /var/vpn/bookmark/
- /nsconfig/dns/
- /nsconfig/htmlinjection/
- /netScaler/htmlinjection/ens/
- /nsconfig/monitors/
- /nsconfig/nstemplates/
- /nsconfig/ssh/
- /nsconfig/rc.netScaler
- /nsconfig/resolv.conf
- /nsconfig/inetd.conf
- /nsconfig/syslog.conf
- /nsconfig/snmpd.conf
- /nsconfig/ntp.conf
- /nsconfig/httpd.conf
- /nsconfig/sshd_config
- /nsconfig/hosts
- /nsconfig/enckey
- /var/nslw.bin/etc/krb5.conf
- /var/nslw.bin/etc/krb5.keytab
- /var/lib/likewise/db/
- /var/download/
- /var/wi/tomcat/webapps/
- /var/wi/tomcat/conf/Catalina/localhost/
- /var/wi/java_home/lib/security/cacerts
- /var/wi/java_home/jre/lib/security/cacerts
- /nsconfig/license/
- /nsconfig/rc.conf

Tip

Files (certificates and key files) that are copied to the cluster configuration coordinator manually (or through the shell) are not automatically available on the other cluster nodes. You must execute the "sync cluster files" command from the cluster IP address before executing a command that depends on these file(s).

To synchronize cluster files by using the command line interface

At the command prompt of the cluster IP address, type:

```
sync cluster files <mode>
```

To synchronize cluster files by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, under Utilities, click Synchronize cluster files.
4. In the Synchronize cluster files dialog box, select the files to be synchronized in the Mode drop-down box.
5. Click OK.

Viewing the Statistics of a Cluster

Feb 13, 2015

You can view the statistics of a cluster instance and cluster nodes to evaluate the performance or to troubleshoot the operation of the cluster.

To view the statistics of a cluster instance by using the command line interface

At the command prompt of the cluster IP address, type:

```
stat cluster instance <clld>
```

To view the statistics of a cluster node by using the command line interface

At the command prompt of the cluster IP address, type:

```
stat cluster node <nodeid>
```

Note: When executed from the cluster IP address, this command displays the cluster level statistics. However, when executed from the NSIP address of a cluster node, the command displays node level statistics.

To view the statistics of a cluster instance by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, in the center of the page, click Statistics.

To view the statistics of a cluster node by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, select a node and click Statistics to view the statistics of the node. To view the statistics of all the nodes, click Statistics without selecting a specific node.

Discovering NetScaler Appliances

Feb 13, 2015

You can discover NetScaler appliances present in the same subnet as the NSIP address of the configuration coordinator. The discovered appliances can then be added to the cluster.

Note: This operation is available only through the configuration utility.

To discover appliances by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, at the bottom of the page, click Discover NetScalers.
4. In the Discover NetScalers dialog box, set the following parameters:
 - IP address range - Specify the range of IP addresses within which you want to discover appliances. For example, you can search for all NSIP addresses between 10.102.29.4 to 10.102.29.15 by specifying this option as 10.102.29.4 - 15.
 - Backplane interface - Specify the interfaces to be used as the backplane interface. This is an optional parameter. If you do not specify this parameter, you must update it after the node is added to the cluster.
5. Click OK.
6. Select the appliances that you want to add to the cluster.
7. Click OK.

Disabling a Cluster Node

Feb 27, 2015

You can temporarily remove a node from a cluster by disabling the cluster instance on that node. A disabled node is not synchronized with the cluster configurations. When the node is enabled again, the cluster configurations are automatically synchronized on it. For more information, see [Cluster Synchronization](#).

A disabled node cannot serve traffic and all existing connections on this node are terminated.

Note: If the configurations of a disabled non-configuration coordinator node are modified (through the NSIP address of the node), the configurations are not automatically synchronized on that node. You must manually synchronize the configurations as described in [Synchronizing Cluster Configurations](#).

To disable a cluster node by using the command line interface

At the command prompt of the node that you want to disable, type:

```
disable cluster instance <clld>
```

Note: To disable the cluster, run the disable cluster instance command on the cluster IP address.

To disable a cluster node by using the configuration utility

1. On the node that you want to disable, navigate to System > Cluster, and click Manage Cluster.
2. In the Configure cluster instance dialog box, unselect the Enable cluster instance check box.

Note: To disable the cluster instance on all the nodes, perform the above procedure on the cluster IP address.

Removing a Cluster Node

Feb 27, 2015

When a node is removed from the cluster, the cluster configurations are cleared from the node (by internally executing the `clear ns config -extended` command). The SNIP addresses and all VLAN configurations (except the default VLAN and NSVLAN) are also cleared from the appliance.

Note:

- If the deleted node was the cluster configuration coordinator, another node is automatically selected as the cluster configuration coordinator, and the cluster IP address is assigned to that node. All the current cluster IP address sessions will be invalid and you will have to start a new session.
- To delete the whole cluster, you must remove each node individually. When you remove the last node, the cluster IP address(es) are deleted.
- When an active node is removed, the traffic serving capability of the cluster is reduced by one node. Existing connections on this node are terminated.

To remove a cluster node by using the command line interface

For NetScaler 10.1 and later versions

Log on to the cluster IP address and at the command prompt, type:

```
rm cluster node <nodeId>
```

Note: If the cluster IP address is unreachable from the node, execute the `rm cluster instance` command on the NSIP address of that node itself.

For NetScaler 10

1. Log on to the node that you want to remove from the cluster and remove the reference to the cluster instance.

```
rm cluster instance <clId>
```

```
save ns config
```

2. Log on to the cluster IP address and remove the node from which you removed the cluster instance.

```
rm cluster node <nodeId>
```

```
save ns config
```

Make sure you do not run the `rm cluster node` command from the local node as this results in inconsistent configurations between the configuration coordinator and the node.

To remove a cluster node by using the configuration utility

On the cluster IP address, navigate to `System > Cluster > Nodes`, select the node you want to remove and click `Remove`.

Removing a Node from a Cluster Deployed Using Cluster Link Aggregation

Feb 13, 2015

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism, you must make sure that the node is made passive so that it does not receive any traffic and then, on the upstream switch, remove the corresponding interface from the channel.

For detailed information on cluster link aggregation, see [Using Cluster Link Aggregation](#).

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism

1. Log on to the cluster IP address.
2. Set the state of the cluster node that you want to remove to PASSIVE.
`set cluster node <nodeId> -state PASSIVE`
3. On the upstream switch, remove the corresponding interface from the channel by using switch-specific commands.
Note: You do not have to manually remove the nodes interface on the cluster link aggregation channel. It is automatically removed when the node is deleted in the next step.
4. Remove the node from the cluster.
`rm cluster node <nodeId>`

Cluster Setup and Usage Scenarios

Mar 31, 2015

This section aims at explaining some scenarios in which the NetScaler cluster can be setup and also how it can be configured for different features and network topologies. These are just some scenarios that we have documented. Provide feedback if you want some other scenarios to be included.

Creating a Two-Node Cluster

Feb 17, 2015

A two-node cluster is an exception to the rule that a cluster is functional only when a minimum of $(n/2 + 1)$ nodes, where n is the number of cluster nodes, are able to serve traffic. If that formula were applied to a two-node cluster, the cluster would fail if one node went down ($n/2 + 1 = 2$).

A two-node cluster is functional even if only one node is able to serve traffic.

Creating a two node cluster is the same as creating any other cluster. You must add one node as the configuration coordinator and the other node as the other cluster node.

Note: Incremental configuration synchronization is not supported in a two-node cluster. Only full synchronization is supported.

Migrating an HA Setup to a Cluster Setup

Feb 17, 2015

An existing high availability (HA) setup can be migrated to a cluster setup by first removing the appliances from the HA setup and then creating the NetScaler cluster. This approach will result in a downtime for the application.

Consider an HA setup with appliances NS0 (10.102.97.131) and NS1 (10.102.97.132). NS0 is the primary and NS1 is the secondary appliance of the HA setup.

To convert a HA setup to cluster setup by using the NetScaler command line

1. Log on to each HA node and remove it from the HA setup.

```
rm HA node <id>
```

Example

```
rm HA node 1
```

2. Go to the shell on one of the HA nodes and copy the ns.conf file to another .conf file (for example, ns_backup.conf).
3. On both the nodes, identify the network interfaces to be used for the cluster backplane. Make sure to configure the backplane switch appropriately.
4. Create the cluster on one of the appliances (for example, 10.102.97.131).

```
//On the NSIP address of the first appliance
```

```
add cluster instance 1
add cluster node 0 10.102.97.131 -state ACTIVE -backplane 0/1/1
add ns ip 10.102.97.133 255.255.255.255 -type CLIP
enable cluster instance 1
save ns config
reboot -warm
```

5. Add the other appliance to the cluster.

```
//On the cluster IP address
```

```
add cluster node 1 10.102.97.132 -state ACTIVE -backplane 1/1/1
```

```
//On the NSIP address of the appliance
```

```
join cluster -clip 10.102.97.133 -password nsroot
save ns config
reboot -warm
```

6. After the two nodes are up and active, log on to the cluster IP address and modify the backed-up configuration file as follows:

1. Remove the features that are not supported on a cluster. For the list of unsupported features, see [NetScaler Features Supported by a Cluster](#). This is an optional step. If you do not perform this step, the execution of unsupported commands will fail.
2. Remove the configurations that have interfaces, or update the interface names from the c/u convention to the n/c/u convention.

Example

```
add vlan 10 -ifnum 0/1
```

should be changed to

```
add vlan 10 -ifnum 0/0/1 1/0/1
```

3. The backup configuration file can have SNIP addresses or MIP addresses. These addresses are striped on all the cluster nodes. It is recommended that you add spotted IP addresses for each node.

Example

```
add ns ip 1.1.1.1 255.255.255.0 -ownerNode 0
```

```
add ns ip 1.1.1.2 255.255.255.0 -ownerNode 1
```

4. Update the hostname to specify the owner node.

Example

```
set ns hostname ns0 -ownerNode 0
```

```
set ns hostname ns1 -ownerNode 1
```

5. Change all other relevant networking configuration that depend on spotted IPs. For example, L3 VLAN, RNAT configuration which uses SNIPs as NATIP, INAT rules that refers to SNIPs/MIPs).
7. Apply configurations from the backup configuration file to the configuration coordinator through the cluster IP address.

```
batch -fileName <input_filename>
```

Example

```
batch -f ns_backup.conf
```

8. Configure appropriate client traffic distribution mechanism (ECMP, cluster LA or linksets).
9. Save the configuration.

```
save ns config
```

The appliances of the HA setup are migrated to a cluster setup.

Migrating an HA Setup to a Cluster Setup without Downtime

Feb 17, 2015

An existing high availability (HA) setup can be migrated to a cluster setup by first removing the secondary appliance from the HA setup and using that appliance to create a single-node cluster. Then, after the cluster becomes operational and serves traffic, the primary appliance of the HA setup is added to the cluster. This approach will not result in a downtime for the application.

Consider an HA setup with appliances NS0 (10.102.97.131) and NS1 (10.102.97.132). NS0 is the primary and NS1 is the secondary appliance of the HA setup.

To convert a HA setup to cluster setup (without downtime) by using the NetScaler command line

1. Go to the shell on one of the HA nodes and copy the ns.conf file to another .conf file (for example, ns_backup.conf).
Note: Make sure HA pair is stable with respect to configurations.
2. Log on to the secondary appliance NS1 and clear all the configurations. This removes the secondary appliance from the HA setup and makes it a standalone appliance.

```
clear ns config full
```

Note:

- The configurations are cleared to make sure that NS1 does not start owning the VIPs once it becomes a standalone appliance.
- At this stage, NS0 is still active and continues to serve traffic.

3. Create a cluster on appliance NS1 and configure it as a PASSIVE node.

```
//On the NSIP address of node NS1
```

```
add cluster instance 1
add cluster node 0 10.102.97.131 -state PASSIVE -backplane 0/1/1
add ns ip 10.102.97.133 255.255.255.255 -type CLIP
enable cluster instance 1
save ns config
reboot -warm
```

4. Modify the backed-up configuration file.

1. Remove the features that are not supported on a cluster. For the list of unsupported features, see [NetScaler Features Supported by a Cluster](#). This is an optional step. If you do not perform this step, the execution of unsupported commands will fail.
2. Remove the configurations that have interfaces, or update the interface names from the c/u convention to the n/c/u convention.

Example

```
add vlan 10 -ifnum 0/1
```

should be changed to

```
add vlan 10 -ifnum 0/0/1 1/0/1
```

3. The backup configuration file can have SNIP addresses or MIP addresses. These addresses are striped on all the cluster nodes. It is recommended that you add spotted IP addresses for each node.

Example

```
add ns ip 1.1.1.1 255.255.255.0 -ownerNode 0
```

```
add ns ip 1.1.1.2 255.255.255.0 -ownerNode 1
```

4. Update the hostname to specify the owner node.

Example

```
set ns hostname ns0 -ownerNode 0
```

```
set ns hostname ns1 -ownerNode 1
```

5. Change all other relevant networking configuration that depend on spotted IPs. For example, L3 VLAN, RNAT configuration which uses SNIPs as NATIP, INAT rules that refers to SNIPs/MIPs).
5. On the cluster, do the following:
 1. Make the topological changes to the cluster by connecting the cluster backplane, the cluster link aggregation channel, and so on.
 2. Apply configurations from the backup configuration file to the configuration coordinator through the cluster IP address.

```
batch -f ns_backup.conf
```
 3. Configure external traffic distribution mechanisms like ECMP or cluster link aggregation.
6. Switch-over the traffic from the HA setup to the single-node cluster setup.
 1. Disable all interfaces on the primary appliance NS0.

```
disable interface <interface id>
```
 2. Configure the cluster node as an ACTIVE node.

```
set cluster node 0 -state ACTIVE
```

Note: There can be a small amount (in the order of seconds) of downtime between disabling the interfaces and making the cluster node active.

7. On the primary appliance NS0, do the following:
 1. Clear all the configurations.

```
clear ns config full
```
 2. Enable all the interfaces.

```
enable interface <interface id>
```
 3. Add the appliance to the cluster.

```
//On the cluster IP address (in this sample, 10.102.97.133)  
add cluster node 1 10.102.97.132 -state PASSIVE -backplane 1/1/1
```

```
//On the NSIP address of the appliance
```

```
join cluster -clip 10.102.97.133 -password nsroot
```

```
save ns config
```

```
reboot -warm
```

4. Perform the required topological and configuration changes.
5. Configure NS0 as an ACTIVE node.

```
set cluster node 1 -state ACTIVE
```

The appliances of the HA setup are migrated to a cluster setup without any downtime for the application.

Setting Up GSLB in a Cluster

Oct 08, 2014

Note: Supported from NetScaler 10.5 Build 52.11 onwards.

To set up GSLB in a cluster you must bind the different GSLB entities to a node group. The node group must have a single member node.

Note:

- The parent-child topology of GSLB is not supported in a cluster.
- If you have configured the static proximity GSLB method, make sure that the static proximity database is present on all the cluster nodes. This happens by default if the database file is available at the default location. However, if the database file is maintained in a directory other than /var/netscaler/locdb/, you must manually synch the file to all the cluster nodes.

To set up GSLB in a cluster by using the command line interface

Log on to the cluster IP address and perform the following operations at the command prompt:

1. Configure the different GSLB entities. For information, see [Configuring Global Server Load Balancing](#).

Note: When creating the GSLB site, make sure that you specify the cluster IP address and public cluster IP address (needed only when the cluster is deployed behind a NAT device). These parameters are required to ensure the availability of the GSLB auto-sync functionality.

```
add gslb site <siteName> <siteType> <siteIPAddress> -publicIP <ip_addr> -clip <ip_addr> <publicCLIP>
```

2. Create a cluster node group.

```
add cluster nodegroup <name> [-sticky ( YES | NO )]
```

Note: Enable the sticky option if you want to set up GSLB based on VPN users.

3. Bind a single cluster node to the node group.

```
bind cluster nodegroup <name> -node <nodeId>
```

4. Bind the local GSLB site to the nodegroup.

```
bind cluster nodegroup <name> -gslbSite <string>
```

Note: Make sure that the IP address of the local GSLB site IP address is striped (available across all cluster nodes).

5. Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

To bind the ADNS service:

```
bind cluster nodegroup <name> -service <string>
```

To bind the DNS load balancing virtual server:

```
bind cluster nodegroup <name> -vServer <string>
```

6. Bind the GSLB virtual server to the node group.

```
bind cluster nodegroup <name> -vServer <string>
```

7. [Optional] To setup GSLB based on VPN users, bind the VPN virtual vserver to the GSLB node group.

```
bind cluster nodegroup <name> -vServer <string>
```

8. Verify the configurations.

```
show gslb runningConfig
```

To set up GSLB in a cluster by using the graphical user interface

Log on to the cluster IP address and perform the following operations in the Configuration tab:

1. Configure the GSLB entities.

Navigate to Traffic Management > GSLB to perform the required configurations.

2. Create a node group and perform other node group related configurations.

Navigate to System > Cluster > Node Groups to perform the required configurations.

For the detailed configurations to be performed, see the description provided in the CLI procedure mentioned above.

Using Cache Redirection in a Cluster

Feb 17, 2015

Cache redirection in a cluster works in the same way as it does on a standalone NetScaler appliance. The only difference is that the configurations are done on the cluster IP address. For more information on cache redirection, see "[Cache Redirection](#)."

Points to remember when using cache redirection in transparent mode on a cluster:

- Before configuring cache redirection, make sure that you have connected all nodes to the external switch and that you have linksets configured. Otherwise, client requests will be dropped.
- When MAC mode is enabled on a load balancing virtual server, make sure MBF mode is enabled on the cluster by using the `enable ns mode MBF` command. Otherwise, the requests are sent to origin server directly instead of being sent to the cache server.

Using L2 Mode in a Cluster Setup

Oct 08, 2014

Note: Supported from NetScaler 10.5 and later releases.

To use L2 mode in a cluster setup, you must make sure of the following:

- Spotted IP addresses must be available on all the nodes as required.
- Linksets must be used to communicate with the external network.
- Asymmetric topologies or asymmetric cluster LA groups are not supported.
- Cluster LA group is recommended.
- Traffic is distributed between the cluster nodes only for deployments where services exist.

Using Cluster LA Channel with Linksets

Feb 17, 2015

In an asymmetric cluster topology, some cluster nodes are not connected to the upstream network. In such a case, you must use linksets. To optimize the performance, you can bind the interfaces that are connected to the switch as a cluster LA channel and then bind the channel to a linkset.

To understand how a combination of cluster LA channel and linksets can be used, consider a three-node cluster for which the upstream switch has only two ports available. You can connect two of the cluster nodes to the switch and leave the other node unconnected.

Note: Similarly, you can also use a combination of ECMP and linksets in an asymmetric topology.

Figure 1. Linksets and cluster LA channel topology

To configure cluster LA channel and linksets by using the NetScaler command line

1. Log on to the cluster IP address.
2. Bind the connected interfaces to a cluster LA channel.
`add channel CLA/1 -ifnum 0/1/2 1/1/2`
3. Bind the cluster LA channel to the linkset.
`add linkset LS/1 -ifnum CLA/1`

Backplane on LA Channel

Feb 17, 2015

In this deployment, LA channels are used for the cluster backplane.

NS0 - nodeId: 0, NSIP: 10.102.29.60

NS1 - nodeId: 1, NSIP: 10.102.29.70

NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with the backplane interfaces as LA channels

1. Create a cluster of nodes NS0, NS1, and NS2.
 1. Log on to the first node that you want to add to the cluster and do the following:

```
create cluster instance 1
add cluster node 0 10.102.29.60 -state ACTIVE
enable cluster instance 1
add ns ip 10.102.29.61 255.255.255.255 -type CLIP
save ns config
reboot -warm
```
 2. Log on to the cluster IP address and do the following:

```
add cluster node 1 10.102.29.70 -state ACTIVE
add cluster node 2 10.102.29.80 -state ACTIVE
```
 3. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
join cluster -clip 10.102.29.61 -password nsroot
save ns config
reboot -warm
```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. Log on to the cluster IP address and do the following:
 1. Create the LA channels for nodes NS0 and NS1.

```
add channel 0/LA/1 -ifnum 0/1/1 0/1/2
add channel 1/LA/2 -ifnum 1/1/1 1/1/2
```
 2. Configure the backplane for the cluster nodes.

```
set cluster node 0 -backplane 0/LA/1
set cluster node 1 -backplane 1/LA/2
set cluster node 2 -backplane 2/1/1
```

Common Interfaces for Client and Server and Dedicated Interfaces for Backplane

Feb 17, 2015

This is a one-arm deployment of the NetScaler cluster. In this deployment, the client and server networks use the same interfaces to communicate with the cluster. The cluster backplane uses dedicated interfaces for inter-node communication.

NS0 - nodeld: 0, NSIP: 10.102.29.60

NS1 - nodeld: 1, NSIP: 10.102.29.70

NS2 - nodeld: 2, NSIP: 10.102.29.80

To deploy a cluster with a common interface for the client and server and a different interface for the cluster backplane

1. Create a cluster of nodes NS0, NS1, and NS2.
 1. Log on to the first node that you want to add to the cluster and do the following:

```
create cluster instance 1
add cluster node 0 10.102.29.60 -state ACTIVE -backplane 0/1/1
enable cluster instance 1
add ns ip 10.102.29.61 255.255.255.255 -type CLIP
save ns config
reboot -warm
```
 2. Log on to the cluster IP address and do the following:

```
add cluster node 1 10.102.29.70 -state ACTIVE -backplane 1/1/1
add cluster node 2 10.102.29.80 -state ACTIVE -backplane 2/1/1
```
 3. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
join cluster -clip 10.102.29.61 -password nsroot
save ns config
```

```
reboot -warm
```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. On the cluster IP address, create VLANs for the backplane interfaces and for the client and server interfaces.

```
//For the backplane interfaces
```

```
add vlan 10
```

```
bind vlan 10 0/1/1 1/1/1 2/1/1
```

```
//For the interfaces that are connected to the client and server networks.
```

```
add vlan 20
```

```
bind vlan 20 0/1/2 1/1/2 2/1/2
```

3. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

```
//For the backplane interfaces. Repeat for each interface...
```

```
interface Ethernet2/47
```

```
switchport access vlan 100
```

```
switchport mode access
```

```
end
```

```
//For the interfaces connected to the client and server networks. Repeat for each interface...
```

```
interface Ethernet2/47
```

```
switchport access vlan 200
```

```
switchport mode access
```

```
end
```

Common Switch for Client, Server, and Backplane

Feb 17, 2015

In this deployment, the client, server, and backplane use dedicated interfaces on the same switch to communicate with the NetScaler cluster.

NS0 - nodeId: 0, NSIP: 10.102.29.60

NS1 - nodeId: 1, NSIP: 10.102.29.70

NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with a common switch for the client, server, and backplane

1. Create a cluster of nodes NS0, NS1, and NS2.
 1. Log on to the first node that you want to add to the cluster and do the following:

```
create cluster instance 1
add cluster node 0 10.102.29.60 -state ACTIVE -backplane 0/1/1
enable cluster instance 1
add ns ip 10.102.29.61 255.255.255.255 -type CLIP
save ns config
```

```
reboot -warm
```

2. Log on to the cluster IP address and do the following:

```
add cluster node 1 10.102.29.70 -state ACTIVE -backplane 1/1/1
```

```
add cluster node 2 10.102.29.80 -state ACTIVE -backplane 2/1/1
```

3. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
join cluster -clip 10.102.29.61 -password nsroot
```

```
save ns config
```

```
reboot -warm
```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

```
//For the backplane interfaces
```

```
add vlan 10
```

```
bind vlan 10 0/1/1 1/1/1 2/1/1
```

```
//For the client-side interfaces
```

```
add vlan 20
```

```
bind vlan 20 0/1/2 1/1/2 2/1/2
```

```
//For the server-side interfaces
```

```
add vlan 30
```

```
bind vlan 30 0/1/3 1/1/3 2/1/3
```

3. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

```
//For the backplane interfaces. Repeat for each interface...
```

```
interface Ethernet2/47
```

```
switchport access vlan 100
```

```
switchport mode access
```

```
end
```

```
//For the client interfaces. Repeat for each interface...
```

```
interface Ethernet2/48
```

```
switchport access vlan 200
```

```
switchport mode access
```

```
end
```

```
//For the server interfaces. Repeat for each interface...
```

```
interface Ethernet2/49
```

```
switchport access vlan 300
```

```
switchport mode access
```

```
end
```

Common Switch for Client and Server and Dedicated Switch for Backplane

Feb 17, 2015

In this deployment, the clients and servers use different interfaces on the same switch to communicate with the NetScaler cluster. The cluster backplane uses a dedicated switch for inter-node communication.

NS0 - nodeld: 0, NSIP: 10.102.29.60

NS1 - nodeld: 1, NSIP: 10.102.29.70

NS2 - nodeld: 2, NSIP: 10.102.29.80

To deploy a cluster with the same switch for the clients and servers and a different switch for the cluster backplane

1. Create a cluster of nodes NS0, NS1, and NS2.
 1. Log on to the first node that you want to add to the cluster and do the following:
create cluster instance 1
add cluster node 0 10.102.29.60 -state ACTIVE -backplane 0/1/1

```
enable cluster instance 1
add ns ip 10.102.29.61 255.255.255.255 -type CLIP
save ns config
reboot -warm
```

2. Log on to the cluster IP address and do the following:

```
add cluster node 1 10.102.29.70 -state ACTIVE -backplane 1/1/1
add cluster node 2 10.102.29.80 -state ACTIVE -backplane 2/1/1
```

3. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
join cluster -clip 10.102.29.61 -password nsroot
save ns config
reboot -warm
```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

```
//For the backplane interfaces
```

```
add vlan 10
bind vlan 10 0/1/1 1/1/1 2/1/1
```

```
//For the client-side interfaces
```

```
add vlan 20
bind vlan 20 0/1/2 1/1/2 2/1/2
```

```
//For the server-side interfaces
```

```
add vlan 30
bind vlan 30 0/1/3 1/1/3 2/1/3
```

3. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

```
//For the backplane interfaces. Repeat for each interface...
```

```
interface Ethernet2/47
switchport access vlan 100
switchport mode access
end
```

```
//For the client interfaces. Repeat for each interface...
```

```
interface Ethernet2/48
switchport access vlan 200
switchport mode access
end
```

```
//For the server interfaces. Repeat for each interface...
```

```
interface Ethernet2/49
switchport access vlan 300
switchport mode access
end
```

Different Switch for Every Node

Feb 17, 2015

In this deployment, each cluster node is connected to a different switch and trunk links are configured between the switches.

The cluster configurations will be the same as the other deployments scenarios. Most of the client-side configurations will be done on the client-side switches.

Sample Cluster Configurations

Feb 09, 2015

The following example can be used to configure a four-node cluster with ECMP, cluster LA, or Linksets.

1. Create the cluster.

1. Log on to first node.
2. Add the cluster instance.
`add cluster instance 1`
3. Add the first node to the cluster.
`add cluster node 0 10.102.33.184 -backplane 0/1/1`
4. Enable the cluster instance.
`enable cluster instance 1`
5. Add the cluster IP address.
`add ns ip 10.102.33.185 255.255.255.255 -type CLIP`
6. Save the configurations.
`save ns config`
7. Warm reboot the appliance.
`reboot -warm`

2. Add the other three nodes to the cluster.

1. Log on to cluster IP address.
2. Add the second node to the cluster.
`add cluster node 1 10.102.33.187 -backplane 1/1/1`
3. Add the third node to the cluster.
`add cluster node 2 10.102.33.188 -backplane 2/1/1`
4. Add the fourth node to the cluster.
`add cluster node 3 10.102.33.189 -backplane 3/1/1`

3. Join the added nodes to the cluster. This step is not applicable for the first node.

1. Log on to each newly added node.
2. Join the node to the cluster.
`join cluster -clip 10.102.33.185 -password nsroot`
3. Save the configuration.
`save ns config`
4. Warm reboot the appliance.
`reboot -warm`

4. Configure the NetScaler cluster through the cluster IP address.

```
// Enable load balancing feature
enable ns feature lb
```

```
// Add a load balancing virtual server
add lb vserver first_lbserver http
```

```
....
....
```

5. Configure any one of the following (ECMP, cluster LA, or Linkset) traffic distribution mechanisms for the cluster.

- **ECMP**

1. Log on to the cluster IP address.

2. Enable the OSPF routing protocol.
enable ns feature ospf
3. Add a VLAN.
add vlan 97
4. Bind the interfaces of the cluster nodes to the VLAN.
bind vlan 97 -ifnum 0/1/4 1/1/4 2/1/4 3/1/4
5. Add a spotted SNIP on each node and enable dynamic routing on it.
add ns ip 1.1.1.10 255.255.255.0 -ownerNode 0 -dynamicRouting ENABLED
add ns ip 1.1.1.11 255.255.255.0 -ownerNode 1 -dynamicRouting ENABLED
add ns ip 1.1.1.12 255.255.255.0 -ownerNode 2 -dynamicRouting ENABLED
add ns ip 1.1.1.13 255.255.255.0 -ownerNode 3 -dynamicRouting ENABLED
6. Bind one of the SNIP addresses to the VLAN.
bind vlan 97 -ipAddress 1.1.1.10 255.255.255.0
7. Configure the routing protocol on ZebOS by using vtysh shell.

- **Static cluster LA**

1. Log on to the cluster IP address.
2. Add a cluster LA channel.
add channel CLA/1 -speed 1000
3. Bind the interfaces to the cluster LA channel.
bind channel CLA/1 0/1/5 1/1/5 2/1/5 3/1/5
4. Perform equivalent configuration on the switch.

- **Dynamic cluster LA**

1. Log on to the cluster IP address.
2. Add the interfaces to the cluster LA channel.
set interface 0/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
set interface 1/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
set interface 2/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
set interface 3/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
3. Perform equivalent configuration on the switch.

- **Linksets.** Assume that the node with nodeId 3 is not connected to the switch. You must configure a linkset so that the unconnected node can use the other node interfaces to communicate with the switch.

1. Log on to the cluster IP address.
2. Add a linkset.
add linkset LS/1
3. Bind the connected interfaces to the linkset.
bind linkset LS/1 -ifnum 0/1/6 1/1/6 2/1/6

6. Update the state of the cluster nodes to ACTIVE.
set cluster node 0 -state ACTIVE
set cluster node 1 -state ACTIVE
set cluster node 2 -state ACTIVE
set cluster node 3 -state ACTIVE

Upgrading or Downgrading the NetScaler Cluster

Feb 19, 2016

All the nodes of a NetScaler cluster must be running the same software version. Therefore, to upgrade or downgrade the cluster, you must upgrade or downgrade each NetScaler appliance of the cluster, one node at a time.

A node that is being upgraded or downgraded is not removed from the cluster. The node continues to be a part of the cluster and serves traffic uninterrupted, except for the down-time when the node reboots after it is upgraded or downgraded.

However, due to software version mismatch among the cluster nodes, configuration propagation is disabled on the cluster and is enabled only after all the cluster nodes are of the same version. Since configuration propagation is disabled during upgrading or downgrading a cluster, you cannot perform any configurations through the cluster IP address during this time.

Points to note before upgrading or downgrading the cluster

- You cannot add cluster nodes while upgrading or downgrading the cluster software version.
- You can perform node-level configurations through the NSIP address of individual nodes, but you must make sure that you perform the same configurations on all the nodes to maintain them in synch.
- You cannot execute the start nstrace command from the cluster IP address when the cluster is being upgraded. However, you can get the trace of individual nodes by performing this operation on individual cluster nodes through their NetScaler IP (NSIP) address.
- Configurations can be lost during the downgrade of the cluster.
- Owing to changes in cluster licensing that were made in NetScaler 10.5 Build 52.11 (see [license requirements](#)), look into the following:
 - If the cluster is setup in a build prior to NetScaler 10.5 Build 52.11, the cluster will work with the separate cluster license file. No changes are required.
 - If the cluster is setup in NetScaler 10.5 Build 52.11 or later releases and then downgraded to a build prior to NetScaler 10.5 Build 52.11, the downgraded cluster will not work as it now expects a separate cluster license file.
- While upgrading from any NetScaler 10.1 build to a later release, syncookie must be disabled on all TCP profiles (using the "set ns tcpProfile <name> -synCookie DISABLED" command) and after that a striped SNIP must be added on the CLIP subnet. Once upgraded, syncookie can be enabled again.
- While upgrading the NetScaler appliance from a NetScaler 10.1 build to a NetScaler 10.5 build, do not execute the "show audit messages" command as this can cause the NetScaler appliance to crash.
- NetScaler 10.5 54.x and 55.x builds are not suitable for cluster deployment. This is because, for services that need probing, SYN packets are processed locally (on the flow receiver) even though syncookie is disabled.
- When a cluster is being upgraded, it is possible that the upgraded nodes have some additional features activated that

are not available on the nodes that are not upgraded. This results in a license mismatch warning while the cluster is being upgraded. This warning will be automatically resolved when all the cluster nodes are upgraded.

Important

- Citrix recommends that you wait for the previous node to become active before upgrading or downgrading the next node.
- Citrix recommends that the cluster configuration node must be upgraded/downgraded last to avoid multiple disconnect of cluster IP sessions.

To upgrade or downgrade the software of the cluster nodes

1. Make sure the cluster is stable and the configurations are synchronized on all the nodes.
2. Access each node through its NetScaler IP (NSIP) address and perform the following:
 1. Upgrade or downgrade the cluster node. For detailed information about upgrading and downgrading the software of an appliance, see "[Upgrading or Downgrading the System Software](#)".
 2. Save the configurations.
 3. Reboot the appliance.
3. Repeat step 2 for each of the other cluster nodes.

Operations Supported on Individual Cluster Nodes

Mar 20, 2015

As a rule, NetScaler appliances that are a part of a cluster cannot be individually configured from their NSIP address. However, there are some operations that are an exception to this rule. These operations, when executed from the NSIP address, are not propagated to other cluster nodes.

The operations are:

- cluster instance (set | rm | enable | disable)
- cluster node (set | rm)
- nstrace (start | show | stop)
- interface (set | enable | disable)
- route (add | rm | set | unset)
- arp (add | rm | send -all)
- force cluster sync
- sync cluster files
- disable ntp sync
- save ns config
- reboot
- shutdown

For example, when you execute the command `disable interface 1/1/1` from the NSIP address of a cluster node, the interface is disabled only on that node. Since the command is not propagated, the interface 1/1/1 remains enabled on all the other cluster nodes.

FAQs

Feb 04, 2016

Click [here](#) for clustering FAQs for NetScaler versions 11.0, 10.5, and 10.1.

Troubleshooting the NetScaler Cluster

Feb 09, 2015

If a failure occurs in a NetScaler cluster, the first step in troubleshooting is to get information on the cluster instance and the cluster nodes by running the `show cluster instance <clid>` and `show cluster node <nodeid>` commands respectively.

If you are not able to find the issue by using the above two approaches, you can use one of the following:

- **Isolate the source of the failure.** Try bypassing the cluster to reach the server. If the attempt is successful, the problem is probably with the cluster setup.
- **Check the commands recently executed.** Run the `history` command to check the recent configurations performed on the cluster. You can also review the `ns.conf` file to verify the configurations that have been implemented.
- **Check the ns.log files.** Use the log files, available in the `/var/log/` directory of each node, to identify the commands executed, status of commands, and the state changes.
- **Check the newnslog files.** Use the `newnslog` files, available in the `/var/nslog/` directory of each node, to identify the events that have occurred on the cluster nodes. You can view multiple `newnslog` files as a single file, by copying the files to a single directory, and then running the following command:

```
nsconmsg -K newnslog-node<id> -K newnslog.node<id> -d current
```

If you still cannot resolve the issue, you can try tracing the packets on the cluster or use the `show techsupport -scope cluster` command to send the report to the technical support team.

Tracing the Packets of a NetScaler Cluster

Feb 09, 2015

The NetScaler operating system provides a utility called *nstrace* to get a dump of the packets that are received and sent out by an appliance. The utility stores the packets in trace files. You can use these files to debug problems in the flow of packets to the cluster nodes. The trace files must be viewed with the Wireshark application.

Some salient aspects of the *nstrace* utility are:

- Can be configured to trace packets selectively by using classic expressions and default expressions.
- Can capture the trace in multiple formats: *nstrace* format (.cap) and TCP dump format (.pcap).
- Can aggregate the trace files of all cluster nodes on the configuration coordinator.
- Can merge multiple trace files into a single trace file (only for .cap files).

You can use the *nstrace* utility from the NetScaler command line or the NetScaler shell.

To trace packets of a standalone appliance

Run the `start nstrace` command on the appliance. The command creates trace files in the `/var/nstrace/<date-timestamp>` directory. The trace file names are of the form `nstrace<id>.cap`.

You can view the status by executing the `show nstrace` command. You can stop tracing the packets by executing the `stop nstrace` command.

Note: You can also run the *nstrace* utility from the NetScaler shell by executing the `nstrace.sh` file. However, it is recommended that you use the *nstrace* utility through the NetScaler command line interface.

To trace packets of a cluster

You can trace the packets on all the cluster nodes and obtain all the trace files on the configuration coordinator.

Run the `start nstrace` command on the cluster IP address. The command is propagated and executed on all the cluster nodes. The trace files are stored in individual cluster nodes in the `/var/nstrace/<date-timestamp>` directory. The trace file names are of the form `nstrace<id>_node<id>.cap`.

You can use the trace files of each node to debug the nodes operations. But if you want the trace files of all cluster nodes in one location, you must run the `stop nstrace` command on the cluster IP address. The trace files of all the nodes are downloaded on the cluster configuration coordinator in the `/var/nstrace/<date-timestamp>` directory as follows:

Merge multiple trace files

You can prepare a single file from the trace files (supported only for .cap files) obtained from the cluster nodes. The single trace files gives you a cumulative view of the trace of the cluster packets. The trace entries in the single trace file are sorted based on the time the packets were received on the cluster.

To merge the trace files, at the NetScaler shell, type:

```
nstracemerge.sh -srcdir <DIR> -dstdir <DIR> -filename <name> -filesize <num>
```

where,

- srcdir is the directory from which the trace files are merged. All trace files within this directory are merged into a single file.
- dstdir is the directory where the merged trace file are created.
- filename is the name of the trace file that is created.
- filesize is the size of the trace file.

Examples

Following are some examples of using the nstrace utility to filter packets.

- To trace the packets on the backplane interfaces of three nodes:

Using classic expressions:

```
start nstrace -filter "INTF == 0/1/1 && INTF == 1/1/1 && INTF == 2/1/1"
```

Using default expressions:

```
start nstrace -filter "CONNECTION.INTF.EQ("0/1/1") && CONNECTION.INTF.EQ("1/1/1") && CONNECTION.INTF.EQ("2/1/1")"
```

- To trace the packets from a source IP address 10.102.34.201 or from a system whose source port is greater than 80 and the service name is not "s1":

Using classic expressions

```
start nstrace -filter "SOURCEIP == 10.102.34.201 || (SVCNAME != s1 && SOURCEPORT > 80)"
```

Using default expressions

```
start nstrace -filter "CONNECTION.SRCIP.EQ(10.102.34.201) || (CONNECTION.SVCNAME.NE("s1") && CONNECTION.SRCPORT.GT(80))"
```

Troubleshooting Common Issues

Feb 09, 2015

While joining a node to the cluster, I get the following message, "ERROR: Invalid interface name/number." What must I do to resolve this error?

This error occurs if you provided an invalid or incorrect backplane interface while using the add cluster node command to add the node. To resolve this error, verify the interface you provided while adding the node. Make sure that you have not specified the appliance's management interface as the backplane interface, and that the <nodeId> bit of the interface is the same as the node's Id. For example, if the nodeId is 3, the backplane interface must be 3/<c>/<u>.

While joining a node to the cluster, I get the following message, "ERROR: Clustering cannot be enabled, because the local node is not a member of the cluster." What must I do to resolve this error?

This error occurs when you try to join a node without adding the node's NSIP to the cluster. To resolve this error, you must first add the node's NSIP address to the cluster by using the add cluster node command and then execute the join cluster command.

While joining a node to the cluster, I get the following message, "ERROR: Connection refused." What must I do to resolve this error?

This error can occur due to the following reasons:

- **Connectivity problems.** The node cannot connect to the cluster IP address. Try pinging the cluster IP address from the node that you are trying to join.
- **Duplicate cluster IP address.** Check to see if the cluster IP address exists on some non-cluster node. If it does, create a new cluster IP address and try re-joining the cluster.

While joining a node to the cluster, I get the following message, "ERROR: License mismatch between the configuration coordinator and the local node." What must I do to resolve this error?

The appliance that you are joining to the cluster must have the same licenses as the configuration coordinator. This error occurs when the licenses on the node you are joining do not match the licenses on the configuration coordinator. To resolve this error, run the following commands on both the nodes and compare the outputs.

From the command line:

- show ns hardware
- show ns license

From the shell:

- nsconmsg -g feature -d stats
- ls /nsconfig/license
- View the contents of the /var/log/license.log file

What must I do when the configurations of a cluster node are not in synch with the cluster configurations?

In most cases, the configurations are automatically synchronized between all the cluster nodes. However, if you feel that the configurations are not synchronized on a specific node, you must force the synchronization by executing the force cluster sync command from the node that you want to synchronize. For more information, see "[Synchronizing Cluster](#)

[Configurations](#)".

When configuring a cluster node, I get the following message, "ERROR: Session is read-only; connect to the cluster IP address to modify the configuration."

All configurations on a cluster must be done through the cluster IP address and the configurations are propagated to the other cluster nodes. All sessions established through the NetScaler IP (NSIP) address of individual nodes are read-only.

Why does the node state show "INACTIVE" when the node health shows "UP"?

A healthy node can be in the INACTIVE state for a number of reasons. A scan of ns.log or error counters can help you determine the exact reason.

How can I resolve the health of a node when its health shows "NOT UP"?

Node health "Not UP" indicates that there are some issues with the node. To know the root cause, you must run the show cluster node command. This command displays the node properties and the reason for the node failure.

What must I do when the health of a node shows as "NOT UP" and the reason indicates that configuration commands have failed on a node?

This issue arises when some commands are not executed on the cluster nodes. In such cases, you must make sure that the configurations are synchronized using one of the following options:

- If some of the cluster nodes are in this state, you must perform the force cluster synchronization operation on those nodes. For more information, see "[Synchronizing Cluster Configurations](#)".
- If all cluster nodes are in this state, you must disable and then enable the cluster instance on all the cluster nodes.

When I run the set vserver command, I get the following message, "No such resource." What must I do to resolve this issue?

The set vserver command is not supported in clustering. The unset vserver, enable vserver, disable vserver, and rm vserver commands are also not supported. However, the show vserver command is supported.

I cannot configure the cluster over a Telnet session. What must I do?

Over a telnet session, the cluster IP address can be accessed only in read-only mode. Therefore, you cannot configure a cluster over a telnet session.

I notice a significant time difference across the cluster nodes. What must I do to resolve this issue?

When PTP packets are dropped due to backplane switch or if the physical resources are over-committed in a virtual environment, the time will not get synchronized.

To synchronize the times, you must do the following on the cluster IP address:

1. Disable PTP.

```
set ptp -state disable
```

2. Configure Network Time Protocol (NTP) for the cluster. For more information, see "[Setting up Clock Synchronization](#)".

What must I do, if there is no connectivity to the cluster IP address and the NSIP address of a cluster node?

If you cannot access to the cluster IP address or the NSIP of a cluster node, you must access the appliance through the serial console. For more information, see "[Using the Command Line Interface](#)".

If the NSIP address is reachable, you can SSH to the cluster IP address from the shell by executing the following command at the shell prompt:

```
# ssh nsroot@<cluster IP address>
```

What must I do to recover a cluster node that has connectivity issues?

To recover a node that has connectivity issues:

1. Disable the cluster instance on that node (since you cannot execute commands from the NSIP of a cluster node).
2. Execute the commands required to recover the node.
3. Enable the cluster instance on that node.

Some nodes of the cluster have two default routes. How can I remove the second default route from the cluster node?

To delete the additional default route, do the following on each node that has the extra route:

1. Disable the cluster instance.
disable cluster instance <clld>
2. Remove the route.
rm route <network> <netmask> <gateway>
3. Enable the cluster instance.
enable cluster instance <clld>

The cluster functionality gets affected when an existing cluster node comes online. What must I do to resolve this issue?

If RPC password of node is changed from the cluster IP address when that node is out of the cluster, then, when the node comes online, there is a mismatch in rpc credentials and this could affect cluster functionality. To solve this issue, use the set ns rpcNode command to update the password on the NSIP of the node which has come online.

CloudBridge Connector

Dec 14, 2016

The CloudBridge Connector feature of the Citrix NetScaler appliance connects enterprise datacenters to external clouds and hosting environments, making the cloud a secure extension of your enterprise network. Cloud-hosted applications appear as though they are running on one contiguous enterprise network. With Citrix CloudBridge Connector, you can augment your datacenters with the capacity and efficiency available from cloud providers.

The CloudBridge Connector enables you to move your applications to the cloud to reduce costs and increase reliability.

In addition to using CloudBridge Connector between a datacenter and a cloud, you can use it to connect two datacenters for a high-capacity secure and accelerated link.

Understanding CloudBridge Connector

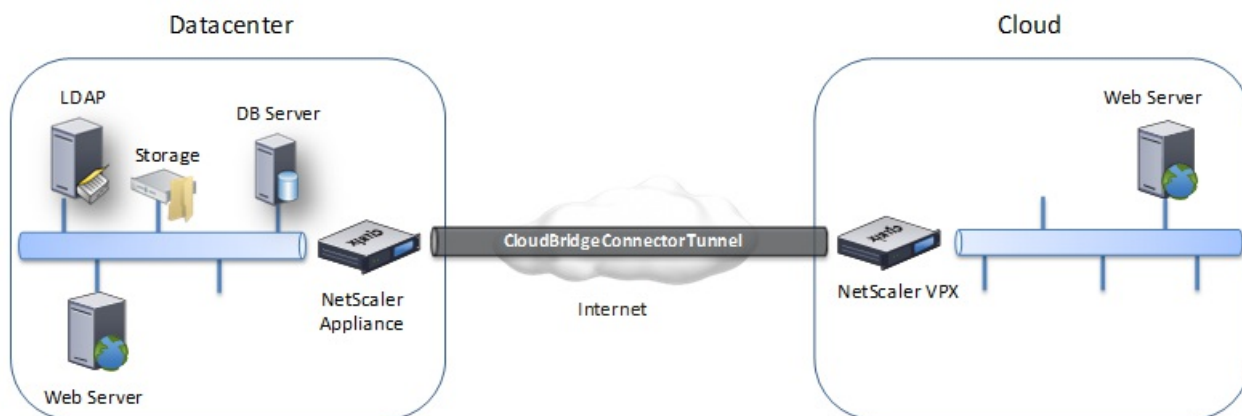

Updated: 2014-04-14

To implement the Citrix CloudBridge Connector solution, you connect a datacenter to another datacenter or an external cloud by setting up a tunnel called the CloudBridge Connector tunnel.

To connect a datacenter to another datacenter, you set up a CloudBridge Connector tunnel between two NetScaler appliances, one in each datacenter.

To connect a datacenter to an external cloud (for example, Amazon AWS cloud), you set up a CloudBridge Connector tunnel between a NetScaler appliance in the datacenter and a virtual appliance (VPX) that resides in the Cloud. The remote end point can be a CloudBridge Connector or a NetScaler VPX with platinum license.

The following illustration shows a CloudBridge Connector tunnel set up between a datacenter and an external cloud.

The appliances between which a CloudBridge Connector tunnel is set up are called the *end points* or *peers* of the CloudBridge Connector tunnel.

A CloudBridge Connector tunnel uses the following protocols:

- Generic Routing Encapsulation (GRE) protocol
- Open-standard IPsec Protocol suite, in transport mode

The GRE protocol provides a mechanism for encapsulating packets, from a wide variety of network protocols, to be

forwarded over another protocol. GRE is used to:

- Connect networks running non-IP and non-routable protocols.
- Bridge across a wide area network (WAN).
- Create a transport tunnel for any type of traffic that needs to be sent unchanged across a different network.

The GRE protocol encapsulates packets by adding a GRE header and a GRE IP header to the packets.

The Internet Protocol security (IPSec) protocol suite secures communication between peers in the CloudBridge Connector tunnel.

In a CloudBridge Connector tunnel, IPSec ensures:

- Data integrity
- Data origin authentication
- Data confidentiality (encryption)
- Protection against replay attacks

IPSec uses the transport mode in which the GRE encapsulated packet is encrypted. The encryption is done by the Encapsulating Security Payload (ESP) protocol. The ESP protocol ensures the integrity of the packet by using a HMAC hash function, and ensures confidentiality by using an encryption algorithm. After the packet is encrypted and the HMAC is calculated, an ESP header is generated. The ESP header is inserted after the GRE IP header and, an ESP trailer is inserted at the end of the encrypted payload.

Peers in the CloudBridge Connector tunnel use the Internet Key Exchange version (IKE) protocol (part of the IPSec protocol suite) to negotiate secure communication, as follows:

- The two peers mutually authenticate with each other, using one of the following authentication methods:
 - **Pre-shared key authentication.** A text string called a pre-shared key is manually configured on each peer. The pre-shared keys of the peers are matched against each other for authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on each of the peers.
 - **Digital certificates authentication.** The initiator (sender) peer signs message interchange data by using its private key, and the other receiver peer uses the sender's public key to verify the signature. Typically, the public key is exchanged in messages containing an X.509v3 certificate. This certificate provides a level of assurance that a peer's identity as represented in the certificate is associated with a particular public key.
- The peers then negotiate to reach agreement on:
 - An encryption algorithm.
 - Cryptographic keys for encrypting data in one peer and decrypting the data in the other.

This agreement upon the security protocol, encryption algorithm and cryptographic keys is called a Security Association (SA). SAs are one-way (simplex). For example, when two peers, CB1 and CB2, are communicating through a Connector tunnel, CB1 has two Security Associations. One SA is used for processing out-bound packets, and the other SA is used for processing inbound packets.

SAs expire after a specified length of time, which is called the *lifetime*. The two peers use the Internet Key Exchange (IKE)

protocol (part of the IPSec protocol suite) to negotiate new cryptographic keys and establish new SAs. The purpose of the limited lifetime is to prevent attackers from cracking a key.

The following table lists some IPSec properties supported by a NetScaler appliance:

IPSec Properties	Types Supported
IKE Versions	<ul style="list-style-type: none">• V1• V2
IKE Authentication Methods	<ul style="list-style-type: none">• Pre-shared key authentication• Digital certificates authentication
Encryption Algorithm	<ul style="list-style-type: none">• AES• 3DES
Hash Algorithm	<ul style="list-style-type: none">• HMAC SHA1• HMAC SHA256• HMAC SHA384• HMAC SHA512• HMAC MD5

Configuring CloudBridge Connector Tunnel between two Datacenters

Aug 02, 2013

You can configure a CloudBridge Connector tunnel between two different datacenters to extend your network without reconfiguring it, and leverage the capabilities of the two datacenters. Having a CloudBridge Connector tunnel configured between the two geographically separated datacenters enables you to implement redundancy and safeguard your setup from failure. The CloudBridge Connector tunnel helps achieve optimal utilization of infrastructure and resources across two datacenters. The applications available across the two datacenters appear as local to the user.

To connect a datacenter to another datacenter, you set up a CloudBridge Connector tunnel between a NetScaler appliance that reside in one datacenter and another NetScaler appliance that reside in the other datacenter.

As an illustration of CloudBridge Connector tunnel between two different datacenters, consider an example in which a CloudBridge Connector tunnel is set up between NetScaler appliance NS_Appliance-1 in datacenter DC1 and NetScaler appliance NS_Appliance-2 in datacenter DC2.

Both NS_Appliance-1 and NS_Appliance-2 function in L2 and L3 mode. They enable communication between private networks in datacenters DC1 and DC2. In L3 mode, NS_Appliance-1 and NS_Appliance-2 enable communication between client CL1 in the datacenter DC1 and server S1 in the datacenter DC2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

Because client CL1 and server S1 are on different private networks, L3 mode is enabled on NS_Appliance-1 and NS_Appliance-2 and routes are updated as the following:

- CL1 have a route to NS_Appliance-1 for reaching S1
- NS_Appliance-1 have a route to NS_Appliance-2 for reaching S1
- S1 should have a route to NS_Appliance-2 for reaching CL1
- NS_Appliance-2 have a route to NS_Appliance-1 for reaching CL1

The following table lists the settings on NetScaler appliance NS_Appliance-1 in datacenter DC1.

Entity	Name	Details
The NSIP address		198.51.100.12
SNIP address		198.51.100.15
CloudBridge Connector tunnel	Cloud_Connector_DC1-DC2	<ul style="list-style-type: none">• Local endpoint IP address of the CloudBridge Connector tunnel = 198.51.100.15• Remote endpoint IP address of the CloudBridge Connector tunnel = 203.0.113.133

		<p>GRE Tunnel Details</p> <ul style="list-style-type: none"> • Name = Cloud_Connector_DC1-DC2 <p>IPSec Profile Details</p> <ul style="list-style-type: none"> • Name = Cloud_Connector_DC1-DC2 • Encryption algorithm = AES • Hash algorithm = HMAC SHA1
--	--	--

The following table lists the settings on NetScaler appliance NS_Appliance-2 in datacenter DC2.

Entity	Name	Details
The NSIP address		203.0.113.131
SNIP address		203.0.113.133
CloudBridge Connector tunnel	Cloud_Connector_DC1-DC2	<ul style="list-style-type: none"> • Local endpoint IP address of the CloudBridge Connector tunnel = 203.0.113.133 • Remote endpoint IP address of the CloudBridge Connector tunnel = 198.51.100.15 <p>GRE Tunnel Details</p> <ul style="list-style-type: none"> • Name = Cloud_Connector_DC1-DC2 <p>IPSec Profile Details</p> <ul style="list-style-type: none"> • Name = Cloud_Connector_DC1-DC2 • Encryption algorithm = AES • Hash algorithm = HMAC SHA1

Following is the traffic flow in the CloudBridge Connector tunnel:

1. Client CL1 sends a request to server S1.
2. The request reaches NetScaler appliance NS-Appliance-1.
3. NS_Appliance-1, checks its routing table and finds that the destination IP address of the request packet belongs to a subnet in datacenter DC2. The appliance decides to forward the packet to be sent across the CC-DC1-DC2 tunnel.
4. NS_Appliance-1 uses the GRE protocol to encapsulate each of the request packets by adding a GRE header and a GRE IP header to the packet. The GRE IP header has the destination IP address set to the IP address of the CloudBridge tunnel (CC-DC1-DC2) end point in DC2 side. This IP Address is a public SNIP address configured on the NetScaler instance running on the NetScaler appliance NS_Appliance-2.
5. For CloudBridge Connector tunnel CC-DC1-DC2, NS_Appliance-1 checks the stored IPSec security association (SA) parameters for processing outbound packets, as agreed between NS_Appliance-1 and NS_Appliance-2 . The IPSec Encapsulating Security Payload (ESP) protocol in NS_Appliance-1 uses these SA parameters for outbound packets, to encrypt the payload of the GRE encapsulated packet.

6. The ESP protocol ensures the packet's integrity and confidentiality by using the HMAC hash function and the encryption algorithm specified for the CloudBridge Connector tunnel CC-DC1-DC2 . The ESP protocol, after encrypting the GRE payload and calculating the HMAC, generates an ESP header and an ESP trailer and inserts them before and at the end of the encrypted GRE payload, respectively.
7. The resulting packet is sent to NS_Appliance-2.
8. NS_Appliance-2 checks the stored IPsec security association (SA) parameters for processing inbound packets, as agreed between NS_Appliance-1 and NS_Appliance-2 for the CloudBridge Connector tunnel CC-DC1-DC2 . The IPsec ESP protocol on NS_Appliance-2 uses these SA parameters for inbound packets, and the ESP header of the request packet, to decrypt the packet.
9. NS_Appliance-2 then decapsulates the packet by removing the GRE header.
10. The resulting packet is the same packet as the one received by NS_Appliance-1 in step 2. This packet has the destination IP address set to the IP address of server S1. NS_Appliance-2 forwards this packet to server S1.
11. S1 processes the request packet and sends out a response packet. The destination IP address in the response packet is the IP address of client CL1, and the source IP address is the IP address of server S1.
12. The response packet reaches NS_Appliance-2.
13. NS_Appliance-2 encapsulates and encrypts the response packet in the same way that NS_Appliance-1 did with the request packet in steps 3-6.
14. NS_Appliance-2 sends the resulting packet to NS_Appliance-1.
15. NS_Appliance-1, upon receiving the packet from NS_Appliance-2, decrypts and decapsulates the packet in the same way that NS_Appliance-2 did with the request packet in steps 9-11.

Prerequisites for Configuring a CloudBridge Connector tunnel between two Datacenters

Before setting up a CloudBridge Connector tunnel, verify that the following tasks have been completed:

1. Deploy and set up a NetScaler appliance in each of the two datacenters.
2. Make sure that the CloudBridge Connector tunnel end-point IP addresses are accessible to each other.

Configuration Steps

To set up a CloudBridge Connector tunnel between a NetScaler appliance that resides in one datacenter and another NetScaler appliance that resides in the other datacenter, use the configuration utility or the command line interface of one of the NetScaler appliance.

When you use the configuration utility, the CloudBridge Connector tunnel configuration created on the first NetScaler appliance, is automatically pushed to the other endpoint (the other NetScaler appliance) of the CloudBridge Connector tunnel. Therefore, you do not have to access the configuration utility of the other NetScaler appliance to create the corresponding CloudBridge Connector tunnel configuration on it.

The CloudBridge Connector tunnel configuration on each of the NetScaler appliance consists of the following entities:

- **IPsec profile.** An IPsec profile entity specifies the IPsec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPsec protocol in the CloudBridge Connector tunnel.
- **GRE tunnel.** An IP tunnel specifies the local IP address (a public SNIP address configured on the local NetScaler appliance), remote IP address (a public SNIP address configured on the remote NetScaler appliance), protocol (GRE) used to set up the CloudBridge Connector tunnel, and an IPsec profile entity.
- **Create a PBR rule and associate the IP tunnel with it**—A PBR entity specifies a set of conditions and an IP tunnel entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the

source IP address range and the destination IP address range to specify the subnet whose traffic is to traverse the CloudBridge Connector tunnel. For example, consider a request packet that originates from a client on the subnet in the first datacenter and is destined to a server on the subnet in the second datacenter. If this packet matches the source and destination IP address range of the PBR entity on the NetScaler appliance in the first datacenter, it is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the command line interface

At the command prompt, type:

```
add ipsec profile <name> [-ikeVersion ( V1 | V2 )] [-encAlgo ( AES | 3DES ) ...] [-hashAlgo <hashAlgo> ...] [-lifetime <positive_integer>] (-psk | (-publickey <string> -privatekey <string> -peerPublicKey <string>)) [-livenessCheckInterval <positive_integer>] [-replayWindowSize <positive_integer>] [-ikeRetryInterval <positive_integer>] [-retransmissionTime <positive_integer>]
```

Example

```
add ipsec profile Cloud_Connector_DC1-DC2 -encAlgo AES -hashAlgo HMAC_SHA1
```

To create an IP tunnel and bind the IPSEC profile to it by using the command line interface

At the command prompt, type:

```
add ipTunnel <name> <remote> <remoteSubnetMask> <local> [-protocol <protocol>] [-ipsecProfileName <string>]
```

Example

```
add ipTunnel Cloud_Connector_DC1-DC2 203.0.113.133 255.255.255.255 198.51.100.15 -protocol GRE -ipsecProfileName Cloud_Connector_DC1-DC2
```

To create a PBR rule and bind the IPSEC tunnel to it by using the command line interface

At the command prompt, type:

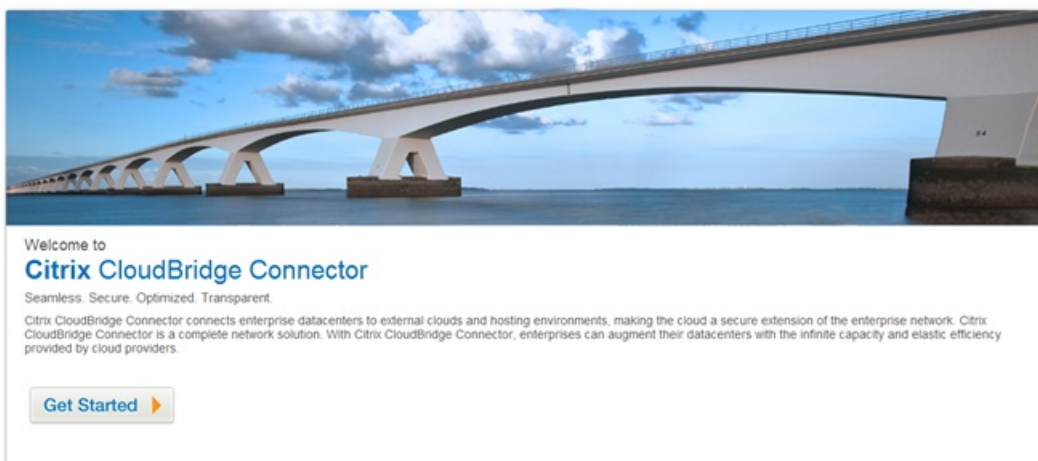

- **add ns pbr** <pbr_name> ALLOW -srcIP = <local_subnet_range> -destIP = <remote_subnet_range> -ipTunnel <tunnel_name>
- **apply ns pbrs**

Example

- add ns pbr PBR-DC1-DC2 ALLOW -srcIP 198.51.100.15 -destIP 203.0.113.133 ipTunnel Cloud_Connector_DC1-DC2
- apply ns pbrs

To configure a CloudBridge Connector tunnel in a NetScaler appliance by using the configuration utility

1. Type the NSIP address of a NetScaler appliance in the address line of a web browser.
2. Log on to the configuration utility of the NetScaler appliance by using your account credentials for the appliance.
3. Navigate to **System > CloudBridge Connector**.
4. In the right pane, under **Getting Started**, click **Create/Monitor CloudBridge**.
5. Click **Get Started**.

Copyright © Citrix Systems, Inc. All rights reserved.

Note: If you already have any CloudBridge Connector tunnel configured on the NetScaler appliance, this screen does not appear, and you are taken to the **CloudBridge Connector Setup** pane.

6. In the **CloudBridge Connector Setup** pane, click **NetScaler**.

Copyright © Citrix Systems, Inc. All rights reserved.

7. In the **NetScaler** pane, provide your account credentials for the remote NetScaler appliance. Click **Continue**.
8. In the **CloudBridge Connector Setting** pane, set the following parameter:
 - **CloudBridge Connector Name**—Name for the CloudBridge Connector configuration on the local appliance. Must begin with an ASCII alphabetic or underscore (`_`) character, and must contain only ASCII alphanumeric, underscore, hash (`#`), period (`.`), space (), colon (`:`), at (`@`), equals (`=`), and hyphen (`-`) characters. Cannot be changed after the

CloudBridge Connector configuration is created.

9. Under **Local Setting**, set the following parameter:
 - **Subnet IP**—IP address of the local endpoint of the CloudBridge Connector tunnel. Must be a public IP address of type SNIP.
10. Under **Remote Setting**, set the following parameter:
 - **Subnet IP**—IP address of the peer endpoint of the CloudBridge Connector tunnel. Must be a public IP address of type SNIP.
11. Under **PBR Setting**, set the following parameters:
 - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
 - **Source IP Low***—Lower source IP address to match against the source IP address of an outgoing IPv4 packet.
 - **Source IP High**—Higher source IP address to match against the source IP address of an outgoing IPv4 packet.
 - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
 - **Destination IP Low***—Lower destination IP address to match against the destination IP address of an outgoing IPv4 packet.
 - **Destination IP High**—Higher destination IP address to match against the destination IP address of an outgoing IPv4 packet.
12. (Optional) Under **Security Settings**, set the following IPSec protocol parameters to be used by the IPSec protocol in the CloudBridge Connector tunnel:
 - **Encryption Algorithm**—Encryption algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
 - **Hash Algorithm**—Hash algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
 - **Key**— Select one of the following IPSec authentication methods to be used by the two peers to mutually authenticate.
 - **Auto Generate Key**— Authentication based on a text string, called a pre-shared key (PSK), generated automatically by the local appliance. The PSKs keys of the peers are matched against each other for authentication.
 - **Specific Key**—Authentication based on a manually entered PSK. The PSKs of the peers are matched against each other for authentication.
 - **Pre Shared Security Key**—The text string entered for pre-shared key based authentication.
 - **Upload Certificates**—Authentication based on digital certificates.
 - **Public Key**—A local digital certificate to be used to authenticate the local NetScaler appliance to the peer before establishing IPSec security associations. The same certificate should be present and set for the Peer Public Key parameter in the peer.
 - **Private Key**—Private key of the local digital certificate.
 - **Peer Public Key**—Digital certificate of the peer. Used to authenticate the peer to the local end point before establishing IPSec security associations. The same certificate should be present and set for the Public key parameter in the peer.
13. Click **Done**.

The new CloudBridge Connector tunnel configuration on both the NetScaler appliances appears on the Home tab of the respective configuration utility. The current status of the CloudBridge connector tunnel is indicated in the Configured CloudBridge Connectors pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

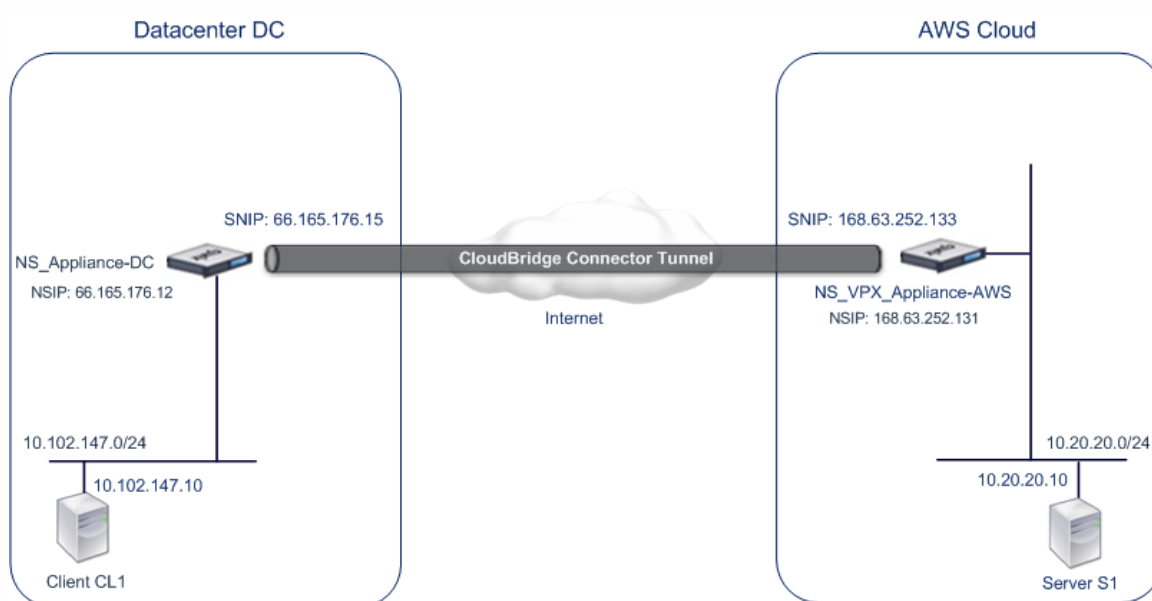

Configuring CloudBridge Connector between Datacenter and AWS Cloud

Jan 28, 2011

You can configure a CloudBridge Connector tunnel between a datacenter and AWS cloud to leverage the infrastructure and computing capabilities of the data center and the AWS cloud. With AWS, you can extend your network without initial capital investment or the cost of maintaining the extended network infrastructure. You can scale your infrastructure up or down, as required. For example, you can lease more server capabilities when the demand increases.

To connect a datacenter to AWS cloud, you set up a CloudBridge Connector tunnel between a NetScaler appliance that resides in the datacenter and a NetScaler virtual appliance (VPX) that resides in AWS cloud.

As an illustration of a CloudBridge Connector tunnel between a datacenter and Amazon AWS cloud, consider an example in which a CloudBridge Connector tunnel is set up between NetScaler appliance NS_Appliance-DC, in datacenter DC, and NetScaler virtual appliance (VPX) NS_VPX_Appliance-AWS.

Both NS_Appliance-DC and NS_VPX_Appliance-AWS function in L3 mode. They enable communication between private networks in datacenter DC and the AWS cloud. NS_Appliance-DC and NS_VPX_Appliance-AWS enable communication between client CL1 in datacenter DC and server S1 in the AWS cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

Note: AWS does not support L2 mode, hence it is necessary to have only L3 mode enabled on both the endpoints.

For proper communication between CL1 and S1, L3 mode is enabled on NS_Appliance-DC and NS_VPX_Appliance-AWS and routes are updated as such:

- CL1 have a route to NS_Appliance-DC for reaching S1.
- NS_Appliance-DC have a route to NS_VPX_Appliance-AWS for reaching S1.
- S1 should have a route to NS_VPX_Appliance-AWS for reaching CL1.
- NS_VPX_Appliance-AWS have a route to NS_Appliance-DC for reaching CL1.

The following table lists the settings on NetScaler appliance NS_Appliance-DC in datacenter DC.

Entity	Name	Details
The NSIP address		66.165.176.12

SNIP address		66.165.176.15
CloudBridge Connector tunnel	CC_Tunnel_DC-AWS	<ul style="list-style-type: none"> Local endpoint IP address of the CloudBridge Connector tunnel: 66.165.176.15 Remote endpoint IP address of the CloudBridge Connector tunnel: 168.63.252.133 <p>GRE Tunnel Details</p> <ul style="list-style-type: none"> Name= CC_Tunnel_DC-AWS <p>IPSec Profile Details</p> <ul style="list-style-type: none"> Name= CC_Tunnel_DC-AWS Encryption algorithm= AES Hash algorithm= HMAC SHA1

The following table lists the settings on NetScaler VPX NS_VPX_Appliance-AWS on AWS cloud.

Entity	Name	Details
NSIP address		10.102.25.30
Public EIP address mapped to the NSIP address		168.63.252.131
SNIP address		10.102.29.30
Public EIP address mapped to the SNIP address		168.63.252.133
CloudBridge Connector tunnel	CC_Tunnel_DC-AWS	<ul style="list-style-type: none"> Local endpoint IP address of the CloudBridge Connector tunnel: 168.63.252.133 Remote endpoint IP address of the CloudBridge Connector tunnel: 66.165.176.15 <p>GRE Tunnel Details</p> <ul style="list-style-type: none"> Name= CC_Tunnel_DC-AWS <p>IPSec Profile Details</p> <ul style="list-style-type: none"> Name= CC_Tunnel_DC-AWS Encryption algorithm= AES Hash algorithm= HMAC SHA1

Prerequisites

Updated: 2015-06-01

Before setting up a CloudBridge Connector tunnel, verify that the following tasks have been completed:

1. Install, configure, and launch an instance of NetScaler Virtual appliance (VPX) on AWS cloud. For instructions on installing NetScaler VPX on AWS, see <http://support.citrix.com/proddocs/topic/netscaler-vpx-10-5/nsvpx-aws-ns-vpxaws-con.html>.
2. Deploy and configure a NetScaler physical appliance, or provisioning and configuring a NetScaler virtual appliance (VPX) on a virtualization platform in the datacenter.

- For instructions on installing NetScaler virtual appliances on XenServer, see <http://support.citrix.com/proddocs/topic/netscaler-vpx-10-5/ns-vpx-install-wrapper-con.html>.
 - For instructions on installing NetScaler virtual appliances on VMware ESX or ESXi, see <http://support.citrix.com/proddocs/topic/netscaler-vpx-10-5/ns-vpx-install-on-esx-wrapper-con.html>.
 - For instructions on installing NetScaler virtual appliances on Microsoft Hyper-V, see <http://support.citrix.com/proddocs/topic/netscaler-vpx-10-5/ns-vpx-install-on-msft-hyperv-wrapper-con.html>.
3. Make sure that the CloudBridge Connector tunnel end-point IP addresses are accessible to each other.

NetScaler VPX License

After the initial instance launch, NetScaler VPX for AWS requires a license. If you are bringing your own license (BYOL), see the VPX Licensing Guide at: <http://support.citrix.com/article/CTX122426>.

You have to:

1. Use the licensing portal within MyCitrix to generate a valid license.
2. Upload the license to the instance.

If this is a **paid** marketplace instance, then you do not need to install a license. The correct feature set and performance will activate automatically.

Configuration Steps

To set up a CloudBridge Connector tunnel between a NetScaler appliance that resides in a datacenter and a NetScaler virtual appliance (VPX) that resides on the AWS cloud, use the configuration utility of the NetScaler appliance.

When you use the configuration utility, the CloudBridge Connector tunnel configuration created on the NetScaler appliance, is automatically pushed to the other endpoint or peer (the NetScaler VPX on AWS) of the CloudBridge Connector tunnel. Therefore, you do not have to access the configuration utility (GUI) of the NetScaler VPX on AWS to create the corresponding CloudBridge Connector tunnel configuration on it.

The CloudBridge Connector tunnel configuration on both peers (the NetScaler appliance that resides in the datacenter and the NetScaler virtual appliance (VPX) that resides on the AWS cloud) consists of the following entities:

- **IPSec profile**—An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol in both the peers of the CloudBridge Connector tunnel.
- **GRE tunnel**—An IP tunnel specifies a local IP address (a public SNIP address configured on the local peer), remote IP address (a public SNIP address configured on the remote peer), protocol (GRE) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity.
- **Create a PBR rule and associate the IP tunnel with it**—A PBR entity specifies a set of conditions and an IP tunnel entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range and the destination IP address range to specify the subnet whose traffic is to traverse the CloudBridge Connector tunnel. For example, consider a request packet that originates from a client on the subnet in the datacenter and is destined to a server on the subnet in the AWS cloud. If this packet matches the source and destination IP address range of the PBR entity on the NetScaler appliance in the datacenter, it is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the command line interface

At the command prompt, type:

```
add ipsec profile <name> [-ikeVersion ( V1 | V2 )] [-encAlgo ( AES | 3DES ) ...] [-hashAlgo <hashAlgo> ...] [-lifetime <positive_integer>]
(-psk | (-publickey <string> -privatekey <string> -peerPublicKey <string>)) [-livenessCheckInterval <positive_integer>]
[-replayWindowSize <positive_integer>] [-ikeRetryInterval <positive_integer>] [-retransmissionTime <positive_integer>]
```

Example

```
add ipsec profile CC_Tunnel_DC-AWS -encAlgo AES -hashAlgo HMAC_SHA1
```

To create an IP tunnel and bind the IPSEC profile to it by using the command line interface

At the command prompt, type:

```
add ipTunnel <name> <remote><remoteSubnetMask> <local> [-protocol <protocol>] [-ipsecProfileName <string>]
```

Example

```
add ipTunnel CC_Tunnel_DC-AWS 168.63.252.133 255.255.255.0 66.165.176.15 -protocol GRE -ipsecProfileName CC_Tunnel_DC-AWS
```

To create a PBR rule and bind the IPSEC tunnel to it by using the command line interface

At the command prompt, type:

- add ns pbr <pbr_name> ALLOW -srcIP = <local_subnet_range> -destIP = <remote_subnet_range> -ipTunnel <tunnel_name>
- apply ns pbrs

Example

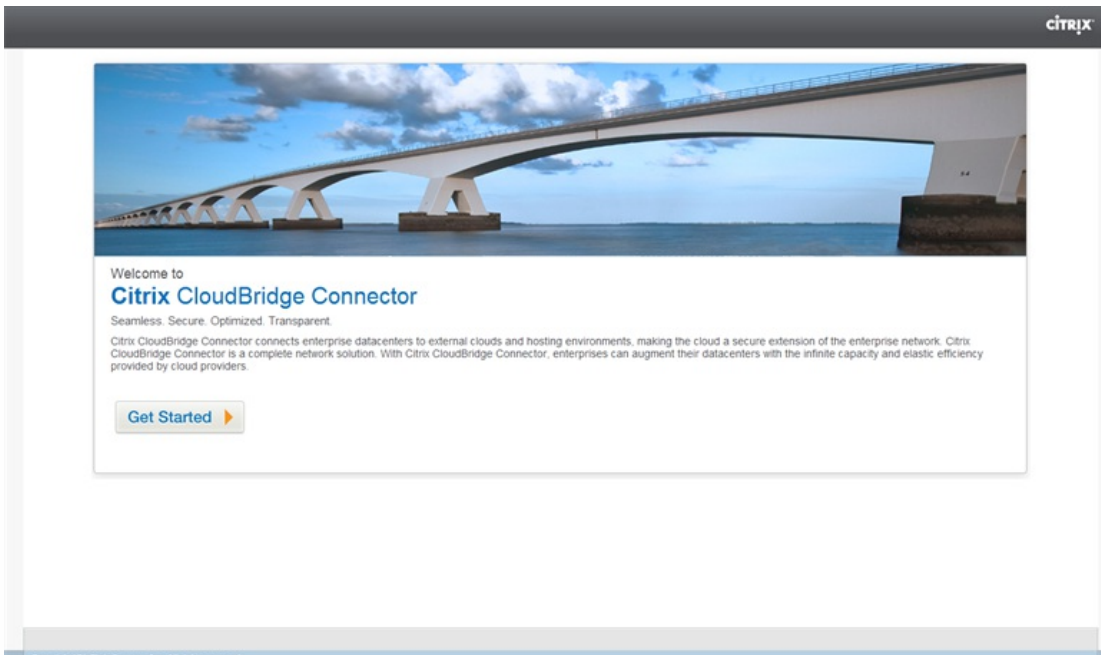

- add ns pbr PBR-DC-AWS ALLOW -srcIP 66.165.176.15 -destIP 168.63.252.133 ipTunnel CC_Tunnel_DC-AWS
- apply ns pbrs

To configure a CloudBridge Connector tunnel in a NetScaler appliance by using the configuration utility

1. Type the NSIP address of a NetScaler appliance in the address line of a web browser.
2. Log on to the configuration utility of the NetScaler appliance by using your account credentials for the appliance.
3. Navigate to System > CloudBridge Connector.
4. In the right pane, under **Getting Started**, click **Create/Monitor CloudBridge**.

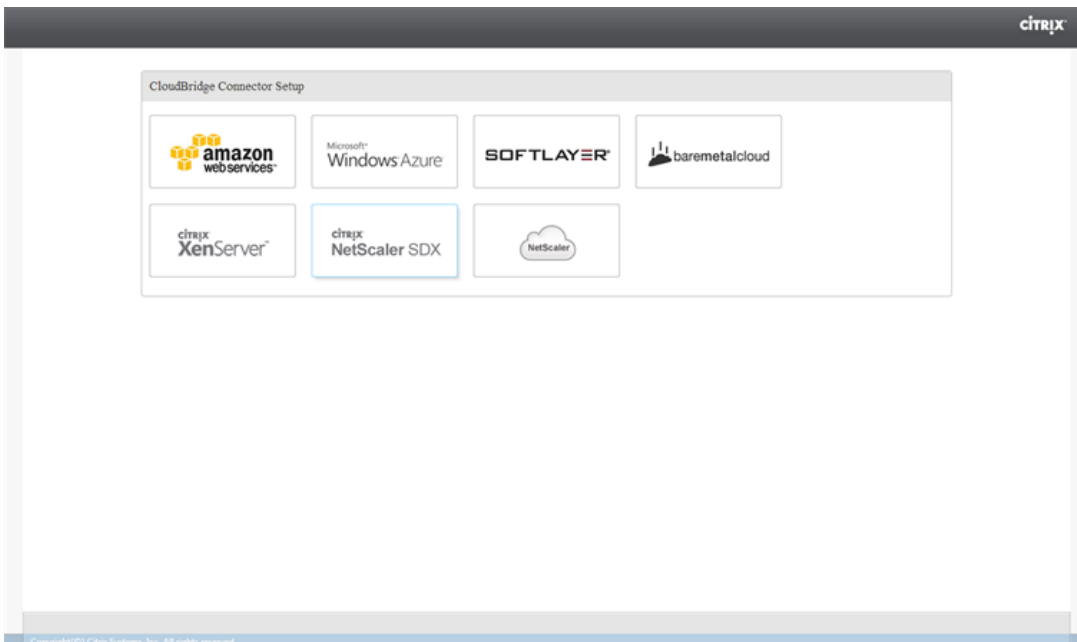

The first time you configure a CloudBridge Connector tunnel on the appliance, a Welcome screen appears.

5. On the Welcome screen click **Get Started**.

Note: If you already have a CloudBridge Connector tunnel configured on the NetScaler appliance, the Welcome screen does not appear, so you do not click **Get Started**.

6. In the **CloudBridge Connector Setup** pane, click **amazon web services**.

7. In the **Amazon** pane, provide your AWS account credentials: AWS Access Key ID and AWS Secret Access Key. You can obtain these access keys from the AWS GUI console. Click **Continue**.
8. In the **NetScaler** pane, select the NSIP address of the NetScaler virtual appliance running on AWS. Then, provide your account credentials for the NetScaler virtual appliance. Click **Continue**.
9. In the **CloudBridge Connector Setting** pane, set the following parameter:
 - **CloudBridge Connector Name**— Name for the CloudBridge Connector configuration on the local appliance. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the CloudBridge Connector configuration is created.
10. Under **Local Setting**, set the following parameter:
 - **Subnet IP**—IP address of the local endpoint of the CloudBridge Connector tunnel. Must be a public IP address of type SNIP.
11. Under **Remote Setting**, set the following parameter:
 - **Subnet IP**— IP address of the CloudBridge Connector tunnel end point on the AWS side. Must be an IP address of type SNIP on the NetScaler VPX instance on AWS.
 - **NAT**—Public IP address (EIP) in AWS that is mapped to the SNIP configured on the NetScaler VPX instance on AWS.
12. Under **PBR Setting**, set the following parameters:
 - **Operation**— Either the equals (=) or does not equal (!=) logical operator.
 - **Source IP Low***—Lowest source IP address to match against the source IP address of an outgoing IPv4 packet.
 - **Source IP High**—Highest source IP address to match against the source IP address of an outgoing IPv4 packet.
 - **Operation**— Either the equals (=) or does not equal (!=) logical operator.
 - **Destination IP Low***—Lowest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
 - **Destination IP High**—Highest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
13. (Optional) Under **Security Settings**, set the following IPSec protocol parameters for the CloudBridge Connector tunnel:
 - **Encryption Algorithm**—Encryption algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
 - **Hash Algorithm**—Hash algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
 - **Key**— Select one of the following IPSec authentication methods to be used by the two peers to mutually authenticate.
 - **Auto Generate Key**— Authentication based on a text string, called a pre-shared key (PSK), generated automatically by the local appliance. The PSKs keys of the peers are matched against each other for authentication.
 - **Specific Key**—Authentication based on a manually entered PSK. The PSKs of the peers are matched against each other for authentication.
 - **Pre Shared Security Key**—The text string entered for pre-shared key based authentication.
 - **Upload Certificates**—Authentication based on digital certificates.
 - **Public Key**—A local digital certificate to be used to authenticate the local peer to the remote peer before establishing IPSec security associations. The same certificate should be present and set for the Peer Public Key parameter in the peer.

- **Private Key**— Private key of the local digital certificate.
- **Peer Public Key**— Digital certificate of the peer. Used to authenticate the peer to the local end point before establishing IPSec security associations. The same certificate should be present and set for the Public key parameter in the peer.

14. Click **Done**.

The new CloudBridge Connector tunnel configuration on the NetScaler appliance in the datacenter appears on the Home tab of the configuration utility.

The corresponding new CloudBridge Connector tunnel configuration on the NetScaler VPX appliance in the AWS cloud appears on the configuration utility.

The current status of the CloudBridge connector tunnel is indicated in the Configured CloudBridge pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

Configuring a CloudBridge Connector Tunnel Between a NetScaler Appliance and Virtual Private Gateway on AWS

Jan 29, 2016

To connect a datacenter to Amazon Web Services (AWS), you can configure a CloudBridge Connector tunnel between a NetScaler appliance in the datacenter and a virtual private gateway on AWS. The NetScaler appliance and the virtual private gateway form the endpoints of the CloudBridge Connector tunnel and are called peers.

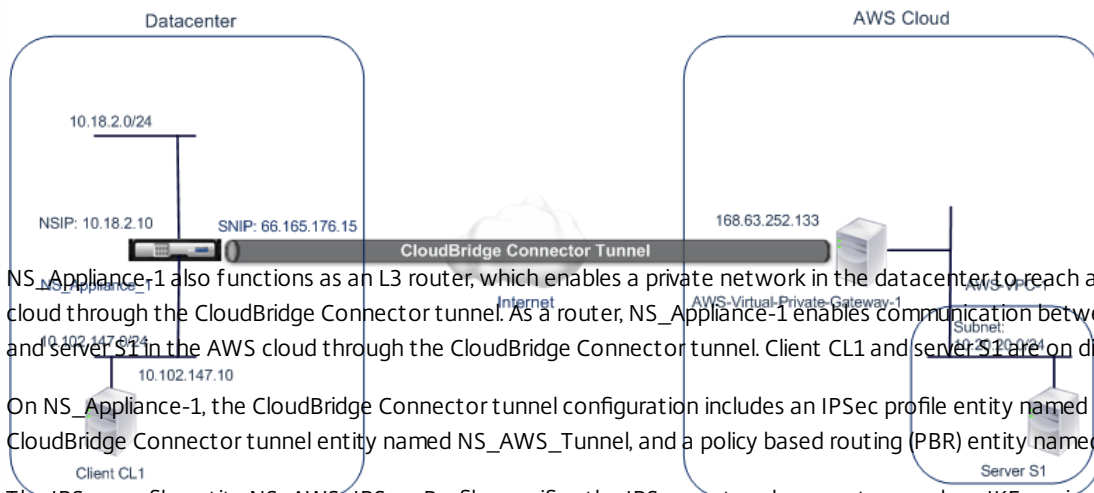

Note: You can also set up a CloudBridge Connector tunnel between a NetScaler appliance in a datacenter and a NetScaler VPX instance (instead of a virtual private gateway) on AWS. For more information, see [Configuring CloudBridge Connector between Datacenter and AWS Cloud](#).

Virtual private gateways on AWS support the following IPsec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPsec settings when you configure the NetScaler appliance for the CloudBridge Connector tunnel.

IPSec Properties	Setting
IPSec mode	Tunnel mode
IKE version	Version 1
IKE Authentication method	Pre-Shared Key
Encryption algorithm	AES
Hash algorithm	HMAC SHA1

Example of CloudBridge Connector Tunnel Configuration and Data Flow

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between NetScaler appliance NS_Appliance-1 in a datacenter and virtual private gateway gateway AWS-Virtual-Private-Gateway-1 on AWS cloud.

NS_Appliance-1 also functions as an L3 router, which enables a private network in the datacenter to reach a private network in the AWS cloud through the CloudBridge Connector tunnel. As a router, NS_Appliance-1 enables communication between client CL1 in the datacenter and server S1 in the AWS cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes an IPSec profile entity named NS_AWS_IPSec_Profile, a CloudBridge Connector tunnel entity named NS_AWS_Tunnel, and a policy based routing (PBR) entity named NS_AWS_Pbr.

The IPSec profile entity NS_AWS_IPSec_Profile specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, and hash algorithm, to be used by the IPSec protocol in the CloudBridge Connector tunnel. NS_AWS_IPSec_Profile is bound to IP tunnel entity NS_AWS_Tunnel.

CloudBridge Connector tunnel entity NS_AWS_Tunnel specifies the local IP address (a public IP—SNIP—address configured on the NetScaler appliance), the remote IP address (the IP address of the AWS-Virtual-Private-Gateway-1), and the protocol (IPSec) used to set up the CloudBridge Connector tunnel. NS_AWS_Tunnel is bound to policy based routing (PBR) entity NS_AWS_Pbr.

The PBR entity NS_AWS_Pbr specifies a set of conditions and a CloudBridge Connector tunnel entity (NS_AWS_Tunnel). The source IP address range and the destination IP address range are the conditions for NS_AWS_Pbr. The source IP address range and the destination IP address range are specified as a subnet in the datacenter and a subnet in the AWS cloud, respectively. Any request packet originating from a client in the subnet in the datacenter and destined to a server in the subnet on the AWS cloud matches the conditions in NS_AWS_Pbr. This packet is then considered for CloudBridge Connector processing and is sent across the CloudBridge Connector tunnel (NS_AWS_Tunnel) bound to the PBR entity.

The following table lists the settings used in this example.

Entity	Name	Details
Settings highlight of the CloudBridge Connector tunnel setup		
IP address of the CloudBridge Connector tunnel end point (NS_Appliance-1) in the datacenter side		66.165.176.15
IP address of the CloudBridge Connector tunnel end point (AWS-Virtual-Private-Gateway-1) in the AWS		168.63.252.133
Datacenter Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel		10.102.147.0/24
AWS Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel		10.20.20.0/24
Settings on NetScaler appliance NS_Appliance-1 in Datacenter		
	SNIP1(for reference purposes only)	66.165.176.15

IPSec profile	NS_AWS_IPSec_Profile	<ul style="list-style-type: none"> • IKE version = v1 • Encryption algorithm = AES • Hash algorithm = HMAC SHA1
CloudBridge Connector tunnel	NS_AWS_Tunnel	<ul style="list-style-type: none"> • Remote IP = 168.63.252.133 • Local IP = 66.165.176.15 • Tunnel protocol = IPSec • IPSec profile = NS_AWS_IPSec_Profile
Policy based route	NS_AWS_Pbr	<ul style="list-style-type: none"> • Source IP range = Subnet in the datacenter = 10.102.147.0-10.102.147.255 • Destination IP range = Subnet in AWS = 10.20.20.0-10.20.20.255 • IP Tunnel = NS_AWS_Tunnel
Settings on Amazon AWS		
Customer Gateway	AWS-Customer-Gateway-1	<ul style="list-style-type: none"> • Routing = Static • IP Address = Internet-routable CloudBridge Connector tunnel endpoint IP address on the NetScaler side = 66.165.176.15
Virtual Private Gateway	AWS-Virtual-Private-Gateway-1	<ul style="list-style-type: none"> • Associated VPC = AWS-VPC-1
VPN Connection	AWS-VPN-Connection-1	<ul style="list-style-type: none"> • Customer Gateway = AWS-Customer-Gateway-1 • Virtual Private Gateway = Virtual-Private-Gateway-1 • Routing Options <ul style="list-style-type: none"> • Type = Static • Static IP Prefixes = Subnets on the NetScaler side = 10.102.147.0/24

Following is the traffic flow in the CloudBridge Connector tunnel:

1. Client C1 sends a request to server S1.
2. The request packet is received by NS_Appliance-1. The request packet matches the condition in NS_AWS_Pbr, because the source IP address and the destination IP address of the request packet are in the source IP range and destination IP range specified in NS_AWS_Pbr.
3. Because CloudBridge Connector tunnel entity NS_AWS_Tunnel is bound to NS_AWS_Pbr, the appliance prepares the packet to be sent across the NS_AWS_Tunnel.
4. IPSec's Encapsulating Security Payload (ESP) protocol encrypts the request packet and then attaches an ESP header and an ESP trailer to the encrypted IP packet. The IPSec protocol encapsulates the resulting packet by adding an IP header before the ESP header. The destination address in the IP header is the IP address of AWS-Virtual-Private-Gateway-1, and the source address is the SNIP1 address.
5. The resulting packet is sent to AWS-Virtual-Private-Gateway-1.
6. AWS-Virtual-Private-Gateway-1, upon receiving the packet from NS_Appliance-1, decapsulates the packet by removing the IPSec IP header, decrypts the packet, and then removes the ESP header and ESP trailer. The resulting packet is the same packet as the one received by NS_Appliance-1 in step 2. This packet has the destination IP address set to the IP address of server S1.
7. AWS-Virtual-Private-Gateway-1 forwards this packet to server S1.
8. S1 processes the request packet and sends a response packet. The destination IP address in the response packet is the IP address of

- client CL1, and the source IP address is the IP address of server S1.
9. The response packet reaches AWS-Virtual-Private-Gateway-1. The IPSec protocol in AWS encrypts and encapsulates the response packet.
 10. AWS-Virtual-Private-Gateway-1 sends the resulting packet to NS_Appliance-1.
 11. NS_Appliance-1, upon receiving the packet from AWS-Virtual-Private-Gateway-1, decapsulates and decrypts the packet. The resulting packet is the same packet that was received by AWS-Virtual-Private-Gateway-1 in step 9. This response packet has the destination IP address set to the IP address of server CL1.
 12. NS_Appliance-1 forwards the response packet to client CL1.

Points to Consider for a CloudBridge Connector Tunnel Configuration

Before configuring a CloudBridge Connector tunnel between a NetScaler appliance and AWS gateway, consider the following points:

1. AWS supports the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings when you configure the NetScaler appliance for the CloudBridge Connector tunnel.
 - IKE version = v1
 - Encryption algorithm = AES
 - Hash algorithm = HMAC SHA1
2. You must configure the firewall at the NetScaler end to allow the following.
 - Any UDP packets for port 500
 - Any UDP packets for port 4500
 - Any ESP (IP protocol number 50) packets
3. You must configure Amazon AWS before specifying the tunnel configuration on the NetScaler, because the public IP address of the AWS end (gateway) of the tunnel and the PSK are automatically generated when you set up the tunnel configuration in AWS. You need this information for specifying the tunnel configuration on the NetScaler appliance.
4. AWS gateway supports static routes and the BGP protocol for route updates. The NetScaler appliance does not support the BGP protocol in a CloudBridge Connector tunnel to AWS gateway. Therefore, appropriate static routes must be used on both sides of the CloudBridge Connector tunnel for proper routing of traffic through the tunnel. Bottom of Form

Configuring Amazon AWS for the CloudBridge Connector Tunnel

To create a CloudBridge Connector tunnel configuration on Amazon AWS, use the Amazon AWS Management Console, which is a web based graphical interface for creating and managing resources on Amazon AWS.

Before you begin the CloudBridge Connector tunnel configuration on AWS cloud, make sure that:

- You have a user account for Amazon AWS cloud.
- You have a virtual private cloud whose networks you want to connect to the networks at the NetScaler side through the CloudBridge Connector tunnel.
- You are familiar with the Amazon AWS Management Console.

Note: The procedures for configuring Amazon AWS for a CloudBridge Connector tunnel might change over time, depending on the Amazon AWS release cycle. Citrix recommends the following Amazon AWS documentation for the latest procedures.

- http://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/VPC_VPN.html

To configure a CloudBridge connector tunnel between a NetScaler and AWS gateway perform the following tasks on the AWS Management Console:

- **Create a Customer Gateway.** A customer gateway is an AWS entity that represents a CloudBridge Connector tunnel endpoint. For a CloudBridge Connector tunnel between a NetScaler appliance and AWS gateway, the customer gateway represents the NetScaler appliance on AWS. The customer gateway specifies a name, the type of routing (static or BGP) used in the tunnel, and the CloudBridge Connector tunnel endpoint IP address on the NetScaler side. The IP address can be an Internet-routable NetScaler owned subnet IP (SNIP) address or, if the NetScaler appliance is behind a NAT device, an Internet-routable NAT IP address that represents the SNIP address.
- **Create a Virtual Private Gateway and attach it to a VPC.** A virtual private gateway is a CloudBridge Connector tunnel endpoint at the AWS side. When you create a virtual private gateway, you assigned it a name or allow AWS to assign the name. You then associate the virtual private gateway with a VPC. This association enables the subnets of the VPC to connect to the subnets at the NetScaler side through the CloudBridge Connector tunnel.
- **Create a VPN Connection.** A VPN connection specifies a customer gateway and a virtual private gateway between which a CloudBridge Connector tunnel is to be created. It also specifies an IP prefix for the networks at the NetScaler side. Only IP prefixes that are known to the virtual private gateway (through static route entry) can receive traffic from the VPC through the tunnel. Also, the virtual private gateway does not route any traffic not destined to the specified IP prefixes through the tunnel. After configuring a VPN connection, you might have to wait few minutes for it to be created.
- **Configure Routing Options.** For the VPC's network to reach the networks at the NetScaler side through the CloudBridge Connector tunnel, you must configure the VPC's routing table to include routes for the networks at the NetScaler side and point those routes to the virtual private gateway. You can include routes in a VPC's routing table in one of the following ways:
 - **Enable Route Propagation.** You can enable route propagation for your routing table, so that routes are automatically propagated to the table. The static IP prefixes that you specify for VPN configuration are propagated to the routing table after you've created the VPN connection.
 - **Enter Static Routes Manually.** If you do not enable route propagation, you must manually enter the static routes for the networks at the NetScaler side.
- **Download Configuration.** After the CloudBridge Connector tunnel (VPN connection) configuration is created on AWS, download the configuration file of the VPN connection to your local system. You might need the information in the configuration file for configuring the CloudBridge Connector tunnel on the NetScaler appliance.

To create a customer gateway

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. Navigate to **VPN Connections > Customer Gateways** and click on **Create Customer Gateway**.
3. In the **Create Customer Gateway** dialog box, set the following parameters and then click **Yes, Create**:

- **Name tag.** A name for the customer gateway.
- **Routing list.** Type of routing between NetScaler appliance and AWS virtual private gateway for advertising routes to each other through the CloudBridge Connector tunnel. Select **Static Routing** from the **Routing list**.

Note: The NetScaler appliance does not support the BGP protocol in a CloudBridge Connector tunnel to AWS gateway. Therefore, appropriate static routes must be used on both sides of the CloudBridge Connector tunnel for proper routing of traffic through the tunnel.

- **IP Address.** Internet-routable CloudBridge Connector tunnel endpoint IP address on the NetScaler side. The IP address can be an Internet-routable NetScaler owned subnet IP (SNIP) address or, if the NetScaler appliance is behind a NAT device, an Internet-routable NAT IP address that represents the SNIP address.

To create a virtual private gateway and attach it to a VPC

1. Navigate to **VPN Connections > Virtual Private Gateways**, and then click **Create Virtual Private Gateway**.
2. Enter a name for the virtual private gateway, and then click **Yes, Create**.
3. Select the virtual private gateway that you created, and then click **Attach to VPC**.
4. In the **Attach to VPC** dialog box, select your VPC from the list, and then choose **Yes, Attach**.

To create a VPN connection

1. Navigate to **VPN Connections > VPN Connections** and then click **Create VPN Connection**.
2. In the **Create VPN Connection** dialog box set the following parameters and then choose **Yes, Create**:
 - **Name tag**. A name for the VPN connection.
 - **Virtual Private Gateway**. Select the virtual private gateway that you created earlier.
 - **Customer Gateway**. Select Existing. Then, from the drop down list, select the customer gateway that you created earlier.
 - **Routing Options**. Type of routing between the virtual private gateway and customer gateway (NetScaler appliance). Select Static. In the Static IP Prefixes field, specify the IP prefixes for the subnet on the NetScaler side, separated by commas.

To enable route propagation

1. Navigate to **Route Tables** and select the routing table that's associated with the subnet whose traffic is to traverse the CloudBridge Connector tunnel.
Note: By default, this is the main routing table for the VPC.
2. On the **Route Propagation** tab in the details pane, choose **Edit**, select the virtual private gateway, and then choose **Save**.

To manually enter static routes

1. Navigate to **Route Tables** and select your routing table.
2. On the **Routes** tab, click **Edit**.
3. In the **Destination** field, enter the static route used by your CloudBridge Connector tunnel (VPN connection).
4. Select the virtual private gateway ID from the **Target** list, and then choose **Save**.

To download the configuration file

1. Navigate to **VPN Connection**, select a VPN connection, and then click **Download Configuration**.
2. In the **Download Configuration** dialog box, set the following parameters, and then click **Yes, Download**.
 - **Vendor**. Select **Generic**.
 - **Platform**. Select **Generic**.
 - **Software**. Select **Vendor Agnostic**.

Configuring the NetScaler Appliance for the CloudBridge Connector Tunnel

To configure a CloudBridge Connector tunnel between a NetScaler appliance and a virtual private gateway on AWS cloud, perform the following tasks on the NetScaler appliance. You can use either the NetScaler command line or the configuration utility:

- **Create an IPsec profile**. An IPsec profile entity specifies the IPsec protocol parameters, such as IKE version, encryption algorithm, hash algorithm and PSK to be used by the IPsec protocol in the CloudBridge Connector tunnel.
- **Create an IP tunnel that uses IPsec protocol and associate the IPsec profile with it**. An IP tunnel specifies the local IP address (a SNIP address configured on the NetScaler appliance), remote IP address (the public IP address of the virtual private gateway in AWS), protocol (IPsec) used to set up the CloudBridge Connector tunnel, and an IPsec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
- **Create a PBR rule and associate it with the IP tunnel**. A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the NetScaler-side subnet whose traffic is to traverse the tunnel, and set the destination IP address range to specify the AWS VPC subnet whose traffic is to traverse the CloudBridge Connector tunnel. Any request packet that originates from a client in the subnet on the NetScaler side and is destined to a server in the AWS cloud subnet, and matches the source and destination IP range of the PBR entity, is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the NetScaler command line

At the Command prompt, type:

- **add ipsec profile** <name> -psk <string> -ikeVersion v1

To create an IPSEC tunnel and bind the IPSEC profile to it by using the NetScaler command line

At the Command prompt, type:

- **add ipTunnel** <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>

To create a PBR rule and bind the IPSEC tunnel to it by using the NetScaler command line

At the Command prompt, type:

- **add pbr** <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>
- **apply pbrs**

```
Sample configuration COPY  
  
The following commands create all settings of NetScaler appliance NS_Appliance-1 used in "Example of CloudBridge Connector Configuration and Data Flow"  
  
> add ipsec profile NS_AWS_IPSec_Profile -psk DkiMgMdcqvYREEulvxsBKkW0Foyabcd -ikeVersion v1 -lifetime 31536000  
  
Done  
  
> add iptunnel NS_AWS_Tunnel 168.63.252.133 255.255.255.255 66.165.176.15 -protocol IPSEC -ipsecProfileName NS_AWS_IPSec_Profile  
  
Done  
  
> add pbr NS_AWS_Pbr -srcIP 10.102.147.0-10.102.147.255 -destIP 10.20.0.0-10.20.255.255 -ipTunnel NS_AWS_Tunnel  
  
Done  
  
> apply pbrs  
  
Done
```

To create an IPSEC profile by using the configuration utility

1. Navigate to **System > CloudBridge Connector > IPsec Profile**.
2. In the details pane, click **Add**.
3. In the **Add IPsec Profile** dialog box, set the following parameters:
 - Name
 - Encryption Algorithm
 - Hash Algorithm
 - IKE Protocol Version (select V1)

4. Select the **Pre-shared Key Authentication** method and set the **Pre-Shared Key Exists** parameter.
5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSEC profile to it by using the configuration utility

1. Navigate to **System > CloudBridge Connector > IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click **Add**.
3. In the **Add IP Tunnel** dialog box, set the following parameters:
 - Name
 - Remote IP
 - Remote Mask
 - Local IP Type (In the Local IP Type drop down list, select Subnet IP).
 - Local IP (All the configured IPs of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
 - Protocol
 - IPsec Profile
4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the configuration utility

1. Navigate to **System > Network > PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** dialog box, set the following parameters:
 - Name
 - Action
 - Next Hop Type (Select IP Tunnel)
 - IP Tunnel Name
 - Source IP Low
 - Source IP High
 - Destination IP Low
 - Destination IP High
4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the NetScaler appliance appears in the configuration utility.

The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

Monitoring the CloudBridge Connector Tunnel

You can view statistics for monitoring the performance of a CloudBridge Connector tunnel between the NetScaler appliance and the AWS gateway. To view CloudBridge Connector tunnel statistics on the NetScaler appliance, use the configuration utility or the NetScaler command line.

The following table lists the statistical counters available for monitoring CloudBridge Connector tunnels on a NetScaler appliance.

Statistical counter	Specifies
---------------------	-----------

Bytes Received	Total number of bytes received by the NetScaler appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Bytes Sent	Total number of bytes sent by the NetScaler appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Packets Received	Total number of packets received by the NetScaler appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Packets Sent	Total number of packets sent by the NetScaler appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.

All these counters are reset to 0 when the NetScaler appliance is restarted. They do not increment during the following phases:

- Internet Key Exchange (IKE) authentication (pre-shared key) phase on any configured CloudBridge Connector tunnel.
- IKE Security Association (SA) establishment phase on any configured CloudBridge Connector tunnel.

To display CloudBridge Connector tunnel statistics by using the command line

At the command prompt, type:

- `stat ipsec counters`

To display CloudBridge Connector tunnel statistics by using the configuration utility

1. Access the configuration utility by using a web browser to connect to the IP address of the NetScaler appliance.

On the Home tab, the IPSec Bytes and IPSec Packets charts display the statistics of all the CloudBridge Connector tunnels configured on the NetScaler appliance.

Configuring a CloudBridge Connector Tunnel Between a Datacenter and Azure Cloud

Apr 28, 2014

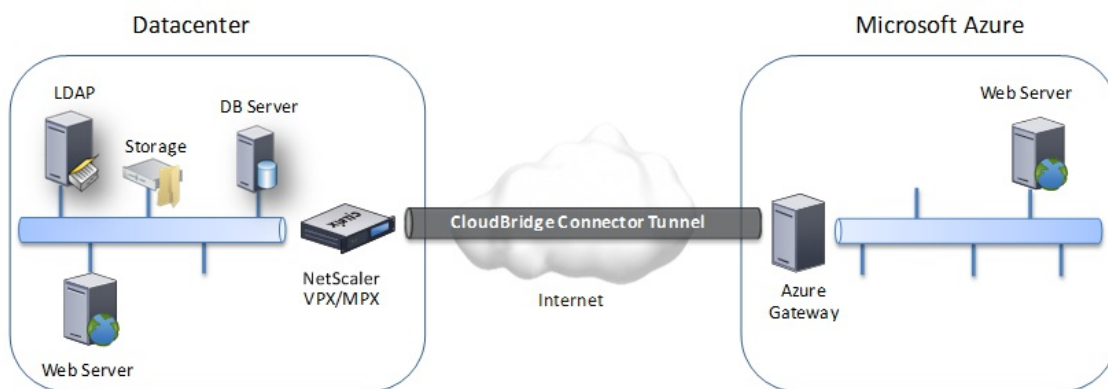

The NetScaler appliance provides connectivity between your enterprise datacenters and the Microsoft cloud hosting provider, Azure, making Azure a seamless extension of the enterprise network. NetScaler encrypts the connection between the enterprise datacenter and Azure cloud so that all data transferred between the two is secure.

This section includes the following:

- [How CloudBridge Connector Tunnel Works](#)
- [Example of CloudBridge Connector Tunnel Configuration and Data Flow](#)
- [Points to Consider for a CloudBridge Connector tunnel Configuration](#)
- [Configuring the CloudBridge Connector Tunnel](#)
- [Monitoring the CloudBridge Connector Tunnel](#)

How CloudBridge Connector Tunnel Works

To connect a datacenter to AWS cloud, you set up a CloudBridge Connector tunnel between a NetScaler appliance that resides in the datacenter and a gateway that resides in the Azure cloud. The NetScaler appliance in the datacenter and the gateway in Azure cloud are the end points of the CloudBridge Connector tunnel and are called peers of the CloudBridge Connector tunnel.

A CloudBridge Connector tunnel between a datacenter and Azure cloud uses the open-standard Internet Protocol security (IPSec) protocol suite, in tunnel mode, to secure communications between peers in the CloudBridge Connector tunnel. In a CloudBridge Connector tunnel, IPSec ensures:

- Data integrity
- Data origin authentication
- Data confidentiality (encryption)
- Protection against replay attacks

IPSec uses the tunnel mode in which the complete IP packet is encrypted and then encapsulated. The encryption uses the Encapsulating Security Payload (ESP) protocol, which ensures the integrity of the packet by using a HMAC hash function and ensures confidentiality by using an encryption algorithm. The ESP protocol, after encrypting the payload and calculating the HMAC, generates an ESP header and inserts it before the encrypted IP packet. The ESP protocol also generates an ESP trailer and inserts it at the end of the packet.

The IPSec protocol then encapsulates the resulting packet by adding an IP header before the ESP header. In the IP header, the destination IP address is set to the IP address of the CloudBridge Connector peer.

Peers in the CloudBridge Connector tunnel use the Internet Key Exchange version 1 (IKEv1) protocol (part of the IPSec protocol suite) to negotiate secure communication, as follows:

1. The two peers mutually authenticate with each other, using pre-shared key authentication, in which the peers exchange a text string called a pre-shared key (PSK). The pre-shared keys are matched against each other for authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on each of the peers.
2. The peers then negotiate to reach agreement on:

- An encryption algorithm
- Cryptographic keys for encrypting data on one peer and decrypting it on the other.

This agreement upon the security protocol, encryption algorithm and cryptographic keys is called a Security Association (SA). SAs are one-way (simplex). For example, when a CloudBridge Connector tunnel is set up between a NetScaler appliance in a datacenter and a gateway in an Azure cloud, both the datacenter appliance and the Azure gateway have two SAs. One SA is used for processing out-bound packets, and the other SA is used for processing inbound packets. SAs expire after a specified interval of time, which is called the lifetime.

Example of CloudBridge Connector Tunnel Configuration and Data Flow

As an illustration of CloudBridge Connector Tunnel, consider an example in which a CloudBridge Connector tunnel is set up between NetScaler appliance CB_Appliance-1 in a datacenter and gateway Azure_Gateway-1 in Azure cloud.

CB_Appliance-1 also functions as an L3 router, which enables a private network in the datacenter to reach a private network in the Azure cloud through the CloudBridge Connector tunnel. As a router, CB_Appliance-1 enables communication between client CL1 in the datacenter and server S1 in the Azure cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On CB_Appliance-1, the CloudBridge Connector tunnel configuration includes an IPSec profile entity named CB_Azure_IPSec_Profile, a CloudBridge Connector tunnel entity named CB_Azure_Tunnel, and a policy based routing (PBR) entity named CB_Azure_Pbr.

The IPSec profile entity CB_Azure_IPSec_Profile specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, and hash algorithm, to be used by the IPSec protocol in the CloudBridge Connector tunnel. CB_Azure_IPSec_Profile is bound to IP tunnel entity CB_Azure_Tunnel.

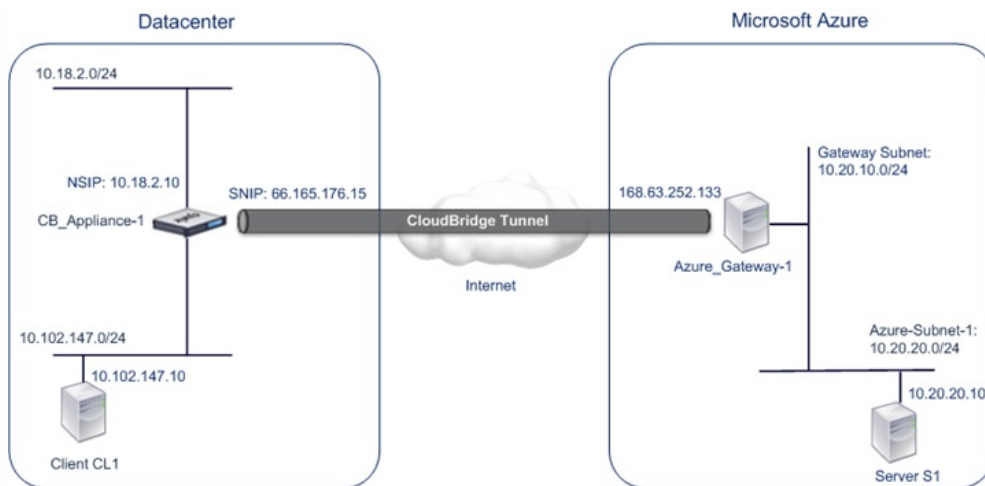

CloudBridge Connector tunnel entity CB_Azure_Tunnel specifies the local IP address (a public IP (SNIP) address configured on the NetScaler appliance), the remote IP address (the IP address of the Azure_Gateway-1), and the protocol (IPSec) used to set up the CloudBridge Connector tunnel. CB_Azure_Tunnel is bound to the PBR entity CB_Azure_Pbr.

The PBR entity CB_Azure_Pbr specifies a set of conditions and a CloudBridge Connector tunnel entity (CB_Azure_Tunnel). The source IP address range and the destination IP address range are the conditions for CB_Azure_Pbr. The source IP address range and the destination IP address range are specified as a subnet in the datacenter and a subnet in the Azure cloud, respectively. Any request packet originating from a client in the subnet in the datacenter and destined to a server in the subnet on the Azure cloud matches the conditions in CB_Azure_Pbr. This packet is then considered for CloudBridge processing and is sent across the CloudBridge Connector tunnel (CB_Azure_Tunnel) bound to the PBR entity.

On Microsoft Azure, the CloudBridge Connector tunnel configuration includes a local network entity named My-Datacenter-Network, a virtual network entity named Azure-Network-for-CloudBridge-Tunnel, and a gateway named Azure_Gateway-1.

The local (local to Azure) network entity My-Datacenter-Network specifies the IP address of the NetScaler appliance on the datacenter side, and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel. The virtual network entity Azure-Network-for-CloudBridge-Tunnel defines a private subnet named Azure-Subnet-1 in Azure. The traffic of the subnet traverses the CloudBridge Connector tunnel. The server S1 is provisioned in this subnet.

The local network entity My-Datacenter-Network is associated with the virtual network entity Azure-Network-for-CloudBridge-Tunnel. This association defines the remote and local network details of the CloudBridge Connector tunnel configuration in Azure. Gateway Azure_Gateway-1 was created for this association to become the CloudBridge end point at the Azure end of the CloudBridge Connector tunnel.

The following table lists the settings used in this example.

Entity	Name	Details
Settings highlight of the CloudBridge Connector tunnel setup		
IP address of the CloudBridge Connector tunnel end point (CB_Appliance-1) in the datacenter side	66.165.176.15	
IP address of the CloudBridge Connector tunnel end point (Azure_Gateway-1) in the Azure	168.63.252.133	
Datacenter Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel	10.102.147.0/24	
Azure Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel	10.20.0.0/16	
Settings on NetScaler appliance CB_Appliance-1 in Datacenter		
	SNIP1(for reference purposes only)	66.165.176.15
IPSec profile	CB_Azure_IPSec_Profile	<ul style="list-style-type: none"> • IKE version = v1 • Encryption algorithm = AES • Hash algorithm = HMAC SHA1
CloudBridge Connector tunnel	CB_Azure_Tunnel	<ul style="list-style-type: none"> • Remote IP = 168.63.252.133 • Local IP= 66.165.176.15 • Tunnel protocol = IPSec • IPSec profile= CB_Azure_IPSec_Profile
Policy based route	CB_Azure_Pbr	<ul style="list-style-type: none"> • Source IP range = Subnet in the datacenter =10.102.147.0-10.102.147.255 • Destination IP range =Subnet in Azure =10.20.0.0-10.20.255.255 • IP Tunnel= CB_Azure_Tunnel

Entity	Name	Details
Settings on Microsoft Azure		
Public IP Address of the Azure_Gateway-1		168.63.252.133
Local Network	My-Datacenter-Network	<ul style="list-style-type: none"> • VPN Device IP address =SNIP address of the NetScaler appliance = 66.165.176.15 • Address space= Subnet in datacenter =10.102.147.0/24
Virtual Network	Azure-Network-for-CloudBridge-Tunnel	<ul style="list-style-type: none"> • Address Space= 10.20.0.0/16 • Subnet in Azure=Azure-Subnet-1= 10.20.20.0/24 • Local Network=My-Datacenter-Network • Gateway Subnet=10.20.10.0/24

Following is the traffic flow in the CloudBridge Connector tunnel:

1. Client C1 sends a request to server S1.
2. The request reaches NetScaler appliance CB_Appliance-1.
3. The request packet in CB_Appliance-1 matches the condition specified in the PBR entity CB_Azure_Pbr as the source IP address and the destination IP address of the request packet belonging to the source IP range and destination IP range, respectively, set in CB_Azure_Pbr.
4. Because CloudBridge Connector tunnel entity CB_Azure_Tunnel is bound to CB_Azure_Pbr, the appliance prepares the packet to be sent across the CB_Azure_Tunnel.
5. For CloudBridge Connector tunnel CB_Azure_Tunnel, CB_Appliance-1 checks the stored IPSec security association (SA) parameters for processing outbound packets, as agreed between CB_Appliance-1 in the datacenter and Azure_Gateway-1 in the Azure cloud. The IPSec Encapsulating Security Payload (ESP) protocol in the NetScaler appliance uses these SA parameters for outbound packets to encrypt the request packet.
6. The ESP protocol ensures the packet's integrity by using a HMAC hash function and the packet's confidentiality by using the AES encryption algorithm. The ESP protocol, after encrypting the request packet and calculating the HMAC, generates an ESP header and then inserts it before the encrypted IP packet. The ESP protocol also generates an ESP trailer and then inserts it at the end of the encrypted IP packet.
7. The IPSec protocol encapsulates the resulting packet by adding an IP header before the ESP header. The destination address in the IP header is the IP address of Azure-gateway-1, and the source address is the SNIP2 address.
8. The resulting packet is sent to Azure_Gateway-1. There is
9. Azure-gateway-1, upon receiving the packet from CB_Appliance-1, decapsulates the packet by removing the IPSec IP header.
10. Azure-gateway-1 then checks the stored IPSec security association (SA) parameters for processing inbound packets, as agreed between CB_Appliance-1 and Azure_Gateway-1. The IPSec ESP protocol on Azure_Gateway-1 uses these SA parameters for inbound packets, and the ESP header of the decapsulated request packet, to decrypt the packet.
11. The resulting packet is the same packet as the one received by CB_Appliance-1 in step 2. This packet has the destination IP address set to the IP address of server S1. Azure_Gateway-1 forwards this packet to server S1.
12. S1 processes the request packet and sends out a response packet. The destination IP address in the response packet is the IP address of client CL1, and source IP address is the IP address of server S1.
13. The response packet reaches Azure_Gateway-1. Microsoft Azure checks the stored IPSec security association (SA) parameters for processing outbound packets, as agreed between CB_Appliance-1 and Azure_Gateway-1. Microsoft Azure encrypts and encapsulates the response packet in the same way that CB_Appliance-1 encrypted and encapsulated the request packet in steps 5, 6, and 7.
14. Azure_Gateway-1 sends the resulting packet to CB_Appliance-1.
15. CB_Appliance-1, upon receiving the packet from Azure_Gateway-1, decapsulates and decrypts the packet in the same way that Azure_Gateway-1 decapsulated and decrypted the request packet in steps 9 and 10.
16. The resulting packet is the same packet that was received by Azure_Gateway-1 in step 13. This response packet has the destination IP address set to the IP address of server CL1. CB_Appliance-1 forwards the response packet to client CL1.

Points to Consider for a CloudBridge Connector tunnel Configuration

Updated: 2014-04-15

Before configuring a CloudBridge Connector tunnel between a NetScaler appliance in datacenter and Microsoft Azure, consider the following points:

1. The NetScaler appliance must have a public facing IPv4 address (type SNIP) to use as a tunnel end-point address for the CloudBridge Connector tunnel. Also, the NetScaler appliance should not be behind a NAT device.
2. Azure supports the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings while configuring the NetScaler for the CloudBridge Connector tunnel.
 - IKE version = v1
 - Encryption algorithm = AES
 - Hash algorithm = HMAC SHA1
3. You must configure the firewall in the datacenter edge to allow the following.
 - Any UDP packets for port 500
 - Any UDP packets for port 4500
 - Any ESP (IP protocol number 50) packets
4. IKE re-keying, which is renegotiation of new cryptographic keys between the CloudBridge Connector tunnel end points to establish new SAs, is not supported. When the Security Associations (SAs) expire, the tunnel goes into the DOWN state. Therefore, you must set a very large value for the lifetimes of SAs.
5. You must configure Microsoft Azure before specifying the tunnel configuration on the NetScaler, because the public IP address of the Azure end (gateway) of the tunnel, and the PSK, are automatically generated when you set up the tunnel configuration in Azure. You need this information for specifying the tunnel configuration on the NetScaler.

Configuring the CloudBridge Connector Tunnel

Updated: 2014-04-15

For setting up a CloudBridge Connector tunnel between your datacenter and Azure, you must install CloudBridge VPX/MPX in your datacenter, configure Microsoft Azure for the CloudBridge Connector tunnel, and then configure the NetScaler appliance in the data center for the CloudBridge Connector tunnel.

Configuring a CloudBridge Connector tunnel between a NetScaler appliance in datacenter and Microsoft Azure consists of the following tasks:

1. **Setting up the NetScaler appliance in the datacenter.** This task involves deploying and configuring a NetScaler physical appliance (MPX), or provisioning and configuring a NetScaler virtual appliance (VPX) on a virtualization platform in the datacenter.
2. **Configuring Microsoft Azure for the CloudBridge Connector tunnel.** This task involves creating local network, virtual network, and gateway entities in Azure. The local network entity specifies the IP address of the CloudBridge Connector tunnel end point (the NetScaler appliance) on the datacenter side, and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel. The virtual network defines a network on Azure. Creating the virtual network includes defining a subnet whose traffic is to traverse the CloudBridge Connector tunnel to be formed. You then associate the local network with the virtual network. Finally, you create a gateway that becomes the end point at the Azure end of the CloudBridge Connector tunnel.
3. **Configuring the NetScaler appliance in the datacenter for the CloudBridge Connector tunnel.** This task involves creating an IPSec profile, an IP tunnel entity, and a PBR entity in the NetScaler appliance in datacenter. The IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used in the CloudBridge Connector tunnel. The IP tunnel specifies the IP address of both the CloudBridge Connector tunnel end points (the NetScaler appliance in datacenter and the gateway in Azure) and the protocol to be used in the CloudBridge Connector tunnel. You then associate the IPSec profile entity with the IP tunnel entity. The PBR entity specifies the two subnets, in the datacenter and in the Azure cloud, that are to communicate with each other through the CloudBridge Connector tunnel. You then associate the IP tunnel entity with the PBR entity.

Configuring Microsoft Azure for the CloudBridge Connector tunnel

Updated: 2014-04-15

To create a CloudBridge Connector tunnel configuration on Microsoft Azure, use the Microsoft Windows Azure Management Portal, which is a web based graphical interface for creating and managing resources on Microsoft Azure.

Before you begin the CloudBridge Connector tunnel configuration on Azure cloud, make sure that:

- You have a user account for Microsoft Azure.

- You have a conceptual understanding of Microsoft Azure.
- You are familiar with the Microsoft Windows Azure Management Portal.

Note: The procedures for configuring Microsoft Azure for a CloudBridge Connector tunnel might change over time, depending on the Microsoft Azure release cycle. Citrix recommends the following Microsoft Azure documentation for the latest procedures.

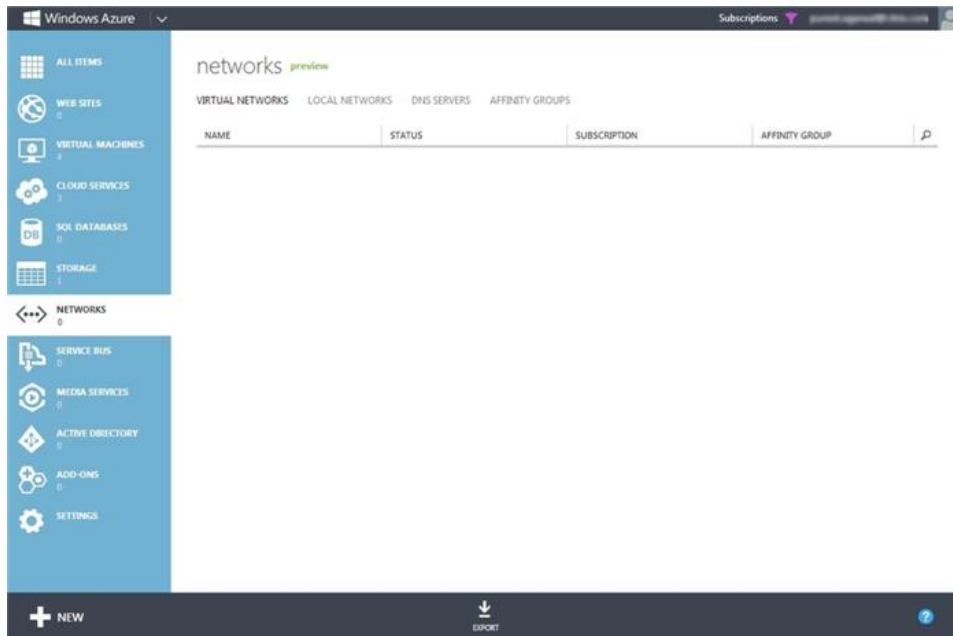

- <http://www.windowsazure.com/en-us/manage/services/networking/cross-premises-connectivity/>

To configure a CloudBridge Connector tunnel between a datacenter and an Azure cloud, perform the following tasks on Microsoft Azure by using the Microsoft Windows Azure Management Portal:

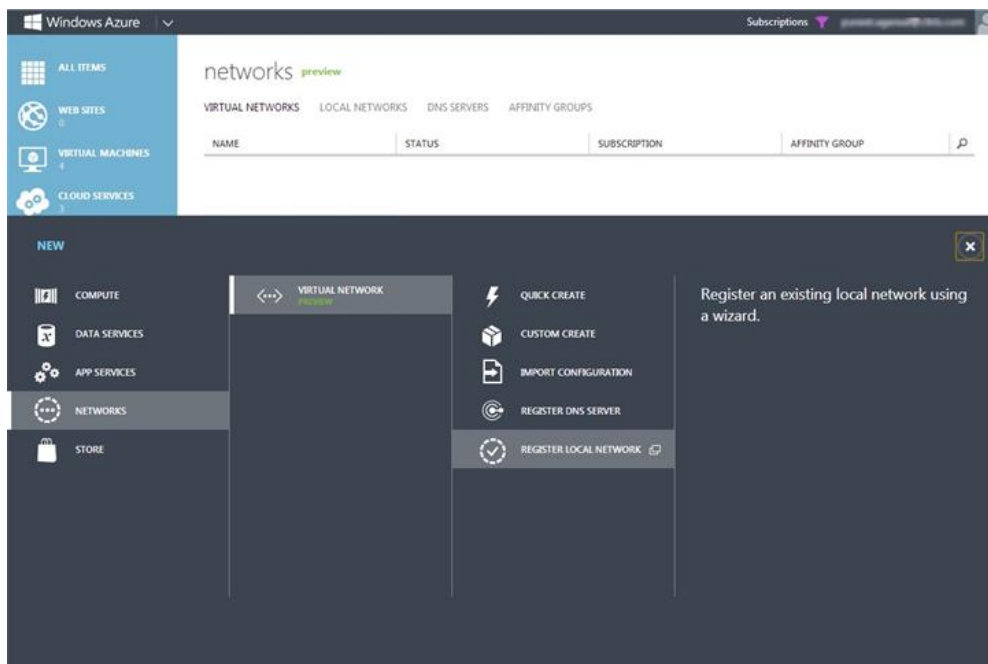

- **Create a local network entity.** Create a local network entity in Windows Azure for specifying the network details of the datacenter. A local network entity specifies the IP address of the CloudBridge Connector tunnel end point (the NetScaler) on the datacenter side and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel.
- **Create a Virtual Network.** Create virtual network entity that defines a network on Azure. This task includes defining a private address space, where you provide a range of private addresses and subnets belonging to the range specified in the address space. The traffic of the subnets will traverse the CloudBridge Connector tunnel. You then associate a local network entity with the virtual network entity. This association lets Azure create a configuration for a CloudBridge Connector tunnel between the virtual network and the data center network. A gateway (to be created) in Azure for this virtual network will be the CloudBridge end point at the Azure end of the CloudBridge Connector tunnel. You then define a private subnet for the gateway to be created. This subnet belongs to the range specified in the address space in the virtual network entity.
- **Create a gateway in Windows Azure.** Create a gateway that becomes the end point at the Azure end of the CloudBridge Connector tunnel. Azure, from its pool of public IP addresses, assigns an IP address to the gateway created.
- **Gather the public IP address of the gateway and the pre-shared key.** For a CloudBridge Connector tunnel configuration on Azure, the public IP address of the gateway and the pre-shared Key (PSK) are automatically generated by Azure. Make a note of this information. You will need it for configuring the CloudBridge Connector tunnel on the NetScaler in datacenter.

To specify a local network by using the Microsoft Windows Azure Management Portal

1. In the left pane, click NETWORKS.
2. In the lower left-hand corner of the screen, click + NEW.

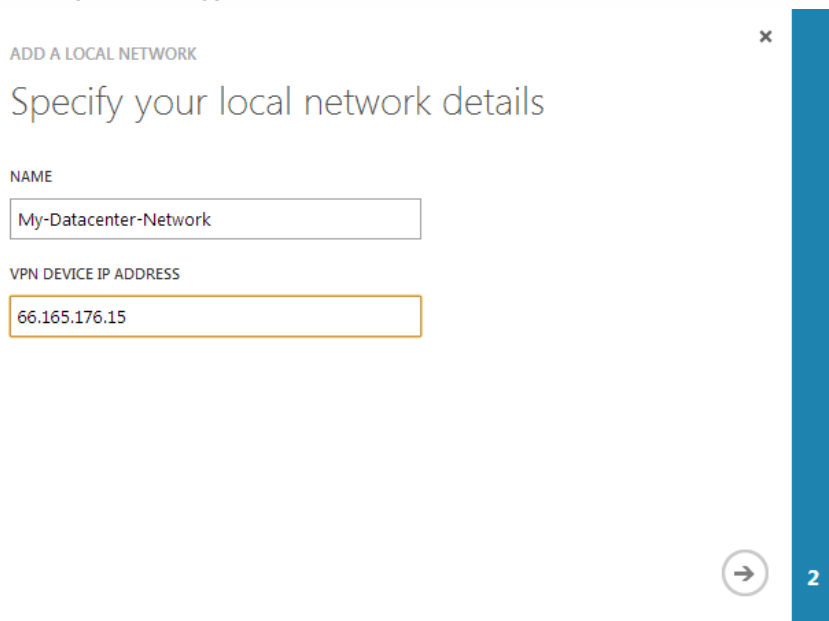

3. In the NEW navigation pane, click NETWORK, then click VIRTUAL NETWORK, and then click REGISTER LOCAL NETWORK.

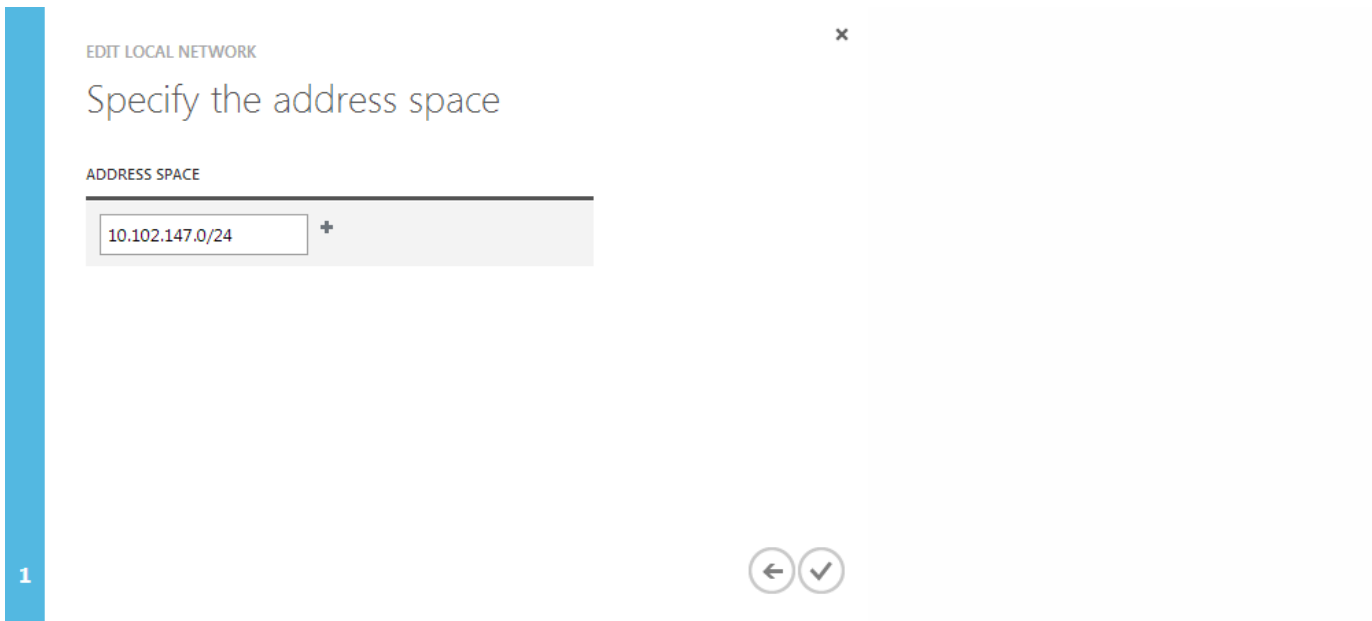

4. In the ADD A LOCAL NETWORK wizard, in the specify your local network details screen, set the following parameters:

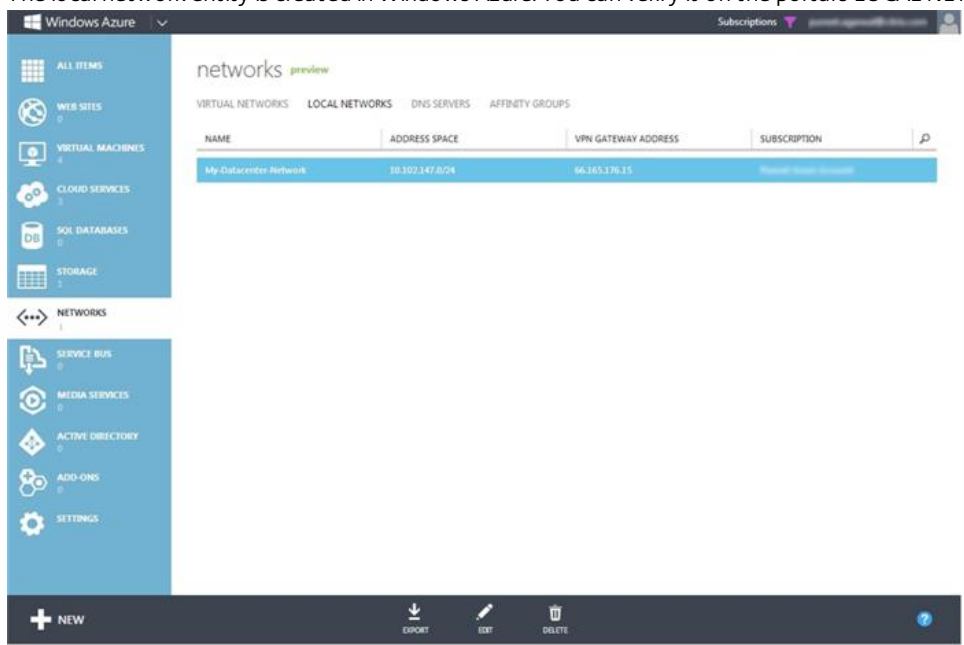

- NAME
- VPN DEVICE IP ADDRESS

5. In the lower right corner of the screen, click -> (forward arrow mark).
6. On the Specify the address space screen, set the following parameter:
 - ADDRESS SPACE

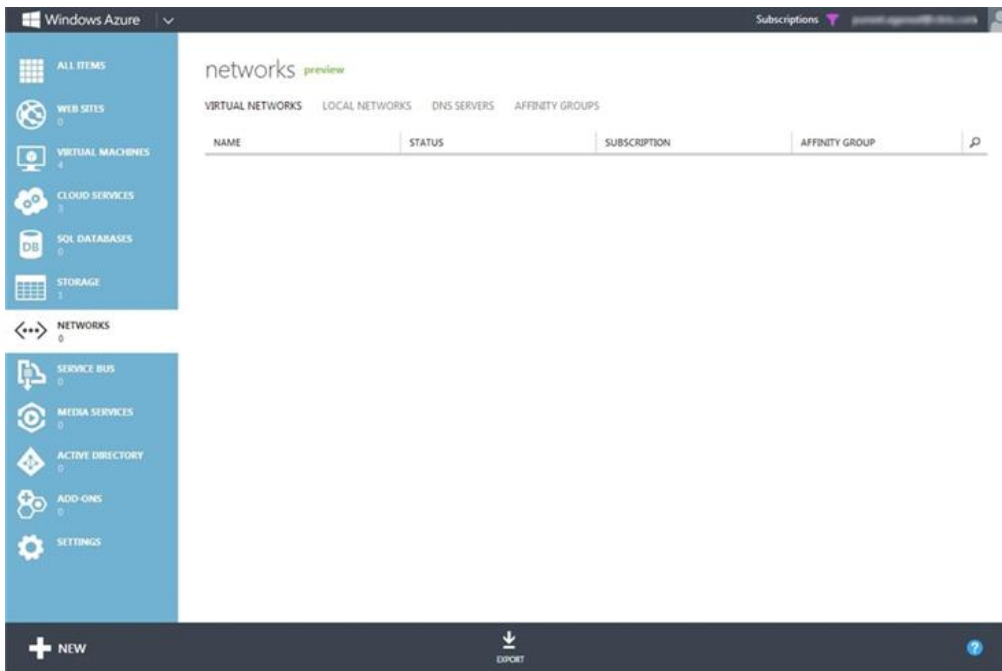

7. In the lower right corner of the screen, click the check mark.
8. The local network entity is created in Windows Azure. You can verify it on the portal's LOCAL NETWORK tab.

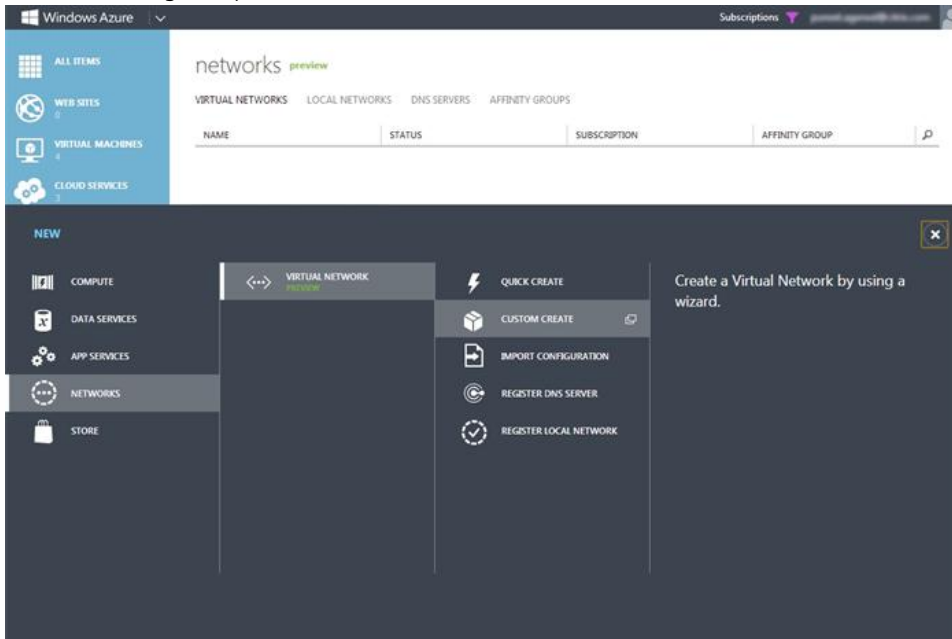

To create a virtual network in Azure by using the Microsoft Windows Azure Management Portal

1. In the left pane, click NETWORKS.
2. In the lower left-hand corner of the screen, click + New.

3. In the NEW navigation pane, click NETWORK, then click VIRTUAL NETWORK, and then click CUSTOM CREATE.

4. In the CREATE A VIRTUAL NETWORK wizard, in the Virtual Network Details screen, set the following parameters:

- NAME
- AFFINITY GROUP
- REGION
- AFFINITY GROUP NAME

- 8. Click the check mark in the lower right-hand corner of the screen.
- 9. The virtual network is created in Windows Azure and is listed on the VIRTUAL NETWORK tab.

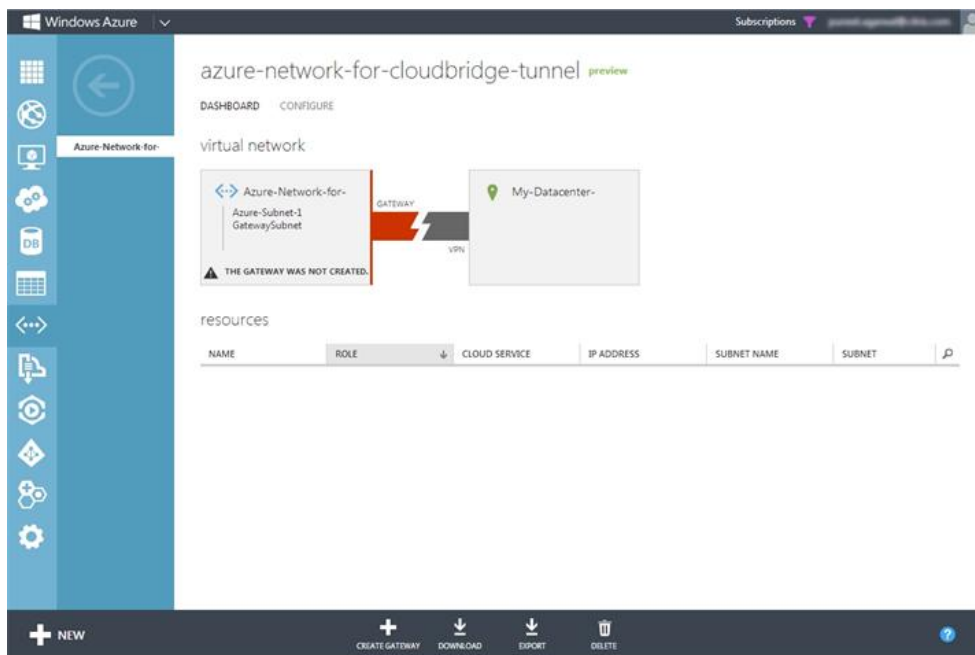

To create a gateway by using the Microsoft Windows Azure Management Portal

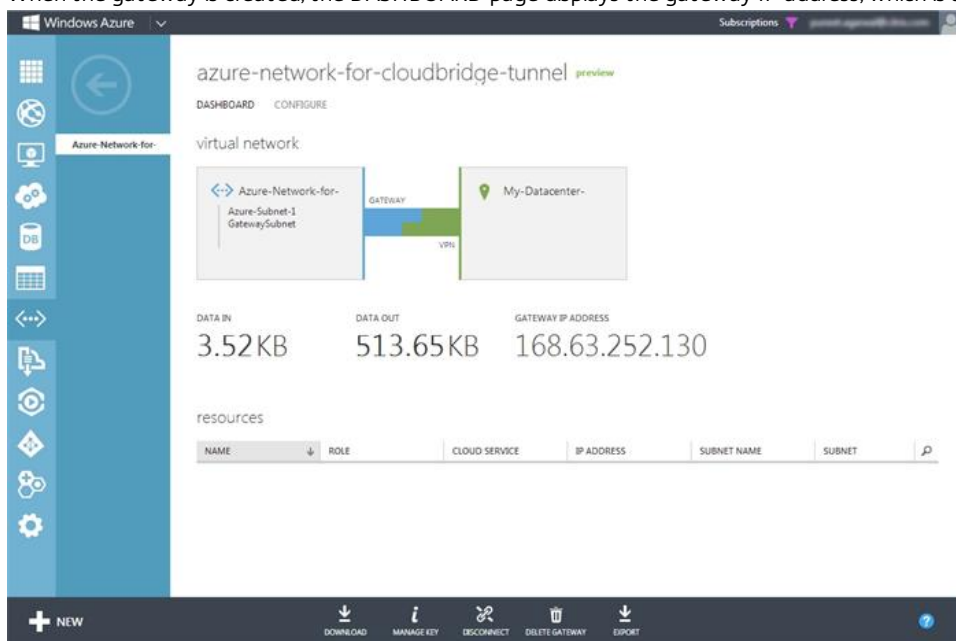

1. In the left pane, click NETWORKS.
2. On the Virtual Network tab, in the Name column, click the virtual network entity for which you want to create a gateway.

3. On the DASHBOARD page of the virtual network, at the bottom of the page, click + Create Gateway.

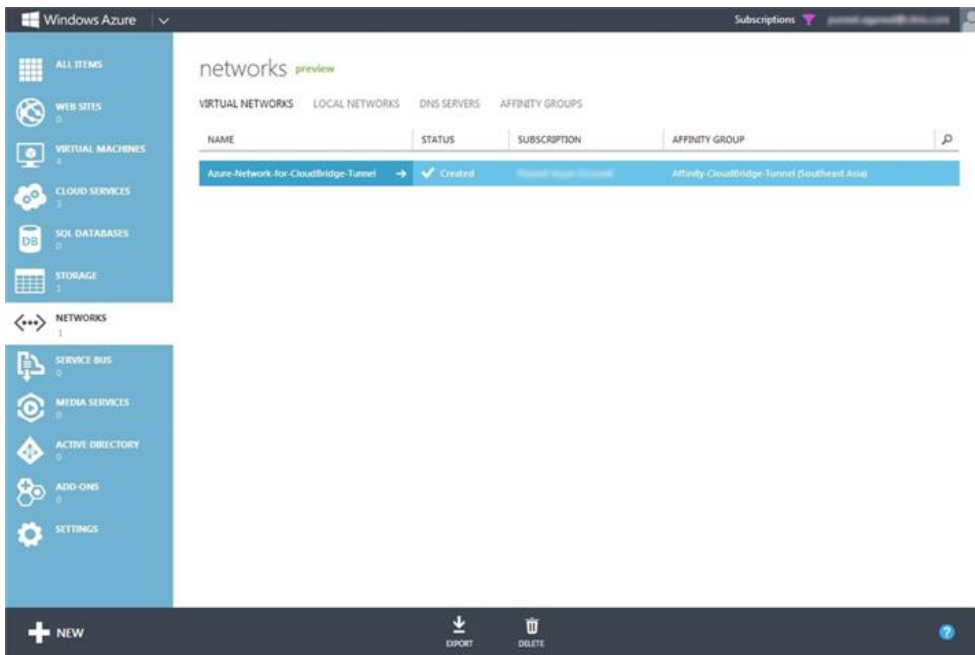

4. When prompted to confirm you want the gateway created, click YES. Creating the gateway can take up to 15 minutes.
5. When the gateway is created, the DASHBOARD page displays the gateway IP address, which is a public IP address.

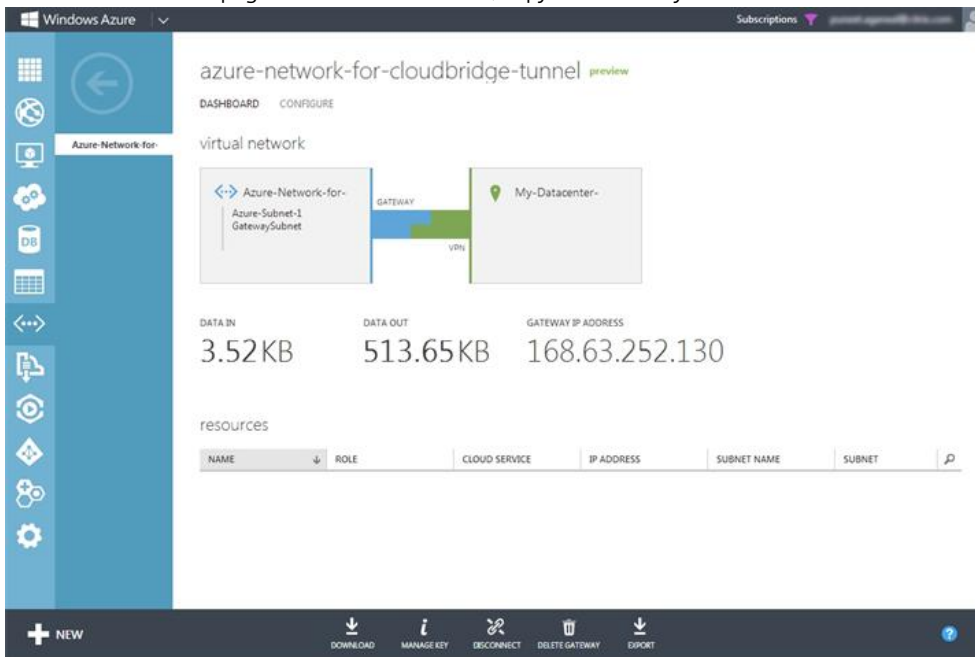

To gather public IP address of the gateway and the pre-shared key information by using the Microsoft Windows Azure Management Portal

1. In the left pane, click NETWORKS.
2. On the Virtual Network tab, in the Name column, click the virtual network entity.

3. On the DASHBOARD page of the virtual network, copy the Gateway IP Address.

4. For the Pre Shared Key (PSK), at the bottom of the page, click MANAGE KEY.

5. In the MANAGE SHARED KEY dialog box, copy the SHARED KEY.

Manage Shared Key

Use this key to configure your local network VPN device to connect to the virtual network.

Configuring the NetScaler Appliance in the Datacenter for the CloudBridge Connector Tunnel

Updated: 2014-04-15

To configure a CloudBridge Connector tunnel between a datacenter and an Azure cloud, perform the following tasks on the NetScaler in the datacenter. You can use either the NetScaler command line or the configuration utility:

- **Create an IPsec profile.** An IPsec profile entity specifies the IPsec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPsec protocol in the CloudBridge Connector tunnel.
- **Create an IP tunnel with IPsec protocol and associate the IPsec profile to it.** An IP tunnel specifies the local IP address (a public SNIP address configured on the NetScaler appliance), remote IP address (the public IP address of the gateway in Azure), protocol (IPsec) used to set up the CloudBridge Connector tunnel, and an IPsec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
- **Create a PBR rule and associate the IP tunnel to it.** A PBR entity specifies a set of conditions and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range to specify the datacenter subnet whose traffic is to traverse the tunnel, and the destination IP address range to specify the Azure subnet whose traffic is to traverse the CloudBridge Connector tunnel. Any request packet originated from a client in the subnet on the datacenter and destined to a server in the subnet on the Azure cloud matches the source and destination IP range of the PBR entity. This packet is then considered for CloudBridge Connector tunnel processing and is sent across sent across the CloudBridge Connector tunnel associated with the PBR entity.

The configuration utility combines all these tasks in a single wizard called the CloudBridge Connector wizard.

To create an IPSEC profile by using the NetScaler command line

At the Command prompt, type:

- add ipsec profile <name> -psk <string> -ikeVersion v1

To create an IPSEC tunnel and bind the IPSEC profile to it by using the NetScaler command line

At the Command prompt, type:

- add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>

To create a PBR rule and bind the IPSEC tunnel to it by using the NetScaler command line

At the Command prompt, type:

- add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>
- apply pbrs

Sample Configuration

The following commands create all settings of NetScaler appliance CB_Appliance-1 used in "Example of CloudBridge Connector Configuration and Data Flow".

```
> add ipsec profile CB_Azure_IPSec_Profile -psk DkiMgMdcBqvYREEulvxsBkKw0FOyDiLM -ikeVersion v1 -lifetime 31536000
```

```
Done
```

```
> add iptunnel CB_Azure_Tunnel 168.63.252.133 255.255.255.255 66.165.176.15 -protocol IPSEC -ipsecProfileName CB_Azure_IPSec_Profile
```

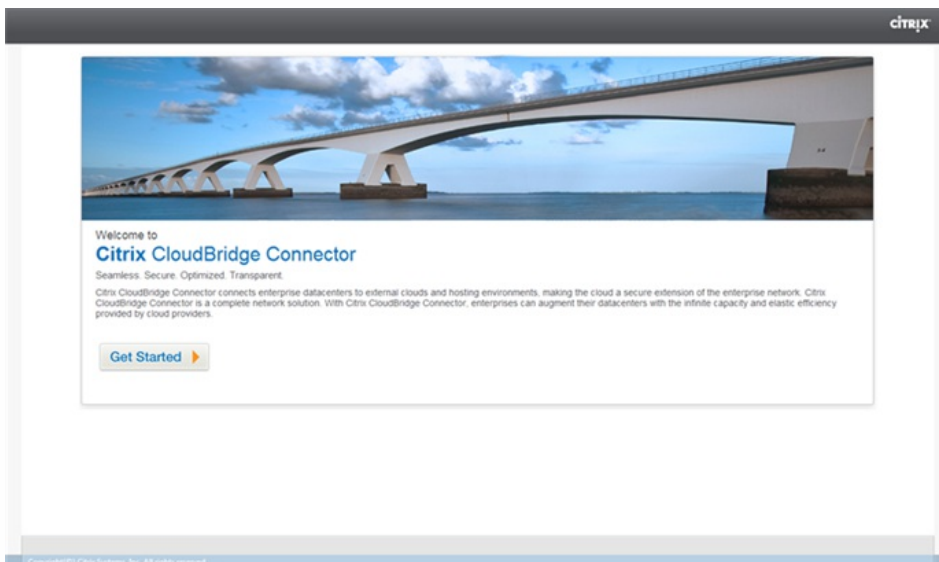

```

Done
> add pbr CB_Azure_Pbr srcIP 10.102.147.0-10.102.147.255 -destIP 10.20.0.0-10.20.255.255 -ipTunnelCB_Azure_Tunnel
Done
> apply pbrs
Done

```

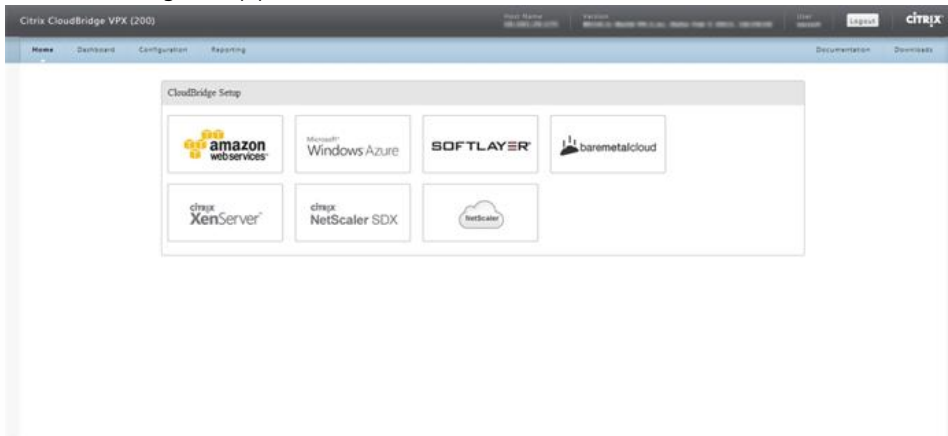

To configure a CloudBridge Connector tunnel in a NetScaler appliance by using the configuration utility

1. Access the configuration utility by using a web browser to connect to the IP address of the NetScaler appliance in the datacenter.
2. Navigate to System > CloudBridge Connector.
3. In the right pane, under Getting Started, click Create/Monitor CloudBridge.
4. Click Get Started.

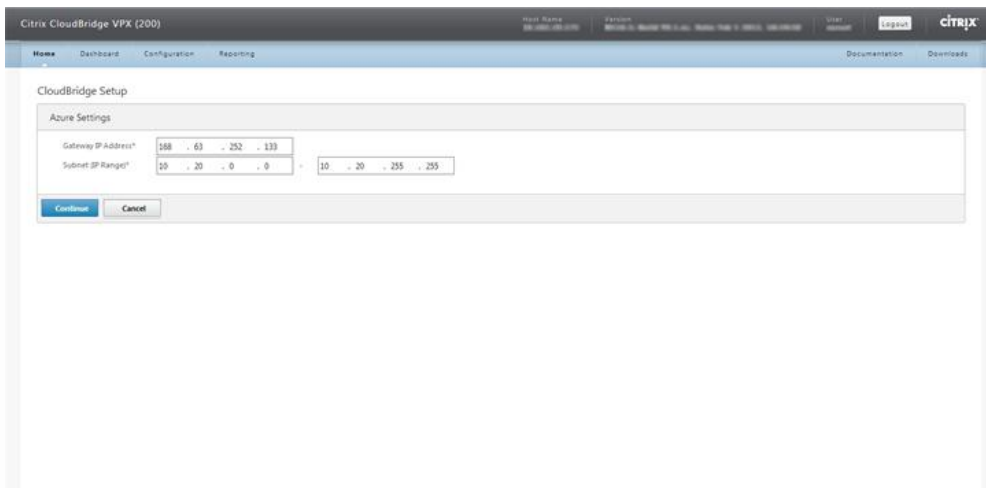

Note: If you already have any CloudBridge Connector tunnel configured on the NetScaler appliance, this screen does not appear, and you are taken to the CloudBridge Connector Setup pane.

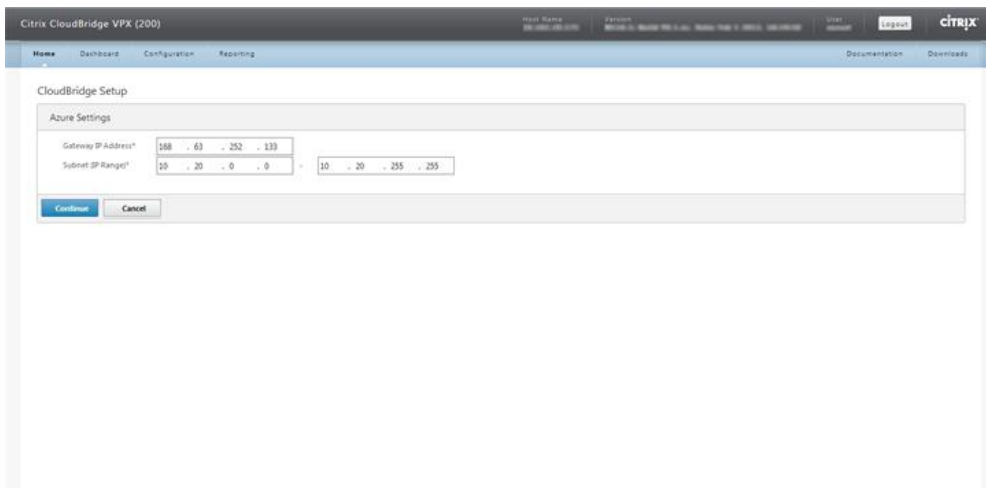

5. In the CloudBridge Setup pane, click Microsoft Windows Azure.

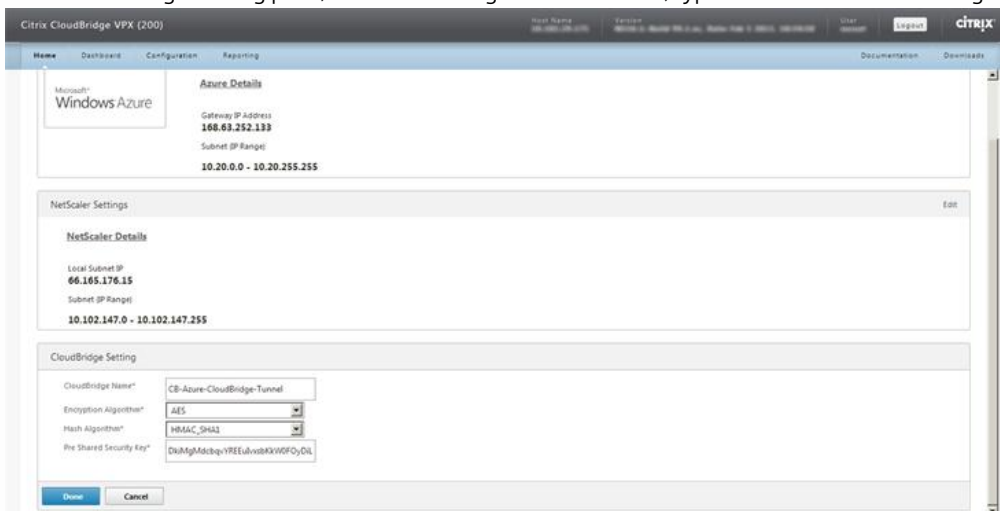

6. In the Azure Settings pane, in the Gateway IP Address* field, type the IP address of the Azure gateway. The CloudBridge Connector tunnel is then set up between the NetScaler appliance and the gateway. In the Subnet (IP Range)* text boxes, specify a subnet range (in Azure cloud), the traffic of which is to traverse the CloudBridge Connector tunnel. Click Continue.

- In the NetScaler Settings pane, from the Local Subnet IP* drop-down list, select a publicly accessible SNIP address configured on the NetScaler appliance. In Subnet (IP Range)* text boxes, specify a local subnet range, the traffic of which is to traverse the CloudBridge Connector tunnel. Click Continue.

- In the CloudBridge Setting pane, in the CloudBridge Name text box, type a name for the CloudBridge that you want to create.

- From the Encryption Algorithm and Hash Algorithm drop-down lists, select the AES and HMAC_SHA1 algorithms, respectively. In the Pre-Shared Security Key text box, type the security key.
- Click Done.

Monitoring the CloudBridge Connector Tunnel

Updated: 2014-04-15

You can view statistics for monitoring the performance of a CloudBridge Connector tunnel between the NetScaler appliance in the datacenter and Microsoft Azure. To view CloudBridge Connector tunnel statistics on the NetScaler appliance, use the configuration utility or the NetScaler command line. To view CloudBridge Connector tunnel statistics in Microsoft Azure, use the Microsoft Windows Azure Management Portal.

Displaying CloudBridge Connector tunnel Statistics in the NetScaler appliance

The following table lists the statistical counters available for monitoring CloudBridge Connector tunnels on a NetScaler appliance.

Statistical counter	Specifies
Bytes Received	Total number of bytes received by the NetScaler appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Bytes Sent	Total number of bytes sent by the NetScaler appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Packets Received	Total number of packets received by the NetScaler appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Packets Sent	Total number of packets sent by the NetScaler appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.

All these counters are reset to 0 when the NetScaler appliance is restarted. They do not increment during the following phases:

- Internet Key Exchange (IKE) authentication (pre-shared key) phase on any configured CloudBridge Connector tunnel.
- IKE Security Association (SA) establishment phase on any configured CloudBridge Connector tunnel.

To display CloudBridge Connector tunnel statistics by using the NetScaler command line

At the command prompt, type:

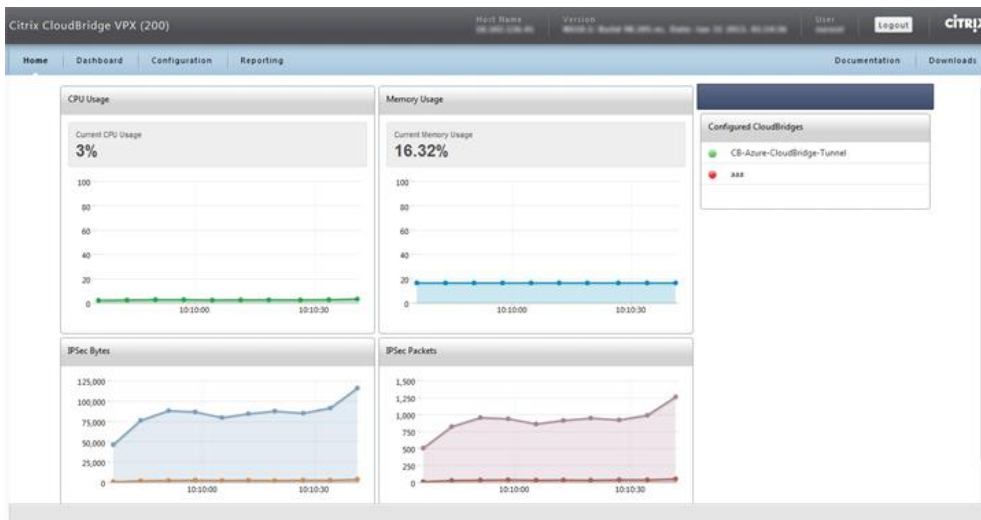

- `stat ipsec counters`

Example

```
> stat ipsec counters
Secure tunnel(s) summary
      Rate (/s)      Total
Bytes Received 0 2811248
Bytes Sent 0 157460630
Packets Received 0 56787
Packets Sent 0 200910
Done
>
```

To display CloudBridge Connector tunnel statistics by using the Configuration utility

1. Access the configuration utility by using a web browser to connect to the IP address of the NetScaler appliance.
2. On the Home tab, the IPSec Bytes and IPSec Packets charts display the statistics of all the CloudBridge Connector tunnels configured on the NetScaler appliance.

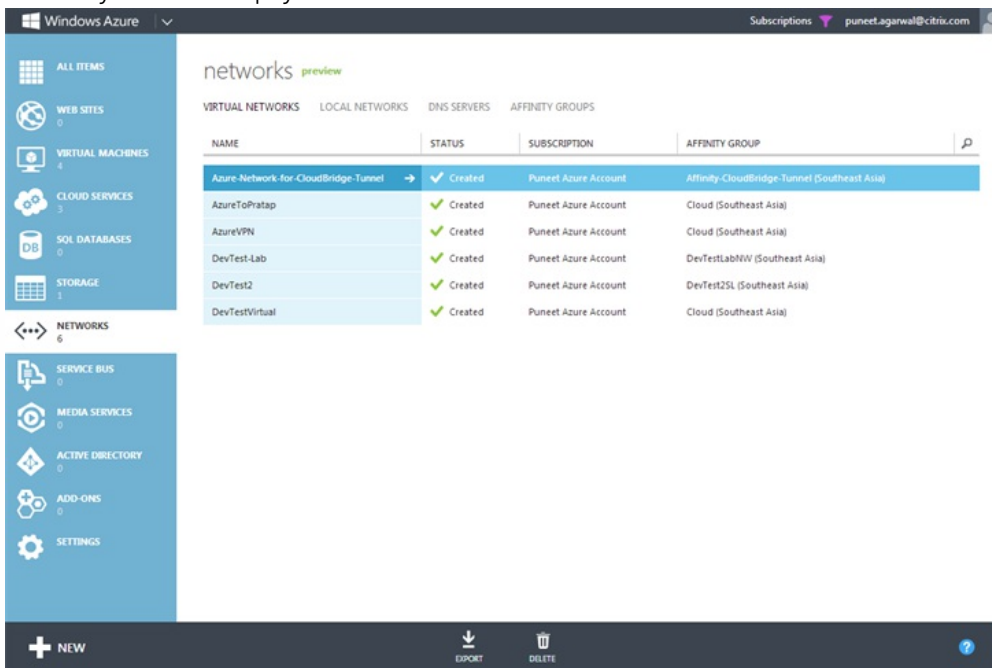

Displaying CloudBridge Connector tunnel Statistics in Microsoft Azure

The following table lists the statistical counters available for monitoring CloudBridge Connector tunnels in Microsoft Azure.

Statistical counter	Specifies
DATA IN	Total number of kilobytes received by the Azure gateway through the CloudBridge Connector tunnel since the gateway was created.
DATA OUT	Total number of kilobytes sent by the Azure gateway through the CloudBridge Connector tunnel since the gateway was created.

To display CloudBridge Connector tunnel statistics by using the Microsoft Windows Azure Management Portal

1. Log on to the Windows Azure Management Portal (<https://manage.windowsazure.com/>) by using your Microsoft Azure account credentials.
2. In the left pane, click NETWORKS.
3. On the Virtual Network tab, in the Name column, select the virtual network entity associated with a CloudBridge Connector tunnel whose statistics you want to display.

4. On the DASHBOARD page of the virtual network, view the DATA IN and DATA OUT counters for the CloudBridge Connector tunnel.

Configuring CloudBridge Connector Tunnel between Datacenter and SoftLayer Enterprise Cloud

Jan 31, 2014

The configuration utility includes a wizard that helps you to easily configure a CloudBridge Connector tunnel between a NetScaler appliance in a datacenter and NetScaler VPX instances on the SoftLayer enterprise cloud.

When you use the wizard of the NetScaler appliance in the datacenter, the CloudBridge Connector tunnel configuration created on the NetScaler appliance, is automatically pushed to the other endpoint or peer (the NetScaler VPX on SoftLayer) of the CloudBridge Connector tunnel.

Using the wizard of the NetScaler appliance in the datacenter, you perform the following steps to configure a CloudBridge Connector tunnel.

1. Connect to the Softlayer enterprise cloud by providing the user log on credentials.
2. Select the Citrix XenServer that is running the NetScaler VPX appliance.
3. Select the NetScaler VPX appliance.
4. Provide CloudBridge Connector tunnel parameters to:
 - Configure a GRE Tunnel.
 - Configure IPsec on the GRE tunnel.
 - Create a netbridge, which is a logical representation of the CloudBridge connector, by specifying a name.
 - Bind the GRE Tunnel to the netbridge.

To configure a CloudBridge Connector tunnel by using the configuration utility

1. Log on to the configuration utility of the NetScaler appliance in the datacenter by using your account credentials for the appliance.
2. Navigate to System > CloudBridge Connector .
3. In the right pane, under Getting Started, click Create/Monitor CloudBridge Connector.
4. Click Get Started.
Note: If you already have any CloudBridge Connector tunnel configured on the NetScaler appliance, this screen does not appear, and you are taken to the CloudBridge Connector Setup pane.
5. In the CloudBridge Connector Setup pane, click Softlayer, and then follow the instructions in the wizard.

High Availability

Mar 19, 2012

A high availability (HA) deployment of two Citrix® NetScaler® appliances can provide uninterrupted operation in any transaction. With one appliance configured as the primary node and the other as the secondary node, the primary node accepts connections and manages servers while the secondary node monitors the primary. If, for any reason, the primary node is unable to accept connections, the secondary node takes over.

The secondary node monitors the primary by sending periodic messages (often called heartbeat messages or health checks) to determine whether the primary node is accepting connections. If a health check fails, the secondary node retries the connection for a specified period, after which it determines that the primary node is not functioning normally. The secondary node then takes over for the primary (a process called failover).

After a failover, all clients must reestablish their connections to the managed servers, but the session persistence rules are maintained as they were before the failover.

With Web server logging persistence enabled, no log data is lost due to the failover. For logging persistence to be enabled, the log server configuration must carry entries for both systems in the log.conf file.

The following figure shows a network configuration with an HA pair.

Figure 1. NetScaler Appliances in a High Availability Configuration

To configure HA, you might want to begin by creating a basic setup, with both nodes in the same subnet. You can then customize the intervals at which the nodes communicate health-check information, the process by which nodes maintain synchronization, and the propagation of commands from the primary to the secondary. You can configure fail-safe mode to prevent a situation in which neither node is primary. If your environment includes devices that do not accept NetScaler gratuitous ARP messages, you should configure virtual MAC addresses. When you are ready for a more complex configuration, you can configure HA nodes in different subnets.

To improve the reliability of your HA setup, you can configure route monitors and create redundant links. In some situations, such as when troubleshooting or performing maintenance tasks, you might want to force a node to fail over (assign primary

status to the other node), or you might want to force the secondary node to stay secondary or the primary node to stay primary.

Considerations for a High Availability Setup

Mar 19, 2012

Note the following requirements for configuring systems in an HA setup:

- In an HA configuration, the primary and secondary NetScaler appliances should be of the same model. Different NetScaler models are not supported in an HA pair (for example, you cannot configure a 10010 model and a 7000 model as an HA pair).
- In an HA setup, both nodes must run the same version of NetScaler, for example, nCore/nCore or classic/classic. If the nodes are running NetScaler classic and you want to migrate to NetScaler nCore of the same NetScaler release, prop and sync are not supported during the migration process. Once migration is complete, prop and sync are auto-enabled. The same applies if you migrate from NetScaler nCore to NetScaler classic.
- Entries in the configuration file (ns.conf) on both the primary and the secondary system must match, with the following exceptions:
 - The primary and the secondary systems must each be configured with their own unique NetScaler IP addresses (NSIPs.)
 - In an HA pair, the node ID and associated IP address of one node must point to the other node. For example, if you have nodes NS1 and NS2, you must configure NS1 with a unique node ID and the IP address of NS2, and you must configure NS2 with a unique node ID and the IP address of NS1.
- If you create a configuration file on either node by using a method that does not go directly through the GUI or the CLI (for example, importing SSL certificates, or changing to startup scripts), you must copy the configuration file to the other node or create an identical file on that node.
- Initially, all NetScaler appliances are configured with the same RPC node password. RPC nodes are internal system entities used for system-to-system communication of configuration and session information. For security, you should change the default RPC node passwords.

One RPC node exists on each NetScaler. This node stores the password, which is checked against the password provided by the contacting system. To communicate with other systems, each NetScaler requires knowledge of those systems, including how to authenticate on those systems. RPC nodes maintain this information, which includes the IP addresses of the other systems, and the passwords they require for authentication.

RPC nodes are implicitly created when adding a node or adding a Global Server Load Balancing (GSLB) site. You cannot create or delete RPC nodes manually.

Note: If the NetScaler appliances in a high availability setup are configured in one-arm mode, you must disable all system interfaces except the one connected to the switch or hub.

- For an IPv6 HA configuration, the following considerations apply:
 - You must install the IPv6PT license on both NetScaler appliances.
 - After installing the IPv6PT license, enable the IPv6 feature by using the configuration utility or the command line interface.
 - Both NetScaler appliances require a global NSIP IPv6 address. In addition, network entities (for example, switches and routers) between the two nodes must support IPv6.

Configuring High Availability

Mar 19, 2012

To set up a high availability configuration, you create two nodes, each of which defines the other's NetScaler IP (NSIP) address as a remote node. Begin by logging on to one of the two NetScaler appliances that you want to configure for high availability, and add a node. Specify the other appliance's NetScaler IP (NSIP) address as the address of the new node. Then, log on to the other appliance and add a node that has the NSIP address of the first appliance. An algorithm determines which node becomes primary and which becomes secondary.

Note: The configuration utility provides an option that avoids having to log on to the second appliance.

The following figure shows a simple HA setup, in which both nodes are in same subnet.

Figure 1. Two NetScaler Appliances Connected in a High Availability Configuration

Adding a Remote Node

To add a remote NetScaler appliance as a node in a high availability setup, you specify a unique node ID and the appliance's NSIP. The maximum number of node IDs in an HA setup is 64. When you add an HA node, you must disable the HA monitor for each interface that is not connected or not being used for traffic. For CLI users, this is a separate procedure.

Note: To ensure that each node in the high availability configuration has the same settings, you should synchronize your SSL certificates, startup scripts, and other configuration files with those on the primary node.

To add a node by using the command line interface

At the command prompt, type:

- add ha node <id> <IPAddress>
- show ha node

Example

```
> add ha node 10 1000:0000:0000:0000:0005:0600:700a:888b
```

To disable an HA monitor by using the command line interface

At the command prompt, type:

- set interface <ifNum> [-haMonitor (**ON** | **OFF**)]
- show interface <ifNum>

Example

```
> set interface 1/3 -haMonitor OFF
```

Done

To add a remote node by using the configuration utility

Navigate to System > High Availability and, on the Nodes tab, add a new remote node, or edit an existing node.

Disabling or Enabling a Node

Updated: 2013-08-28

You can disable or enable only a secondary node. When you disable a secondary node, it stops sending heartbeat messages to the primary node, and therefore the primary node can no longer check the status of the secondary. When you enable a node, the node takes part in the high availability configuration.

To disable or enable a node by using the command line interface

At the command prompt, type one of the following commands:

- set ha node -hastatus DISABLED
- set ha node -hastatus ENABLED

To disable or enable a node by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. In the High Availability Status list, select ENABLED (Actively Participate in HA) or DISABLED (Do not participate in HA).

Removing a Node

Updated: 2013-08-28

If you remove a node, the nodes are no longer in high availability configuration.

To remove a node by using the command line interface

At the command prompt, type:

```
rm ha node <id>
```

Example

```
> rm ha node 10
```

```
Done
```

To remove a node by using the configuration utility

Navigate to System > High Availability and, on the Nodes tab, delete the node.

Note: You can use the Network Visualizer to view the NetScaler appliances that are configured as a high availability (HA) pair and perform high availability configuration tasks. For more information, see "[Using the Network Visualizer](#)."

Configuring the Communication Intervals

Mar 19, 2012

The hello interval is the interval at which the heartbeat messages are sent to the peer node. The dead interval is the time interval after which the peer node is marked DOWN if heartbeat packets are not received. The heartbeat messages are UDP packets sent to port 3003 of the other node in an HA pair.

To set the hello and dead intervals by using the command line interface

At the command prompt, type:

- set HA node [-helloInterval <msecs>] [-deadInterval <secs>]
- show HA node <id>

To set the hello and dead intervals by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Set the following parameters:
 - Hello Interval (msecs)
 - Dead Interval (secs)

Configuring Synchronization

Mar 19, 2012

Synchronization is a process of duplicating the configuration of the primary node on the secondary node. The purpose of synchronization is to ensure that there is no loss of configuration information between the primary and the secondary nodes, regardless of the number of failovers that occur. Synchronization uses port 3010.

Synchronization is triggered by either of the following circumstances:

- The secondary node in an HA setup comes up after a restart.
- The primary node becomes secondary after a failover.

Automatic synchronization is enabled by default. You can also force synchronization.

Disabling or Enabling Synchronization

Updated: 2013-08-28

Automatic HA synchronization is enabled by default on each node in an HA pair. You can enable or disable it on either node.

To disable or enable automatic synchronization by using the command line interface

At the command prompt, type:

- set HA node -haSync DISABLED
- set HA node -haSync ENABLED

To disable or enable synchronization by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Under HA Synchronization, clear or select the Secondary node will fetch the configuration from Primary option.

Forcing the Secondary Node to Synchronize with the Primary Node

Updated: 2013-08-28

In addition to automatic synchronization, the NetScaler supports forced synchronization. You can force the synchronization from either the primary or the secondary node. When you force synchronization from the secondary node, it starts synchronizing its configuration with the primary node.

However, if synchronization is already in progress, forced synchronization fails and the system displays a warning. Forced synchronization also fails in any of the following circumstances:

- You force synchronization on a standalone system.
- The secondary node is disabled.
- HA synchronization is disabled on the secondary node.

To force synchronization by using the command line interface

At the command prompt, type:

force HA sync

To force synchronization by using the configuration utility

1. Navigate to System > High Availability.
2. On the Nodes tab, in the Action list, click Force Synchronization.

Synchronizing Configuration Files in a High Availability Setup

Sep 05, 2013

In a high availability setup, you can synchronize various configuration files from the primary node to the secondary node.

To perform the synchronization, you can use the command line interface or the configuration utility at either the primary or the secondary node. Files located on the secondary that are specific to the secondary (not present on the primary) are not deleted during the synchronization.

To synchronize files in a high availability setup by using the command line interface

At the command prompt, type:

```
sync HA files <mode>
```

Example

```
> sync HA files all
```

```
Done
```

To synchronize files in a high availability setup by using the configuration utility

Navigate to System > Diagnostics and, in the Utilities group, click Start HA files synchronization.

Configuring Command Propagation

Aug 28, 2013

In an HA setup, any command issued on the primary node propagates automatically to, and is executed on, the secondary before it is executed on the primary. If command propagation fails, or if command execution fails on the secondary, the primary node executes the command and logs an error. Command propagation uses port 3010.

In an HA pair configuration, command propagation is enabled by default on both the primary and secondary nodes. You can enable or disable command propagation on either node in an HA pair. If you disable command propagation on the primary node, commands are not propagated to the secondary node. If you disable command propagation on the secondary node, commands propagated from the primary are not executed on the secondary node.

Note: After reenabling propagation, remember to force synchronization.

If synchronization occurs while you are disabling propagation, any configuration-related changes that you make before the disabling of propagation takes effect are synchronized with the secondary node. This is also true for cases where propagation is disabled while synchronization is in progress.

To disable or enable command propagation by using the command line interface

At the command prompt, type:

- set HA node -haProp DISABLED
- set HA node -haProp ENABLED

To disable or enable command propagation by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Clear or select the Primary node will propagate configuration to the Secondary option.

Restricting High-Availability Synchronization Traffic to a VLAN

Dec 18, 2015

In a high availability (HA) deployment, traffic related to maintaining the HA configuration flows between the two HA nodes. This traffic is of the following types:

- Config synchronization
- Config propagation
- Connection mirroring
- Load balancing persistency config synchronization
- Persistent session synchronization
- Session state synchronization

Proper flow of this HA related traffic between the two nodes is critical for the functioning of the HA deployment. Typically, the HA related traffic is small in volume but can become very high during a failover. It becomes very high if stateful connection failover is enabled and the node that was primary before the failover was handling a large number of connections.

By default, the HA related traffic flows through the VLANs to which the NSIP address is bound. To accommodate a potential surge in this traffic, you can separate the HA related traffic from the management traffic and restrict its flow to a separate VLAN. This VLAN is called the HA SYNC VLAN.

Points to Consider before Configuring an HA SYNC VLAN

- The configuration of an HA SYNC VLAN is neither propagated nor synchronized. In other words, the HA SYNC VLAN is node specific and is configured independently on each nodes.
- HA SYNC VLAN configuration is removed when you clear the configuration in only FULL mode.
- HA MON must be set to OFF for interfaces that are part of the HA SYNC VLAN, to avoid a situation in which both nodes function as the primary node.
- Management interfaces (for example, 0/1 and 0/2) must not be part of the HA SYNC VLAN, so that HA related traffic does not flow through management interfaces.

To configure an HA SYNC VLAN on a NetScaler node, specify a configured VLAN with the HA SYNC VLAN parameter of the local node entity.

To configure an HA SYNC VLAN on a local node by using the command line

At the command prompt, type:

```
> set node -hasyncvlan <VLANID>
```

```
> show node
```

Parameter Description

Hasyncvlan (Sync VLAN)

VLAN on which HA related traffic is sent. This includes traffic for synchronization, propagation, connection mirroring, load balancing persistency, configuration synchronization, persistent session synchronization, and session state synchronization. However, HA he any interface.

To configure an HA SYNC VLAN on a node by using the configuration utility

1. Navigate to System > High Availability.

Set the Sync VLAN parameter while modifying the local node.

Configuring Fail-Safe Mode

Aug 28, 2013

In an HA configuration, fail-safe mode ensures that one node is always primary when both nodes fail the health check. This is to ensure that when a node is only partially available, backup methods are enabled to handle traffic as best as possible. The HA fail-safe mode is configured independently on each node.

The following table shows some of the fail-safe cases. The NOT_UP state means that the node failed the health check yet it is partially available. The UP state means that the node passed the health check.

Table 1. Fail-Safe Mode Cases

Node A (Primary) Health State	Node B (Secondary) Health State	Default HA Behavior	Fail-Safe Enabled HA Behavior	Description
NOT_UP (failed last)	NOT_UP (failed first)	A (Secondary), B (Secondary)	A (Primary), B (Secondary)	If both nodes fail, one after the other, the node that was the last primary remains primary.
NOT_UP (failed first)	NOT_UP (failed last)	A (Secondary), B (Secondary)	A (Secondary), B (Primary)	If both nodes fail, one after the other, the node that was the last primary remains primary.
UP	UP	A (Primary), B (Secondary)	A (Primary), B (Secondary)	If both nodes pass the health check, no change in behavior with fail-safe enabled.
UP	NOT_UP	A (Primary), B (Secondary)	A (Primary), B (Secondary)	If only the secondary node fails, no change in behavior with fail-safe enabled.
NOT_UP	UP	A (Secondary), B (Primary)	A (Secondary), B (Primary)	If only the primary fails, no change in behavior with fail-safe enabled.
NOT_UP	UP (STAYSECONDARY)	A (Secondary), B (Secondary)	A (Primary), B (Secondary)	If the secondary is configured as STAYSECONDARY, the primary remains primary even if it fails.

To enable fail-safe mode by using the command line interface

At the command prompt, type:

```
set HA node [-failSafe ( ON | OFF )]
```

Example

```
set ha node -failsafe ON
```

To enable fail-safe mode by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Under Fail-Safe Mode, select the Maintain one Primary node even when both nodes are unhealthy option.

Configuring Virtual MAC Addresses

Mar 19, 2012

A Virtual MAC address (VMAC) is a floating entity shared by the primary and the secondary nodes in an HA setup.

In an HA setup, the primary node owns all of the floating IP addresses, such as the MIPs, SNIPs, and VIPs. The primary node responds to Address Resolution Protocol (ARP) requests for these IP addresses with its own MAC address. As a result, the ARP table of an external device (for example, an upstream router) is updated with the floating IP address and the primary node's MAC address.

When a failover occurs, the secondary node takes over as the new primary node. It then uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it acquired from the primary. However, the MAC address that the new primary advertises is the MAC address of its own interface.

Some devices (notably a few routers) do not accept the GARP messages generated by the NetScaler appliance. As a result, some external devices retain the old IP to MAC mapping advertised by the old primary node. This can result in a site going down.

You can overcome this problem by configuring a VMAC on both nodes of an HA pair. Both nodes then possess identical MAC addresses. Therefore, when failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

To create a VMAC, you need to first create a Virtual Router ID (VRID) and bind it to an interface. (In an HA setup, you need to bind the VRID to the interfaces on both nodes.) Once the VRID is bound to an interface, the system generates a VMAC with the VRID as the last octet.

This section includes the following details:

- [Configuring IPv4 VMACs](#)
- [Configuring IPv6 VMAC6s](#)

Configuring IPv4 VMACs

When you create a IPv4 VMAC address and bind it to a interface, any IPv4 packet sent from the interface uses the VMAC address that is bound to the interface. If there is no IPv4 VMAC bound to an interface, the interface's physical MAC address is used.

The generic VMAC is of the form 00:00:5e:00:01:<VRID>. For example, if you create a VRID with a value of 60 and bind it to an interface, the resulting VMAC is 00:00:5e:00:01:3c, where 3c is the hex representation of the VRID. You can create 255 VRIDs with values from 1 to 255.

Creating or Modifying an IPv4 VMAC

Updated: 2013-08-28

You create an IPv4 virtual MAC by assigning it a virtual router ID. You can then you bind the VMAC to an interface. You cannot bind multiple VRIDs to the same interface. To verify the VMAC configuration, you should display and examine the VMACs and the interfaces bound to the VMACs.

To add a VMAC by using the command line interface

At the command prompt, type:

- add vrid <id>
- bind vrid <id> -ifnum <interface_name>
- show vrid

Example

```
> add vrid 100
Done
> bind vrid 100 -ifnum 1/1 1/2 1/3
Done
```

To unbind interfaces from a VMAC by using the command line interface

At the command prompt, type:

- unbind vrid <id> -ifnum <interface_name>
- show vrid

To configure a VMAC by using the configuration utility

Navigate to System > Network > VMAC and, on the VMAC tab, add a new VMAC, or edit an existing VMAC.

Removing an IPv4 VMAC

Updated: 2013-08-28

To remove an IPv4 virtual MAC, you delete its virtual router ID.

To remove an IPv4 VMAC by using the command line interface

At the command prompt, type:

```
rm vrid <id>
```

Example

```
rm vrid 100s
```

To remove an IPv4 VMAC by using the configuration utility

Navigate to System > Network > VMAC and, on the VMAC tab, delete the IPv4 VMAC.

Configuring IPv6 VMAC6s

The NetScaler supports VMAC6 for IPv6 packets. You can bind any interface to a VMAC6, even if an IPv4 VMAC is bound to the interface. Any IPv6 packet sent from the interface uses the VMAC6 bound to that interface. If there is no VMAC6 bound to an interface, an IPv6 packet uses the physical MAC.

Creating or Modifying a VMAC6

Updated: 2013-08-28

You create an IPv6 virtual MAC by assigning it an IPv6 virtual router ID. You can then you bind the VMAC to an interface. You cannot bind multiple IPv6 VRIDs to an interface. To verify the VMAC6 configuration, you should display and examine the VMAC6s and the interfaces bound to the VMAC6s.

To add a VMAC6 by using the command line interface

At the command prompt, type:

- add vrid6 <id>
- bind vrid6 <id> -if num <interface_name>
- show vrid6

Example

```
> add vrid6 100
```

```
Done
```

```
> bind vrid6 100 -ifnum 1/1 1/2 1/3
```

```
Done
```

To unbind interfaces from a VMAC6 by using the command line interface

At the command prompt, type:

- unbind vrid6 <id> -if num <interface_name>
- show vrid6

To configure a VMAC6 by using the configuration utility

Navigate to System > Network > VMAC and, on the VMAC6 tab, add a new VMAC6, or edit an existing VMAC6.

Removing a VMAC6

Updated: 2013-08-28

To remove an IPv4 virtual MAC, you delete its virtual router ID.

To remove a VMAC6 by using the command line interface

At the command prompt, type:

```
rm vrid6 <id>
```

Example

```
rm vrid6 100s
```

To remove a VMAC6 by using the configuration utility

Navigate to System > Network > VMAC and, on the VMAC6 tab, delete the virtual router ID.

Configuring High Availability Nodes in Different Subnets

Mar 19, 2012

The following figure shows an HA deployment with the two systems located in different subnets:

Figure 1. High Availability over a Routed Network

In the figure, the systems NS1 and NS2 are connected to two separate routers, R3 and R4, on two different subnets. The NetScaler appliances exchange heartbeat packets through the routers. This configuration could be expanded to accommodate deployments involving any number of interfaces.

Note: If you use static routing on your network, you must add static routes between all the systems to ensure that heartbeat packets are sent and received successfully. (If you use dynamic routing on your systems, static routes are unnecessary.)

If the nodes in an HA pair reside on two separate networks, the primary and secondary node must have independent network configurations. This means that nodes on different networks cannot share entities such as MIPs, SNIPs, VLANs, and routes. This type of configuration, where the nodes in an HA pair have different configurable parameters, is known as Independent Network Configuration (INC) or Symmetric Network Configuration (SNC).

The following table summarizes the configurable entities and options for an INC, and shows how they must be set on each node.

Table 1. Behavior of NetScaler Entities and Options in an Independent Network Configuration

NetScaler entities	Options

NetScaler entities	Options
IPs (NSIP/MIP/SNIPs)	Node-specific. Active only on that node.
VIPs	Floating.
VLANs	Node-specific. Active only on that node.
Routes	Node-specific. Active only on that node. Link load balancing routes are floating.
ACLs	Floating (Common). Active on both nodes.
Dynamic routing	Node-specific. Active only on that node. The secondary node should also run the routing protocols and peer with upstream routers.
L2 mode	Floating (Common). Active on both nodes.
L3 mode	Floating (Common). Active on both nodes.
Reverse NAT (RNAT)	Node-specific. RNAT with VIP, because NATIP is floating.

As in configuring HA nodes in the same subnet, to configure HA nodes in different subnets, you log on to each of the two NetScaler appliances and add a remote node representing the other appliance.

Adding a Remote Node

When two nodes of an HA pair reside on different subnets, each node must have a different network configuration. Therefore, to configure two independent systems to function as an HA pair, you must specify INC mode during the configuration process.

When you add an HA node, you must disable the HA monitor for each interface that is not connected or not being used for traffic. For CLI users, this is a separate procedure.

To add a node by using the command line interface

At the command prompt, type:

- add ha node <id> <IPAddress> -inc ENABLED
- show ha node

Example

```
> add ha node 3 10.102.29.170 -inc ENABLED
Done
> add ha node 3 1000:0000:0000:0000:0005:0600:700a:888b
```

Done

To disable an HA monitor by using the command line interface

At the command prompt, type:

- set interface <ifNum> [-haMonitor (**ON** | **OFF**)]
- show interface <ifNum>

Example

```
> set interface 1/3 -haMonitor OFF
```

Done

To add a remote node by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, add a new remote node.
2. Make sure to select the Turn off HA monitor on interfaces/channels that are down and Turn on INC (Independent Network Configuration) mode on self mode options.

Removing a Node

Updated: 2013-08-28

If you remove a node, the nodes are no longer in high availability configuration.

To remove a node by using the command line interface

At the command prompt, type:

```
rm ha node <id>
```

Example

```
> rm ha node 2
```

Done

To remove a node by using the configuration utility

Navigate to System > High Availability and, on the Nodes tab, delete the node.

Note: You can use the Network Visualizer to view the NetScaler appliances that are configured as a high availability (HA) pair and perform high availability configuration tasks. For more information, see "[Using the Network Visualizer](#)."

Configuring Route Monitors

Sep 06, 2013

You can use route monitors to make the HA state dependent on the internal routing table, whether or not the table contains any dynamically learned or static routes. In an HA configuration, a route monitor on each node watches the internal routing table to make sure that a route entry for reaching a particular network is always present. If the route entry is not present, the state of the route monitor changes to DOWN.

When a NetScaler appliance has only static routes for reaching a network, and you want to create a route monitor for the network, you must enable monitored static routes (MSR) for the static routes. MSR removes unreachable static routes from the internal routing table. If MSR is disabled on static routes, an unreachable static route can remain in the internal routing table, defeating the purpose of having the route monitor.

Route Monitors are supported both in non-INC and INC mode.

Route Monitors in HA in non-INC mode	Route Monitors in HA in INC mode
Route monitors are propagated by nodes and exchanged during synchronization.	Route monitors are neither propagated by nodes nor exchanged during synchronization.
Route monitors are active only in the current primary node.	Route monitors are active on both the primary and the secondary node.
The NetScaler appliance always displays the state of a route monitor as UP irrespective of the whether the route entry is present or not in the internal routing table.	The NetScaler appliance displays the state of the route monitor as DOWN if the corresponding route entry is not present in the internal routing table.
A route monitor starts monitoring its route after 180 seconds in the following cases [This is done to allow dynamic routes to get learnt, which may take 180 secs]: <ul style="list-style-type: none">• reboot• failover• set route6 command for v6 routes• set route msr enable/disable command for v4 routes.• adding a new route monitor	-

Route monitors are useful in a non-INC mode HA configuration where you want the non-reachability of a gateway from a primary node to be one of the conditions for HA failover.

Consider an example of a non-INC mode HA setup in a two-arm topology that has NetScaler appliances NS1 and NS2 in the same subnet, with router R1 and switches SW1, SW2, and SW3.

Because R1 is the only router in this setup, you want the HA setup to failover whenever R1 is not reachable from the current primary node. You can configure a route monitor (say, RM1 and RM2, respectively) on each of the nodes to monitor the reachability of R1 from that node.

Figure 1.

With NS1 as the current primary node, the execution flow is as follows:

1. Route monitor RM1 on NS1 monitors NS1's internal routing table for the presence of a route entry for router R1. NS1 and NS2 exchange heartbeat messages through switch SW1 or SW3 at regular intervals.
2. If switch SW1 goes down, the routing protocol on NS1 detects that R1 is not reachable and therefore removes the route entry for R1 from the internal routing table. NS1 and NS2 exchanges heartbeat messages through switch SW3 at regular intervals.
3. Detecting that the route entry for R1 is not present in the internal routing table, RM1 initiates a failover. If route to R1 is down from both NS1 and NS2, failover happens every 180 seconds till one of the appliances is able to reach R1 and restore the connectivity.

Adding a Route Monitor to a High Availability Node

A single procedure creates a route monitor and binds it to an HA node.

To add a route monitor by using the command line interface

At the command prompt, type:

- bind HA node <id> (-routeMonitor <ip_addr|ipv6_addr> [<netmask>])
- show HA node

Example

```
> bind HA node 0 -routeMonitor 10.102.71.0 255.255.255.0
Done
> bind HA node 0 -routeMonitor 1000:0000:0000:0000:0005:0600:700a:888b
Done
```

To add a route monitor by using the configuration utility

Navigate to System > High Availability and, on the Route Monitors tab, click Configure.

Removing Route Monitors

Updated: 2013-08-28

To remove a route monitor by using the command line interface

At the command prompt, type:

- unbind HA node <id> (-routeMonitor <ip_addr| ipv6_addr> [<netmask>])
- show ha node

Example

```
unbind HA node 3 -routeMonitor 10.102.71.0 255.255.255.0
```

```
unbind HA node 3 -routeMonitor 1000:0000:0000:0000:0005:0600:700a:888b
```

To remove a route monitor by using the configuration utility

Navigate to System > High Availability and, on the Route Monitors tab, delete the route monitor.

Limiting Failovers Caused by Route Monitors in non-INC mode

Aug 28, 2013

In an HA configuration in non-INC mode, if route monitors fail on both nodes, failover happens every 180 seconds until one of the nodes is able to reach all of the routes monitored by the respective route monitors.

However, for a node, you can limit the number of failovers for a given interval by setting the Maximum Number of Flips and Maximum Flip Time parameters on the nodes. When either limit is reached, no more failovers occur, and the node is assigned as primary even if any route monitor fails on that node. If the node is then able to reach all of the monitored routes, the next monitor failure triggers resetting of the Maximum Number of Flips and Maximum Flip Time parameters on the node and starting the time specified in the Maximum Flip Time parameter.

These parameters are set independently on each node and therefore are neither propagated nor synchronized.

Parameters for limiting the number of failovers

Maximum Number of Flips (maxFlips)

Maximum number of failovers allowed, within the Maximum Flip Time interval, for the node in HA in non INC mode, if the failovers are caused by route-monitor failure.

Maximum Flip Time (maxFlipTime)

Amount of time, in seconds, during which failovers resulting from route-monitor failure are allowed for the node in HA in non INC mode.

To limit the number of failovers by using the command line interface

At the command prompt, type:

- set HA node [-maxFlips < positive_integer>] [-maxFlipTime <positive_integer>]
- show HA node [< id>]

Example

```
> set ha node -maxFlips 30 -maxFlipTime 60
```

```
Done
```

```
> sh ha node
```

```
1) Node ID: 0
```

```
IP: 10.102.169.82 (NS)
```

```
Node State: UP
```

```
Master State: Primary
```

```
Fail-Safe Mode: OFF
```

```
INC State: DISABLED
```

```
Sync State: ENABLED
```

```
Propagation: ENABLED
```

```
Enabled Interfaces : 1/1
```

```
Disabled Interfaces : None
```

```
HA MON ON Interfaces : 1/1
```

Interfaces on which heartbeats are not seen :None
Interfaces causing Partial Failure:None
SSL Card Status: NOT PRESENT
Hello Interval: 200 msec
Dead Interval: 3 secs
Node in this Master State for: 0:4:24:1
(days:hrs:min:sec)
2) Node ID: 1
IP: 10.102.169.81
Node State: UP
Master State: Secondary
Fail-Safe Mode: OFF
INC State: DISABLED
Sync State: SUCCESS
Propagation: ENABLED
Enabled Interfaces : 1/1
Disabled Interfaces : None
HA MON ON Interfaces : 1/1
Interfaces on which heartbeats are not seen : None
Interfaces causing Partial Failure: None
SSL Card Status: NOT PRESENT

Local node information:

Configured/Completed Flips: 30/0
Configured Flip Time: 60
Critical Interfaces: 1/1

Done

To limit the number of failovers by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the local node.
2. Set the following parameters:
 - Maximum Number of Flips
 - Maximum Flip Time

Configuring Failover Interface Set

Mar 19, 2012

A Failover Interface Set (FIS) is a logical group of interfaces. In an HA configuration, using a FIS is a way to prevent failover by grouping interfaces so that, when one interface fails, other functioning interfaces are still available. A FIS can also be configured for the nodes of a NetScaler cluster.

HA MON interfaces that are not bound to an FIS are known as critical interfaces (CI) because if any of them fails, failover is triggered.

Note

An FIS does not create an active and standby Interfaces or channels. It also does not prevent bridging loops when connecting to links to the same VLAN

Creating or Modifying an FIS

To add an FIS and bind interfaces to it by using the command line interface

At the command prompt, type:

- add fis <name>
- bind fis <name> <ifnum> ...
- show fis <name>

Example

```
> add fis fis1
Done
> bind fis fis1 1/3 1/5
Done
```

An unbound interface becomes a critical interface (CI) if it is enabled and HA MON is on.

To unbind an interface from an FIS by using the command line interface

At the command prompt, type:

- unbind fis <name> <ifnum> ...
- show fis <name>

Example

```
> unbind fis fis1 1/3
Done
```

To configure an FIS by using the configuration utility

Navigate to System > High Availability and, on the Failover Interface Set tab, add a new FIS, or edit an existing FIS.

Removing an FIS

Updated: 2013-08-28

When the FIS is removed, its interfaces are marked as critical interfaces.

To remove an FIS by using the command line interface

At the command prompt, type:

```
rm fis <name>
```

Example

```
> rm fis fis1
```

```
Done
```

To remove an FIS by using the configuration utility

Navigate to System > High Availability and, on the Failover Interface Set tab, delete the FIS.

Understanding the Causes of Failover

Sep 30, 2013

The following events can cause failover in an HA configuration:

1. If the secondary node does not receive a heartbeat packet from the primary for a period of time that exceeds the dead interval set on the secondary. (See Note: 1.)
2. The primary node experiences a hardware failure of its SSL card.
3. The primary node does not receive any heartbeat packets on its network interfaces for three seconds.
4. On the primary node, a network interface that is not part of a Failover Interface Set (FIS) or a Link Aggregation (LA) channel and has the HA Monitor (HAMON) enabled, fails. (See Note: 2.)
5. On the primary node, all interfaces in an FIS fail. (See Note: 2.)
6. On the primary node, an LA channel with HAMON enabled fails. (See Note: 2.)
7. On the primary node, all interfaces fail (see Note: 2). In this case, failover occurs regardless of the HAMON configuration.
8. On the primary node, all interfaces are manually disabled. In this case, failover occurs regardless of the HAMON configuration.
9. You force a failover by issuing the force failover command on either node.
10. A route monitor that is bound to the primary node goes DOWN.

Note: 1. For more information about setting the dead interval, see [Configuring the Communication Intervals](#). Possible causes for a node not receiving heartbeat packets from a peer node include:

- A network configuration problem prevents heartbeats from traversing the network between the HA nodes.
- The peer node experiences a hardware or software failure that causes it to freeze (hang), reboot, or otherwise stop processing and forwarding heartbeat packets.

Note: 2. In this case, fail means that the interface was enabled but goes to the DOWN state, as can be seen from the show interface command or from the configuration utility. Possible causes for an enabled interface to be in the DOWN state are LINK DOWN and TXSTALL.

Forcing a Node to Fail Over

Mar 19, 2012

You might want to force a failover if, for example, you need to replace or upgrade the primary node. You can force failover from either the primary or the secondary node. A forced failover is not propagated or synchronized. To view the synchronization status after a forced failover, you can view the status of the node.

A forced failover fails in any of the following circumstances:

- You force failover on a standalone system.
- The secondary node is disabled.
- The secondary node is configured to remain secondary.

The NetScaler appliance displays a warning message if it detects a potential issue when you run the force failover command. The message includes the information that triggered the warning, and requests confirmation before proceeding.

You can force a failover on a primary node, secondary node, and when nodes are in listen mode.

- **Forcing Failover on the Primary Node.**

If you force failover on the primary node, the primary becomes the secondary and the secondary becomes the primary. Forced failover is possible only when the primary node can determine that the secondary node is UP.

If the secondary node is DOWN, the force failover command returns the following error message: "Operation not possible due to invalid peer state. Rectify and retry."

If the secondary system is in the claiming state or inactive, it returns the following error message: "Operation not possible now. Please wait for system to stabilize before retrying."

- **Forcing Failover on the Secondary Node.**

If you run the force failover command from the secondary node, the secondary node becomes primary and the primary node becomes secondary. A force failover can occur only if the secondary node's health is good and it is not configured to stay secondary.

If the secondary node cannot become the primary node, or if secondary node was configured to stay secondary (using the STAYSECONDARY option), the node displays the following error message: "Operation not possible as my state is invalid. View the node for more information."

- **Forcing Failover When Nodes Are in Listen Mode.**

When the two nodes of an HA pair are running different versions of the system software, the node running the higher version switches to the listen mode. In this mode, neither command propagation nor synchronization works.

Before upgrading the system software on both nodes, you should test the new version on one of the nodes. To do this, you need to force a failover on the system that has already been upgraded. The upgraded system then takes over as the primary node, but neither command propagation or synchronization occurs. Also, all connections need to be re-established.

To force failover on a node by using the command line interface

At the command prompt, type:

```
force HA failover
```

To force failover on a node by using the configuration utility

Navigate to System > High Availability and, on the Nodes tab, select the node, in the Action list, select Force Failover.

Forcing the Secondary Node to Stay Secondary

Aug 28, 2013

In an HA setup, the secondary node can be forced to stay secondary regardless of the state of the primary node.

For example, suppose the primary node needs to be upgraded and the process will take a few seconds. During the upgrade, the primary node may go down for a few seconds, but you do not want the secondary node to take over; you want it to remain the secondary node even if it detects a failure in the primary node.

When you force the secondary node to stay secondary, it will remain secondary even if the primary node goes down. Also, when you force the status of a node in an HA pair to stay secondary, it does not participate in HA state machine transitions. The status of the node is displayed as STAYSECONDARY.

Forcing the node to stay secondary works on both standalone and secondary nodes. On a standalone node, you must use this option before you can add a node to create an HA pair. When you add the new node, the existing node continues to function as the primary node, and the new node becomes the secondary node.

Note: When you force a system to remain secondary, the forcing process is not propagated or synchronized. It affects only the node on which you run the command.

To force the secondary node to stay secondary by using the command line interface

At the command prompt, type:

```
set ha node -hastatus STAYSECONDARY
```

To force the secondary node to stay secondary by using the configuration utility

Navigate to System > High Availability, on the Nodes tab, open the local node, and select STAY SECONDARY.

Forcing the Primary Node to Stay Primary

Aug 28, 2013

In an HA setup, you can force the primary node to remain primary even after a failover. You can enable this option either on a primary node in an HA pair or on a standalone system.

On a standalone system, you must run this command before you can add a node to create an HA pair. When you add the new node, it becomes the primary node. The existing node stops processing traffic and becomes the secondary node in the HA pair.

To force the primary node to stay primary by using the command line interface

At the command prompt, type:

```
set ha node -hastatus STAYPRIMARY
```

To force the primary node to stay primary by using the configuration utility

Navigate to System > High Availability, on the Nodes tab, open the local node, and select STAY PRIMARY.

Understanding the High Availability Health Check Computation

Mar 19, 2012

The following table summarizes the factors examined in a health check computation:

- State of the CIs
- State of the FISs
- State of the route monitors

The following table summarizes the health check computation.

Table 1. High Availability Health Check Computation

FIS	CI	Route monitor	Condition
N	Y	N	If the system has any CIs, all of those CIs must be UP.
Y	Y	N	If the system has any FISs, all of those FISs must be UP.
Y	Y	Y	If the system has any route monitors configured, all monitored routes must be present in the FIS.

High Availability FAQs

Jul 16, 2013

What are the various ports used to exchange the HA-related information between the nodes in an HA configuration?

In an HA configuration, both nodes use the following ports to exchange HA related information:

- UDP Port 3003, to exchange heartbeat packets.
- Port 3010, for synchronization and command propagation.

What are the conditions that trigger synchronization?

Synchronization is triggered by any of the following conditions:

- The incarnation number of the primary node, received by the secondary, does not match that of the secondary node.
Note: Both nodes in an HA configuration maintain a counter called *incarnation number*, which counts the number of configurations in the node's configuration file. Each node sends its incarnation number to each other node in the heartbeat messages. The incarnation number is not incremented for the following commands:
 1. All HA configuration related commands. For example, add ha node, set ha node, and bind ha node.
 2. All Interface related commands. For example, set interface and unset interface.
 3. All channel-related commands. For example, add channel, set channel, and bind channel.
- The secondary node comes up after a restart.
- The primary node becomes secondary after a failover.

What configurations are not synced or propagated in an HA configuration in INC or non-INC mode?

The following commands are neither propagated nor synced to the secondary node:

- All node specific HA configuration commands. For example, add ha node, set ha node, and bind ha node.
- All Interface related configuration commands. For example, set interface and unset interface.
- All channel related configuration commands. For example, add channel, set channel, and bind channel.

What configurations are not synced nor propagated in an HA configuration in INC mode?

The following configurations are not synced or propagated. Each node has its own.

- MIPs
- SNIPs
- VLANs
- Routes (except LLB routes)
- Route monitors
- RNAT rules (except any RNAT rule with VIP as the NAT IP)
- Dynamic routing configurations.

Does a configuration added to the secondary node get synchronized on the primary?

No, a configuration added to the secondary node is not synchronized to the primary.

What could be the reason for both nodes claiming to be the primary in an HA configuration?

The most likely reason is that the primary and secondary nodes are both healthy but the secondary does not receive the heartbeat packets from the primary. The problem could be with the network between the nodes.

Does an HA configuration run into any issues if you deploy the two nodes with different system clock settings?

Different system-clock settings on the two nodes can cause the following issues:

- The time stamps in the log file entries do not match. This situation makes it difficult to analyze the log entries for any issues.
- After a failover, you might have problems with any type of cookie based persistence for load balancing. A significant difference between the times can cause a cookie to expire sooner than expected, resulting in termination of the persistence session.
- Similar considerations apply to any time related decisions on the nodes.

What are the conditions for failure of the *force HA sync* command?

Forced synchronization fails in any of the following circumstances:

- You force synchronization when synchronization is already in progress.
- You force synchronization on a standalone NetScaler appliance.
- The secondary node is disabled.
- HA synchronization is disabled on the current secondary node.
- HA propagation is disabled on the current primary node and you force synchronization from the primary.

What are the conditions for failure of the *sync HA files* command?

Synchronizing configuration files fail in either of the following circumstances:

- On a standalone system.
- With the secondary node disabled.

In an HA configuration, if the secondary node takes over as the primary, does it switch back to secondary status if the original primary comes back online?

No. After the secondary node takes over as the primary, it remains as primary even if the original primary node comes back online again. To interchange the primary and secondary status of the nodes, run the *force failover* command.

What are the conditions for failure of the *force failover* command?

A forced failover fails in any of the following circumstances:

- You force failover on a standalone system.
- The secondary node is disabled.
- The secondary node is configured to remain secondary.
- The primary node is configured to remain primary.
- The state of the peer node is unknown.

Troubleshooting High Availability Issues

Jul 29, 2013

The most common high availability issues involve the high availability feature not working at all, or working only intermittently. Following are common high availability issues, and probable causes and resolutions.

- **Issue**

The inability of the NetScaler appliances to pair the NetScaler appliances in a high availability set up.

- **Cause**

Network connectivity

Resolution

Verify that both the appliances are connected to the switch and the interfaces are enabled.

- **Cause**

Mismatch in the Password for the default Administrator account

Resolution

Verify that the password on both the appliances is the same.

- **Cause**

IP conflict

Resolution

Verify that both the appliances have unique NetScaler IP (NSIP) address. The appliances should not have the same NSIP address.

- **Cause**

Node ID mismatch

Resolution

Verify that the Node ID Configuration on both the appliances is unique. The appliances should not have the same Node ID configuration. Additionally, you must assign value for a Node ID between 1 and 64.

- **Cause**

Mismatch in the password of the RPC node

Resolution

Verify that both the nodes have the same RPC node password.

- **Cause**

An administrator has disabled the remote node

Resolution

Enable the remote node.

- **Cause**
The Firewall application has blocked the heartbeat packets

Resolution

Verify that the UDP port 3003 is allowed.

- **Issue**
Both the appliances claim to be the primary appliance.

- **Cause**
Missing heartbeat packets between the appliances

Resolution

Verify that the UDP port 3003 is not blocked for communication between the appliances.

- **Issue**
The NetScaler appliance is not able to synchronize the configuration.

- **Cause**
A Firewall application is blocking the required port.

Resolution

Verify that the UDP port 3010 (or UDP port 3008 with secure synchronization) is not blocked for communication between the appliances.

- **Cause**
An administrator has disabled synchronization.

Resolution

Enable synchronization on the appliance that has the issue.

- **Cause**
Different NetScaler releases or builds are installed on appliances.

Resolution

Upgrade the appliances to the same NetScaler release or build.

- **Issue**
Command propagation fails between the appliances.

- **Cause**
A Firewall application is blocking the port.

Resolution

Verify that the UDP port 3011 (or UDP port 3009 with secure propagation) is not blocked for communication between the appliances.

- **Cause**
An administrator has disabled command propagation.

Resolution

Enable command propagation on the appliance that has the issue.

- **Cause**

Different NetScaler releases or builds are installed on appliances.

Resolution

Upgrade the appliances to the same NetScaler release or build.

- **Issue**

The NetScaler appliances in the high availability pair are unable to run the force failover process.

- **Cause**

The Secondary node is disabled.

Resolution

Enable the secondary node.

- **Cause**

The Secondary node is configured to stay secondary.

Resolution

Set the secondary high availability status of the secondary node to Enable from Stay Secondary.

- **Issue**

The secondary appliance does not receive any traffic after the failover process.

- **Cause**

The upstream router does not understand GARP messages of NetScaler appliance.

Resolution

Configure Virtual MAC (VMAC) address on the secondary appliance.

Networking

Sep 30, 2013

The following topics provide a conceptual reference and instructions for configuring the various networking components on the NetScaler appliance.

IP Addressing	Learn the various types of NetScaler-owned IP addresses and how to create, customize, and remove them.
Interfaces	Configure some of the basic network configurations that must be done to get started.
Access Control Lists (ACLs)	Configure the different types of Access Control Lists and how to create, customize, and remove them.
IP Routing	Learn and configure the routing functionality of the NetScaler appliance, both static and dynamic.
Internet Protocol version 6 (IPv6)	Learn how the NetScaler appliance supports IPv6.
Traffic Domains	Learn and configure traffic domains to segment network traffic for different applications.
VXLAN	Learn and configure VXLANs to meet the scalability needs in your datacenter.
Large Scale NAT	Learn and configure Large Scale NAT to meet the IPv4 client scalability requirements for telecom service providers.

IP Addressing

Aug 28, 2013

Before you can configure the NetScaler appliance, you must assign the NetScaler IP Address (NSIP), also known as the Management IP address. You can also create other NetScaler-owned IP addresses for abstracting servers and establishing connections with the servers. In this type of configuration, the appliance serves as a proxy for the abstracted servers. You can also proxy connections by using network address translations (INAT and RNAT). When proxying connections, the appliance can behave either as a bridging (Layer 2) device or as a packet forwarding (Layer 3) device. To make packet forwarding more efficient, you can configure static ARP entries. For IPv6, you can configure neighbor discovery (ND).

This document includes the following information:

- [Configuring NetScaler-Owned IP Addresses](#)
- [How the NetScaler Proxies Connections](#)
- [Enabling Use Source IP Mode](#)
- [Configuring Network Address Translation](#)
- [Configuring Static ARP](#)
- [Setting the Timeout for Dynamic ARP Entries](#)
- [Configuring Neighbor Discovery](#)
- [Configuring IP Tunnels](#)

Configuring NetScaler-Owned IP Addresses

Mar 20, 2012

The NetScaler-owned IP Addresses—NetScaler IP Address (NSIP), Virtual IP Addresses (VIPs), Subnet IP Addresses (SNIPs), Mapped IP Addresses (MIPs), and Global Server Load Balancing Site IP Addresses (GSLBIPs)—exist only on the NetScaler appliance. The NSIP uniquely identifies the NetScaler on your network, and it provides access to the appliance. A VIP is a public IP address to which a client sends requests. The NetScaler terminates the client connection at the VIP and initiates a connection with a server. This new connection uses a SNIP or a MIP as the source IP address for packets forwarded to the server. If you have multiple data centers that are geographically distributed, each data center can be identified by a unique GSLBIP.

You can configure some NetScaler-owned IP addresses to provide access for management applications.

This document includes the following information:

- [Configuring the NetScaler IP Address \(NSIP\)](#)
- [Configuring and Managing Virtual IP \(VIP\) Addresses](#)
- [Configuring ARP response Suppression for Virtual IP addresses \(VIPs\)](#)
- [Configuring Subnet IP Addresses \(SNIPs\)](#)
- [Configuring Mapped IP Addresses \(MIPs\)](#)
- [Configuring GSLB Site IP Addresses \(GSLBIP\)](#)
- [Removing a NetScaler-Owned IP Address](#)
- [Configuring Application Access Controls](#)

Configuring the NetScaler IP Address (NSIP)

Aug 28, 2013

The NetScaler IP (NSIP) address is the IP address at which you access the NetScaler for management purposes. The NetScaler can have only one NSIP, which is also called the Management IP address. You must add this IP address when you configure the NetScaler for the first time. If you modify this address, you must reboot the NetScaler. You cannot remove an NSIP address. For security reasons, NSIP should be a non-routable IP address on your organization's LAN.

Note: Configuring the NetScaler IP address is mandatory.

To create the NetScaler IP address by using the command line interface

At the command prompt, type:

- `set ns config [-IPAddress <ip_addr> -netmask <netmask>]`
- `show ns config`

Example

```
> set ns config -ipaddress 10.102.29.170 -netmask 255.255.255.0  
Done
```

To configure the NetScaler IP address by using the configuration utility

1. In the navigation pane, click System.
2. On the System Information tab, click Setup Wizard.
3. In the Setup Wizard dialog box, click Next.
4. Under System Configuration, set the following parameters:
 - IP Address
 - Netmask
5. Follow the instructions in the Setup Wizard to complete the configuration.

Configuring and Managing Virtual IP (VIP) Addresses

Nov 23, 2015

Configuration of a virtual server IP (VIP) address is not mandatory during initial configuration of the NetScaler ADC. When you configure load balancing, you assign VIP addresses to virtual servers.

For more information about configuring a load balancing setup, see "[Load Balancing](#)."

In some situations, you need to customize VIP attributes or enable or disable a VIP address. A VIP address is usually associated with a virtual server, and some of the VIP attributes are customized to meet the requirements of the virtual server. You can host the same virtual server on multiple NetScaler appliances residing on the same broadcast domain, by using ARP and ICMP attributes. After you add a VIP (or any IP address), the NetScaler sends, and then responds to, ARP requests. VIPs are the only NetScaler-owned IP addresses that can be disabled. When a VIP address is disabled, the virtual server using it goes down and does not respond to ARP, ICMP, or L4 service requests.

As an alternative to creating VIP addresses one at a time, you can specify a consecutive range of VIP addresses.

To create a VIP address by using the command line interface

At the command prompt, type:

- `add ns ip <IPAddress> <netmask> -type <type>`
- `show ns ip <IPAddress>`

Example

```
> add ns ip 10.102.29.59 255.255.255.0 -type VIP
Done
```

To create a range of VIP addresses by using the command line interface

At the command prompt, type:

- `add ns ip <IPAddress> <netmask> -type <type>`
- `show ns ip <IPAddress>`

Example

```
> add ns ip 10.102.29.[60-64] 255.255.255.0 -type VIP
ip "10.102.29.60" added
ip "10.102.29.61" added
ip "10.102.29.62" added
ip "10.102.29.63" added
ip "10.102.29.64" added
Done
```

To configure a VIP address by using the configuration utility

Navigate to System > Network > IPs > IPv4s, and add a new IP address or edit an existing address.

To create a range of VIP addresses by using the configuration utility

1. Navigate to System > Network > IPs > IPv4s.
2. In the Action list, select Add Range.

To enable or disable an IPv4 VIP address by using the command line interface

At the command prompt, type one of the following sets of commands to enable or disable a VIP and verify the configuration:

- enable ns ip <IPAddress>
- show ns ip <IPAddress>
- disable ns ip <IPAddress>
- show ns ip <IPAddress>

Example

```
> enable ns ip 10.102.29.79
```

```
Done
```

```
> show ns ip 10.102.29.79
```

```
IP: 10.102.29.79  
Netmask: 255.255.255.255  
Type: VIP  
state: Enabled  
arp: Enabled  
icmp: Enabled  
vserver: Enabled  
management access: Disabled  
telnet: Disabled  
ftp: Disabled  
ssh: Disabled  
gui: Disabled  
snmp: Disabled  
Restrict access: Disabled  
dynamic routing: Disabled  
hostroute: Disabled
```

```
Done
```

```
> disable ns ip 10.102.29.79
```

```
Done
```

```
> show ns ip 10.102.29.79
```

```
IP: 10.102.29.79  
Netmask: 255.255.255.255  
Type: VIP  
state: Disabled  
arp: Enabled  
icmp: Enabled  
vserver: Enabled  
management access: Disabled  
telnet: Disabled
```

ftp: Disabled
ssh: Disabled
gui: Disabled
snmp: Disabled
Restrict access: Disabled
dynamic routing: Disabled
hostroute: Disabled

Done

To disable or enable a VIP address by using the configuration utility

1. Navigate to **System > Network > IPs > IPV4s**.
2. Do one of the following:
 - Select a VIP address.
 - Hold down the **Ctrl** key and select multiple address entries.
 - Hold down the **Shift** key and select a range of address entries.
 - Select all the address entries by selecting the check box on the left side of the header row.
3. From the **Action** list, select **Disable** or **Enable**.

Configuring ARP response Suppression for Virtual IP addresses (VIPs)

Aug 28, 2013

You can configure the NetScaler appliance to respond or not respond to ARP requests for a Virtual IP (VIP) address on the basis of the state of the virtual servers associated with that VIP.

For example, if virtual servers V1, of type HTTP, and V2, of type HTTPs, share VIP address 10.102.29.45 on a NetScaler appliance, you can configure the appliance to not respond to any ARP request for VIP 10.102.29.45 if both V1 and V2 are in the DOWN state.

The following three options are available for configuring ARP-response suppression for a virtual IP address.

- **NONE.** The NetScaler appliance responds to any ARP request for the VIP address, irrespective of the state of the virtual servers associated with the address.
- **ONE VSERVER.** The NetScaler appliance responds to any ARP request for the VIP address if at least one of the associated virtual servers is in UP state.
- **ALL VSERVER.** The NetScaler appliance responds to any ARP request for the VIP address if all of the associated virtual servers are in UP state.

Following table shows the sample behavior of NetScaler appliance for a VIP configured with two virtual servers:

Associated virtual servers for a VIP	STATE 1	STATE 2	STATE 3	STATE 4
NONE				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	Yes	Yes	Yes
ONE VSERVER				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	Yes	Yes	No
ALL VSERVER				
V1	UP	UP	DOWN	DOWN

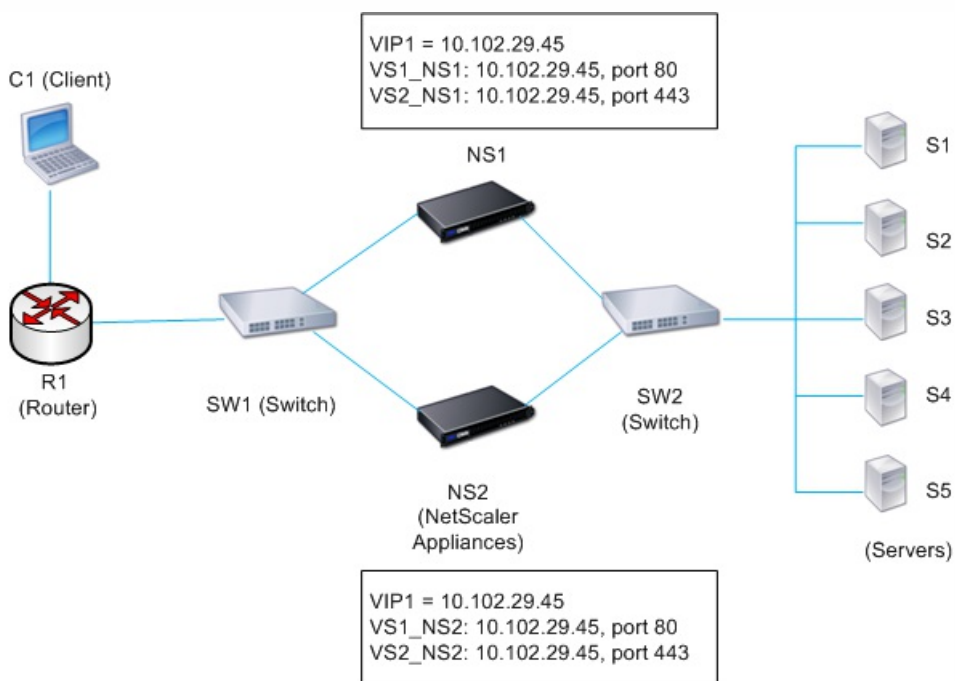

Associated virtual servers for a VIP	STATE 1	STATE 2	STATE 3	STATE 4
Respond to an ARP request for this VIP?	Yes	No	No	No

Consider an example where you want to test the performance of two virtual servers, V1 and V2, which have the same VIP address but are of different types and are each configured on NetScaler appliances NS1 and NS2. Let's call the shared VIP address *VIP1*.

V1 load balances servers S1, S2, and S3. V2 load balances servers S4 and S5.

On both NS1 and NS2, for VIP1, the ARP suppression parameter is set to ALL_VSERVER. If you want to test the performance of V1 and V2 on NS1, you must manually disable V1 and V2 on NS2, so that NS2 does not respond to any ARP request for VIP1.

Figure 1.

The execution flow is as follows:

1. Client C1 sends a request to V1. The request reaches R1.
2. R1 does not have an ARP entry for the IP address (VIP1) of V1, so R1 broadcasts an ARP request for VIP1.
3. NS1 replies with source MAC address MAC1 and source IP address VIP1. NS2 does not reply to the ARP request.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table, and R1 updates the ARP entry with MAC1 and VIP1.
5. R1 forwards the packet to address VIP1 on NS1.
6. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP or MIP addresses and S2. When S2 sends a response to the client, the response returns by the same path.
7. Now you want to test the performance of V1 and V2 on NS2, so you enable V1 and V2 on NS2 and disable them on NS1. NS2 now broadcasts an ARP message for VIP1. In the message, MAC2 is the source MAC address and VIP1 is the source IP address.

8. SW1 learns the port number for reaching MAC2 from the ARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS2. R1 updates its ARP table.
9. Now suppose the ARP entry for VIP1 times out in the ARP table of R1, and client C1 sends a request for V1. Because R1 does not have an APR entry for VIP1, it broadcasts an ARP request for VIP1.
10. NS2 replies with a source MAC address and VIP1 as the source IP address. NS1 does not reply to the ARP request.

To configure ARP response suppression by using the command line interface

At the command prompt, type:

- set ns ip -arpResponse <arpResponse>]
- show ns ip <IPAddress>

Example

```
> set ns ip 10.102.29.96 -arpResponse ALL_VSERVERS
```

```
Done
```

To configure ARP response suppression by using the configuration utility

1. Navigate to System > Network > IPs > IPV4s.
2. Open an IP address entry and select the type of ARP Response.

Configuring Subnet IP Addresses (SNIPs)

May 23, 2014

A subnet IP address (SNIP) is a NetScaler owned IP address that is used by the NetScaler ADC to communicate with the servers.

The NetScaler ADC uses the subnet IP address as a source IP address to proxy client connections to servers. It also uses the subnet IP address when generating its own packets, such as packets related to dynamic routing protocols, or to send monitor probes to check the health of the servers.

Depending on your network topology, you might have to configure one or more SNIPs for different scenarios. Following are three typical scenarios in which you have to configure SNIPs:

- [Using SNIPs for a Directly Connected Server Subnet](#)
- [Using SNIPs for Server Subnets Connected through a Router](#)
- [Using SNIPs for Multiple Server Subnets \(VLANs\) on an L2 Switch](#)

To configure a SNIP address on a NetScaler ADC, you add the SNIP address and then enable global Use Subnet IP (USNIP) mode.

As an alternative to creating SNIPs one at a time, you can specify a consecutive range of SNIPs.

To configure a SNIP address by using the command line interface

At the command prompt, type:

- `add ns ip <IPAddress> <netmask> -type SNIP`
- `show ns ip <IPAddress>`

Example

```
> add ns ip 10.102.29.203 255.255.255.0 -type SNIP
```

Done

To create a range of SNIP addresses by using the command line interface

At the command prompt, type:

- `add ns ip <IPAddress> <netmask> -type SNIP`
- `show ns ip <IPAddress>`

Example

```
> add ns ip 10.102.29.[205-209] 255.255.255.0 -type SNIP
```

```
ip "10.102.29.205" added
```

```
ip "10.102.29.206" added
```

```
ip "10.102.29.207" added
```

```
ip "10.102.29.208" added
```

```
ip "10.102.29.209" added
```

Done

To enable or disable USNIP mode by using the command line interface

At the command prompt, type one of the following commands:

- enable ns modeUSNIP
- disable ns modeUSNIP

To configure a SNIP address by using the configuration utility

Navigate to System > Network > IPs > IPv4s, and add a new SNIP address or edit an existing address.

To create a range of SNIP addresses by using the configuration utility

1. Navigate to System > Network > IPs > IPv4s.
2. In the Action list, select Add Range.

To enable or disable USNIP mode by using the command line interface

At the command prompt, type one of the following commands:

- enable ns mode USNIP
- disable ns mode USNIP

To enable or disable USNIP mode by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change modes.
2. Select or clear the Use Subnet IP option.

Using SNIPs for a Directly Connected Server Subnet

Updated: 2014-05-23

To enable communication between the NetScaler and a server that is either connected directly to the NetScaler or connected through only an L2 switch, you must configure a subnet IP address that belongs to the subnet of the server. You must configure at least one subnet IP address for each directly connected subnet, except for the directly connected management subnet that is connected through NSIP.

Consider an example of a load balancing set up in which load balancing virtual server LBVS1 on NetScaler ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to the same subnet.

SNIP address SNIP1, which belongs to the same subnet as S1 and S2, is configured on NS1. As soon as SNIP1 is configured, NS1 broadcasts ARP packets for SNIP1.

Services SVC-S1 and SVC-S2 on NS1 represent S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for S1 and S2 to resolve IP-to-MAC mapping. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about configuring load balancing on a NetScaler ADC, see [Load Balancing](#).

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
 - Source IP = IP address of the client (198.51.100.10)
 - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP1 and S2.
5. NS1 sends the request packet to S2 from SNIP1. The request packet has:
 - Source IP = SNIP1 (192.0.1.10)
 - Destination IP = IP address of S2 (192.0.1.30)
6. S2's response returns by the same path.

Using SNIPs for Server Subnets Connected through a Router

Updated: 2014-05-23

To enable communication between the NetScaler ADC and servers in subnets connected through a router, you must configure at least one subnet IP address that belongs to the subnet of the directly connected interface to the router. The ADC uses this subnet IP address to communicate with servers in subnets that can be reached through the router.

Consider an example of a load balancing set up in which load balancing virtual server LBVS1 on NetScaler ADC NS1 is used to load balance servers S1, S2, S3, and S4, which are connected to NS1 through router R1.

S1 and S2 belong to same subnet, 192.0.2.0/24, and are connected to R1 through L2 switch SW1. S3 and S4 belong to a different subnet, 192.0.3.0/24, and are connected to R1 through L2 switch SW2.

NetScaler ADC NS1 is connected to router R1 through subnet 192.0.1.0/24. SNIP address SNIP1, which belongs to the same subnet as the directly connected interface to the router (192.0.1.0/24), is configured on NS1. NS1 uses this address to communicate with servers S1 and S2, and with servers S3 and S4.

For more information about configuring load balancing on a NetScaler ADC, see [Load Balancing](#).

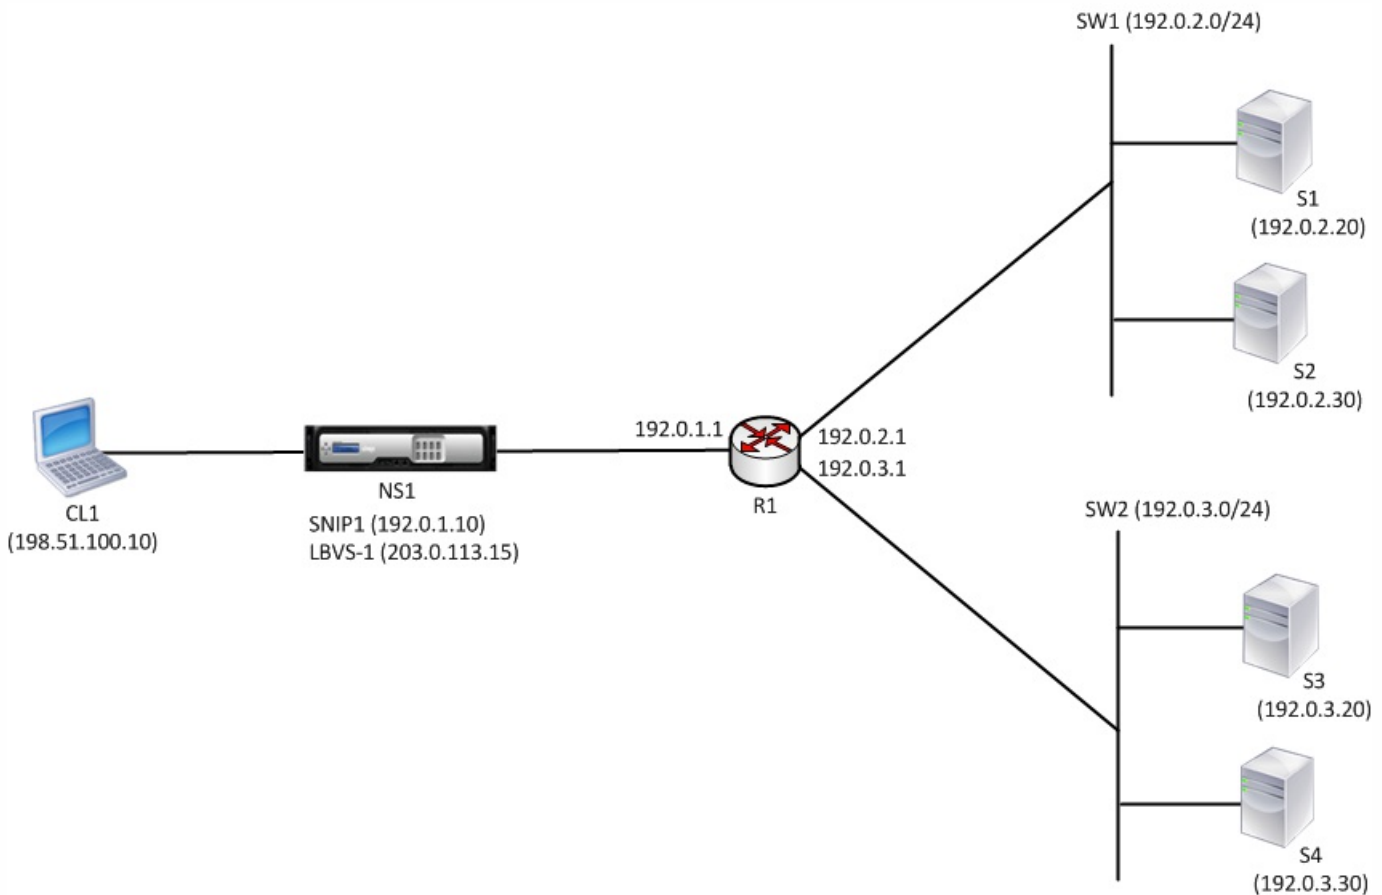

As soon as address SNIP1 is configured, NS1 broadcasts ARP announcement packets for SNIP1.

NS1's routing table consists of route entries for S1, S2, S3, and S4 through R1. These route entries are either static route entries or advertised by R1 to NS1, using dynamic routing protocols.

Services SVC-S1, SVC-S2, SVC-S3, and SVC-S4 on NS1 represent servers S1, S2, S3, and S4. NS1 finds, in its routing tables,

that these servers are reachable through R1. NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about IP routing on a NetScaler ADC, see [IP Routing](#).

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
 - Source IP = IP address of the client (198.51.100.10)
 - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S3.
4. NS1 checks its routing table and finds that S3 is reachable through R1. SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as router R1, NS1 opens a connection between SNIP1 and S3 through R1.
5. NS1 sends the request packet to R1 from SNIP1. The request packet has:
 - Source IP address = SNIP1 (192.0.1.10)
 - Destination IP address = IP address of S3 (192.0.3.20)
6. The request reaches R1, which checks its routing table and forwards the request packet to S3.
7. S3's response returns by the same path.

Using SNIPs for Multiple Server Subnets (VLANs) on an L2 Switch

Updated: 2014-05-23

When you have multiple server subnets (VLANs) on an L2 switch that is connected to a NetScaler ADC, you must configure at least one SNIP address for each of the server subnets, so that the NetScaler ADC can communicate with these server subnets.

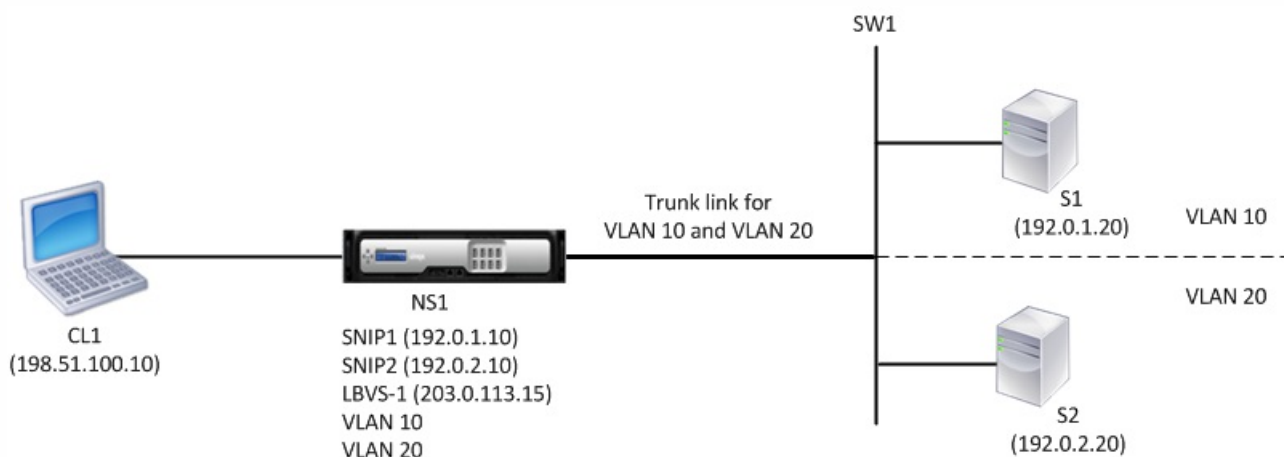

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on NetScaler ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to different subnets and are part of VLAN 10 and VLAN20, respectively. The link between NS1 and SW1 is a trunk link and is shared by VLAN10 and VLAN20.

For more information about configuring load balancing on a NetScaler ADC, see [Load Balancing](#).

Subnet IP addresses SNIP1 (for reference purposes only) and SNIP2 (for reference purposes only) are configured on NS1. NS1 uses SNIP1 (on VLAN 10) to communicate with server S1, and SNIP2 (on VLAN 20) to communicate with S2. As soon as SNIP1 and SNIP2 are configured, NS1 broadcasts ARP announcement packets for SNIP1 and SNIP2.

For more information about configuring VLANs on a NetScaler ADC, see [Configuring a VLAN](#).

Services SVC-S1 and SVC-S2 on NS1 represent servers S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for them. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals to check their health. NS1 sends monitoring probes to S1 from address SNIP1, and to S2 from address SNIP2.

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
 - Source IP = IP address of the client (198.51.100.10)
 - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP2 (192.0.2.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP2 and S2.
Note: If S1 is selected, NS1 opens a connection between SNIP1 and S1.
5. NS1 sends the request packet to S2 from SNIP2. The request packet has:
 - Source IP = SNIP1 (192.0.2.10)
 - Destination IP = IP address of S2 (192.0.2.20)
6. S2's response returns by the same path.

Configuring Mapped IP Addresses (MIPs)

Sep 30, 2013

Mapped IP addresses (MIP) are used for server-side connections. A MIP can be considered a default Subnet IP (SNIP) address, because MIPs are used when a SNIP is not available or Use SNIP (USNIP) mode is disabled.

If the mapped IP address is the first in the subnet, the NetScaler appliance adds a route entry, with this IP address as the gateway to reach the subnet. You can create or delete a MIP during run time without rebooting the appliance.

As an alternative to creating MIPs one at a time, you can specify a consecutive range of MIPs.

The following diagram shows the use of the MIP and SNIP addresses in a NetScaler appliance that connects to the backend servers across the subnets.

Figure 1. MIP and SNIP addresses

In the setup, if the NetScaler appliance and the backend servers are in the 10.1.1.0/24 subnet, then the appliance uses the MIP address to communicate to the servers. However, if the setup has backend servers on additional subnets, such as 10.2.2.0/24, and there is no router between the NetScaler appliance and the subnet, then you can configure a SNIP address that has a range of 10.2.2.x/24, such as 10.2.2.9 in this case, to communicate to the additional subnet.

You can enable the NetScaler appliance to use MIP to communicate to the additional subnet. However, if the setup has a Firewall application between the appliance and the server, then the Firewall might prevent the traffic other than 10.2.2.0/24. In such cases, you need a SNIP address to communicate to the servers.

To create a MIP address by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.171 255.255.255.0 -type MIP
```

Done

To create a range of MIP addresses by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.[173-175] 255.255.255.0 -type MIP
```

```
ip "10.102.29.173" added
```

```
ip "10.102.29.174" added
```

```
ip "10.102.29.175" added
```

Done

To configure a MIP address by using the configuration utility

Navigate to System > Network > IPs > IPv4s, and add a new MIP address or edit an existing address.

To create a range of MIP addresses by using the configuration utility

1. Navigate to System > Network > IPs > IPv4s.
2. In the Action list, select Add Range.

Configuring GSLB Site IP Addresses (GSLBIP)

Aug 28, 2013

A GSLB site IP (GSLBIP) address is an IP address associated with a GSLB site. It is not mandatory to specify a GSLBIP address when you initially configure the NetScaler appliance. A GSLBIP address is used only when you create a GSLB site.

For more information about creating a GSLB site IP address, see "[Global Server Load Balancing](#)."

Removing a NetScaler-Owned IP Address

Aug 28, 2013

You can remove any IP address except the NSIP. The following table provides information about the processes you must follow to remove the various types of IP addresses. Before removing a VIP, remove the associated virtual server.

Table 1. Implications of Removing a NetScaler-Owned IP Address

IP address type	Implications
Subnet IP address (SNIP)	If IP address being removed is the last IP address in the subnet, the associated route is deleted from the route table. If the IP address being removed is the gateway in the corresponding route entry, the gateway for that subnet route is changed to another NetScaler-owned IP address.
Mapped IP address (MIP)	If a SNIP exists, you can remove the MIPs. The NetScaler uses NSIP and SNIPs to communicate with the servers when the MIP is removed. Therefore, you must also enable use SNIP (USNIP) mode. For information about enabling and disabling USNIP mode, see " Configuring Subnet IP Addresses (SNIPs) ."
Virtual Server IP address (VIP)	Before removing a VIP, you must first remove the vserver associated with it. For information about removing the vserver, see " Load Balancing ."
GSLB-Site-IP address	Before removing a GSLB site IP address, you must remove the site associated with it. For information about removing the site, see " Global Server Load Balancing ."

To remove an IP address by using the command line interface

At the command prompt, type:

```
rm ns ip <IPAddress>
```

Example

```
rm ns ip 10.102.29.54
```

To remove an IP address by using the configuration utility

Navigate to System > Network > IPs > IPV4s, delete the IP address.

Configuring Application Access Controls

Sep 30, 2015

Application access controls, also known as management access controls, form a unified mechanism for managing user authentication and implementing rules that determine user access to applications and data. You can configure MIPs and SNIPs to provide access for management applications. Management access for the NSIP is enabled by default and cannot be disabled. You can, however, control it by using ACLs.

For information about using ACLs, see "[Access Control Lists \(ACLs\)](#)."

The NetScaler appliance does not support management access to VIPs.

The following table provides a summary of the interaction between management access and specific service settings for Telnet.

Management Access	Telnet (State Configured on the NetScaler)	Telnet (Effective State at the IP Level)
Enable	Enable	Enable
Enable	Disable	Disable
Disable	Enable	Disable
Disable	Disable	Disable

The following table provides an overview of the IP addresses used as source IP addresses in outbound traffic.

Application/ IP	NSIP	MIP	SNIP	VIP
ARP	Yes	Yes	Yes	No
Server side traffic	No	Yes	Yes	No
RNAT	No	Yes	Yes	Yes
ICMP PING	Yes	Yes	Yes	No
Dynamic routing	Yes	No	Yes	Yes

The following table provides an overview of the applications available on these IP addresses.

Application/ IP	NSIP	MIP	SNIP	VIP
-----------------	------	-----	------	-----

SNMP Application/ IP	Yes NSIP	Yes MIP	Yes SNIP	Yes VIP
System access	Yes	Yes	Yes	No

You can access and manage the NetScaler by using applications such as Telnet, SSH, GUI, and FTP.

Note: Telnet and FTP are disabled on the NetScaler for security reasons. To enable them, contact the customer support. After the applications are enabled, you can apply the controls at the IP level.

To configure the NetScaler to respond to these applications, you need to enable the specific management applications. If you disable management access for an IP address, existing connections that use the IP address are not terminated, but no new connections can be initiated.

Also, the non-management applications running on the underlying FreeBSD operating system are open to protocol attacks, and these applications do not take advantage of the NetScaler appliance's attack prevention capabilities.

You can block access to these non-management applications on a MIP, SNIP, or NSIP. When access is blocked, a user connecting to a NetScaler by using the MIP, SNIP, or NSIP is not be able to access the non-management applications running on the underlying operating system.

To configure management access for an IP address by using the command line interface

At the command prompt, type:

```
set ns ip <IPAddress> -mgmtAccess <value> -telnet <value> -ftp <value> -gui <value> -ssh <value> -snmp <value> -
restrictAccess (ENABLED | DISABLED)
```

Example

```
> set ns ip 10.102.29.54 -mgmtAccess enabled -restrictAccess ENABLED
Done
```

To enable management access for an IP address by using the configuration utility

1. Navigate to System > Network > IPs > IPV4s.
2. Open an IP address entry, and select the Enable Management Access control to support the below listed applications option.

How the NetScaler Proxies Connections

Aug 28, 2013

When a client initiates a connection, the NetScaler appliance terminates the client connection, initiates a connection to an appropriate server, and sends the packet to the server. The appliance does not perform this action for service type UDP or ANY.

For more information about service types, see "[Load Balancing](#)."

You can configure the NetScaler to process the packet before initiating the connection with a server. The default behavior is to change the source and destination IP addresses of a packet before sending the packet to the server. You can configure the NetScaler to retain the source IP address of the packets by enabling Use Source IP mode.

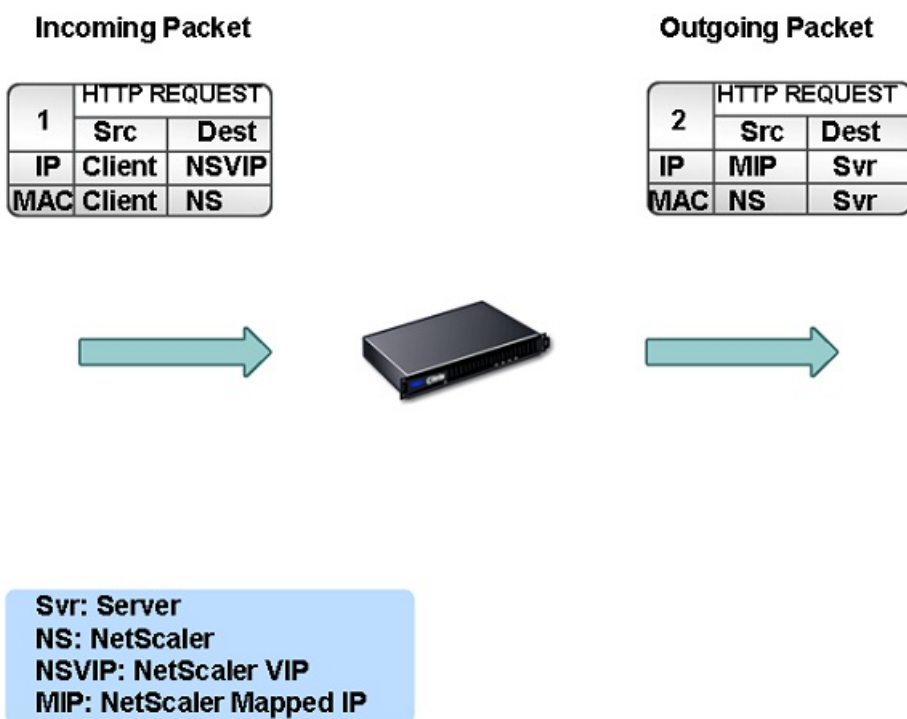

This section includes the following details:

- [How the Destination IP Address Is Selected](#)
- [How the Source IP Address Is Selected](#)

How the Destination IP Address Is Selected

Traffic sent to the NetScaler appliance can be sent to a virtual server or to a service. The appliance handles traffic to virtual servers and services differently. The NetScaler terminates traffic received at a virtual server IP (VIP) address and changes the destination IP address to the IP address of the server before forwarding the traffic to the server, as shown in the following diagram.

Figure 1. Proxying Connections to VIPs

Packets destined for a service are sent directly to the appropriate server, and the NetScaler does not modify the

destination IP addresses. In this case, the NetScaler functions as a proxy.

How the Source IP Address Is Selected

When the NetScaler appliance communicates with the physical servers or peer devices, by default, it does not use the IP address of the client. NetScaler maintains a pool of mapped IP addresses (MIPs) and subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address of a connection to the physical server. Depending on the subnet in which the physical server is placed, NetScaler decides whether a MIP should be used or SNIP.

Note: If the Use Source IP (USIP) option is enabled, NetScaler uses the IP address of the client.

Enabling Use Source IP Mode

Dec 16, 2013

When the NetScaler appliance communicates with the physical servers or peer devices, by default, it uses one of its own IP addresses as the source IP. The appliance maintains a pool of mapped IP addresses (MIPs) and subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address for a connection to the physical server. The decision of whether to select a MIP or a SNIP depends on the subnet in which the physical server resides.

If necessary, you can configure the NetScaler appliance to use the client's IP address as source IP. Some applications need the actual IP address of the client. The following use cases are a few examples:

- Client's IP address in the web access log is used for billing purposes or usage analysis.
- Client's IP address is used to determine the country of origin of the client or the originating ISP of the client. For example, many search engines such as Goggle provide content relevant to the location to which the user belongs.
- The application must know the client's IP address to verify that the request is from a trustworthy source.
- Sometimes, even though an application server does not need the client's IP address, a firewall placed between the application server and the NetScaler may need the client's IP address for filtering the traffic.

Enable Use Source IP mode (USIP) mode if you want NetScaler to use the client's IP address for communication with the servers. By default, USIP mode is disabled. USIP mode can be enabled globally on the NetScaler or on a specific service. If you enable it globally, USIP is enabled by default for all subsequently created services. If you enable USIP for a specific service, the client's IP address is used only for the traffic directed to that service.

As an alternative to USIP mode, you have the option of inserting the client's IP address (CIP) in the request header of the server-side connection for an application server that needs the client's IP address.

In earlier NetScaler releases, USIP mode had the following source-port options for server-side connections:

- Use the client's port. With this option, connections cannot be reused. For every request from the client, a new connection is made with the physical server.
- Use proxy port. With this option, connection reuse is possible for all requests from the same client. Before NetScaler release 8.1 this option imposed a limit of 64000 concurrent connections for all server-side connections.

In the later NetScaler releases, if USIP is enabled, the default is to use a proxy port for server-side connections and not reuse connections. Not reusing connections may not affect the speed of establishing connections.

By default, the Use Proxy Port option is enabled if the USIP mode is enabled.

For more information about the Use Proxy Port option, see "[Using the Client Port When Connecting to the Server.](#)"

Note: If you enable the USIP mode, it is recommended to enable the Use Proxy Port option.

The following figure shows how the NetScaler uses IP addresses in USIP mode.

Figure 1. IP Addressing in USIP Mode

Recommended Usage

Enable USIP in the following situations:

- Load balancing of Intrusion Detection System (IDS) servers
- SMTP load balancing
- Stateless connection failover
- Sessionless load balancing
- If you use the Direct Server Return (DSR) mode

Note: When USIP is enabled, you must set server's gateway to one of the NetScaler owned IP addresses (either of type Subnet IP (SNIP) or mapped IP (MIP)) so that server's response always go through the NetScaler appliance. For more information about NetScaler owned IP addresses, see "[Configuring NetScaler owned IP addresses.](#)"

- If you enable USIP, set the idle timeout for server connections to a value lower than the default value, so that idle connections are cleared quickly on the server side.
For more information about setting an idle time-out value, "[Load Balancing.](#)"
- For transparent cache redirection, if you enable USIP, enable L2CONN also.
- Because HTTP connections are not reused when USIP is enabled, a large number of server-side connections may accumulate. Idle server connections can block connections for other clients. Therefore, set limits on maximum number of connections to a service. Citrix also recommends setting the HTTP server time-out value, for a service on which USIP is enabled, to a value lower than the default, so that idle connections are cleared quickly on the server side.

To globally enable or disable USIP mode by using the command line interface

At the command prompt, type one of the following commands:

- enable ns mode USIP
- disable ns mode USIP

To enable USIP mode for a service by using the command line interface

At the command prompt, type:

```
set service <name>@ -usip (YES | NO)
```

Example

```
set service Service-HTTP-1 -usip YES
```

To globally enable or disable USIP mode by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change modes.
2. Select or clear the Use Source IP option.

To enable USIP mode for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Use Source IP Address.

Configuring Network Address Translation

Jul 05, 2013

Network address translation (NAT) involves modification of the source and/or destination IP addresses and/or the TCP/UDP port numbers of IP packets that pass through the NetScaler appliance. Enabling NAT on the appliance enhances the security of your private network, and protects it from a public network such as the Internet, by modifying your networks source IP addresses when data passes through the NetScaler. Also, with the help of NAT entries, your entire private network can be represented by a few shared public IP addresses. The NetScaler supports the following types of network address translation:

- Inbound NAT (INAT), in which the NetScaler replaces the destination IP address in the packets generated by the client with the private IP address of the server.
- Reverse NAT (RNAT), in which the NetScaler replaces the source IP address in the packets generated by the servers with the public NAT IP addresses.

This document includes the following information:

- [Configuring INAT](#)
- [Coexistence of INAT and Virtual Servers](#)
- [Stateless NAT46 Translation](#)
- [DNS64](#)
- [Stateful NAT64 Translation](#)
- [Configuring RNAT](#)
- [Configuring Prefix-Based IPv6-IPv4 Translation](#)

Configuring INAT

Aug 28, 2013

When a client sends a packet to a NetScaler appliance that is configured for Inbound Network Address Translation (INAT), the appliance translates the packet's public destination IP address to a private destination IP address and forwards the packet to the server at that address.

The following configurations are supported:

- **IPv4-IPv4 Mapping:** A public IPv4 address on the NetScaler appliance listens to connection requests on behalf of a private IPv4 server. The NetScaler appliance translates the packet's public destination IP address to the destination IP address of the server and forwards the packet to the server at that address.
- **IPv4-IPv6 Mapping:** A public IPv4 address on the NetScaler appliance listens to connection requests on behalf of a private IPv6 server. The NetScaler appliance creates an IPv6 request packet with the IP address of the IPv6 server as the destination IP address.
- **IPv6-IPv4 Mapping:** A public IPv6 address on the NetScaler appliance listens to connection requests on behalf of a private IPv4 server. The NetScaler appliance creates an IPv4 request packet with the IP address of the IPv4 server as the destination IP address.
- **IPv6-IPv6 Mapping:** A public IPv6 address on the NetScaler appliance listens to connection requests on behalf of a private IPv6 server. The NetScaler appliance translates the packet's public destination IP address to the destination IP address of the server and forwards the packet to the server at that address.

When the appliance forwards a packet to a server, the source IP address assigned to the packet is determined as follows:

- If use subnet IP (USNIP) mode is enabled and use source IP (USIP) mode is disabled, the NetScaler uses a subnet IP address (SNIP) as the source IP address.
- If USNIP mode is disabled and USIP mode is disabled, the NetScaler uses a mapped IP address (MIP) as the source IP address.
- If USIP mode is enabled, and USNIP mode is disabled the NetScaler uses the client IP (CIP) address as the source IP address.
- If both USIP and USNIP modes are enabled, USIP mode takes precedence.
- You can also configure the NetScaler to use a unique IP address as the source IP address, by setting the proxyIP parameter.
- If none of the above modes are enabled and a unique IP address has not been specified, the NetScaler attempts to use a MIP as the source IP address.
- If both USIP and USNIP modes are enabled and a unique IP address has been specified, the order of precedence is as follows: USIP-unique IP-USNIP-MIP-Error.

To protect the NetScaler from DoS attacks, you can enable TCP proxy. However, if other protection mechanisms are used in your network, you may want to disable them.

You can create, modify, or remove an INAT entry.

To create an INAT entry by using the command line interface

At the command prompt, type the following commands to create an INAT entry and verify its configuration:

- `add inat <name> <publicIP> <privateIP> [-tcpproxy (ENABLED | DISABLED)] [-ftp (ENABLED | DISABLED)] [-usip (ON | OFF)] [-usnip (ON | OFF)] [-proxyIP <ip_addr | ipv6_addr>]`

- show inat [<name>]

Example

```
> add inat ip4-ip4 172.16.1.2 192.168.1.1 -proxyip 10.102.29.171
Done
```

To modify an INAT entry by using the command line interface

To modify an INAT entry, type the set inat command, the name of the entry, and the parameters to be changed, with their new values.

To remove an INAT configuration by using the command line interface

At the command prompt, type:

```
rm inat <name>
```

Example

```
> rm inat ip4-ip4
Done
```

To configure an INAT entry by using the configuration utility

Navigate to System > Network > Routes > INAT, and add a new INAT entry or edit an existing INAT entry.

To remove an INAT configuration by using the configuration utility

Navigate to System > Network > Routes > INAT, delete the INAT configuration.

Coexistence of INAT and Virtual Servers

Mar 20, 2012

If both INAT and RNAT are configured, the INAT rule takes precedence over the RNAT rule. If RNAT is configured with a network address translation IP (NAT IP) address, the NAT IP address is selected as the source IP address for that RNAT client.

The default public destination IP in an INAT configuration is the virtual IP (VIP) address of the NetScaler device. Virtual servers also use VIPs. When both INAT and a virtual server use the same IP address, the Vserver configuration overrides the INAT configuration.

Following are a few sample configuration setup scenarios and their effects.

Case	Result
You have configured a virtual server and a service to send all data packets received on a specific NetScaler port to the server directly. You have also configured INAT and enabled TCP. Configuring INAT in this manner sends all data packets received through a TCP engine before sending them to the server.	All packets received on the NetScaler, except those received on the specified port, pass through the TCP engine.
You have configured a virtual server and a service to send all data packets of service type TCP, that are received on a specific port on the NetScaler, to the server after passing through the TCP engine. You have also configured INAT and disabled TCP. Configuring INAT in this manner sends the data packets received directly to the server.	Only packets received on the specified port pass through the TCP engine.
You have configured a virtual server and a service to send all data packets received to either of two servers. You are attempting to configure INAT to send all data packets received to a different server.	The INAT configuration is not allowed.
You have configured INAT to send all received data packets directly to a server. You are attempting to configure a virtual server and a service to send all data packets received to two different servers.	The vserver configuration is not allowed.

Stateless NAT46 Translation

Aug 28, 2013

The stateless NAT46 feature enables communication between IPv4 and IPv6 networks through IPv4 to IPv6 packet translation, and vice versa, without maintaining any session information on the NetScaler appliance.

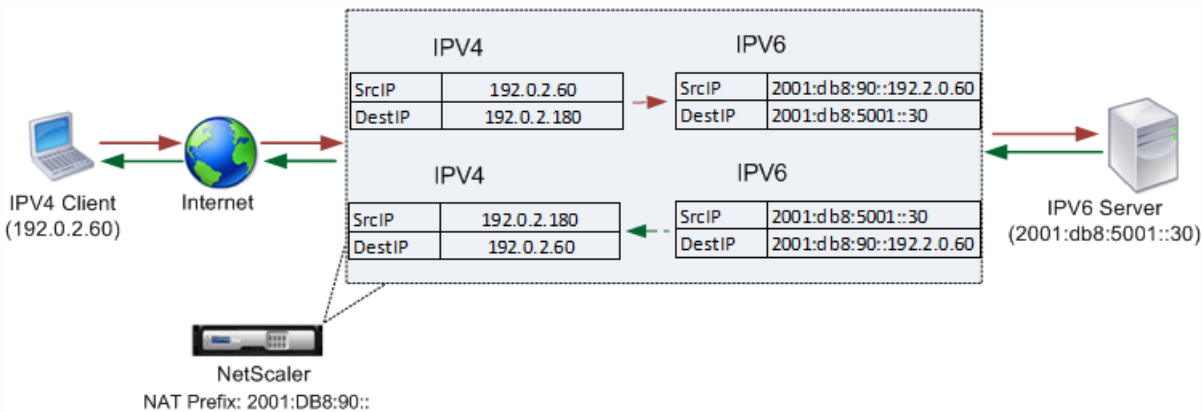

For a stateless NAT46 configuration, the appliance translates an IPv4 packet to IPv6 or an IPv6 packet to IPv4 as defined in RFCs 6145 and 2765.

Note: This feature is supported only on NetScaler 10.e and later.

A stateless NAT46 configuration on the NetScaler appliance has the following components:

- IPv4-IPv6 INAT entry**—An INAT entry defining a 1:1 relationship between an IPv4 address and an IPv6 address. In other words, an IPv4 address on the appliance listens to connection requests on behalf of an IPv6 server. An IPv4 request packet for this IPv4 address is translated into an IPv6 packet, and then the IPv6 packet is sent to the IPv6 server. The appliance translates an IPv6 response packet into an IPv4 response packet with its source IP address field set as the IPv4 address specified in the INAT entry. The translated packet is then sent to the client.
- NAT46 IPv6 prefix**—A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance. During IPv4 packet to IPv6 packet translation, the appliance sets the source IP address of the translated IPv6 packet to a concatenation of the NAT46 IPv6 prefix [96 bits] and the IPv4 source address [32 bits] that was received in the request packet. During IPv6 packet to IPv4 packet translation, the appliance sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

Consider an example in which an enterprise hosts site www.example.com on server S1, which has an IPv6 address. To enable communication between IPv4 clients and IPv6 server S1, NetScaler appliance NS1 is deployed with a stateless NAT46 configuration that includes an IPv4-IPv6 INAT entry for server S1, and a NAT46 Prefix. The INAT entry includes an IPv4 address at which the appliance listens to connection requests from IPv4 clients on behalf of the IPv6 server S1.

The following table lists the settings used in this example:

Entities	Name	Value
IP address of the client	Client_IPv4 (for reference purposes only)	192.0.2.60
IPv6 address of the server	Sevr_IPv6 (for reference purposes only)	2001:DB8:5001::30

Entities	Name	Value
IPv4 address defined in the INAT entry for IPv6 server S1	Map-Sevr-IPv4 (for reference purposes only)	192.0.2.180
IPv6 prefix for NAT 46 translation	NAT46_Prefix (for reference purposes only)	2001:DB8:90::

Following is the traffic flow in this example:

1. IPv4 Client CL1 sends a request packet to the Map-Sevr-IPv4 (192.0.2.180) address on the NetScaler appliance.
2. The appliance receives the request packet and searches the NAT46 INAT entries for the IPv6 address mapped to the Map-sevr-IPv4 (192.0.2.180) address. It finds the Sevr-IPv6 (2001:DB8:5001::30) address.
3. The appliance creates a translated IPv6 request packet with:
 - Destination IP address field = Sevr-IPv6 = 2001:DB8:5001::30
 - Source IP address field = Concatenation of NAT Prefix (First 96 bits) and Client_IPv4 (last 32 bits) = 2001:DB8:90::192.0.2.60
4. The appliance sends the translated IPv6 request to Sevr-IPv6.
5. The IPv6 server S1 responds by sending an IPv6 packet to the NetScaler appliance with:
 - Destination IP address field = Concatenation of NAT Prefix (First 96 bits) and Client_IPv4 (last 32 bits)= 2001:DB8:90::192.0.2.60
 - Source IP address field = Sevr-IPv6 = 2001:DB8:5001::30
6. The appliance receives the IPv6 response packet and verifies that its destination IP address matches the NAT46 prefix configured on the appliance. Because the destination address matches the NAT46 prefix, the appliance searches the NAT46 INAT entries for the IPv4 address associated with the Sevr-IPv6 address (2001:DB8:5001::30). It finds the Map-Sevr-IPv4 address (192.0.2.180).
7. The appliance creates an IPv4 response packet with:
 - Destination IP address field = The NAT46 prefix stripped from the destination address of the IPv6 response = Client_IPv4 (192.0.2.60)
 - Source IP address field = Map-Sevr-IPv4 address (192.0.2.180)
8. The appliance sends the translated IPv4 response to client CL1.

This section includes the following details:

- [Configuring Stateless NAT46](#)
- [Setting Global Parameters for Stateless NAT46](#)
- [Limitations of Stateless NAT46](#)

Configuring Stateless NAT46

Updated: 2013-09-04

Creating the required entities for stateless NAT46 configuration on the NetScaler appliance involves the following procedures:

1. Create an IPv4-IPv6 mapping INAT entry with stateless mode enabled.
2. Add a NAT46 IPv6 prefix.

To configure an INAT mapping entry by using the command line interface

At the command prompt, type:

- add inat <name> <publicIPv4> <privateIPv6> -mode STATELESS
- show inat <name>

To add an NAT46 prefix by using the command line interface

At the command prompt, type:

- set inatparam -nat46v6Prefix <ipv6_addr|*>
- show inatparam

Example

```
> add inat exmpl-com-stls-nat46 192.0.2.180
2001:DB8:5001::30 -mode stateless
Done
```

```
> set inatparam -nat46v6Prefix 2001:DB8:90::96
Done
```

To configure an INAT mapping entry by using the configuration utility

1. Navigate to System > Network > Routes > INAT.
 2. Add a new INAT entry, or edit an existing INAT entry.
 3. Set the following parameters:
 - Name*
 - Public IP Address*
 - Private IP Address* (Select the IPv6 check box and enter the address in IPv6 format.)
 - Mode (Select Stateless from the drop down list.)
- * A required parameter

To add a NAT46 prefix by using the configuration utility

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

Setting Global Parameters for Stateless NAT46

The appliance provides some optional global parameters for stateless NAT46 configurations.

To set global parameters for stateless NAT46 by using the command line interface

At the command prompt, type:

- set inatparam [-nat46IgnoreTOS (YES | NO)] [-nat46ZeroChecksum (ENABLED | DISABLED)] [-nat46v6Mtu <positive_integer>] [-nat46FragHeader (ENABLED | DISABLED)]
- show inatparam

Example

```
> set inatparam -nat46IgnoreTOS YES -nat46ZeroChecksum DISABLED -nat46v6Mtu 1400 -nat46FragHeader DISABLED
Done
```

To set global parameters for stateless NAT46 by using the configuration utility

Navigate to System > Network, in the Settings group, click Configure INAT Parameters.

Limitations of Stateless NAT46

The following limitations apply to stateless NAT46:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.

- Translation of ESP and EH headers of IPv4 packets is not supported.
- Translation of multicast packets is not supported.
- Translation of destination option headers and source routing headers is not supported.
- Translation of fragmented IPv4 UDP packets that do not contain UDP checksum is not supported.

DNS64

Feb 23, 2014

The NetScaler DNS64 feature responds with a synthesized DNS AAAA record to an IPv6 client sending an AAAA request for an IPv4-only domain. The DNS64 feature is used with the NAT64 feature to enable seamless communication between IPv6-only clients and IPv4-only servers. DNS64 enables discovery of the IPv4 domain by the IPv6 only clients, and NAT64 enables communication between the clients and servers.

For synthesizing an AAAA record, the NetScaler appliance fetches a DNS A record from a DNS server. The DNS64 prefix is a 96-bit IPv6 prefix configured on the NetScaler appliance. The NetScaler appliance synthesizes the AAAA record by concatenation of the DNS64 Prefix (96 bits) and the IPv4 address (32 bits).

For enabling communication between IPv6 clients and IPv4 servers, a NetScaler appliance with DNS64 and NAT64 configuration can be deployed either on the IPv6 client side or on the IPv4 server side. In both cases, the DNS64 configuration on the NetScaler appliance is similar and includes a load balancing virtual server acting as a proxy server for DNS servers. If the NetScaler appliance is deployed on the client side, the load balancing virtual server must be specified, on the IPv6 client, as the nameserver for a domain.

Consider an example where a NetScaler appliance with DNS64 and NAT64 configuration is configured on the IPv4 side. In this example, an enterprise hosts site `www.example.com` on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, NetScaler appliance NS1 is deployed with a DNS64 and stateful NAT64 configuration.

The DNS64 configuration includes DNS load balancing virtual server LBVS-DNS64-1, on which the DNS64 option is enabled. A DNS64 policy named DNS64-Policy-1, and an associated DNS64 action named DNS64-Action-1, are also configured on NS1, and DNS64-Policy-1 is bound to LBVS-DNS64-1. LBVS-DNS64-1 acts as a DNS proxy server for DNS servers DNS-1 and DNS-2.

When traffic arriving at LBVS-DNS64-1 matches the conditions specified in DNS64-Policy-1, the traffic is processed according to the settings in DNS64-Action-1. DNS64-Action-1 specifies the DNS64 prefix used, with the A record received from a DNS server, to synthesize an AAAA record.

The global DNS parameter `cacherecords` is enabled on the NetScaler appliance, so the appliance caches DNS records. This setting is necessary for the DNS64 to work properly.

The following table lists the settings used in the above example:

Entity	Name	Value
IPv6 client	CL1 (for reference purposes only)	<ul style="list-style-type: none">IP address = 2001:DB8:5001::30
DNS64 Prefix		<ul style="list-style-type: none">2001:DB8:300::
Service on NS representing DNS server DNS-1	SVC-DNS-1	<ul style="list-style-type: none">IP address = 203.0.113.50Port = 53

Service on NS representing DNS server DNS-2	SVC-DNS-2	<ul style="list-style-type: none"> • IP address = 203.0.113.60 • Port = 53
DNS64 action	DNS64-Action-1	<ul style="list-style-type: none"> • DNS64 Prefix=2001:DB8:300::
DNS64 policy	DNS64-Policy-1	<ul style="list-style-type: none"> • DNS64 action = DNS64-Action-1 • Rule= CLIENT.IP.SRC.IN_SUBNET(2001:DB8:5001::/64)
DNS load balancing virtual server	LBVS-DNS64-1	<ul style="list-style-type: none"> • IP address=2001:DB8:9999::99 • Bound DNS services= SVC-DNS-1, SVC-DNS-2 • DNS64=Enabled • Bound DNS64 policy= DNS64-Policy-1

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a DNS AAAA request for the IPv6 address of the site www.example.com.
2. The request is received by the DNS load balancing virtual server LBVS-DNS64-1 on NetScaler appliance NS1.
3. NS1 checks its DNS cache records for the requested AAAA record and finds that AAAA record for the site www.example.com does not exist in the DNS cache.
4. LBVS-DNS64-1's load balancing algorithm selects DNS server DNS-1 and forwards the AAAA request to it.
5. Because the site www.example.com is hosted on an IPv4 server, the DNS server DNS-1 does not have any AAAA record for the site www.example.com.
6. DNS-1 sends either an empty DNS AAAA response or an error message to LBVS-DNS64-1.
7. Because DNS64 option is enabled on LBVS-DNS64-1 and the AAAA request from CL1 matches the condition specified in DNS64-Policy-1, NS1 sends a DNS A request to DNS-1 for the IPv4 address of www.example.com.
8. DNS-1 responds by sending the DNS A record for www.example.com to LBVS-DNS64-1. The A record includes the IPv4 address for www.example.com.
9. NS1 synthesizes an AAAA record for the site www.example.com with:
 - IPv6 address for site www.example.com = Concatenation of DNS64 Prefix (96 bits) specified in the associated DNS64action, and IPv4 address of DNS A record (32 bits) = 2001:DB8:300::192.0.2.60
10. NS1 sends the synthesized AAAA record to IPv6 client CL1. NS1 also caches the A record into its memory. NS1 uses the cached A record to synthesize AAAA records for subsequent AAAA requests.

This section includes the following details:

- [Points to Consider for a DNS64 Configuration](#)
- [Configuration Steps](#)

Points to Consider for a DNS64 Configuration

Before configuring DNS64 on a NetScaler appliance, consider the following points:

- The DNS64 feature of the NetScaler appliance is compliant with RFC 6174.
- The DNS64 feature of the NetScaler appliance does not support DNSSEC. The NetScaler appliance does not synthesize an AAAA record from a DNSSEC response received from a DNS server. A response is classified as a DNSSEC response, only if it contains RRSIG records.

- The NetScaler appliance supports DNS64 prefix of length of only 96 bits.
- Though the DNS64 feature is used with the NAT64 feature, the DNS64 and NAT64 configurations are independent on the NetScaler appliance. For a particular flow, you must specify the same IPv6 prefix value for the DNS64 prefix and the NAT64 prefix parameters, so that the synthesized IPv6 addresses received by the client are routed to the particular NAT64 configuration. For more information on configuring NAT64 on a NetScaler appliance, see "[Stateful NAT64](#)."
- The following are the different cases of DN64 processing by the NetScaler appliance:
 - If the AAAA response from the DNS server includes AAAA records, then each record in the response is checked for the set of exclusion rule configured on the NetScaler appliance for the particular DNS64 configuration. The NetScaler removes the IPv6 addresses, whose prefix matches the exclusion rule, from the response. If the resulting response includes at least one IPv6 record, the NetScaler appliance forwards this response to the client, else, the appliance synthesizes a AAAA response from the A record of the domain and sends it to the IPv6 client.
 - If the AAAA response from the DNS server is an empty answer response, the appliance requests for A resource records with the same domain name or searches in its own records if the appliance is an authentic domain name server for the domain. If the request results in an empty answer or error, the same is forwarded to the client.
 - If the response from the DNS server includes RCODE=1 (format error), the NetScaler appliance forwards the same to the client. If there is no response before the timeout, the NetScaler appliance sends a response with RCODE=2 (server failure) to the client.
 - If the response from the DNS server includes a CNAME, the chain is followed until the terminating A or AAAA record is reached. If the CNAME does not have any AAAA resource records, the NetScaler appliance fetches the DNS A record to be used for synthesizing AAAA record. The CNAME chain is added to the answer section along with the synthesized AAAA record and then sent to the client.
- The DNS64 feature of the NetScaler appliance also supports responding to PTR request. When a PTR request for a domain of an IPv6 address is received on the appliance and the IPv6 address matches any of the configured DNS64 prefix, the appliance creates a CNAME record mapping the IP6-ARPA domain into the corresponding IN-ADDR.ARPA domain and the newly formed IN-ADDR.ARPA domain is used for resolution. The appliance searches the local PTR records and if the records are not present, the appliance sends a PTR request for IN-ADDR.ARPA domain to the DNS server. The NetScaler appliance uses the response from the DNS server to synthesize response for the initial PTR request.

Configuration Steps

Updated: 2013-09-30

Creating the required entities for stateful NAT64 configuration on the NetScaler appliance involves the following procedures:

- **Add DNS services.** DNS services are logical representation of DNS servers for which the NetScaler appliance acts as a DNS proxy server. For more information on setting optional parameters of a service, see "[Load Balancing](#)".
- **Add DNS64 action and DNS64 policy and then bind the DNS64 action to the DNS64 policy.** A DNS64 policy specifies conditions to be matched against traffic for DNS64 processing according to the settings in the associated DNS64 action. The DNS64 action specifies the mandatory DNS64 prefix and the optional exclude rule and mapped rule settings.
- **Create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it.** The DNS load balancing virtual server acts as a DNS proxy server for DNS servers represented by the bound DNS services. Traffic arriving at the virtual server is matched against the bound DNS64 policy for DNS64 processing. For more information on setting optional parameters of a load balancing virtual server, see "[Load Balancing](#)".

Note: The command line interface has separate commands for these two tasks, but the configuration utility combines them in a single dialog box.

- **Enable caching of DNS records.** Enable the global parameter for the NetScaler appliance to cache DNS records, which are obtained through DNS proxy operations. For more information on enabling caching of DNS records, see "[Enabling Caching of DNS Records](#)".

To create a service of type DNS by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> ...

To create a DNS64 action by using the command line interface

At the command prompt, type:

- add dns action64 <actionName> -Prefix <ipv6_addr| *> [-mappedRule <expression>] [-excludeRule <expression>]

To create a DNS64 policy by using the command line interface

At the command prompt, type:

- add dns policy64 <name> -rule <expression> -action <string>

To create a DNS load balancing virtual server by using the command line interface

At the command prompt, type:

- add lb vserver <name> DNS <IPAddress> <port> -dns64 (ENABLED | DISABLED) [-bypassAAAA (YES | NO)] ...

To bind the DNS services and the DNS64 policy to the DNS load balancing virtual server by using the command line interface

At the command prompt, type:

- bind lb vserver <name> <serviceName> ...
- bind lb vserver <name> -policyName <string> -priority <positive_integer> ...

Example

```
> add service SVC-DNS-1 203.0.113.50 DNS 53
Done
```

```
> add service SVC-DNS-2 203.0.113.60 DNS 53
Done
```

```
> add dns Action64 DNS64-Action-1 -Prefix 2001:DB8:300::/96
Done
```

```
> add dns Policy64 DNS64-Policy-1 -rule "CLIENT.IPv6.SRC.IN_SUBNET(2001:DB8:5001::/64)"
-action DNS64-Action-1
Done
```

```
> add lb vserver LBVS-DNS64-1 DNS 2001:DB8:9999::99 53 -dns64 ENABLED
Done
```

```
> bind lb vserver LBVS-DNS64-1 SVC-DNS-1
Done
```

```
> bind lb vserver LBVS-DNS64-1 SVC-DNS-2
```

Done

```
> bind lb vserver LBVS-DNS64-1 -policyname DNS64-Policy-1 -priority 2
```

Done

To create a service of type DNS by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and add a new service.
2. Set the following parameters:
 - Service Name*
 - Server*
 - Protocol* (Select DNS from the drop down list.)
 - Port*

To create a DNS64 action by using the configuration utility

Navigate to Traffic Management > DNS > Actions, on the DNS Actions64 tab, add a new DNS64 action.

To create a DNS64 policy by using the configuration utility

Navigate to Traffic Management > DNS > Policies, on the DNS Policies64 tab, add a new DNS64 policy.

To create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a new virtual server.
2. Set the following parameters:
 - Name*
 - IP Address*
 - Protocol* (Select DNS from the drop down list.)
 - Port*
3. Select the Enable DNS64 option.
4. In the Services pane, bind the service to the virtual server.
5. In the Policies pane, bind the policy to the virtual server.

Stateful NAT64 Translation

May 11, 2012

The stateful NAT64 feature enables communication between IPv6 clients and IPv4 servers through IPv6 to IPv4 packet translation, and vice versa, while maintaining session information on the NetScaler appliance.

A stateful NAT64 configuration on the NetScaler appliance has the following components:

- **NAT64 rule**— An entry consisting of an ACL6 rule and a netprofile, which consists of a pool of NetScaler owned SNIP Addresses.
- **NAT64 IPv6 Prefix**— A global IPv6 prefix of length 96 bits ($128-32=96$) configured on the appliance.

Note: Currently the NetScaler appliance supports only one prefix to be used commonly with all NAT 64 rules.

The NetScaler appliance considers an incoming IPv6 packet for NAT64 translation when all of the following conditions are met:

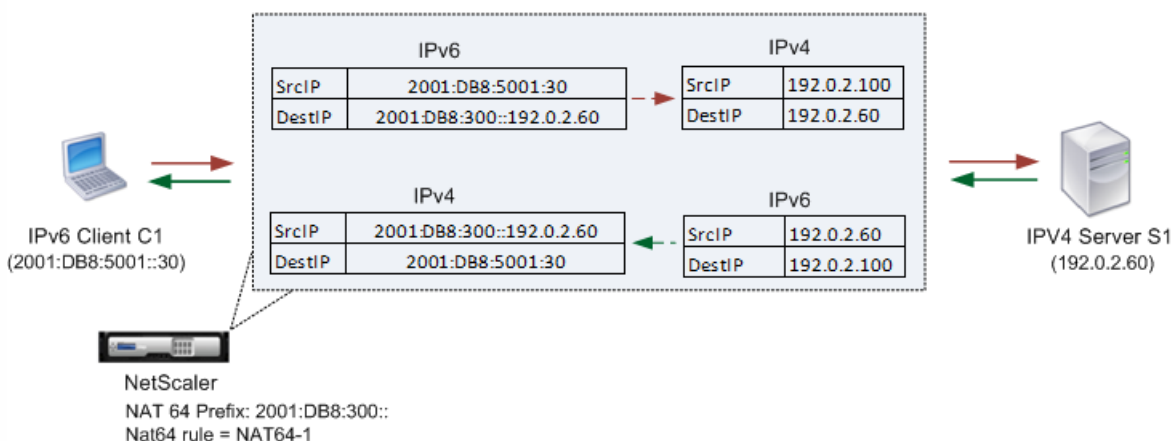

- The incoming IPv6 packet matches the ACL6 rule bound to a NAT64 rule.
- The destination IP address of the IPv6 packet matches the NAT64 IPv6 prefix.

When an IPv6 request packet received by the NetScaler appliance matches an ACL6 defined in a NAT64 rule and the destination IP of the packet matches the NAT64 IPv6 prefix, the NetScaler appliance considers the IPv6 packet for translation.

The appliance translates this IPv6 packet to an IPv4 packet with a source IP address matching one of the IP address bound to the netprofile defined in the NAT64 rule, and a destination IP address consisting of the last 32 bits of the destination IPv6 address of the IPv6 request packet. The NetScaler appliance creates a NAT64 session for this particular flow and forwards the packet to the IPv4 server. Subsequent responses from the IPv4 server and requests from the IPv6 client are translated accordingly by the appliance, on the basis of information in the particular NAT64 session.

Consider an example in which an enterprise hosts site `www.example.com` on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, NetScaler appliance NS1 is deployed with a stateful NAT64 configuration that includes a NAT64 rule and a NAT64 prefix. A mapped IPv6 address of server S1 is formed by concatenating the NAT64 IPv6 prefix [96 bits] and the IPv4 source address [32 bits]. This mapped IPv6 address is then manually configured in the DNS servers. The IPv6 clients get the mapped IPv6 address from the DNS servers to communicate with IPv4 server S1.

NAT64 Translation

The following table lists the settings used in this example:

Entities	Name	Value
IPv6 address of client CL1	Client_IPv6 (for reference purposes only)	2001:DB8:5001::30
IPv4 address of server S1	Sevr_IPv4 (for reference purposes only)	192.0.2.60
IPv6 prefix for NAT64 translation	NAT64_Prefix (for reference purposes only)	2001:DB8:300::
Mapped IPv6 address (NAT64_Prefix + Sevr_IPv4) of server S1 for IPv6 clients to reach server S1	Map-Sevr-IPv6 (for reference purposes only)	2001:DB8:300::192.0.2.60
ACL6 rule	ACL6-1	<ul style="list-style-type: none"> Action = ALLOW Source IP address = 2001:DB8:5001::30
IPset	IPset-1	IP addresses bound (of type SNIPs) = 192.0.2.100 and 192.0.2.102
Netprofile	Netprofile-1	Source IP address = IPset-1
NAT64 rule	NAT64-1	ACL6 rule = ACL6-1 Netprofile = Netprofile-1

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a request packet to Map-Sevr-IPv6 (2001:DB8:300::192.0.2.60) address.
2. The NetScaler appliance receives the request packet. If the request packet matches the ACL6 defined in the NAT64 rule, and the destination IP address of the packet matches the NAT64 IPv6 prefix, the NetScaler considers the IPv6 packet for translation.
3. The appliance creates a translated IPv4 request packet with:
 - Destination IP address field containing the NAT64 prefix stripped from the destination address of the IPv6 request (Sevr_IPv4 = 192.0.2.60)
 - Source IP address field containing one of the IPv4 address bound to Netprofile-1(in this case, 192.0.2.100)
4. The NetScaler appliance creates a NAT64 session for this flow and sends the translated IPv4 request to server S1.
5. IPv6 server S1 responds by sending an IPv4 packet to the NetScaler appliance with:
 - Destination IP address field containing 192.0.2.100
 - Source IP address field containing the address of Sevr_IPv4(192.0.2.60)
6. The appliance receives the IPv4 response packet, searches all the session entries, and finds that the IPv6 response packet matches the NAT64 session entry created in step 4. The appliance considers the IPv4 packet for translation.

7. The appliance creates a translated IPv6 response packet with:
 - Destination IP address field=Client_IPv6=2001:DB8:5001::30
 - Source IP address field = Concatenation of NAT64 Prefix (First 96 bits) and Sevr_IPv4 (last 32 bits)
=2001:DB8:300::192.0.2.60
8. The appliance sends the translated IPv6 response to client CL1.

This section includes the following details:

- [Limitations of Stateful NAT64](#)
- [Configuring Stateful NAT64](#)

Limitations of Stateful NAT64

The following limitations apply to stateful NAT64 translation:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv6 packets is not supported.
- Translation of multicast packets is not supported.
- Packets of Stream Control Transmission Protocol (SCTP), Datagram Congestion Control Protocol (DCCP), and IPSec, are not translated.

Configuring Stateful NAT64

Updated: 2013-10-31

Creating the required entities for stateful NAT64 configuration on the NetScaler appliance involves the following procedures:

1. Add an ACL6 rule with action ALLOW.
2. Add an ipset, which binds multiple IP addresses.
3. Add a netprofile and bind the ipset to it. If you want to bind only one IP address, you need not create an ipset entity. In that case, bind the IP address directly to the netprofile.
4. Add a NAT64 rule, which includes binding the ACL6 rule and the netprofile to the NAT 64 rule.
5. Add a NAT64 IPv6 prefix.

To add an ACL6 rule by using the command line interface

At the command prompt, type:

- add ns acl6 <acl6name> <acl6action> ...

To add an IPset and bind multiple IPs to it by using the command line interface

At the command prompt, type:

- add ipset <name>
- bind ipset <name> <IPaddress ...>

To add a netprofile by using the command line interface

At the command prompt, type:

- add netprofile <name> -srcIP <IPaddress or IPset>

To add a NAT64 rule by using the command line interface

At the command prompt, type:

- add nat64 <name> <acl6name> -netProfile <string>

To add a NAT64 prefix by using the command line interface

At the command prompt, type:

- `set ipv6 -natprefix <ipv6_addr|*>`

Example

```
> add acl6 ACL6-1 ALLOW -srcIPv6 2001:DB8:5001::30
```

Done

```
> apply acls6
```

Done

```
> add ip 192.0.2.100 255.255.255.0 -type SNIP
```

Done

```
> add ip 192.0.2.102 255.255.255.0 -type SNIP
```

Done

```
> add ipset IPset-1
```

Done

```
> bind ipset IPset-1 192.0.2.100 192.0.2.102
```

```
IPAddress "192.0.2.100" bound
```

```
IPAddress "192.0.2.102" bound
```

Done

```
> add netprofile Netprofile-1 -srcIP IPset-1
```

Done

```
> add nat64 NAT64-1 ACL6-1 -netprofile Netprofile-1
```

Done

```
> set ipv6 -natprefix 2001:DB8:300::96
```

Done

To add a NAT64 rule by using the configuration utility

Navigate to System > Network > Routes > NAT64, and add a new NAT64 rule, or edit an existing rule.

To add a NAT64 prefix by using the configuration utility

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

Configuring RNAT

May 11, 2012

In Reverse Network Address Translation (RNAT), the NetScaler appliance replaces the source IP addresses in the packets generated by the servers with public NAT IP addresses. By default, the appliance uses a Mapped IP address (MIP) as the NAT IP address. You can also configure the appliance to use a unique NAT IP address for each subnet. You can also configure RNAT by using Access Control Lists (ACLs). Use Source IP (USIP), Use Subnet IP (USNIP), and Link Load Balancing (LLB) modes affect the operation of RNAT. You can display statistics to monitor RNAT.

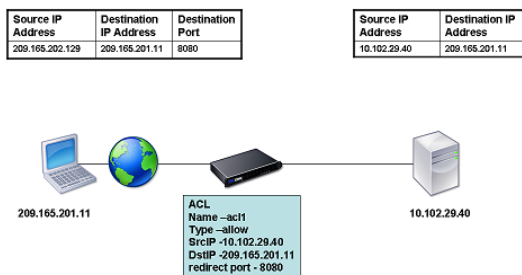

Note: The ephemeral port range for RNAT on the NetScaler appliance is 1024-65535.

You can use either a network address or an extended ACL as the condition for an RNAT entry:

- **Using a Network address.** When you use a network address, RNAT processing is performed on all of the packets coming from the specified network.
- **Using Extended ACLs.** When you use ACLs, RNAT processing is performed on all packets that match the ACLs. To configure the NetScaler appliance to use a unique IP address for traffic that matches an ACL, you must perform the following three tasks:
 1. Configure the ACL.
 2. Configure RNAT to change the source IP address and Destination Port.
 3. Apply the ACL.

The following diagram illustrates RNAT configured with an ACL.

Figure 1. RNAT with an ACL

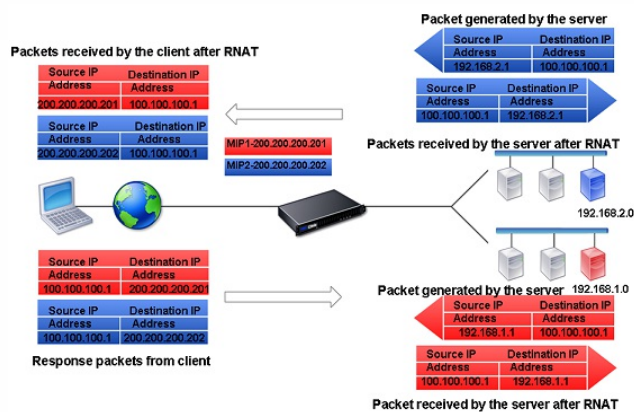

You have the following basic choices for the type of NAT IP address:

- **Using a MIP or SNIP as the NAT IP Address.** When using a MIP as the NAT IP address, the NetScaler appliance replaces the source IP addresses of server-generated packets with the a MIP. Therefore, the MIP address must be a public IP address. If Use Subnet IP (USNIP) mode is enabled, the NetScaler can use a subnet IP address (SNIP) as the NAT IP address.
- **Using a Unique IP Address as the NAT IP Address.** When using a unique IP address as the NAT IP address, the NetScaler appliance replaces the source IP addresses of server-generated packets with the unique IP address specified. The unique IP address must be a public NetScaler-owned IP address. If multiple NAT IP addresses are configured for a subnet, NAT IP selection uses the round robin algorithm.

This configuration is illustrated in the following diagram.

Figure 2. Using a Unique IP Address as the NAT IP Address

This section includes the following details:

- [Creating an RNAT Entry](#)
- [Monitoring RNAT](#)
- [RNAT in USIP, USNIP, and LLB Modes](#)
- [Configuring RNAT for IPv6 Traffic](#)

Creating an RNAT Entry

Updated: 2013-08-28

The following instructions provide separate command-line procedures for creating RNAT entries that use different conditions and different types of NAT IP addresses. In the configuration utility, all of the variations can be configured in the same dialog box, so there is only one procedure for configuration utility users.

To create an RNAT entry by using the command line interface

At the command prompt, type one the following commands to create, respectively, an RNAT entry that uses a network address as the condition and a MIP or SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a MIP or SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:

- `set nat <IPAddress> <netmask>`
- `set nat IPAddress <netMask> -natip <NATIPAddress>`
- `set nat <aclname> [-redirectPort <port>]`
- `set nat <aclname> [-redirectPort <port>] -natIP <NATIPAddress>`

Use the following command to verify the configuration:

- `show nat`

Examples

A network address as the condition and a MIP or SNIP as the NAT IP address:

```
> set nat 192.168.1.0 255.255.255.0
Done
```

A network address as the condition and a unique IP address as the NAT IP address:

```
> set nat 192.168.1.0 255.255.255.0 -natip 10.102.29.50
Done
```

If instead of a single NAT IP address you specify a range, RNAT entries are created with all the NetScaler-owned IP addresses, except the NSIP, that fall within the range specified:

```
> set nat 192.168.1.0 255.255.255.0 -natIP 10.102.29.[50-110]
Done
```

An ACL as the condition and a MIP or SNIP as the NAT IP address:

```
> set nat acl1
Done
```

An ACL as a condition and a unique IP address as the NAT IP address:

```
> set nat acl1 -natIP 209.165.202.129
Done
```

If instead of a single NAT IP address you specify a range, RNAT entries are created with all the NetScaler-owned IP addresses, except the NSIP, that fall within the range specified:

```
> set nat acl1 -natIP 10.102.29.[50-70]
Done
```

To create an RNAT entry by using the configuration utility

1. Navigate to System > Network > Routes > RNAT.
2. In the Action list, select Configure RNAT.

Monitoring RNAT

Updated: 2013-09-27

You can display RNAT statistics to troubleshoot issues related to IP address translation.

To view RNAT statistics by using the command line interface

At the command prompt, type:

```
stat nat
```

Example

```
> stat nat
```

RNAT summary

	Rate (/s)	Total
Bytes Received	0	0
Bytes Sent	0	0
Packets Received	0	0
Packets Sent	0	0
Syn Sent	0	0
Current RNAT sessions	--	0

Done

>

The following tables describes the statistics associated with RNAT and RNAT IP.

Table 1. RNAT Statistics

Statistic	Description
Bytes received	Bytes received during RNAT sessions
Bytes sent	Bytes sent during RNAT sessions
Packets received	Packets received during RNAT sessions
Packets sent	Packets sent during RNAT sessions
Syn sent	Requests for connections sent during RNAT sessions
Current sessions	Currently active RNAT sessions

To monitor RNAT by using the configuration utility

Navigate to System > Network > Routes > RNAT, and click Statistics.

RNAT in USIP, USNIP, and LLB Modes

Updated: 2013-12-18

Before configuring a RNAT rule, consider the following points:

- When RNAT and Use Source IP (USIP) are both configured on the NetScaler appliance, RNAT takes precedence. In other words, the source IP address of the packets, which matches a RNAT rule, is replaced according to the setting in the RNAT rule.
- When RNAT and Use SNIP (USNIP) are configured on the NetScaler appliance, selection of the source IP address is based on the state of USNIP, as follows:
 - If USNIP is off, the NetScaler appliance uses the mapped IP addresses.
 - If USNIP is on, the NetScaler uses a SNIP address as the NAT IP address.

This behavior does not apply when a unique NAT IP address is used.

In a topology where the NetScaler appliance performs both Link Load Balancing (LLB) and RNAT for traffic originating from the server, the appliance selects the source IP address based on the router. The LLB configuration determines selection of the router. For more information about LLB, see "[Link Load Balancing](#)."

Configuring RNAT for IPv6 Traffic

Updated: 2013-10-31

Reverse Network Address Translation (RNAT) rules for IPv6 packets are called RNAT6s. When an IPv6 packet generated by a server matches the conditions specified in the RNAT6 rule, the appliance replaces the source IPv6 address of the IPv6 packet with a configured NAT IPv6 address before forwarding it to the destination. The NAT IPv6 address is one of the NetScaler owned SNIP6 or VIP6 addresses.

When configuring an RNAT6 rule, you can specify either an IPv6 prefix or an ACL6 as the condition:

- **Using a IPv6 network address.** When you use an IPv6 prefix, the appliance performs RNAT processing on those IPv6 packets whose IPv6 address matches the prefix.
- **Using ACL6s.** When you use an ACL6, the appliance performs RNAT processing on those IPv6 packets that match the conditions specified in the ACL6.

You have one of the following options to set the NAT IP address:

- Specify a set of NetScaler owned SNIP6 and VIP6 addresses for an RNAT6 rule. The NetScaler appliance uses any one of the IPv6 addresses from this set as a NAT IP address for each session. The selection is based on the round robin algorithm and is done for each session.
- Do not specify any NetScaler owned SNIP6 or VIP6 address for an RNAT6 rule. The NetScaler appliance uses any one of the NetScaler owned SNIP6 or VIP6 addresses as a NAT IP address. The selection is based on the next hop network to which an IPv6 packet that matches the RNAT rule is destined.

To create an RNAT6 rule by using the command line interface

At the command prompt, to create the rule and verify the configuration, type:

- `add nat6 <name> (<network> | (<acl6name> [-redirectPort <port>]))`
- `bind nat6 <name> <natIP6>@ ...`
- `show nat6`

To modify or remove an RNAT6 rule by using the command line interface

- To modify an RNAT6 rule whose condition is an ACL6, type the `set nat6 <name>` command, followed by a new value for the `redirectPort` parameter.
- To remove an RNAT6 rule, type the `clear nat6 <name>` command.
- `show nat6`

To configure an RNAT6 rule by using the configuration utility

Navigate to `System > Network > Routes > RNAT6`, and add a new RNAT6 rule, or edit an existing rule.

Configuring Prefix-Based IPv6-IPv4 Translation

Aug 28, 2013

Prefix-based translation is a process of translating packets sent from private IPv6 servers into IPv4 packets, using an IPv6 prefix configured in the NetScaler appliance. This prefix has a length of 96 bits (128-32=96). The IPv6 servers embed the destination IP address of the IPv4 servers or hosts in the last 32 bits of the destination IP address field of the IPv6 packets. The first 96 bits of the destination IP address field are set as the IPv6 NAT prefix.

The NetScaler appliance compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix. If there is a match, the NetScaler appliance generates an IPv4 packet and sets the destination IP address as the last 32 bits of the destination IP address of the matched IPv6 packet. IPv6 packets addressed to this prefix have to be routed to the NetScaler so that the IPv6-IPv4 translation is done by the NetScaler.

In the following diagram, 3ffe::/96 is configured as the IPv6 NAT prefix on NetScaler NS1. The IPv6 host sends an IPv6 packet with destination IP address 3ffe::74.125.91.105. NS1 compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix, and they match. NS1 then generates an IPv4 packet and sets the destination IP address as 74.125.91.105.

Figure 1. IPv6-IPv4 Prefix-Based Translation

To configure prefix-based IPv6-IPv4 translation by using the command line interface

At the command prompt, type the following commands to set a NAT prefix and verify its configuration:

- set ipv6 [-natprefix <ipv6_addr | *>]
- show ipv6

Example

```
> set ipv6 -natprefix 3ffe::/96  
Done
```

To configure prefix-based IPv6-IPv4 translation by using the configuration utility

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

Configuring Static ARP

Aug 28, 2013

You can add static ARP entries to and remove static ARP entries from the ARP table. After adding an entry, you should verify the configuration. If the IP address, port, or MAC address changes after you create a static ARP entry, you must remove or manually adjust the static entry. Therefore, creating static ARP entries is not recommended unless necessary.

To add a static ARP entry by using the command line interface

At the command prompt, type:

- `add arp -IPAddress <ip_addr> -mac<mac_addr> -ifnum <interface_name>`
- `show arp <IPAddress>`

Example

```
> add arp -ip 10.102.29.6 -mac 00:24:e8:73:ca:ec -ifnum 1/1  
Done
```

To remove a static ARP entry by using the command line interface

At the command prompt, type the `rm arp` command and the IP address.

To add a static ARP entry by using the configuration utility

Navigate to `System > Network > ARP Table`, and add a new ARP entry.

Setting the Timeout for Dynamic ARP Entries

Aug 28, 2013

You can globally set an aging time (time-out value) for dynamically learned ARP entries. The new value applies only to ARP entries that are dynamically learned after the new value is set. Previously existing ARP entries expire after the previously configured aging time.

You can specify an ARP time-out value of from 1 through 1200 seconds.

To set the time-out for dynamic ARP entries by using the command line interface

At the command prompt, type the following commands to set the time-out for dynamic ARP entries and verify its configuration:

- `set arpparam -timeout <positive_integer>`
- `show arpparam`

Example

```
> set arpparam -timeout 500
```

```
Done
```

To set the time-out for dynamic ARP entries to its default value by using the command line interface

At the command prompt, type the following commands to set the time-out for dynamic ARP entries to its default value and verify its configuration:

- `unset arpparam`
- `show arpparam`

Example

```
> unset arpparam
```

```
Done
```

To set the time-out for dynamic ARP entries by using the configuration utility

Navigate to System > Network, in the Settings group, click Configure ARP Global Parameters, and set the ARP Table Entry Timeout parameter.

Configuring Neighbor Discovery

May 10, 2012

Neighbor discovery (ND) is one of the most important protocols of IPv6. It is a message-based protocol that combines the functionality of the Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Router Discovery. ND allows nodes to advertise their link layer addresses and obtain the MAC addresses or link layer addresses of the neighboring nodes. This process is performed by the Neighbor Discovery protocol (ND6).

Neighbor discovery can perform the following functions:

Router Discovery

Enables a host to discover the local routers on an attached link and automatically configure a default router.

Prefix Discovery

Enables the host to discover the network prefixes for local destinations.

Note: Currently, the NetScaler does not support Prefix Discovery.

Parameter Discovery

Enables a host to discover additional operating parameters, such as MTU and the default hop limit for outbound traffic.

Address Autoconfiguration

Enables hosts to automatically configure IP addresses for interfaces both with and without stateful address configuration services such as DHCPv6. The NetScaler does not support Address Autoconfiguration for Global IPv6 addresses.

Address Resolution

Equivalent to ARP in IPv4, enables a node to resolve a neighboring node's IPv6 address to its link-layer address.

Neighbor Unreachability Detection

Enables a node to determine the reachability state of a neighbor.

Duplicate Address Detection

Enables a node to determine whether an NSIP address is already in use by a neighboring node.

Redirect

Equivalent to the IPv4 ICMP Redirect message, enables a router to redirect the host to a better first-hop IPv6 address to reach a destination.

Note: The NetScaler does not support IPv6 Redirect.

To enable neighbor discovery, you create entries for the neighbors.

This section includes the following details:

- [Adding IPv6 Neighbors](#)
- [Removing IPv6 Neighbors](#)

Adding IPv6 Neighbors

Updated: 2013-08-28

Adding IPv6 neighbors enables neighbor discovery.

To add an IPv6 neighbor by using the command line interface

At the command prompt, type:

- add nd6 <neighbor> <mac> <if num> [-vlan <integer>]
- show nd6

Example

```
> add nd6 2001::1 00:04:23:be:3c:06 1/1 -vlan 1
Done
> show nd6
Neighbor          MAC-Address(Vlan, Interface)  State    TIME
-----
1) ::1            00:d0:68:0b:58:da( 1, LO/1) REACHABLE PERMANENT
2) fe80::2d0:68ff:fe0b:58da 00:d0:68:0b:58:da( 1, LO/1) REACHABLE PERMANENT
3) 2001::1        00:04:23:be:3c:06( 1, 1/1) REACHABLE  STATIC
Done
```

To add an IPv6 neighbor by using the configuration utility

Navigate to System > Network > IPv6 Neighbors, and add a new IPv6 neighbor.

Removing IPv6 Neighbors

Updated: 2013-08-28

To remove a neighbor discovery entry by using the command line interface

At the command prompt, type:

```
rm nd6 <Neighbor> -vlan <VLANID>
```

Example

```
rm nd6 3ffe:100:100::1 -vlan 1
```

To remove all neighbor discovery entries by using the command line interface

At the command prompt, type:

```
clear nd6
```

To remove a neighbor discovery entry by using the configuration utility

Navigate to System > Network > IPv6 Neighbors, delete the IPv6 neighbor.

To remove all neighbor discovery entries by using the configuration utility

Navigate to System > Network > IPv6 Neighbors, and click Clear.

Configuring IP Tunnels

Mar 20, 2012

An IP Tunnel is a communication channel, that can be created by using encapsulation technologies, between two networks that do not have a routing path. Every IP packet that is shared between the two networks is encapsulated within another packet and then sent via the tunnel.

The NetScaler appliance implements IP Tunneling in the following ways:

- NetScaler as an Encapsulator (Load Balancing with DSR mode)
- NetScaler as a Decapsulator

NetScaler as an Encapsulator (Load Balancing with DSR Mode)

Consider an organization that has multiple data centers across different countries, where the NetScaler maybe at one location and the back-end servers are located in a different country. In essence, the NetScaler and the back-end servers are on different networks and are connected via a router.

When you configure Direct Server Return (DSR) on this NetScaler, the packet sent from the source subnet is encapsulated by the NetScaler and sent via a router and tunnel to the appropriate back-end server. The back-end server decapsulates the packet and responds directly to the client, without allowing the packet to pass via the NetScaler.

NetScaler as a Decapsulator

Consider an organization having multiple data centers each having NetScalers and back-end servers. When a packet is sent from data center A to data center B it is usually sent via an intermediary, say a router or another NetScaler. The NetScaler processes the packet and then forwards the packet to the back-end server. However, if an encapsulated packet is sent, the NetScaler must be able to decapsulate the packet before sending it to the back-end servers. To enable the NetScaler to function as a decapsulator, a tunnel is added between the router and the NetScaler. When the encapsulated packet, with additional header information, reaches the NetScaler, the data packet is decapsulated i.e. the additional header information is removed, and the packet is then forwarded to the appropriate back-end servers.

The NetScaler can also be used as a decapsulator for the Load Balancing feature, specifically in scenarios when the number of connections on a vserver exceeds a threshold value and all the new connections are then diverted to a back-up vserver.

This section includes the following details:

- [Creating IP Tunnels](#)
- [Customizing IP Tunnels Globally](#)

Creating IP Tunnels

Updated: 2013-10-31

To create an IP tunnel by using the command line interface

At the command prompt type:

- add iptunnel <name> <remote> <remoteSubnetMask> <local> -type -protocol (ipoverip | GRE) -ipseccprofile <name>
- show iptunnel

Note: While configuring an IP tunnel in a cluster setup, the local IP address must be a striped SNIP or MIP address.

To remove an IP tunnel by using the command line interface

To remove an IP tunnel, type the `rm iptunnel` command and the name of the tunnel.

To create an IP Tunnel by using the configuration utility

Navigate to `System > Network > IP Tunnels`, add a new IP tunnel.

To create an IPv6 tunnel by using the command line interface

At the command prompt type:

- `add ip6tunnel <name> <remoteIp> <local>`
- `show ip6tunnel`

To remove an IPv6 tunnel by using the command line interface

To remove an IPv6 tunnel, type the `rm ip6tunnel` command and the name of the tunnel.

To create an IPv6 Tunnel by using the configuration utility

Navigate to `System > Network > IP Tunnels > IPv6 Tunnels`, and add a new IPv6 tunnel.

Customizing IP Tunnels Globally

Updated: 2013-10-31

By globally specifying the source IP address, you can assign a common source IP address across all tunnels. Also, because fragmentation is CPU-intensive, you can globally specify that the NetScaler appliance drop any packet that requires fragmentation. Alternatively, if you would like to fragment all packets as long as a CPU threshold value is not reached, you can globally specify the CPU threshold value.

To globally customize IP tunnels by using the command line interface

At the command prompt, type the following commands to globally customize IP tunnels and verify the configuration:

- `set ipTunnelParam -srcIP <sourceIPAddress> -srcIPRoundRobin (YES | NO)-dropFrag [YES | NO]-dropFragCpuThreshold <Positive integer>`
- `show ipTunnelParam`

Example

```
> set iptunnelparam -srcIP 12.12.12.22 -dropFrag Yes -dropFragCpuThreshold 50
Done
```

```
> set iptunnelparam -srcIPRoundRobin YES -dropFrag Yes -dropFragCpuThreshold 50
Done
```

Note: To create a new MIP or SNIP address to use as the global source IP address, use the `add ns ip` command before you type the `set iptunnelparam` command.

To globally customize IP tunnels by using the configuration utility

Navigate to `System > Network`, in the Settings group, click `IPv4 Tunnel Global Settings`.

1. Navigate to System > Network.
2. In the details pane, in the Settings group, click IPv4 Tunnel Global Settings.
3. In the Configure IP Tunnel Global Parameters dialog box, set the parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
4. Click OK and then click Close.

To globally customize IPv6 tunnels by using the command line interface

At the command prompt, type the following commands to globally customize IPv6 tunnels and verify the configuration:

- `set ip6tunnelparam -srcIP <IPv6Address> -srcIPRoundRobin (YES | NO)-dropFrag [YES | NO] -dropFragCpuThreshold <Positive integer>`
- `show ip6tunnelparam`

Note: To create a new VIP6 or SNIP6 address to use as the global source IP address, use the `add ns ip6` command before you type the `set ip6tunnelparam` command.

To globally customize IPv6 tunnels by using the configuration utility

Navigate to System > Network, in the Settings group, click IPv6 Tunnel Global Settings.

Interfaces

Aug 29, 2013

Before you begin configuring interfaces, decide whether your configuration can use MAC-based forwarding mode, and either enable or disable this system setting accordingly. The number of interfaces in your configuration is different for the different models of the Citrix NetScaler appliance. In addition to configuring individual interfaces, you can logically group interfaces, using VLANs to restrict data flow within a set of interfaces, and you can aggregate links into channels. In a high availability setup, you can configure a virtual MAC (VMAC) address if necessary. If you use L2 mode, you might want to modify the aging of the bridge table.

When your configuration is complete, decide whether you should enable the system setting for path MTU discovery. NetScaler appliances can be deployed in active-active mode using VRRP. An active-active deployment, in addition to preventing downtime, makes efficient use of all the NetScaler appliances in the deployment. You can use the Network Visualizer tool to view the network configuration of a NetScaler deployment and configure interfaces, channels, VLANs, and bridge groups.

Configuring MAC-Based Forwarding

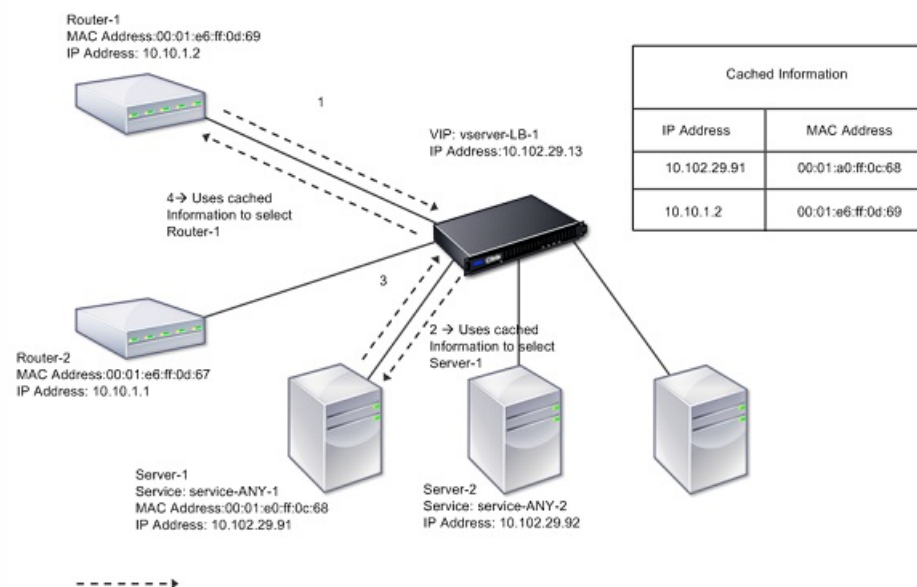

Oct 31, 2013

With MAC-based forwarding (MBF) enabled, when a request reaches the NetScaler appliance, the appliance remembers the source MAC address of the frame and uses it as the destination MAC address for the resulting replies. MAC-based forwarding can be used to avoid multiple-route/ARP lookups and to avoid asymmetrical packet flows. MAC-based forwarding may be required when the NetScaler is connected to multiple stateful devices, such as VPNs or firewalls, because it ensures that the return traffic is sent to the same device that the initial traffic came from.

MAC-based forwarding is useful when you use VPN devices, because it guarantees that all traffic flowing through a VPN passes back through the same VPN device.

The following topology diagram illustrates the process of MAC-based forwarding.

Figure 1. MAC-Based Forwarding Mode

When MAC-based forwarding (MBF) is enabled, the NetScaler caches the MAC address of:

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server replies through the NetScaler appliance, the appliance sets the destination MAC address of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when the NetScaler initiates a connection, it uses the route and ARP tables for the lookup function. In a direct server return configuration, you must enable MAC-based forwarding.

For more information about direct server return configurations, see "[Load Balancing](#)."

Some deployment topologies may require the incoming and outgoing paths to flow through different routers. MAC-based forwarding would break this topology design.

MBF should be disabled in the following situations:

- **When you configure link load balancing.** In this case, asymmetric traffic flows are desirable because of link costs.
- **When a server uses network interface card (NIC) teaming without using LACP (802.1ad Link Aggregation).** To enable MAC-based forwarding in this situation, you must use a layer 3 device between the NetScaler and server. Note: MBF can be enabled when the server uses NIC teaming with LACP, because the virtual interface uses one MAC address.
- When firewall clustering is used. Firewall clustering assumes that ARP is used to resolve the MAC address for inbound traffic. Sometimes the inbound MAC address can be a non-clustered MAC address and should not be used for inbound packet processing.

When MBF is disabled, the NetScaler uses L2 or L3 connectivity to forward the responses from servers to the clients. Depending on the route table, the routers used for outgoing connection and incoming connection can be different. In the case of reverse traffic (response from the server):

- If the source and destination are on different IP subnets, the NetScaler uses the route lookup to locate the destination.
- If the source is on the same subnet as the destination, the NetScaler looks up the ARP table to locate the network interface and forwards the traffic to it. If the ARP table does not exist, the NetScaler requests the ARP entries.

To enable or disable MAC-based forwarding by using the command line interface

At the command prompt, type:

- enable ns mode MBF
- disable ns mode MBF

To enable or disable MAC-based forwarding by using the configuration utility

1. Navigate to System > Settings, in the Modes and Features group, click Configure modes.
2. Select or clear the MAC-based forwarding option.

Configuring Network Interfaces

Mar 19, 2012

Network interfaces in the NetScaler appliance are numbered in <slot>/<port> notation. After configuring your interfaces, you should display the interfaces and their settings to verify the configuration. You can also display this information to troubleshoot a problem in the configuration.

To manage the network interfaces, you might have to enable some interfaces and disable others. You can reset an interface to renegotiate its settings. You can clear the accumulated statistics for an interface. To verify the configuration, you can display the interface settings. You can display the statistics for an interface to evaluate its health.

Updated: 2013-09-06

The network interface configuration is neither synchronized nor propagated. For an HA pair, you must perform the configuration on each unit independently.

Network interface parameters include Link Aggregate Control Protocol (LACP) settings. For more information about Link Aggregate Control Protocol (LACP), see "[Configuring Link Aggregation Using the Link Aggregate Channel Protocol](#)."

To set the network interface parameters by using the command line interface

At the command prompt, type:

- `set interface <id> [-speed <speed>] [-duplex <duplex>] [-flowControl <flowControl>] [-autoneg (DISABLED | ENABLED)] [-haMonitor (ON | OFF)] [(ON | OFF)] [-tagall (ON | OFF)] [-lacpMode <lacpMode>] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT)] [-ifAlias <string>] [-throughput <positive_integer>] [-bandwidthHigh <positive_integer>] [-bandwidthNormal <positive_integer>]`
- `show interface [<id>]`

Example

```
> set interface 1/8 -duplex full
Done
```

To set the network interface parameters by using the configuration utility

Navigate to System > Network > Interfaces, select the network interface that you want to modify (for example, 1/8), click Edit, and then set the parameters.

Updated: 2013-08-29

By default, the network interfaces are enabled. You must disable any network interface that is not connected to the network, so that it cannot send or receive packets. Disabling a network interface that is connected to the network in a high availability setup can cause failover.

For more information about high availability, see "[High Availability](#)."

To enable or disable a network interface by using the command line interface

At the command prompt, type one of the following pairs of commands to enable or disable an interface and verify the setting:

- enable interface <interface_num>
- show interface <interface_num>
- disable interface <interface_num>
- show interface <interface_num>

Example

```
> enable interface 1/8
Done
> show interface 1/8
  Interface 1/8 (Gig Ethernet 10/100/1000 Mbits) #2
  flags=0x4004000 <ENABLED, DOWN, BOUND to LA/1, down, autoneg, 802.1q>
  MTU=1514, MAC=00:d0:68:15:fd:3d, downtime 906h58m40s
  Requested: media UTP, speed AUTO, duplex FULL, fctl OFF, throughput 0
  RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
  TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
  NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
  Bandwidth thresholds are not set.
Done
```

To enable or disable a network interface by using the configuration utility

1. Navigate to System > Network > Interfaces.
2. Select the network interface and, in the Action list, select Enable or Disable.

Updated: 2013-09-30

Network interface settings control properties such as duplex and speed. To renegotiate the settings of a network interface, you must reset it.

To reset a network interface by using the command line interface

At the command prompt, type the following commands to reset an interface and verify the setting:

- reset interface <interface_num>
- show interface <interface_num>

Example

```
> reset interface 1/8
Done
```

To reset a network interface by using the configuration utility

1. Navigate to System > Network > Interfaces.
2. Select the network interface and, in the Action list, select Reset Interface.

Updated: 2013-08-29

You can display network interface statistics to monitor parameters such as packets sent and packets received, throughput, Link Aggregate Control Protocol (LACP) data units, and errors, and use the information to check the health of the network interface. You can clear the statistics of a network interface to monitor its statistics from the time the statistics are cleared.

To display the statistics of the network interfaces by using the command line interface

At the command prompt, type:

```
stat interface <interface_num>
```

To display the statistics of an Interface by using the configuration utility

Navigate to System > Network > Interfaces, select the network interface, and click Interface Statistics.

To clear a network interface's statistics by using the command line interface

At the command prompt, type:

```
clear interface <interface_num>
```

Example

```
> clear interface 1/8  
Done
```

To clear a network interface's statistics by using the configuration utility

1. Navigate to System > Network > Interfaces.
2. Select the network interface and, in the Action list, select Clear Statistics.

Configuring Forwarding Session Rules

Jun 11, 2014

By default, the NetScaler appliance does not create session entries for traffic that it only forwards (L3 mode). For a case in which a client request that the appliance forwards to a server results in a response that has to return by the same path, you can create a forwarding-session rule. A forwarding-session rule creates forwarding-session entries for traffic that originates from or is destined for a particular network and is forwarded by the NetScaler. You can create forwarding session rules for IPv4 traffic as well as IPv6 traffic.

When configuring an IPv4 forwarding-session rule, you can specify either an IPv4 network address or an extended ACL as the condition for identifying IPv4 traffic for which to create a forwarding-session entry:

- **Network address.** When you specify an IPv4 network address, the appliance creates forwarding sessions for IPv4 traffic whose source or destination matches the network address.
- **Extended ACL rule.** When you specify an extended ACL rule, the appliance creates forwarding sessions for IPv4 traffic that matches the conditions specified in the extended ACL rule.

When configuring an IPv6 forwarding-session rule, you can specify either an IPv6 prefix or an ACL6 as the condition for identifying IPv6 traffic for which to create a forwarding-session entry:

- **IPv6 prefix.** When you specify an IPv6 prefix, the appliance creates forwarding sessions for IPv6 traffic whose source or destination matches the IPv6 prefix.
- **ACL6 rule.** When you specify an ACL6 rule, the appliance creates forwarding sessions for IPv6 traffic that matches the conditions specified in the ACL6 rule.

At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:

- `add forwardingSession <name> [<network> <netmask>] | [-aclname <string>] -connfailover (ENABLED | DISABLED)`
- `show forwardingSession`

Example

A network address as the condition:

```
> add forwardingSession fs-nw-1 10.102.105.51 255.255.255.255
Done
```

An ACL as the condition:

```
> add forwardingSession fs-acl-1 acl1
Done
```

Navigate to System > Network > Forwarding Sessions, add a new IPv4 forwarding session, or edit an existing forwarding session.

At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:

- `add forwardingSession <name> [<IPv6 prefix>] | [-acl6name <string>]`

- show forwardingSession

Example

An IPv6 prefix as the condition:

```
> add forwardingSession fsv6-pfx-1 3ffe::/64  
Done
```

An ACL6 rule as the condition:

```
> add forwardingSession fsv6-acl6-1 --acl6name ACL6-FS  
Done
```

Navigate to System > Network > Forwarding Sessions, add a new IPv6 forwarding session, or edit an existing forwarding session.

Understanding VLANs

Mar 19, 2012

A NetScaler appliance supports Layer 2 port and IEEE 802.1q tagged VLANs. VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface as a part of multiple VLANs by using IEEE 802.1q tagging.

You can configure VLANs and bind them to IP subnets. The NetScaler then performs IP forwarding between these VLANs (if it is configured as the default router for the hosts on these subnets).

The NetScaler supports the following types of VLANs:

Port-Based VLANs. The membership of a port-based VLAN is defined by a set of network interfaces that share a common, exclusive Layer 2 broadcast domain. You can configure multiple port-based VLANs. By default, all network interfaces on the NetScaler are members of VLAN 1.

If you apply 802.1q tagging to the port, the network interface belongs to a port-based VLAN. Layer 2 traffic is bridged within a port-based VLAN, and Layer 2 broadcasts are sent to all members of the VLAN if Layer 2 mode is enabled. When you add an untagged network interface as a member of a new VLAN, it is removed from its current VLAN.

Default VLAN. By default, the network interfaces on the NetScaler are included in a single, port-based VLAN as untagged network interfaces. This VLAN is the default VLAN. It has a VLAN ID (VID) of 1. This VLAN exists permanently. It cannot be deleted, and its VID cannot be changed.

When you add a network interface to a different VLAN as an untagged member, the network interface is automatically removed from the default VLAN. If you unbind a network interface from its current port-based VLAN, it is added to the default VLAN again.

Tagged VLANs. 802.1q tagging (defined in the IEEE 802.1q standard) allows a networking device (such as the NetScaler) to add information to a frame at Layer 2 to identify the VLAN membership of the frame. Tagging allows network environments to have VLANs that span multiple devices. A device that receives the packet reads the tag and recognizes the VLAN to which the frame belongs. Some network devices do not support receiving both tagged and untagged packets on the same network interface—in particular, Force10 switches. In such cases, you need to contact customer support for assistance.

The network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of one VLAN only (its native VLAN). This network interface transmits the frames for the native VLAN as untagged frames. A network interface can be a part of more than one VLAN if the other VLANs are tagged.

When you configure tagging, be sure to match the configuration of the VLAN on both ends of the link. The port to which the NetScaler connects must be on the same VLAN as the NetScaler network interface.

Note: This VLAN configuration is neither synchronized nor propagated, therefore you must perform the configuration on each unit in an HA pair independently.

VLANs have two types of rules for classifying frames:

Ingress rules. Ingress rules classify each frame as belonging only to a single VLAN. When a frame is received on a network interface, the following rules are applied to classify the frame:

- If the frame is untagged, or has a tag value equal to 0, the VID of the frame is set to the port VID (PVID) of the receiving interface, which is classified as belonging to the native VLAN. (PVIDs are defined in the IEEE 802.1q standard.)
- If frame has a tag value equal to FFF, the frame is dropped.
- If the VID of the frame specifies a VLAN of which the receiving network interface is not a member, the frame is dropped. For example, if a packet is sent from a subnet associated with VLAN ID 12 to a subnet associated with VLAN ID 10, the packet is dropped. If an untagged packet with VID 9 is sent from the subnet associated with VLAN ID 10 to a network interface PVID 9, the packet is dropped.

Egress Rules. The following egress rules are applied:

- If the VID of the frame specifies a VLAN of which the transmission network interface is not a member, the frame is discarded.
- During the learning process (defined by the IEEE 802.1q standard), the Src MAC and VID are used to update the bridge lookup table of the NetScaler.
- A frame is discarded if its VID specifies a VLAN that does not have any members. (You define members by binding network interfaces to a VLAN.)

VLANs and Packet Forwarding on the NetScaler

The forwarding process on the NetScaler appliance is similar to that on any standard switch. However, the NetScaler performs forwarding only when Layer 2 mode is on. The key features of the forwarding process are:

- Topology restrictions are enforced. Enforcement involves selecting each network interface in the VLAN as a transmission port (depending on the state of the network interface), bridging restrictions (do not forward on the receiving network interface), and MTU restrictions.
- Frames are filtered on the basis of information in the bridge table lookup in the forwarding database (FDB) table of the NetScaler. The bridge table lookup is based on the destination MAC and the VID. Packets addressed to the MAC address of the NetScaler are processed at the upper layers.
- All broadcast and multicast frames are forwarded to each network interface that is a member of the VLAN, but forwarding occurs only if L2 mode is enabled. If L2 mode is disabled, the broadcast and multicast packets are dropped. This is also true for MAC addresses that are not currently in the bridging table.
- A VLAN entry has a list of member network interfaces that are part of its untagged member set. When forwarding frames to these network interfaces, a tag is not inserted in the frame.
- If the network interface is a tagged member of this VLAN, the tag is inserted in the frame when the frame is forwarded.

When a user sends any broadcast or multicast packets without the VLAN being identified, that is, during duplicate address detection (DAD) for NSIP or ND6 for the next hop of the route, the packet is sent out on all the network interfaces, with appropriate tagging based on either the Ingress and Egress rules. ND6 usually identifies a VLAN, and a data packet is sent on this VLAN only. Port-based VLANs are common to IPv4 and IPv6. For IPv6, the NetScaler supports prefix-based VLANs.

Configuring a VLAN

May 26, 2015

You can implement VLANs in the following environments:

- Single subnet
- Multiple subnets
- Single LAN
- VLANs (no tagging)
- VLANs (802.1q tagging)

If you configure VLANs that have only untagged network interfaces as their members, the total number of possible VLANs is limited to the number of network interfaces available in the NetScaler. If more IP subnets are required with a VLAN configuration, 802.1q tagging must be used.

When you bind a network interface to a VLAN, the network interface is removed from the default VLAN. If the network interfaces need to be a part of more than one VLAN, you can bind the network interfaces to the VLANs as tagged members.

You can configure the NetScaler to forward traffic between VLANs at Layer 3. In this case, a VLAN is associated with a single IP subnet. The hosts in a VLAN that belong to a single subnet use the same subnet mask and one or more default gateways connected to that subnet. Configuring Layer 3 for a VLAN is optional. Layer 3 is used for IP forwarding (inter-VLAN routing). Each VLAN has a unique IP address and subnet mask that define an IP subnet for the VLAN. In an HA configuration, this IP address is shared with the other NetScaler appliances. The NetScaler forwards packets between configured IP subnets (VLANs).

When you configure the NetScaler, you must not create overlapping IP subnets. Doing so impedes Layer 3 functionality.

Each VLAN is a unique Layer 2 broadcast domain. Two VLANs, each bound to separate IP subnets, cannot be combined into a single broadcast domain. Forwarding traffic between two VLANs requires a Layer 3 forwarding (routing) device, such as the NetScaler appliance.

VLAN configuration for a high-availability setup requires that the NetScaler appliances have the same hardware configuration, and the VLANs configured on them must be mirror images.

The correct VLAN configuration is implemented automatically when the configuration is synchronized between the NetScaler appliances. The result is identical actions on all the appliances. For example, adding network interface 0/1 to VLAN2 adds this network interface to VLAN 2 on all the appliances participating in the high-availability setup.

Note: If you use network-interface-specific commands in an HA setup, the configurations you create are not propagated to the other NetScaler appliance. You must perform these commands on each appliance in an HA pair to ensure that the configuration of the two appliances in the HA pair remains synchronized.

Updated: 2013-08-29

To configure a VLAN, you create a VLAN entity, and then bind network interfaces and IP addresses to the VLAN. If you remove a VLAN, its member interfaces are added to the default VLAN.

To create a VLAN by using the command line interface

At the command prompt, type:

```
add vlan <id> [-aliasName <string>] [-ipv6DynamicRouting (ENABLED | DISABLED)]
```

Example

```
> add vlan 2 -aliasName "Network A" Done
```

To bind an interface to a VLAN by using the command line interface

At the command prompt, type:

```
bind vlan <id> -ifnum <slot/port>
```

Example

```
> bind vlan 2 -ifnum 1/8 Done
```

To bind an IP address to a VLAN by using the command line interface

At the command prompt, type:

```
bind vlan <id> -IPAddress <IPAddress> <netMask>
```

Example

```
> bind vlan 2 -IPAddress 10.102.29.54 255.255.255.0 Done
```

To remove a VLAN by using the command line interface

At the command prompt, type:

```
rm vlan <id>
```

To configure a VLAN by using the configuration utility

1. Navigate to System > Network > VLANs, add a new VLAN, or edit an existing VLAN.
2. To bind an IP address to a VLAN, under IP Bindings, select the Active option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The Type column displays the IP address type (such as mapped IP, virtual IP, or subnet IP) for each IP address in the IP Address column.
3. To bind a network interface to a VLAN, under Interface Bindings, select the Active option corresponding to the interface that you want to bind to the VLAN.

Updated: 2013-08-29

You can display VLAN statistics such as packets received, bytes received, packets sent, and bytes sent, and use the information to identify anomalies and or debug a VLAN.

To view the statistics of a VLAN by using the command line interface

At the command prompt, type:

```
stat vlan <vlanID>
```

Example

stat vlan 2

To view the statistics of a VLAN by using the configuration utility

1. Navigate to System > Network > VLANs.
2. Select the VLAN, and click Statistics.

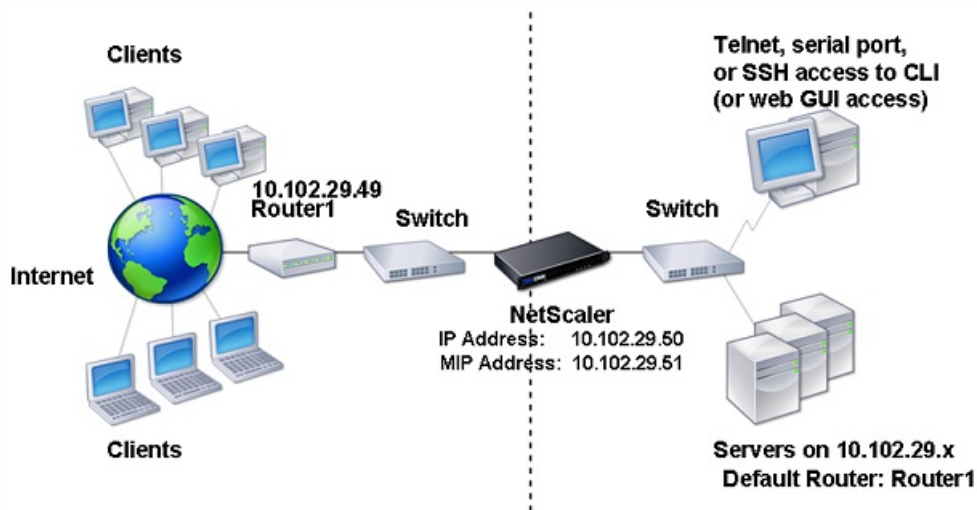

Configuring VLANs on a Single Subnet

Aug 29, 2013

Before configuring a VLAN on a single subnet, make sure that Layer 2 Mode is enabled.

The following figure shows a single subnet environment

Figure 1. VLAN on a Single Subnet

In the above figure:

1. The default router for the NetScaler and the servers is Router 1.
2. Layer 2 mode must be enabled on the NetScaler for the NetScaler to have direct access to the servers.
3. For this subnet, a virtual server can be configured for load balancing on the NetScaler appliance.

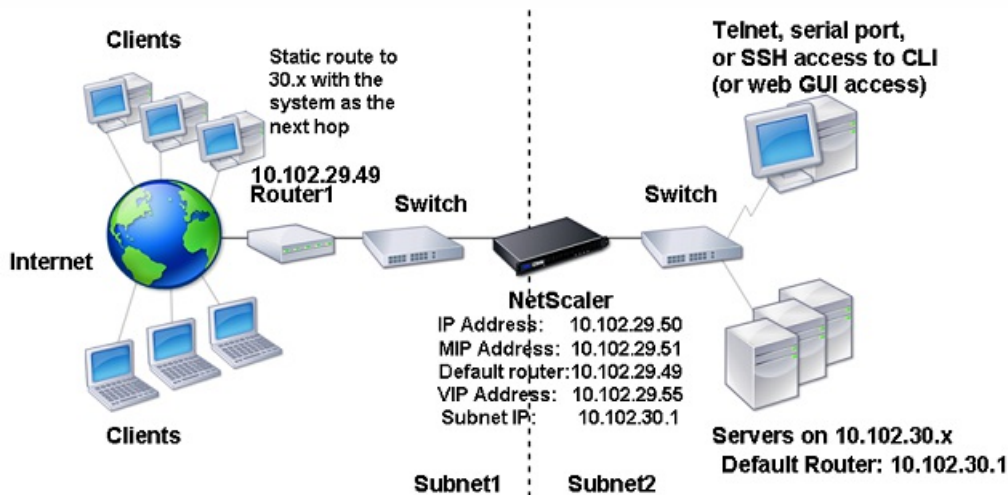

To configure a VLAN on a single subnet, follow the procedures described in "Creating or Modifying a VLAN" in [Configuring a VLAN](#). VLAN configuration parameters are not required, because the network interfaces are members of this VLAN.

Configuring VLANs on Multiple Subnets

Aug 29, 2013

To configure a single VLAN across multiple subnets, you must add a VIP for the VLAN and configure the routing appropriately. The following figure shows a single VLAN configured across multiple subnets.

Figure 1. Multiple Subnets in a Single VLAN

To configure a single VLAN across multiple subnets, perform the following tasks:

1. Disable Layer 2 mode. For the procedure to disable Layer 2 mode, see "[Enabling and Disabling Layer 2 Mode.](#)"

2. Add a VIP.

For the procedure to add a VIP, see "[Configuring and Managing Virtual IP Addresses \(VIPs\).](#)"

3. Configure RNAT ID.

For the procedure to configure the RNAT ID, see "[Configuring RNAT.](#)"

Configuring Multiple Untagged VLANs across Multiple Subnets

Aug 29, 2013

In environments with multiple untagged VLANs across multiple subnets, a VLAN is configured for each IP subnet. A network interface is bound to one VLAN only. The following figure shows this configuration.

Figure 1. Multiple Subnets with VLANs - No Tagging

To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.

For the procedure to create a VLAN, see "Creating or Modifying a VLAN" in [Configuring a VLAN](#).

2. Bind the 1/2 network interface of the NetScaler to VLAN 2 as an untagged network interface.

For the procedure to bind a network interface to a VLAN, see "Creating or Modifying a VLAN" in [Configuring a VLAN](#).

3. Bind the IP address and subnet mask to VLAN 2.

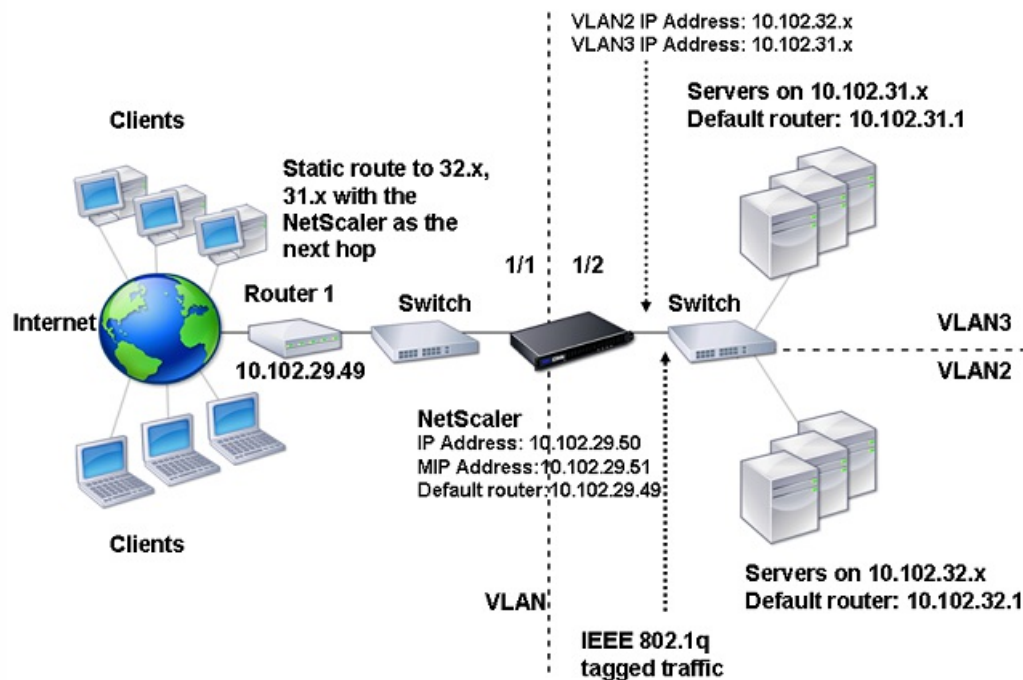

For the procedure to bind a network interface to a VLAN, see "Creating or Modifying a VLAN" in [Configuring a VLAN](#).

Configuring Multiple VLANs with 802.1q Tagging

Aug 29, 2013

For multiple VLANs with 802.1q tagging, each VLAN is configured with a different IP subnet. Each network interface is in one VLAN. One of the VLANs is set up as tagged. The following figure shows this configuration.

Figure 1. Multiple VLANs with IEEE 802.1q Tagging

To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.

For the procedure to create a VLAN, see "Creating or Modifying a VLAN" in [Configuring a VLAN](#).

2. Bind the 1/2 network interface of the NetScaler to VLAN 2 as an untagged network interface.

For the procedure to bind a network interface to a VLAN, see "Creating or Modifying a VLAN" in [Configuring a VLAN](#).

3. Bind the IP address and netmask to VLAN 2.

For the procedure to bind an IP address to a VLAN, see "Creating or Modifying a VLAN" in [Configuring a VLAN](#).

4. Add VLAN 3.

For the procedure to create a VLAN, see "Creating or Modifying a VLAN" in [Configuring a VLAN](#).

5. Bind the 1/2 network interface of the NetScaler to VLAN 3 as a tagged network interface.

For the procedure to bind a network interface to a VLAN, see "Creating or Modifying a VLAN" in [Configuring a VLAN](#).

For the procedure to bind a tagged network interface, see "Creating or Modifying a VLAN" in [Configuring a VLAN](#).

6. Bind the IP address and netmask to VLAN 3.

For the procedure to bind an IP address to a VLAN, see "Creating or Modifying a VLAN" in [Configuring a VLAN](#).

Configuring NSVLAN

Jul 05, 2013

NSVLAN is a VLAN to which the NetScaler management IP (NSIP) address's subnet is bound. The NSIP subnet is available only on interfaces that are associated with NSVLAN. By default, NSVLAN is VLAN1, but you can designate a different VLAN as NSVLAN. If you do so, you must reboot the NetScaler appliance for the change to take effect. After the reboot, NSIP subnet traffic is restricted to the new NSVLAN.

The traffic from the NetScaler IP subnet can be tagged (802.1q) with the VLAN ID specified for NSVLAN. You must configure the attached switch interface to tag and allow this same VLAN ID on the connected interface.

If you remove your NSVLAN configuration, the NSIP subnet is automatically bound to VLAN1, restoring the default NSVLAN.

At the command prompt, type:

- `set ns config -nsvlan <positive_integer> -ifnum <interface_name> ... [-tagged (YES | NO)]`
- `show ns config`

Note: The configuration takes effect after the NetScaler appliance is rebooted.

Example

```
> set ns config -nsvlan 300 -ifnum 1/1 1/2 1/3 -tagged NO
Done

> save config
Done
```

At the command prompt, type:

- `unset ns config -nsvlan`
- `show ns config`

Example

```
> unset ns config -nsvlan
Done
```

Navigate to System > Settings, in the Settings group, click Change NSVLAN Settings.

Configuring Bridge Groups

Aug 29, 2013

Typically, when you want to merge two or more VLANs into a single domain, you change the VLAN configuration on all the devices in the separate domains. This can be a tedious task. To more easily merge multiple VLANs into a single broadcast domain, you can use bridge groups.

The bridge groups feature works the same way as a VLAN. Multiple VLANs can be bound to a single bridge group, and all VLANs bound to same bridge group form a single broadcast domain. You can bind only Layer 2 VLANs to a bridge group. For Layer 3 functionality, you must assign an IP address to a bridge group.

In Layer 2 mode, a broadcast packet received on an interface belonging to a particular VLAN is bridged to other VLANs that belong to the same bridge group. In the case of a unicast packet, the NetScaler appliance searches its bridge table for the learned MAC addresses of all the VLANs belonging to same bridge group.

In Layer 3 forwarding mode, an IP subnet is bound to a bridge group. The NetScaler accepts incoming packets belonging to the bound subnet and forwards the packets only on VLANs that are bound to the bridge group.

IPv6 routing can be enabled on a configured bridge group.

To add a bridge group and bind VLANs and verify the configuration, type the following commands:

- add bridgegroup <id> [-ipv6DynamicRouting (ENABLED | DISABLED)]
- show bridgegroup <id>
- bind bridgegroup <id> -vlan <positive_integer>
- show bridgegroup <id>

Example

```
> add bridgegroup 12
Done
```

At the command prompt, type:

```
rm bridgegroup <id>
```

Example

```
rm bridgegroup 12
```

Navigate to System > Network > Bridge Groups, add a new bridge group, or edit an existing bridge group.

Configuring VMACs

Aug 29, 2013

The primary and secondary nodes in a high availability (HA) setup share the Virtual MAC address (VMAC) floating entity. The primary node owns the floating IP addresses (such as MIP, SNIP, and VIP) and responds to ARP requests for these IP addresses with its own MAC address. Therefore, the ARP table of an external device, such as an upstream router, is updated with the floating IP address and the MAC address of the primary node.

When a failover occurs, the secondary node takes over as the new primary node. The former secondary node uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it had learned from the old primary node. The MAC address that the new primary node advertises is the MAC address of its own network interface. Some devices (a few routers) do not accept these GARP messages. Therefore, these external devices retain the IP address-to-MAC address mapping that the old primary node had advertised. This can result in a GSLB site going down.

Therefore, you must configure a VMAC on both nodes of an HA pair. This means that both nodes have identical MAC addresses. When a failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

For the procedures to configure a VMAC, see "[High Availability](#)."

Configuring Link Aggregation

Sep 06, 2013

Link aggregation combines data coming from multiple ports into a single high-speed link. Configuring link aggregation increases the capacity and availability of the communication channel between the NetScaler appliance and other connected devices. An aggregated link is also referred to as a "channel." You can configure the channels manually, or you can use Link Aggregation Control Protocol (LACP). You cannot apply LACP to a manually configured channel, nor can you manually configure a channel created by LACP.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. (That is, the network interface parameters are ignored.) A network interface can be bound only to one channel.

When a network interface is bound to a channel, it drops its VLAN configuration. When network interfaces are bound to a channel, either manually or by LACP, they are removed from the VLANs that they originally belonged to and added to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you bind the network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then bind them to a channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them back to VLAN 2.

This section includes the following details:

- [Configuring Link Aggregation Manually](#)
- [Configuring Link Aggregation by Using the Link Aggregation Control Protocol](#)
- [Configuring Link Redundancy using LACP channels](#)

Updated: 2013-08-29

When you create a link aggregation channel, its state is DOWN until you bind an active interface to it. You can modify a channel at any time. You can remove channels, or you can enable/disable them.

To create a link aggregation channel by using the command line interface

At the command prompt, type:

- `add channel <id> [-ifnum <interfaceName> ...] [-state (ENABLED | DISABLED)] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor (ON | OFF)] [-tagall (ON | OFF)] [-ifAlias <string>] [-throughput <positive_integer>] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]`
- `show channel`

Example

```
add channel LA/1 -ifnum 1/8
show channels
```

To bind an interface to or unbind an interface from an existing link aggregation channel by using the command line interface

At the command prompt, type one of the following commands:

- bind channel <id> <interfaceName>
- unbind channel <id> <interfaceName>

Example

```
bind channel LA/1 1/8
```

To modify a link aggregation channel by using the command line interface

At the command prompt, type the set channel command, the channel ID, and the parameters to be changed, with their new values.

To configure a link aggregation channel by using the configuration utility

Navigate to System > Network > Channels, add a new channel, or edit an existing channel.

To remove a link aggregation channel by using the command line interface

Important: When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

At the command prompt, type:

```
rm channel <id>
```

Example

```
> rm channel LA/1
```

```
Done
```

To remove a link aggregation channel by using the configuration utility

Important: When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

Navigate to System > Network > Channels, select the channel that you want to remove and click Delete.

The Link Aggregation Control Protocol (LACP) enables network devices to exchange link aggregation information by exchanging LACP Data Units (LACPDUs). Therefore, you cannot enable LACP on network interfaces that are members of a channel that you created manually.

When using LACP to configure link aggregation, you use different commands and parameters for modifying link aggregation channels than you do for creating link aggregation channels. To remove a channel, you must disable LACP on all interfaces that are part of the channel.

Note: In an High Availability configuration, LACP configurations are neither propagated nor synchronized.

Configuring the LACP System Priority

Updated: 2013-10-01

The LACP system priority determines which peer device of an LACP LA channel can have control over the LA channel. This number is globally applied to all LACP channels on the appliance. The lower the value, the higher the priority.

At the command prompt, type the following commands to set the priority for a standalone appliance and verify the configuration:

- `set lacp -sysPriority <positive_integer>`
- `show lacp`

Example:

```
set lacp -sysPriority 50
```

To set the priority for a specific cluster node, log on to the cluster IP address and at the command prompt, type the following commands:

- `set lacp -sysPriority <positive_integer> -ownerNode <positive_integer>`
- `show lacp`

Example:

```
set lacp -sysPriority 50 -ownerNode 2
```

1. Navigate to System > Network > Interfaces and, in the Action list, select Set LACP.
2. Specify the system priority and the owner node (applicable only for a cluster setup).

Creating Link Aggregation Channels

Updated: 2013-08-29

For creating a link aggregation channel by using LACP, you need to enable LACP and specify the same LACP key on each interface that you want to be the part of the channel. For example, if you enable LACP and set the LACP Key to 3 on interfaces 1/1 and 1/2, a link aggregation channel LA/3 is created and interfaces 1/1 and 1/2 are automatically bound to it.

Note: When enabling LACP on a network interface, you must specify the LACP Key. By default, LACP is disabled on all network interfaces.

At the command prompt, type:

- `set interface <id> [-lacpMode <lacpMode>] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT)]`
- `show interface [<id>]`

Navigate to System > Network > Interfaces, open the network interface, and set the parameters.

Modifying Link aggregation Channels

Updated: 2013-08-29

After you have created an LACP channel by specifying interfaces, you can modify properties of the channel.

At the command prompt, type:

- `set channel <id> [-if num <interfaceName> ...] [-state (ENABLED | DISABLED)] [-speed <speed>] [-flowControl`

<flowControl> [-haMonitor (ON | OFF)] [-ifAlias <string>] [-throughput <positive_integer>] [-tagall (ON | OFF)] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]

- show channel

Example

```
> set channel LA/3 -state ENABLED -speed 10000
Done
```

Navigate to System > Network > Channels, and modify an existing LACP channel.

Removing a Link Aggregation Channel

Updated: 2013-08-29

To remove a link aggregation channel that was created by using LACP, you need to disable LACP on all the interfaces that are part of the channel.

At the command prompt, type:

- set interface <id> -lacpMode Disable
- show interface [<id>]

Navigate to System > Network > Interfaces, open the network interface, and clear the Enable LACP option.

Updated: 2014-04-08

Link Redundancy using LACP channels enables the NetScaler ADC to divide an LACP channel into logical subchannels, with one subchannel active and the others in standby mode. If the active subchannel fails to meet a minimum threshold of throughput, one of the standby subchannels becomes active and takes over.

A subchannel is created from links that are part of the LACP channel and are connected to a particular device. For example, for an LACP channel with four interfaces on a NetScaler ADC, with two of the interfaces connected to device A and the other two connected to device B, the ADC creates two logical subchannels, one subchannel with two links to device A, and another subchannel with two links to device B.

To configure link redundancy for an LACP channel, set the `lrMinThroughput` parameter, which specifies the minimum throughput threshold (in Mbps) to be met by the active subchannel. Setting this parameter automatically creates the subchannels. When the maximum supported throughput of the active channel falls below the `lrMinThroughput` value, link failover occurs and a standby subchannel becomes active.

If you unset the `lrMinThroughput` parameter of an LACP channel, or set the value to zero, link redundancy for that channel is disabled, which is the default setting.

Example

Consider an example of link redundancy configured between NetScaler ADC NS1 and switches SW1 and SW2.

NS1 is connected to network device NW-A through SW1 and SW2.

On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000Mbps.

When the `lrMinThroughput` parameter is set to some value (say 2000), NS1 creates two logical subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2).

NS1 applies an algorithm to make one subchannel (say subchannel 1) active and put the other on standby. NS1 and network device NW-A are accessible to each other through only the active subchannel.

Say subchannel 1 is active, and its maximum supported throughput falls below the `lrMinThroughput` value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over.

Points to Consider when Configuring Link Redundancy in a High Availability setup

In a high availability (HA) configuration, if you want to configure throughput (throughput parameter) based HA failover and link redundancy (`lrMinThroughput` parameter) on an LACP channel, you must set the throughput parameter to a value less than or equal to that of the `lrMinThroughput` parameter.

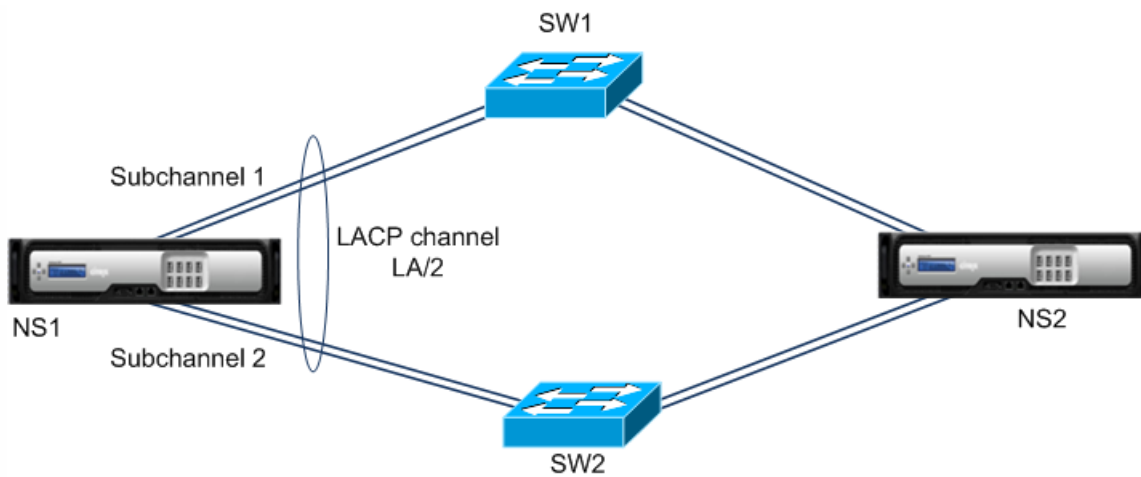

The maximum supported throughput of an LACP channel is calculated as the maximum supported throughput of the active subchannel.

If the throughput parameter value is equal to or less than the `lrminthroughput` parameter value, HA failover occurs when both of the following conditions exist at the same time:

- None of the subchannels' maximum supported throughput meet the `lrMinThroughput` parameter value
- The maximum supported throughput of the LACP channel does not meet the throughput parameter value

Consider an example of an HA setup that has NetScaler ADCs NS1 and NS2, with switches SW1 and SW2. NS1 is connected to NS2 through SW1 and SW2.

On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000 Mbps.

Following are the LACP-parameter settings in this example:

Parameter	Value
Throughput	2000
lrmintthroughput	2000

NS1 forms two subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2). Each of the two subchannels supports a maximum throughput of 2000 Mbps. Applying an algorithm, NS1 makes one subchannel (say subchannel 1) active and the other standby.

Say subchannel 1 is active, and its maximum supported throughput falls below the lrmintthroughput value (for example, one of its links fails, and maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over. HA failover does not occur, because the maximum supported throughput of the LACP channel is not less than the throughput parameter value:

Maximum supported throughput of the LACP channel = Maximum supported throughput of the active channel = Maximum supported throughput of subchannel 2 = 2000 Mbps

If subchannel 2's maximum supported throughput also falls below the lrmintthroughput value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps), HA failover occurs, because the maximum supported throughput of the LACP channel is then less than the throughput parameter value:

To configure link redundancy for a LACP channel by using the command line interface

At the command prompt, type the following commands to configure the channel and verify the configuration:

- set channel <id> -lrmintthroughput <positive_integer>
- show channel

Example

```
> set channel la/1 -lrmintthroughput 2000
Done
> set channel la/2 -throughput 2000 -lrmintthroughput 2000
```

Done

To configure link redundancy for a LACP channel by using configuration utility

1. Navigate to System > Network > Channels.
2. In the details pane, select an LACP channel for which you want to configure link redundancy, and then click Edit.
3. In the Configure LACP channel dialog box, set the `lrMinThroughput` parameter.
4. Click Close.

Redundant Interface Set

Oct 20, 2016

A redundant interface set is a set of interfaces where one of the interfaces is active and the remaining ones are standby. If the active interface fails, one of the standby interfaces takes over and becomes active.

The following are the main benefits of using redundant interface sets:

- A redundant interface set ensures connection reliability between the NetScaler appliance and a peer device by providing back up links between them.
- Unlike link redundancy using LACP, no configuration is required on the peer device for a redundant interface set. To the peer device, redundant interface set appear as individual interfaces and not as a set or collection.
- In an high availability configuration (HA), redundant interface sets can minimize the number the HA failovers.

A link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.

Note: This feature is available in NetScaler release 10.5.e.

Note

Redundant Interface Set was formerly known as 'NIC bundling' when first introduced in 10.5 release.

For a redundant interface set, the NetScaler appliance derives a MAC address on the basis of an internal algorithm and assigns it to the redundant interface set. This MAC address is shared by all the member interfaces and is used only by the active interface at a time. The active interface broadcasts GARP messages, which contains the MAC address assigned to the redundant interface set and not the interface's own physical MAC address. When the current active interface fails and is taken over by another interface, the new active interface sends GARP messages. The peer device updates its forwarding table with the new active interface information. The standby interfaces do not send any GARP messages. The standby interfaces do not send any packets and they drop any packets they receive.

In a redundant interface set, selection of the member interface as active is based on either of the following factors:

- **Redundant interface priority.** This is a parameter of an interface and it defines the priority of the interface in a redundant interface set for the active member selection. This parameter specifies a positive integer. Lower the value higher the priority of active member selection. The member interface with the highest priority (lowest value) is selected as the active interface of the redundant interface set.
- **Binding order of the member interfaces.** If all the member interfaces have the same redundant interface priority, the member interface that was bound first to the redundant interface set is selected as the active interface of the redundant interface set.

In a redundant interface set, active interface selection is triggered in one of the following events:

- When the current active interface fails or you disable it.
- When you set the priority of a standby interface to a value lower than that of the current active interface. The standby interface takes over as the active interface.
- When you bind an interface whose priority is lower than that of the current active interface. The newly bound interface takes over as the active interface.

Updated: 2015-03-2

Consider the following points before you configure a redundant interface set:

- In a high availability configuration, redundant interface set configurations do not propagate or synchronize to the secondary node.
- In a NetScaler cluster configuration, redundant interface sets are not supported.
- You can configure a maximum of four redundant interface sets.
- You can bind a maximum of 16 interfaces to a redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to another redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to a LA channel.
- LA channels cannot be bound to a redundant interface set.

Configuring redundant interface set on a NetScaler appliance consists of the following tasks:

- **Create a redundant interface set.** Use the channel command operation for creating a redundant interface set.

A link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.

- **Bind interfaces to the redundant interface set.** Associate the desired interfaces with the redundant interface set. An interface cannot be a part of multiple redundant interface sets.
- **(Optional) Set a redundant interface priority on the member interface.** Use the interface command operation for setting the redundant interface priority on a desired member interface of a redundant interface set.

To create a redundant interface set by using the command line interface

At the command prompt:

- add channel <ID>
- show channel <ID>

To bind interfaces to a redundant interface set by using the command line interface

At the command prompt:

- bind channel <ID> <ifnum>
- show channel <ID>

To set a redundant interface priority of an interface by using the command line interface

At the command prompt:

- set interface <ID> -lrsetpriority <positive_integer>
- show interface <ID>

In the following example, redundant interface set LR/1 is created, and interfaces 1/1, 1/2, 1/3, and 1/4 are bound to LR/1. The redundant interface priority is set to a default value of 1024 for all these member interfaces. Output of the show channel command displays that the interface 1/1 is the current active interface for the redundant interface set lr/1.

```
> add channel lr/1
Done
> bind channel lr/1 1/1 1/2 1/3 1/4
Done
> show channel
1) Interface LR/1 (Link Redundant) #23

Binding an SNIP address to an Interface

Aug 29, 2013

You can now bind a NetScaler owned SNIP address to an interface without using Layer 3 VLANs. Any packets related to the SNIP address will go only through the bound interface.

This feature can be useful in a scenario where the upstream switch does not support Link Aggregation channels and you want the NetScaler appliance to load balance traffic, originated from a server, across the four links to the upstream switch as shown in the following illustration.

The following tables describe the example settings for the scenario:

Entity	Name	Value
SNIP addresses on NS1	SNIP2 (for reference purpose only)	10.10.10.2
	SNIP3 (for reference purpose only)	10.10.10.3
	SNIP4 (for reference purpose only)	10.10.10.4

Entity	Name	Value
	SNIP5 (for reference purpose only)	10.10.10.5
LLB virtual server on NS1	LLB_VSERVER1	-
Transparent monitor on NS1	TRANS_MON	-
LLB services on NS1	LLB_SVC2	10.10.10.240
	LLB_SVC3	10.10.10.120
	LLB_SVC4	10.10.10.60
	LLB_SVC5	10.10.10.30
MAC address of interface 1/2 on NS1	NS_MAC_2 (for reference purpose only)	00:e0:ed:0f:bc:e0
MAC address of interface 1/3 on NS1	NS_MAC_3 (for reference purpose only)	00:e0:ed:0f:bc:df
MAC address of interface 1/4 on NS1	NS_MAC_4 (for reference purpose only)	00:e0:ed:0f:bc:de
MAC address of interface 1/5 on NS1	NS_MAC_5 (for reference purpose only)	00:e0:ed:1c:89:53
IP address of Router R1	Router_IP (for reference purpose only)	10.10.10.1
MAC address of interface of R1	ROUTER_MAC1 (for reference purpose only)	00:21:a1:2d:db:cc

1. Add four different SNIPs in different subnet ranges. This is for ARP to be resolved on four different links. For more information on creating a SNIP address, see "[Configuring Subnet IP Addresses \(SNIPs\)](#)."

Command Line Interface example

```
> add ns ip 10.10.10.2 255.255.255.0 -type SNIP
Done
> add ns ip 10.10.10.3 255.255.255.128 -type SNIP
Done
> add ns ip 10.10.10.4 255.255.255.192 -type SNIP
Done
> add ns ip 10.10.10.5 255.255.255.224 -type SNIP
Done
```

2. Add four different dummy services in the added SNIP subnets. This is to ensure that the traffic is sent out with source IP as one of the four configured SNIPs. For more information on creating a service, see "[Configuring Services](#)."

Command Line Interface example

```
> add service LLB_SVC2 10.10.10.240 any *
Done
> add service LLB_SVC3 10.10.10.120 any *
Done
> add service LLB_SVC4 10.10.10.60 any *
Done
> add service LLB_SVC5 10.10.10.30 any *
Done
```

3. Add a transparent ping monitor for monitoring the gateway. Bind the monitor to each of the configured dummy services. This is to make the state of the services as UP. For more information on creating a transparent monitor, see "[Creating and Binding a Transparent Monitor](#)."

Command Line Interface example

```
> add monitor TRANS_MON ping -destIP 10.10.10.1 -transparent YES
Done
> bind monitor TRANS_MON LLB_SVC2
Done
> bind monitor TRANS_MON LLB_SVC3
Done
> bind monitor TRANS_MON LLB_SVC4
Done
> bind monitor TRANS_MON LLB_SVC5
Done
```

4. Add a link load balancing (LLB) virtual server and bind the dummy services to it. For more information on creating an LLB virtual server, see "[Configuring an LLB Virtual Server and Binding a Service](#)."

Command Line Interface example

```
> add lb vserver LLB_VSERVER1 any
Done
> set lb vserver LLB_VSERVER1 -lbmethod ROUNDROBIN
Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
Done
```

5. Add the LLB virtual server as the default LLB route. For more information on creating an LLB route see "[Configuring an](#)

[LLB Route.](#)"

Command Line Interface example

```
> add lb route 0.0.0.0 0.0.0.0 LLB_VSERVER1  
Done
```

6. Add an ARP entry for each of the dummy services with the MAC address of the gateway. This way the gateway is reachable through these dummy services. For more information on adding an ARP entry, see "[Configuring Static ARP.](#)"

Command Line Interface example

```
> add arp -ipaddress 10.10.10.240 -mac 00:21:a1:2d:db:cc -ifnum 1/2  
Done  
> add arp -ipaddress 10.10.10.120 -mac 00:21:a1:2d:db:cc -ifnum 1/3  
Done  
> add arp -ipaddress 10.10.10.60 -mac 00:21:a1:2d:db:cc -ifnum 1/4  
Done  
> add arp -ipaddress 10.10.10.30 -mac 00:21:a1:2d:db:cc -ifnum 1/5  
Done
```

7. Bind a specific interface to an SNIP by adding an ARP entry for each of these SNIPs. This is to ensure that the response traffic will reach the same interface through which the request went out. For more information on adding an ARP entry, see "[Configuring Static ARP.](#)"

Command Line Interface example

```
> add arp -ipAddress 10.10.10.2 -mac 00:e0:ed:0f:bc:e0 -ifnum 1/2  
Done  
> add arp -ipAddress 10.10.10.3 -mac 00:e0:ed:0f:bc:df -ifnum 1/3  
Done  
> add arp -ipAddress 10.10.10.4 -mac 00:e0:ed:0f:bc:de -ifnum 1/4  
Done  
> add arp -ipAddress 10.10.10.5 -mac 00:e0:ed:1c:89:53 -ifnum 1/5  
Done
```

Monitoring the Bridge Table and Changing the Aging time

Aug 29, 2013

NetScaler appliance bridges frames on the basis of bridge table lookup of the destination MAC address and the VLAN ID. However, the appliance performs forwarding only when Layer 2 mode is enabled.

The bridge table is dynamically generated, but you can display it, modify the aging time for the bridge table, and view bridging statistics.

All the MAC entries in the bridge table are updated with the aging time.

At the command prompt, type:

- set bridgetable -bridgeAge <positive_integer>
- show bridgetable

Example

```
> set bridgetable -bridgeage 70  
Done
```

1. Navigate to System > Network > Bridge Table.
2. Click Change Ageing Time, and set the Ageing Time (seconds) parameter.
3. In the Action list, select Change Ageing Time, and set the Ageing Time (seconds) parameter.

At the command prompt, type:

```
stat bridge
```

Navigate to System > Network > Bridge Table, select the MAC address, and click Statistics.

Understanding NetScaler Appliances in Active-Active Mode Using VRRP

Aug 29, 2013

An active-active deployment, in addition to preventing downtime, makes efficient use of all the NetScaler appliances in the deployment. In active-active deployment mode, the same VIPs are configured on all NetScaler appliances in the configuration, but with different priorities, so that a given VIP can be active on only one appliance at a time.

Note: This feature is supported only on NetScaler nCore builds.

The active VIP is called the master VIP, and the corresponding VIPs on the other NetScaler appliances are called the backup VIPs. If a master VIP fails, the backup VIP with the highest priority takes over and becomes the master VIP. All the NetScaler appliances in an active-active deployment use the Virtual Router Redundancy Protocol (VRRP) protocol to advertise their VIPs and the corresponding priorities at regular intervals.

NetScaler appliances in active-active mode can be configured so that no NetScaler is idle. In this configuration, different sets of VIPs are active on each NetScaler. For example, in the following diagram, VIP1, VIP2, VIP3, and VIP4 are configured on appliances NS1, NS2, and NS3. Because of their priorities, VIP1 and VIP 2 are active on NS1, VIP3 is active on NS2 and VIP 4 is active on NS3. If, for example, NS1 fails, VIP1 on NS3 and VIP2 on NS2 become active.

Figure 1. An Active-Active Configuration

The NetScaler appliances in the above diagram process traffic as follows:

1. Client C1 sends a request to VIP1. The request reaches R1.
2. R1 does not have an APR entry for VIP1, so it broadcasts an ARP request for VIP1.
3. VIP1 is active in NS1, so NS1 replies with a source MAC address as the VMAC (for example VMAC1) associated with VIP1, and VIP1 as the source IP address.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table.
5. R1 updates the ARP entry with VMAC1 and VIP1.
6. R1 forwards the packet to the VIP1 on NS1.
7. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP or MIP addresses and S2.
8. S2 replies to the SNIP or MIP on the NetScaler.
9. NS1 sends S2's reply to the client. In the reply, NS1 inserts MAC address of the physical interface as the source MAC address and VIP1 as the source IP address.
10. Should NS1 fail, the NetScaler appliances use the VRRP protocol to select the VIP1 with the highest priority. In this case, VIP1 on NS3 becomes active, and the following two steps update the active-active configuration.
11. NS3 broadcasts a GARP message for VIP1. In the message, VMAC1 is the source MAC address and VIP1 is the source IP address.
12. SW1 learns the new port for VMAC1 from the GARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS3. R1 updates its ARP table.

The priority of a VIP can be modified by health tracking. If you enable health tracking, you should make sure that preemption is also enabled, so that a VIP whose priority is lowered can be preempted by another VIP.

In some situations, traffic might reach a backup VIP. To avoid dropping such traffic, you can enable sharing, on a per-node basis, as you create an active-active configuration. Or you can enable the global send to master option. On a node on which sharing is enabled, it takes precedence over send to master.

Base priority (BP-range 1-255) ordinarily determines which VIP is the master VIP, but effective priority (EP) can also affect the determination.

For example, if a VIP on NS1 has a priority of 101 and same VIP on NS2 has a priority of 99, the VIP on NS1 is active. However, if two vservers are using the VIP on NS1 and one of them goes DOWN, health tracking can reduce the EP of VIP on NS1. VRRP then makes the VIP on NS2 the active VIP.

Following are the health tracking options for modifying EP:

- **NONE.** No tracking. EP = BP
- **ALL.** If all virtual servers are UP, then EP = BP. Otherwise, EP = 0.
- **ONE.** If at least one virtual server is UP, then EP = BP. Otherwise, EP = 0.
- **PROGRESSIVE.** If ALL virtual servers are UP, then EP = BP. If ALL virtual servers are DOWN then EP = 0. Otherwise EP = BP $(1 - K/N)$, where N is the total number of virtual servers associated with the VIP and k is the number of virtual servers that are down.

Note: If you specify a value other than NONE, preemption should be enabled, so that the backup VIP with the highest priority becomes active if the priority of the master VIP is downgraded.

Preemption of an active VIP by another VIP that attains a higher priority is enabled by default, and normally should be enabled. In some cases, however, you may want to disable it. Preemption is a per-node setting for each VIP.

Preemption can occur in the following situations:

- An active VIP goes down and a VIP with a lower priority takes its place. If the VIP with the higher priority comes back online, it preempts the currently active VIP.
- Health tracking causes the priority of a backup VIP to become higher than that of the active VIP. The backup VIP then preempts the active VIP.

In the event that traffic reaches a backup VIP, the traffic is dropped unless the sharing option is enabled on the backup VIP. This behavior is a per node setting for each VIP and is disabled by default.

In the figure "An Active-Active Configuration," VIP1 on NS1 is active and VIP1 VIPs on NS2 and NS3 are backups. Under certain circumstances, traffic may reach VIP1 on NS2. If Sharing is enabled on NS2, this traffic is processed instead of dropped.

Configuring Active-Active Mode

Mar 19, 2012

On each NetScaler appliance that you want to deploy in active-active mode, you must add a VMAC and bind the VMAC to a VIP. The VMAC for a given VIP must be same on each appliance. For example, if VIP 10.102.29.5, is created on the appliances, a virtual router ID must be created on each NetScaler and bound to VIP 10.102.29.5 on each NetScaler. When you bind a VMAC to a VIP, the NetScaler sends VRRP advertisements to each VLAN that is bound to that VIP. The VMAC can be shared by different VIPs configured on the same NetScaler.

This section includes the following details:

- [Adding a VMAC](#)
- [Configuring Send to Master](#)
- [Configuring VRRP Communication Intervals](#)
- [Changing the Priority of a VIP Address Automatically in Active-Active Configuration \(VRRP\)](#)
- [An Active-Active Deployment Scenario](#)

Updated: 2013-08-29

To add a VMAC for an active-active configuration, you create a virtual router ID. To bind a VMAC to a VIP, you associate the VMAC's virtual router ID with the VIP.

To add a VMAC by using the command line interface

At the command prompt, type:

```
add vrID <value> -priority <value> -preemption (ENABLED | DISABLED) -sharing (ENABLED | DISABLED) -tracking (NONE | ONE | ALL | PROGRESSIVE)
```

Example

```
add vrID 125 -priority 100 -sharing ENABLED -tracking ONE
```

To add a VMAC by using the configuration utility

1. Navigate to System > Network > VMAC, on the VMAC tab, add a new VMAC, or edit an existing VMAC.
2. Set the following parameters:
 - Virtual Router ID
 - Priority
 - Tracking
 - Preemption
 - Sharing

To bind a VMAC by using the command line interface

At the command prompt, type:

```
set ns ip <VIP address> -vrid <value>
```

Example

```
set ns ip 10.102.29.5 -vrid 125
```

To bind a VMAC to a VIP by using the NetScaler configuration utility

1. Navigate to System > Network > IPs, on the IPV4s tab, open the VIP address that you want to bind to a VMAC.
2. In the Virtual Router Id drop down box, select a virtual router ID.

Updated: 2013-08-29

Usually, the traffic destined to a VIP reaches the NetScaler appliance on which the VIP is active, because an ARP request with the VIP and a VMAC on that appliance has reached the upstream router. But in some cases, such as static routes configured on the upstream router for the VIP subnet, or a topology that blocks this route, the traffic can reach a NetScaler appliance on which the VIP is in backup state. If you want this appliance to forward the data packets to the appliance on which the VIP is active, you need to enable the send to master option. This behavior is a per node setting and is disabled by default.

For example, in the following diagram, VIP1 is configured on NS1, NS2, and NS3 and is active on NS1. Under certain circumstances, traffic for VIP1 (active on NS1) may reach VIP1 on NS3. When the send to master option is enabled on NS3, NS3 forwards the traffic to NS1 through NS2 by using route entries for NS1.

Figure 1. An Active-Active Configuration with Send to Master Option Enabled

To enable send to master by using the command line interface

At the command prompt, type:

```
set vrIDParam -sendToMaster (ENABLED | DISABLED)
```

Example

```
> set vrIDParam -sendToMaster ENABLED
```

Done

To enable send to master by using the configuration utility

1. Navigate to System > Network, in the Settings group, click Virtual Router Parameters.
2. Select the Send to Master option.

In an active-active deployment, all NetScaler nodes use the Virtual Router Redundancy Protocol (VRRP) to advertise their master VIP addresses and the corresponding priorities in VRRP advertisement packets (hello messages) at regular intervals.

VRRP uses the following communication intervals:

- **Hello Interval.** Interval between the VRRP hello messages that a node of a master VIP address sends to its peer nodes.

- **Dead Interval.** Time after which a node of a backup VIP address considers the state of the master VIP address as DOWN if VRRP hello messages are not received from the node of the master VIP address. After the dead interval, the backup VIP address takes over and becomes the master VIP address.

You can change these intervals to a desired value. Both of these communication intervals are per node setting for all VIP addresses in that node.

Note: This feature is available in NetScaler release 10.5.e.

To configure VRRP communication intervals by using the command line interface

At the command prompt, type:

```
set vrIDParam [-helloInterval <msecs>] [-deadInterval <secs>]
```

```
> set vrIDParam -helloInterval 500 -deadInterval 2
Done
```

To configure VRRP communication intervals by using the configuration utility

1. Navigate to System > Network, in the Settings group, click Virtual Router Parameters.
2. Under Configure Virtual Router Parameter, set the Hello Interval and Dead Interval parameters.
3. Click OK.

Example 1: Nodes with the Same VRRP Dead Intervals

Consider an active-active deployment consisting of NetScaler ADCs NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3 are configured on each of these ADCs. Because of their priorities, VIP1 is active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

As shown in the table below, the dead interval is set to the same value (2 seconds) on all the three nodes.

The VRRP communication intervals (hello interval and dead interval) of a node apply to all the VRIDs configured on the node, and in turn apply to all VIP addresses associated with the VRIDs on the node.

On each node, the VIP addresses that are active (master) on that node use the hello interval, and the dead interval is used by the VIP addresses that are inactive (backup) on that node.

Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example.

	Settings on NS1	Settings on NS2	Settings on NS3
VIP addresses			
VIP1 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.10 • VRID: 10 • Priority: 90 	<ul style="list-style-type: none"> • IP address: 192.0.1.10 • VRID: 11 • Priority: 30 	<ul style="list-style-type: none"> • IP address: 192.0.1.10 • VRID: 15 • Priority: 60

VIP2 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.20 • VRID: 20 • Priority: 100 	<ul style="list-style-type: none"> • IP address: 192.0.1.20 • VRID: 21 • Priority: 300 	<ul style="list-style-type: none"> • IP address: 192.0.1.20 • VRID: 25 • Priority: 200
VIP3 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.30 • VRID: 30 • Priority: 70 	<ul style="list-style-type: none"> • IP address: 192.0.1.30 • VRID: 31 • Priority: 140 	<ul style="list-style-type: none"> • IP address: 192.0.1.30 • VRID: 35 • Priority: 210
Communication Intervals			
Hello Interval	400 milliseconds	400 milliseconds	400 milliseconds
Dead Interval	2 seconds	2 seconds	2 seconds

The execution flow is as follows:

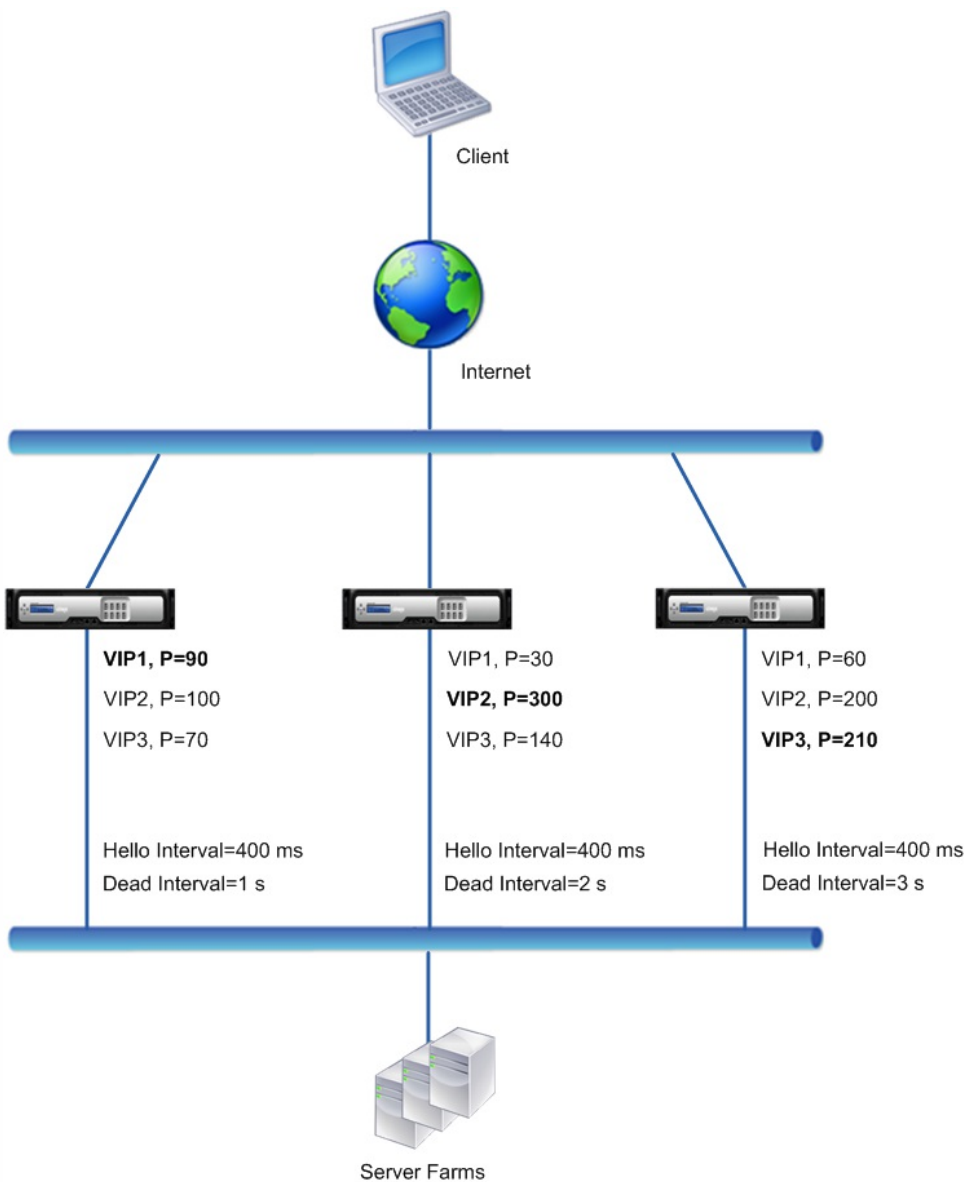

1. NS1 sends hello messages at a set hello interval of 200 ms to NS2 and NS3 for the VIP1 address, because VIP1 is active (the master) on NS1. Similarly, NS2 sends hello messages at a set interval (600 ms) for VIP2, and NS3 sends hello messages at a set interval (800ms) for VIP3.
2. On NS1, the set dead interval applies to VIP2 and VIP3, because they are inactive (backups) on NS1. Similarly, on NS2, the set dead interval applies to VIP1 and VIP3, and on NS3, the set dead interval applies to VIP1 and VIP2.
3. If NS1 goes down, NS2 and NS3 consider NS1 to be down if they receive no hello messages from NS1 for 2 seconds (the dead interval). VIP1 on NS3 takes over and becomes active (master), because its VRID priority (60) is higher than that of VIP1 of NS2 (30).

Example 2: Nodes with Different VRRP Dead Intervals

Consider a VRRP deployment similar to the deployment described in Example1 but with a different dead interval on each node (NS1, NS2, and NS3). Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example.

	Settings on NS1	Settings on NS2	Settings on NS3
VIP addresses			
VIP1 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.10 • VRID: 10 • Priority: 90 	<ul style="list-style-type: none"> • IP address: 192.0.1.10 • VRID: 11 • Priority: 30 	<ul style="list-style-type: none"> • IP address: 192.0.1.10 • VRID: 15 • Priority: 60
VIP2 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.20 • VRID: 20 • Priority: 100 	<ul style="list-style-type: none"> • IP address: 192.0.1.20 • VRID: 21 • Priority: 300 	<ul style="list-style-type: none"> • IP address: 192.0.1.20 • VRID: 25 • Priority: 200
VIP3 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.30 • VRID: 30 • Priority: 70 	<ul style="list-style-type: none"> • IP address: 192.0.1.30 • VRID: 31 • Priority: 140 	<ul style="list-style-type: none"> • IP address: 192.0.1.30 • VRID: 35 • Priority: 210
Communication Intervals			
Hello Interval	400 milliseconds	400 milliseconds	400 milliseconds
Dead Interval	1 second	2 seconds	3 seconds

The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to be down after not receiving any hello messages from NS1 for 2 seconds (NS2's dead interval).
2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages for VIP1.

Even though VIP1 on NS3 has a higher VRIP priority (60) than does VIP1 on NS2 (30), NS3's larger dead interval (3 seconds, vs. 2 seconds for NS2), prevents VIP1 on NS3 from taking over before VIP 1 on NS2 has already done so.

Example 3: Nodes with Different Dead Intervals and Preemption Enabled

Consider a VRRP deployment similar to the deployment described in Example1 but with different dead intervals on the three nodes, NS1, NS2, and NS3, and with preemption enabled for the VIP1 address on NS3.

The following table lists the settings used in this example.

	Settings on NS1	Settings on NS2	Settings on NS3
VIP addresses			

VIP1 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.10 • VRID: 10 • Priority: 90 	<ul style="list-style-type: none"> • IP address: 192.0.1.10 • VRID: 11 • Priority: 30 	<ul style="list-style-type: none"> • IP address: 192.0.1.10 • VRID: 15 • Priority: 60
VIP2 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.20 • VRID: 20 • Priority: 100 	<ul style="list-style-type: none"> • IP address: 192.0.1.20 • VRID: 21 • Priority: 300 	<ul style="list-style-type: none"> • IP address: 192.0.1.20 • VRID: 25 • Priority: 200
VIP3 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.30 • VRID: 30 • Priority: 70 	<ul style="list-style-type: none"> • IP address: 192.0.1.30 • VRID: 31 • Priority: 140 	<ul style="list-style-type: none"> • IP address: 192.0.1.30 • VRID: 35 • Priority: 210
Communication Intervals			
Hello Interval	400 milliseconds	400 milliseconds	400 milliseconds
Dead Interval	1 second	2 seconds	3 seconds

The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to be down after not receiving any hello messages from NS1 for 2 seconds (NS2's set dead interval). At this time, NS3, with a dead interval of 3 seconds, does not consider NS1 to be down.
2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages for VIP1.
3. Upon receiving hello messages from NS2 for VIP1, NS3 preempts NS2 for VIP1 because preemption is enabled for VIP1 of NS3 and the VRID priority (60) of VIP1 of NS3 is higher than that (30) of VIP1 of NS2.
4. VIP1 on NS3 takes over and becomes active (master). NS3 now starts sending hello messages for VIP1.

Updated: 2015-05-22

To ensure that a backup VIP address takes over as the master VIP before the node of the current master VIP address goes down completely, you can configure a node to change the priority of a VIP address on the basis of interfaces' state on that node. For example, the node reduces the priority of a VIP address when the state of an interface changes to DOWN, and increases the priority when the state of the interface changes to UP.

This feature is a per node configuration for each VIP address.

To configure this feature on a node for a VIP address, you set the Reduced Priority (trackifNumPriority) parameter and then associate the interfaces whose state is to be tracked for changing the priority of the VIP address. When any of the associated interface's state changes to DOWN or UP, the node reduces or increases the priority of the VIP address by the configured Reduced Priority (trackifNumPriority) value.

Note: This feature is available in NetScaler release 10.5.e.

To set reduced priority and bind interfaces to the virtual router ID by using the command line interface

At the command prompt, type:

- set vrID <id> [-trackifNumPriority <positive_integer>]
- bind vrID <id> -trackifNum <interface_name>
- show vrID <id>

```
> set vrID 125 -trackifNumPriority 10
```

```
> bind vrID 125 -trackifNum 1/4 1/5
```

To set reduced priority and bind interfaces to the virtual router ID by using the configuration utility

1. Navigate to System > Network > VAMC, select a virtual router ID.
2. Under Configure VMAC, set the Reduced Priority parameter.
3. Select the Interfaces tracked for the vrid option and, under Associate Interfaces, add interfaces to the virtual router ID.

Example

Consider an active-active deployment consisting of NetScaler ADCs NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3, and VIP4 are configured on each of these ADCs. Because of their priorities, VIP1 and VIP4 are active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

To ensure that the active VIP addresses on NS1 are taken over by either NS2 or NS3 before NS1 goes down completely, interface-based health tracking is configured for the VIP1 and VIP4 addresses on NS1. Configuring interface-based health tracking for a VIP address includes associating the desired interfaces and setting the reduced priority (trackifNumPriority) parameter for the associated VRID of the VIP address. For example, on NS1, interfaces 1/2, 1/3, and 1/5 are associated to the VRID of VIP1, and reduced priority is set to 20.

Preemption is enabled for these VIP addresses in all three nodes.

The following table lists the settings used in this example.

	Settings on NS1	Settings on NS2	Settings on NS3
VIP addresses			
VIP1 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.10 • VRID: 10 	<ul style="list-style-type: none"> • IP address: 192.0.1.10 • VRID: 11 	<ul style="list-style-type: none"> • IP address: 192.0.1.10 • VRID: 15

	<ul style="list-style-type: none"> • Priority: 90 	<ul style="list-style-type: none"> • Priority: 30 	<ul style="list-style-type: none"> • Priority: 60
VIP2 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.20 • VRID: 20 • Priority: 100 	<ul style="list-style-type: none"> • IP address: 192.0.1.20 • VRID: 21 • Priority: 300 	<ul style="list-style-type: none"> • IP address: 192.0.1.20 • VRID: 25 • Priority: 200
VIP3 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.30 • VRID: 30 • Priority: 70 	<ul style="list-style-type: none"> • IP address: 192.0.1.30 • VRID: 31 • Priority: 140 	<ul style="list-style-type: none"> • IP address: 192.0.1.30 • VRID: 35 • Priority: 210
VIP4 (for reference purposes only)	<ul style="list-style-type: none"> • IP address: 192.0.1.40 • VRID: 40 • Priority: 250 • Track interfaces: 1/5, 1/7 • Reduced priority: 55 	<ul style="list-style-type: none"> • IP address: 192.0.1.40 • VRID: 41 • Priority: 160 	<ul style="list-style-type: none"> • IP address: 192.0.1.40 • VRID: 45 • Priority: 150

* Packet Interfaces = 1/2, 1/3, 1/5
Reduced Priority = 20

** Packet Interfaces = 1/5, 1/7
Reduced Priority = 55

The execution flow is as follows on NS1 when some interfaces on NS1 go down:

1. If interface 1/3 goes down, the priority of VIP1 address is reduced by 20 (VIP1's reduced priority value), because interface 1/3 is associated with VIP1:
 - Effective priority of VIP1 = (Current priority - reduced priority) = (90-20) = 70
2. Similarly, if interface 1/5 goes down, the priority of VIP1 address is further reduced:
 - Effective priority of VIP1 = (Current priority - reduced priority) = (70-20) = 50
3. At this point, the effective priority of VIP1 on NS1 is less than the priority of VIP1 on NS3. NS3 preempts NS1 for VIP1. VIP1 on NS3 takes over and becomes active (master).
4. Also, because interface 1/5 is also associated with VIP4, the priority of VIP4 is reduced by the VIP4's reduced priority value (55).

- Effective priority of VIP4 = $(250 - 55) = 195$
5. If interface 1/7 goes down, the priority of VIP4 is further reduced:
- Effective priority of VIP4 = $(\text{Current priority} - \text{reduced priority}) = (195 - 55) = 145$
6. At this point, the effective priority of VIP4 on NS1 is less than the priority of VIP4 on NS2. NS2 preempts NS1 for VIP4. VIP4 on NS3 takes over and becomes active (master). This configuration ensures that none of the four VIP addresses are active on NS1 before it completely goes down.

Following is an example of a possible active-active deployment scenario.

In the following diagram, VIP1, VIP 2 and VIP3 are configured on all three appliances, NS1, NS2, and NS3. Base Priorities for each VIPs are as shown in the diagram. Health tracking is disabled for each VIP. The priorities of VIPs are set so that VIP1, VIP2, and VIP3 are active on NS3. If NS3 fails, VIP1, VIP2, and VIP3 become active on NS1.

Figure 2. An Active-Active Deployment Scenario

Using the Network Visualizer

Aug 29, 2013

The Network Visualizer is a tool that you can use to view the network configuration of a NetScaler node, including the network configuration of the nodes in a high availability (HA) deployment. You can also modify the configuration of VLANs, interfaces, channels, and bridge groups, and perform HA configuration tasks.

In an HA deployment, you can both view and configure network entities on the node to which you are logged on, but you can view the details of only the network entities that are configured on the peer node. However, you can perform certain tasks, such as viewing details and statistics of the peer node and forcing a failover.

When you are logged on to a standalone appliance, you can use the Network Visualizer to do the following:

- View a consolidated graphical summary of key network components, such as VLANs, interfaces, channels, and bridge groups. You can also view the individual details of various network components.
- Modify appliance settings.
- Add, modify, and enable and disable interfaces and channels that are configured on the NetScaler appliance.
- Add and modify VLANs and bridge groups.
- Configure an HA deployment (add a node).
- View node details, node statistics, and statistics for VLANs and interfaces.
- Copy the properties of a network entity to a document or spreadsheet.

When you are logged on to an appliance in an HA deployment, you can perform the above tasks only on the appliance to which you are logged on. Following are additional tasks that you can perform in the Network Visualizer when you are logged on to one of the appliances in an HA pair:

- View the configuration details and high availability details of both nodes in an HA pair.
- Perform HA configuration tasks, such as synchronization and force failover.
- Remove the peer node from the HA configuration.
- View statistics for the peer node.
- Copy the properties of the peer node to a document or spreadsheet.

1. Navigate to System > Network.
2. In Monitor Connections, click Network Visualizer.

1. Open the Network Visualizer, and then do the following:

- To locate a VLAN or bridge group, in the Search text field, begin typing the ID of the VLAN or the bridge group that you want to locate.

Alternatively, begin typing the IP address of a bound subnet or the ID of a bound interface. The VLANs or bridge groups whose names match the typed characters are highlighted.

To highlight multiple entities simultaneously, separate the IDs and IP addresses with white spaces. Entities whose IDs or IP addresses match any of the typed IDs and IP addresses are highlighted.

- To clear the Search field, click the x adjacent to the field.

1. Open the Network Visualizer and click the icon representing the appliance to which you are logged on.
2. In Related Tasks, click Open.

1. Open the Network Visualizer and click a network interface.
2. In Related Tasks, click Add Channel.

1. Open the Network Visualizer, click the appliance to which you are logged on, and then do one of the following:
 - Click an existing VLAN, and then, in Related Tasks, click Add.
 - Click an existing bridge group, and then, in Related Tasks, click Add VLAN.

1. Open the Network Visualizer, click the appliance to which you are logged on, and then do one of the following:
 - Click an existing bridge group, and then, in Related Tasks, click Add.
 - Click an existing VLAN, and then, in Related Tasks, click Add Bridge Group.

1. Open the Network Visualizer and click the interface whose settings you want to modify.
2. In Related Tasks, click Open.

1. Open the Network Visualizer and click the interface or channel that you want to enable or disable.
2. In Related Tasks, do one of the following.
 - To enable the interface or channel, click Enable.
 - To disable the interface or channel, click Disable.

1. Open the Network Visualizer and click the channel, VLAN, or bridge group that you want to remove from the configuration.
2. In Related Tasks, click Remove.

1. Open the Network Visualizer and click the node, interface, or VLAN whose statistics you want to view.
2. In Related Tasks, click Statistics.

1. Open the Network Visualizer and click the appliance.
2. In Related Tasks, click HA Setup.

1. Open the Network Visualizer and click one of the nodes.
2. In Related Tasks, click Force Failover.

1. Open the Network Visualizer and click one of the nodes.
2. In Related Tasks, click Force Synchronization.

1. Open the Network Visualizer and click the peer node.
2. In Related Tasks, click Remove.

1. Open the Network Visualizer and click the appliance or network entity whose properties you want to copy to a document or spreadsheet.
2. In Related Tasks, click Copy Properties.

Configuring Link Layer Discovery Protocol

Jun 11, 2014

The NetScaler ADC supports the industry standard (IEEE 802.1AB) Link Layer Discovery Protocol (LLDP). LLDP is a layer 2 protocol that enables the NetScaler ADC to advertise its identity and capabilities to the directly connected devices, and also learn the identity and capabilities of these neighbour devices. Using LLDP, the NetScaler ADC transmits and receives information in the form of LLDP messages known as LLDP packet data units (LLDPUs).

An LLDPDU is a sequence of type, length, value (TLV) information elements. Each TLV holds a specific type of information about the device that transmits the LLDPDU. The NetScaler ADC sends the following TLVs in each LLDPDU:

- Chassis ID
- Port ID
- Time-to-live value
- System name
- System description
- Port description
- System capabilities
- Management address
- Port VLAN ID
- Link aggregation

Note: You cannot specify the TLVs to be sent in LLDP messages.

NetScaler interfaces support the following LLDP modes:

- **NONE**. The interface neither receives from nor transmits LLDP messages to the directly connected device.
- **TRANSMITTER**. The interface transmits LLDP messages to the directly connected device but does not receive LLDP messages from the directly connected device.
- **RECEIVER**. The interface receives LLDP messages from the directly connected device but does not transmit LLDP messages to the directly connected device.
- **TRANSCEIVER**. The interface transmits LLDP messages to and receives LLDP messages from the directly connected device.

The LLDP mode of an interface depends on the LLDP mode configured at the global and the interface levels. The following table shows the modes resulting from the available combinations of global- and interface-level settings:

Interface Level LLDP mode	Global Level LLDP mode			
	NONE	TRANSMITTER	RECEIVER	TRANSCEIVER
NONE	NONE	NONE	NONE	NONE
TRANSMITTER	NONE	TRANSMITTER	NONE	TRANSMITTER
RECEIVER	NONE	NONE	RECEIVER	RECEIVER
TRANSCEIVER	NONE	NONE	RECEIVER	RECEIVER

Transmitting LLDP messages

The NetScaler ADC transmits LLDPUs from interfaces that are operating in either TRANSMITTER or TRANSCEIVER LLDP mode.

Following are the global LLDP transmitting parameters on the NetScaler ADC:

- **Timer.** Interval, in seconds, between LLDPUs that the NetScaler ADC sends to a directly connected device.
- **Holdtime Multiplier.** A multiplier for calculating the duration for which the receiving device stores the LLDP information in its database before discarding or removing it. The duration is calculated as the **Holdtime Multiplier** parameter value multiplied by the Timer parameter value.

Receiving LLDP Messages

The NetScaler ADC stores the LLDPDU information in its Management Information base (MIB). The stored LLDP information is classified or grouped under the ID of the interface that received the LLDPDU. The NetScaler ADC retains this LLDP information for the duration specified in the received LLDPDU.

If the ADC receives another LLDPDU on an interface before the stored LLDP information for that interface is discarded, the ADC replaces the stored LLDP information for that interface with information in the new LLDPDU.

Configuration Steps

Configuring LLDP on a NetScaler appliance consists of the following tasks:

1. Set global level LLDP parameters. In this task, you set the global LLDP parameters such as LLDP Timer, Hold Time Multiplier, and LLDP mode.
2. Set the interface level LLDP parameters. In this task, you set the LLDP mode for an interface.
3. (Optional) Display neighbor-device information. You can display the neighbor-device LLDP information collected on all of the NetScaler ADC's interfaces, or just the LLDP information collected on specified interfaces. If you do not specify an interface, the information is shown for all interfaces.

Following are the prerequisites for configuring LLDP on a NetScaler ADC:

1. Make sure that you understand the standard LLDP protocol (IEEE 802.1AB).
2. Verify that you have configured LLDP on the desired directly connected devices.

To set global level LLDP parameters by using the command line interface

At the command prompt, type:

- `set lldp param [-holdtimeTxMult <positive_integer>][-timer <positive_integer>] [-Mode <Mode>]`
- `show lldp param`

To set the global level LLDP parameters by using configuration utility

1. Navigate to System > Network, and click Configure LLDP Parameters.
2. Set the following parameters:
 - Hold Timer Multiplier
 - Timer
 - Mode

To configure an interface for LLDP by using the command line interface

At the command prompt, type:

- `set interface <id> -lldpmode <lldpmode>`

- show interface <id>

To configure an interface for LLDP by using configuration utility

Navigate to System > Network > Interfaces, open the interface, and set the LLDP mode parameter.

To display neighbor device information by using the command line interface

At the command prompt, type one of the following commands:

- show lldp neighbors
- show lldp neighbors <ifnum>

To display neighbor device information by using configuration utility

Navigate to System > Network > Interfaces and, in the Action list, select View LLDP Neighbors.

Jumbo Frames

Jun 20, 2014

NetScaler appliances support receiving and transmitting jumbo frames containing up to 9216 bytes of IP data. Jumbo frames can transfer large files more efficiently than it is possible with the standard IP MTU size of 1500 bytes.

A NetScaler appliance can use jumbo frames in the following deployment scenarios:

- Jumbo to Jumbo. The appliance receives data as jumbo frames and sends it as jumbo frames.
- Non-Jumbo to Jumbo. The appliance receives data as regular frames and sends it as jumbo frames.
- Jumbo to Non-Jumbo. The appliance receives data as jumbo frames and sends it as regular frames.

The NetScaler appliance supports jumbo frames in a load balancing configuration for the following protocols:

- TCP
- Any protocol over TCP (for example, HTTP)
- SIP
- RADIUS

This document includes the following information:

- [Configuring Jumbo Frames Support on a NetScaler Appliance](#)
- [Use Case 1 - Jumbo to Jumbo Setup](#)
- [Use Case 2 - Non-Jumbo to Jumbo Setup](#)
- [Use Case 3 - Coexistence of Jumbo and Non-Jumbo flows on the Same Set of Interfaces](#)

Configuring Jumbo Frames Support on a NetScaler Appliance

Apr 10, 2014

To enable the NetScaler appliance to support jumbo frames, you set the MTU to more than 1500 on interfaces or LA channels, and on VLANs on which you want the NetScaler appliance to support jumbo frames.

Points to consider before setting the MTU of interfaces, LA channels, or VLANs on a NetScaler appliance

1. Jumbo frames are not supported on NetScaler MPX 15000 and MPX 17000 Platforms.
2. When you create an LA channel, the channel takes the MTU of the first bound interface if no MTU is specified for the channel.
3. The MTU for a channel is propagated to all the bound interfaces.
4. When an interface is bound to the channel whose MTU is different from the interface's MTU, the interface goes onto the inactive list.
5. When you change the MTU of a member interface, the interface goes onto the inactive list.
6. When an interface is unbound from the channel, the interface retains the MTU value of the channel.
7. You can set the MTU for an interface, channel, or VLAN to a value in the range of 1500-9216.
8. You cannot set the MTU on the default VLAN. The NetScaler appliance uses the MTU of the interface through which it receives or sends data from or to the default VLAN.
9. For TCP based traffic on a load balancing configuration on a NetScaler appliance, MSSs are set accordingly at each end point for supporting jumbo frames:
 - For a connection between a client and a load balancing virtual server on the NetScaler appliance, the MSS on the NetScaler appliance is set in a TCP profile, which is then bound to the load balancing virtual server.
 - For a connection between the NetScaler appliance and a server, the MSS on NS1 is set in a TCP profile, which is then bound to the service representing the server on the NetScaler appliance.
 - By default, a TCP profile `nstcp_default_profile` is bound to all TCP based load balancing servers and services on the NetScaler appliance.
 - For supporting jumbo frames, you can either change the MSS value of the TCP profile `nstcp_default_profile`, or create a custom TCP profile and set its MSS accordingly, and then bind the custom TCP profile to the desired load balancing virtual servers and services.
 - The default MSS value of any TCP profile is 1460.

To set the MTU of an interface by using the command line interface

At the command prompt, type:

- `set interface <id> -mtu <positive_integer>`
- `show interface <id>`

Example

```
> set interface 10/1 -mtu 9000
```

Done

To set the MTU of a channel by using the command line interface

At the command prompt, type:

- `set channel <id> -mtu <positive_integer>`

- show channel <id>

Example

```
> set channel LA/1 -mtu 9000
```

Done

To set the MTU of a VLAN by using the command line interface

At the command prompt, type:

- add vlan <id> -mtu <positive_integer>
- show vlan <id>

Example

```
> set vlan 20 -mtu 9000
```

Done

To set the MTU of an interface by using the configuration utility

Navigate to System > Network > Interfaces, open the interface, and set the Maximum Transmission Unit parameter.

To set the MTU of a channel by using the configuration utility

Navigate to System > Network > Channels, open the channel, and set the Maximum Transmission Unit parameter.

To set the MTU of a VLAN by using the configuration utility

Navigate to System > Network > VLANs, open the VLAN, and set the Maximum Transmission Unit parameter.

Use Case 1 – Jumbo to Jumbo Setup

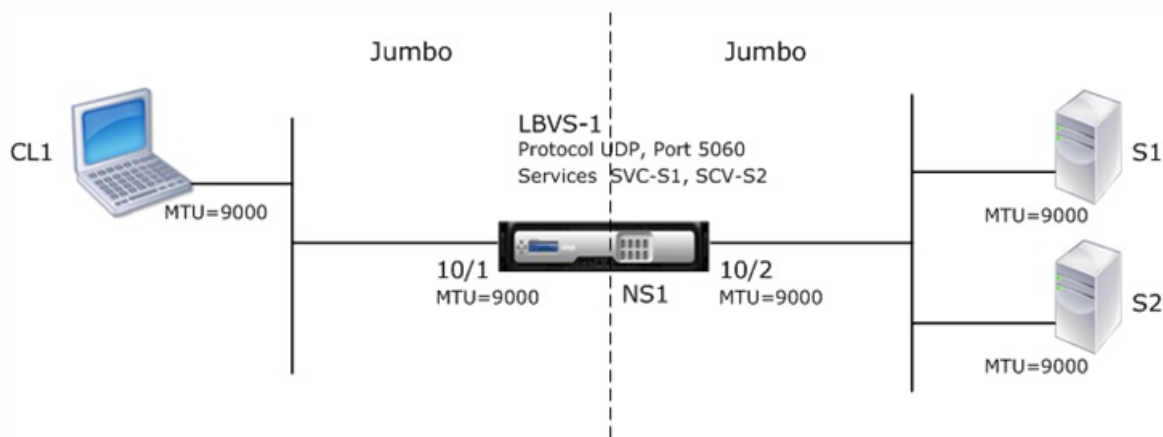

May 06, 2014

Consider an example of a jumbo to jumbo setup in which SIP load balancing virtual server LBVS-1, configured on NetScaler appliance NS1, is used to load balance SIP traffic across servers S1 and S2. The connection between client CL1 and NS1, and the connection between NS1 and the servers support jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2. Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively.

For supporting jumbo frames, the MTU is set to 9216, on NS1, for interfaces 10/1, 10/2, and VLANs VLAN 10, VLAN 20.

All other network devices, including CL1, S1, S2, in this setup example are also configured for supporting jumbo frames.

The following table lists the settings used in the example.

Entity	Name	Details
IP address of client CL1		192.0.2.10
IP address of servers	S1	198.51.100.19
	S2	198.51.100.20
SNIP address on NS1		198.51.100.18
MTU specified for interfaces and VLANs on NS1	10/1	9000
	10/2	9000
	VLAN 10	9000
	VLAN 20	9000

Entity	Name	Details
Services on NS1 representing servers	SVC-S1	<ul style="list-style-type: none"> • IP address: 198.51.100.19 • Protocol: SIP • Port: 5060
	SVC-S2	<ul style="list-style-type: none"> • IP address: 198.51.100.20 • Protocol: SIP • Port: 5060
Load balancing virtual server on VLAN 10	LBVS-1	<ul style="list-style-type: none"> • IP address: 203.0.113.15 • Protocol: SIP • Port: 5060 • Bound services: SVC-S1, SVC-S2

Following is the traffic flow of CL1's request to NS1:

1. CL1 creates a 20000-byte SIP request to send to LBVS-1 of NS1.
2. CL1 sends the request data in IP fragments to LBVS-1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which CL1 sends these fragments to NS1.
 - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
 - Size of the second IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
 - Size of the last IP fragment = [IP header + SIP data segment] = [20 + 2048] = 2068
3. NS1 receives the request IP fragments at interface 10/1. NS1 accepts these fragments, because the size of each of these fragments is equal to or less than the MTU (9000) of interface 10/1.
4. NS1 reassembles these IP fragments to form the 20000-byte SIP request. NS1 processes this request.
5. LBVS-1's load balancing algorithm selects server S1.
6. NS1 sends the request data in IP fragments to S1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/2, from which NS1 sends these fragments to S1. The IP packets are sourced with a SNIP address of NS1.
 - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
 - Size of the second IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
 - Size of the last IP fragment = [IP header + SIP data segment] = [20 + 2048] = 2068

Following is the traffic flow of S1's response to CL1 in this example:

1. Server S1 creates a 30000-byte SIP response to send to the SNIP address of NS1.
2. S1 sends the response data in IP fragments to the SNIP address of NS1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which S1 sends these fragments to NS1.
 - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
 - Size of the second and third IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
 - Size of the last IP fragment = [IP header + SIP data segment] = [20 + 3068] = 3088
3. NS1 receives the response IP fragments at interface 10/2. NS1 accepts these fragments, because the size of each fragment is equal to or less than the MTU (9000) of interface 10/2.
4. NS1 reassembles these IP fragments to form the 30000-byte SIP response. NS1 processes this response.
5. NS1 sends the response data in IP fragments to CL1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/1, from which NS1 sends these fragments to CL1. The IP fragments are sourced with LBVS-1's IP address.

- Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
- Size of the second and third IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
- Size of the last IP fragment=[IP header + SIP data segment] = [20 + 3068] = 3088

Configuration Tasks

Updated: 2014-01-16

The following table list the tasks, NetScaler commands, and examples for creating the required configuration on the NetScaler appliance.

Tasks	NetScaler Command Syntax	Examples
Set the MTU of the desired interfaces for supporting jumbo frames	set interface <id> -mtu <positive_integer> show interface <id>	set int 10/1 -mtu 9000 set int 10/2 -mtu 9000
Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames	add vlan <id> -mtu <positive_integer> show vlan <id>	add vlan 10 -mtu 9000 add vlan 20 -mtu 9000
Bind interfaces to VLANs	bind vlan <id> -if num <interface_name> show vlan <id>	bind vlan 10 -if num 10/1 bind vlan 20 -if num 10/2
Add a SNIP address	add ns ip <IPAddress> <netmask> -type SNIP show ns ip	add ns ip 198.51.100.18 255.255.255.0 -type SNIP
Create services representing SIP servers	add service <serviceName> <ip> SIP_UDP <port> show service <name>	add service SVC-S1 198.51.100.19 SIP_UDP 5060 add service SVC-S2 198.51.100.20 SIP_UDP 5060
Create SIP load balancing virtual servers and bind the services to it	add lb vserver <name> SIP_UDP <ip> <port> bind lb vserver <vserverName> <serviceName> show lb vserver <name>	add lb vserver LBVS-1 SIP_UDP 203.0.113.15 5060 bind lb vserver LBVS-1 SVC-S1 bind lb vserver LBVS-1 SVC-S2
Save the configuration	save ns config show ns config	

1.

Use Case 2 – Non-Jumbo to Jumbo Setup

May 06, 2014

Consider an example of a regular to jumbo setup in which load balancing virtual server LBVS-1, configured on a NetScaler appliance NS1, is used to load balance traffic across servers S1 and S2. The connection between client CL1 and NS1 supports regular frames, and the connection between NS1 and the servers supports jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2.

Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively. For supporting only regular frames between CL1 and NS1, the MTU is set to the default value of 1500 for both interface 10/1 and VLAN 10

For supporting jumbo frames between NS1 and the servers, the MTU is set to 9000 for interface 10/2 and VLAN 20. Servers and all other network devices between NS1 and the servers are also configured for supporting jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For supporting jumbo frames for the connection between a SNIP address of NS1 and S1 or S2, the MSS on NS1 is set accordingly in a custom TCP profile, which is bound to the services (SVC-S1 and SVC-S2) representing S1 and S2 on NS1.
- For supporting only regular frames for the connection between CL1 and virtual server LBVS-1 of NS1, default TCP profile nstcp_default_profile is used that is by default bound to LBVS-1 and has the MSS set to the default value of 1460.

The following table lists the settings used in this example.

Entity	Name	Details
IP address of client CL1	CL1	192.0.2.10
IP address of servers	S1	198.51.100.19
	S2	198.51.100.20

Entity	Name	Details
SNIP address on NS1		198.51.100.18
MTU specified for interfaces and VLANs on NS1	10/1	1500
	10/2	9000
	VLAN 10	1500
	VLAN 20	9000
Default TCP profile	nstcp_default_profile	MSS:1460
Custom TCP profile	NS1-SERVERS-JUMBO	MSS: 8960
Services on NS1 representing servers	SVC-S1	<ul style="list-style-type: none"> • IP address: 198.51.100.19 • Protocol: HTTP • Port: 80 • TCP profile: NS1-SERVERS-JUMBO (MSS: 8960)
	SVC-S2	<ul style="list-style-type: none"> • IP address: 198.51.100.20 • Protocol: HTTP • Port: 80 • TCP profile: NS1-SERVERS-JUMBO (MSS: 8960)
Load balancing virtual server on VLAN 10	LBVS-1	<ul style="list-style-type: none"> • IP address = 203.0.113.15 • Protocol: HTTP • Port:80 • Bound services: SVC-S1, SVC-S2 • TCP Profile: nstcp_default_profile (MSS:1460)

Following is the traffic flow of CL1's request to S1 in this example:

1. Client CL1 creates a 200-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their respective TCP MSS values while establishing the connection.
3. Because NS1's MSS is larger than the HTTP request, CL1 sends the request data in a single IP packet to NS1.
Size of the request packet = [IP Header + TCP Header + TCP Request] = [20 + 20 + 200] = 240
4. NS1 receives the request packet at interface 10/1 and then processes the HTTP request data in the packet.
5. LBVS-1's load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and

S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.

6. Because S1's MSS is larger than the HTTP request, NS1 sends the request data in a single IP packet to S1.

Size of the request packet = [IP Header + TCP Header + [TCP Request]] = [20 + 20 + 200] = 240

Following is the traffic flow of S1's response to CL1 in this example:

1. Server S1 creates an 18000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.
 - Size of the first two packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000
 - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120
3. NS1 receives the response packets at interface 10/2.
4. From these IP packets, NS1 assembles all the TCP segments to form the HTTP response data of 18000 bytes. NS1 processes this response.
5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets, from interface 10/1, to CL1. These IP packets are sourced from LBVS-1's IP address and destined to CL1's IP address.
 - Size of all packets except the last one = [IP Header + TCP Header + (TCP payload=CL1's MSS size)] = [20 + 20 + 1460] = 1500
 - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 480] = 520

Configuration Tasks

Updated: 2014-01-16

The following table list the tasks, NetScaler commands, and examples for creating the required configuration on the NetScaler appliance.

Tasks	NetScaler Command line Syntax	Examples
Set the MTU of the desired interfaces for supporting jumbo frames	set interface <id> -mtu <positive_integer> show interface <id>	set int 10/1 -mtu 1500 set int 10/2 -mtu 9000
Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames	add vlan <id> -mtu <positive_integer> show vlan <id>	add vlan 10 -mtu 1500 add vlan 20 -mtu 9000
Bind interfaces to VLANs	bind vlan <id> -ifnum <interface_name> show vlan <id>	bind vlan 10 -ifnum 10/1 bind vlan 20 -ifnum 10/2
Add a SNIP address	add ns ip <IPAddress> <netmask> -type SNIP show ns ip	add ns ip 198.51.100.18 255.255.255.0 -type SNIP
Create services representing HTTP servers	add service <serviceName> <ip> HTTP <port> show service <name>	add service SVC-S1 198.51.100.19 http 80 add service SVC-S2 198.51.100.20 http 80
Create HTTP load balancing virtual servers and bind the services to it	add lb vserver <name> HTTP <ip> <port> bind lb vserver <vserverName> <serviceName> show lb vserver <name>	add lb vserver LBVS-1 http 203.0.113.15 80 bind lb vserver LBVS-1 SVC-S1 bind lb vserver LBVS-1 SVC-S2
Create a custom TCP profile and set its MSS for	add tcpProfile <name> -mss <positive_integer> show tcpProfile	add tcpprofile NS1-SERVERS-JUMBO -mss 8960

supporting jumbo frames Tasks	<name> NetScaler Command line Syntax	Examples
Bind the custom TCP profile to the desired services	set service <Name> -tcpProfileName <string> show service <name>	set service SVC-S1 -tcpProfileName NS1-SERVERS-JUMBO set service SVC-S2 -tcpProfileName NS1-SERVERS-JUMBO
Save the configuration	save ns config show ns config	

Use Case 3 – Coexistence of Jumbo and Non-Jumbo flows on the Same Set of Interfaces

May 06, 2014

Consider an example in which load balancing virtual servers LBVS-1 and LBVS-2 are configured on NetScaler appliance NS1. LBVS-1 is used to load balance HTTP traffic across servers S1 and S2, and LBVS-2 is used to load balance traffic across servers S3 and S4.

CL1 is on VLAN 10, S1 and S2 are on VLAN20, CL2 is on VLAN 30, and S3 and S4 are on VLAN 40. VLAN 10 and VLAN 20 support jumbo frames, and VLAN 30 and VLAN 40 support only regular frames.

In other words, the connection between CL1 and NS1, and the connection between NS1 and server S1 or S2 support jumbo frames. The connection between CL2 and NS1, and the connection between NS1 and server S3 or S4 support only regular frames.

Interface 10/1 of NS1 receives or sends traffic from or to clients. Interface 10/2 of NS1 receives or sends traffic from or to the servers.

Interface 10/1 is bound to both VLAN 10 and VLAN 30 as a tagged interface, and interface 10/2 is bound to both VLAN 20 and VLAN 40 as a tagged interface.

For supporting jumbo frames, the MTU is set to 9216 for interfaces 10/1 and 10/2.

On NS1, the MTU is set to 9000 for VLAN 10 and VLAN 20 for supporting jumbo frames, and the MTU is set to the default value of 1500 for VLAN 30 and VLAN 40 for supporting only regular frames.

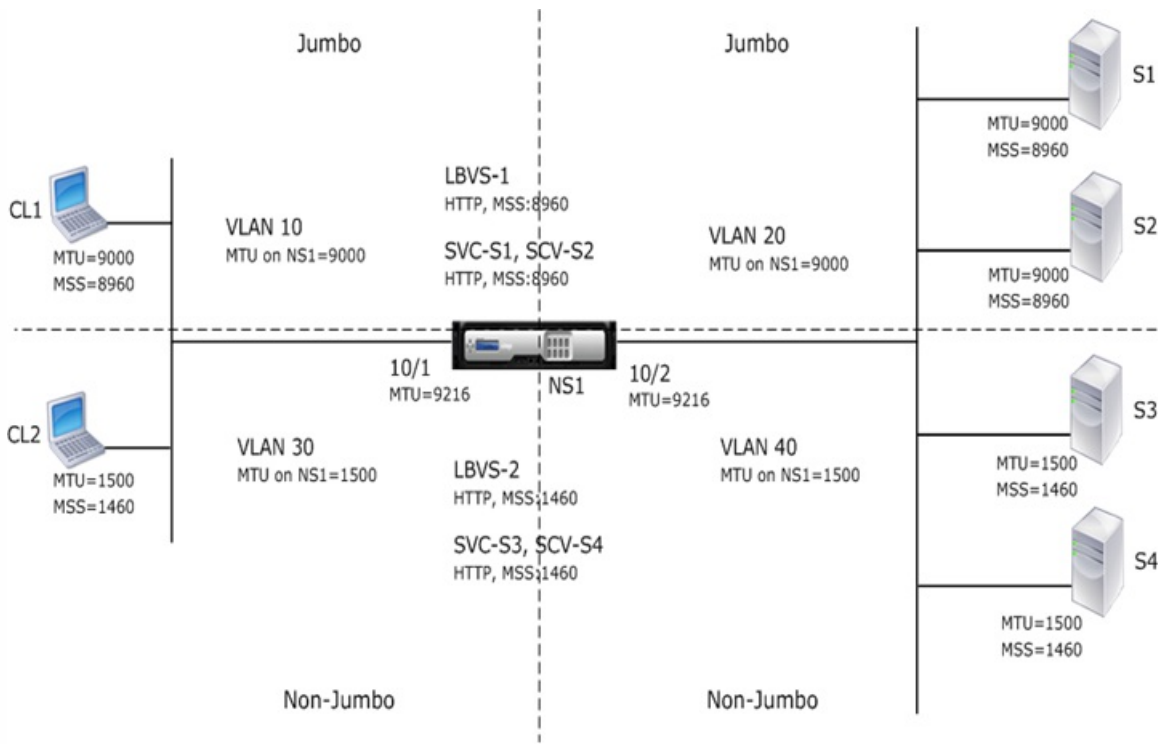

The effective MTU on a NetScaler interface for VLAN tagged packets is of the MTU of the interface or the MTU of the VLAN, whichever is lower. For example:

- The MTU of interface 10/1 is 9216. The MTU of VLAN 10 is 9000. On interface 10/1, the MTU of VLAN 10 tagged packets is 9000.
- The MTU of interface 10/2 is 9216. The MTU of VLAN 20 is 9000. On interface 10/2, the MTU of VLAN 20 tagged packets is 9000.
- The MTU of interface 10/1 is 9216. The MTU of VLAN 30 is 1500. On interface 10/1, the MTU of VLAN 30 tagged packets is 1500.
- The MTU of interface 10/2 is 9216. The MTU of VLAN 40 is 1500. On interface 10/2, the MTU of VLAN 40 tagged packets is 9000.

CL1, S1, S2, and all network devices between CL1 and S1 or S2 are configured for jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For the connection between CL1 and virtual server LBVS-1 of NS1, the MSS on NS1 is set in a TCP profile, which is then bound to LBVS-1.
- For the connection between a SNIP address of NS1 and S1, the MSS on NS1 is set in a TCP profile, which is then bound to the service (SVC-S1) representing S1 on NS1.

The following table lists the settings used in this example.

Entity	Name	Details
IP address of clients	CL1	192.0.2.10
	CL2	192.0.3.20
IP address of servers	S1	198.51.100.19
	S2	198.51.100.20
	S3	198.51.101.19
	S4	198.51.101.20
SNIP addresses on NS1		<ul style="list-style-type: none"> • 198.51.100.18 • 198.51.101.18
MTU specified for interfaces and VLANs on NS1	10/1	9216
	10/2	9216
	VLAN 10	9000

	VLAN 20	9000
	VLAN 30	1500
	VLAN 40	1500
Default TCP profile	nstcp_default_profile	MSS:1460
Custom TCP profile	ALL-JUMBO	MSS: 8960
Services on NS1 representing servers	SVC-S1	<ul style="list-style-type: none"> • IP address: 198.51.100.19 • Protocol: HTTP • Port: 80 • TCP profile: ALL-JUMBO (MSS: 8960)
	SVC-S2	<ul style="list-style-type: none"> • IP address: 198.51.100.20 • Protocol: HTTP • Port: 80 • TCP profile: ALL-JUMBO (MSS: 8960)
	SVC-S3	<ul style="list-style-type: none"> • IP address: 198.51.101.19 • Protocol: HTTP • Port: 80 • TCP Profile: nstcp_default_profile (MSS:1460)
	SVC-S4	<ul style="list-style-type: none"> • IP address: 198.51.101.20 • Protocol: HTTP • Port: 80 • TCP Profile: nstcp_default_profile (MSS:1460)
Load balancing virtual servers on NS1	LBVS-1	<ul style="list-style-type: none"> • IP address = 203.0.113.15 • Protocol: HTTP • Port:80 • Bound services: SVC-S1, SVC-S2 • TCP profile: ALL-JUMBO (MSS: 8960)
	LBVS-2	<ul style="list-style-type: none"> • IP address = 203.0.114.15 • Protocol: HTTP • Port:80 • Bound services: SVC-S3, SVC-S4

- TCP Profile: nstcp_default_profile (MSS:1460)

Following is the traffic flow of CL1's request to S1:

1. Client CL1 creates a 20000-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their TCP MSS values while establishing the connection.
3. Because NS1's MSS value is smaller than the HTTP request, CL1 segments the request data into multiples of NS1's MSS and sends these segments in IP packets tagged as VLAN 10 to NS1.
 - Size of the first two packets = [IP Header + TCP Header + (TCP segment=NS1 MSS)] = [20 + 20 + 8960] = 9000
 - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120
4. NS1 receives these packets at interface 10/1. NS1 accepts these packets because the size of these packets is equal to or less than the effective MTU (9000) of interface 10/1 for VLAN 10 tagged packets.
5. From the IP packets, NS1 assembles all the TCP segments to form the 20000-byte HTTP request. NS1 processes this request.
6. LBVS-1's load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
7. NS1 segments the request data into multiples of S1's MSS and sends these segments in IP packets tagged as VLAN 20 to S1.
 - Size of the first two packets = [IP Header + TCP Header + (TCP payload=S1 MSS)] = [20 + 20 + 8960] = 9000
 - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120

Following is the traffic flow of S1's response to CL1:

1. Server S1 creates a 30000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets tagged as VLAN 20 to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.
 - Size of first three packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000
 - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160
3. NS1 receives the response packets at interface 10/2. NS1 accepts these packets, because their size is equal to or less than the effective MTU value (9000) of interface 10/2 for VLAN 20 tagged packets.
4. From these IP packets, NS1 assembles all the TCP segments to form the 30000-byte HTTP response. NS1 processes this response.
5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets tagged as VLAN 10, from interface 10/1, to CL1. These IP packets are sourced from LBVS's IP address and destined to CL1's IP address.
 - Size of first three packet = [IP Header + TCP Header + [(TCP payload=CL1's MSS size)] = [20 + 20 + 8960] = 9000
 - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160

Configuration Tasks

Updated: 2014-01-16

Following table lists tasks, commands, and examples for creating the required configuration on the NetScaler appliance.

Task	Syntax	Examples
Set the MTU of the desired interfaces for supporting jumbo frames	set interface <id> -mtu <positive_integer>	set int 10/1 -mtu 9216 set int 10/2 -mtu 9216

Task	Syntax	Examples
Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames	<pre>show interface <id> add vlan <id> -mtu <positive_integer> show vlan <id></pre>	<pre>add vlan 10 -mtu 9000 add vlan 20 -mtu 9000 add vlan 30 -mtu 1500 add vlan 40 -mtu 1500</pre>
Bind interfaces to VLANs	<pre>bind vlan <id> -ifnum <interface_name> show vlan <id></pre>	<pre>bind vlan 10 -ifnum 10/1 -tagged bind vlan 20 -ifnum 10/2 -tagged bind vlan 30 -ifnum 10/1 -tagged bind vlan 40 -ifnum 10/2 -tagged</pre>
Add a SNIP address	<pre>add ns ip <IPAddress> <netmask> -type SNIP show ns ip</pre>	<pre>add ns ip 198.51.100.18 255.255.255.0 -type SNIP add ns ip 198.51.101.18 255.255.255.0 -type SNIP</pre>
Create services representing HTTP servers	<pre>add service <serviceName> <ip> HTTP <port> show service <name></pre>	<pre>add service SVC-S1 198.51.100.19 http 80 add service SVC-S2 198.51.100.20 http 80 add service SVC-S3 198.51.101.19 http 80 add service SVC-S4 198.51.101.20 http 80</pre>
Create HTTP load balancing virtual servers and bind the services to it	<pre>add lb vserver <name> HTTP <ip> <port> bind lb vserver <vserverName> <serviceName></pre>	<pre>add lb vserver LBVS-1 http 203.0.113.15 80 bind lb vserver LBVS-1 SVC-S1 bind lb vserver LBVS-1 SVC-S2</pre>

Task	Syntax	Examples
	<pre>show lb vserver <name></pre>	<pre>show lb vserver LBVS-2 http 203.0.114.15 80 bind lb vserver LBVS-2 SVC-S3 bind lb vserver LBVS-2 SVC-S4</pre>
<p>Create a custom TCP profile and set its MSS for supporting jumbo frames</p>	<pre>add tcpProfile <name> -mss <positive_integer> show tcpProfile <name></pre>	<pre>add tcpprofile ALL-JUMBO -mss 8960</pre>
<p>Bind the custom TCP profile to the desired load balancing virtual server and services</p>	<pre>set service <Name> - tcpProfileName <string> show service <name></pre>	<pre>set lb vserver LBVS-1 - tcpProfileName ALL-JUMBO set service SVC-S1 - tcpProfileName ALL-JUMBO set service SVC-S2 - tcpProfileName ALL-JUMBO</pre>
<p>Save the configuration</p>	<pre>save ns config show ns config</pre>	

Access Control Lists

May 10, 2012

Access Control Lists (ACLs) filter IP traffic and secure your network from unauthorized access. An ACL is a set of conditions that the NetScaler ADC evaluates to determine whether to allow access. For example, the Finance department probably does not want to allow its resources to be accessed by other departments, such as HR and Documentation, and those departments want to restrict access to their data.

When the NetScaler ADC receives a data packet, it compares the information in the data packet with the conditions specified in the ACL and allows or denies access. The administrator of the organization can configure ACLs to function in the following processing modes:

- **ALLOW**—Process the packet.
- **BRIDGE**—Bridge the packet to the destination without processing it. The packet is directly sent by Layer 2 and Layer 3 forwarding.
- **DENY**—Drop the packet.

ACL rules are the first level of defense on the NetScaler ADC.

NetScaler supports the following types of ACLs:

- **Simple ACLs** filter packets on the basis of their source IP address and, optionally, their protocol, destination port, or traffic domain. Any packet that has the characteristics specified in the ACL is dropped.
- **Extended ACLs** filter data packets on the basis of various parameters, such as source IP address, source port, action, and protocol. An extended ACL defines the conditions that a packet must satisfy for the NetScaler ADC to process the packet, bridge the packet, or drop the packet.

Nomenclature

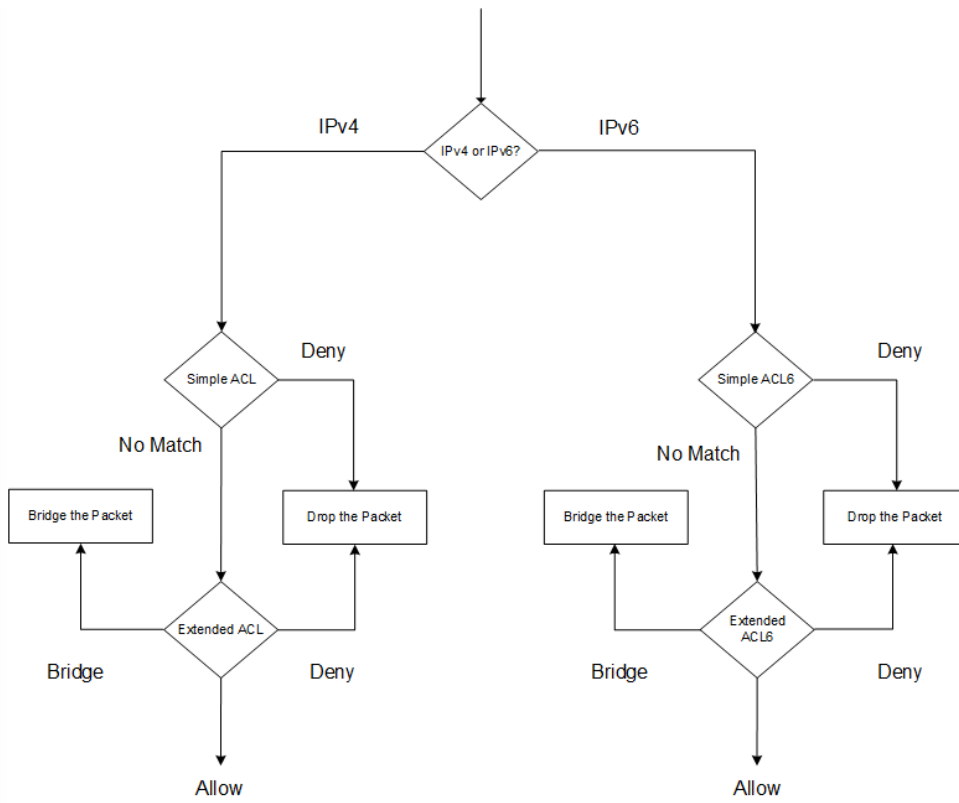

In the NetScaler user interfaces, the terms simple ACL and extended ACL refer to ACLs that process IPv4 packets. An ACL that processes IPv6 packets is called a simple ACL6 and or extended ACL6. When discussing both types, this documentation sometimes refers to both of them as simple ACLs or extended ACLs.

ACL Precedence

If both simple and extended ACLs are configured, incoming packets are compared to the simple ACLs first.

The NetScaler ADC first determines whether the incoming packet is an IPv4 or an IPv6 packet, and then compares the packet's characteristics to either simple ACLs or simple ACL6s. If a match is found, the packet is dropped. If no match is found, the packet is compared to extended ACLs or extended ACL6s. If that comparison results in a match, the packet is handled as specified in the ACL. The packet can be bridged, dropped, or allowed. If no match is found, the packet is allowed.

Figure 1. Simple and Extended ACLs Flow Sequence

Simple ACLs and Simple ACL6s

May 21, 2015

A simple ACL or simple ACL6 uses few parameters and can be configured only to drop IP packets. Packets can be dropped on the basis of their source IP address and, optionally, their protocol, destination port, or traffic domain.

When creating a simple ACL or simple ACL6, you can specify a time to live (TTL), in seconds, after which the ACL expires. ACLs with TTLs are not saved when you save the configuration. You can display simple ACLs and simple ACL6s to verify their configuration, and you can display their statistics.

This section includes the following details:

- [Configuring Simple ACLs and Simple ACL6s](#)
- [Displaying Simple ACL and Simple ACL6 Statistics](#)
- [Terminating Established Connections](#)

Configuring Simple ACLs and Simple ACL6s

Configuring a simple ACL or simple ACL6 on a NetScaler ADC can include the following tasks.

- Create simple ACLs or simple ACL6s to drop (deny) packets on the basis of their source IP address and, optionally, their protocol, destination port, or traffic domain.
- Remove simple ACLs or simple ACL6s. These ACLs cannot be modified once created. If you need to modify a simple ACL or simple ACL6, you must remove it and create a new one.

To create a simple ACL by using the command line interface

At the command prompt, type the following commands to add an ACL and verify the configuration:

- **add ns simpleacl** <aclname> DENY -srcIP <ip_addr> [-destPort <port> -protocol (TCP | UDP)] [-TTL <positive_integer>]
- **show ns simpleacl** [<aclname>]

Example

```
> add simpleacl rule1 DENY -srcIP 10.102.29.5 -TTL 600
Done
```

To create a simple ACL6 by using the command line interface

At the command prompt, type the following commands to add a simple ACL6 and verify the configuration:

- **add ns simpleacl6** <aclname> DENY -srcIPv6 <ipv6_addr|null> [-destPort <port> -protocol (TCP | UDP)] [-TTL <positive_integer>]
- **show ns simpleacl6** [<aclname>]

Example

```
> add ns simpleacl6 rule1 DENY -srcIPv6 3ffe:192:168:215::82 -destPort 80 -Protocol TCP -TTL 9000
Done
```

To remove a single simple ACL by using the command line interface

At the command prompt, type:

- **rm ns simpleacl** <aclname>
- **show ns simpleacl**

To remove a single simple ACL6 by using the command line interface

At the command prompt, type:

- **rm ns simpleacl6**<aclname>
- **show ns simpleacl6**

To remove all simple ACLs by using the command line interface

At the command prompt, type:

- **clear ns simpleacl**
- **show ns simpleacl**

To remove all simple ACL6s by using the command line interface

At the command prompt, type:

- **clear ns simpleacl6**
- **show ns simpleacl6**

To create a simple ACL by using the configuration utility

Navigate to System > Network > ACLs and, on the **Simple ACLs** tab, add a new simple ACL.

To create a simple ACL6 by using the configuration utility

Navigate to System > Network > ACLs and, on the **Simple ACL6s** tab, add a new simple ACL6.

To remove a single simple ACL by using the configuration utility

Navigate to System > Network > ACLs and, on the **Simple ACLs** tab, delete the simple ACL.

To remove a single simple ACL6 by using the configuration utility

Navigate to System > Network > ACLs and, on the **Simple ACL6s** tab, delete the simple ACL6.

To remove all simple ACLs by using the configuration utility

1. Navigate to System > Network > ACLs.
2. On the **Simple ACLs** tab, in the **Action** list, click **Clear**.

To remove all simple ACL6s by using the configuration utility

1. Navigate to System > Network > ACLs.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Clear**.

Displaying Simple ACL and Simple ACL6 Statistics

You can display the simple ACL (or simple ACL6) statistics, which include the number of hits, the number of misses, and the number of simple ACLs configured.

The following table describes statistics you can display for simple ACLs and simple ACL6s.

Statistic	Indicates
ACL hits	Packets matching an ACL
ACL misses	Packets not matching any ACL
ACL count	Number of ACLs configured

To display simple ACL statistics by using the command line interface

At the command prompt, type:

```
stat ns simpleacl
```

Example

```
> stat ns simpleacl
```

SimpleACL Statistics

	Rate (/s)	Total
SimpleACL hits	0	0
SimpleACL misses	0	51872
SimpleACLs count	--	2

Done

To display simple ACL6 statistics by using the command line interface

At the command prompt, type:

```
stat ns simpleacl6
```

To display simple ACL statistics by using the configuration utility

Navigate to System > Network > ACLs and, on the **Simple ACLs** tab, select the ACL and click **Statistics**.

To display simple ACL6 statistics by using the configuration utility

Navigate to System > Network > ACLs and, on the **Simple ACL6s** tab, select the simple ACL6 and click **Statistics**.

Terminating Established Connections

For a simple ACL or simple ACL6, the NetScaler ADC blocks any new connections that match the conditions specified in the ACL. Packets related to existing connections that were established before the ACL was created are not blocked. To terminate previously established connections that match an existing ACL, you can run a flush operation from the command

line interface or the configuration utility.

Flush can be useful in the following cases:

- You receive a list of blacklisted IP addresses and want to completely block those IP addresses from accessing the NetScaler ADC. In this case, you create simple ACLs or simple ACL6s to block any new connections from these IP addresses, and then flush any existing connections associated with those addresses.
- You want to terminate a large number of connections from a particular network without taking the time to terminate them one by one.

When you run flush, the NetScaler ADC searches through all of its established connections and terminates those that match conditions specified in any of the simple ACLs configured on the ADC.

Note: If you plan to create more than one simple ACL and flush existing connections that match any of them, you can minimize the effect on performance by first creating all of the simple ACLs and then running flush only once.

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the command line interface

At the command prompt, type:

```
flush simpleacl -estSessions
```

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the command line interface

At the command prompt, type:

```
flush simpleacl6 -estSessions
```

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the configuration utility

1. Navigate to System > Network > ACLs.
2. On the **Simple ACLs** tab, in the **Action** list, click **Flush**.

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the configuration utility

1. Navigate to System > Network > ACLs.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Flush**.

Extended ACLs and Extended ACL6s

Jan 31, 2011

Extended ACLs and extended ACL6s provide parameters and actions not available with simple ACLs. You can filter data on the basis of parameters such as source IP address, source port, action, and protocol. You can specify tasks to allow a packet, deny a packet, or bridge a packet.

Extended ACLs and ACL6s can be modified after they are created, and you can renumber their priorities to specify the order in which they are evaluated.

Note: If you configure both simple and extended ACLs, simple ACLs take precedence over extended ACLs. The following actions can be performed on extended ACLs and ACL6s: Modify, Apply, Disable, Enable, Remove, and Renumber (the priority). You can display extended ACLs and ACL6s to verify their configuration, and you can display their statistics.

You can configure the NetScaler ADC to log details for packets that match an extended ACL. However, you cannot log details of packets that match an ext

Applying Extended ACLs and Extended ACL6s

Unlike simple ACLs and ACL6s, extended ACLs and ACL6s created on the NetScaler ADC do not work until they are applied. Also, if you make any modifications to an extended ACL or ACL6, such as disabling the ACLs, changing a priority, or deleting the ACLs, you must reapply the extended ACLs or ACL6s. You must also reapply them after enabling logging. The procedure to apply extended ACLs or ACL6s reapplies all of them. For example, if you have applied extended ACL rules 1 through 10, and you then create and apply rule 11, the first 10 rules are applied afresh.

If a session has a DENY ACL related to it, that session is terminated when you apply the ACLs.

Extended ACLs and ACL6s are enabled by default. When they are applied, the NetScaler ADC starts comparing incoming packets against them. However, if you disable them, they are not used until you reenables them, even if they are reapplied.

Renumbering the priorities of Extended ACLs and Extended ACL6s

Priority numbers determine the order in which extended ACLs or ACL6s are matched against a packet. An ACL with a lower priority number has a higher priority. It is evaluated before ACLs with higher priority numbers (lower priorities), and the first ACL to match the packet determines the action applied to the packet.

When you create an extended ACL or ACL6, the NetScaler ADC automatically assigns it a priority number that is a multiple of 10, unless you specify otherwise. For example, if two extended ACLs have priorities of 20 and 30, respectively, and you want a third ACL to have a value between those numbers, you might assign it a value of 25. If you later want to retain the order in which the ACLs are evaluated but restore their numbering to multiples of 10, you can use the renumber procedure.

This section includes the following details:

- [Configuring Extended ACLs and Extended ACL6s](#)
- [Logging Extended ACLs \(IPv4 Only\)](#)
- [Displaying Extended ACL and Extended ACL6s Statistics](#)
- [Sample Configurations](#)

Configuring Extended ACLs and Extended ACL6s

Configuring an extended ACL or ACL6 on a NetScaler ADC consists of the following tasks.

- Create an extended ACL or ACL6 to either allow, deny, or bridge a packet. You can specify an IP address or range of IP addresses to match against the source or destination IP addresses of the packets. You can specify a protocol to match against the protocol of incoming packets.
- (Optional) You can modify extended ACLs or ACL6s that you previously created. Or, if you want to temporarily take one out of use you can disable it, and later reenable it.
- Apply extended ACLs or ACL6s. After you create, modify, disable or reenable, or delete an extended ACL or ACL6, you must apply the extended ACLs or ACL6s to activate them.
- (Optional) Renumber the priorities of extended ACLs or ACL6s. If you have configured ACLs with priorities that are not multiples of 10 and want to restore the numbering to multiples of 10, use the renumber procedure.

To create an extended ACL by using the command line interface

At the command prompt, type:

- **add ns acl** <aclname> <aclaction> [-**srcIP** [<operator>] <srcIPVal>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIP** [<operator>] <destIPVal>] [-**destPort** [<operator>] <destPortVal>] [-**TTL** <positive_integer>] [-**srcMac** <mac_addr>] [(-**protocol** <protocol> [-established]) | -**protocolNumber** <positive_integer>] [-**vlan** <positive_integer>] [-**interface** <interface_name>] [-**icmpType** <positive_integer> [-**icmpCode** <positive_integer>]] [-**priority** <positive_integer>] [-**state** (ENABLED | DISABLED)] [-**logstate** (ENABLED | DISABLED)] [-**ratelimit** <positive_integer>]]
- **show ns acl** [<aclName>]

Example

```
> add ns acl restrict DENY -srcport 45-1024 -destIP 192.168.1.1 -protocol TCP
Done
```

To create an extended ACL6 by using the command line interface

At the command prompt, type:

- **add ns acl6** <acl6name> <acl6action> [-**srcIPv6** [<operator>] <srcIPv6Val>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIPv6** [<operator>] <destIPv6Val>] [-**destPort** [<operator>] <destPortVal>] [-**TTL** <positive_integer>] [-**srcMac** <mac_addr>] [(-**protocol** <protocol> [-established]) | -**protocolNumber** <positive_integer>] [-**vlan** <positive_integer>] [-**interface** <interface_name>] [-**icmpType** <positive_integer> [-**icmpCode** <positive_integer>]] [-**priority** <positive_integer>] [-**state** (ENABLED | DISABLED)]
- **show ns acl6** [<aclName>]

Example

```
> add ns acl6 rule6 DENY -srcport 45-1024 -destIPv6 2001::45 -protocol TCP
Done
```

To modify an extended ACL by using the command line interface

To modify an extended ACL, type the **set ns acl** command, the name of the extended ACL, and the parameters to be changed, with their new values.

To modify an extended ACL6 by using the command line interface

To modify an extended ACL6, type the **set ns acl** command, the name of the extended ACL6, and the parameters to be changed, with their new values.

To disable or enable an extended ACL by using the command line interface

At the command prompt, type one of the following commands:

- **disable ns acl** <aclname>
- **enable ns acl** <aclname>

To disable or enable an extended ACL6 by using the command line interface

At the command prompt, type one of the following commands:

- **disable ns acl6** <aclname>
- **enable ns acl6** <aclname>

To apply extended ACLs by using the command line interface

At the command prompt, type:

apply ns acls

To apply extended ACL6s by using the command line interface

At the command prompt, type:

apply ns acls6

To renumber the priorities of extended ACLs by using the command line interface

At the command prompt, type:

renumber ns acls

To renumber the priorities of extended ACL6s by using the command line interface

At the command prompt, type:

renumber ns acls6

To configure an extended ACL by using the configuration utility

Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, add a new extended ACL or edit an existing extended ACL. To enable or disable an existing extended ACL, select it, and then select **Enable** or **Disable** from the **Action** list.

To configure an extended ACL6s by using the configuration utility

Navigate to **System > Network > ACLs** and, on the **Extended ACL6s** tab, add a new extended ACL6 or edit an existing extended ACL6. To enable or disable an existing extended ACL6, select it, and then select **Enable** or **Disable** from the **Action** list.

To apply extended ACLs by using the configuration utility

Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Apply**.

To apply extended ACLs by using the configuration utility

Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Apply**.

To renumber the priorities of extended ACLs by using the configuration utility

Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Renumber Priority (s)**.

To renumber the priorities of extended ACLs by using the configuration utility

Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Renumber Priority (s)**.

Logging Extended ACLs (IPv4 Only)

You can configure the NetScaler ADC to log details for packets that match extended ACLs.

Note: You cannot enable logging for extended ACLs.

In addition to the ACL name, the logged details include packet-specific information such as the source and destination IP addresses. The information is stored either in the syslog file or in the nslog file, depending on the type of global logging (syslog or nslog) enabled.

Logging must be enabled at both the global level and the ACL level. The global setting takes precedence. For more information about enabling logging globally, see "[Audit Logging](#)."

To optimize logging, when multiple packets from the same flow match an ACL, only the first packet's details are logged, and the counter is incremented for every packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the source IP address, destination IP address, source port, destination port, and protocol parameters. To avoid flooding of log messages, the NetScaler ADC performs internal rate limiting so that packets belonging to the same flow are not repeatedly logged. The total number of different flows that can be logged at any given time is limited to 10,000.

Note: You must apply ACLs after you enable logging.

To configure extended ACL Logging by using the command line interface

At the command prompt, type the following commands to configure logging and verify the configuration:

- **set ns acl** <aclName> [-logState (ENABLED | DISABLED)] [-rateLimit <positive_integer>]
- **show ns acl** [<aclName>]

Example

```
> set ns acl restrict -logstate ENABLED -ratelimit 120
```

Warning: ACL modified, apply ACLs to activate change

To configure extended ACL Logging by using the configuration utility

1. Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, open the extended ACL.
2. Set the following parameters:
 - **Log State**— Enable or disable logging of events related to the extended ACL rule. The log messages are stored in the configured syslog or auditlog server.

- **Log Rate Limit**—Maximum number of log messages to be generated per second. If you set this parameter, you must enable the Log State parameter.

Displaying Extended ACL and Extended ACL6s Statistics

You can display statistics of extended ACLs and ACL6s.

The following table lists the statistics associated with extended ACLs and ACL6s, and their descriptions.

Statistic	Specifies
Allow ACL hits	Packets matching ACLs with processing mode set to ALLOW. The NetScaler ADC processes these packets.
NAT ACL hits	Packets matching a NAT ACL, resulting in a NAT session.
Deny ACL hits	Packets dropped because they match ACLs with processing mode set to DENY.
Bridge ACL hits	Packets matching a bridge ACL, which in transparent mode bypasses service processing.
ACL hits	Packets matching an ACL.
ACL misses	Packets not matching any ACL.

To display the statistics of all extended ACLs by using the command line interface

At the command prompt, type:

```
stat ns acl
```

To display the statistics of all extended ACL6s by using the command line interface

At the command prompt, type:

```
stat ns acl6
```

To display the statistics of an extended ACL by using the configuration utility

Navigate to System > Network > ACLs, on the **Extended ACLs** tab, select the extended ACL, and click **Statistics**.

To display the statistics of an extended ACL6 by using the configuration utility

Navigate to System > Network > ACLs, on the **Extended ACL6s** tab, select the extended ACL, and click **Statistics**.

Sample Configurations

The following table shows examples of configuring extended ACL rules through the command line interface.

Action - ALLOW

Tasks	Steps
Create an extended ACL rule to allow a particular host to access the servers.	>add ns acl allow-client ALLOW -srcIP = 40.40.40.1 Done
Create an extended ACL rule to allow a particular network to access the servers.	>add ns acl allow-client-net ALLOW -srcIP = 40.40.40.0-40.40.40.255 Done
Create extended ACL rules to allow HTTP, TFTP, and ICMP traffic.	>add acl allow-http ALLOW -protocol tcp - destport 80 Done Done >add acl allow-tftp ALLOW -protocol udp - destport 69 Done >add acl allow-icmp ALLOW - protocol icmp Done
Create an extended ACL rule to allow access to a particular destination/network.	>add acl allow-dest-access ALLOW -destip 20.20.20.0-20.20.20.255 Done
Create an extended ACL rule to allow traffic coming from a particular VLAN.	>add acl allow-vlan ALLOW -vlan 3000 Done
Action - DENY	
Tasks	Steps
Create an extended ACL rule to deny access to the servers by a particular host.	>add ns acl deny-client DENY -srcIP = 50.50.50.1 Done
Create an extended ACL rule to deny access to the servers from a particular network.	> add ns acl deny-client-net DENY -srcIP = 50.50.50.0-50.50.50.255 Done

Create extended ACL rules to deny Telnet and FTP traffic.	<pre>>add ns acl deny-client-Telnet DENY -protocol TCP -destPort 23</pre> <p>Done</p> <pre>> add ns acl deny-client-FTP DENY -protocol TCP - destPort 20-21</pre> <p>Done</p>
Create an extended ACL rule to deny TCP traffic to port 80 from a particular host/network.	<pre>>add ns acl deny-client-TCP DENY -protocol TCP - destPort 80 -destIP 20.20.20.0-20.20.20.255</pre> <p>Done</p>
Create an extended ACL rule to deny traffic from a particular VLAN.	<pre>> add acl deny-vlan DENY -vlan 2000</pre> <p>Done</p>
Action - BRIDGE	
Tasks	Steps
Create an extended ACL rule to bridge FTP traffic.	<pre>>add ns acl bridge-ftp BRIDGE -protocol TCP - destport 21</pre> <p>Done</p> <pre>>add ns acl bridge-ftp-data BRIDGE -protocol TCP -destport 21</pre> <p>Done</p>
Create an extended ACL rule to bridge all traffic from a particular VLAN.	<pre>>add ns acl bridge-client-vlan BRIDGE -vlan 1000</pre> <p>Done</p>
MAC Address Filtering	
Tasks	Steps
Create an extended ACL rule to allow traffic from a particular MAC address to a particular host.	<pre>>add ns acl allow-mac-host ALLOW -srcMAC 2a:c1:69:92:a0:7b -destIP 10.10.10.1</pre> <p>Done</p>

ACL with RNAT (Typically, RNAT is used to allow servers configured with private non-routable IP addresses to initiate connections to the Internet.)

Tasks	Steps
Create an RNAT rule for a particular host.	>add ns acl nat-acl-host ALLOW -srcIP 40.40.40.1 Done >apply ns acls Done >set nat nat-acl Done
Create an RNAT rule for a particular network.	>add ns acl nat-acl-network ALLOW -srcIP 40.40.40.0-40.40.40.255 Done >set nat nat-acl- network -NATIP 5.5.5.1 Done
ACL with Forwarding Session	
Create a forwarding session rule for a case in which a client request forwarded to a server results in a response that has to return by the same path.	>add ns acl forward-acl-host ALLOW -srcIP 20.20.20.1 Done >add forwardingSession fs - aclname forward-acl-host Done

IP Routing

Sep 06, 2013

NetScaler appliances support both dynamic and static routing. Because simple routing is not the primary role of a NetScaler, the main objective of running dynamic routing protocols is to enable route health injection (RHI), so that an upstream router can choose the best among multiple routes to a topographically distributed virtual server.

Most NetScaler implementations use some static routes to reduce routing overhead. You can create backup static routes and monitor routes to enable automatic switchover in the event that a static route goes down. You can also assign weights to facilitate load balancing among static routes, create null routes to prevent routing loops, and configure IPv6 static routes. You can configure policy based routes (PBRs), for which routing decisions are based on criteria that you specify.

This document includes the following information:

- [Configuring Dynamic Routes](#)
- [Configuring Static Routes](#)
- [Route Health Injection Based on Virtual Server Settings](#)
- [Configuring Policy-Based Routes](#)
- [Troubleshooting Routing Issues](#)

Configuring Dynamic Routes

Sep 30, 2015

When a dynamic routing protocol is enabled, the corresponding routing process monitors route updates and advertises routes. Routing protocols enable an upstream router to use the equal cost multipath (ECMP) technique to load balance traffic to identical virtual servers hosted on two standalone NetScaler appliances. Dynamic routing on a NetScaler appliance uses three routing tables. In a high-availability set up, the routing tables on the secondary appliance mirror those on the primary.

For command reference guides and unsupported commands on dynamic routing protocol, see [Dynamic Routing Protocol Command Reference Guides and Unsupported Commands](#).

The NetScaler supports the following protocols:

- Routing Information Protocol (RIP) version 2
- Open Shortest Path First (OSPF) version 2
- Border Gateway Protocol (BGP)
- Routing Information Protocol next generation (RIPng) for IPv6
- Open Shortest Path First (OSPF) version 3 for IPv6
- ISIS Protocol

You can enable more than one protocol simultaneously.

Routing Tables in the NetScaler

In a NetScaler appliance, the NetScaler kernel routing table, the FreeBSD kernel routing table, and the NSM FIB routing table each hold a different set of routes and serve a different purpose. They communicate with each other by using UNIX routing sockets. Route updates are not automatically propagated from one routing table to another. You must configure propagation of route updates for each routing table.

NS Kernel Routing Table

The NS kernel routing table holds subnet routes corresponding to the NSIP and to each SNIP and MIP. Usually, no routes corresponding to VIPs are present in the NS kernel routing table. The exception is a VIP added by using the `add ns ip` command and configured with a subnet mask other than 255.255.255.255. If there are multiple IP addresses belonging to the same subnet, they are abstracted as a single subnet route. In addition, this table holds a route to the loopback network (127.0.0.0) and any static routes added through the command line interface (CLI). The entries in this table are used by the NetScaler in packet forwarding. From the NetScaler CLI, they can be inspected with the `show route` command.

FreeBSD Routing Table

The sole purpose of the FreeBSD routing table is to facilitate initiation and termination of management traffic (telnet, ssh, etc.). In a NetScaler appliance, these applications are tightly coupled to FreeBSD, and it is imperative for FreeBSD to have the necessary information to handle traffic to and from these applications. This routing table contains a route to the NSIP subnet and a default route. In addition, FreeBSD adds routes of type WasCloned(W) when the NetScaler establishes connections to hosts on local networks. Because of the highly specialized utility of the entries in this routing table, all other route updates from the NS kernel and NSM FIB routing tables bypass the FreeBSD routing table. Do not modify it with the `route` command. The FreeBSD routing table can be inspected by using the `netstat` command from any UNIX shell.

Network Services Module (NSM) FIB

The NSM FIB routing table contains the advertisable routes that are distributed by the dynamic routing protocols to their peers in the network. It may contain:

Connected routes

IP subnets that are directly reachable from the NetScaler. Typically, routes corresponding to the NSIP subnet and subnets over which routing protocols are enabled are present in NSM FIB as connected routes.

Kernel routes

All the VIP addresses on which the `-hostRoute` option is enabled are present in NSM FIB as kernel routes if they satisfy the required RHI Levels. In addition, NSM FIB contains any static routes configured on the NetScaler CLI that have the `-advertise` option enabled. Alternatively, if the NetScaler is operating in Static Route Advertisement (SRADV) mode, all static routes configured on the NetScaler CLI are present in NSM FIB. These static routes are marked as kernel routes in NSM FIB, because they actually belong to the NS kernel routing table.

Static routes

Normally, any static route configured in VTYSH is present in NSM FIB. If administrative distances of protocols are modified, this may not always be the case. An important point to note is that these routes can never get into the NS kernel routing table.

Learned routes

If the NetScaler is configured to learn routes dynamically, the NSM FIB contains routes learned by the various dynamic routing protocols. Routes learned by OSPF, however, need special processing. They are downloaded to FIB only if the `fib-install` option is enabled for the OSPF process. This can be done from the `router-config` view in VTYSH.

High Availability Setup

In a high availability setup, the primary node runs the routing process and propagates routing table updates to the secondary node. The routing table of the secondary node mirrors the routing table on the primary node.

Non-Stop Forwarding

After failover, the secondary node takes some time to start the protocol, learn the routes, and update its routing table. But this does not affect routing, because the routing table on the secondary node is identical to the routing table on the primary node. This mode of operation is known as non-stop forwarding.

Black Hole Avoidance Mechanism

After failover, the new primary node injects all its VIP routes into the upstream router. However, that router retains the old primary node's routes for 180 seconds. Because the router is not aware of the failover, it attempts to load balance traffic between the two nodes. During the 180 seconds before the old routes expire, the router sends half the traffic to the old, inactive primary node, which is, in effect, a black hole.

To prevent this, the new primary node, when injecting a route, assigns it a metric that is slightly lower than the one specified by the old primary node.

Interfaces for Configuring Dynamic Routing

To configure dynamic routing, you can use either the configuration utility or a command-line interface. The NetScaler supports two independent command-line interfaces: the NetScaler CLI and the Virtual Teletype Shell (VTYSH). The

NetScaler CLI is the appliance's native shell. VTYSH is exposed by ZebOS. The NetScaler routing suite is based on ZebOS, the commercial version of GNU Zebra.

Note: Citrix recommends that you use VTYSH for all commands except those that can be configured only on the NetScaler CLI. Use of the NetScaler CLI should generally be limited to commands for enabling the routing protocols, configuring host route advertisement, and adding static routes for packet forwarding.

Dynamic Routing Protocol Command Reference Guides and Unsupported Commands

The following table lists command reference guide links, for various dynamic routing protocols, and unsupported commands on the NetScaler appliance:

Dynamic Routing Protocol	Command Reference Guide	Unsupported Commands
OSPF	OSPF Command Reference	<ul style="list-style-type: none"> • Domain-id command • Graceful restart related commands • OSPF-TE related commands • OSPF-VPN related commands • CSPF-TE related commands • ip ospf resync-timeout command • capability opaque command • enable ext-ospf-multi-inst command
IPv6 OSPF (OSPFv3)	OSPF Command Reference	<ul style="list-style-type: none"> • Graceful restart related commands • OSPF-TE related commands
BGP	BGP Command Reference	<ul style="list-style-type: none"> • VPN/VRF related commands • Graceful restart related commands • MPLS related commands • 6PE commands (IPv6 provider edge) • MD5 authentication related commands • Multicast options • set-overload-bit command
IS-IS	IS-IS Command Reference	<ul style="list-style-type: none"> • capability cspf command • enable-cspf command • mpls traffic-eng command • mpls traffic-eng router-id command • multi-topology for ipv6 address family related commands
RIP and IPv6 RIP (RIPng)	-	<ul style="list-style-type: none"> • neighbor command

Configuring RIP

Mar 20, 2012

Routing Information Protocol (RIP) is a Distance Vector protocol. The NetScaler supports RIP as defined in RFC 1058 and RFC 2453. RIP can run on any subnet.

After enabling RIP, you need to configure advertisement of RIP routes. For troubleshooting, you can limit RIP propagation. You can display RIP settings to verify the configuration.

Enabling and Disabling RIP

Updated: 2013-08-30

Use either of the following procedures to enable or disable RIP. After you enable RIP, the NetScaler appliance starts the RIP process. After you disable RIP, the appliance stops the RIP process.

To enable or disable RIP routing by using the command line interface

At the command prompt, enter one of the following commands to enable or disable RIP:

- enable ns feature RIP
- disable ns feature RIP

To enable or disable RIP routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the RIP Routing option.

Advertising Routes

Updated: 2013-08-30

RIP enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertisement enables an upstream router to track network entities located behind the NetScaler.

To configure RIP to advertise routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router rip	Start the RIP routing process and enter configuration mode for the routing process.

Command redistribute static	Specifies Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router rip
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting RIP Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you can configure listen-only mode on any given interface.

To limit RIP propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router rip	Start the RIP routing process and enter configuration mode for the routing process.
passive-interface <vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router rip
NS(config-router)# passive-interface VLAN0
```

Verifying the RIP Configuration

Updated: 2013-08-30

You can display the routing table and other RIP settings.

To view the RIP settings by using the VTYSH command line

At the command prompt, type the following commands in the following order:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh rip	Display updated RIP routing table.
sh rip interface <vlan_name>	Displays RIP information for the specified VLAN.

Example

```
NS# VTYSH
NS# sh rip
NS# sh rip interface VLAN0
```

Configuring OSPF

Feb 07, 2014

The NetScaler supports Open Shortest Path First (OSPF) Version 2 (RFC 2328). The features of OSPF on the NetScaler are:

- If a vserver is active, the host routes to the vserver can be injected into the routing protocols.
- OSPF can run on any subnet.
- Route learning advertised by neighboring OSPF routers can be disabled on the NetScaler.
- The NetScaler can advertise Type-1 or Type-2 external metrics for all routes.
- The NetScaler can advertise user-specified metric settings for VIP routes. For example, you can configure a metric per VIP without special route maps.
- You can specify the OSPF area ID for the NetScaler.
- The NetScaler supports not-so-stubby-areas (NSSAs). An NSSA is similar to an OSPF stub area but allows injection of external routes in a limited fashion into the stub area. To support NSSAs, a new option bit (the N bit) and a new type (Type 7) of Link State Advertisement (LSA) area have been defined. Type 7 LSAs support external route information within an NSSA. An NSSA area border router (ABR) translates a type 7 LSA into a type 5 LSA that is propagated into the OSPF domain. The OSPF specification defines only the following general classes of area configuration:
 - Type 5 LSA: Originated by routers internal to the area are flooded into the domain by AS boarder routers (ASBRs).
 - Stub: Allows no type 5 LSAs to be propagated into/throughout the area and instead depends on default routing to external destinations.

After enabling OSPF, you need to configure advertisement of OSPF routes. For troubleshooting, you can limit OSPF propagation. You can display OSPF settings to verify the configuration.

Enabling and Disabling OSPF

Updated: 2013-09-05

To enable or disable OSPF, you must use either the command line interface or the configuration utility. When OSPF is enabled, the NetScaler starts the OSPF process. When OSPF is disabled, the NetScaler stops the OSPF routing process.

To enable or disable OSPF routing by using the command line interface

At the command prompt, type one of the following commands:

1. `enable ns feature OSPF`
2. `disable ns feature OSPF`

To enable or disable OSPF routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the OSPF Routing option.

Advertising OSPF Routes

Updated: 2013-08-30

OSPF enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure OSPF to advertise routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enters global configuration mode.
router OSPF	Start OSPF routing process and enter configuration mode for the routing process.
network A.B.C.D/M area <0-4294967295>	Enable routing on an IP network.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router OSPF
NS(config-router)# network 10.102.29.0/24 area 0
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting OSPF Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you can configure listen-only mode on any given VLAN.

To limit OSPF propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router OSPF	Start OSPF routing process and enters configuration mode for the routing process.

Command	Specifies
passive-interface <vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router OSPF
NS(config-router)# passive-interface VLAN0
Verifying the OSPF Configuration
```

Updated: 2013-08-30

You can display current OSPF neighbors, and OSPF routes.

To view the OSPF settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh OSPF neighbor	Displays current neighbors.
sh OSPF route	Displays OSPF routes.

Example

```
>VTYSH
NS# sh OSPF neighbor
NS# sh OSPF route
```

Configuring BGP

Mar 20, 2012

The NetScaler appliance supports BGP (RFC 4271). The features of BGP on the NetScaler are:

- The NetScaler advertises routes to BGP peers.
- The NetScaler injects host routes to virtual IP addresses (VIPs), as determined by the health of the underlying virtual servers.
- The NetScaler generates configuration files for running BGP on the secondary node after failover in an HA configuration.
- This protocol supports IPv6 route exchanges.

After enabling BGP, you need to configure advertisement of BGP routes. For troubleshooting, you can limit BGP propagation. You can display BGP settings to verify the configuration.

Prerequisites for IPv6 BGP

Before you begin configuring IPv6 BGP, do the following:

- Make sure that you understand the IPv6 BGP protocol.
- Install the IPv6PT license on the NetScaler appliance.
- After installing the IPv6PT license, enable the IPv6 feature.

Enabling and Disabling BGP

Updated: 2013-09-05

To enable or disable BGP, you must use either the command line interface or the configuration utility. When BGP is enabled, the NetScaler appliance starts the BGP process. When BGP is disabled, the appliance stops the BGP process.

To enable or disable BGP routing by using the command line interface

At the command prompt, type one of the following commands:

- `enable ns feature BGP`
- `disable ns feature BGP`

To enable or disable BGP routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the BGP Routing option.

Advertising IPv4 Routes

Updated: 2013-08-30

You can configure the NetScaler appliance to advertise host routes to VIPs and to advertise routes to downstream networks.

To configure BGP to advertise IPv4 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
Neighbor < IPv4 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the link local IPv4 address of the neighbor in the specified autonomous system.
Address-family ipv4	Enter address family configuration mode.
Neighbor < IPv4 address> activate	Exchange prefixes for the IPv4 router family between the peer and the local node by using the link local address.
redistribute kernel	Redistribute kernel routes.
redistribute static	Redistribute static routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router BGP 5
NS(config-router)# Neighbor a1bc::102 remote-as 100
NS(config-router)# Address-family ipv4
NS(config-router-af)# Neighbor 10.102.29.170 activate
NS(config-router)# redistribute kernel
NS(config-router)# redistribute static
Advertising IPv6 BGP Routes
```

Updated: 2013-08-30

Border Gateway Protocol (BGP) enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure BGP to advertise IPv6 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
Neighbor < IPv6 address> remote-as < as-number>	Update the IPv6 BGP neighbor table with the link local IPv6 address of the neighbor in the specified autonomous system.
Address-family ipv6	Enter address family configuration mode.
Neighbor < IPv6 address> activate	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address.
redistribute kernel	Redistribute kernel routes.
redistribute static	Redistribute static routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router BGP 5
NS(config-router)# Neighbor a1bc::102 remote-as 100
NS(config-router)# Address-family ipv6
NS(config-router-af)# Neighbor a1bc::102 activate
NS(config-router)# redistribute kernel
NS(config-router)# redistribute static
Verifying the BGP Configuration
```

Updated: 2013-08-30

You can use VTYSH to display BGP settings.

To view the BGP settings using the VTYSH command line

At the command prompt, type:

```
VTYSH
You are now in the VTYSH command prompt. An output similar to the following appears:
NS170#
At the VTYSH command prompt, type:
```

```
NS170# sh ip BGP
NS170# sh BGP
NS170# sh ip BGP neighbors
NS170# sh ip BGP summary
NS170# sh ip BGP route-map <map-tag>
```

Configuring IPv6 RIP

Mar 20, 2012

IPv6 Routing Information Protocol (RIP) or RIPng is a Distance Vector protocol. This protocol is an extension of RIP to support IPv6. After enabling IPv6 RIP, you need to configure advertisement of IPv6 RIP routes. For troubleshooting, you can limit IPv6 RIP propagation. You can display IPv6 RIP settings to verify the configuration.

Prerequisites for IPv6 RIP

Before you begin configuring IPv6 RIP, do the following:

- Make sure that you understand the IPv6 RIP protocol.
- Install the IPv6PT license on the NetScaler appliance.
- Enable the IPv6 feature.

Enabling IPv6 RIP

Updated: 2013-08-30

You can enable or disable IPv6 RIP by using VTYSH. After you enable IPv6 RIP, the NetScaler starts the IPv6 RIP daemon. After you disable IPv6 RIP, the NetScaler stops the RIP daemon.

To enable IPv6 RIP by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
ns IPv6-routing	Start IPv6 dynamic routing daemon.
interface <vlan_name>	Enter VLAN configuration mode.
router ipv6 RIP	Start IPv6 RIP routing process on the VLAN.

Example

```
> VTYSH
NS# configure terminal
NS(config)# ns IPv6-routing
NS(config)# interface vlan0
NS(config-if)# router ipv6 RIP
```

Advertising IPv6 RIP Routes

Updated: 2013-08-30

IPv6 RIP enables an upstream router to load balance traffic between two identical vservers hosted on two standalone NetScaler devices. Route advertisement enables an upstream router to track network entities located behind the NetScaler.

To configure IPv6 RIP to advertise IPv6 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 rip	Start IPv6 RIP routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 rip
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting IPv6 RIP Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given interface.

To limit IPv6 RIP propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.

Command	Specifies
router ipv6 rip	Start IPv6 RIP routing process and enter configuration mode for the routing process.
passive-interface <vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 rip
NS(config-router)# passive-interface VLAN0
```

Verifying the IPv6 RIP Configuration

Updated: 2013-08-30

You can use VTYSH to display the IPv6 RIP routing table and IPv6 RIP information for a specified VLAN.

To view the IPv6 RIP settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
sh ipv6 rip	Display updated IPv6 RIP routing table.
sh ipv6 rip interface <vlan_name>	Display IPv6 RIP information for the specified VLAN.

Example

```
NS# VTYSH
NS# sh ipv6 rip
NS# sh ipv6 rip interface VLAN0
```

Configuring IPv6 OSPF

Mar 20, 2012

IPv6 OSPF or OSPF version 3 (OSPF v3) is a link state protocol that is used to exchange IPv6 routing information. After enabling IPv6 OSPF, you need to configure advertisement of IPv6 OSPF routes. For troubleshooting, you can limit IPv6 OSPF propagation. You can display IPv6 OSPF settings to verify the configuration.

Prerequisites for IPv6 OSPF

Before you begin configuring IPv6 OSPF, do the following:

- Make sure that you understand the IPv6 OSPF protocol.
- Install the IPv6PT license on the NetScaler appliance.
- Enable the IPv6 feature.

Enabling IPv6 OSPF

Updated: 2013-08-30

To enable IPv6 OSPF, you must use the VTYSH command line. When IPv6 OSPF is enabled, the NetScaler appliance starts the IPv6 OSPF daemon. When IPv6 OSPF is disabled, the appliance stops the IPv6 OSPF daemon.

To enable IPv6 OSPF by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
ns IPv6-routing	Start IPv6 dynamic routing process.
interface <vlan_name>	Enter the VLAN configuration mode.
ipv6 router OSPF area <area-id>	Start IPv6 OSPF routing process on a VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# ns IPv6-routing
NS(config)# interface vlan0
NS(config-if)# ipv6 router OSPF area 3
```

Advertising IPv6 Routes

Updated: 2013-08-30

IPv6 OSPF enables an upstream router to load balance traffic between two identical vservers hosted on two standalone NetScaler devices. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure IPv6 OSPF to advertise IPv6 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 OSPF	Start IPv6 OSPF routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 OSPF
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
Limiting IPv6 OSPF Propagations
```

Updated: 2013-08-30

If you need to troubleshoot your configuration, you use VTYSH to configure listen-only mode on any given VLAN.

To limit IPv6 OSPF propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.

Commands	Specifies
router ipv6 OSPF	Start IPv6 OSPF routing process and enter configuration mode for the routing process.
passive-interface < vlan_name >	Suppress routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 OSPF
NS(config-router)# passive-interface VLAN0
Verifying the IPv6 OSPF Configuration
```

Updated: 2013-08-30

You use VTYSH to display IPv6 OSPF current neighbors and IPv6 OSPF routes.

To view the IPv6 OSPF settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh ipv6 OSPF neighbor	Display current neighbors.
sh ipv6 OSPF route	Display IPv6 OSPF routes.

Example

```
>VTYSH
NS# sh ipv6 OSPF neighbor
NS# sh ipv6 OSPF route
```

Configuring ISIS

Apr 29, 2016

The NetScaler appliance supports the Intermediate System-to-Intermediate System (IS-IS or ISIS) dynamic routing protocol. This protocol supports IPv4 as well as IPv6 route exchanges. IS-IS is a link state protocol and is therefore less prone to routing loops. With the advantages of faster convergence and the ability to support larger networks, ISIS can be very useful in Internet Service Provider (ISP) networks.

Prerequisites for configuring ISIS

Before you begin configuring ISIS, do the following:

- Make sure that you understand the ISIS protocol.
- For IPV6 routes, enable:
 - IPv6 protocol translation feature.
 - IPv6 Dynamic Routing option on the VLANs on which you want to run ISIS protocol.

Enabling ISIS

Updated: 2013-08-30

Use either of the following procedures to enable the ISIS routing feature on the NetScaler appliance.

To enable ISIS routing by using the command line interface

At the command prompt, type:

```
enable ns feature ISIS
```

To enable ISIS routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the ISIS Routing option.

Creating an ISIS Routing Process and Starting It on a VLAN

Updated: 2013-08-30

To create an ISIS routing process, you must use the VTYSH command line.

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Creates an ISIS routing process and configuration mode for the routing process.

net Command XX...XXXX.YYYY.YYYY.YYYY.00	Description
	<p>Specifies a NET value for the routing process, where:</p> <ul style="list-style-type: none"> • · XX. . . XXXX is the Area Address (can be 1-13 bytes) • · YYYY.YYYY.YYYY is the System ID (6 bytes) • · 00 is the N-selector (1 byte) <p>A NET value can be 8 to 20 bytes in length. The last byte is always the n-selector, and must be zero. The n-selector indicates that there is no transport entity and means that the packet is for the routing software of the appliance. The six bytes directly preceding the n-selector are the system ID. The system ID length is fixed and cannot be changed. The system ID must be unique throughout each area (Level 1) and throughout the backbone (Level 2). The bytes preceding the system ID are the area ID, which can be from 1 to 13 bytes in length. A maximum of three NETs per routing process are allowed with different area ID, but the system ID should be the same for all NETs.</p>
is-type (level-1 level-1-2 level-2-only)	Sets the ISIS routing process to the specified level of routing. Default: level-1-2.
ns IPv6-routing	Starts the IPv6 dynamic routing daemon.
interface <vlan_name>	Enters the VLAN configuration mode.
ip router ISIS	Enables the ISIS routing process on the VLAN for IPv4 route exchanges.
ipv6 router ISIS	Enables the ISIS routing process on the VLAN for IPv6 route exchanges.

Example

```
> VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# net 15.aabb.cccd.0097.00
NS(config-router)# is-type level-1
NS(config-router)# exit
NS(config)# ns IPv6-routing
NS(config)# interface vlan0
NS(config-if)# ip router isis 11
NS(config-if)# ipv6 router isis 11
```

Advertising Routes

Updated: 2013-08-30

Route advertisement enables an upstream router to track network entities located behind the NetScaler appliance.

To configure ISIS to advertise routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Description

VTYSH Command	Description
configure terminal	Displays the VTYSH command prompt. Enters the global configuration mode.
router ISIS [tag]	Enters the global configuration mode. Starts the ISIS routing instance and enter configuration mode for the routing process.
redistribute connected (level-1 level-1-2 level-2)	Redistributes connected routes, where <ul style="list-style-type: none"> • level-1 : Redistribute connected routes into Level-1. • level-1-2 : Redistribute connected routes into Level-1 and Level-2. • level-2 : Redistribute connected routes into Level-2.
redistribute kernel(level-1 level-1-2 level-2)	Redistributes kernel routes, where: <ul style="list-style-type: none"> • level-1 : Redistribute kernel routes into Level-1. • level-1-2 : Redistribute kernel routes into Level-1 and Level-2. • level-2 : Redistribute kernel routes into Level-2.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# redistribute connected level-1
NS(config-router)# redistribute kernel level-1
```

Limiting ISIS Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given VLAN.

To limit ISIS propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router isis [tag]	Enters the configuration mode for the routing process.
passive-interface <vlan_name>	Suppresses routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# passive-interface VLAN0
Verifying the ISIS Configuration
```

Updated: 2013-08-30

You can use VTYSH to display the ISIS routing table and ISIS information for a specified VLAN.

To view the ISIS settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Description
VTYSH	Displays the VTYSH command prompt.
show ip isis route	Displays updated IPv4 ISIS routing table.
show ipv6 isis route	Displays updated IPv6 ISIS routing table.
sh isis interface <vlan_name>	Displays IPv6 ISIS information for the specified VLAN.

Example

```
NS# VTYSH
NS# show ip isis route
NS# show ipv6 isis route
NS# sh isis interface VLAN0
```

Installing Routes to the NetScaler Routing Table

Aug 30, 2013

The NetScaler appliance can use routes learned by various routing protocols after you install the routes in the appliance's routing table.

To install various routes to the internal routing table by using the VTYSH command line

At the command prompt, type the following commands as appropriate for the routes that you want to install:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
ns route-install Default	Install IPv4 default routes to the internal routing table.
ns route-install RIP	Install IPv4 RIP specific routes to the internal routing table.
ns route-install BGP	Install IPv4 BGP specific routes to the internal routing table.
ns route-install OSPF	Install IPv4 OSPF specific routes to the internal routing table.
ns route-install IPv6 Default	Install IPv6 default routes to the internal routing table.
ns route-install IPv6 RIP	Install IPv6 RIP specific routes to the internal routing table.
ns route-install IPv6 BGP	Install IPv6 BGP specific routes to the internal routing table.
ns route-install IPv6 OSPF	Install IPv6 OSPF specific routes to the internal routing table.

Example

```
>VTYSH
NS# configure terminal
NS# ns route-install Default
NS(config)# ns route-install RIP
NS(config)# ns route-install BGP
NS(config)# ns route-install OSPF
NS# ns route-install IPv6 Default
NS(config)# ns route-install IPv6 RIP
```

```
NS(config)# ns route-install IPv6 BGP
NS(config)# ns route-install IPv6 OSPF
```

Configuring Static Routes

Sep 06, 2013

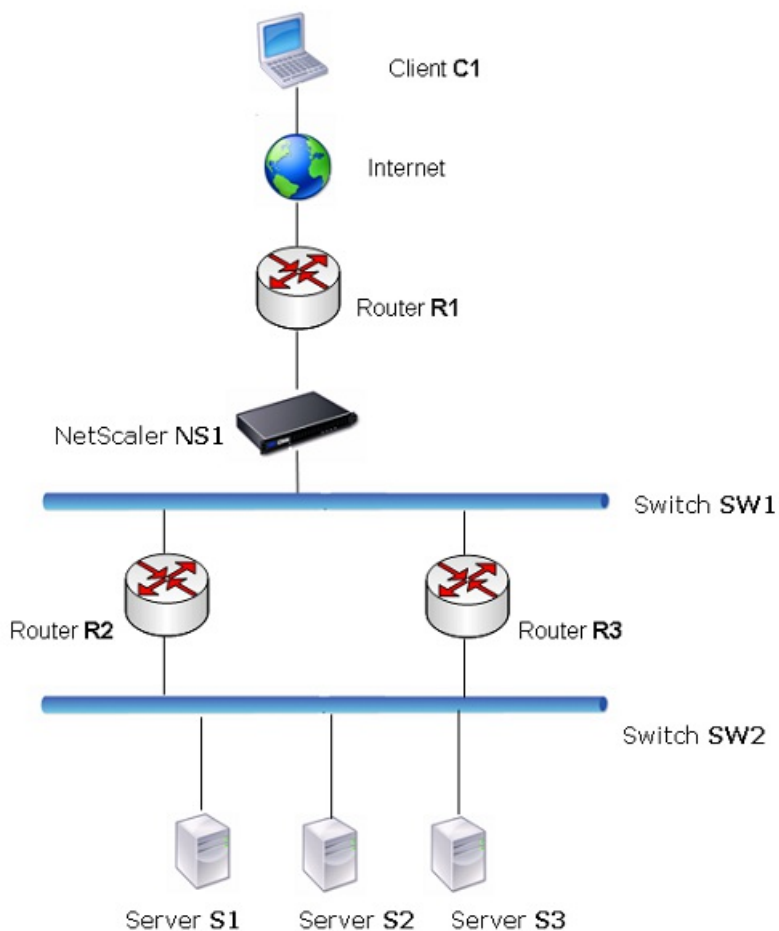

Static routes are manually created to improve the performance of your network. You can monitor static routes to avoid service disruptions. Also, you can assign weights to ECMP routes, and you can create null routes to prevent routing loops.

Monitored Static Routes

If a manually created (static) route goes down, a backup route is not automatically activated. You must manually delete the inactive primary static route. However, if you configure the static route as a monitored route, the NetScaler appliance can automatically activate a backup route.

Static route monitoring can also be based on the accessibility of the subnet. A subnet is usually connected to a single interface, but it can be logically accessed through other interfaces. Subnets bound to a VLAN are accessible only if the VLAN is up. VLANs are logical interfaces through which packets are transmitted and received by the NetScaler. A static route is marked as DOWN if the next hop resides on a subnet that is unreachable.

Note: In a high availability (HA) setup, the default value for monitored state routes (MSRs) on the secondary node is UP. The value is set to avoid a state transition gap upon failover, which could result in dropping packets on those routes. Consider the following simple topology, in which a NetScaler is load balancing traffic to a site across multiple servers.

Router R1 moves traffic between the client and the NetScaler appliance. The appliance can reach servers S1 and S2 through routers R2 or R3. It has two static routes through which to reach the servers' subnet, one with R2 as the gateway and another with R3 as the gateway. Both these routes have monitoring enabled. The administrative distance of the static route with gateway R2 is lower than that of the static route with gateway R3. Therefore, R2 is preferred over R3 to forward traffic to the servers. Also, the default route on the NetScaler points to R1 so that all Internet traffic exits properly.

If R2 fails while monitoring is enabled on the static route, which uses R2 as the gateway, the NetScaler marks it as DOWN. The NetScaler now uses the static route with R3 as the gateway and forwards the traffic to the servers through R3.

The NetScaler supports monitoring of IPv4 and IPv6 static routes. You can configure the NetScaler to monitor an IPv4 static route either by creating a new ARP or PING monitor or by using existing ARP or PING monitors. You can configure the NetScaler to monitor an IPv6 static route either by creating a new Neighbor discovery for IPv6 (ND6) or PING monitor or by using the existing ND6 or PING monitors.

Weighted Static Routes

When the NetScaler appliance makes routing decisions involving routes with equal distance and cost, that is, Equal Cost Multi-Path (ECMP) routes, it balances the load between them by using a hashing mechanism based on the source and destination IP addresses. For an ECMP route, however, you can configure a weight value. The NetScaler then uses both the weight and the hashed value for balancing the load.

Null Routes

If the route chosen in a routing decision is inactive, the NetScaler appliance chooses a backup route. If all the backup routes become inaccessible, the appliance might reroute the packet to the sender, which could result in a routing loop leading to network congestion. To prevent this situation, you can create a null route, which adds a null interface as a gateway. The null route is never the preferred route, because it has a higher administrative distance than the other static routes. But it is selected if the other static routes become inaccessible. In that case, the appliance drops the packet and prevents a routing loop.

This section includes the following details:

- [Configuring IPv4 Static Routes](#)
- [Configuring IPv6 Static Routes](#)

Configuring IPv4 Static Routes

Updated: 2013-09-06

You can add a simple static route or a null route by setting a few parameters, or you can set additional parameters to configure a monitored or monitored and weighted static route. You can change the parameters of a static route. For example, you might want to assign a weight to an unweighted route, or you might want to disable monitoring on a monitored route.

To create a static route by using the command line interface

At the command prompt, type the following commands to create a static route and verify the configuration:

- `add route <network> <netmask> <gateway>[-cost <positive_integer>][-advertise (DISABLED | ENABLED)]`
- `show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]`

Example

```
> add route 10.102.29.0 255.255.255.0 10.102.29.2 -cost 2 -advertise ENABLED
Done
```

To create a monitored static route by using the command line interface

At the command prompt, type the following commands to create a monitored static route and verify the configuration:

- `add route <network> <netmask> <gateway> [-distance <positive_integer>][-weight <positive_integer>][-msr (ENABLED | DISABLED)][-monitor <string>]`
- `show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]`

Example

```
> add route 10.102.29.0 255.255.255.0 10.102.29.3 -distance 5 -weight 6 -msr ENBLED -monitor PING
Done
```

To create a null route by using the command line interface

At the command prompt type:

- add route <network> <netmask> null
- show route <network> <netmask>

Example

```
> add route 10.102.29.0 255.255.255.0 null
Done
```

To remove a static route by using the command line interface

At the command prompt, type:

```
rm route <network> <netmask> <gateway>
```

Example

```
> rm route 10.102.29.0 255.255.255.0 10.102.29.3
Done
```

To configure a static route by using the configuration utility

Navigate to System > Network > Routes and, on the Basic tab, add a new static route, or edit an existing static route.

To remove a route by using the configuration utility

Navigate to System > Network > Routes and, on the Basic tab, delete the static route.

Configuring IPv6 Static Routes

Updated: 2013-09-06

You can configure a maximum of six default IPv6 static routes. IPv6 routes are selected on the basis of whether the MAC address of the destination device is reachable. This can be determined by using the IPv6 Neighbor Discovery feature. Routes are load balanced and only source/destination-based hash mechanisms are used. Therefore, route selection mechanisms such as round robin are not supported. The next hop address in the default route need not belong to the NSIP subnet.

To create an IPv6 route by using the command line interface

At the command prompt, type the following commands to create an IPv6 route and verify the configuration:

- add route6 <network> <gateway> [-vlan <positive_integer>]
- show route6 [<network> [<gateway>]]

Example

```
> add route6 ::/0 FE80::67 -vlan 5
Done
```

To create a monitored IPv6 static route by using the command line interface

At the command prompt, type the following commands to create a monitored IPv6 static route and verify the

configuration:

- add route6 <network> <gateway> [-msr (ENABLED | DISABLED)] [-monitor <string>]
- show route6 [<network> [<gateway>]

Example

```
> add route6 ::/0 2004::1 -msr ENABLED -monitor PING
Done
```

To remove an IPv6 route by using the command line interface

At the command prompt, type:

```
rm route6 <network> <gateway>
```

Example

```
> rm route6 ::/0 FE80::67
Done
```

To configure an IPv6 route by using the configuration utility

Navigate to System > Network > Routes and, on the IPV6 tab, add a new IPv6 route, or edit an existing IPv6 route.

To remove an IPv6 route by using the configuration utility

Navigate to System > Network > Routes and, on the IPV6 tab, delete the IPv6 route.

Route Health Injection Based on Virtual Server Settings

Apr 11, 2014

The following option and parameter are introduced for controlling the Route Health Injection (RHI) functionality of the NetScaler appliance for advertising the route of a VIP address.

- **VSVR_CNTRLD.** It is an option for the (Vserver RHI Level) parameter of a VIP address. When this option is set to the Vserver RHI Level parameter, the RHI behavior for advertising the route of the VIP address depends on the RHI STATE parameter setting on all the associated virtual servers of the VIP address along with their states.
- **RHI STATE.** It is a parameter of virtual server. You can set the RHI STATE parameter to either PASSIVE or ACTIVE. By default, the RHI STATE parameter is set to PASSIVE.

For a VIP address, when RHI (Vserver RHI Level) parameter is set to VSVR_CNTRLD, the following are different RHI behaviours for the VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address:

- If you set RHI STATE to PASSIVE on all virtual servers, the NetScaler ADC always advertises the route for the VIP address.
- If you set RHI STATE to ACTIVE on all virtual servers, the NetScaler ADC advertises the route for the VIP address if at least one of the associated virtual servers is in UP state.
- If you set RHI STATE to ACTIVE on some and PASSIVE on others, the NetScaler ADC advertises the route for the VIP address if at least one of the associated virtual servers, whose RHI STATE set to ACTIVE, is in UP state.

Following table displays the sample RHI behaviour for a VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address. The NetScaler appliance has two virtual servers V1 and V2 associated with the VIP address:

Associated virtual servers for a VIP	State 1	State 2	State 3	State 4
RHI State set to PASSIVE on all virtual servers				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	Yes	Yes
RHI State set to ACTIVE on all virtual servers				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	Yes	No

Associated virtual servers for a VIP RHI State set to ACTIVE on the Virtual server and PASSIVE on the other	State 1	State 2	State 3	State 4
V1 (RHI State = ACTIVE)	UP	UP	DOWN	DOWN
V2 (RHI State = PASSIVE)	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	No	No

To configure RHI for a VIP address, to be based on the RHI (RHI State) parameter setting of the associated virtual servers, perform the following steps:

- Set the RHI (Vserver RHI Level) parameter to VSVR_CNTRL for the VIP address.
- Set the RHI State parameter for each virtual server associated with the VIP address.

To set the vServer RHI Level for a VIP address by using command line interface

At the command prompt, type:

- set ns ip <IPAddress> [-vserverRHILevel <vserverRHILevel>]

To set the RHI State parameter of a virtual server by using command line interface

At the command prompt, type:

- set lb vserver <name> [-RHILstate (PASSIVE | ACTIVE)]

To set the vServer RHI Level for a VIP address by using configuration utility

1. Navigate to System > Network > IPs.
2. Select a VIP address, and then click Edit.
3. Set the Vserver RHI Level parameter to VSVR_CNTRL, and then click OK.

To set the RHI State parameter of a virtual server by using configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Select a load balancing virtual server, and then click Edit.
3. Set the RHI State parameter, and then click OK.

Configuring Policy-Based Routes

Jun 11, 2012

Policy-based routing bases routing decisions on criteria that you specify. A policy-based route (PBR) specifies criteria for selecting packets and, typically, a next hop to which to send the selected packets. For example, you can configure the NetScaler appliance to route outgoing packets from a specific IP address or range to a particular next hop router. Each packet is matched against each configured PBR, in the order determined by the specified priorities, until a match is found. If no match is found, or if the matching PBR specifies a DENY action, the NetScaler applies the routing table for normal destination-based routing.

A PBR bases routing decisions for the data packets on parameters such as source IP address, source port, destination IP address, destination port, protocol, and source MAC address. A PBR defines the conditions that a packet must satisfy for the NetScaler to route the packet. These actions are known as "processing modes." The processing modes are:

- ALLOW - The NetScaler sends the packet to the designated next-hop router.
- DENY - The NetScaler applies the routing table for normal destination-based routing.

You can create PBRs for outgoing IPv4 and IPv6 traffic.

Many users begin by creating PBRs and then modifying them. To activate a new PBR, you must apply it. To deactivate a PBR, you can either remove or disable it. You can change the priority number of a PBR to give it a higher or lower precedence.

This document includes the following information:

- [Configuring a Policy-Based Routes \(PBR\) for IPv4 Traffic](#)
- [Configuring a Policy-Based Routes \(PBR6\) for IPv6 Traffic](#)

Configuring a Policy-Based Routes (PBR) for IPv4 Traffic

Mar 20, 2012

Configuring PBRs involves the following tasks:

- Create a PBR.
- Apply PBRs.
- (Optional) Disable or enable a PBR.
- (Optional) Renumber the priority of the PBR.

Creating or Modifying a PBR

Updated: 2013-10-31

You cannot create two PBRs with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR. The priority (an integer value) defines the order in which the NetScaler appliance evaluates PBRs. When you create a PBR without specifying a priority, the NetScaler automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR, the NetScaler performs an action. If the packet does not match the condition defined by the PBR, the NetScaler compares the packet against the PBR with the next highest priority.

Instead of sending the selected packets to a next hop router, you can configure the PBR to send them to a link load balancing virtual server to which you have bound multiple next hops. This configuration can provide a backup if a next hop link fails.

Consider the following example. Two PBRs, p1 and p2, are configured on the NetScaler and automatically assigned priorities 20 and 30. You need to add a third PBR, p3, to be evaluated immediately after the first PBR, p1. The new PBR, p3, must have a priority between 20 and 30. In this case, you can specify the priority as 25.

To create a PBR by using the command line interface

At the command prompt, type:

- `add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED)] [-monitor <string>]] [-state (ENABLED | DISABLED)]`
- `show ns pbr`

Example

```
> add ns pbr pbr1 allow -srcip 10.102.37.252 -destip 10.10.10.2 -nexthop 10.102.29.77
Done
```

To modify the priority of a PBR by using the command line interface

At the command prompt, type the following commands to modify the priority and verify the configuration:

- `set ns pbr <name> [-action (ALLOW | DENY)] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED)] [-monitor <string>]] [-state (ENABLED | DISABLED)]`
- `show ns pbr [<name>]`

Example

```
> set ns pbr pbr1 -priority 23
Done
```

To remove one or all PBRs by using the command line interface

At the command prompt, type one of the following commands:

- `rm ns pbr <name>`
- `clear ns pbrs`

Example

```
> rm ns pbr pbr1
Done
> clear ns PBRs
Done
```

To create a PBR by using the configuration utility

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR, or edit an existing PBR.

To remove one or all PBRs by using the configuration utility

Navigate to System > Network > PBRs, on the PBRs tab, delete the PBR.

Applying a PBR

Updated: 2013-08-30

You must apply a PBR to activate it. The following procedure reapplies all PBRs that you have not disabled. The PBRs constitute a memory tree (lookup table). For example, if you create 10 PBRs (p1 - p10), and then you create another PBR (p11) and apply it, all of the PBRs (p1 - p11) are freshly applied and a new lookup table is created. If a session has a DENY PBR related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR. For example, you must follow this procedure after disabling a PBR.

Note: PBRs created on the NetScaler appliance do not work until they are applied.

To apply a PBR by using the command line interface

At the command prompt, type:

```
apply ns PBRs
```

To apply a PBR by using the configuration utility

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Apply.

Enabling or Disabling PBRs

Updated: 2013-08-30

By default, the PBRs are enabled. This means that when PBRs are applied, the NetScaler appliance automatically compares incoming packets against the configured PBRs. If a PBR is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBRs are applied. After the PBRs are applied, the NetScaler does not compare incoming packets against disabled PBRs.

To enable or disable a PBR by using the command line interface

At the command prompt, type one of the following commands:

- enable ns pbr <name>
- disable ns pbr <name>

Examples

```
> enable ns PBR pbr1
```

```
Done
```

```
> show ns PBR pbr1
```

```
1) Name: pbr1
   Action: ALLOW           Hits: 0
   srcIP = 10.102.37.252
   destIP = 10.10.10.2
   srcMac:                 Protocol:
   Vlan:                   Interface:
   Active Status: ENABLED   Applied Status: APPLIED
   Priority: 10
   NextHop: 10.102.29.77
```

```
Done
```

```
> disable ns PBR pbr1
```

```
Warning: PBR modified, use 'apply pbrs' to commit this operation
```

```
> apply pbrs
```

```
Done
```

```
> show ns PBR pbr1
```

```
1) Name: pbr1
   Action: ALLOW           Hits: 0
   srcIP = 10.102.37.252
```

```
destIP = 10.10.10.2
srcMac:          Protocol:
Vlan:           Interface:
Active Status: DISABLED      Applied Status: NOTAPPLIED
Priority: 10
NextHop: 10.102.29.77
```

Done

To enable or disable a PBR by using the configuration utility

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Enable or Disable.

Renumbering PBRs

Updated: 2013-08-30

You can automatically renumber the PBRs to set their priorities to multiples of 10.

To renumber PBRs by using the command line interface

At the command prompt, type:

```
renumber ns pbrs
```

To renumber PBRs by using the configuration utility

Navigate to System > Network > PBRs, on the PBRs tab, in the Action list, select Renumber Priority (s).

Use Case - PBR with Multiple Hops

Updated: 2013-08-30

Consider a scenario in which two PBRs, PBR1 and PBR2, are configured on NetScaler appliance NS1. PBR1 routes all the outgoing packets, with source IP address as 10.102.29.30, to next hop router R1. PBR2 routes all the outgoing packets, with source IP address as 10.102.29.90, to next hop router R2. R3 is another next hop router connected to NS1.

If router R1 fails, all the outgoing packets that matched against PBR1 are dropped. To avoid this situation, you can specify a link load balancing (LLB) virtual server in the next hop field while creating or modifying a PBR. Multiple next hops are bound to the LLB virtual server as services (for example R1, R2, and R3). Now, if R1 fails, all the packets that matched against PBR1 are routed to R2 or R3 as determined by the LB method configured on the LLB virtual server.

The NetScaler appliance throws an error if you attempt to create a PBR with an LLB virtual server as the next hop in the following cases:

- Adding another PBR with the same LLB virtual server.
- Specifying a nonexistent LLB virtual server.
- Specifying an LLB virtual server for which the bound services are not next hops.
- Specifying an LLB virtual server for which the LB method is not set to one of the following:
 - LEASTPACKETS
 - LEASTBANDWIDTH
 - DESTIPHASH
 - SOURCEIPHASH

- WEIGHTDRR
- SRCIPDESTIP_HASH
- LTRM
- CUSTOM LOAD
- Specifying an LLB virtual server for which the LB persistence type is not set to one of the following:
 - DESTIP
 - SOURCEIP
 - SRCDSTIP

The following table lists the names and values of the entities configured on the NetScaler appliance:

Table 1. Sample Values for Creating Entities

Entity Type	Name	IP Address
Link load balancing virtual server	LLB1	NA
Services (next hops)	Router1	1.1.1.254
	Router2	2.2.2.254
	Router3	3.3.3.254
PBRs	PBR1	NA
	PBR2	NA

To implement the configuration described above, you need to:

1. Create services Router1, Router2, and Router3 that represent next hop routers R1, R2, and R3.
2. Create link load balancing virtual server LLB1 and bind services Router1, Router2, and Router3 to it.
3. Create PBRs PBR1 and PBR2, with next hop fields set as LLB1 and 2.2.2.254 (IP address of the router R2), respectively.

To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port>
- show service <name>

Example

```
> add service Router1 1.1.1.254 ANY *
Done
> add service Router2 2.2.2.254 ANY *
Done
> add service Router3 3.3.3.254 ANY *
```

Done

To create a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create a link load balancing virtual server and bind a service by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType>
- bind lb vserver < name> <serviceName>
- show lb vserver < name>

Example

```
> add lb vserver LLB1 ANY
```

Done

```
> bind lb vserver LLB1 Router1 Router2 Router3
```

Done

To create a link load balancing virtual server and bind a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.
Note: Make sure that **Directly Addressable** is unchecked.
2. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

To create a PBR by using the command line interface

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-nextHop <nextHopVal>]
- show ns pbr

Example

```
> add pbr PBR1 ALLOW -srcIP 10.102.29.30 -nextHop LLB1
```

Done

```
> add pbr PBR2 ALLOW -srcIP 10.102.29.90 -nextHop 2.2.2.254
```

Done

To create a PBR by using the configuration utility

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR.

Configuring a Policy-Based Routes (PBR6) for IPv6 Traffic

Mar 20, 2012

Configuring PBR6s involves the following tasks:

- Create a PBR6.
- Apply PBR6s.
- (Optional) Disable or enable a PBR6.
- (Optional) Renumber the priority of the PBR6.

Creating or Modifying a PBR6

Updated: 2013-09-06

You cannot create two PBR6s with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR6. The priority (an integer value) defines the order in which the NetScaler appliance evaluates PBR6s. When you create a PBR6 without specifying a priority, the NetScaler automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR6, the NetScaler performs an action. If the packet does not match the condition defined by the PBR6, the NetScaler compares the packet against the PBR6 with the next highest priority.

To create a PBR6 by using the command line interface

At the command prompt, type:

- `add ns pbr6 <name> <action> [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>] [-srcMac <mac_addr>] [-protocol <protocol>] [-protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-state (ENABLED | DISABLED)] [-msr (ENABLED | DISABLED)] [-monitor <string>]] [-nextHop <nextHopVal>] [-nextHopVlan <positive_integer>]`
- `show ns pbr`

To modify or remove a PBR6 by using the command line interface

To modify a PBR6, type the `set pbr6 <name>` command and the parameters to be changed, with their new values.

To remove one or all PBR6s by using the command line interface

At the command prompt, type one of the following commands:

- `rm ns pbr6 <name>`
- `clear ns pbr6`

To create or modify a PBR6 by using the configuration utility

Navigate to System > Network > PBRs and, on the PBR6s tab, add a new PBR6, or edit an existing PBR6.

To remove one or all PBR6s by using the configuration utility

Navigate to System > Network > PBRs and, on the PBR6s tab, delete the PBR6.

Applying PBR6s

Updated: 2013-08-30

You must apply a PBR6 to activate it. The following procedure reapplies all PBR6s that you have not disabled. The PBR6s constitute a memory tree (lookup table). For example, if you create 10 PBR6s (p6_1 - p6_10), and then you create another PBR6 (p6_11) and apply it, all of the PBR6s (p6_1 - p6_11) are freshly applied and a new lookup table is created. If a session has a DENY PBR6 related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR6. For example, you must follow this procedure after disabling a PBR6.

Note: PBR6s created on the NetScaler appliance do not work until they are applied.

To apply PBR6s by using the command line interface

At the command prompt, type:

```
apply ns PBR6
```

To apply PBR6s by using the configuration utility

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Apply.

Enabling or Disabling a PBR6

Updated: 2013-08-30

By default, the PBR6s are enabled. This means that when PBR6s are applied, the NetScaler appliance automatically compares outgoing IPv6 packets against the configured PBR6s. If a PBR6 is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBR6s are applied. After the PBR6s are applied, the NetScaler does not compare incoming packets against disabled PBR6s.

To enable or disable a PBR6 by using the command line interface

At the command prompt, type one of the following commands:

- enable ns pbr <name>
- disable ns pbr <name>

To enable or disable a PBR6 by using the configuration utility

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Enable or Disable.

Renumbering PBR6s

Updated: 2013-08-30

You can automatically renumber the PBR6s to set their priorities to multiples of 10.

To renumber PBR6s by using the command line interface

At the command prompt, type:

```
renumber ns pbr6
```

To renumber PBR6s by using the configuration utility

Navigate to System > Network > PBRs, on the PBR6s tab, in the Action list, select Renumber Priority (s).

Troubleshooting Routing Issues

May 11, 2012

To make your troubleshooting process as efficient as possible, begin by gathering information about your network. You need to obtain the following information about the NetScaler appliance and other systems in the Network:

- Complete Topology diagram, including interface connectivity and intermediate switch details.
- Running Configuration. You can use the show running command to get the running configuration for ns.conf and ZebOS.conf.
- Output of the History command, to determine whether any configuration changes were made when the issue arose.
- Output of the Top and ps -ax commands, to determine whether any routing daemon is over utilizing the CPU or is misbehaving.
- Any routing related core files in /var/core - nsm, bgpd, ospfd, or ripd. Check the time stamp to see if they are relevant.
- dr_error.log and dr_info.log files from /var/log.
- Output of the date command and time details for all relevant systems. Print dates across all devices one after another, so that the times on the log messages can be correlated with various events.
- Relevant ns.log, newslog files.
- Configuration files, log files and command history details from upstream and downstream routers.

This document includes the following information:

- [Generic Routing FAQs](#)
- [Troubleshooting OSPF-Specific Issues](#)

Generic Routing FAQs

Mar 20, 2012

Users typically have the following questions about how to troubleshoot generic routing issues:

- How do I save the config files?

The write command from VTYSH saves only ZebOS.conf. Run the save ns config command from NetScaler CLI to save both ns.conf and ZebOS.conf files.

- If I have configured both a static default route and a dynamically learned default route, which is the preferred default route?

The dynamically learned route is the preferred default route. This behavior is unique to default routes. However, in case of the Network Services Module (NSM), unless the administrative distances are modified, a statically configured route in the RIB is preferred over a dynamic route. The route that is downloaded to the NSM FIB is the static route.

- How do I block the advertisement of default routes?

After release 7.0, the default route is not injected into ZebOS.

However, if you are working with 7.0 or an earlier release, you must apply a suitable route map with the

However, if you are working with 7.0 or an earlier release, you must apply a suitable route map with the redistribute kernel command for each protocol to block default route advertisement. For example:

```
ns(config)#access-list 1 deny 0.0.0.0
ns(config)#access-list 2 permit any
ns(config)#route-map redist-kernel permit 5
ns(config-route-map)#match ip address 1
ns(config)#route-map redist-kernel permit 10
ns(config-route-map)#match ip address 2
ns(config-route-map)#q
ns(config)#router ospf 1
ns(config-router)#redistribute kernel route-map redist-kernel
ns(config-router)#q
ns(config)#q
ns#show route-map
route-map redist-kernel, permit, sequence 5
  Match clauses:
    ip address 1
  Set clauses:
route-map redist-kernel, permit, sequence 10
  Match clauses:
    ip address 2
  Set clauses:
ns#show access-list
Standard IP access list 1
```

```
deny 0.0.0.0
Standard IP access list 2
  permit any
ns#
```

- How do I view the debug output of networking daemons?

You can write debugging output from networking daemons to a file by entering the following log file command from the global configuration view in VTYSH:

```
ns(config)#log file /var/ZebOS.log
```

With release 8.1, you can direct debug output to the console by entering the terminal monitor command from VTYSH user view:

```
ns#terminal monitor
```

- How do I collect cores of running daemons?

You can use the `gcore` utility to collect cores of running daemons for processing by `gdb`. This might be helpful in debugging misbehaving daemons without bringing the whole routing operation to a standstill.

```
gcore [-s] [-c core] [executable] pid
```

The `-s` option temporarily stops the daemon while gathering the core image. This is a recommended option, because it guarantees that the resulting image shows the core in a consistent state.

```
root@ns#gcore -s -c nsm.core /netcaler/nsm 342
```

- How do I run a batch of ZebOS commands?

You can run a batch of ZebOS commands from a file by entering the VTYSH `-f <file-name>` command. This does not replace the running configuration, but appends to it. However, by including commands to delete the existing configuration in the batch file and then add those for the new, desired configuration, you can use this mechanism to replace a specific configuration:

```
!
router bgp 234
network 1.1.1.1 255.255.255.0
!
route-map bgp-out2 permit 10
set metric 9900
set community 8602:300
!
```

Troubleshooting OSPF-Specific Issues

Mar 20, 2012

Before you start debugging any OSPF specific issue, you must collect information from the NetScaler appliance and all systems in the affected LAN, including upstream and downstream routers. To begin, enter the following commands:

1. show interface from both nscli and VTYSH
2. show ip ospf interface
3. show ip ospf neighbor detail
4. show ip route
5. show ip ospf route
6. show ip ospf database summary
 1. If there are only few LSAs in the database, then enter show ip ospf database router, show ip ospf database A. network, show ip ospf database external, and other commands to get the full details of LSAs.
 2. If there are a large number of LSAs in the database, enter the show ip ospf database self-originated command.
7. show ip ospf
8. show ns ip. This ensures that the details of all VIPs of interest are included.
9. Get the logs from peering devices and run the following command:

```
gcore -s -c xyz.core /netscaler/ospfd <pid>
```

Note: The gcore command is non-disruptive.

Collect additional information from the NetScaler as follows:

1. Enable logging of error messages by entering the following command from the global configuration view in VTYSH:

```
ns(config)#log file /var/ospf.log
```

2. Enable debugging ospf events and log them by using the following command:

```
ns(config)#log file /var/ospf.log
```

Enable debug ospf lsa packet only if the number of LSAs in the database is relatively small (< 500).

Internet Protocol version 6 (IPv6)

Mar 20, 2012

A NetScaler appliance supports both server-side and client-side IPv6 and can therefore function as an IPv6 node. It can accept connections from IPv6 nodes (both hosts and routers) and from IPv4 nodes, and can perform Protocol Translation (RFC 2765) before sending traffic to the services. You have to license the IPv6 feature before you can implement it.

The following table lists some of the IPv6 features that the NetScaler appliance supports.

Table 1. Some Supported IPv6 Features

IPv6 features
IPv6 addresses for SNIPs (NSIP6, VIP6, and SNIP6)
Neighbor Discovery (Address Resolution, Duplicated Address Detection, Neighbor Unreachability Detection, Router Discovery)
Management Applications (ping6, telnet6, ssh6)
Static Routing and Dynamic routing (OSPF)
Port Based VLANs
Access Control Lists for IPv6 addresses (ACL6)
IPv6 Protocols (TCP6, UDP6, ICMP6)
Server Side Support (IPv6 addresses for vservers, services)
USIP (Use source IP) and DSR (Direct Server Return) for IPv6
SNMP and CVPN for IPv6
HA with native IPv6 node address
IPv6 addresses for MIPs
Path-MTU discovery for IPv6

The following table lists NetScaler components that support IPv6 addresses and provides references to the topics that

document the components.

Table 2. NetScaler Components That Support IPv6 Addresses and the Corresponding Documentation

NetScaler component	Topic that documents IPv6 support
Network	Adding, Customizing, Removing, Removing all, and Viewing routes.
SSL Offload	Creating IPv6 vservers for SSL Offload
SSL Offload	Specifying IPv6 SSL Offload Monitors
SSL Offload	Creating IPv6 SSL Offload Servers
Load Balancing	Creating IPv6 vservers for Load Balancing
Load Balancing	Specifying IPv6 Load Balancing Monitors
Load Balancing	Creating IPv6 Load Balancing Servers
DNS	Creating AAAA Records

You can configure IPv6 support for the above features after implementing the IPv6 feature on your NetScaler appliance. You can configure both tagged and prefix-based VLANs for IPv6. You can also map IPv4 addresses to IPv6 addresses.

Implementing IPv6 Support

IPv6 support is a licensed feature, which you have to enable before you can use or configure it. If IPv6 is disabled, the NetScaler does not process IPv6 packets. It displays the following warning when you run an unsupported command:

```
"Warning: Feature(s) not enabled [IPv6PT]"
```

The following message appears if you attempt to run IPv6 commands without the appropriate license:

```
"ERROR: Feature(s) not licensed"
```

After licensing the feature, use either of the following procedures to enable or disable IPv6.

To enable or disable IPv6 by using the command line interface

At the command prompt, type one of the following commands:

- `enable ns feature ipv6pt`
- `disable ns feature ipv6pt`

To enable or disable IPv6 by using the configuration utility

1. Navigate to System > Settings, in the Modes and Features group, click Configure Advanced Features.
2. Select or clear the IPv6 Protocol Translation option.

VLAN Support

Updated: 2013-08-30

If you need to send broadcast or multicast packets without identifying the VLAN (for example, during DAD for NSIP, or ND6 for the next hop of the route), you can configure the NetScaler appliance to send the packet on all the interfaces with appropriate tagging. The VLAN is identified by ND6, and a data packet is sent only on the VLAN.

For more information about ND6 and VLANs, see "[Configuring Neighbor Discovery.](#)"

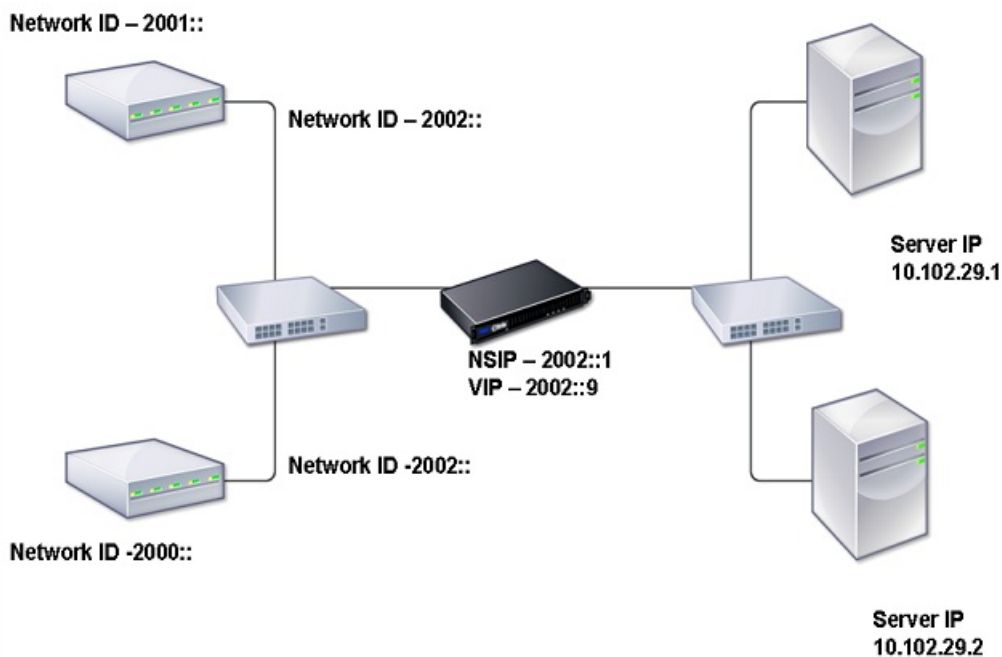

Port-based VLANs are common for IPv4 and IPv6. Prefix-based VLANs are supported for IPv6.

Simple Deployment Scenario

Updated: 2013-08-30

Following is an example of a simple load balancing set-up consisting of an IPv6 vserver and IPv4 services, as illustrated in the following topology diagram.

Figure 1. IPv6 Sample Topology

The following table summarizes the names and values of the entities that must be configured on the NetScaler.

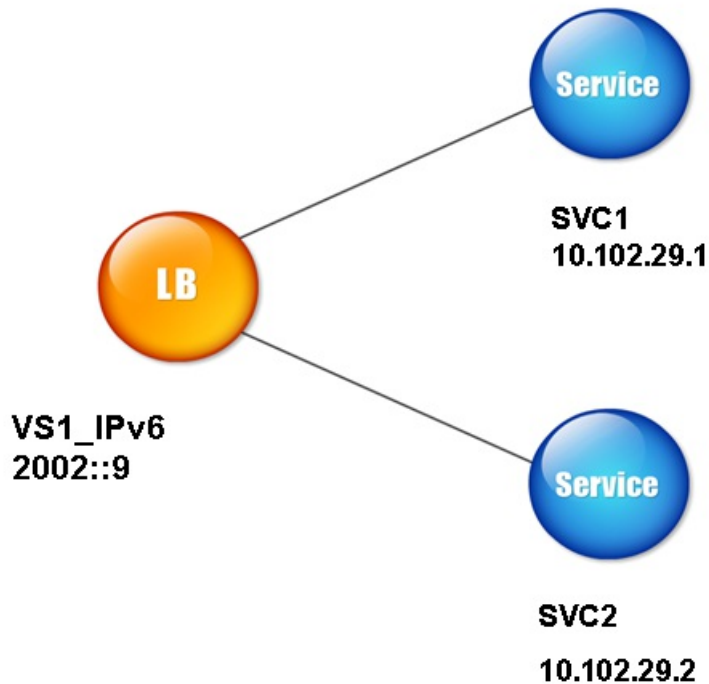

Table 3. Sample Values for Creating Entities

Entity type	Name	Value
LB Vserver	VS1_IPv6	2002::9
Services	SVC1	10.102.29.1

Entity type	Name	Value
	SVC2	10.102.29.2

The following figure shows the entities and values of the parameters to be configured on the NetScaler.

Figure 2. IPv6 Entity Diagram

To configure this deployment scenario, you need to do the following:

1. Create an IPv6 service.
2. Create an IPv6 LB vserver.
3. Bind the services to the vserver.

To create IPv4 services by using the command line interface

At the command prompt, type:

```
add service <Name> <IPAddress> <Protocol> <Port>
```

Example

```
add service SVC1 10.102.29.1 HTTP 80
add service SVC2 10.102.29.2 HTTP 80
```

To create IPv4 services by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, click Add, and then set the following parameters:

- Service Name
- IP Address
- Protocol
- Port

To create IPv6 vserver by using the command line interface

At the command prompt, type:

```
add lb vserver <Name> <IPAddress> <Protocol> <Port>
```

Example

```
add lb vserver VS1_IPv6 2002::9 HTTP 80
```

To create IPv6 vserver by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, click Add, and select the IPv6 check box.
2. Set the following parameters:
 - Name
 - Protocol
 - IP Address Type
 - IP Address
 - Port

To bind a service to an LB vserver by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <service>
```

Example

```
bind lb vserver VS1_IPv6 SVC1
```

The vservers receive IPv6 packets and the NetScaler performs Protocol Translation (RFC 2765) before sending traffic to the IPv4-based services.

To bind a service to an LB vserver by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers page, select the vserver for which you want to bind the service (for example, VS1_IPv6).
3. Click Open.
4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box corresponding to the service that you want to bind to the vserver (for example, SVC1).
5. Click OK.
6. Repeat Steps 1-4 to bind the service (for example, SVC2 to the vserver).

Host Header Modification

Updated: 2013-08-30

When an HTTP request has an IPv6 address in the host header, and the server does not understand the IPv6 address, you must map the IPv6 address to an IPv4 address. The IPv4 address is then used in the host header of the HTTP request sent to the vserver.

To change the IPv6 address in the host header to an IPv4 address by using the command line interface

At the command prompt, type:

```
set ns ip6 <IPv6Address> -map <IPAddress>
```

Example

```
set ns ip6 2002::9 -map 200.200.200.200
```

To change the IPv6 address in the host header to an IPv4 address by using the configuration utility

1. Navigate to System > Network > IPs and, on the IPV6s tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:9, and click Edit.
2. In the Mapped IP text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

VIP Insertion

Updated: 2013-08-30

If an IPv6 address is sent to an IPv4-based server, the server may not understand the IP address in the HTTP header, and may generate an error. To avoid this, you can map an IPv4 address to the IPv6 VIP and enable VIP insertion.

To configure a mapped IPv6 address by using the command line interface

At the command prompt, type:

```
set ns ip6 <IPv6Address> -map <IPAddress>
```

Example

```
> set ns ip6 2002::9 -map 200.200.200.200
```

Done

To configure a mapped IPv6 address by using the configuration utility

1. Navigate to System > Network > IPs, on the IPV6s tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:9, and click Edit.
2. In the Mapped IP text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

Use either of the following procedures to enable insertion of an Ipv4 VIP address and port number in the HTTP requests sent to the servers.

To enable VIP insertion by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -insertVserverIPPort <Value>
```

Example

```
> set lb vserver VS1_IPv6 -insertVserverIPPort ON
```

Done

To enable VIP insertion by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, select the vserver that you want to enable port insertion, and click Edit.
2. In the Advanced tab, under Traffic Settings, in the Vserver IP Port Insertion drop-down list box, select VIPADDR.
3. In the Vserver IP Port Insertion text box, type the vip header.

Traffic Domains

Jun 23, 2016

Important

Citrix recommends you to use Admin Partitioning over Traffic Domains. For more information about Admin Partitions, see [Admin Partitioning](#) page.

Traffic domains are a way to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments within a NetScaler appliance. An application belonging to a specific traffic domain communicates with entities and processes traffic within that domain. The traffic belonging to one traffic domain cannot cross the boundary of another traffic domain.

Traffic domains are a way to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments within a NetScaler appliance. An application belonging to a specific traffic domain communicates with entities and processes traffic within that domain. The traffic belonging to one traffic domain cannot cross the boundary of another traffic domain.

Benefits of using Traffic Domains

The main benefits of using traffic domains on a NetScaler appliance are the following:

- **Use of duplicate IP addresses in a Network.** Traffic domains allow you to use duplicate IP address on the network. You can assign the same IP address or network address to multiple devices on a network, or multiple entities on a NetScaler appliance, as long as each of the duplicate address belongs to a different traffic domain.
- **Use of Duplicate entities on the NetScaler appliance.** Traffic domains also allow you to use duplicate NetScaler feature entities on the appliance. You can create entities with the same settings as long as each entity is assigned to a separate traffic domain.
Note: Duplicate entities with same name is not supported.
- **Multitenancy.** Using traffic domains, you can provide hosting services for multiple customers by isolating each customer's type of application traffic within a defined address space on the network.

A traffic domain is uniquely identified by an identifier, which is an integer value. Each traffic domain needs a VLAN or a set of VLANs. The isolation functionality of the traffic domain depends on the VLANs bound to the traffic domain. More than one VLAN can be bound to a traffic domain, but the same VLAN cannot be a part of multiple traffic domains. Therefore, the maximum number of traffic domains that can be created depends on the number of VLANS configured on the appliance.

Default Traffic Domain

A NetScaler appliance has a preconfigured traffic domain, called the *default traffic domain*, which has an ID of 0. All factory settings and configurations are part of the default traffic domain. You can create other traffic domains and then segment traffic between the default traffic domain and each of the other traffic domains. You cannot remove the default traffic domain from the NetScaler appliance. Any feature entity that you create without setting the traffic domain ID is automatically associated with the default traffic domain.

Note: Some features and configurations are supported only in the default traffic domain. They do not work in nondefault traffic domains. For a list of the features supported in all traffic domains, see "[Supported NetScaler Features in Traffic](#)

Domains ."

This section includes the following details:

- [How Traffic Domains Work](#)
- [Supported NetScaler Features in Traffic Domains](#)
- [Configuring Traffic Domains](#)
- [Inter Traffic Domain Entity Bindings](#)
- [VMAC Based Traffic Domains](#)

How Traffic Domains Work

As an illustration of traffic domains, consider an example in which two traffic domains, with IDs 1 and 2, are configured on NetScaler appliance NS1.

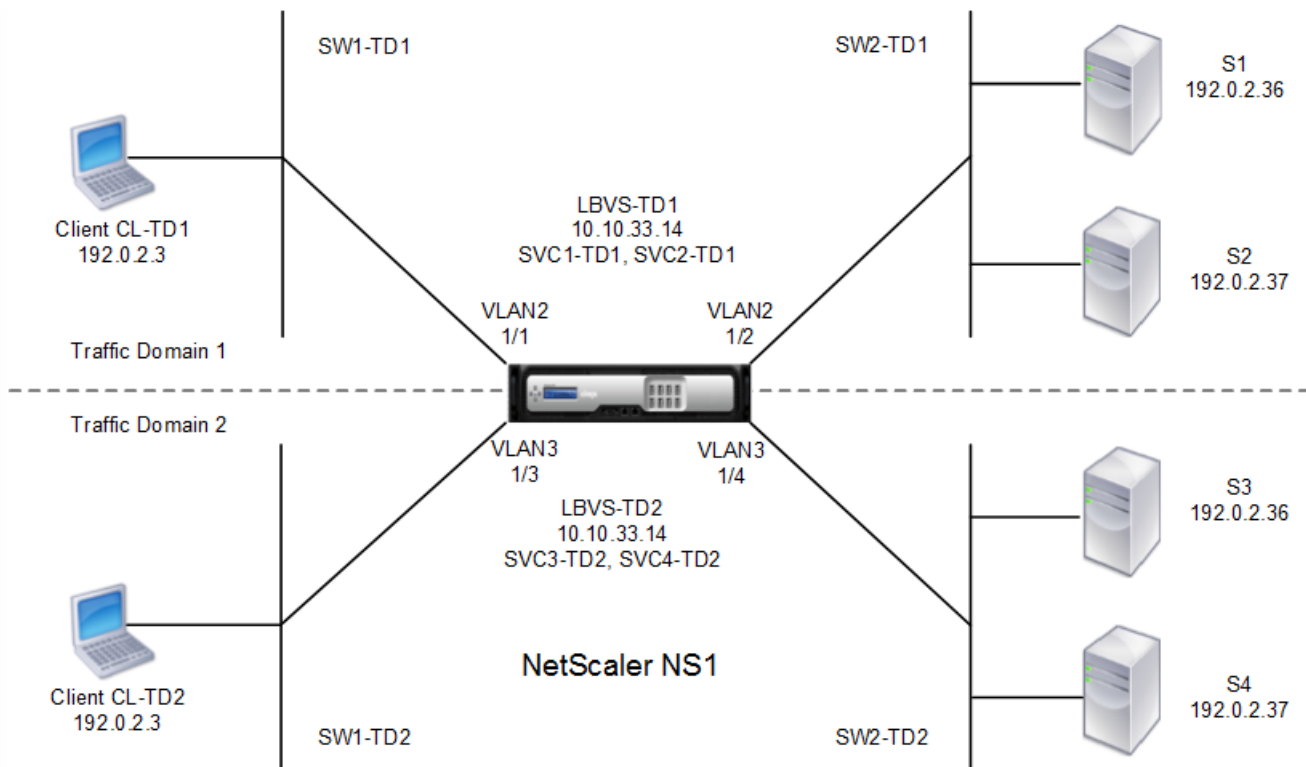

In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the NetScaler appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. Servers S1 and S2 are connected to NS1 through L2 switch SW2-TD1. Client CL-TD1 is on a private network connected to NS1 through L2 switch SW1-TD1. SW1-TD1 and SW2-TD1 are connected to VLAN 2 of NS1. VLAN 2 is bound to traffic domain 1, which means that client CL-TD1 and servers S1 and S2 are part of traffic domain 1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the NetScaler appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. Servers S3 and S4 are connected to NS1 through L2 switch SW2-TD2. Client CL-TD2 is on a private network connected to NS1 through L2 switch SW1-TD2. SW1-TD2 and SW2-TD2 are connected to VLAN 3 of NS1. VLAN 3 is bound to traffic domain 2, which means that client CL-TD2 and servers S3 and S4 are part of traffic domain 2.

On the NetScaler appliance, entities LBVS-TD1 and LBVS-TD2 share the same settings, including the IP address. The same is true for SVC1-TD1 and SVC3-TD2, and for SVC2-TD1 and SVC4-TD2. This is possible because these entities are in different traffic domains.

Similarly, servers S1 and S3, S2 and S4 share the same IP address, and clients CL-TD1 and CL-TD2 each have the same IP address.

Figure 1. How traffic domains work

The following table lists the settings used in the example.

Entity	Name	Details
Settings in traffic domain 1		
VLANs bound to traffic domain 1	VLAN 2	VLAN Id: 2 Interfaces bound: 1/1, 1/2
Client connected to TD1	CL-TD1 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD1	LBVS-TD1	IP address: 192.0.2.15
Service bound to virtual server LBVS-TD1	SVC1-TD1	IP address: 192.0.2.36
	SVC2-TD1	IP address: 192.0.2.37
SNIP	SNIP-TD1 (for reference purposes only)	IP address: 192.0.2.27
Settings in traffic domain 2		
VLAN bound to traffic domain 2	VLAN 3	VLAN Id: 3 Interfaces bound: 1/3, 1/4

Client Entity	CL-TD2 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD2	LBVS-TD2	IP address: 192.0.2.15
Service bound to virtual server LBVS-TD2	SVC3-TD2	IP address: 192.0.2.36
	SVC4-TD2	IP address: 192.0.2.37
SNIP in TD2	SNIP-TD2 (for reference purposes only)	IP address: 192.0.2.29

Following is the traffic flow in traffic domain 1:

1. Client CL-TD1 broadcasts an ARP request for the IP address of 192.0.2.15.
2. The ARP request reaches NS1 on interface 1/1, which is bound to VLAN 2. Because VLAN 2 is bound to traffic domain 1, NS1 updates the ARP table of traffic domain 1 for the IP address of client CL-TD1.
3. Because the ARP request is received on traffic domain 1, NS1 looks for an entity configured on traffic domain 1 that has an IP address of 192.0.2.15. NS1 finds that a load balancing virtual server LBVS-TD1 is configured on traffic domain 1 and has the IP address 192.0.2.15.
4. NS1 sends an ARP response with the MAC address of interface 1/1.
5. The ARP reply reaches CL-TD1. CL-TD1 updates its ARP table for the IP address of LBVS-TD1 with the MAC address of interface 1/1 of NS1.
6. Client CL-TD1 sends a request to 192.0.2.15. The request is received by LBVS-TD1 on port 1/1 of NS1.
7. LBVS-TD1's load balancing algorithm selects server S2, and NS1 opens a connection between a SNIP in traffic domain 1 (192.0.2.27) and S2.
8. S2 replies to SNIP 192.0.2.27 on NS1.
9. NS1 sends S2's reply to client CL-TD1.

Following is the traffic flow in traffic domain 2:

1. Client CL-TD2 broadcasts an ARP request for the IP address of 192.0.2.15.
2. The ARP request reaches NS1 on interface 1/3, which is bound to VLAN 3. Because VLAN 3 is bound to traffic domain 2, NS1 updates traffic-domain 2's ARP-table entry for the IP address of client CL-TD2, even though an ARP entry for the same IP address (CL-TD1) is already present in the ARP table of traffic domain 1.
3. Because the ARP request is received in traffic domain 2, NS1 searches traffic domain 2 for an entity that has an IP address of 192.0.2.15. NS1 finds that load balancing virtual server LBVS-TD2 is configured in traffic domain 2 and has the IP address 192.0.2.15. NS1 ignores LBVS-TD1 in traffic domain 1, even though it has the same IP address as LBVS-TD2.
4. NS1 sends an ARP response with the MAC address of interface 1/3.
5. The ARP reply reaches CL-TD2. CL-TD2 updates its ARP table entry for the IP address of LBVS-TD2 with the MAC address of interface 1/3 of NS1.
6. Client CL-TD2 sends a request to 192.0.2.15. The request is received by LBVS-TD2 on interface 1/3 of NS1.
7. LBVS-TD2's load balancing algorithm selects server S3, and NS1 opens a connection between a SNIP in traffic domain 2 (192.0.2.29) and S3.
8. S2 replies to SNIP 192.0.2.29 on NS1.
9. NS1 sends S2's reply to client CL-TD2.

Supported NetScaler Features in Traffic Domains

The NetScaler features in the following list are supported in all traffic domains.

Supported features in traffic domains

- | | |
|---|---|
| <ul style="list-style-type: none">• ARP table• ND6 table• Bridge table• All types of IPv4 and IPv6 addresses• IPv4 and IPv6 routes• ACL and ACL6• PBR & PBR6• INAT• RNAT• RNAT6• MSR• MSR6• Net profiles• SNMP MIBs• Fragmentation• Monitors (Scriptable Monitors are not supported)• Content Switching• Cache Redirection | <ul style="list-style-type: none">• Persistency• Service (Domain based services are not supported)• Servicegroup (Domain based service groups are not supported)• Policies (*)• PING• TRACEROUTE• PMTU• High Availability (connection mirroring is not supported)• Cluster (Supported on L2 clusters. Not supported on L3 clusters)• Cookie Persistency• MSS• Logging• Priority Queuing• Surge Protection• HTTP DOSP (*)• Load balancing (The following types are not supported:<ul style="list-style-type: none">• TFTP• RTSP• Diameter• SIP)• NAT46• NAT64• DNS64• Forwarding Session Rules• SNMP |
|---|---|

Important

Any NetScaler feature not listed above is supported only in the default traffic domain.

Note

Global Server Loading Balancing (GSLB) and ADNS features in NetScaler are not aware of Traffic Domains. If the GSLB configuration needs to be shared across all traffic domains then GSLB methods Static Proximity and Round Trip Time (RTT) do not work. As a workaround in this scenario you can use GSLB methods other than RTT and Static Proximity. For more information, see <http://support.citrix.com/article/CTX202277>.

Configuring Traffic Domains

Configuring a traffic domain on the NetScaler appliance consists of the following tasks:

- **Add VLANs.** Create VLANs and bind specified interfaces to them.
- **Create a traffic domain entity and bind VLANs to it.** This involves the following two tasks:
 - Create a traffic domain entity uniquely identified by an ID, which is an integer value.
 - Bind the specified VLANs to the traffic domain entity. All the interfaces that are bound to the specified VLANs are associated with the traffic domain. More than one VLAN can be bound to a traffic domain, but a VLAN cannot be a part of multiple traffic domains.
- **Create feature entities on the traffic domain.** Create the required feature entities in the traffic domain. The CLI commands and configuration dialog boxes of all the supported features in a nondefault traffic domain include a parameter called a *traffic domain identifier* (td). When configuring a feature entity, if you want the entity to be associated with a particular traffic domain, you must specify the td. Any feature entity that you create without setting the td is automatically associated with the default traffic domain.

To give you an idea of how feature entities are associated with a traffic domain, this topic covers the procedures for configuring all the entities mentioned in the figure titled "[How Traffic Domains Work](#)."

The command line interface has two commands for these two tasks, but the configuration utility combines them in a single dialog box.

To create a VLAN and bind interfaces to it by using the command line interface

At the command prompt, type:

- add vlan <id>
- bind vlan <id> -if num <slot/port>
- show vlan <id>

To create a traffic domain entity and bind VLANs to it by using the command line interface

At the command prompt, type:

- add ns trafficdomain <td>
- bind ns trafficdomain <td> -vlan <id>
- show ns trafficdomain <td>

To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> -td <id>
- show service <name>

To create a load balancing virtual server and bind services to it by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType> <IPAddress> <port> -td <id>
- bind lb vserver <name> <serviceName>
- show lb vserver <name>

To create a VLAN by using the configuration utility

Navigate to System > Network > VLANs, click Add, and set the parameters.

To create a traffic domain entity by using the configuration utility

Navigate to System > Network > Traffic Domains, click Add, and in the Create Traffic Domain dialog box, set the parameters.

To create a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, click Add, and set the parameters.

To create a load balancing virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, click Add, and set the parameters.

Inter Traffic Domain Entity Bindings

Jun 17, 2014

You can bind services in one traffic domain to a virtual server in another traffic domain. All the services to be bound to a virtual server in a different traffic domain must reside in the same traffic domain.

You configure this support by using the existing `bind lb vserver` command or the related configuration utility procedure.

This capability can facilitate interaction between different traffic domains. In an enterprise, servers can be grouped in different traffic domains. Virtual servers are created in a traffic domain that faces the internet. A virtual server from this traffic domain can be configured to load balance servers in another traffic domain. This virtual server receives connection requests from the Internet to be forwarded to the bound servers.

When a NetScaler ADC is used in a cloud infrastructure, each tenant can be assigned a separate traffic domain, and all the resources (including servers) for a tenant can be grouped together in the tenant's traffic domain. For each tenant, a virtual server is created for load balancing servers in its traffic domain. All of these virtual servers are grouped together in a single traffic domain that faces the Internet.

Consider an example of in which cloud service provider Example-Cloud-A has three traffic domains, with IDs 10, 20, and 30, configured on NetScaler appliance NS1.

Example-Org-A and Example-Org-B are tenants of Example-Cloud-A. Tenant A is assigned traffic domain 20, and tenant B is assigned domain 30. Servers S1 and S2 reside in traffic domain 20 and servers S3 and S4 reside in traffic domain 30.

Traffic domain 10 faces the internet. Virtual servers LBVS-1 and LBVS-2 are created in traffic domain 10. LBVS-1, in traffic domain 10, is configured to load balance servers S1 and S2, which are in traffic domain 20. LBVS-2, in traffic domain 10, is configured to load balance servers S3 and S4, which are in traffic domain 30.

Therefore, these virtual servers accept Internet connection requests for servers that are in a different traffic domain than that of the virtual servers.

VMAC Based Traffic Domains

Jan 31, 2011

You can associate a traffic domain with a VMAC address instead of with VLANs. The NetScaler ADC then sends the traffic domain's VMAC address in all responses to ARP queries for network entities in that domain. As a result, the ADC can segregate subsequent incoming traffic for different traffic domains on the basis of the destination MAC address, because the destination MAC address is the VMAC address of a traffic domain. After creating entities on a traffic domain, you can easily manage and monitor them by performing traffic domain level operations.

Following are points to consider before you configure VMAC based traffic domain:

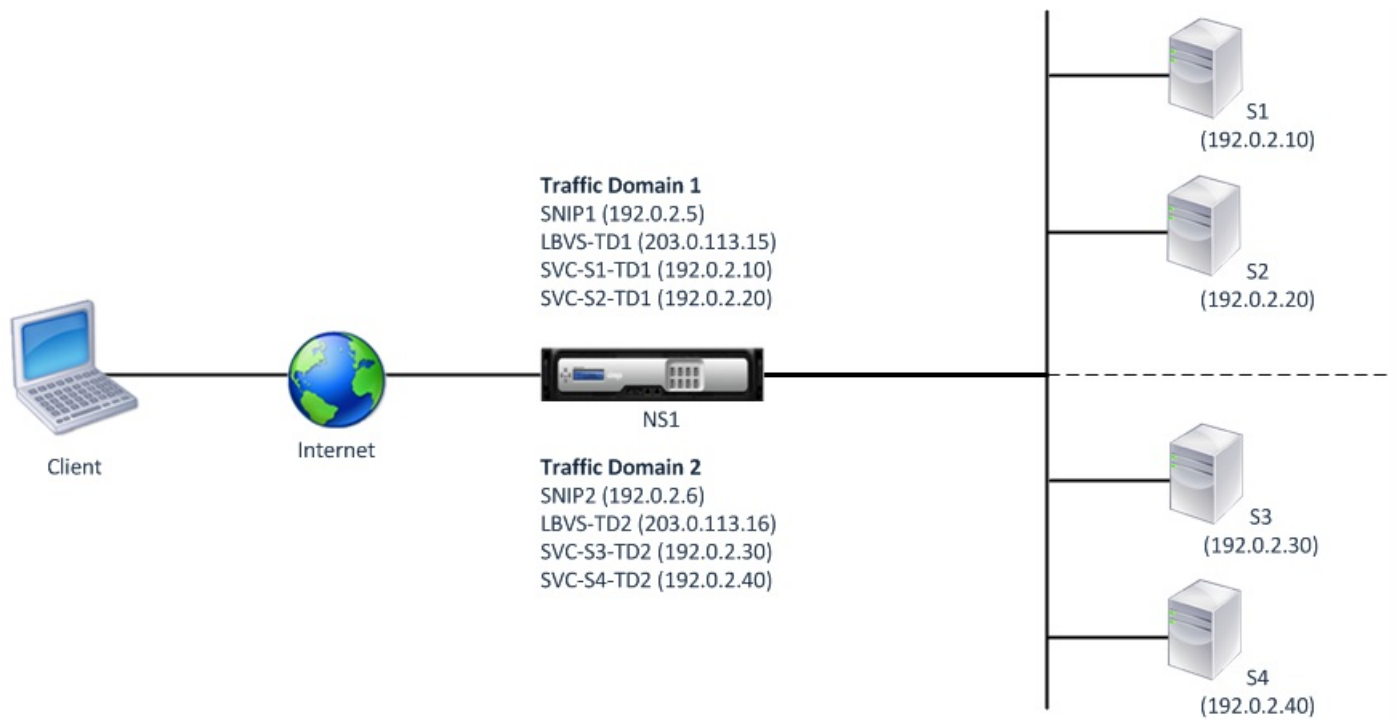

1. VMAC based traffic domains are easiest way to achieve network traffic segregation.
2. Because VMAC based traffic domains segregate network traffic based on VMAC addresses and not VLANs, you cannot create duplicate IP addresses on different VMAC based traffic domains on a NetScaler ADC.
3. VMAC based traffic domains do not work when the NetScaler is deployed only in L2 Mode.
4. Both VLAN and VMAC based traffic domains can coexist on a NetScaler ADC. VMAC based traffic domains actually runs on all VLANs that are not bound to any VLAN based traffic domain.

Consider an example in which two traffic domains, with IDs 1 and 2, are configured on NetScaler appliance NS1. The NetScaler creates a VMAC address VMAC1 and associates it with traffic domain 1. Similarly, the NetScaler created another VMAC address VMAC2 and associates with traffic domain 2.

In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the NetScaler appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. A subnet IP address (SNIP) SNIP1 is configured for enabling the NetScaler to communicate with S1 and S2. Because VMAC1 is associated with traffic domain 1, the NetScaler sends VMAC1 as the MAC address in all ARP announcements and ARP responses for LBVS-TD1 and SNIP1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the NetScaler appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. A SNIP address SNIP2 is configured for enabling the NetScaler to communicate with S3 and S4. Because VMAC2 is associated with traffic domain 2, the NetScaler sends VMAC2 as the MAC address in all ARP announcements and ARP responses for LBVS-TD2 and SNIP2.

The NetScaler segregate subsequent incoming traffic for traffic domains 1 or 2 on the basis of the destination MAC address, if the destination MAC address is VMAC1 or VMAC2.

The following table lists the settings used in the example.

Entity	Name	Details
Settings in traffic domain 1		
VMAC Address	VMAC1 (for reference purposes only)	NS1 automatically creates VMAC1 and associates with traffic domain 1
SNIP address	SNIP1 (for reference purposes only)	192.0.2.5
Services on NS1 representing servers S1 and S2	SVC-S1-TD1	<ul style="list-style-type: none"> IP address: 192.0.2.10 Protocol: HTTP Port: 80
	SVC-S2-TD1	<ul style="list-style-type: none"> IP address: 192.0.2.20 Protocol: HTTP Port: 80
Load balancing virtual server	LBVS-TD1	<ul style="list-style-type: none"> IP address: 203.0.113.15 Protocol: HTTP Port: 80 Bound services: SVC-S1, SVC-S2
Settings in traffic domain 2		

VMAC Address Entity	VMAC2 (for reference purposes only) Name	NS1 automatically creates VMAC2 and associates with traffic domain 2 Details
SNIP address	SNIP2(for reference purposes only)	192.0.2.6
Services on NS1 representing servers S1 and S2	SVC-S3-TD2	<ul style="list-style-type: none"> • IP address: 192.0.2.30 • Protocol: HTTP • Port: 80
	SVC-S4-TD2	<ul style="list-style-type: none"> • IP address: 192.0.2.40 • Protocol: HTTP • Port: 80
Load balancing virtual server	LBVS-TD2	<ul style="list-style-type: none"> • IP address: 203.0.113.16 • Protocol: HTTP • Port: 80 • Bound services: SVC-S3, SVC-S4

Configuration Steps

Configuring a VMAC based traffic domain on a NetScaler appliance consists of the following tasks:

- Create a traffic domain entity and enable the VMAC option. Create a traffic domain entity uniquely identified by an ID, which is an integer value, and then enable the VMAC option. After creating the traffic domain entity, the NetScaler ADC creates a virtual MAC address and then associates it to the traffic domain entity.
- Create feature entities on the traffic domain. Create the required feature entities in the traffic domain by specifying the traffic domain identifier (td) when configuring these feature entities. NetScaler owned network entities created in a VMAC based traffic domain are associated with the VMAC address, which is associated with the traffic domain. The NetScaler ADC then sends the traffic domain's VMAC address in ARP announcements and ARP responses for these network entities.

To create a VMAC based traffic domain by using the command line interface

At the command prompt, type:

- add ns trafficDomain <td> [-vmac (ENABLED | DISABLED)]
- show ns trafficdomain <td>

To configure a SNIP address by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP -td <id>
- show ns ip <IPAddress> -td <id>

To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> -td <id>
- show service <name> -td <id>

To create a load balancing virtual server and bind services to it by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType> <IPAddress> <port> -td <id>
- bind lb vserver <name> <serviceName>
- show lb vserver <name> -td <id>

Example

```
> add ns trafficDomain 1 -vmac ENABLED
```

```
Done
```

```
> add ns trafficDomain 2 -vmac ENABLED
```

```
Done
```

```
> add ns ip 192.0.2.5 255.255.255.0 -type -SNIP -td 1
```

```
Done
```

```
> add service SVC-S1-TD1 192.0.2.10 HTTP 80 -td 1
```

```
Done
```

```
> add service SVC-S2-TD1 192.0.2.20 HTTP 80 -td 1
```

```
Done
```

```
> add lb vserver LBVS-TD1 HTTP 203.0.113.15 80 -td 1
```

```
Done
```

```
> bind lb vserver LBVS-TD1 SVC-S1-TD1
```

```
Done
```

```
> bind lb vserver LBVS-TD1 SVC-S2-TD1
```

```
Done
```

```
> add ns ip 192.0.2.6 255.255.255.0 -type -SNIP -td 2
```

```
Done
```

```
> add service SVC-S3-TD2 192.0.2.30 HTTP 80 -td 2
```

```
Done
```

```
> add service SVC-S4-TD2 192.0.2.40 HTTP 80 -td 2
```

```
Done
```

```
> add lb vserver LBVS-TD1 HTTP 203.0.113.16 80 -td 1
```

```
Done
```

```
> bind lb vserver LBVS-TD2 SVC-S3-TD2
```

```
Done
```

```
> bind lb vserver LBVS-TD2 SVC-S3-TD2
```

```
Done
```

To create a VMAC based traffic domain by using the configuration utility

1. Navigate to System > Network > Interfaces.
2. In the details pane, click Add.
3. On the Create Traffic Domain page, set the following parameters:
 - Traffic Domain ID*
 - Enable Mac
4. Click Create.

To configure a SNIP address by using the configuration utility

1. Navigate to System > Network > IPs > IPv4

2. Navigate to Network > IPs > IPv4
3. In the details pane, click Add
4. In the Create IP page, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
 - IP Address
 - Netmask
 - IP Type
 - Traffic Domain ID
5. Click Create.

To create a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Basic Settings Page, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
 - Service Name
 - Server
 - Protocol
 - Port
 - Traffic Domain ID
4. Click Continue, and click Done.
5. Repeat steps 2-4 to create another service.
6. Click Close.

To create a load balancing virtual server and bind services to it by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers pane, click Add.
3. In the Create Virtual Servers (Load Balancing) dialog box, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
 - Name
 - IP Address
 - Protocol
 - Port
 - Traffic Domain ID
4. Click Continue, on the Service Pane, click >.
5. On the Service page, click Insert, and then select the check box for the services that you want to bind to the virtual server.
6. Click Continue, and click Done.
7. Repeat steps 2-5 to create another virtual server

VXLAN

Aug 07, 2014

NetScaler appliances support Virtual eXtensible Local Area Networks (VXLANs). A VXLAN overlays Layer 2 networks onto a layer 3 infrastructure by encapsulating Layer-2 frames in UDP packets. Each overlay network is known as a VXLAN Segment and is identified by a unique 24-bit identifier called the VXLAN Network Identifier (VNI). Only network devices within the same VXLAN can communicate with each other.

VXLANs provide the same Ethernet Layer 2 network services that VLANs do, but with greater extensibility and flexibility. The two main benefits of using VXLANs are the following:

- **Higher scalability.** Server virtualization and cloud computing architectures have dramatically increased the demand for isolated Layer 2 networks in a datacenter. The VLAN specification uses a 12-bit VLAN ID to identify a Layer 2 network, so you cannot scale beyond 4094 VLANs. That number can be inadequate when the requirement is for thousands of isolated Layer 2 networks. The 24-bit VNI accommodates up to 16 million VXLAN segments in the same administrative domain.
- **Higher flexibility.** Because VXLAN carries Layer 2 data frames over Layer 3 packets, VXLANs extend L2 networks across different parts of a datacenter and across geographically separated datacenters. Applications that are hosted in different parts of a datacenter and in different datacenters but are part of the same VXLAN appear as one contiguous network.

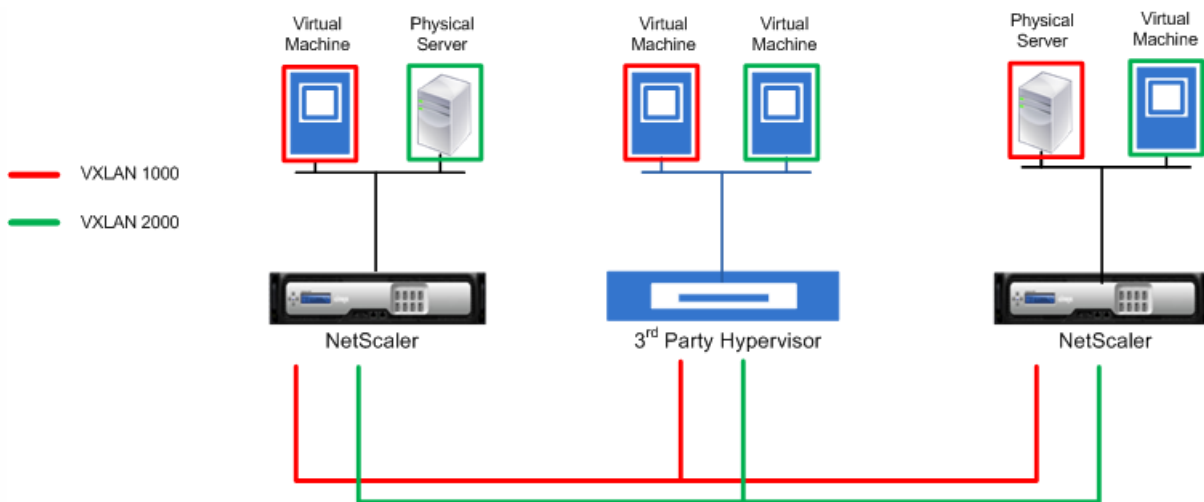

This section includes the following details:

- [How VXLANs Work](#)
- [VXLAN Use Case: Load Balancing across Datacenters](#)
- [Points to Consider for Configuring VXLANs](#)
- [Configuration Steps](#)

How VXLANs Work

VXLAN Segments are created between VXLAN Tunnel End Points (VTEPs). VTEPs support the VXLAN protocol and perform VXLAN encapsulation and decapsulation. You can think of a VXLAN segment as a tunnel between two VTEPs, where one VTEP encapsulates a Layer2 frame with a UDP header and an IP header and sends it through the tunnel. The other VTEP receives and decapsulates the packet to get the Layer 2 frame. A NetScaler ADC is one example of a VTEP. Other examples are third-party hypervisors, VXLAN aware virtual machines, and VXLAN capable switches.

The following illustration displays virtual machines and physical servers connected through VXLAN tunnels.

The following illustration displays the format of a VXLAN packet.

VXLANs on a NetScaler ADC use a Layer 2 mechanism for sending broadcast, multicast, and unknown unicast frames. A VXLAN supports the following modes for sending these L2 frames.

- Unicast mode: In this mode, you specify the IP addresses of VTEPs while configuring a VXLAN on a NetScaler ADC. The NetScaler ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to all VTEPs of this VXLAN.
- Multicast mode: In this mode, you specify a multicast group IP address while configuring a VXLAN on a NetScaler ADC. NetScaler ADCs do not support Internet Group Management Protocol (IGMP) protocol. NetScaler ADCs rely on the upstream router to join a multicast group, which shares a common multicast group IP address. The NetScaler ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to the multicast group IP address of this VXLAN.

Similar to a Layer 2 bridge table, NetScaler ADCs maintain VXLAN mapping tables based on the inner and outer header of the received VXLAN packets. This table maps of remote host MAC addresses to VTEP IP addresses for a particular VXLAN. The NetScaler ADC uses the VXLAN mapping table to look up the destination MAC address of a Layer 2 frame. If an entry for this MAC address is present in the VXLAN table, the NetScaler ADC sends the Layer 2 frame over Layer 3, using the VXLAN protocol, to the mapped VTEP IP address specified in the mapping entry for a VXLAN.

On a NetScaler ADC, you configure a VXLAN by creating a VXLAN tunnel and a VXLAN entity, and then bind the VXLAN tunnel to the VXLAN entity. A VXLAN tunnel is an IP tunnel with VXLAN as the underlying protocol. The VXLAN tunnel also specifies the local VTEP IP address and the remote VTEP IP address. The local VTEP IP address can be one of the configured subnet IP addresses on the NetScaler ADC. The remote IP address can be the IP address of a VTEP or the IP address of a multicast group. The VXLAN entity specifies the desired VXLAN Network Identifier (VNI).

Because VXLANs function similarly to VLANs, most of the NetScaler features that support VLAN as a classification parameter support VXLAN. These features include an optional VXLAN parameter setting, which specifies the VXLAN VNI.

In a high availability (HA) configuration, the VXLAN configuration is propagated or synchronized to the secondary node.

VXLAN Use Case: Load Balancing across Datacenters

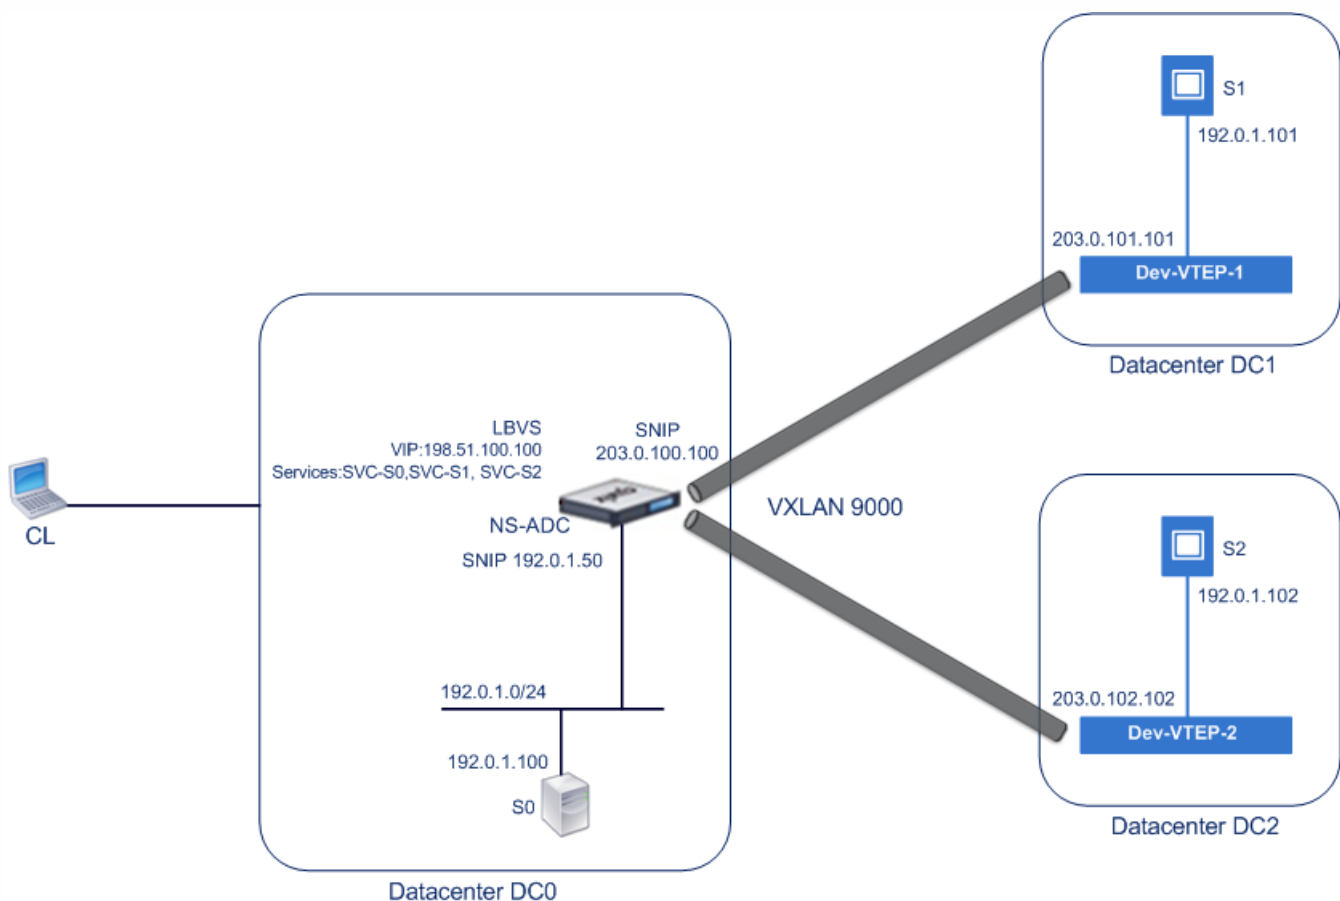

To understand the VXLAN functionality of a NetScaler ADC, consider an example in which Example Corp hosts a site at

www.example.com. To ensure application availability, the site is hosted on three servers, S0, S1, and S2. A load balancing virtual server, LBVS, on NetScaler ADC NS-ADC is used to load balance these servers. S0, S1, and S2 reside in datacenters DC0, DC1, and DC2, respectively. In DC0, server S0 is connected to NS-ADC.

S0 is a physical server, and S1 and S2 are virtual machines (VMs). S1 runs on virtualization host device Dev-VTEP-1 in datacenter DC1, and S2 runs on host device Dev-VTEP-2 in DC2. NS-ADC, Dev-VTEP-1, and Dev-VTEP-2 support the VXLAN protocol.

S0, S1, and S2 are part of the same private subnet, 192.0.1.0/24. For enabling NS-ADC, S0, S1, and S2 be part of a common broadcast domain, VXLAN 9000 is configured on NS-ADC, Dev-VTEP-1, and Dev-VTEP-2. Servers S1 and S2 are made part of VXLAN9000 on Dev-VTEP-1 and Dev-VTEP-2, respectively.

On NS-ADC, VXLAN 9000 configuration consists of a VXLAN entity, with an ID (VNI) of 9000, and two IP tunnels, VXLAN-9000-Tunnel-1 and VXLAN-9000-Tunnel-2. Both tunnels use VXLAN as the tunnel protocol. VXLAN-9000-Tunnel-1 is a VXLAN tunnel between a SNIP address (SNIP-VTEP-0) of NS-ADC and the IP address of Dev-VTEP-1. VXLAN-9000-Tunnel-2 is a VXLAN tunnel between a SNIP address (SNIP-VTEP-0) of NS-ADC and the IP address of Dev-VTEP-2. Both VXLAN tunnels are bound to VXLAN 9000.

The following table lists the settings used in this example.

Entity	Name	Details
Settings on NetScaler ADC NS-ADC in Datacenter DC-0		

Entity	Name	Details
Subnet IP address used by NS-ADC for communicating with servers S0, S1, and S2	SNIP-for-Servers (for reference purposes only)	IP address: 192.0.1.50

VXLAN Settings on Dev-VTEP-2		<ul style="list-style-type: none"> ID (VNI): 9000 UDP Port : 4789 Remote VTEP IP address: 203.0.100.100 Local VTEP IP address: 203.0.102.102
Server S2		<ul style="list-style-type: none"> IP address: 192.0.1.102

Services SVC-S0, SVC-S1, and SVC-S2 on NS-ADC represent S0, S1, and S2. As soon as these services are configured, NS-ADC broadcasts ARP requests for S0, S1, and S2 to resolve IP-to-MAC mapping. These ARP requests are also sent over VXLAN 9000 to Dev-VTEP-1 and Dev-VTEP-2.

Following is the traffic flow for resolving the ARP request for S2:

- NS-ADC broadcasts an ARP request for S2 to resolve IP-to-MAC mapping. This packet has:
 - Sourced IP address = Subnet IP address SNIP-for-Servers (192.0.1.50)
 - Source MAC address = MAC address of the NS-ADC's interface from which the packet is sent out = NS-MAC-1
- NS-ADC prepares the ARP packet to be sent over the VXLAN 9000 by encapsulating the packet with following headers:
 - VXLAN header with an ID (VNI) of 9000
 - Standard UDP header, UDP checksum set to 0x0000, and destination port set to 4789.
- NS-ADC sends the resulting encapsulated packet to Dev-VTEP-1 and Dev-VTEP-2 on tunnels VXLAN-9000-Tunnel-1 and VXLAN-9000-Tunnel-2, respectively. The encapsulated packet has:
 - Source IP address = SNIP-VTEP-0 (203.0.100.100).
- Dev-VTEP-2 receives the UDP packet and decapsulates the UDP header, from which Dev-VTEP-2 learns that the packet is a VXLAN related packet. Dev-VTEP-2 then decapsulates the VXLAN header and learns the VXLAN ID of the packet. The resulting packet is the ARP request packet for S2, which is same as in step 1.
- From the inner and outer header of the VXLAN packet, Dev-VTEP-2 makes an entry in its VXLAN mapping table that shows the mapping of MAC address (NS-MAC-1) and SNIP-VTEP-0 (203.0.100.100) for VXLAN9000.
- Dev-VTEP-2 sends the ARP packet to S2. S2's response packet reaches Dev-VTEP-2. Dev-VTEP-2 performs a lookup in its VXLAN mapping table and gets a match for the destination MAC address NS-MAC-1. The Dev-VTEP-2 now knows that NS-MAC-1 is reachable through SNIP-VTEP-0 (203.0.100.100) over VXLAN 9000.
- S2 responds with its MAC address (MAC-S2). The ARP response packet has:
 - Destination IP address = Subnet IP address SNIP-for-Servers (192.0.1.50)
 - Destination MAC address = NS-MAC-1
- S2's response packet reaches Dev-VTEP-2. Dev-VTEP-2 performs a lookup in its VXLAN mapping table and gets a match for the destination MAC address NS-MAC-1. The Dev-VTEP-2 now knows that NS-MAC-1 is reachable through SNIP-

VTEP-0 (203.0.100.100) over VXLAN 9000. Dev-VTEP-2 encapsulates the ARP response with VXLAN and UDP headers, and sends the resultant packet to SNIP-VTEP-0 (203.0.100.100) of NS-ADC.

9. NS-ADC on receiving the packet, decapsulates the packet by removing the VXLAN and UDP headers. The resultant packet is S2's ARP response. NS-ADC updates its VXLAN mapping table for S2's MAC address (MAC-S2) with Dev-VTEP-2's IP address (203.0.102.102) for VXLAN 9000. NS-ADC also updates its ARP table for S2's IP address (192.0.1.102) with S2's MAC address (MAC-S2).

Following is the traffic flow for load balancing virtual server LBVS in this example:

1. Client CL sends a request packet to LBVS of NS-ADC. The request packet has:
 - Source IP address = IP address of client CL (198.51.100.90)
 - Destination IP address = IP address (VIP) of LBVS = 198.51.110.100
2. LBVS of NS-ADC receives the request packet, and its load balancing algorithm selects server S2 of datacenter DC2.
3. NS-ADC processes the request packet, changing its destination IP address to the IP address of S2 and its source IP address to one of the Subnet IP (SNIP) addresses configured on NS-ADC. The request packet has:
 - Source IP address = Subnet IP address on NS-ADC= SNIP-for-Servers (192.0.1.50)
 - Destination IP address = IP address of S2 (192.0.1.102)
4. NS-ADC finds a VXLAN mapping entry for S2 in its bridge table. This entry indicates that S2 is reachable through Dev-VTEP-2 over VXLAN 9000.
5. NS-ADC prepares the packet to be sent over the VXLAN 9000 by encapsulating the packet with following headers:
 - VXLAN header with an ID (VNI) of 9000
 - Standard UDP header, UDP checksum set to 0x0000, and destination port set to 4789.
6. NS-ADC sends the resulting encapsulated packet to Dev-VTEP-2. The request packet has:
 - Source IP address = SNIP address = SNIP-VTEP-0 (203.0.100.100)
 - Destination IP address = IP address of Dev-VTEP-2 (203.0.102.102)
7. Dev-VTEP-2 receives the UDP packet and decapsulates the UDP header, from which Dev-VTEP-2 learns that the packet is a VXLAN related packet. Dev-VTEP-2 then decapsulates the VXLAN header and learns the VXLAN ID of the packet. The resulting packet is the same packet as in step 3.
8. Dev-VTEP-2 then forwards the packet to S2.
9. S2 processes the request packet and sends the response to the SNIP address of NS-ADC. The response packet has:
 - Source IP address = IP address of S2 (192.0.1.102)
 - Destination IP address = Subnet IP address on NS-ADC= SNIP-for-Servers (192.0.1.50)
10. Dev-VTEP-2 encapsulates the response packet in the same way that NS-ADC encapsulated the request packet in steps 4 and 5. Dev-VTEP-2 then sends the encapsulated UDP packet to SNIP address SNIP-for-Servers (192.0.1.50) of NS-ADC.
11. NS-ADC, upon receiving the encapsulated UDP packet, decapsulates the packet by removing the UDP and VXLAN headers in the same way that Dev-VTEP-2 decapsulated the packet in step 7. The resultant packet is the same response packet as in step 9.
12. NS-ADC then uses the session table for load balancing virtual server LBVS, and forwards the response packet to client CL. The response packet has:
 - Source IP address = IP address of client CL (198.51.100.90)
 - Destination IP address = IP address (VIP) of LBVS (198.51.110.100)

Points to Consider for Configuring VXLANs

Consider the following points before configuring VXLANs on a NetScaler ADC:

- A maximum of 2048 VXLANs can be configured on a NetScaler ADC.
- VXLANs are not supported in a cluster.
- Link-local IPv6 addresses cannot be configured for each VXLAN.

- NetScaler ADCs do not support Internet Group Management Protocol (IGMP) protocol to form a multicast group. NetScaler ADCs rely on the IGMP protocol of its upstream router to join a multicast group, which share a common multicast group IP address. You can specify a multicast group IP address while creating a VXLAN tunnel but the multicast group must be configured on the upstream router. The NetScaler ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to the multicast group IP address of this VXLAN. The upstream router then forwards the packet to all the VTEPs that are part of the multicast group.
- VXLAN encapsulation adds an overhead of 50 bytes to each packet:
Outer Ethernet Header (14) + UDP header (8) + IP header (20) + VXLAN header (8) = 50 bytes

To avoid fragmentation and performance degradation, you must adjust the MTU settings of all network devices in a VXLAN pathway, including the VXLAN VTEP devices, to handle the 50 bytes of overhead in the VXLAN packets.

Important: Jumbo frames are not supported on the NetScaler VPX virtual appliances, NetScaler SDX appliances, and NetScaler MPX 15000/17000 appliances. These appliances support an MTU size of only 1500 bytes and cannot be adjusted to handle the 50 bytes overhead of VXLAN packets. VXLAN traffic might be fragmented or suffer performance degradation, if one of these appliances is in the VXLAN pathway or acts as a VXLAN VTEP device.

- On NetScaler SDX appliances, VLAN filtering does not work for VXLAN packets.
- IPv6 Dynamic Routing is not supported on VXLAN.
- You cannot set a MTU value on a VXLAN.
- You cannot bind interfaces to a VXLAN.

Configuration Steps

Updated: 2014-08-07

Configuring a VXLAN on a NetScaler appliance consists of the following tasks.

- **Create an IP tunnel of type VXLAN.** Create an IP tunnel with VXLAN as the protocol for the IP tunnel. You specify one of the configured SNIP address for the local IP address of the tunnel. For the remote IP address you can specify either a multicast group IP address or a unicast address of a VTEP device. If you specify a multicast group IP address, you must configure IGMP on the upstream router of the NetScaler ADC to join the multicast group. Also, you can specify the configured VLAN through which the NetScaler ADC sends VXLAN packets to the multicast group IP address. In other words, the upstream router must be available on this VLAN. The upstream router forwards the VXLAN packets, from NS-ADC, to all the VTEPs that are part of the multicast group.
- **Create a VXLAN entity.** Create a VXLAN entity uniquely identified by a positive integer, which is also called the VXLAN Network Identifier (VNI). In this step, you can also specify the destination UDP port of remote VTEP on which the VXLAN protocol is running. By default, the destination UDP port parameter is set to 4789 for the VXLAN entity. This UDP port setting must match the settings on all remote VTEPs for this VXLAN. In this step, you can also bind VLANs to this VXLAN. The traffic (which includes broadcasts, multicasts, unknown unicasts) of all bound VLANs are allowed over this VXLAN. If no VLANs are bound to the VXLAN, the NetScaler ADC allows traffic of all VLANs, on this VXLAN, that are not part of any other VXLANs.
- **Bind the VXLAN tunnel to the VXLAN entity.** Bind the desired IP tunnels, of type VXLAN, to the VXLAN entity. More than one VXLAN tunnels can be bound to the VXLAN entity. These VXLAN tunnels form the broadcast domain for the VXLAN identified by its VNI.
- **(Optional) Bind different feature entities to the configured VXLAN.** VXLANs function similarly to VLANs, most of the NetScaler ADC features that support VLAN as a classification parameter also support VXLAN. These features include an optional VXLAN parameter setting, which specifies the VXLAN VNI.
- **(Optional) Display the VXLAN mapping table.** Display the VXLAN mapping table, which includes mapping entries for remote host MAC address to VTEP IP address for a particular VXLAN. In other words, a VXLAN mapping states that a

host is reachable through the VTEP on a particular VXLAN. The NetScaler ADC learns VXLAN mappings and updates its mapping table from the VXLAN packets it receives. The NetScaler ADC uses the VXLAN mapping table to lookup for the destination MAC address of a Layer 2 frame. If an entry for this MAC address is present in the VXLAN table, the NetScaler ADC sends the Layer 2 frame over Layer 3, using the VXLAN protocol, to the mapped VTEP IP address specified in the mapping entry for a VXLAN.

Configuration Using the Command Line Interface

To create a VXLAN tunnel by using the command line interface

At the command prompt, type:

- add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol VXLAN [-vlan <positive_integer>]
- show ipTunnel <name>

To create a VXLAN entity by using the command line interface

At the command prompt, type:

- add vxlan <id> [-vlan <positive_integer>] [-port <port>]
- show vxlan <id>

To bind a VXLAN tunnel to a VXLAN entity by using the command line interface

At the command prompt, type:

- bind vxlan <id> -tunnel <string>
- show vxlan <id>

To display the VXLAN forwarding table by using the command line interface

At the command prompt, type:

```
show bridgetable
```

Example

```
> add ipTunnel VXLAN-9000-Tunnel-1 203.0.101.101 255.255.255.255 203.0.100.100 -protocol VXLAN
Done
```

```
> add ipTunnel VXLAN-9000-Tunnel-2 203.0.102.102 255.255.255.255 203.0.100.100 -protocol VXLAN
Done
```

```
> add vxlan 9000
Done
```

```
> bind vxlan 9000 -tunnel VXLAN-9000-Tunnel-1
Done
```

```
> bind vxlan 9000 -tunnel VXLAN-9000-Tunnel-2
Done
```

Configuration Using the Configuration Utility

To create a VXLAN tunnel by using the configuration utility

Navigate to System > Network > IP Tunnels, and add a tunnel of type VXLAN.

To create a VXLAN entity and bind a VXLAN tunnel by using the configuration utility

1. Navigate to System > Network > VXLANs, and add a new VXLAN entity.
2. Open a VXLAN entity, in the VXLAN IP Tunnel Bindings pane, bind a VXLAN tunnel to the VXLAN entity.

To display the VXLAN forwarding table by using the configuration utility

Navigate to System > Network > Bridge Table.

Large Scale NAT

May 21, 2015

The Internet's phenomenal growth has resulted in a shortage of public IPv4 addresses. Large Scale NAT (LSN/CGNAT) provides a solution to this issue, maximizing the use of available public IPv4 addresses by sharing a few public IPv4 addresses among a large pool of Internet users.

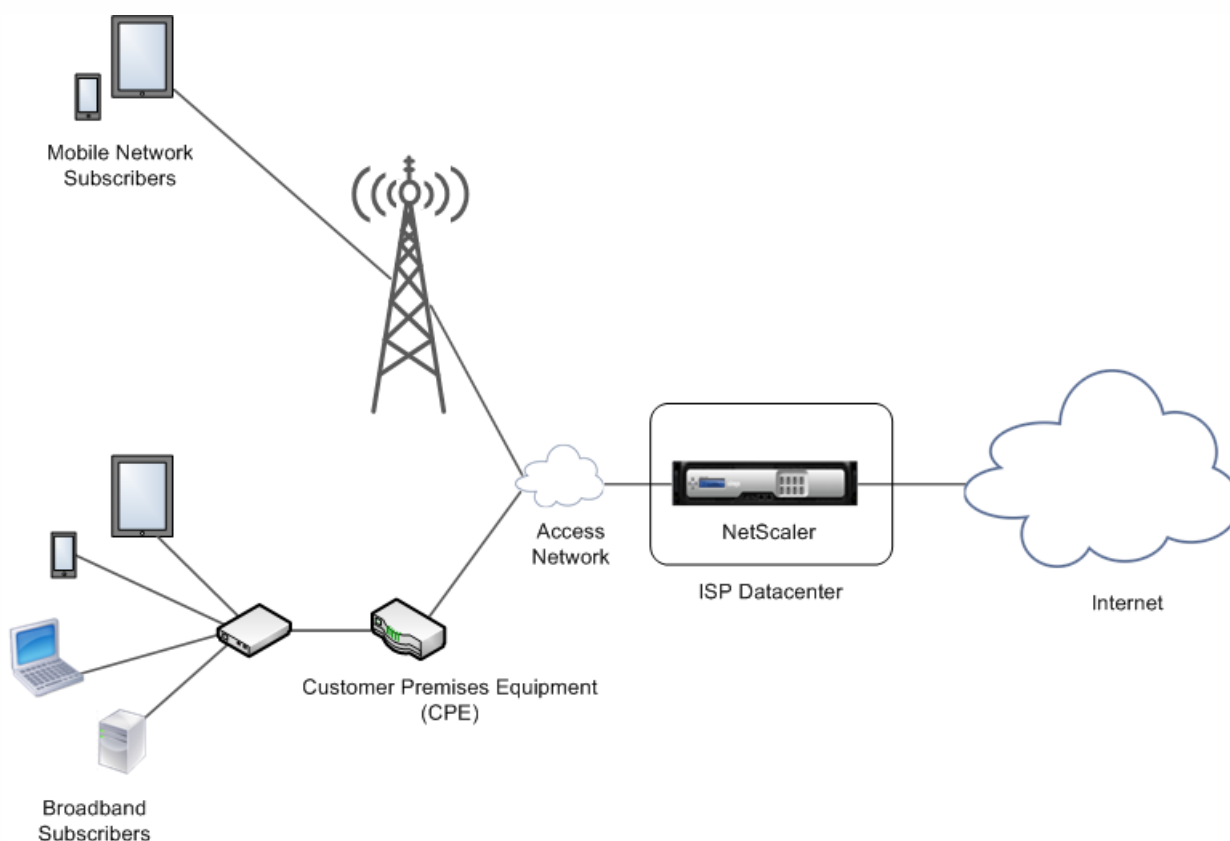

LSN translates private IPv4 addresses into public IPv4 addresses. It includes network address and port translation methods to aggregate many private IP addresses into fewer public IPv4 addresses. LSN is designed to handle NAT on a large scale. The NetScaler LSN feature is very useful for Internet Service Providers (ISPs) and carriers providing millions of translations to support a large number of users (subscribers) and at very high throughput.

Note: This feature is available in NetScaler release 10.5.e.

LSN Architecture

The LSN architecture of an ISP using Citrix products consists of subscribers (Internet users) in private address spaces accessing the Internet through a NetScaler appliance deployed in ISP's core network. Subscribers are connected to the ISP through the ISP's access network. Usually, subscribers for commercial use of the Internet are directly connected to the ISP's access network. Serving those subscribers requires only one level of NAT (NAT44).

Noncommercial subscribers, however, are typically behind customer-premises equipment (CPE), such as routers and modems, that also implements NAT. These two levels of NAT create the NAT444 model. Deploying a NetScaler ADC in an ISP's core network for LSN functionality is transparent to the subscribers and requires no configuration changes to subscribers or the CPEs.

The NetScaler ADC receives all subscriber packets destined to the Internet. The ADC is configured with a pool of pre-

defined NAT IP addresses to use for LSN. The NetScaler ADC uses its LSN feature to translate the source IP address (private) and port of the packet to the NAT IP address (public) and NAT port, and then sends the packet to its destination on the Internet. The ADC maintains a record of all active sessions that use the LSN feature. These sessions are called *LSN sessions*. The NetScaler ADC also maintains the mappings between subscriber IP address and port, and NAT IP address and port, for each session. These mappings are called *LSN mappings*. From LSN sessions and LSN mappings, the NetScaler ADC recognizes a response packet (received from the Internet) belonging to a particular session. The ADC translates the destination IP address and port of the response packet from NAT IP address:port to the subscriber IP address:port, and sends the translated packet to the subscriber.

LSN Features Supported on NetScaler ADC

The following describes some of the LSN features supported on NetScaler ADC:

NAT Resource Allocation

The NetScaler ADC allocates NAT IP addresses and ports, from its pre-defined NAT resource pool, to subscribers to translate their packets for transmission to external hosts (Internet). The NetScaler ADC supports the following types of NAT IP address and port allocation for subscribers:

- **Deterministic.** The NetScaler ADC allocates a NAT IP address and a block of ports to each subscriber. The ADC sequentially allocates NAT resources to these subscribers. It assigns the first block of ports on the beginning NAT IP address to the beginning subscriber IP address. The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. At that point, the first port block on the next NAT address is assigned to the subscriber, and so on.

The NetScaler appliance logs the allocated NAT IP address and the port block for a subscriber. For a connection, a subscriber can be identified just by its mapped NAT IP address and port block. Because of this reason, the NetScaler appliance does not log any LSN session created or deleted. If the entire block of ports is being used, the NetScaler ADC drops any new connection from the subscriber.

- **Dynamic.** The NetScaler ADC allocates a random NAT IP address and a port from the LSN NAT pool for a subscriber's connection. The ADC can also allocate a random NAT IP address and a block of ports for a subscriber when it initiates a connection for the first time. The ADC then allocates this NAT IP address and one of the ports from the allocated block to each subsequent connection from this subscriber. If the entire block of ports is being used, the ADC allocates a new random port block to the subscriber when it initiates a new connection. One of the port in the new port block is allocated for the new connection.

IP Pooling

The following NAT resource allocation options are available for subsequent sessions of a subscriber who was allocated a random NAT IP address and port for an existing session.

- **Paired.** The NetScaler ADC allocates the same NAT IP address for all sessions associated with the same subscriber. When no more ports are available for that address, the ADC drops any new connections from the subscriber. This option is needed for proper functioning of certain applications that require creation of multiple sessions on the same source IP address (for example in peer-to-peer applications that use RTP or RTCP protocol).
- **Random.** The NetScaler ADC allocates random NAT IP addresses, from the pool, for different sessions associated with the same subscriber.

Reusing LSN Mappings

The NetScaler ADC can reuse an existing LSN map for new connections originating from the same subscriber IP address and port. The NetScaler LSN feature supports the following types of LSN mapping reuse:

1. **Endpoint Independent.** The NetScaler ADC reuses the LSN mapping for subsequent packets sent from the same subscriber IP address and port (X:x) to any external IP address and port. This type of LSN map reuse is useful for proper functioning of VOIP and peer-to-peer applications.
2. **Address dependent.** The NetScaler ADC reuses the LSN mapping for subsequent packets sent from the same subscriber IP address and port (X:x) to the same external IP address (Y), regardless of the external port.
3. **Address port dependent.** The NetScaler ADC reuses the LSN mapping for subsequent packets sent from the same internal IP address and port (X:x) to the same external IP address and port (Y:y) while the mapping is still active.

LSN Filtering

The NetScaler ADC can filter packets from external hosts based on the active LSN sessions and LSN mappings. Consider an example of an LSN mapping that includes the mapping of subscriber IP:port (X:x), NAT IP:port (N:n), and external host IP:port (Y:y). The NetScaler LSN feature supports the following types of filtering:

1. **Endpoint Independent.** The NetScaler ADC filters out only those packets that are not destined to the subscriber IP address and port X:x, regardless of the external host IP address and port source (Z:z). The NetScaler ADC forwards any packets destined to X:x. In other words, sending packets from the subscriber to any external IP address is sufficient to allow packets from any external host to the subscriber. This type of filtering is useful for proper functioning of VOIP and peer-to-peer applications.
2. **Address dependent.** The NetScaler ADC filters out packets not destined to subscriber IP address and port X:x. In addition, the ADC filters out packets from external host IP address and port (Y:y) destined for the subscriber (X:x) if the client has not previously sent packets to Y:anyport (external port independent). In other words, receiving packets from a specific external host requires that the subscriber first send packets to that specific external host's IP address.
3. **Address port dependent.** The NetScaler ADC filters out packets not destined to subscriber IP address and port X:x. In addition, the ADC filters out packets from external host IP address and port (Y:y) destined for the subscriber (X:x) if the subscriber has not previously sent packets to Y:y. In other words, receiving packets from a specific external host requires that the subscriber first send packets to that external IP address and port.

Quotas

The NetScaler ADC can limit the number of NAT ports and sessions for each subscriber to ensure fair distribution of resources among subscribers.

- **Port quota.** The NetScaler ADC can limit the LSN NAT ports to be used at a time by each subscriber for a specified protocol. For example, you could limit each subscriber to a maximum of 500 TCP NAT ports. When the LSN NAT mappings for a subscriber reach the limit, the NetScaler ADC does not allocate additional NAT ports of the specified protocol to that subscriber.
- **Session quota.** The number of concurrent session for a subscriber can be more than its port quota. The NetScaler ADC can limit the LSN sessions allowed for each subscriber for a specified protocol. When the number of LSN sessions reaches the limit for a subscriber, the NetScaler ADC does not allow the subscriber to open additional sessions of the specified protocol.

Application Layer Gateways

For some Application layer protocols, the IP addresses and protocol port numbers are also communicated in the packet's payload. Application Layer Gateway for a protocol parses the packet's payload and does necessary changes to ensure that the protocol continues to work over LSN.

The NetScaler appliance supports ALG for the following protocols:

- FTP
- ICMP
- TFTP
- PPTP

Hairpin Support

The NetScaler ADC supports communication between subscribers or internal hosts using NAT IP addresses. This type of communication between two subscribers using NAT IP addresses is called hairpin flow. Hairpin flow is enabled by default, and you cannot disable it.

Points to Consider before Configuring LSN

Oct 17, 2014

Consider the following points before configuring LSN on a NetScaler ADC:

- Make sure that you understand the different components of Large Scale NAT, described in RFCs 6888, 5382, 5508, and 4787.
- Endpoint independent mapping and endpoint independent filtering are disabled by default. Citrix recommends enabling these options for proper functioning of VoIP and peer-to-peer (P2P) applications.
- For logging LSN information, Citrix recommends:
 - Logging the LSN information on external log servers instead of on the NetScaler ADC. Logging on external servers facilitates optimal performance when the ADC creates large numbers of LSN log entries (in order of millions).
 - Using NSLOG instead of SYSLOG, because NSLOG uses TCP but SYSLOG uses UDP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data.
- Citrix recommends configuring the LSN feature in a high availability deployment of two NetScaler ADCs for uninterrupted and seamless operation of all LSN sessions.
- In a high availability deployment, Citrix recommends:
 - Setting the SYNC VLAN parameter for dedicating a VLAN for all HA related communication.
 - Synchronizing the symmetric RSS key of the primary node to the secondary node for stateful synchronization of a large number of LSN mappings and sessions.
 - Binding the subnet of LSN IP addresses to a VLAN to avoid flooding of GARP broadcasts on all VLANs after a failover.
- Important: LSN feature is not supported on a high availability deployment in INC mode.
- If you disable the LSN feature when some LSN sessions exist on the NetScaler ADC, these sessions continue to exist for the duration of the configured timeout interval.
- LSN takes precedence over RNAT. If a packet from a specified LSN subscriber also matches a RNAT rule, the packet is translated according to the LSN configuration.
- Forwarding of packets related only to the LSN sessions is based on the NetScaler ADC's routing table.
- Unlike with subnet IP addresses, selection of an LSN NAT IP address for a subscriber's connection is not based on the routing entry for the destination IP address.
- For inbound packets, static LSN mappings take precedence over dynamic LSN mappings.
- For outbound packets, LSN application profiles take precedence over static mapping.
- When a large number of LSN sessions (> 1 million) exist on the NetScaler ADC, Citrix recommends displaying selected LSN sessions instead of all of them. In the command line interface or the configuration utility, use the selection parameters for showing LSN session operation.
- The L2 connection parameter of a load balancing virtual server does not work with the LSN feature.
- LSN is not supported in a NetScaler cluster.
- MBF (MAC based Forwarding) does not apply to packets related only to the LSN sessions.
- To reduce the amount of active memory allocated to the LSN feature, you must warm restart the NetScaler ADC after changing the configured-memory setting. Without a warm restart, you can only increase the amount of active memory.

Configuration Steps for LSN

Jan 31, 2011

Configuring LSN on a NetScaler ADC consists of the following tasks:

1. **Set the global LSN parameters.** Global parameters include the amount of NetScaler memory reserved for the LSN feature and synchronization of LSN sessions in a high availability setup.
2. **Create an LSN client entity and bind subscribers to it.** An LSN client entity is a set of subscribers on whose traffic you want the NetScaler ADC to perform LSN. The client entity includes IPv4 addresses and extended ACL rules for identifying subscribers. An LSN client can be bound to only one LSN group. The command line interface has two commands for creating an LSN client entity and binding a subscriber to the LSN client entity. The configuration utility combines these two operations on a single screen.
3. **Create an LSN pool and bind NAT IP addresses to it.** An LSN pool defines a pool of NAT IP addresses to be used by the NetScaler ADC to perform LSN. The pool is assigned parameters, such as port block allocation and NAT type (Deterministic or Dynamic). An LSN pool bound to an LSN group applies to all subscribers of an LSN client entity bound to the same group. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiple LSN pools can be bound to an LSN group. For Dynamic NAT, an LSN pool can be bound to multiple LSN groups. For Deterministic NAT, pools bound to an LSN group cannot be bound to other LSN groups. The command line interface has two commands for creating an LSN pool and binding NAT IP addresses to the LSN pool. The configuration utility combines these two operations on a single screen.
4. **(Optional) Create an LSN Transport Profile for a specified protocol.** An LSN transport profile defines various timeouts and limits, such as maximum LSN sessions and maximum ports usage, that a subscriber can have for a given protocol. You bind an LSN transport profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. A profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN transport profile with default settings for TCP, UDP, and ICMP protocols is bound to an LSN group during its creation. This profile is called default transport profile. An LSN transport profile that you bind to an LSN group overrides the default LSN transport profile for that protocol.
5. **(Optional) Create an LSN Application Profile for a specified protocol and bind a set of destination ports to it.** An LSN application profile defines the LSN mapping and LSN filtering controls of a group for a given protocol and for a set of destination ports. For a set of destination ports, you bind an LSN profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. An LSN application profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN application profile with default settings for TCP, UDP, and ICMP protocols for all destination ports is bound to an LSN group during its creation. This profile is called a default application profile. When you bind an LSN application profile, with a specified set of destination ports, to an LSN group, the bound profile overrides the default LSN application profile for that protocol at that set of destination ports. The command line interface has two commands for creating an LSN application profile and binding a set of destination ports to the LSN application profile. The configuration utility combines these two operations on a single screen.
6. **Create an LSN Group and bind LSN pools, (optional) LSN transport profiles, and (optional) LSN application profiles to the LSN group.** An LSN group is an entity consisting of an LSN client, LSN pool(s), LSN transport profile(s), and LSN application profiles(s). A group is assigned parameters, such as port block size and logging of LSN sessions. The parameter settings apply to all the subscribers of an LSN client bound to the LSN group. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiples LSN pools can be bound to an LSN group. For Dynamic NAT, an LSN pool can be bound to multiple LSN groups. For Deterministic NAT, pools bound to an LSN group cannot be bound to other LSN groups. Only one LSN client entity can be bound to an LSN group, and an LSN client entity bound to an LSN group cannot be bound to other LSN groups. The command line interface has two commands

for creating an LSN group and binding LSN pools, LSN transport profiles, LSN application profiles to the LSN group. The configuration utility combines these two operations in a single screen.

The following table lists the maximum numbers of different LSN entities and bindings that can be created on a NetScaler ADC. These limits are also subject to memory available on the NetScaler ADC.

LSN entities and bindings	Limit
LSN clients	1024
LSN pools	128
LSN groups	1024
Subscriber networks that can be bound to an LSN client	64
Extended ACLs that can be bound to an LSN client	1024
NAT IP addresses in a Pool	4096
LSN pools that can be bound to an LSN group	8
LSN groups that can use the same LSN pool	16
LSN transport profiles that can be bound to an LSN group	3 (one each for TCP, UDP, and ICMP protocols)
LSN groups that can use same LSN transport profile	8
LSN application profiles that can be bound to an LSN group	64
LSN groups that can use same LSN application profile	8
Port ranges that can be bound to an LSN application profile	8

Configuration Using the Command Line Interface

To create an LSN client by using the command line interface

At the command prompt, type:

- add lsn client <clientname>
- show lsn client

To bind an LSN client to a network and ACL by using the command line interface

At the command prompt, type:

- bind lsn client <clientname> ([-network <ip_addr> [-netmask <netmask>] [-td <positive_integer>]) | -aclname <string>)
- show lsn client

To create an LSN pool by using the command line interface

At the command prompt, type:

- add lsn pool <poolname> [-nattype (DYNAMIC | DETERMINISTIC)] [-portblockallocation (ENABLED | DISABLED)] [-portrealloctimeout <secs>] [-maxPortReallocTmq <positive_integer>]
- show lsn pool

To bind an LSN pool to an IP address range by using the command line interface

At the command prompt, type:

- bind lsn pool <poolname> <lsnip>
- show lsn pool

Note: For removing LSN IP addresses from an LSN pool, use the unbind lsn pool command.

To create an LSN transport profile by using the command line interface

At the command prompt, type:

- add lsn transportprofile <transportfilename> <transportprotocol> [-sessiontimeout <secs>] [-finrsttimeout <secs>] [-portquota <positive_integer>] [-sessionquota <positive_integer>] [-portpreserveparity (ENABLED | DISABLED)] [-portpreserverange (ENABLED | DISABLED)] [-syncheck (ENABLED | DISABLED)]
- show lsn transportprofile

To create an LSN application profile by using the command line interface

At the command prompt, type:

- add lsn appsprofile <appsfilename> <transportprotocol> [-ippooling (PAIRED | RANDOM)] [-mapping <mapping>] [-filtering <filtering>] [-tcpproxy (ENABLED | DISABLED)] [-td <positive_integer>]
- show lsn appsprofile

To bind an LSN application profile to an application protocol port range by using the command line interface

At the command prompt, type:

- bind lsn appsprofile <appsfilename> <lsnport>
- show lsn appsprofile

To create an LSN group by using the command line interface

At the command prompt, type:

- add lsn group <groupname> -clientname <string> [-nattype (DYNAMIC | DETERMINISTIC)] [-portblocksize <positive_integer>] [-logging (ENABLED | DISABLED)] [-sessionLogging (ENABLED | DISABLED)] [-sessionSync (ENABLED | DISABLED)] [-snmptraplimit<positive_integer>] [-ftp (ENABLED | DISABLED)]
- show lsn group

To bind an LSN group to protocol profiles and pools by using the command line interface

At the command prompt, type:

- bind lsn group <groupname> (-poolname <string> | -transportprofilename <string> | -appsprofilename <string>)
- show lsn group

Configuration Using the Configuration Utility

To configure an LSN client by using the configuration utility

Navigate to System > Network > Large Scale NAT > Clients, and add a new client or edit an existing client.

To bind an LSN client to a network and ACL by using the configuration utility

1. Navigate to System > Network > Large Scale NAT > Clients, and select a client.
2. On the Network or ACL tab, select a network or ACL to bind.

To configure an LSN pool by using the configuration utility

Navigate to System > Network > Large Scale NAT > Pools, and add a new pool or edit an existing pool.

To bind an LSN pool to an IP address range by using the configuration utility

1. Navigate to System > Network > Large Scale NAT > Pools, and select a pool.
2. Under IP Bindings, add an IP address range.

To configure an LSN transport profile by using the configuration utility

Navigate to System > Network > Large Scale NAT > Transport Profiles, and add a new transport profile or edit an existing profile.

To configure an LSN application profile by using the configuration utility

Navigate to System > Network > Large Scale NAT > Application Profiles, and add a new application profile or edit an existing profile.

To bind an LSN application profile to an application protocol port range by using the configuration utility

1. Navigate to System > Network > Large Scale NAT > Application Profiles, and select an application profile.
2. Under Port Range, add a port range.

To configure an LSN group by using the configuration utility

Navigate to System > Network > Large Scale NAT > Groups, and add a new group or edit an existing group.

To bind protocol profiles and pools to an LSN group by using the configuration utility

1. Navigate to System > Network > Large Scale NAT > Groups, and select a group.
2. On the Pool, Transport Profile, or Application Profile tab, select a pool, transport profile, or an application profile to bind.

Parameter Descriptions (of commands listed in the CLI procedure)

add lsn client

clientname

Name for the LSN client entity. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN client is created. The following requirement applies only to the NetScaler CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn client1" or 'lsn client1').

This is a mandatory argument. Maximum Length: 127

Parameter Descriptions (of commands listed in the CLI procedure)

bind lsn client

clientname

Name for the LSN client entity. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN client is created. The following requirement applies only to the NetScaler CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn client1" or 'lsn client1').

This is a mandatory argument. Maximum Length: 127

network

IPv4 address(es) of the LSN subscriber(s) or subscriber network(s) on whose traffic you want the NetScaler ADC to perform Large Scale NAT.

netmask

Subnet mask for the IPv4 address specified in the Network parameter.

Default value: 255.255.255.255

td

ID of the traffic domain on which this subscriber or the subscriber network (as specified by the network parameter) belongs.

If you do not specify an ID, the subscriber or the subscriber network becomes part of the default traffic domain.

Default value: 0

Minimum value: 0

Maximum value: 4094

aclname

Name(s) of any configured extended ACL(s) whose action is ALLOW. The condition specified in the extended ACL rule

identifies the traffic from an LSN subscriber for which the NetScaler ADC is to perform large scale NAT. Maximum Length: 127

Parameter Descriptions (of commands listed in the CLI procedure)

add lsn pool

poolname

Name for the LSN pool. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN pool is created. The following requirement applies only to the NetScaler CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn pool1" or 'lsn pool1').

This is a mandatory argument. Maximum Length: 127

nattype

Type of NAT IP address and port allocation (from the LSN pools bound to an LSN group) for subscribers (of the LSN client entity bound to the LSN group):

Available options function as follows:

- **Deterministic**—Allocate a NAT IP address and a block of ports to each subscriber (of the LSN client bound to the LSN group). The NetScaler ADC sequentially allocates NAT resources to these subscribers. The NetScaler ADC assigns the first block of ports (block size determined by the port block size parameter of the LSN group) on the beginning NAT IP address to the beginning subscriber IP address. The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. In this case, the first port block on the next NAT address is used for the subscriber, and so on. Because each subscriber now receives a deterministic NAT IP address and a block of ports, a subscriber can be identified without any need for logging. For a connection, a subscriber can be identified based only on the NAT IP address and port, and the destination IP address and port.
- **Dynamic**—Allocate a random NAT IP address and a port from the LSN NAT pool for a subscribers connection. If port block allocation is enabled (in LSN pool) and a port block size is specified (in the LSN group), the NetScaler ADC allocates a random NAT IP address and a block of ports for a subscriber when it initiates a connection for the first time. The ADC allocates this NAT IP address and a port (from the allocated block of ports) for different connections from this subscriber. If all the ports are allocated (for different subscribers connections) from the subscribers allocated port block, the ADC allocates a new random port block for the subscriber. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiples LSN pools can be bound to an LSN group.

Possible values: DYNAMIC, DETERMINISTIC

Default value: DYNAMIC

portblockallocation

Allocate a random NAT port block, from the available NAT port pool of an NAT IP address, for each subscriber when the NAT allocation is set as Dynamic NAT. For any connection initiated from a subscriber, the NetScaler ADC allocates a NAT port from the subscribers allocated NAT port block to create the LSN session.

You must set the port block size in the bound LSN group. For a subscriber, if all the ports are allocated from the subscribers allocated port block, the NetScaler ADC allocates a new random port block for the subscriber.

For Deterministic NAT, this parameter is enabled by default, and you cannot disable it.

Possible values: ENABLED, DISABLED

Default value: DISABLED

portreallocateout

The waiting time, in seconds, between deallocating LSN NAT ports (when an LSN mapping is removed) and reallocating them for a new LSN session. This parameter is necessary in order to prevent collisions between old and new mappings and sessions. It ensures that all established sessions are broken instead of redirected to a different subscriber. This is not applicable for ports used in:

- Deterministic NAT
- Address-Dependent filtering and Address-Port-Dependent filtering
- Dynamic NAT with port block allocation

In these cases, ports are immediately reallocated.

Default value: 0

Maximum value: 600

maxPortReallocTmq

Maximum number of ports for which the port reallocation timeout applies for each NAT IP address. In other words, the maximum deallocated-port queue size for which the reallocation timeout applies for each NAT IP address.

When the queue size is full, the next port deallocated is reallocated immediately for a new LSN session.

Default value: 65536

Maximum value: 65536

Parameter Descriptions (of commands listed in the CLI procedure)

bind lsn pool

poolname

Name for the LSN pool. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN pool is created. The following requirement applies only to the NetScaler CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn pool1" or 'lsn pool1').

This is a mandatory argument. Maximum Length: 127

lsnip

IPv4 address or a range of IPv4 addresses to be used as NAT IP address(es) for LSN.

After the pool is created, these IPv4 addresses are added to the NetScaler ADC as NetScaler owned IP address of type LSN. An LSN IP address associated with an LSN pool cannot be shared with other LSN pools. IP addresses specified for this parameter must not already exist on the NetScaler ADC as any NetScaler owned IP addresses. In the command line interface, separate the range with a hyphen. For example: 10.102.29.30-10.102.29.189. You can later remove some or all the LSN IP addresses from the pool, and add IP addresses to the LSN pool.

Parameter Descriptions (of commands listed in the CLI procedure)

add lsn transportprofile

transportprofilename

Name for the LSN transport profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN transport profile is created. The following requirement applies only to the NetScaler CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn transport profile1" or 'lsn transport profile1').

This is a mandatory argument. Maximum Length: 127

transportprotocol

Protocol for which to set the LSN transport profile parameters.

This is a mandatory argument.

Possible values: TCP, UDP, ICMP

sessiontimeout

Timeout, in seconds, for an idle LSN session. If an LSN session is idle for a time that exceeds this value, the NetScaler ADC removes the session.

This timeout does not apply for a TCP LSN session when a FIN or RST message is received from either of the endpoints.

Default value: 120

Minimum value: 60

finrsttimeout

Timeout, in seconds, for a TCP LSN session after a FIN or RST message is received from one of the endpoints.

If a TCP LSN session is idle (after the NetScaler ADC receives a FIN or RST message) for a time that exceeds this value, the NetScaler ADC removes the session.

Since the LSN feature of the NetScaler ADC does not maintain state information of any TCP LSN sessions, this timeout accommodates the transmission of the FIN or RST, and ACK messages from the other endpoint so that both endpoints can properly close the connection.

Default value: 30

portquota

Maximum number of LSN NAT ports to be used at a time by each subscriber for the specified protocol. For example, each subscriber can be limited to a maximum of 500 TCP NAT ports. When the LSN NAT mappings for a subscriber reach the limit, the NetScaler ADC does not allocate additional NAT ports for that subscriber.

Default value: 0

Minimum value: 0

Maximum value: 65535

sessionquota

Maximum number of concurrent LSN sessions allowed for each subscriber for the specified protocol. When the number of

LSN sessions reaches the limit for a subscriber, the NetScaler ADC does not allow the subscriber to open additional sessions.

Default value: 0

Minimum value: 0

Maximum value: 65535

portpreserveparity

Enable port parity between a subscriber port and its mapped LSN NAT port. For example, if a subscriber initiates a connection from an odd numbered port, the NetScaler ADC allocates an odd numbered LSN NAT port for this connection. You must set this parameter for proper functioning of protocols that require the source port to be even or odd numbered, for example, in peer-to-peer applications that use RTP or RTCP protocol.

Possible values: ENABLED, DISABLED

Default value: DISABLED

portpreserverange

If a subscriber initiates a connection from a well-known port (0-1023), allocate a NAT port from the well-known port range (0-1023) for this connection. For example, if a subscriber initiates a connection from port 80, the NetScaler ADC can allocate port 100 as the NAT port for this connection.

This parameter applies to dynamic NAT without port block allocation. It also applies to Deterministic NAT if the range of ports allocated includes well-known ports.

When all the well-known ports of all the available NAT IP addresses are used in different subscribers connections (LSN sessions), and a subscriber initiates a connection from a well-known port, the NetScaler ADC drops this connection.

Possible values: ENABLED, DISABLED

Default value: DISABLED

syncheck

Silently drop any non-SYN packets for connections for which there is no LSN-NAT session present on the NetScaler ADC.

If you disable this parameter, the NetScaler ADC accepts any non-SYN packets and creates a new LSN session entry for this connection.

Following are some reasons for the NetScaler ADC to receive such packets:

- LSN session for a connection existed but the NetScaler ADC removed this session because the LSN session was idle for a time that exceeded the configured session timeout.
- Such packets can be a part of a DoS attack.

Possible values: ENABLED, DISABLED

Default value: ENABLED

Parameter Descriptions (of commands listed in the CLI procedure)

add lsn appsprofile

appsprofilename

Name for the LSN application profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN application profile is created. The following requirement applies only to the NetScaler CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn application profile1" or 'lsn application profile1').

This is a mandatory argument. Maximum Length: 127

transportprotocol

Name of the protocol for which the parameters of this LSN application profile applies.

This is a mandatory argument.

Possible values: TCP, UDP, ICMP

ippooling

NAT IP address allocation options for sessions associated with the same subscriber.

Available options function as follows:

- **Paired**—The NetScaler ADC allocates the same NAT IP address for all sessions associated with the same subscriber. When all the ports of a NAT IP address are used in LSN sessions (for same or multiple subscribers), the NetScaler ADC drops any new connection from the subscriber.
- **Random**—The NetScaler ADC allocates random NAT IP addresses, from the pool, for different sessions associated with the same subscriber.

This parameter is applicable to dynamic NAT allocation only.

Possible values: PAIRED, RANDOM

Default value: RANDOM

mapping

Type of LSN mapping to apply to subsequent packets originating from the same subscriber IP address and port.

Consider an example of an LSN mapping that includes the mapping of the subscriber IP:port (X:x), NAT IP:port (N:n), and external host IP:port (Y:y).

Available options function as follows:

- **ENDPOINT-INDEPENDENT**—Reuse the LSN mapping for subsequent packets sent from the same subscriber IP address and port (X:x) to any external IP address and port.
- **ADDRESS-DEPENDENT**—Reuse the LSN mapping for subsequent packets sent from the same subscriber IP address and port (X:x) to the same external IP address (Y), regardless of the external port.
- **ADDRESS-PORT-DEPENDENT**—Reuse the LSN mapping for subsequent packets sent from the same internal IP address and port (X:x) to the same external IP address and port (Y:y) while the mapping is still active.

Possible values: ENDPOINT-INDEPENDENT, ADDRESS-DEPENDENT, ADDRESS-PORT-DEPENDENT

Default value: ADDRESS-PORT-DEPENDENT

filtering

Type of filter to apply to packets originating from external hosts.

Consider an example of an LSN mapping that includes the mapping of subscriber IP:port (X:x), NAT IP:port (N:n), and external host IP:port (Y:y).

Available options function as follows:

- **ENDPOINT INDEPENDENT**—Filters out only packets not destined to the subscriber IP address and port X:x, regardless of the external host IP address and port source (Z:z). The NetScaler ADC forwards any packets destined to X:x. In other words, sending packets from the subscriber to any external IP address is sufficient to allow packets from any external hosts to the subscriber.
- **ADDRESS DEPENDENT**—Filters out packets not destined to subscriber IP address and port X:x. In addition, the ADC filters out packets from Y:y destined for the subscriber (X:x) if the client has not previously sent packets to Y:anyport (external port independent). In other words, receiving packets from a specific external host requires that the subscriber first send packets to that specific external host's IP address.
- **ADDRESS PORT DEPENDENT** (the default)—Filters out packets not destined to subscriber IP address and port (X:x). In addition, the NetScaler ADC filters out packets from Y:y destined for the subscriber (X:x) if the subscriber has not previously sent packets to Y:y. In other words, receiving packets from a specific external host requires that the subscriber first send packets first to that external IP address and port.

Possible values: ENDPOINT-INDEPENDENT, ADDRESS-DEPENDENT, ADDRESS-PORT-DEPENDENT

Default value: ADDRESS-PORT-DEPENDENT

tcpproxy

Enable TCP proxy, which enables the NetScaler appliance to optimize the TCP traffic by using Layer 4 features.

Possible values: ENABLED, DISABLED

Default value: DISABLED

td

ID of the traffic domain through which the NetScaler ADC sends the outbound traffic after performing LSN.

If you do not specify an ID, the ADC sends the outbound traffic through the default traffic domain, which has an ID of 0.

Default value: 65535

Maximum value: 65535

Parameter Descriptions (of commands listed in the CLI procedure)

bind lsn appsprofile

appsprofilename

Name for the LSN application profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN application profile is created. The following requirement applies only to the NetScaler CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn application profile1" or 'lsn application profile1').

This is a mandatory argument. Maximum Length: 127

lsnport

Port numbers or range of port numbers to match against the destination port of the incoming packet from a subscriber. When the destination port is matched, the LSN application profile is applied for the LSN session. Separate a range of ports with a hyphen. For example, 40-90.

Parameter Descriptions (of commands listed in the CLI procedure)

add lsn group

groupname

Name for the LSN group. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN group is created. The following requirement applies only to the NetScaler CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn group1" or 'lsn group1').

This is a mandatory argument. Maximum Length: 127

clientname

Name of the LSN client entity to be associated with the LSN group. You can associate only one LSN client entity with an LSN group. You cannot remove this association or replace with another LSN client entity once the LSN group is created.

This is a mandatory argument. Maximum Length: 127

nattype

Type of NAT IP address and port allocation (from the bound LSN pools) for subscribers:

Available options function as follows:

- **Deterministic**—Allocate a NAT IP address and a block of ports to each subscriber (of the LSN client bound to the LSN group). The NetScaler ADC sequentially allocates NAT resources to these subscribers. The NetScaler ADC assigns the first block of ports (block size determined by the port block size parameter of the LSN group) on the beginning NAT IP address to the beginning subscriber IP address. The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. In this case, the first port block on the next NAT address is used for the subscriber, and so on. Because each subscriber now receives a deterministic NAT IP address and a block of ports, a subscriber can be identified without any need for logging. For a connection, a subscriber can be identified based only on the NAT IP address and port, and the destination IP address and port.
- **Dynamic**—Allocate a random NAT IP address and a port from the LSN NAT pool for a subscriber's connection. If port block allocation is enabled (in LSN pool) and a port block size is specified (in the LSN group), the NetScaler ADC allocates a random NAT IP address and a block of ports for a subscriber when it initiates a connection for the first time. The ADC allocates this NAT IP address and a port (from the allocated block of ports) for different connections from this subscriber. If all the ports are allocated (for different subscribers connections) from the subscribers allocated port block, the ADC allocates a new random port block for the subscriber.

Possible values: DYNAMIC, DETERMINISTIC

Default value: DYNAMIC

portblocksize

Size of the NAT port block to be allocated for each subscriber.

To set this parameter for Dynamic NAT, you must enable the port block allocation parameter in the bound LSN pool. For

Deterministic NAT, the port block allocation parameter is always enabled, and you cannot disable it.

In Dynamic NAT, the NetScaler ADC allocates a random NAT port block, from the available NAT port pool of an NAT IP address, for each subscriber. For a subscriber, if all the ports are allocated from the subscribers allocated port block, the ADC allocates a new random port block for the subscriber.

The default port block size is 512 for Deterministic NAT, and 0 for Dynamic NAT.

Default value: 0

Minimum value: 512

Maximum value: 65536

logging

Log mapping entries and sessions created or deleted for this LSN group. The NetScaler ADC logs LSN sessions for this LSN group only when both logging and session logging parameters are enabled.

The ADC uses its existing syslog and audit log framework to log LSN information. You must enable global level LSN logging by enabling the LSN parameter in the related NSLOG action and SYLOG action entities. When the Logging parameter is enabled, the NetScaler ADC generates log messages related to LSN mappings and LSN sessions of this LSN group. The ADC then sends these log messages to servers associated with the NSLOG action and SYSLOG actions entities.

A log message for an LSN mapping entry consists of the following information:

- NSIP address of the NetScaler ADC
- Time stamp
- Entry type (MAPPING or SESSION)
- Whether the LSN mapping entry is created or deleted
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
 - Destination IP address and port are not logged for Endpoint-Independent mapping
 - Only Destination IP address (and not port) is logged for Address-Dependent mapping
 - Destination IP address and port are logged for Address-Port-Dependent mapping

Possible values: ENABLED, DISABLED

Default value: DISABLED

sessionLogging

Log sessions created or deleted for the LSN group. The NetScaler ADC logs LSN sessions for this LSN group only when both logging and session logging parameters are enabled.

A log message for an LSN session consists of the following information:

- NSIP address of the NetScaler ADC
- Time stamp
- Entry type (MAPPING or SESSION)
- Whether the LSN session is created or removed

- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

Possible values: ENABLED, DISABLED

Default value: DISABLED

sessionSync

In a high availability (HA) deployment, synchronize information of all LSN sessions related to this LSN group with the secondary node. After a failover, established TCP connections and UDP packet flows are kept active and resumed on the secondary node (new primary).

For this setting to work, you must enable the global session synchronization parameter.

Possible values: ENABLED, DISABLED

Default value: ENABLED

snmptraplimit

Maximum number of SNMP Trap messages that can be generated for the LSN group in one minute.

Default value: 100

Minimum value: 0

Maximum value: 10000

ftp

Enable Application Layer Gateway (ALG) for the FTP protocol. For some application-layer protocols, the IP addresses and protocol port numbers are usually communicated in the packets payload. When acting as an ALG, the NetScaler changes the packets payload to ensure that the protocol continues to work over LSN.

Note: The NetScaler ADC also includes ALG for ICMP and TFTP protocols. ALG for the ICMP protocol is enabled by default, and there is no provision to disable it. ALG for the TFTP protocol is disabled by default. ALG is enabled automatically for an LSN group when you bind a UDP LSN application profile, with endpoint-independent-mapping, endpoint-independent filtering, and destination port as 69 (well-known port for TFTP), to the LSN group.

Possible values: ENABLED, DISABLED

Default value: ENABLED

Parameter Descriptions (of commands listed in the CLI procedure)

bind lsn group

groupname

Name for the LSN group. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN group is created. The following requirement applies only to the NetScaler CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn group1" or 'lsn group1').

This is a mandatory argument. Maximum Length: 127

poolname

Name of the LSN pool to bind to the specified LSN group. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiple LSN pools can be bound to an LSN group.

For Deterministic NAT, pools bound to an LSN group cannot be bound to other LSN groups. For Dynamic NAT, pools bound to an LSN group can be bound to multiple LSN groups. Maximum Length: 127

transportprofilename

Name of the LSN transport profile to bind to the specified LSN group. Bind a profile for each protocol for which you want to specify settings.

By default, one LSN transport profile with default settings for TCP, UDP, and ICMP protocols is bound to an LSN group during its creation. This profile is called a default transport.

An LSN transport profile that you bind to an LSN group overrides the default LSN transport profile for that protocol. Maximum Length: 127

appsprofilename

Name of the LSN application profile to bind to the specified LSN group. For each set of destination ports, bind a profile for each protocol for which you want to specify settings.

By default, one LSN application profile with default settings for TCP, UDP, and ICMP protocols for all destination ports is bound to an LSN group during its creation. This profile is called a default application profile.

When you bind an LSN application profile, with a specified set of destination ports, to an LSN group, the bound profile overrides the default LSN application profile for that protocol at that set of destination ports. Maximum Length: 127

Sample LSN Configurations

Jan 28, 2011

The following table shows examples of configuring LSN through command line interface.

Task	Steps
Create a simple LSN configuration with a single subscriber network, single LSN NAT IP address, and default settings.	<pre>>set lsn parameter -memLimit 4000 Done >add lsn client LSN-CLIENT-1 Done >bind lsn client LSN-CLIENT-1 - network 192.0.2.0 -netmask 255.255.255.0 Done >add lsn pool LSN-POOL-1 Done >bind lsn pool LSN-POOL-1 203.0.113.3 Done >add lsn group LSN-GROUP-1 - clientname LSN-CLIENT-1 Done >bind lsn group LSN-GROUP-1 - poolname pool1 LSN-POOL-1 Done</pre>
Create an LSN configuration with an extended ACL for identifying LSN subscribers	<pre>>add ns acl LSN-ACL-2 ALLOW - srcIP 192.0.2.10-192.0.2.20 Done >apply acls Done >add lsn client LSN-CLIENT-2</pre>

Task	Done Steps
	<pre> >bind lsn client LSN-CLIENT-2 - aclname LSN-ACL-2 Done >add lsn pool LSN-POOL-2 Done >bind lsn pool LSN-POOL-2 203.0.113.5-203.0.113.10 Done >add lsn group LSN-GROUP-2 - clientname LSN-CLIENT-2 Done >bind lsn group LSN-GROUP-2 - poolname LSN-POOL-2 Done </pre>
<p>Create an LSN configuration with endpoint-independent mapping for HTTP protocol (port 80) and address-port dependent mapping for SSH protocol (port 22). Also, restrict each subscriber to use a maximum of 1000 NAT ports (sessions) for TCP protocol and 100 NAT ports (sessions) for UDP protocol.</p>	<pre> >add lsn client LSN-CLIENT-3 Done >bind lsn client LSN-CLIENT-3 - network 192.0.3.0 -netmask 255.255.255.0 Done >add lsn pool LSN-POOL-3 Done >bind lsn pool LSN-POOL-3 203.0.113.11 Done >add lsn group LSN-GROUP-3 - clientname LSN-CLIENT-3 Done >bind lsn group LSN-GROUP-3 - poolname LSN-POOL-3 </pre>

Task	Done Steps
	<pre> >add lsn appprofile LSN-APPS- HTTPPROFILE-3 TCP -mapping ENDPOINT-INDEPENDENT Done >bind lsn appprofile LSN-APPS- HTTPPROFILE-3 80 Done >bind lsn group LSN-GROUP-3 - applicationprofile LSN- APPS-HTTPPROFILE-3 Done >add lsn appprofile LSN-APPS- SSHPROFILE-3 TCP -mapping ADDRESS-PORT-DEPENDENT Done >bind lsn appprofile LSN-APPS- SSHPROFILE-3 22 Done >bind lsn group LSN-GROUP-3 - applicationprofile LSN- APPS-SSHPROFILE-3 Done >add lsn transportprofile LSN- TRANS-PROFILE-TCP-3 TCP - portquota 1000 Done >bind lsn group LSN-GROUP-3 - transportprofile LSN- TRANS-PROFILE-TCP-3 Done >add lsn transportprofile LSN- TRANS-PROFILE-UDP-3 UDP - portquota 100 Done </pre>

Task	Steps
	<pre>>bind lsn group LSN-GROUP-3 - transport profilename LSN- TRANS-PROFILE-UDP-3 Done</pre>
<p>Create an LSN configuration for a large set of subscribers.</p>	<pre>>set lsn parameter -memLimit 22462 Done >add lsn client LSN-CLIENT-4 Done >bind lsn client LSN-CLIENT-4 - network 192.0.4.0 -netmask 255.255.255.0 Done >bind lsn client LSN-CLIENT-4 - network 192.0.5.0 -netmask 255.255.255.0 Done >bind lsn client LSN-CLIENT-4 - network 192.0.6.0 -netmask 255.255.255.0 Done >bind lsn client LSN-CLIENT-4 - network 192.0.7.0 -netmask 255.255.255.0 Done >bind lsn client LSN-CLIENT-4 - network 192.0.8.0 -netmask 255.255.255.0 Done >add lsn pool LSN-POOL-4 Done >bind lsn pool LSN-POOL-4 203.0.113.30-203.0.113.40</pre>

Task	Done Steps
	<pre> >bind lsn pool LSN-POOL-4 203.0.113.45-203.0.113.50 Done >bind lsn pool LSN-POOL-4 203.0.113.55-203.0.113.60 Done >add lsn group LSN-GROUP-4 - clientname LSN-CLIENT-4 Done >bind lsn group LSN-GROUP-4 - poolname LSN-POOL-4 Done >add lsn appsprofile LSN-APPS- WELLKNOWNPROFILE-4 TCP - mapping ENDPOINT- INDEPENDENT Done >bind lsn appsprofile LSN-APPS- WELLKNOWN-PORTS-PROFILE- 4 1- 1023 Done >bind lsn group LSN-GROUP-4 - applicationprofilename LSN- APPS-WELLKNOWN-PORTS- PROFILE-4 Done </pre>
<p>Create an LSN configuration with sharing of NAT resources among multiple LSN groups. In this example, LSN pool LSN-POOL-5 is shared with LSN groups LSN-GROUP-5 and LSN-GROUP-6.</p>	<pre> >add lsn client LSN-CLIENT-5 Done >bind lsn client LSN-CLIENT-5 - network 192.0.15.0 -netmask 255.255.255.0 Done </pre>

Task	Steps
	<pre> >add lsn pool LSN-POOL-5 Done >bind lsn pool LSN-POOL-5 203.0.113.12-203.0.113.14 Done >add lsn group LSN-GROUP-5 - clientname LSN-CLIENT-5 Done >bind lsn group LSN-GROUP-5 - poolname LSN-POOL-5 Done >add lsn client LSN-CLIENT-6 Done >bind lsn client LSN-CLIENT-6 - network 192.0.16.0 -netmask 255.255.255.0 Done >add lsn pool LSN-POOL-6 Done >bind lsn pool LSN-POOL-6 203.0.113.15-203.0.113.18 Done >add lsn group LSN-GROUP-6 - clientname LSN-CLIENT-6 Done >bind lsn group LSN-GROUP-6 - poolname LSN-POOL-6 Done >bind lsn group LSN-GROUP-6 - poolname LSN-POOL-5 Done </pre>
Create an LSN configuration with deterministic NAT resource allocation.	<pre> >add lsn client LSN-CLIENT-7 </pre>

Task	Done Steps
	<pre> >bind lsn client LSN-CLIENT-7 - network 192.0.17.0 -netmask 255.255.255.0 Done >add lsn pool LSN-POOL-7 - nattype DETERMINISTIC Done >bind lsn pool LSN-POOL-7 203.0.113.19-203.0.113.23 Done >add lsn group LSN-GROUP-7 - clientname LSN-CLIENT-7 - nattype DETERMINISTIC - portblocksize 1024 Done >bind lsn group LSN-GROUP-7 - poolname LSN-POOL-7 Done </pre>
<p>Create an LSN configuration with multiple subscriber networks having the same network address but each network belonging to a different traffic domain. Also, restrict the outbound traffic related to HTTP protocol (port 80), sending it through a particular traffic domain (td 5).</p>	<pre> >add lsn client LSN-CLIENT-8 Done >bind lsn client LSN-CLIENT-8 - network 192.0.18.0 -netmask 255.255.255.0 -td 1 Done >bind lsn client LSN-CLIENT-8 - network 192.0.18.0 -netmask 255.255.255.0 -td 2 Done >bind lsn client LSN-CLIENT-8 - network 192.0.18.0 -netmask 255.255.255.0 -td 3 Done </pre>

Task	Steps
	<pre> >add lsn pool LSN-POOL-8 Done >bind lsn pool LSN-POOL-8 203.0.113.80-203.0.113.86 Done >add lsn group LSN-GROUP-8 - clientname LSN-CLIENT-8 Done >bind lsn group LSN-GROUP-8 - poolname LSN-POOL-8 Done >add lsn appprofile LSN-APPS- HTTP-PROFILE-8 TCP -td 5 Done >bind lsn appprofile LSN-APPS- HTTP-PROFILE-8 80 Done >bind lsn group LSN-GROUP-8 - applicationprofilename LSN- APPS-HTTP-PROFILE-8 Done </pre>
<p>Create an LSN configuration that restricts the outbound traffic of a specific protocol (TCP), sending it through a particular traffic domain (td 5). With endpoint-independent filtering, receive inbound traffic related to this protocol (TCP) on any traffic domain.</p>	<pre> >add lsn client LSN-CLIENT-9 Done >bind lsn client LSN-CLIENT-9 - network 192.0.9.0 -netmask 255.255.255.0 -td 1 Done >add lsn pool LSN-POOL-9 Done >bind lsn pool LSN-POOL-9 203.0.113.90 Done </pre>

Task	Steps
	<pre> >add lsn group LSN-GROUP-9 - clientname LSN-CLIENT-9 Done >bind lsn group LSN-GROUP-9 - poolname LSN-POOL-9 Done >add lsn appsprofile LSN-APPS- PROFILE-9 TCP -filtering ENDPOINT-INDEPENDENT -td 5 Done >bind lsn group LSN-GROUP-9 - appprofile LSN-APPS-PROFILE-9 Done </pre>
<p>Create an LSN configuration that restricts outbound HTTP (port 80) traffic, sending it through a particular traffic domain (td 10). With address-dependent filtering, receive inbound traffic related to this protocol (HTTP) on the specified traffic domain (td 10).</p>	<pre> >add lsn client LSN-CLIENT-10 Done >bind lsn client LSN-CLIENT-10 - network 192.0.10.0 -netmask 255.255.255.0 -td 1 Done >add lsn pool LSN-POOL-10 Done >bind lsn pool LSN-POOL-10 203.0.113.100 Done >add lsn group LSN-GROUP-10 - clientname LSN-CLIENT-10 Done >bind lsn group LSN-GROUP-10 - poolname LSN-POOL-10 Done >add lsn appsprofile LSN-APPS- PROFILE-10 TCP -mapping </pre>

Task	Steps
	<p>ENDPOINT -INDEPENDENT - filtering ADDRESS-DEPENDENT - td 10</p> <p>Done</p> <p>>bind lsn appprofile LSN-APPS- PROFILE-10 80</p> <p>Done</p> <p>>b ind lsn group LSN-GROUP-10 - appprofile LSN-APPS-PROFILE-10</p> <p>Done</p>

Configuring Static LSN Maps

Jan 31, 2011

The NetScaler ADC supports manual creation of a one-to-one LSN mapping between a subscriber IP address:port and a NAT IP address:port. Static LSN mappings are useful in cases where you want to ensure that a connection initiated from a particular subscriber IP address:port always get mapped to a particular NAT IP address:port.

To create a static LSN mapping by using the command line interface

At the command prompt, type:

- `add lsn static <name> <transportprotocol> <subscrIP> <subscrPort> [-td <positive_integer>] [<natIP> [<natPort>]] [-destIP <ip_addr> [-dsttd <positive_integer>]]`
- `show lsn static`

To create a static LSN mapping by using the configuration utility

Navigate to System > Network > Large Scale NAT > Static, and add a new static mapping.

Parameter Descriptions (of commands listed in the CLI procedure)

add lsn static

name

Name for the LSN static mapping entry. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN group is created. The following requirement applies only to the NetScaler CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn static1" or 'lsn static1').

This is a mandatory argument. Maximum Length: 127

transportprotocol

Protocol for the LSN mapping entry.

This is a mandatory argument.

Possible values: TCP, UDP, ICMP

subscrIP

IPv4 address of an LSN subscriber for the LSN mapping entry.

This is a mandatory argument.

subscrPort

Port of the LSN subscriber for the LSN mapping entry.

This is a mandatory argument. Maximum value: 65535

td

ID of the traffic domain to which the subscriber belongs.

If you do not specify an ID, the subscriber is assumed to be a part of the default traffic domain.

Default value: 0

Minimum value: 0

Maximum value: 4094

natIP

IPv4 address, already existing on the NetScaler ADC as type LSN, to be used as NAT IP address for this mapping entry.

natPort

NAT port for this LSN mapping entry.

destIP

Destination IP address for the LSN mapping entry.

dsttd

ID of the traffic domain through which the destination IP address for this LSN mapping entry is reachable from the NetScaler ADC.

If you do not specify an ID, the destination IP address is assumed to be reachable through the default traffic domain, which has an ID of 0.

Default value: 0

Minimum value: 0

Maximum value: 4094

Logging and Monitoring LSN

Jan 28, 2011

You can log LSN information to diagnose, troubleshoot problems, and to meet legal requirements. You can monitor the performance of the LSN feature by using LSN statistical counters and displaying current LSN sessions.

This section includes the following details:

- [Logging LSN](#)
- [Displaying Current LSN Sessions](#)
- [Displaying LSN Statistics](#)

Logging LSN

Updated: 2015-05-22

Logging LSN information is one of the important functions required by the ISPs to meet legal requirements and for identifying the source of traffic at any given time.

A NetScaler ADC logs LSN mapping entries and the LSN sessions created or deleted for each LSN group. You can control logging of LSN information for an LSN group by using the logging and session logging parameters of the LSN group. These are group level parameters and are disabled by default. The NetScaler ADC logs LSN sessions for an LSN group only when both logging and session logging parameters are enabled.

The following table displays the logging behavior for an LSN group for various settings of logging and session logging parameters.

Logging	Session Logging	Logging Behavior
Enabled	Enabled	Logs LSN mapping entries as well as LSN sessions.
Enabled	Disabled	Logs LSN mapping entries but not LSN sessions.
Disabled	Enabled	Logs neither mapping entries nor LSN sessions.

A log message for an LSN mapping entry consists of the following information:

- NSIP address of the NetScaler ADC
- Time stamp
- Entry type (MAPPING)
- Whether the LSN mapping entry was created or deleted
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
 - Destination IP address and port are not logged for Endpoint-Independent mapping.
 - Only the destination IP address is logged for Address-Dependent mapping. The port is not logged.
 - Destination IP address and port are logged for Address-Port-Dependent mapping.

A log message for an LSN session consists of the following information:

- NSIP address of the NetScaler ADC
- Time stamp
- Entry type (SESSION)
- Whether the LSN session is created or removed
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

The ADC uses its existing syslog and audit log framework to log LSN information. You must enable global level LSN logging by enabling the LSN parameter in the related NSLOG action and SYSLOG action entities. When the Logging parameter is enabled, the NetScaler ADC generates log messages related to LSN mappings and LSN sessions of this LSN group. The ADC then sends these log messages to servers associated with the NSLOG action and SYSLOG action entities.

For logging LSN information, Citrix recommends:

- Logging the LSN information on external log servers instead of on the NetScaler ADC. Logging on external servers facilitates optimal performance when the ADC creates large amounts of LSN log entries (in order of millions).
- Using NSLOG instead of SYSLOG. NSLOG uses TCP, but SYSLOG uses UDP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data.

Note:

- The SYSLOG generated on NetScaler appliance are dynamically sent to the external log servers.
- When using SYSLOG over TCP, if the TCP connection is down or the SYSLOG server is busy, then the NetScaler appliances stores the logs in buffer and send the data once the connection is active.

For more information about configuring logging, see [Audit Logging](#).

Configuring LSN logging consists of the following tasks:

- **Configuring the NetScaler ADC for logging.** This task involves creating and setting various entities and parameters of the NetScaler ADC:
 - Create a SYSLOG or NSLOG audit logging configuration. Creating an audit logging configuration involves the following tasks:
 - Create a NSLOG or SYSLOG audit action and enable the LSN parameter. Audit actions specify the IP addresses of log servers.
 - Create a SYSLOG or NSLOG audit policy and bind the audit action to the audit policy.
 - Bind the audit policy to system global.

Note: For an existing audit logging configuration, just enable the LSN parameter for logging LSN information in the server specified by the audit action.

 - Enable logging and session logging parameters, either as you add LSN groups or after you have created the groups. The NetScaler ADC generates log messages related to these LSN groups and sends them to the server of those audit actions that have the LSN parameter enabled.
- **Configuring log servers.** This task involves installing SYSLOG or NSLOG packages on the desired servers. This task also involves specifying the NSIP address of the NetScaler ADC in the configuration file of SYSLOG or NSLOG. Specifying the NSIP address enables the server to identify the log information sent by the NetScaler ADC for storing them in a log file.

For more information about configuring logging, see [Audit Logging](#).

SYSLOG Configuration Using the Command Line Interface

To create a SYSLOG server action for LSN logging by using the command line interface

At the command prompt, type:

```
add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel>... [-lsn ( ENABLED | DISABLED )]
```

To create a SYSLOG server policy for LSN logging by using the command line interface

At the command prompt, type:

```
add audit syslogPolicy <name> <rule> <action>
```

To bind a SYSLOG server policy to system global for LSN logging by using the command line interface

At the command prompt, type:

```
bind system global [<policyName> [-priority <positive_integer>]]
```

SYSLOG Configuration Using the Configuration Utility

To configure a SYSLOG server action for LSN logging by using the configuration utility

1. Navigate to Systems > Auditing > Syslog and, on the Servers tab, add a new auditing server or edit an existing server.
2. To enable LSN logging, select the Large Scale NAT Logging option.

To configure a SYSLOG server policy for LSN logging by using the configuration utility

Navigate to Systems > Auditing > Syslog and, on the Policies tab, add a new policy or edit an existing policy.

To bind a SYSLOG server policy to system global for LSN logging by using the configuration utility

1. Navigate to Systems > Auditing > Syslog.
2. On the Policies tab, in the Action list, click Global Bindings to bind the audit global policies.

NSLOG Configuration Using the Command Line Interface

To create a NSLOG server action for LSN logging by using the command line interface

At the command prompt, type:

```
add audit nslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> ... [-lsn ( ENABLED | DISABLED )]
```

To create a NSLOG server policy for LSN logging by using the command line interface

At the command prompt, type:

```
add audit nslogPolicy <name> <rule> <action>
```

To bind a NSLOG server policy to system global for LSN logging by using the command line interface

At the command prompt, type:

```
bind system global [<policyName>]
```

NSLOG Configuration Using the Configuration Utility

To configure a NSLOG server action for LSN logging by using the configuration utility

1. Navigate to Systems > Auditing > Nslog and, on the Servers tab, add a new auditing server or, edit an existing server.
2. To enable LSN logging, select the Large Scale NAT Logging option.

To configure a NSLOG server policy for LSN logging by using the configuration utility

Navigate to Systems > Auditing > Nslog and, on the Policies tab, add a new policy or edit an existing policy. To bind a NSLOG server policy to system global for LSN logging by using the configuration utility

1. Navigate to Systems > Auditing > Nslog.
2. On the Policies tab, in the Action list, click Global Bindings to bind the audit global policies.

Example

The following configuration specifies two SYSLOG and two NSLOG servers for storing log entries including LSN logs. LSN Logging is configured for LSN groups LSN-GROUP-2 and LSN-GROUP-3.

The NetScaler ADC generates log messages related to LSN mappings and LSN sessions of these LSN groups, and sends them to the specified log servers.

```
>add audit syslogAction SYS-ACTION-1 198.51.101.10 -logLevel ALL -lsn ENABLED
```

```
Done
```

```
>add audit syslogPolicy SYSLOG-POLICY-1 ns_true SYS-ACTION-1
```

```
Done
```

```
>bind system global SYSLOG-POLICY-1
```

```
Done
```

```
>add audit syslogAction SYS-ACTION-2 198.51.101.20 -logLevel ALL -lsn ENABLED
```

```
Done
```

```
>add audit syslogPolicy SYSLOG-POLICY-2 ns_true SYS-ACTION-2
```

```
Done
```

```
>bind system global SYSLOG-POLICY-2
```

```
Done
```

```
>add audit nslogAction NSLOG-ACTION-1 198.51.101.30 -logLevel ALL -lsn ENABLED
```

```
Done
```

```
>add audit nslogPolicy NSLOG-POLICY-1 ns_true NSLOG-ACTION-1
```

```
Done
```

```
>bind system global NSLOG-POLICY-1
```

```
Done
```

```
>add audit nslogAction NSLOG-ACTION-2 198.51.101.40 -logLevel ALL -lsn ENABLED
```

```
Done
```

```
>add audit nslogPolicy NSLOG-POLICY-2 ns_true NSLOG-ACTION-2
```

```
Done
```

```
>bind system global NSLOG-POLICY-2
```

```
Done
```

```
> add lsn group LSN-GROUP-3 -clientname LSN-CLIENT-2 -logging ENABLED -sessionLogging ENABLED
```

```
Done
```

```
> set lsn group LSN-GROUP-2 -logging ENABLED -sessionLogging ENABLED
```

```
Done
```

The following table displays sample LSN log entries of each type stored on the configured log servers. These LSN log entries are generated by a NetScaler ADC whose NSIP address is 10.102.37.115.

LSN Log Entry Type	Sample Log Entry
LSN session creation	Local4.Informational 10.102.37.115 08/05/2014:09:59:48 GMT 0-PPE-0 : LSN LSN_SESSION 2581750 : SESSION CREATED Client IP:Port:TD 192.0.2.10: 15136:0, NatIP:NatPort 203.0.113.6: 6234, Destination IP:Port:TD 198.51.100.9: 80:0, Protocol: TCP
LSN session deletion	Local4.Informational 10.102.37.115 08/05/2014:10:05:12 GMT 0-PPE-0 : LSN LSN_SESSION 3871790 : SESSION DELETED Client IP:Port:TD 192.0.2.11: 15130:0, NatIP:NatPort 203.0.113.6: 7887, Destination IP:Port:TD 198.51.101.2:80:0, Protocol: TCP
LSN mapping creation	Local4.Informational 10.102.37.115 08/05/2014:09:59:47 GMT 0-PPE-0 : LSN LSN_MAPPING 2581580 : EIM CREATED Client IP:Port 192.0.2.15: 14567, NatIP:NatPort 203.0.113.5: 8214, Protocol: TCP
LSN mapping deletion	Local4.Informational 10.102.37.115 08/05/2014:10:05:12 GMT 0-PPE-0 : LSN LSN_MAPPING 3871700 : EIM DELETED Client IP:Port 192.0.3.15: 14565, NatIP:NatPort 203.0.113.11: 8217, Protocol: TCP

Displaying Current LSN Sessions

You can display the current LSN sessions for detecting any unwanted or inefficient LSN sessions on the NetScaler ADC. You can display all or some LSN sessions on the basis of selection parameters.

Note: When more than a million LSN sessions exist on the NetScaler ADC, Citrix recommends displaying selected LSN sessions instead of all by using the selection parameters.

Configuration Using the Command Line Interface

To display all LSN sessions by using the command line interface

At the command prompt, type:

```
show lsn session
```

To display selective LSN sessions by using the command line interface

At the command prompt, type:

```
show lsn session [-clientname <string>] [-network <ip_addr> [-netmask <netmask>] [-td <positive_integer>]] [-natIP <ip_addr> [-natPort <port>]]
```

Example

To display all LSN sessions existing on a NetScaler ADC

```
> show lsn session
```

```

Configuration Using the Configuration Utility

To display all LSN sessions by using the configuration utility

Navigate to System > Network > Large Scale NAT > Sessions.

Parameter Descriptions (of commands listed in the CLI procedure)

show lsn session

clientname

Name of the LSN Client entity. Maximum Length: 127

network

IP address or network address of subscriber(s).

netmask

Subnet mask for the IP address specified by the network parameter.

Default value: 255.255.255.255

td

Traffic domain ID of the LSN client entity.

Default value: 0

Minimum value: 0

Maximum value: 4094

natIP

Mapped NAT IP address used in LSN sessions.

Displaying LSN Statistics

You can display statistics related to the LSN feature for evaluating the performance of the LSN feature or to troubleshoot problems. You can display a summary of statistics of the LSN feature or of a particular LSN group. The statistical counters reflect events since the NetScaler ADC was last restarted. All these counters are reset to 0 when the NetScaler ADC is restarted.

To display all LSN statistics by using the command line interface

At the command prompt, type:

```
stat lsn
```

To display statistics for a specified LSN group by using the command line interface

At the command prompt, type:

```
stat lsn group [<groupname>]
```

Example

```
> stat lsn
```

Large Scale NAT statistics

	Rate(/s)	Total
LSN TCP Received Packets	0	40
LSN TCP Received Bytes	0	3026
LSN TCP Transmitted Packets	0	40

LSN TCP Transmitted Bytes	0	3026
LSN TCP Dropped Packets	0	0
LSN TCP Current Sessions	0	0
LSN UDP Received Packets	0	0
LSN UDP Received Bytes	0	0
LSN UDP Transmitted Packets	0	0
LSN UDP Transmitted Bytes	0	0
LSN UDP Dropped Packets	0	0
LSN UDP Current Sessions	0	0
LSN ICMP Received Packets	0	982
LSN ICMP Received Bytes	0	96236
LSN ICMP Transmitted Packets	0	0
LSN ICMP Transmitted Bytes	0	0
LSN ICMP Dropped Packets	0	982
LSN ICMP Current Sessions	0	0
LSN Subscribers	0	1

Done

> stat lsn group LSN-GROUP-1

LSN Group Statistics

	Rate (/s)	Total
TCP Translated Pkts	0	40
TCP Translated Bytes	0	3026
TCP Dropped Pkts	0	0
TCP Current Sessions	0	0
UDP Translated Pkts	0	0
UDP Translated Bytes	0	0
UDP Dropped Pkts	0	0
UDP Current Sessions	0	0
ICMP Translated Pkts	0	0
ICMP Translated Bytes	0	0
ICMP Dropped Pkts	0	0
ICMP Current Sessions	0	0
Current Subscribers	0	1

Done

Parameter Descriptions (of commands listed in the CLI procedure)

stat lsn group

groupname

Name of the LSN Group. Maximum Length: 127

detail

Specifies detailed output (including more statistics). The output can be quite voluminous. Without this argument, the output will show only a summary.

fullValues

Specifies that numbers and strings should be displayed in their full form. Without this option, long strings are shortened and large numbers are abbreviated.

ntimes

The number of times, in intervals of seven seconds, the statistics should be displayed.

Default value: 1

logFile

The name of the log file to be used as input.

clearstats

Clear the statistics / counters

Possible values: basic, full

Clearing LSN Sessions

Jan 31, 2011

You can remove any unwanted or inefficient LSN sessions from the NetScaler ADC. The ADC immediately releases resources (such as NAT IP address, port, and memory) allocated for these sessions, making the resources available for new sessions. The ADC also drops all the subsequent packets related to these removed sessions. You can remove all or selected LSN sessions from the NetScaler ADC.

To clear all LSN sessions by using the command line interface

At the command prompt, type:

- flush lsn session
- show lsn session

To clear selective LSN sessions by using the command line interface

At the command prompt, type:

- flush lsn session [-clientname <string>] [-network <ip_addr> [-netmask <netmask>] [-td <positive_integer>]] [-natIP <ip_addr> [-natPort <port>]]
- show lsn session

Example

Clear all LSN sessions existing on a NetScaler ADC

```
> flush lsn session  
Done
```

Clear all LSN sessions related to LSN client entity LSN-CLIENT-1

```
> flush lsn session -clientname LSN-CLIENT-1  
Done
```

Clear all LSN sessions related to a subscriber network (192.0.2.0) of LSN client entity LSN-CLIENT-2 belonging to traffic domain 100

```
> flush lsn session -clientname LSN-CLIENT-2 -network 192.0.2.0 -netmask 255.255.255.0 -td 100  
Done
```

To clear all LSN sessions by using the configuration utility

Navigate to System > Network > Large Scale NAT > Sessions, and click Flush Sessions.

Parameter Descriptions (of commands listed in the CLI procedure)

flush lsn session

clientname

Name of the LSN Client entity. Maximum Length: 127

network

IP address or network address of subscriber(s).

netmask

Subnet mask for the IP address specified by the network parameter.

Default value: 255.255.255.255

td

Traffic domain ID of the LSN client entity.

Default value: 0

Minimum value: 0

Maximum value: 4094

natIP

Mapped NAT IP address used in LSN sessions.

natPort

Mapped NAT port used in the LSN sessions.

AppExpert

Jan 07, 2014

The following topics provide a conceptual reference and configuration instructions for the AppExpert and other features of the NetScaler appliance.

Action Analytics	Collects run-time statistics on the basis of pre-defined criteria. When used with policies, the feature also provides you with the infrastructure for automatic, real-time traffic optimization.
AppExpert Applications and Templates	Simplify configuration steps for the Citrix® NetScaler® appliance by using applications, application templates, NetScaler Gateway applications, and entity templates.
Entity Templates	Describes how to use entity templates to set up and configure individual NetScaler entities, such as a policy or virtual server. An entity template provides a specification and a set of defaults for the object.
AppQoE	Application level Quality of Experience (AppQoE) integrates several existing policy-based security features of the NetScaler appliance into a single integrated feature that takes advantage of a new queuing mechanism, fair queuing.
HTTP Callouts	An HTTP request that the NetScaler appliance generates and sends to an external application when certain criteria are met during policy evaluation.
Pattern Sets	Allow string matching during the evaluation of a default syntax policy.
Policies and Expressions	Rules that determine the operations that the NetScaler appliance must perform.
Rate Limiting	Defines the maximum load for a given network entity or virtual entity on the NetScaler appliance.
Responder	Bases responses on who sends the request, where it is sent from, and other criteria with security and system management implications.
Rewrite	Rewrites information in the requests or responses handled by the NetScaler appliance.
String Maps	Perform pattern matching in all NetScaler features that use the default policy syntax.

Action Analytics

Sep 16, 2013

The performance of your website or application depends on how well you optimize the delivery of the most frequently requested content. Techniques such as caching and compression help accelerate the delivery of services to clients, but you need to be able to identify the resources that are requested most frequently, and then cache or compress those resources. You can identify the most frequently used resources by aggregating real-time statistics about website or application traffic. Statistics such as how frequently a resource is accessed relative to other resources and how much bandwidth is consumed by those resources help you determine whether those resources need to be cached or compressed to improve server performance and network utilization. Statistics such as response times and the number of concurrent connections to the application help you determine whether you must enhance server-side resources.

If the website or application does not change frequently, you can use products that collect statistical data, and then manually analyze the statistics and optimize the delivery of content. However, if you do not want to perform manual optimizations, or if your website or application is dynamic in nature, you need infrastructure that can not only collect statistical data but can also automatically optimize the delivery of resources on the basis of the statistics. On the NetScaler appliance, this functionality is provided by the action analytics feature. The feature operates on a single NetScaler appliance and collects run-time statistics on the basis of criteria that you define. When used with NetScaler policies, the feature also provides you with the infrastructure that you need for automatic, real-time traffic optimization.

When configuring the action analytics feature, you specify the request attributes for which you want to collect statistical data (for example, URLs and HTTP methods) by configuring default syntax expressions in an entity called a selector. Then, you configure an identifier to configure settings such as the sampling interval and sample count. You also configure a policy that enables the appliance to evaluate traffic as specified by the selector-identifier pair. Finally, you bind the policy to a bind point to begin collecting statistics.

The appliance also provides you with a set of built-in selectors, identifiers, and responder policies that you can use to get started with the feature.

The appliance aggregates the following statistics:

- The number of requests.
- The bandwidth consumed by the requests.
- The response time.
- The number of concurrent connections.

You can configure the feature to perform run-time sorting of the records on an attribute of your choice. You can view the statistical data by using either the command-line interface or the Stream Sessions tool in the configuration utility.

Configuring a Selector

Sep 16, 2013

A selector is a filter for identifying requests. It consists of up to five individual default syntax expressions that identify request attributes such as the client IP address and the URL in the request. Each expression is a non-compound default syntax expression and is considered to be in an AND relationship with the other expressions. Following are some examples of selector expressions:

- HTTP.REQ.URL
- CLIENT.IP.SRC
- HTTP.RES.BODY(1000).AFTER_STR("<string>").BEFORE_STR("<string>")
- CLIENT.IP.SRC.SUBNET(24)

Selectors are used in rate limiting and action analytics configurations. A selector is optional in a rate limiting configuration, but is required in a action analytics configuration.

The order in which you specify parameters is significant. For example, if you configure an IP address and a domain (in that order) in one selector, and then specify the domain and the IP address (in the reverse order) in another selector, the NetScaler considers these values to be unique. This can lead to the same transaction being counted twice. Also, if multiple policies invoke the same selector, the NetScaler, again, can count the same transaction more than once.

If you modify an expression in a selector, you may get an error if any policy that invokes it is bound to a new policy label or bind point. For example, suppose that you create a selector named myLimitSelector1, invoke it from myLimitID1, and invoke the identifier from a DNS policy named dnsRateLimit1. If you change the expression in myLimitSelector1, you might receive an error when binding dnsRateLimit1 to a new bind point. The workaround is to modify these expressions before creating the policies that invoke them.

The NetScaler appliance provides the following built-in selectors for some of the most common use cases:

Table 1. Built-in Selectors

Selector	Selector Expressions
Top_URL	HTTP.REQ.URL
Top_CLIENTS	CLIENT.IP.SRC
Top_URL_CLIENTS_LBVSERVER	1. HTTP.REQ.URL 2. CLIENT.IP.SRC 3. HTTP.REQ.LB_VSERVER.NAME
Top_URL_CLIENTS_CSVSERVER	1. HTTP.REQ.URL 2. CLIENT.IP.SRC 3. HTTP.REQ.CS_VSERVER.NAME
Top_MSSQL_QUERY_DB_LBVSERVER	1. MSSQL.REQ.QUERY.TEXT 2. MSSQL.REQ.LB_VSERVER.NAME

Selector	Selector Expressions
Top_MYSQL_QUERY_DB_LBVSERVER	1. MYSQL.REQ.QUERY.TEXT 2. MYSQL.REQ.LB_VSERVER.NAME

You can also configure a selector with expressions that identify the request attributes of your choice. For example, you might want to create a record for a request that arrives with a specific header. To evaluate the header, you can add `HTTP.REQ.HEADER("<header_name>")` to the selector that you intend to use.

To configure a selector by using the command line interface

At the command prompt, type the following commands to configure a selector and verify the configuration:

- `add stream selector <name> <rule> ...`
- `show stream selector`

Example

```
> add stream selector myselector HTTP.REQ.URL CLIENT.IP.SRC
Done
> show stream selector myselector
Name: myselector
Expressions:
  1) HTTP.REQ.URL
  2) CLIENT.IP.SRC
Done
>
```

To modify or remove a selector by using the command line interface

- To modify a selector, type the `set stream selector` command, the name of the selector, and the rule parameter with the expressions. Enter the existing expressions that you want to retain, along with the new expressions that you want to add.
- To remove a selector, type the `rm stream selector` command and the name of the selector.

To configure a selector by using the configuration utility

1. Navigate to AppExpert > Action Analytics > Selectors.
2. In the details pane, do one of the following:
 - To create a selector, click Add.
 - To modify a selector, select the selector, and then click Open.
3. In the Create Limit Selector or Configure Limit Selector dialog box, set one or more of the following parameters:
 - Name
 - Expressions

To add the expression to the selector configuration, click Add. To remove an expression from the selector configuration, in the Expression box, select the expression, and then click Remove.

Note: In the Expressions box, enter a valid parameter. For example, enter HTTP. Then, enter a period after this parameter. A drop-down menu appears. The contents of this menu provide the keywords that can follow the initial keyword that you entered. To select the next keyword in this expression prefix, double-click the selection in the drop-down menu. The Expressions text box displays both the first and second keywords for the expression prefix, for

example, HTTP.REQ. Continue adding expression components until the complete expression is formed.

4. Click Add.
5. Continue adding up to five non-compound expressions.
6. Click Create or OK.

Configuring a Stream Identifier

Aug 30, 2013

You configure a stream identifier to specify parameters for collecting statistical data from requests identified by a given selector. An identifier specifies the selector to be used, the statistics collection interval, the sample count, and the field on which the records are to be sorted.

The NetScaler appliance includes the following built-in stream identifiers for common use cases. All the built-in identifiers specify a sample count of 1 and an interval of 1 minute. Additionally, they sort the data on the REQUESTS attribute. They differ only in being associated with different built-in selectors. Each built-in identifier is associated with a built-in selector of the same name (for example, the built in identifier Top_URL is associated with the built-in selector Top_URL). Following are the built-in identifiers:

- Top_URL
- Top_CLIENTS
- Top_URL_CLIENTS_LBVSERVER
- Top_URL_CLIENTS_CSVSERVER
- Top_MSSQL_QUERY_DB_LBVSERVER
- Top_MYSQL_QUERY_DB_LBVSERVER

For more information about the built-in selectors, see "[Configuring a Selector](#)."

Note: The maximum length for storing string results of selectors (for example, HTTP.REQ.URL) is 60 characters. If the string (for example, URL) is 1000 characters long, of which 50 characters are enough to uniquely identify a string, use an expression to extract only the required 50 characters.

You cannot modify a built-in identifier's configuration. However, you can create an identifier with a configuration of your choice.

To configure a stream identifier by using the command line interface

At the command prompt, type the following commands to configure a stream identifier and verify the configuration:

- add stream identifier <name> <selectorName> [-interval <positive_integer>] [-SampleCount <positive_integer>] [-sort <sort>]
- show stream identifier <name>

Example

```
> add stream identifier myidentifier Top_URL -interval 10 -sampleCount 100
Done
```

To configure a stream identifier by using the configuration utility

1. Navigate to AppExpert > Action Analytics > Stream Identifiers.
2. In the details pane, do one of the following:
 - To create a stream identifier, click Add.
 - To modify a stream identifier, select the identifier, and then click Open.
3. In the Configure Stream Identifier dialog box, set one or more of the following parameters:
 - Name
 - Selector
 - Interval

- Sample Count
- Sort

4. Click Create or OK, and then click Close.

Viewing Statistics

Aug 30, 2013

You can view the collected statistics in tabular format in the command-line interface and in graphical format in the configuration utility.

The following table describes the collected statistics:

Table 1. Statistical Information Displayed for a Stream Identifier

Statistics	Column name in the output of the stat stream identifier <identifier name> command	Description
Number of requests	Req	The number of requests for which records were created in the last <interval> number of minutes.
Bandwidth consumed	BandW	<p>The total bandwidth consumed by the requests that were received in the last <interval> number of minutes. The total bandwidth of a request is the bandwidth consumed by the request and its response.</p> <p>The value is rounded off to the next higher or next lower integer value. Consequently, it might differ slightly from the expected value. For example, if a request's total bandwidth consumption is 2.2 KB, one instance of the request might be shown as having consumed 2 KB and two instances might be shown as having consumed 4 KB, but three instances might be shown as having consumed 7 KB.</p>
Response time	RspTime	The average response time for all the requests received in the last <interval> number of minutes.
Concurrent connections	Conn	The total number of concurrent connections that are currently open.

To view the statistical data collected for a stream identifier by using the command line

At the command prompt, type:

```
stat stream identifier <name> [<pattern> ...] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-sortBy <sortBy> [<sortOrder>]]
```

Examples

Example 1 sorts the output on the BandW column, in the descending order. Example 2 sorts the output in Example 1, on the Req column, and in the ascending order

Example 1

```
> stat stream identifier myidentifier -sortBy BandW Descending -fullValues
```

Stream Session statistics

	Req	BandW
User1	508	125924
User2	5020	12692
User3	2025	4316

	RspTime	Conn
User1	5694	0
User2	109	0
User3	3	0

Done

Example 2

```
> stat stream identifier myidentifier -sortBy Req Ascending -fullValues
```

Stream Session statistics

	Req	BandW
User1	508	125924
User3	2025	4316
User2	5020	12692

	RspTime	Conn
User1	5694	0
User3	3	0
User2	109	0

Done

To view the statistical data collected for a stream identifier by using the configuration utility

1. Navigate to AppExpert > Action Analytics > Stream Identifiers.
2. Select the stream identifier whose sessions you want to view, and then click Stream Sessions. For information about how you can group the output on the basis of the values collected for various selector expressions, see "[Grouping Records on Attribute Values.](#)"

Grouping Records on Attribute Values

Sep 30, 2013

Statistical information such as the number of times a particular URL has been accessed overall and per client, and the total number of GET and POST requests per client can provide valuable insights into whether any of your resources need to be expanded to meet the demand or be optimized for delivery. To obtain such statistics, you must use an appropriate set of selector expressions, and then use the pattern parameter in the stat stream identifier command. The grouping is based on the pattern that is specified in the command. Grouping can be performed concurrently on the values of multiple expressions.

In the command-line interface, you can group the output by using patterns of your choice. In the configuration utility, the pattern depends on the choices you make when drilling down through the values of various selector expressions. For example, consider a selector that has the expressions HTTP.REQ.URL, CLIENT.IP.SRC, and HTTP.REQ.LB_VSERVER.NAME, in that order. The statistics home page displays icons for each of these expressions. If you click the icon for CLIENT.IP.SRC, the output is based on the patterns * ? *. The output displays statistics for each client IP address. If you click an IP address, the output is based on the patterns * <IP address> ? and ? <IP address> * where <IP address> is the IP address you selected. In the resulting output, if you click a URL, the pattern used is <URL> <IP address> ?.

To group the records on the values of selector expressions by using the command line interface

At the command prompt, enter the following command to group the records on the basis of a selector expression:

```
stat stream identifier <name> [<pattern> ...]
```

Examples

Each example uses a different pattern to demonstrate the effect of the pattern on the output of the stat stream identifier command. The selector expressions are HTTP.REQ.URL and HTTP.REQ.HEADER("UserHeader"), in that order. The requests contain a custom header whose name is UserHeader. Note that in the examples, a given statistical value changes as determined by the grouping, but the sum total of the values for a given field remains the same.

Example 1

In the following command, the pattern used is ? ?. The appliance groups the output on the values collected for both selector expressions. The row headers consist of the expression values separated by a question mark (?). The row with the header /mysite/mypage1.html?Ed displays statistics for requests made by user Ed for the URL /mysite/mypage1.html.

```
> stat stream identifier myidentifier ? ? -fullValues
```

Stream Session statistics

	Req	BandW
/mysite/mypage2.html?Grace	1	2553
/mysite/mypage1.html?Grace	2	4
/mysite/mypage1.html?Ed	8	16
/mysite/mypage2.html?Joe	1	2554
/mysite/mypage1.html?Joe	5	10
/mysite/?Joe	1	4

RspTime	Conn
---------	------

```

/mysite/mypage2.html?Grace      0      0
/mysite/mypage1.html?Grace      0      0
/mysite/mypage1.html?Ed         0      0
/mysite/mypage2.html?Joe        0      0
/mysite/mypage1.html?Joe        0      0
/mysite/?Joe                    6      0
Done

```

Example 2

In the following command, the pattern used is * ?. The appliance groups the output on the values accumulated for the second expression HTTP.REQ.HEADER("UserHeader"). The rows display statistics for all requests made by users Grace, Ed, and Joe.

```

> stat stream identifier myidentifier * ?
Stream Session statistics
      Req  BandW  RspTime  Conn
Grace    3  2557    0    0
Ed       8   16     0    0
Joe      7  2568    6    0
Done

```

Example 3

In the following command, the pattern used is ? *, which is the default pattern. The output is grouped on the values collected for the first selector expression. Each row displays statistics for one URL.

```

> stat stream identifier myidentifier ? * -fullValues
Stream Session statistics
      Req      BandW
/mysite/mypage2.html      2      5107
/mysite/mypage1.html     15       30
/mysite/                   1       4

      RspTime      Conn
/mysite/mypage2.html      0       0
/mysite/mypage1.html      0       0
/mysite/                   6       0
Done

```

Example 4

In the following command, the pattern used is ** . The appliance displays one set of collective statistics for all the requests received, with no row title.

```

> stat stream identifier myidentifier **
Stream Session statistics
      Req  BandW  RspTime  Conn
      18  5141   6    0
Done

```

Example 5

In the following command, the pattern is /mysite/mypage1.html *. The appliance displays one set of collective statistics for

all the requests received for the URL /mysite/mypage1.html, with no row title.

```
> stat stream identifier myidentifier /mysite/mypage1.html *
```

Stream Session statistics

Req	BandW	RspTime	Conn
15	30	0	0

Done

To group the records on the values of selector expressions by using the configuration utility

1. Navigate to AppExpert > Action Analytics > Stream Identifiers.
2. In the details pane, click the stream identifier for which you want to view statistics, and then click Stream Sessions.
3. On the Home page, click the icon for the stream selector by which you want to group the output.
4. To return to the Home page from the statistics page for a selector expression, click Home.
5. To view statistics for the value of a given selector expression, click the value. You can repeat this step for a selector expression value in each subsequent output until you obtain the statistics you want.

Clearing a Stream Session

Aug 30, 2013

You can flush all the records that have been accumulated for a stream identifier.

To clear a stream session by using the command line interface

At the command prompt, enter the following commands to clear a stream session and verify the results:

- clear stream session <name>
- stat stream identifier <name>

Example

This example uses the stat stream identifier command first, so that a comparison can be made with the stat stream identifier command that is used for verifying the result of the clear stream session command.

```
>stat stream identifier myidentifier
Stream Session statistics
      Req  BandW  RspTime  Conn
/aed....html  2    0    0    0
/           636   303   12    0
Done
>clear stream session myidentifier
Done
>stat stream identifier myidentifier
Done
```

To clear a stream session by using the configuration utility

1. Navigate to AppExpert > Action Analytics > Stream Identifiers.
2. Select the stream identifier whose sessions you want to clear, and then click Clear Sessions.

Configuring a Policy for Analyzing and Optimizing Traffic

Sep 16, 2013

To put the selector-identifier pair in your action analytics configuration into effect, you must associate the pair with the point in the traffic flow at which you want to collect statistics. You can do so by configuring a default syntax policy and referencing the stream identifier from the policy rule. You can use compression policies, caching policies, rewrite policies, application firewall policies, responder policies, and any other policies whose action is based on a Boolean expression.

The action analytics feature introduces a set of default syntax expressions and functions for collecting and evaluating data. The expression `ANALYTICS.STREAM(<identifier_name>)` is used for referencing the identifier that you want to use. The expression `COLLECT_STATS` is used to collect statistical data. Functions such as `IS_TOP(<uint>)` and `IS_TOP_FREQUENTS(<uint>)` are used for making automatic, real-time traffic optimization decisions.

- **IS_TOP(<number>)**. Finds if a given object is in the top <number> of elements. For example, is the element among the top 10 elements. When multiple elements have the count, they are considered to be similar in nature. The sort function must be turned on to avoid an undef condition.
- **IS_TOP_FREQUENTS(<frequency>)**. Finds if a given object is in the top <frequency> of the elements that are in the top elements. For example, is the element among the top 50% of all the top elements maintained. Elements having the same values are considered similar in nature. The sort function must be turned on to avoid an undef condition.

It is your policy configuration that determines whether the NetScaler appliance must only collect data from traffic or also perform an action. If the appliance must only collect statistical data, you can configure a policy with the rule `ANALYTICS.STREAM(<identifier_name>).COLLECT_STATS` and the action `NOOP`. The `NOOP` policy must be the policy with the highest priority at the bind point. This policy is sufficient if you are only collecting statistics. Traffic optimization decisions, such as what to compress or cache, must be based on manual, periodic evaluation of the statistical data.

If, in addition to collecting statistics, the appliance must also perform an action on the traffic, you must configure the `gotoPriorityExpression` parameter of the `NOOP` policy such that another policy that has the desired rule and action is evaluated subsequently. This second policy must have a rule that begins with the `ANALYTICS.STREAM(<identifier_name>)` prefix and a function that evaluates the data.

Following is an example of two responder policies that are configured and bound globally. The policy `responder_stat_collection` enables the appliance to collect statistics based on the identifier, `myidentifier`. The policy `responder_notify` evaluates the data that is collected.

Example

```
> add responder action send_notification respondwith "You are in the Top 10 list for bandwidth consumption"  
Done  
> add responder policy responder_stat_collection 'ANALYTICS.STREAM("myidentifier").COLLECT_STATS' NOOP  
Done  
> add responder policy responder_notify 'ANALYTICS.STREAM("myidentifier").BANDWIDTH.IS_TOP(10)' send_notification  
Done  
> bind responder global responder_stat_collection 10 NEXT  
Done  
> bind responder global responder_notify 20 END
```

Done

Use Case: Limiting Bandwidth Consumption per User or Client Device

Sep 16, 2013

Your web site, application, or file hosting service has finite network and server resources available to it to serve all its users. One of the most important resources is bandwidth. Substantial bandwidth consumption by only a subset of the user base can result in network congestion and reduced resource availability to other users. To prevent network congestion, you might have to limit a client's bandwidth consumption by using temporary service denial techniques such as responding to a client request with an HTML page if it has exceeded a preconfigured bandwidth value over a fixed time period leading up to the request.

In general, you can regulate bandwidth consumption either per client device or per user. This use case demonstrates how you can limit bandwidth consumption per client to 100 MB over a time period of one hour. The use case also demonstrates how you can regulate bandwidth consumption per user to 100 MB over a time period of one hour, by using a custom header that provides the user name. In both cases, the tracking of bandwidth consumption over a moving time period of one hour is achieved by setting the interval parameter in the stream identifier to 60 minutes. The use cases also demonstrate how you can import an HTML page to send to a client that has exceeded the limit. Importing an HTML page not only simplifies the configuration of the responder action in these use cases, but also simplifies the configuration of all responder actions that need the same response.

To limit bandwidth consumption per user or client device by using the command line interface

In the command-line interface, perform the following tasks to configure action analytics for limiting a client's or user's bandwidth consumption. Each step includes sample commands and their output.

1. **Set up your load balancing configuration.** Configure load balancing virtual server `mysitevip`, and then configure all the services that you need. Bind the services to the virtual server. The following example creates ten services and binds the services to `mysitevip`.

```
> add lb vserver mysitevip HTTP 192.0.2.17 80
Done
> add service service[1-10] 192.0.2.[240-249] HTTP 80
service "service1" added
service "service2" added
service "service3" added
.
.
.
service "service10" added
Done
> bind lb vserver vserver1 service[1-10]
service "service1" bound
service "service2" bound
service "service3" bound
.
.
.
```

service "service10" bound

Done

2. **Configure the stream selector.** Configure one of the following stream selectors:

- To limit bandwidth consumption per client, configure a stream selector that identifies the client IP address.

```
> add stream selector myselector CLIENT.IP.SRC
```

Done

- To limit bandwidth consumption per user on the basis of the value of a request header that provides the user name, configure a stream selector that identifies the header. In the following example, the name of the header is UserHeader.

```
> add stream selector myselector HTTP.REQ.HEADER("UserHeader")
```

Done

3. **Configure a stream identifier.** Configure a stream identifier that uses the stream selector. Set the interval parameter to 60 minutes.

```
> add stream identifier myidentifier myselector -interval 60 -sampleCount 1 -sort BANDWIDTH
```

Done

4. **Configure the responder action.** Import the HTML page that you want to send to users or clients that have exceeded the bandwidth consumption limit, and then use the page in responder action `crossed_limits`.

```
> import responder htmlpage http://192.0.2.20:80/stdpages/wait.html crossed-limits.html
```

This operation may take some time, Please wait...

Done

```
> add responder action crossed_limits respondwithhtmlpage crossed-limits.html
```

Done

5. **Configure the responder policies.** Configure responder policy `myrespol1` with the rule `ANALYTICS.STREAM("myidentifier").COLLECT_STATS` and the action `NOOP`. Then, configure policy `myrespol2` for determining whether a client or user has crossed the 100 MB limit. The policy `myrespol2` is configured with the responder action `crossed_limits`.

```
> add responder policy myrespol1 'ANALYTICS.STREAM("myidentifier").COLLECT_STATS' NOOP
```

Done

```
> add responder policy myrespol2 'ANALYTICS.STREAM("myidentifier").BANDWIDTH.GT(1048576)' crossed_limits
```

Done

6. **Bind the responder policies to the load balancing virtual server.** The policy `myrespol1`, which only collects statistical data, must have the higher priority and a `GOTO` expression of `NEXT`.

```
> bind lb vserver mysitevip -policyName myrespol1 -priority 1 -gotoPriorityExpression NEXT
```

Done

```
> bind lb vserver mysitevip -policyName myrespol2 -priority 2 -gotoPriorityExpression END
```

Done

7. **Test the configuration.** Test the configuration by sending test HTTP requests, from multiple clients or users, to the load balancing virtual server and using the `stat stream identifier` command to view the statistics that are collected for the specified identifier. The following output displays statistics for clients.

```
> stat stream identifier myidentifier -sortBy BandW -fullValues
```

Stream Session statistics

	Req	BandW
192.0.2.30	5000	3761
192.0.2.31	29	2602
192.0.2.32	25	51

	RspTime	Conn
192.0.2.30	2	0
192.0.2.31	0	0
192.0.2.32	0	0
Done

AppExpert Applications and Templates

May 21, 2015

An AppExpert application is a collection of configuration information that you set up on the Citrix NetScaler appliance for securing and optimizing traffic for a Web application, such as Microsoft SharePoint. Managing AppExpert applications is simplified by a graphical user interface (GUI) that allows you to specify application traffic subsets and a distinct set of security and optimization policies for processing each traffic subset. Additionally, it consolidates all deployment tasks in one view, so you can quickly configure target IP addresses for clients and specify host servers.

Prebuilt application templates for widely used Web applications, such as Microsoft Outlook Web Access and Microsoft SharePoint, are available on the AppExpert Templates page of the Citrix Community website at "<http://community.citrix.com/display/ns/AppExpert+Templates>."

Each prebuilt template provides you with an initial configuration for managing the associated Web application. You can customize prebuilt application templates for your organization. If a prebuilt application template does not suit your requirements, you can create a custom application without using a template.

Regardless of whether you use a prebuilt application template or you create a custom application, you can export the configuration to a template file. You can then share the template with other administrators or import the template to other NetScaler appliances that require a similar AppExpert application configuration.

To get started with an AppExpert application, you must first obtain the appropriate application template and import the template to the NetScaler appliance. After the AppExpert application is set up, you must verify that the application is working correctly. If required, you can customize the configuration to suit your requirements.

Periodically, you can verify and monitor the configuration by viewing the hit counters for various application components, statistics, and the Application Visualizer. You can also configure authentication, authorization, and auditing (AAA) policies for the application.

AppExpert Application Terminology

Updated: 2013-08-30

Following are the terms used in the AppExpert applications feature and the descriptions of the entities for which the terms are used:

Public Endpoint. The IP address and port combination at which the NetScaler appliance receives client requests for the associated web application. A public endpoint can be configured to receive either HTTP or secure HTTP (HTTPS) traffic. All client requests for the web application must be sent to a public endpoint. An AppExpert application can be assigned multiple endpoints. You configure public endpoints after you import a template.

Application Unit. An AppExpert application entity that processes a subset of web application traffic and load balances a set of services that host the associated content. The subset of traffic that an application unit must manage is defined by a rule. Each application unit also defines its own set of traffic optimization and security policies for the requests and responses that it manages. The NetScaler services associated with these policies are Compression, Caching, Rewrite, Responder, and application firewall.

By default, every AppExpert application with at least one application unit includes a default application unit, which cannot be deleted. The default application unit is not associated with a rule for identifying requests and is always placed last in the

order of application units. It defines a set of policies for processing any request that does not match the rules that are configured for the other application units, thereby ensuring that all client requests are processed.

Application units and their associated rules, policies, and actions are included in AppExpert application templates.

Service. The combination of the IP address of the server that hosts the web application instance and the port to which the application is mapped on the server, in the format <IP address>:<Port>. A web application that serves a large number of requests is usually hosted on multiple servers. Each server is said to host an instance of the web application, and each such instance of the web application is represented by a service on the NetScaler appliance. Services are deployment-specific, and are therefore not included in templates. You must configure services after you import a template.

Application Unit Rule. Either a classic expression or a default syntax expression that defines the characteristics of a traffic subset for an application unit. The following example rule is a default syntax expression that identifies a traffic subset that consists of four image types:

```
HTTP.REQ.URL.SUFFIX.EQ("bmp") || HTTP.REQ.URL.SUFFIX.EQ("gif") || HTTP.REQ.URL.SUFFIX.EQ("png") ||  
HTTP.REQ.URL.SUFFIX.EQ("jpg")
```

For more information about default syntax expressions and classic policy expressions, see "[Policies and Expressions](#)."

Traffic Subset. A set of client requests that require a common set of traffic optimization and security policies. A traffic subset is managed by an application unit and is defined by a rule.

How an AppExpert Application Works

When the endpoint receives a client request, the NetScaler appliance evaluates the request against the rule that is configured for the topmost application unit. If the request satisfies this rule, the request is processed by the policies that are configured for the application unit, and then forwarded to a service. The choice of service depends on which services are configured for the application, and on settings such as the load balancing algorithm and persistence method configured for the application unit.

If the request does not satisfy the rule, the request is evaluated against the rule for the next topmost application unit. In this order, the request is evaluated against each application unit rule until the request satisfies a rule. If the request does not satisfy any of the configured rules, it is processed by the default application unit, which is always the last application unit.

You can configure multiple public endpoints for an AppExpert application. In such a configuration, by default, each application unit processes requests received by all the public endpoints and load balances all the services that are configured for the application. However, you can specify that an application unit processes traffic from only a subset of the public endpoints and load balances only a subset of the services that are configured for the AppExpert application.

How AppExpert Application Works

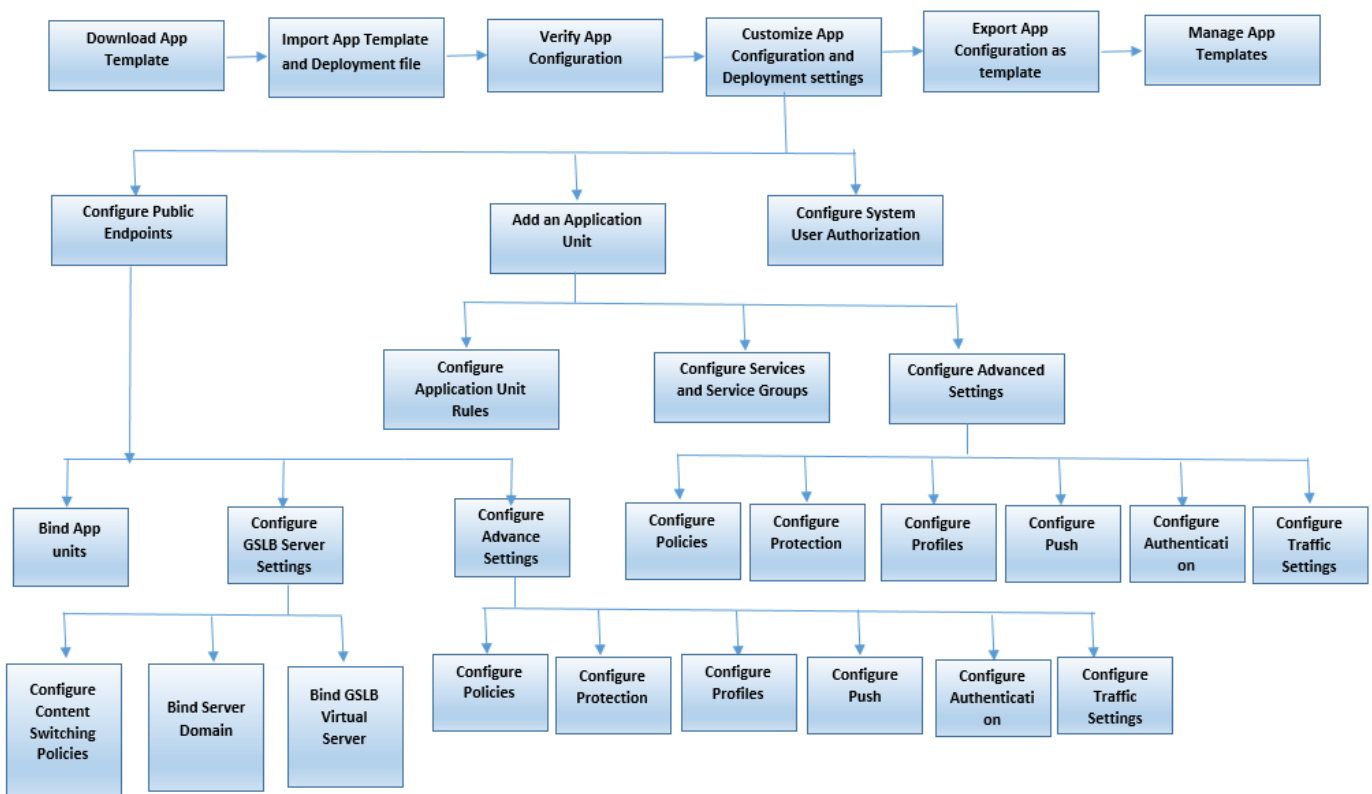

Jan 07, 2016

When the endpoint receives a client request, the NetScaler appliance evaluates the request against the rule that is configured for the topmost application unit. If the request satisfies this rule, the request is processed by the policies that are configured for the application unit, and then forwarded to a service. The choice of service depends on which services are configured for the application, and on settings such as the load balancing algorithm and persistence method configured for the application unit.

If the request does not satisfy the rule, the request is evaluated against the rule for the next topmost application unit. In this order, the request is evaluated against each application unit rule until the request satisfies a rule. If the request does not satisfy any of the configured rules, it is processed by the default application unit, which is always the last application unit.

You can configure multiple public endpoints for an AppExpert application. In such a configuration, by default, each application unit processes requests received by all the public endpoints and load balances all the services that are configured for the application. However, you can specify that an application unit processes traffic from only a subset of the public endpoints and load balances only a subset of the services that are configured for the AppExpert application.

The following flow diagram illustrates the AppExpert Application flow sequence for using a built-in application template.

If you prefer to create a customized application without using a template, do the following:

1. Create a custom application.

2. Configure application and deployment settings.
3. Export the configuration to new template files (optional).
4. Import the template files to other NetScaler appliances that require a similar AppExpert application configuration

Getting Started with an AppExpert Application

Jan 07, 2016

To get started with an AppExpert application, you must first obtain an application template and import the template to a NetScaler appliance. After the AppExpert application is set up, you must verify that the application is working correctly. If required, you can customize the configuration to suit your requirements.

Periodically, you can verify and monitor the configuration by viewing the hit counters for various application components. You can also configure authentication, authorization, and auditing (AAA) policies for the application.

The process of setting up an application can be done in two ways:

1. Using a prebuilt application template
2. Creating a custom application without using a template.

If you prefer to set up the application by using a prebuilt application template, do the following:

1. Download an application template.
2. Import template files to Netscaler appliance.
3. Verify application setup.
4. Configure application and deployment settings.
5. Export the configuration to new template files (optional).
6. Import the template files to other NetScaler appliances that require a similar AppExpert application configuration.

Downloading an Application Template

Jan 04, 2016

AppExpert application setup begins with downloading an application template from the Citrix Community Web site at <http://community.citrix.com/display/ns/AppExpert+Templates> to your local computer or NetScaler appliance. The application templates are designed to be imported and exported, so that you can easily share application-specific configurations within an organization or across organizations. An application template includes the following set of entities:

1. Application components (for example, web pages, files, archives, and web services)
2. Traffic management entities (for example, virtual server IP addresses and associated load-balancing algorithms, and SSL offload settings) for the application components.
3. Netscaler policies used for optimizing the application traffic.

Note: Application templates are available in different versions for configuring different types of NetScaler appliances.

Importing an Application Template

Jan 04, 2016

For NetScaler software version 9.3 or later, each AppExpert template has two XML files: a Template file and a Deployment file. You must import both files from your local computer to a Netscaler appliance. You can either import the template files from your computer to the AppExpert application templates directory in Netscaler appliance or upload files to a NetScaler appliance and then import them from the appliance.

Note: When you import a template from an appliance, you have to provide the variable value available in the template. By default, the pre-configured value is displayed.

After you import the template files, the application-configuration and deployment information populates the target application automatically. The appliance imports all the configuration from the template files through the NITRO API. If you do not import the deployment file, the system generates an application populated with content switching virtual server configuration. For more information about the format of application templates and deployment files, see "[Understanding Netscaler Application Templates and Deployment Files](#)" section.

When you import a template, if you do not include a deployment file, you have to configure the public endpoints in the application that the system automatically generates from the template. One endpoint for HTTP and another endpoint for HTTPS. When configuring a public endpoint of type HTTPS, make sure you enable the SSL feature, bind the server certificate, and include the server-certificate and certificate-key files.

For more information about configuring endpoints after you import a template, see "[Configuring Public Endpoints](#)" topic.

To import AppExpert application template files to a NetScaler appliance by using the configuration utility:

1. Navigate to **AppExpert > Applications**.
2. In the details pane, click **Import Template**.
3. On the **Import** page, set the following parameters:
 1. Application Name (mandatory)
 2. Template File (mandatory)
 3. Use deployment file
4. Click **Continue** to auto populate application-configuration and deployment information into an application.

Verifying and Testing Application Configuration

Jan 06, 2016

Verifying the Configuration

The NetScaler configuration utility includes icons that indicate the states of the entities in the AppExpert application. These icons are displayed for applications and application units and are based on the health checks that the NetScaler appliance performs periodically on services and entities. The following table lists the icons and describes their meanings.

Table 1. Descriptions of State Indicator Icons

Icon	Entity	Indicates that
	Application	At least one public endpoint is up. The application will accept client requests from the public endpoints that are up.
	Application unit	The application unit is up. The application unit is up when at least one service or service group is up.
	Application	The public endpoint is out of service (disabled). This indicator is displayed when only one public endpoint is configured for the AppExpert application.
	Application	All the endpoints that are configured for the application are out of service. This indicator is displayed only when multiple endpoints are configured for the application.
	Application unit	All the services configured for the application unit are down.

You must ensure that the icons for each application and its application units are green at all times. If the icon that is displayed for an application is not green, verify that you have configured the public endpoints correctly. If the icon that is displayed for an application unit is not green, verify that the services are configured correctly. However, note that a green indicator does not mean that the state of all associated entities is UP. It only means that the application has sufficient resources (endpoints and services) to serve client requests. To verify that the state of all associated entities is UP, check the health of all the entities on the statistics page for the application.

Customizing the Configuration

Jan 07, 2016

After you verify that the AppExpert application is working correctly, you can customize the configuration to suit your requirements.

You can configure public endpoints and services for the AppExpert application and specify only a subset of the endpoints and services for each application unit. When you want the AppExpert application to manage a traffic subset that is not included in the template, you can either add an application unit for the new traffic subset or modify an existing application unit rule. You can also specify the order of evaluation of the traffic subsets that the AppExpert application manages.

Finally, you can modify the policies that the template provided. If the AppExpert application template does not include policies for a particular NetScaler feature, such as Rewrite or application firewall, you can configure your own policies.

The order in which you perform these tasks depends on your requirement. However, before you configure a service for an application, you must configure the service for the parent application.

Configuring Public Endpoints

Aug 30, 2013

If you did not specify a public endpoint when importing an AppExpert application, you can specify public endpoints after you create the application. You can configure one public endpoint of type HTTP and one public endpoint of type HTTPS for your AppExpert application.

If endpoints are already configured for the application, you can dissociate endpoints from the AppExpert application and delete any endpoints that you no longer need. Note that when you dissociate a public endpoint from the AppExpert application, the endpoint is automatically unbound from the associated application unit, but it is not deleted from the system.

To configure public endpoints for an AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application for which you want to configure public endpoints, and then click Configure Public Endpoints.
3. In the Choose Public Endpoints dialog box for the application, do one of the following:
 - If the endpoints you want are listed in the dialog box, click the corresponding check boxes.
 - If you want to specify all the public endpoints, click Activate All.
 - If you want to dissociate endpoints from the AppExpert application, clear the corresponding check boxes.
 - If you want to create a new public endpoint, click Add. Then, in the Create public endpoint dialog box, configure endpoint settings, and then click OK.

In the Create public endpoint dialog box, you can specify only the name, IP address, port, and protocol for the endpoint. You can specify additional endpoint settings after you create the public endpoint. To specify additional endpoint settings, after you create the endpoint, in the Choose Public Endpoints dialog box, click the endpoint, and then click Open. Then, in the Configure Public Endpoint dialog box, provide additional settings, and then click OK.

For more information about the parameters in the Create public endpoint and Configure Public Endpoint dialog boxes, see "[Content Switching](#)."

- If you want to modify a public endpoint, click the endpoint, and then click Open. Then, in the Configure Public Endpoint dialog box, modify settings for the endpoint, and then click OK.

For more information about the parameters in the Configure Public Endpoint dialog box, see "[Content Switching](#)."

4. Click Close.

Configuring Endpoints for an Application Unit

Aug 30, 2013

When you configure multiple public endpoints for an AppExpert application, by default, all endpoints are bound to each application unit, and each application unit processes the requests received by all the endpoints. However, you can specify that a given application unit manages the traffic that is received by only a subset of the endpoints that are configured for the AppExpert application.

To configure endpoints for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application unit for which you want to specify public endpoints, and then click Configure Public Endpoints.
3. In the Choose Public Endpoints dialog box for the application unit, do one of the following:
 - If you are specifying endpoints for the application unit for the first time, clear the check boxes that correspond to the endpoints that you do not want to be bound to the application unit.
 - If you want to specify endpoints that are listed in the dialog box but not currently bound to the application unit, click the corresponding check boxes.
4. Click OK.

Configuring Services and Service Groups

Aug 30, 2013

When you configure a service or service group, you either modify an existing service or service group, or add new services to the AppExpert application. You add services or service groups if you did not specify them when you imported the application template. You also add services and service groups when you increase the number of servers that host instances of the application. You can configure a service and service group for an application unit only after you configure the service or service group for the AppExpert application.

To configure a service or service group for the AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application for which you want to configure services or service groups, and then click Configure Backend Services.
3. In the Configure Backend Services dialog box, do one of the following:
 - To configure services, click the Services tab.
 - To configure service groups, click the Service Groups tab.
4. On the Service or Service Groups tab, do one of the following:
 - If the services or service groups that you want are listed on the tab, click the corresponding check boxes.
 - If you want to specify all the services or service groups, click Activate All.
 - If you want to create a new service or service group, click Add. Then, in the Create Service dialog box or Create Service Group dialog box, configure settings for the service or service group, respectively, and then click Create.
 - If you want to modify a service, click the service, and then click Open. Then, in the Configure Service dialog box or Create Service Group dialog box, configure settings for the service or service group, respectively, and then click OK.

For information about the settings in the Create Service, Configure Service, and Create Service Group dialog boxes, see "[Load Balancing](#)."

Configuring Services, Service Groups, and Load Balancing Parameters for an Application Unit

Aug 30, 2013

When you configure services and service groups for an AppExpert application, by default, all the services and service groups are bound to each application unit. However, depending on how you have configured your web application, the application resources that are managed by an application unit might be hosted on only some of the servers that are configured as services for the AppExpert application. Or, a set of servers might host content that is meant for the requests received at one or more specific public endpoints. In such scenarios, if all the services and service groups that are configured for the AppExpert application are associated with the application unit, a request that is forwarded to a server that does not host the requested content might not be served or might be served incorrect content. Therefore, you must ensure that each application unit is configured to manage only those services that can serve the requested content.

When configuring services and service groups for an application unit, you might choose to specify load balancing settings such as the weights that services must be assigned and the desired load balancing, persistence, and spillover methods. For more information about these settings, see [Load Balancing](#).

To configure services or service groups for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application unit for which you want to configure a service or service group, and then click Configure Backend Services.
3. In the Configure Backend Services dialog box, do one of the following:
 - To configure services, click the Services tab.
 - To configure service groups, click the Service Groups tab.
4. In the Services or Service Groups tab, do one of the following:
 - Clear the check boxes that correspond to the services or service groups that you do not want configured for the application unit. Make sure that the check boxes that correspond to the services or service groups that you want configured for the application unit are selected. Then, in the Weight column, specify the weight that you want to assign to each configured service.
 - To specify all services or service groups, click Activate All.
5. On the Method and Persistence and Advanced tabs, specify the desired parameters.
6. Click OK.

Creating Application Units

Aug 30, 2013

You might need to add application units for traffic subsets that are either specific to your web application implementation or not defined in the template. When creating an application unit, you must configure a rule for the application unit.

To create an application unit for the AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application for which you want to add an application unit, and then click Add.
3. Click Create.

Configuring Application Unit Rules

Aug 30, 2013

You might want to configure an application unit rule to include or exclude certain types of traffic. When you configure the rule, you can also define the syntax of the expression.

To configure an application unit rule

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Applications.
2. In the details pane, right-click the application unit for which you want to modify the rule, and then click Open.
3. In the Configure Application Unit dialog box, do the following:
 1. To specify the format of the new expression, do one of the following:
 - To specify that you want to configure a classic expression in the Rule box, click Classic Syntax.
 - To specify that you want to configure an advanced expression in the Rule box, click Default Syntax.
 2. In the Rule box, configure the expression.
4. Click OK.

Specifying the Order of Evaluation of Application Units

Aug 30, 2013

Application unit rules are evaluated in the order in which they are placed in the graphical user interface (GUI). The rule that is configured for the topmost application unit is always configured first, followed by the rule that is configured for the second topmost application unit, and so on. The default application unit is always evaluated last.

When a request matches the rule that is configured for an application unit, the request is processed by the application unit, and no further matching is performed. Therefore, the order of evaluation of application units becomes an important factor if the traffic subsets for two or more application units overlap. If the traffic subsets for two or more application units overlap, you must specify the order in which an incoming request is matched against the application unit rules.

To specify the order of evaluation of application units

1. Navigate to AppExpert > Applications.
2. In the details pane, do the following:
 - To move an application unit up by one step, right-click the application unit, and then click Move Up.
 - To move an application unit down by one step, right-click the application unit, and then click Move Down.

Configuring Policies for Application Units

Apr 24, 2014

For an AppExpert application, you can configure policies for Compression, Caching, Rewrite, Responder, and Application Firewall. The templates that you download from the Citrix Community web site provide you with a set of policies that fulfill the most common application management requirements. You might want to fine-tune or customize these policies. If the set of policies provided for a given application unit does not include policies for a particular feature, you can create and bind your own policies for that feature.

If you create an AppExpert application without using a template, you must configure all the policies that the web application needs.

The GUI uses various icons to indicate whether or not policies are configured for a feature. For an application unit, if a policy is configured for a given feature, an icon that represents the feature is displayed. For example, if a compression policy is configured for an application unit, a compression icon is displayed in the Compression column for the application unit. For features for which no policy is configured, an icon depicting a plus sign (+) is displayed.

Note: When configuring policies for application units, you might need to configure policies and expressions that are either in the classic or default syntax. Additionally, when you configure default syntax policies, you might need to specify parameters such as Goto expressions and invoke policy banks. For information about configuring policies and expressions in both formats, see "[Policies and Expressions](#)."

Configuring Compression Policies

You can use either classic policies or advanced policies to configure compression, but you cannot bind compression policies of both types to the same application unit.

To configure a compression policy for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, in the row for the application unit you want to configure, click the icon provided in the Compression column.
3. In the Configure Compression Policies dialog box, do one or more of the following, depending on the configuration tasks you want to perform:
 - Click Switch to Default Syntax if you want to configure a default syntax compression policy. If you want to bind or configure classic compression policies, and if you are in the default syntax view, you can click Switch to Classic Syntax to return to the classic policy view and begin modifying bound classic policies or create and bind new classic compression policies.

Important: This setting also determines what policies are displayed when you want to insert a policy. For example, if you are in the default syntax view, when you click Insert Policy, the list that appears in the Policy Name column will include only default syntax policies. You cannot bind policies of both types to an application unit.
 - If you want to configure classic policies, click either Request or Response, depending on whether you want the policy to be evaluated at request-time or at response-time.

You can configure both request-time and response-time classic compression policies for an application unit. After evaluating all of the request-time policies, if no match is found, the appliance evaluates response-time policies.
 - To modify a compression policy that is already bound to the application unit, click the name of the policy, and then click Modify Policy. Then, in the Configure Compression Policy dialog box, modify the policy, and then click OK.

For information about modifying a compression policy, see "[Compression](#)."

- To unbind a policy, click the name of the policy, and then click Unbind Policy.
- To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
- To regenerate assigned priorities, click Regenerate Priorities.
- To insert a new policy, click Insert Policy and, in the list that is displayed in the Policy Name column, click New Policy. Then, in the Create Compression Policy dialog box, configure the policy, and then click Create.

For information about modifying a compression policy, see "[Compression](#)."

- If you are configuring a default syntax expression, do the following:
 - In the Goto Expression column, select a Goto expression.
 - In the Invoke column, specify the policy bank that you want to invoke if the current policy evaluates to TRUE.
4. Click Apply Changes, and then click Close.

Configuring Caching Policies

You can use only default syntax policies and expressions to configure Caching policies.

To configure Caching policies for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, in the row for the application unit you want to configure, click the icon provided in the Caching column.
3. In the Configure Cache Policies dialog box, do one or more of the following, depending on the configuration tasks you want to perform:
 - Click either Request or Response, depending on whether you want the policy to be evaluated at request-time or at response-time.

You can configure both request-time and response-time Caching policies for an application unit. After evaluating all of the request-time policies, if no match is found, the appliance evaluates response-time policies.

- To modify a Caching policy that is already bound to the application unit, click the name of the policy, and then click Modify Policy. Then, in the Configure Cache Policy dialog box, modify the policy, and then click OK.

For information about modifying a Caching policy, see "[Integrated Caching](#)."

- To unbind a policy, click the name of the policy, and then click Unbind Policy.
- To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
- To regenerate assigned priorities, click Regenerate Priorities.
- To insert a new policy, click Insert Policy and, in the list that is displayed in the Policy Name column, click New Policy. Then, in the Create Cache Policy dialog box, configure the policy, and then click Create.

For information about modifying a Caching policy, see "[Integrated Caching](#)."

- In the Goto Expression column, select a Goto expression.
 - In the Invoke column, specify the policy bank that you want to invoke if the current policy evaluates to TRUE.
4. Click Apply Changes, and then click Close.

Configuring Rewrite Policies

You can use only default syntax policies and expressions to configure Rewrite policies.

To configure Rewrite policies for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, in the row for the application unit you want to configure, click the icon provided in the Rewrite column.
3. In the Configure Rewrite Policies dialog box, do one or more of the following, depending on the configuration tasks you want to perform:
 - Click either Request or Response, depending on whether you want the policy to be evaluated at request-time or at response-time.

You can configure both request-time and response-time Rewrite policies for an application unit. After evaluating all of the request-time policies, if no match is found, the appliance evaluates response-time policies.

- To modify a Rewrite policy that is already bound to the application unit, click the name of the policy, and then click Modify Policy. Then, in the Configure Rewrite Policy dialog box, modify the policy, and then click OK.

For information about modifying a Rewrite policy, see "[Rewrite](#)."

- To unbind a policy, click the name of the policy, and then click Unbind Policy.
- To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
- To regenerate assigned priorities, click Regenerate Priorities.
- To insert a new policy, click Insert Policy and, in the list that is displayed in the Policy Name column, click New Policy. Then, in the Create Rewrite Policy dialog box, configure the policy, and then click Create.

For information about modifying a Rewrite policy, see "[Rewrite](#)."

- In the Goto Expression column, select a Goto expression.
 - In the Invoke column, specify the policy bank that you want to invoke if the current policy evaluates to TRUE.
4. Click Apply Changes, and then click Close.

Configuring Responder Policies

You can use only default syntax policies and expressions to configure Responder policies.

To configure Responder policies for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, in the row for the application unit you want to configure, click the icon provided in the Responder column.
3. In the Configure Responder Policies dialog box, do one or more of the following, depending on the configuration tasks you want to perform:
 - To modify a Filter policy that is already bound to the application unit, click the name of the policy, and then click Modify Policy. Then, in the Configure Responder Policy dialog box, modify the policy, and then click OK.

For information about modifying a Responder policy, see "[Responder](#)."

- To unbind a policy, click the name of the policy, and then click Unbind Policy.
- To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
- To regenerate assigned priorities, click Regenerate Priorities.

- To insert a new policy, click Insert Policy and, in the list that is displayed in the Policy Name column, click New Policy. Then, in the Create Responder Policy dialog box, configure the policy, and then click Create.

For information about modifying a Responder policy, see "[Responder](#)."

- In the Goto Expression column, select a Goto expression.
 - In the Invoke column, specify the policy bank that you want to invoke if the current policy evaluates to TRUE.
4. Click Apply Changes, and then click Close.

Configuring Application Firewall Policies

You can configure both classic and default syntax policies and expressions for Application Firewall. However, if a policy of one type is already bound globally or to a virtual server that is configured on the appliance, you cannot bind a policy of the other type to an application unit. For example, if a default syntax policy is already bound either globally or to a virtual server, you cannot bind a classic policy to an application unit.

To configure Application Firewall policies for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, in the row for the application unit you want to configure, click the icon provided in the Application Firewall column.
3. In the Configure Application Firewall Policies dialog box, do one or more of the following, depending on the configuration tasks you want to perform:

- Click either Classic Expression or Advanced Expression depending on the type of expression you want to configure for the Application Firewall policy.

Important: This setting also determines what policies are displayed when you want to insert a policy. For example, if you select Advanced Expression, when you click Insert Policy, the list that appears in the Policy Name column will include only default syntax policies. You cannot bind policies of both types to an application unit. This option is not available if a policy of either type is already bound either globally or to a virtual server.

- To modify an application firewall policy that is already bound to the application unit, click the name of the policy, and then click Modify Policy. Then, in the Configure Application Firewall Policy dialog box, modify the policy, and then click OK.

For information about modifying a application firewall policy, see "[Policies](#)."

- To unbind a policy, click the name of the policy, and then click Unbind Policy.
- To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
- To regenerate assigned priorities, click Regenerate Priorities.
- To insert a new policy, click Insert Policy and, in the list that is displayed in the Policy Name column, click New Policy. Then, in the Create Application Firewall Policy dialog box, configure the policy, and then click Create.

For information about modifying a application firewall policy, see "[Policies](#)."

4. Click Apply Changes, and then click Close.

Configuring Persistency Groups for Application Units

Aug 30, 2013

You can configure a persistency group for the application units in an AppExpert application. In the context of an AppExpert application, a persistency group is a group of application units that you can treat as a single entity for the purpose of applying common persistence settings. When the application is exported to an application template file, the persistency group settings are included, and they are automatically applied to the application units when you import the AppExpert application.

To configure a persistency group for an application by using the configuration utility

1. Navigate to AppExpert > Applications.
2. In the Applications View dialog box, click the name of the application for whose application units you want to configure a persistency group, and then click Configure Persistency Groups.
3. In the Configure Persistency Groups dialog box, do one of the following:
 - To add a persistency group, click Add.
 - To modify a persistency group, click Open.
4. In the Create Persistency Group or Configure Persistency Group dialog box, set the following parameters:
 - **Group Name***—Name of the persistency group. For the NetScaler appliance to recognize the persistency group as part of the application's configuration, the name of the AppExpert application must be included in the name of the persistency group, as a prefix. Therefore, by default, the appliance displays the prefix in the Group Name box, and you cannot remove that prefix. Enter a name of your choice after the prefix.
 - **Persistence**—Type of persistence for the virtual server. If you select SOURCEIP, in the IPv4 Netmask box, enter a network mask that specifies the number of bits that the appliance must consider when creating persistence sessions. If you select COOKIEINSERT, in the Cookie Domain and Cookie Name boxes, specify a domain attribute to send in the Set-Cookie directive, and a name for the cookie, respectively.
 - **Timeout**—Time period for which a persistence session is in effect.
 - **Backup Persistence**—Type of backup persistence for the group.
 - **Backup Timeout**—Time period, in minutes, for which backup persistence is in effect.
 - **Application Units**—To add an application unit to the persistency group, in the Available Application Units box, click the application unit, and then click Add. To remove an application unit from the persistency group, in the Configured Application Units box, click the application unit, and then click Remove.
5. Click OK.

Viewing AppExpert Applications and Configuring Entities by Using the Application Visualizer

Aug 30, 2013

The Application Visualizer is a graphical representation of an AppExpert application. The Visualizer displays the public endpoints, application units, backend services, and policies that are configured for the application. You can use the Visualizer to obtain a visual overview of an AppExpert application's configuration and configure some of the displayed entities. By default, the Visualizer displays application units, services, and monitors for the selected application.

To view an AppExpert application by using the Application Visualizer

1. Navigate to AppExpert > Applications.
2. In the details pane, click the name of the application that you want to view, and then click Visualizer.
3. Do one or more of the following:
 - To optimize the display area, choose Best Fit, Zoom In, or Zoom out. If an item that you want to see disappears from view after zooming in, you can click and drag the viewable area.
 - To save the graph as an image file, click Save Image.
 - To find a particular entity, in the Search in field, type an entity name. In the view area, the entity names that begin with the search string are highlighted. To restrict the search, click the drop-down menu and select the specific entity that you want to search for.
 - To view the policies that an application uses, click one or more icons to display feature-specific policies. The policy types are Compression, Filter, Rewrite, Responder, Cache, application firewall, Authorization, Auditing, HTML Injection, SureConnect, Priority Queuing, and Traffic.
 - To view the rule that is configured for an application unit, click the curve that connects the public endpoint to the application unit. The rule is displayed on the Related Tasks tab.
 - To view the binding information for an application unit, policy, or monitor, click the displayed icon, click the Related Tasks tab, and then click Show Bindings
 - To view member services, click the icon for the service, click the Related Tasks tab, and then click Show Member Services.
 - To view detailed statistics for a public endpoint or application unit, click the icon that is displayed, click the Related Tasks tab, and then click Statistics.
 - To view the Load Balancing Visualizer for an application unit, click the application unit, click Related Tasks, and then click Visualizer.
 - To view the number of requests received per second at a given point in time by the load balancing virtual server and the number of hits per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time and has to be refreshed manually. To refresh this information, click Refresh Stats.

To configure and view entities in an AppExpert application by using the Application Visualizer

1. Navigate to AppExpert > Applications.
2. In the details pane, click the name of the application that you want to configure or view, and then click Visualizer.
3. Do one or more of the following:
 - To configure an entity that is displayed in the viewing area, click the icon for the entity, click the Related Tasks tab, and then click Modify public endpoint.In the Application Visualizer, you can modify only public endpoints and services.

- To bind additional monitors to a service, click the Available Resources tab, select Monitors from the drop-down list, and then click and drag a monitor to a service.
- To unbind a service from an application unit, click the curve that connects the application unit and the service, click Related Tasks, and then click Unbind.
- To unbind a monitor from a service, click the curve that connects the service and the monitor, click Related Tasks, and then click Unbind.
- To modify a monitor, click the monitor, click Related Tasks, and then click Open.
- To modify the binding parameters for a monitor, click the curve that connects the monitor to the associated service, click Related Tasks, and then click Modify Parameters.
- To apply a common service configuration across multiple service containers that are displayed when the services bound to a vserver do not have the same configuration, click the service container whose configuration you want to apply to all the containers, and then, in Related Tasks, click Apply Configuration.
- To view a comparative list of the parameters whose values differ across service containers, click the icon for a container, click the Related Tasks tab, and then click Service Attributes Diff. The comparative list helps you determine which service container has the service configuration that you want to apply to all the containers. After you determine which service container has the configuration you want, right-click the container, and then click Apply this Configuration.
- To copy the configuration of an entity (other than the configuration of the AppExpert application) to the local computer's clipboard, click the entity, click the Related Tasks tab, and then click Copy Properties. You can then paste the configuration information in a word processing document or spreadsheet.

Monitoring a NetScaler Application

Mar 18, 2011

After you customize the AppExpert application, you can view application statistics to make sure that the application and all its entities are working correctly. You can also use the Application Visualizer to monitor statistics associated with certain entities such as policies and virtual servers.

You can also view the hit counters for various entities at regular intervals to make sure that counters are being updated.

Viewing Application Statistics

Updated: 2013-08-30

In the Applications node, you can select an application and view the Statistics page for the application. On the Statistics page, you can monitor the health and states of public endpoints and application units, and view the following statistical information:

- Requests and responses per second for each of the public endpoints and application units.
- Bytes per second, at each endpoint, for incoming and outgoing traffic.
- Application unit hit counters and the number of client and server connections for each application unit.
- Statistics for the services that are bound to the application units.

On the Statistics page, you can also view CPU usage, memory usage, and system logs.

To view statistics for an application

1. Navigate to AppExpert > Applications.
2. In the details pane, click the application for which you want to view statistics, and then click Statistics.

Monitoring an Application by Using the Application Visualizer

Updated: 2013-08-30

You can use the Application Visualizer to monitor the number of requests received per second at a given point in time by the vservers and the number of hits per second at a given point in time for Rewrite, Responder, and Cache policies.

To view statistical information for vservers, Rewrite policies, Responder policies, and Cache policies in the Visualizer

1. Navigate to AppExpert > Applications.
2. In the details pane, select the application for which you want to view statistical information, and then click Visualizer.
3. In the Application Visualizer window, do the following:
 - To view the statistics, click Show Stats.

The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time and has to be refreshed manually.

- To refresh the statistical information, click Refresh Stats.

Viewing Hits

Updated: 2013-08-30

The hit counters that are provided for various AppExpert application entities enable you to monitor the functioning of public endpoints and application units. For an application, the Hits dialog box displays the total number of requests received by each configured public endpoint. For an application unit, the Hits dialog box displays the number of requests that the application unit processed from each of the public endpoints and the total hit count. For instructions on viewing hit counters, see "[Verifying and Testing the Configuration](#)."

Deleting an Application

Jan 07, 2016

If you no longer need an application and its application units, you can delete it. When you delete an AppExpert application, backend services are not deleted, and any public endpoints that the application used become available for use by other applications.

When deleting an application, you are also prompted to specify whether you want to delete any bound policies and actions that are not used elsewhere.

To delete an application

1. Navigate to AppExpert > Applications.
2. In the details pane, click the name of the application that you want to delete, and then click Remove.

Configuring Authentication, Authorization, and Auditing

May 21, 2015

You can configure Authentication, Authorization, and Auditing (AAA) for the applications that you configure on the appliance. An authentication policy that is configured for an application defines the type of authentication to apply when a user or group attempts to access the application. If external authentication is used, the policy also specifies the external authentication server. Authorization policies configured for an application specify whether a particular user or group can access the application. Auditing policies define the audit log type, the level at which logging is performed, and other audit server settings. Authentication and auditing policies use the classic policy format.

Authentication policies, authorization policies, and auditing policies can be configured in any order. However, before you configure AAA for an application, you must configure a public endpoint for the application.

This document includes the following details:

- [Configuring Authentication](#)
- [Configuring Authorization](#)
- [Configuring Auditing](#)
- [Disabling AAA for an Application](#)

Configuring Authentication

Updated: 2013-08-30

Configuring authentication for an application involves specifying an authentication FQDN, an authentication virtual server, a server certificate, and authentication and session policies. Authentication policies are automatically bound to the authentication virtual server specified for the application.

To configure authentication for an AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, click the name of the application for which you want to configure authentication, and then click Authentication.
3. In the Authentication Wizard, on the Introduction page, click Next.
4. Follow the instructions in the Authentication Wizard.

Configuring Authorization

Updated: 2013-08-30

You can configure authorization for users and groups to enable them to access an AppExpert application. If the AAA user or group for which you want to configure permissions has not already been created, you can create it from AppExpert and then configure permissions for application access.

To configure permissions for a AAA user or group to access an AppExpert application

1. Navigate to AppExpert > Applications.

2. In the details pane, click the AppExpert application for which you want to configure user or group access, and then click Authorization.
3. Do one of the following:
 - If the AAA user or group for which you want to configure permissions is already in the Groups/Users tree, drag the user or group from the Groups/Users tree to the Users or Groups node in the application tree. Then, right-click the user or group and click Allow.
 - If the AAA user or group for which you want to configure permissions is not configured on the appliance, in the application tree, right-click Users or Groups, and then click Add. In the Create AAA Group or Create AAA User dialog box, fill in the values, click Create, and then click Close.

The user or group is created with the permission set to Allow. To change the permission setting, right-click the group or user, and then click the permission setting.

4. Click Close.

Configuring Auditing

Updated: 2013-08-30

When you configure auditing policies for an application, you must specify the server to which the log messages must be directed, the format of the messages logged, and the log level. Optionally, you can configure other settings, such as the log facility and date format. Auditing policies are automatically bound to all the AppExpert application's public endpoints.

To configure auditing policies for an application

1. Navigate to AppExpert > Applications.
2. In the details pane, click the application for which you want to configure auditing policies, and then click Auditing.
3. In the Configure Auditing Policies dialog box, click Insert Policy.
 - To specify an existing auditing policy, under Policy Name, click the name of the policy, and then do the following:
 - To modify the priority that is assigned to the policy by default, under Priority, double-click the priority, and then type a new priority value.
 - To modify the settings of the audit server, under Server, double-click the name of the server, and then, in the Configure Auditing Server dialog box, modify the settings as appropriate. You can modify all the settings in this dialog box except the name of the audit server and the audit type. For more information about the settings in the Configure Auditing Server dialog box, see "[Auditing Policies](#)."
 - To create a new auditing policy, under Policy Name, click New Policy, and then, in the Create Auditing Policy dialog box, do the following:
 - In the Name box, type a name for the policy.
 - The Name box already contains the string that is required at the beginning of the server name. You cannot modify the string.
 - From the Auditing Type list, select the auditing type (either SYSLOG or NSLOG).
 - If the audit server you want to specify is already listed in the Server list, select the server from the list, and then, if you want to modify the server settings, click Modify. In the Configure Auditing Server dialog box, modify the settings as appropriate, and then click OK. For more information about the settings in the Configure Auditing Server dialog box, see "[Auditing Policies](#)."
 - If you want to configure a new audit server, click New, and then, in the Create Auditing Server dialog box, type a name for the server, specify the server IP address, port number, and other settings as appropriate. When finished,

click OK.

- Click Create.
 - To change the priorities for the new auditing policies you created, under Priority, for each policy for which you want to change the priority, double-click the priority value and type new priority value.
 - To regenerate priorities, click Regenerate Priorities.
 - To unbind a policy, click the policy, and then click Unbind Policy.
 - To modify a policy, click the policy, and then click Modify Policy.
4. Click Apply Changes, and then click Close.

Disabling AAA for an Application

Updated: 2013-08-30

After you configure AAA for an application, you can disable the AAA configuration for that application. When you disable AAA for an application, the configuration is not lost. You can enable AAA for the application when you want to reapply the configuration.

To enable or disable AAA for an application

1. Navigate to AppExpert > Applications.
2. In the details pane, click the application for which you want to enable or disable AAA, and then do one of the following:
 - To disable AAA for the application, click Turn Off AAA.
 - To enable AAA for the application, click Turn On AAA.

Setting Up a Custom NetScaler Application

May 21, 2015

If an AppExpert application template is not available for the Web application that you want to manage through the NetScaler appliance, or if available AppExpert application templates do not suit your requirements, you can create an AppExpert application without a template.

To create an AppExpert application without a template, you must first create an application and application units. Then, you configure public endpoints, services, and service groups. Finally, you configure the policies that determine how application traffic is evaluated and processed.

After you create the application and application units and configure policies, you must verify the configuration and test it to make sure that it is working correctly, just as you would when you configure an application by using a prebuilt AppExpert application template. Then, you must monitor the application to make sure that the application and its entities are working correctly.

This document includes the following details:

- [Creating an Application](#)
- [Creating Application Units](#)
- [Configuring Public Endpoints for an AppExpert Application](#)
- [Configuring Public Endpoints for an Application Unit](#)
- [Configuring Services and Service Groups for an AppExpert Application](#)
- [Configuring Services and Service Groups for an Application Unit](#)
- [Configuring Policies](#)

Creating an Application

Updated: 2013-08-30

When you create an AppExpert application, the appliance creates a container to which you can add application units. The default application unit is not created until you create the first application unit.

To create an AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click Applications, and then click Add.
3. In the Create Application dialog box, in Name, enter a name for the application, and then click OK.

Creating Application Units

Updated: 2013-08-30

For each subset of traffic associated with your web application, you must create an application unit.

To create an application unit for the AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application for which you want to add an application unit, and then click Add.
3. Click Create.

Configuring Public Endpoints for an AppExpert Application

Updated: 2013-08-30

After you have created all the application units that you require, you must configure one or more public endpoints to enable clients to access the web application through the NetScaler appliance.

To configure public endpoints for an AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application for which you want to configure public endpoints, and then click Configure Public Endpoints.
3. In the Choose Public Endpoints dialog box for the application, do one of the following:
 - If the endpoints you want are listed in the dialog box, click the corresponding check boxes.
 - If you want to specify all the public endpoints, click Activate All.
 - If you want to dissociate endpoints from the AppExpert application, clear the corresponding check boxes.
 - If you want to create a new public endpoint, click Add. Then, in the Create public endpoint dialog box, configure endpoint settings, and then click OK.

In the Create public endpoint dialog box, you can specify only the name, IP address, port, and protocol for the endpoint. You can specify additional endpoint settings after you create the public endpoint. To specify additional endpoint settings, after you create the endpoint, in the Choose Public Endpoints dialog box, click the endpoint, and then click Open. Then, in the Configure Public Endpoint dialog box, provide additional settings, and then click OK.

For more information about the parameters in the Create public endpoint and Configure Public Endpoint dialog boxes, see "[Content Switching](#)."

- If you want to modify a public endpoint, click the endpoint, and then click Open. Then, in the Configure Public Endpoint dialog box, modify settings for the endpoint, and then click OK.

For more information about the parameters in the Configure Public Endpoint dialog box, see "[Content Switching](#)."

4. Click Close.

Configuring Public Endpoints for an Application Unit

Updated: 2013-08-30

For an application unit, you specify public endpoints in the same way as you would specify public endpoints for an application that is created from an AppExpert application template. For more information about specifying a subset of the endpoints for an application unit, see "[Configuring Endpoints for an Application Unit](#)."

To configure endpoints for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application unit for which you want to specify public endpoints, and then click Configure Public Endpoints.
3. In the Choose Public Endpoints dialog box for the application unit, do one of the following:
 - If you are specifying endpoints for the application unit for the first time, clear the check boxes that correspond to the endpoints that you do not want to be bound to the application unit.
 - If you want to specify endpoints that are listed in the dialog box but not currently bound to the application unit, click

the corresponding check boxes.

4. Click OK.

Configuring Services and Service Groups for an AppExpert Application

Updated: 2013-08-30

Services and service groups are available for application units only after you configure the services and service groups for the AppExpert application. Therefore, you must configure services and service groups for the AppExpert application before you configure the services for the application units. All the services and service groups that you configure for an AppExpert application must use the same protocol (either HTTP or HTTPS). The procedure for configuring services and service groups for an AppExpert application that is not created from a template is the same as that for an application created from a template.

To configure a service or service group for the AppExpert application

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application for which you want to configure services or service groups, and then click Configure Backend Services.
3. In the Configure Backend Services dialog box, do one of the following:
 - To configure services, click the Services tab.
 - To configure service groups, click the Service Groups tab.
4. On the Service or Service Groups tab, do one of the following:
 - If the services or service groups that you want are listed on the tab, click the corresponding check boxes.
 - If you want to specify all the services or service groups, click Activate All.
 - If you want to create a new service or service group, click Add. Then, in the Create Service dialog box or Create Service Group dialog box, configure settings for the service or service group, respectively, and then click Create.
 - If you want to modify a service, click the service, and then click Open. Then, in the Configure Service dialog box or Create Service Group dialog box, configure settings for the service or service group, respectively, and then click OK.

For information about the settings in the Create Service, Configure Service, and Create Service Group dialog boxes, see "[Load Balancing](#)."

Configuring Services and Service Groups for an Application Unit

Updated: 2013-08-30

After you configure services and service groups, you must configure services and service groups for each application unit. However, this step is not necessary if each backend service hosts all the content associated with the web application. You configure services and service groups for an application unit if the content associated with the application unit is hosted on only a subset of the backend servers.

To configure services or service groups for an application unit

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application unit for which you want to configure a service or service group, and then click Configure Backend Services.
3. In the Configure Backend Services dialog box, do one of the following:
 - To configure services, click the Services tab.
 - To configure service groups, click the Service Groups tab.

4. In the Services or Service Groups tab, do one of the following:
 - Clear the check boxes that correspond to the services or service groups that you do not want configured for the application unit. Make sure that the check boxes that correspond to the services or service groups that you want configured for the application unit are selected. Then, in the Weight column, specify the weight that you want to assign to each configured service.
 - To specify all services or service groups, click Activate All.
5. On the Method and Persistence and Advanced tabs, specify the desired parameters.
6. Click OK.

Configuring Policies

Updated: 2013-08-30

The procedures for configuring policies for an AppExpert application that is created without using a template are the same as those for an AppExpert application that was created from a template. For more information, see "[Configuring Policies for Application Units.](#)"

Creating and Managing Template Files

May 10, 2012

After you set up an AppExpert application and customize it to suit your requirements, you can create a template from the application and then share the template with other administrators. Or, you can create a template and then import the template to other NetScaler appliances that require a similar AppExpert application configuration. This simplifies and expedites the process of setting up similar applications on other appliances. You can also export a content switching configuration to a template file. When creating a template file, you can configure variables in the policy expressions and actions that are configured for an application.

AppExpert application template files can be exported either to the template directory on the NetScaler appliance or to a folder on your local computer. You can then upload and download the templates to and from the NetScaler appliance and rename the templates that are stored in the AppExpert application templates directory on your appliance.

This document includes the following information:

- [Exporting an AppExpert Application to a Template File](#)
- [Exporting a Content Switching Virtual Server Configuration to a Template File](#)
- [Creating Variables in Application Templates](#)
- [Uploading and Downloading Template Files](#)
- [Understanding NetScaler Application Templates and Deployment Files](#)

Exporting an AppExpert Application to a Template File

Sep 30, 2013

When you export an AppExpert application, all application-configuration information is exported to a template file and all deployment-specific information is exported to a deployment file. The string `_deployment` is automatically appended to the name of the template file to create the name of the deployment file. Both files are in XML format. If you choose to export the application template file to the NetScaler appliance, the template file is stored in the `/nsconfig/nstemplates/applications` directory on the NetScaler appliance and the deployment file is stored in the `/nsconfig/nstemplates/applications/deployment_files/` directory. For more information about the format of application templates and deployment files, see "[Understanding NetScaler Application Templates and Deployment Files](#)". If you have configured NetScaler Gateway application, when you export the AppExpert configuration, you can choose to include the NetScaler Gateway policies in the template.

To export an AppExpert application to a template file

1. Navigate to AppExpert > Applications.
2. In the details pane, click the name of the application that you want to export as a template file, and then click Export.
3. In the Export...as Template dialog box, do the following:
 1. In the Name box, modify the name of the template, if necessary.
 2. If you want to configure variables for the template, click Configure Variables, and then, in the Configure Variables dialog box, configure the variables that you want.

For more information about configuring variables in application templates, see "[Creating Variables in Application Templates](#)".

3. If you want to export the template file to the application templates directory on the appliance, make sure that Browse (Appliance) is displayed.
4. If you want to export the template file to your computer, click the Browse (Appliance) drop-down menu, click Local, browse to the location to which you want to save the file, and then click Save.
5. Provide the following information:
 - **Introduction Description**—Any text that introduces the AppExpert application template during import. This text is displayed on the Specify Application Name page of the AppExpert Template Wizard when the template is imported.
 - **Summary Description**—Any summary that you might want to display on the Summary page of the AppExpert Template Wizard when the template is imported.
 - **Author**—The name of the author of the template.
 - **Major**—The major version number of the template.
 - **Minor**—The minor version number of the template. This number is appended to the major version number and displayed on the Summary page of the AppExpert Template Wizard, during import, in the format Major.Minor.
6. Click OK.

If NetScaler Gateway policies have been configured for the application, you will be prompted to include the NetScaler Gateway configuration in the application template. If you want to include the NetScaler Gateway configuration in the template, at the prompt, click Yes.

Exporting a Content Switching Virtual Server Configuration to a Template File

Aug 30, 2013

You can also export a content switching configuration as an application template. You can export a content switching virtual server configuration to an application template either from the Content Switching Virtual Servers pane or from the Content Switching Visualizer. Configuration information, which includes the content switching virtual server, all associated load balancing virtual servers, services, service groups, and policies, is exported to a template file and all deployment-specific information is exported to a deployment file. The string "_deployment" is automatically appended to the name of the template file to create the name of the deployment file. Both files are in XML format. If you choose to export the application template file to the NetScaler appliance, the template file is stored in the /nsconfig/nstemplates/applications directory on the NetScaler appliance and the deployment file is stored in the /nsconfig/nstemplates/applications/deployment_files/ directory. For more information about the format of application templates and deployment files, see "[Understanding NetScaler Application Templates and Deployment Files](#)." The configuration information that is exported includes the content switching virtual server, all associated load balancing virtual servers, services, service groups, and policies.

However, if the content switching virtual server is already configured as the public endpoint for an AppExpert application, you cannot export the configuration to a template file. In this scenario, you must export the associated AppExpert application to a template. For more information about exporting an AppExpert application to a template file, see "[Exporting an AppExpert Application to a Template File](#)."

To export a content switching configuration to an application template file from the Content Switching Visualizer

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, click the name of the content switching virtual server whose configuration you want to export as a template file, and then click Visualizer.
3. In the Content Switching Visualizer, click the icon for the content switching vserver, click Related Tasks, and then click Create Template.
4. In the Export...as Template dialog box, enter a name for the template file, and then do one of the following:
 - To export the template file to the appliance, make sure that Browse (Appliance) is displayed.
 - To export the template file to your computer, click the Browse (Appliance) drop-down menu, click Local, browse to the location to which you want to save the file, and then click Save.
5. Provide the following information:
 - **Introduction Description**—Any text that introduces the AppExpert application template during import. This text is displayed on the Specify Application Name page of the AppExpert Template Wizard when the template is imported.
 - **Summary Description**—Any summary that you might want to display on the Summary page of the AppExpert Template Wizard when the template is imported.
 - **Author**—The name of the author of the template.
 - **Major**—The major version number of the template.
 - **Minor**—The minor version number of the template. This number is appended to the major version number and displayed on the Summary page of the AppExpert Template Wizard, during import, in the format Major.Minor.
6. Click OK.

To export a content switching configuration to an application template file from the Content Switching

Virtual Servers pane

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, click the name of the content switching virtual server whose configuration you want to export as a template file, and then click Create AppExpert Template.
3. Perform steps 4 through 6 described in "[To export a content switching configuration to an application template file from the Content Switching Visualizer](#)".

Creating Variables in Application Templates

Aug 30, 2013

Application templates support the declaration of variables in the policy expressions and actions that are configured for an application. The ability to declare variables in policy expressions and actions enables you to replace preconfigured values in expressions (for example, configurable parameters such as the host name of a server or the target for a Rewrite action) with values that suit the environment into which you are importing the template. If variables have been configured for an AppExpert application template, the AppExpert Template Wizard, which appears when you import an AppExpert application template, includes a Specify Variable Values page on which you can specify appropriate values for the variables that are configured for the template.

As an example, consider the following policy expression that is configured to evaluate the value of the Host header in an HTTP request:

```
HTTP.REQ.HEADER("Host").CONTAINS("server1")
```

If you want the server name to be configurable at import time, you can specify the string "server1" as a variable. When importing the template, you can specify a new value for the variable on the Variables tab.

After you create a variable, you can do the following:

- Assign additional strings to an existing variable. After you create a variable for a string, you can select and assign other parts of the same or different expression to the variable. The strings you assign to a variable need not be the same. At import time, all the strings that are assigned to the variable are replaced with the value that you provide.
- View the string or strings that are assigned to the variable.
- View a list of all the entities and parameters that use the variable.

In the export application template wizard, you can define variables in certain fields (fields with an adjacent  button) for the following entities:

- Cache policies
- Rewrite policies
- Rewrite actions
- Responder policies
- Responder actions

To configure a variable in a policy expression or action

1. Navigate to AppExpert > Applications.
2. In the details pane, right-click the application that you want to export to a template file, and then click Export.
3. In the Export...as Template dialog box, modify the default template file name if required, specify the location where you want to save the template, and then click Configure Variables.
4. In the Configure Variables dialog box, click the tab that lists the policy expression or action for which you want to configure a variable, select the expression, and then click Configure Variables.
5. In the Variables dialog box, click the  button next to the expression or value in which you want to create a variable.
6. In the Variables dialog box, do the following:
 - To create a variable, in the text box that displays the configured expression or value, select the string that you want to be configurable at import time, and then click Add. In the Add Variable dialog box, specify a name and a description for the variable, and then click Create.

- The name of the variable, its value, and the description you provided appear in the Available Variables listing in the dialog box. The name you provide will be the name of the associated field in the template import wizard, and the description will appear as alt text when the user positions the mouse pointer over the field.
- To modify a variable, in the Available Variables list, click the variable, and then click Open. In the Add Variable dialog box, modify the value and the description, and then click OK.
- To view all the strings that are assigned to a given variable, in the Available Variables listing, click the name of the variable. The strings that are assigned to the variable are highlighted.
- To view a list of all the entities and parameters in which the variable is used, in the Available Variables listing, click the variable whose references you want to view, and then click Show References.
- To assign a string to an existing variable, in the text box that displays the expression you configured, select the string you want to assign to an existing variable, right-click the selection, click Use Existing Selection, and then click the name of the variable to which you want to assign the string.

If a variable has multiple strings assigned to it, when you specify a new value for the variable during import, all strings assigned to the variable are replaced with the new value.

7. Click Close.

Uploading and Downloading Template Files

Aug 30, 2013

Template files can be uploaded from your local computer to the NetScaler appliance or downloaded from the appliance to your local computer. On the appliance, AppExpert application templates are always stored in the AppExpert application templates directory, which is `/nsconfig/nstemplates/applications/`.

To upload an AppExpert application template from your local computer to the NetScaler appliance

1. Navigate to AppExpert > Templates.
2. In the details pane, click Manage Templates.
3. In the Manage Application Templates dialog box, click Application Templates, and then click Upload.
4. In the Upload Application Template dialog box, browse to the directory in which the template file is stored, click the template file, and then click Select.

The template file is uploaded to the AppExpert application template directory on the appliance.

To download an AppExpert application template from the NetScaler appliance to your local computer

1. Navigate to AppExpert > Templates.
2. In the details pane, click Manage Templates.
3. In the Manage Application Templates dialog box, click the AppExpert application template that you want to download, and click Download.
4. In the Download Application Template dialog box, browse to the location to which you want to save the file, and then click Save.

Understanding NetScaler Application Templates and Deployment Files

Mar 28, 2012

When you export a NetScaler application, the following two files are automatically created:

- **NetScaler application template file.** Contains application-configuration information such as application units, rules, and configured policies.
- **Deployment file.** Contains deployment-specific information such as public endpoints, services, associated IP addresses, and configured variables.

In the application template and deployment file, each unit of application-configuration information is encapsulated in a specific XML element that is meant for that unit type. For example, each public endpoint and associated endpoint details are encapsulated within the <appendpoint> and </appendpoint> tags, and all the endpoint elements are encapsulated within the <appendpoint_list> and </appendpoint_list> tags.

Note: After you export a NetScaler application, you can add elements, remove elements, and modify existing elements before importing the application to a NetScaler appliance.

Example of a NetScaler Application Template

Following is an example of a template file that was created from a NetScaler application called "SharePoint_Team_Site":

```
<?xml version="1.0" encoding="UTF-8" ?>
<template>
<template_info>
  <application_name>SharePoint_Team_Site</application_name>
  <templateversion_major>1</templateversion_major>
  <templateversion_minor>1</templateversion_minor>
  <author>Ed</author>
  <introduction>An application for managing a SharePoint team site with images, reports, and, XML content.</introduction>
  <summary>This template includes variables</summary>
  <version_major>9</version_major>
  <version_minor>3</version_minor>
  <build_number>38</build_number>
</template_info>
<apptemplate>
  <rewrite>
    <rewriteaction_list>
      <rewriteaction>
        <name>Rw_name</name>
        <type>replace</type>
        <target>HTTP.REQ.BODY(10000).AFTER_REGEX(re/number/).BEFORE_REGEX(re/address/)</target>
        <stringbuilderexpr>"NA"</stringbuilderexpr>
        <allow_unsafe_pi1>NO</allow_unsafe_pi1>
      </rewriteaction>
      <rewriteaction>
        .
      </rewriteaction>
    </rewriteaction_list>
  </rewrite>
</apptemplate>
```

```

.
</rewriteaction>
.
.
.
</rewriteaction_list>
<rewritepolicy_list>
  <rewritepolicy>
    <name>Rw_number_NA</name>
    <rule>HTTP.REQ.BODY(100000).CONTAINS("admin")</rule>
    <action>Rw_name</action>
  </rewritepolicy>
  <rewritepolicy>
    .
    .
    .
  </rewritepolicy>
  .
  .
  .
</rewritepolicy_list>
</rewrite>
<appunit_list>
  <appunit>
    <name>SharePoint_Team_Sitedefault</name>
    <rule />
    <expressiontype>PE</expressiontype>
    <servicetype>HTTP</servicetype>
    <ipv46>0.0.0.0</ipv46>
    <ipmask>*</ipmask>
    <port>0</port>
    <range>1</range>
    <persistencetype>NONE</persistencetype>
    <timeout>2</timeout>
    <persistencebackup>NONE</persistencebackup>
    <backupperstencetimeout>2</backupperstencetimeout>
    <lbmethod>LEASTCONNECTION</lbmethod>
    <persistmask>255.255.255.255</persistmask>
    <v6persistmasklen>128</v6persistmasklen>
    <pq>OFF</pq>
    <sc>OFF</sc>
    <m>IP</m>
    <datalength>0</datalength>
    <dataoffset>0</dataoffset>
    <sessionless>DISABLED</sessionless>
    <state>ENABLED</state>
    <connfailover>DISABLED</connfailover>
    <clttimeout>180</clttimeout>

```

```

<somehtod>NONE</somehtod>
<soopersistence>DISABLED</soopersistence>
<redirectportrewrite>DISABLED</redirectportrewrite>
<downstateflush>DISABLED</downstateflush>
<gt2gb>DISABLED</gt2gb>
<ipmapping>0.0.0.0</ipmapping>
<disableprimaryon-down>DISABLED</disableprimaryon-down>
<insertvserveripport>OFF</insertvserveripport>
<authentication>OFF</authentication>
<authn401>OFF</authn401>
<push>DISABLED</push>
<pushlabel>none</pushlabel>
<l2conn>OFF</l2conn>
</appunit>
<appunit>
.
.
.
</appunit>
.
.
.
</appunit_list>
</apptemplate>
<parameters>
  <property_list>
    <property>
      <variable_definition_list>
        <variable_definition>
          <name>body_size</name>
          <defaultvalue>10000</defaultvalue>
          <description>Evaluation Scope</description>
          <startindex>14</startindex>
          <length>5</length>
        </variable_definition>
        .
        .
        .
      </variable_definition_list>
      <object_type>rewriteaction</object_type>
      <object_name>Rw_name</object_name>
      <name>target</name>
    </property>
    .
    .
    .
  </property_list>
</parameters>

```

</template>

Example of a Deployment File

Following is the deployment file associated with the "SharePoint_Team_Site" application in the preceding example:

```
<?xml version="1.0" encoding="UTF8" ?>
<template_deployment>
  <template_info>
    <application_name>SharePoint_Team_Site</application_name>
    <templateversion_major>1</templateversion_major>
    <templateversion_minor>1</templateversion_minor>
    <author>Ed</author>
    <introduction>An application for managing a SharePoint team site with images, reports, and, XML content.</introduction>
    <summary>This template includes variables</summary>
    <version_major>9</version_major>
    <version_minor>3</version_minor>
    <build_number>38</build_number>
  </template_info>
  <appendpoint_list>
    <appendpoint>
      <ipv46>10.111.111.1</ipv46>
      <port>80</port>
      <servicetype>HTTP</servicetype>
    </appendpoint>
  </appendpoint_list>
  <service_list>
    <service>
      <ip>10.102.29.5</ip>
      <port>80</port>
      <servicetype>HTTP</servicetype>
    </service>
    <service>
      .
      .
      .
    </service>
    .
    .
    .
  </service_list>
  <variable_list>
    <variable>
      <name>body_size</name>
      <description>Evaluation Scope</description>
      <value>10000</value>
    </variable>
    <variable>
      .
      .
      .
    </variable>
  </variable_list>

```

```
</variable>
.
.
.
</variable_list>
</template_deployment>
```

NetScaler Gateway Applications

May 21, 2015

When you configure an AppExpert application to manage a web application through the Citrix® NetScaler® appliance, you also create a set of application units and configure a set of traffic optimization and security policies for each unit. The policies that you configure for each application unit (policies for features such as Compression, Caching, and Rewrite) evaluate traffic that is meant only for that unit. In addition to these policies, you might want to configure Access Gateway policies for the application as a whole to optimize the application traffic when accessed through the Access Gateway. The Access Gateway Applications feature enables you to configure Access Gateway policies (Authorization, Traffic, Clientless Access, and TCP Compression) for an AppExpert application. After you configure NetScaler Gateway policies for AppExpert applications, you can include the policy configuration in the AppExpert application templates that you create.

You can also configure NetScaler Gateway policies for intranet subnets, file shares, and other network resources.

Finally, you can create bookmarks for AppExpert applications and certain resources if you want users to be able to access them from the NetScaler Gateway home page.

You can configure the entities in the NetScaler Gateway Applications feature only by using the configuration utility.

How an NetScaler Gateway Application Works

Updated: 2013-07-17

When you create an AppExpert application in the Applications node in the configuration utility, a corresponding Access Gateway application is automatically created in the Access Gateway Applications node. Additionally, a rule that uses the AppExpert application's configured public endpoint is automatically created for the Access Gateway application entry. If multiple endpoints are configured for the AppExpert application, the rule includes all the configured public endpoints. The NetScaler appliance uses this rule to apply any configured Access Gateway policies to the traffic received at the AppExpert application's public endpoint. Traffic received at the AppExpert application's public endpoint is first evaluated against the NetScaler Gateway policies and then evaluated against the policies configured for AppExpert application's application units.

The rule that is created for the Clientless Access policies for an Access Gateway application is an advanced expression that also uses the public endpoint that is configured for the AppExpert application. Therefore, before you configure NetScaler Gateway policies for an AppExpert application, you must configure public endpoints for the AppExpert application.

When you include the NetScaler Gateway configuration in an application template, deployment-specific information, such as IP address and port information, and the rule that is created from this information are not included in the template.

How a NetScaler Configuration for a File Share Works

On the NetScaler appliance, you can configure Authorization policies for a file share that is hosted on your organization's network.

When you create a file share, you specify a name for the file share and the network path to the file share. In the network path, you can specify either the name of the server or the server IP address. A rule that uses the components of the file share path is automatically created for the file share. This rule enables the appliance to identify requests for files hosted on the file share server. Any Authorization policies that are configured for the file share are applied to incoming requests.

The NetScaler configuration for a file share cannot be saved in AppExpert application templates.

How a NetScaler Configuration for an Intranet Subnet Works

For the intranet subnets that form a part of your network, you can configure policies for Authorization, Traffic, and TCP Compression on the NetScaler appliance. When adding an intranet subnet, you specify the IP address and the netmask of the intranet subnet. A rule that uses these two parameters is automatically created for the intranet subnet. The appliance applies the configured policies to any request that has a destination IP address and netmask set to the subnet's IP address and netmask, respectively.

The NetScaler configuration for an intranet subnet cannot be saved in AppExpert application templates.

How the Other Resources Category Works

Updated: 2013-07-18

The Other Resources category enables you to configure Access Gateway policies for any network resource by using a rule of your choice. When you configure the NetScaler appliance to process requests for the network resource, you configure a classic expression to identify the requests that are associated with the network resource. You can configure Authorization, Traffic, Clientless Access, and TCP Compression policies for a network resource in Other Resources. The NetScaler appliance applies the configured NetScaler Gateway policies to any requests that match the configured rule.

The NetScaler configuration for a network resource in Other Resources cannot be saved in AppExpert application templates.

Entity Naming Conventions

The NetScaler Gateway Applications feature enforces a naming convention for some of the entities that you create in this feature. For example, the names of the profiles that you create for Traffic policies for an intranet subnet always begin with a string that consists of the name of the intranet subnet followed by an underscore (_). The name that you provide for the entity is appended to this string. If the name of a subnet is "subnet1," the name of the profile begins with "subnet1_." When such a naming convention is required (in the text box in which you type the name of an entity, for example), the user interface automatically inserts the string with which the name of the entity must begin and does not allow you to modify it.

Adding File Shares

Mar 28, 2012

When creating a file share, you provide the network path to the file share. Any policies that you configure for a file share use the rule that is automatically created when you created the file share.

To configure a file share

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, click File Shares, and then do one of the following:
 - To add a file share, click File Shares, and then click Add.
 - To modify a file share, click File Shares, and then click Open.
3. In the Create File Share or Configure File Share dialog box, do the following:
 1. In the Name box, type a name for the file share you are adding. This parameter cannot be changed for an existing file share.
 2. In the Path box, type the path to the file share.
The path to the file share may use either the name of the server or the IP address of the server.
 3. In Bookmark, in the Text to Display box, type a name for the file share as you would want it to appear on the Access Gateway home page.
 4. Click Create or OK, and then click Close.

Adding Intranet Subnets

Mar 28, 2012

You can specify authorization and Traffic policies for traffic that is bound for the intranet subnets that are configured in your network. The rules for these policies are automatically created by using the parameters you specify for the subnet.

To configure an intranet subnet

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, do one of the following:
 - To add an intranet subnet, click Intranet Subnets, and then click Add.
 - To modify an intranet subnet, click an intranet subnet, and then click Open.
3. In the Create Intranet Subnet or Configure Intranet Subnet dialog box, do the following:
 1. In the Name box, type a name for the intranet subnet you are adding. This parameter cannot be changed for an existing intranet subnet.
 2. In the IP Address box, type the IP address of the intranet subnet.
 3. In the Netmask box, type the netmask that will be used for the intranet subnet.
 4. Click Create or OK, and then click Close.

Adding Other Resources

Jul 17, 2013

For a network resource that you add to Other Resources, you must configure a classic expression that identifies the subset of traffic associated with the resource. For more information about configuring a classic expression, see the .

To configure a resource in Other Resources

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, do one of the following:
 - To add a resource, click Other Resources, and then click Add.
 - To modify a resource, click a resource, and then click Open.
3. In the Create Resource or Configure Resource dialog box, do the following:
 1. In the Name box, type a name for the resource you are adding. This parameter cannot be changed for an existing resource.
 2. In the Rule box, type the rule that will identify the subset of traffic that is associated with the resource you are adding.
Alternatively, click Configure, and then create the rule in the Create Expression dialog box.
3. Click Create or OK, and then click Close.

Configuring Authorization Policies

Mar 28, 2012

You can configure NetScaler Gateway authorization policies for AAA users and groups to access a resource.

To configure permissions for a AAA user or group to access a resource

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, in the Authorization column, click the icon for the application, file share, intranet subnet, or resource for which you want to configure authorization policies for AAA users and groups.
3. Do one of the following:
 - If the AAA user or group for which you want to configure permissions is already in the Groups/Users tree, drag the user or group from the Groups/Users tree to the Users or Groups node in the <application name> tree. Then, right-click the user or group and click Allow.
 - If the AAA user or group for which you want to configure permissions is not configured on the appliance, in the <application name> tree, right-click Users or Groups, and then click Add. In the Create AAA Group or Create AAA User dialog box, fill in the values, click Create, and then click Close.

The user or group is created with the permission set to Allow. To change the permission setting, right-click the group or user, and then click the permission setting.

4. Click Close.

Configuring Traffic Policies

Dec 16, 2013

The traffic policies that you configure for the resources in the NetScaler Gateway Applications node control client connections to the application. You do not have to configure a rule for the resource. The rule created automatically when you create the resource. You only need to associate a request profile with the traffic policy. In the traffic profile, you specify parameters such as the protocol, application time-out, and file type association.

To configure traffic policies for a resource

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, in the Traffic column, click the icon provided for the application, file share, intranet subnet, or resource for which you want to configure traffic policies.
3. In the Configure Traffic Policies dialog box, do the following:
 - To specify an existing traffic policy, click Insert Policy, and then, in the Policy Name column, click the name of the policy.
 - To configure a new policy, click Insert Policy, and then, in the Policy Name column, click New Policy. In the Create Traffic Policy dialog box, in the Name box, after the underscore (_), type a name for the policy. Then, in Request Profile, either select an existing request profile or click New to configure a new request profile. You can also select an existing profile and then click Modify to modify the profile.

For more information about configuring a traffic policy or profile, see NetScaler Gateway , Enterprise Edition at <http://edocs.citrix.com/>.

- To modify a policy that you have inserted, in the Policy Name column, click the policy name, and then click Modify Policy. To modify only the associated profile, in the Profile column, click the name of the profile, and then click Modify Profile.
 - To regenerate the priorities assigned to the policies, click Regenerate Priorities.
 - To specify a new priority value for a policy, in the Priority column, double-click the assigned priority, and then enter the value you want.
 - To unbind a policy, click the policy, and then click Unbind Policy.
4. Click Apply Changes, and then click Close.

Configuring Clientless Access Policies

Dec 16, 2013

Clientless access, when configured for a resource on the NetScaler appliance, allows end-users to access the resource without using the NetScaler Gateway client software. Users can use web browsers to access resources such as Outlook Web Access. You configure clientless access for a resource by configuring a clientless access policy that is associated with a clientless access profile.

To configure a clientless access policy for a resource in the NetScaler Gateway Applications node

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, in the Clientless Access column, click the icon for the application, file share, intranet subnet, or resource for which you want to configure a clientless access policy.
3. In the Configure Clientless Access Policies dialog box, do the following:
 - To specify an existing clientless access policy, click Insert Policy, and then, in the Policy Name column, click the name of the policy.
 - To configure a new clientless access policy, click Insert Policy, and then, in the Policy Name column, click New Policy. In the Create Clientless Access Policy dialog box, in the Name box, after the underscore (_), type a name for the policy. Then, in Profile, either select an existing profile or click New to configure a new profile. You can also select an existing profile and then click Modify to modify the profile.

For more information about configuring a clientless access policy or profile, see NetScaler Gateway , Enterprise Edition at <http://edocs.citrix.com/>.

- To modify a policy that you have inserted, in the Policy Name column, click the policy name, and then click Modify Policy. To modify only the associated profile, in the Profile column, click the name of the profile, and then click Modify Profile.
 - To specify a new priority value for a policy, in the Priority column, double-click the assigned priority, and then enter the value you want.
 - To unbind a policy, click the policy, and then click Unbind Policy.
4. Click Apply Changes, and then click Close.

Configuring TCP Compression Policies

Dec 16, 2013

You can configure TCP compression policies for an application to increase the performance of the application. TCP compression reduces network latency, reduces bandwidth requirements, and increases the speed of transmission. When configuring a TCP compression policy, you associate a compression action with the policy. The compression action specifies either Compress, GZIP, Deflate, or NoCompress as the compression type. For more information about the compression policies, and compression actions, see NetScaler Gateway , Enterprise Edition at <http://edocs.citrix.com/>.

To configure a TCP compression policy for a resource in the NetScaler Gateway Applications node

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, in the TCP Compression column, click the icon for the application, file share, intranet subnet, or resource for which you want to configure a TCP compression policy.
3. In the Configure TCP Compression Policies dialog box, do the following:
 - To specify an existing TCP compression policy, click Insert Policy, and then, in the Policy Name column, click the name of the policy.
 - To create a new TCP compression policy, click Insert Policy, and then, in the Policy Name column, click New Policy. In the Create TCP Compression Policy dialog box, in the Policy Name box, after the underscore (“_”), type a name for the policy. Then, in Action, either select an existing action or click New and configure a new action. You can also click View to view the configured compression type.

For more information about configuring a TCP compression policy or action, see NetScaler Gateway , Enterprise Edition at <http://edocs.citrix.com/>.

- To modify a policy that you have inserted, in the Policy Name column, click the policy name, and then click Modify Policy.
 - To regenerate the priorities assigned to the policies, click Regenerate Priorities.
 - To specify a new priority value for a policy, in the Priority column, double-click the assigned priority, and then enter the value you want.
 - To unbind a policy, click the policy, and then click Unbind Policy.
4. Click Apply Changes, and then click Close.

Configuring Bookmarks

Dec 16, 2013

You can configure bookmarks for an application or for a resource that you configure in the Other Resources category if you want the application or resource to be accessible from the NetScaler Gateway home page.

To configure a bookmark for an NetScaler Gateway application or a resource in the Other Resources category

1. In the navigation pane of the NetScaler configuration utility, expand AppExpert, and then click Access Gateway Applications.
2. In the details pane, click the application or resource for which you want to configure a bookmark, and then click Configure Bookmark.
3. In the Create Bookmark dialog box, configure values for the parameters.
For more information about the parameters in the Create Bookmark dialog box, see NetScaler Gateway , Enterprise Edition at <http://edocs.citrix.com/>.
4. Click Create, and then click Close.

Configuring User Authentication, Authorization, and Auditing

Aug 04, 2016

You can configure authorization for users and groups to enable them to access an AppExpert application. If the AAA user or group for which you want to configure permissions has not already been created, you can create it from AppExpert and then configure permissions for application access.

To configure AAA users and AAA user groups for an application by using the configuring utility

1. Navigate to **AppExpert > Applications**, select an application entity, and then click **Edit**.
2. In the **Advanced Settings** section, click **Authorization**, and configure authorized users and user groups.
3. Click the **AAA** user section to bind authorized users to the application.
4. In the **AAA User** slider, set the parameters .
5. Click **Continue**, and then click **Authorization Policies** in the **Advanced Settings** section.
6. In the **Authorization Policy** slider, bind an authorization policy to the application.
7. Click **Continue**, and then click the **Authorization Group** section in the **Advanced Settings** section.
8. In the **AAA Group Binding** slider, bind an authorization user group to the application.
9. Click **Continue**, and then click **Policies** in the **Advanced Settings** section.
10. In the **Policies** slider, bind an **Audit Syslog** or **Audit NSlog** policy to the application.
11. Click **Continue** and then **Done**.

To edit AAA users and AAA user groups for an application by using the configuration utility

Navigate to **AppExpert > Applications > Advanced Settings** and click **Authorization**. Then click the edit icon and specify values for user or user-group authorization settings.

To delete AAA users and AAA user groups by using the configuration utility

Navigate to **AppExpert > Applications**, select an application and click **Edit**. In the **Applications** page, click **Advanced Settings** and click **Authorization**. Click the delete icon next to the entity.

AppQoE

Sep 30, 2015

Application level Quality of Experience (AppQoE) integrates several existing policy-based security features of the NetScaler appliance into a single integrated feature that takes advantage of a new queuing mechanism, fair queuing. Fair queuing manages requests to load-balanced web servers and applications at the virtual server level instead of at the service level, allowing it to handle queuing of all requests to a web site or application as one group before load balancing, instead of as separate streams after load balancing.

The features that are integrated into AppQoE are HTTP Denial-of-Service Protection (HDOSP), Priority Queuing (PQ), and SureConnect. Collectively these services provide protection against a number of problems:

- **Simple overload.** Any server, no matter how robust, can accept only a limited number of connections at one time. When a protected web site or application receives too many requests at once, the Surge Protection feature detects the overload and queues the excess connections til the server can accept them. The Priority Queuing feature ensures that whoever most needs access to a resource is provided access without having to wait behind other lower-priority requests. The SureConnect feature displays an alternate web page that notifies users that the resource that they requested is not available.
- **Denial-of-Service (DOS) attacks.** Any public-facing resource is vulnerable to attacks whose purpose is to bring that service down and deny legitimate users access to it. The Surge Protection, Priority Queuing, and SureConnect features help manage DOS attacks as well as other types of high load. In addition, the HTTP Denial-of-Service Protection feature targets DOS attacks against your web sites, sending challenges to suspected attackers and dropping connections if the clients do not send an appropriate response.

Until the current version of the NetScaler operating system, these features were implemented at the service level, which means that each service was assigned its own queues. While service-level queues work, they also have some disadvantages, most of which are due to the NetScaler appliance having to load balance requests before implementing any of the protection features that rely on queuing. Implementing protection features before queuing has a number of advantages, some of which are listed below:

- Absolute priority of connections as configured in the priority queuing feature can be maintained.
- Connections are not flushed if a service transitions state, as they are in a service-level queue.
- During periods of high load, such as a denial-of-service attack, HTTP DoS and SureConnect come into play before load balancing, allowing these features to detect and divert unwanted or lower-priority traffic from the load balancer before the load balancer must cope with it.

In addition to implementing fair queuing, AppQoE integrates a set of features that each provide a different set of tools to achieve a common goal: protecting your networked resources from excessive or inappropriate demand. Putting these features into a common framework enables you to configure and implement them more easily.

Enabling AppQoE

Apr 20, 2013

To configure AppQoE, you must first enable the feature.

To enable AppQoE by using the command line

At the command prompt, type the following commands:

- enable ns feature appqoe
- show ns feature

Example

```
> enable ns feature appqoe
```

```
Done
```

```
> show ns feature
```

	Feature	Acronym	Status
	-----	-----	-----
1)	Web Logging	WL	ON
2)	Surge Protection	SP	ON
3)	Load Balancing	LB	ON
...			
29)	AppQoE	AppQoE	ON

```
Done
```

To enable AppQoE by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, click Configure Advanced Features.
3. In the Configure Advanced Features dialog box, select the AppQoE check box.
4. Click OK.

AppQOE Actions

Oct 02, 2014

After enabling the AppQoE feature, you must configure one or more actions for handling requests.

Important: No specific individual parameters are required to create an action, but you must include at least one parameter or you cannot create the action.

To configure an AppQoE action by using the command line

At the command prompt, type the following commands:

- add appqoe action <name> [-priority <priority>] [-respondWith (ACS | NS) [<customfile>] [-altContentSvcName <string>] [-altContentPath <string>] [-maxConn <positive_integer>] [-delay <usecs>] [-polqDepth <positive_integer>] [-priqDepth <positive_integer>] [-dosTrigExpression <expression>] [-dosAction (SimpleResponse | HICResponse)]
- show appqoe action

Example

To configure priority queuing with policy queue depths of 10 and 1000 for medium and lowest priority queues, respectively:

```
> add appqoe action appqoe-act-basic-prhigh -priority HIGH
```

```
Done
```

```
> add appqoe action appqoe-act-basic-prmedium -priority MEDIUM -polqDepth 10
```

```
Done
```

```
> add appqoe action appqoe-act-basic-prlow -priority LOW -polqDepth 1000
```

```
Done
```

```
> show appqoe action
```

- 1) Name: appqoe-act-basic-prhigh
ActionType: PRIORITY_QUEUEING
Priority: HIGH
PolicyQdepth: 0
Qdepth: 0
- 2) Name: appqoe-act-basic-prmedium
ActionType: PRIORITY_QUEUEING
Priority: MEDIUM
PolicyQdepth: 10
Qdepth: 0
- 3) Name: appqoe-act-basic-prlow
ActionType: PRIORITY_QUEUEING
Priority: LOW
PolicyQdepth: 1000
Qdepth: 0

```
Done
```

To modify an existing AppQoE action by using the command line

At the command prompt, type the following commands:

- `set appqoe action <name> [-priority <priority>] [-altContentSvcName <string>] [-altContentPath <string>] [-polqDepth <positive_integer>] [-priqDepth <positive_integer>] [-maxConn <positive_integer>] [-delay <usecs>] [-dosTrigExpression <expression>] [-dosAction (SimpleResponse | HICResponse)]`
- `show appqoe action`

To remove an AppQoE action by using the command line

At the command prompt, type the following commands:

- `rm appqoe action <name>`
- `show appqoe action`

Parameters for configuring an AppQoE action

name

A name for the new action, or the name of the existing action that you want to modify. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to letters, numbers, and the hyphen (-), period (.) pound (#), space (), at sign (@), equals (=), colon (:), and underscore (_) symbols.

priority

The priority queue to which the request is assigned. When a protected web server or application is heavily loaded and cannot accept additional requests, specifies the order in which waiting requests are to be fulfilled when resources are available. The choices are:

1. **HIGH.** Fulfills the request as soon as resources are available.
2. **MEDIUM.** Fulfills the request after it has fulfilled all requests in the HIGH priority queue.
3. **LOW.** Fulfills the request after it has fulfilled all requests in the HIGH and MEDIUM priority queues.
4. **LOWEST.** Fulfills the request only after it has fulfilled all requests in higher-priority queues.

If priority is not configured, then the NetScaler appliance assigns the request to the LOWEST priority queue by default.

respondWith

Configures the NetScaler ADC to take the specified Responder action when the specified threshold is reached. Must be used with one of the following settings:

- **ACS:** Serves content from an alternate content service. Threshold: maxConn (maximum connections) or delay.
- **NS:** Serves a built-in response from the NetScaler ADC. Threshold: maxConn (maximum connections) or delay.
- **NO ACTION:** Serves no alternative content. Assigns connections to the LOWEST priority queue if the maxConn (maximum connections) or delay threshold is reached.

altContentSvcName

If `-responseWith ACS` is specified, the name of the alternative content service, usually an absolute URL to the web server that hosts the alternate content.

altContentPath

If `-responseWith (ACS | NS)` is specified, the path to the alternative content.

polqDepth

Policy queue depth threshold value for the policy queue associated with this action. When the number of connections in the policy queue associated with this action increases to the specified number, subsequent requests are assigned to the LOWEST policy queue. Minimum value: 1 Maximum value: 4,294,967,294

priqDepth

Policy queue depth threshold value for the specified priority queue. If the number of requests in the specified queue on the virtual server to which the policy associated with the current action is bound increases to the specified number, subsequent requests are assigned to the LOWEST priority queue. Minimum value: 1 Maximum value: 4,294,967,294

maxConn

The maximum number of connections that can be open for requests that match the policy rule. Minimum value: 1 Maximum value: 4,294,967,294

delay

The delay threshold, in microseconds, for requests that match the policy rule. If a matching request has been delayed for longer than the threshold, the NetScaler appliance performs the specified action. If NO ACTION is specified, then the appliance assigns requests to the LOWEST priority queue. Minimum value: 1 Maximum value: 599999,999

dosTrigExpression

Adds an optional second-level check to trigger DoS actions.

dosAction

Action to take when the ADC determines that it or a protected server is under DoS attack. Possible values: SimpleResponse, HICResponse

To configure an AppQoE action by using the configuration utility

1. Navigate to App-Expert > AppQoE > Actions.
2. In the details pane, do one of the following:
 - To create a new action, click Add.
 - To modify an existing action, select the action, and then click Edit.
3. In the Create AppQoE Action or the Configure AppQoE Action screen, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring the AppQoE Action" as follows (asterisk indicates a required parameter):
 - Name—name
 - Action type—respondWith
 - Priority—priority
 - Policy Queue Depth—polqDepth
 - Queue Depth—priqDepth
 - DOS Action—dosAction
4. Click Create or OK.

AppQoE Parameters

Oct 02, 2014

In the AppQoE parameters, you configure the session life of an AppQoE session, the file name of the file containing the customized response, and the number of client connections that can be placed in a queue.

To configure the AppQoE parameter settings by using the command line

At the command prompt, type the following commands:

- set appqoe parameter [-sessionLife <secs>] [-avgwaitingclient <positive_integer>] [-MaxAltRespBandWidth <positive_integer>] [-dosAttackThresh <positive_integer>]
- show appqoe parameter

Parameters for configuring the AppQoE parameters

sessionLife

Number of seconds to wait after displaying alternate content before the ADC displays the same content again. Default value: 300 Minimum value: 1 Maximum value: 4,294,967,294

avgwaitingclient

The average number of client requests that can be in the service waiting queue. Default value: 1000000 Maximum value: 4,294,967,294

MaxAltRespBandWidth

The maximum bandwidth to consume when sending alternate responses. If the maximum is reached, the ADC quits sending the alternate content til bandwidth consumption drops. Default value: 100 Minimum value: 1 Maximum value: 4,294,967,294

dosAtckThrsh

The denial-of-service attack threshold. The number of connections that must be waiting in queues before the ADC responds with DoS protection measures. Default value: 2000 Minimum value: 0 Maximum value: 4,294,967,294

To configure the AppQoE parameter settings by using the configuration utility

1. Navigate to AppExpert > AppQoE.
2. In the details pane, click Configure AppQoE Parameters.
3. In the Configure AppQoE params screen, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring the AppQoE Parameters" as follows (asterisk indicates a required parameter):
 - Session Life (secs)—sessionLife
 - Average waiting client—avgwaitingclient
 - Alternate Response Bandwidth Limit(Mbps) — MaxAltRespBandWidth
 - DOS Attack Threshold — dosAttackThresh
4. Click OK.

AppQoE Policies

Oct 02, 2014

To implement AppQoE, you must configure at least one policy to tell your NetScaler ADC how to distinguish the connections to be queued in a specific queue.

To configure an AppQoE policy by using the command line

At the command prompt, type the following command:

```
add appqoe policy <name> -rule <expression> -action <string>
```

Example

The following example selects requests with a User-Agent header that contains "Android", and assigns them to the medium priority queue. These requests come from smartphones and tablets that run the Google Android operating system.

```
> add appqoe action appqoe-act-primd -priority MEDIUM
Done
> add appqoe policy appqoe-pol-primd -rule "HTTP.REQ.HEADER("User-Agent").CONTAINS("Android")" -action appqoe-act-primd
Done
> sh appqoe policy appqoe-pol-primd
  Name: appqoe-pol-primd
  Rule: HTTP.REQ.HEADER("User-Agent").CONTAINS("Android")
  Action: appqoe-act-primd
  Hits: 0
```

Done

Parameters for configuring an AppQoE policy

name

A name for the AppQoE policy. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space (), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should chose a name that helps identify the type of action.

rule

A NetScaler expression that tells the appliance which connections it should handle. For complete information about policy expressions, see the *Citrix NetScaler Policy Configuration and Reference Guide* at .

action

The AppQoE action to perform when a connection matches the policy.

To configure an AppQoE policy by using the configuration utility

1. Navigate to App-Expert > AppQoE > Policies.
2. In the details pane, do one of the following:
 - To create a new policy, click Add.
 - To modify an existing policy, select the policy, and then click Edit.
3. If you are creating a new policy, in the Create AppQoE Policy dialog, in the Name text box, type a name for your new policy. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space (), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should chose a name that helps identify the purpose and effect of this policy.

If you are modifying an existing policy, skip this step. You cannot change the name of an existing policy.

4. In the Action drop-down list, choose the AppQoE action to perform when the policy matches a connection. Click the plus (+) to open the Add AppQoE Action dialog and add a new action.
5. In the Rule text box, either enter the policy expression directly, or click New to create a policy expression. If you click New, perform the following steps:

1. In the Create Expression dialog box, click Add.
2. In the Add Expression dialog box, select a common expression from the Frequently Used Expressions drop-down list, or use the Construct Expression drop-down lists to create the expression that defines which traffic to filter.

If you choose to create your own expression, you start by selecting the first term from the first drop-down list on the left side of the Construct Expression area. The choices in that list are:

- HTTP: All traffic to port 80 and port 443.
- SYS:
- CLIENT:
- SERVER:
- ANALYTICS:
- TEXT:

The default choice is HTTP. After you make a choice in the first drop-down list (or accept the default), you can choose the next term in your expression from the drop-down list to the right of it. The terms in that list and other lists that follow change depending on your previous choices; the lists offer only terms that are valid choices. Continue to select terms until you have finished the expression.

Use the Help and Preview Expression areas for assistance when creating the expression. For a complete description of the available choices, see the *Citrix NetScaler Policy Configuration and Reference Guide* at .

3. When you have created the expression that you want, click OK. The expression is added in the Expression text box.
6. Click Create. The expression appears in the Rule text box.

Entity Templates

May 21, 2015

An entity template is a collection of configuration information for an individual entity on a Citrix® NetScaler® appliance. It provides a specification and a set of defaults for a configurable NetScaler entity, such as a policy, virtual server, service, or action. By using a template that defines a set of defaults, you can quickly configure multiple entities that require a similar configuration while eliminating several configuration steps.

Entity templates are available only in the configuration utility. You use the NetScaler configuration utility to create, manage, and use any type of entity template. You can share entity templates with other administrators and manage local folders that contain the templates. You can also import entity templates from and export entity templates to your local computer.

Before creating a template, you should be familiar with the configuration of the entity.

Note: You use entity templates to configure individual entities. To configure multiple entities related to a particular Web application, you must use an application template. For more information, see "[AppExpert Applications and Templates](#)."

How Entity Templates Work

When you create a template for a NetScaler entity, you specify default values for the entity. You specify what values must be read-only, what values must not be displayed, and what values users can configure. You also configure the pages that compose the template import wizard. All the information and settings you provide are stored in the template file.

When a user imports the entity template to a NetScaler appliance, a wizard guides the user through the various pages that you configured for the template. The wizard displays the read-only parameter values and prompts the user to specify values for the configurable parameters. After the user follows the instructions in the wizard, the appliance creates the entity with the configured values.

For example, you can create an entity template for HTTP services that provides a text box for a service name and assigns preset values for the service protocol, timeouts, thresholds, and monitors. Later, when you use the template to create new HTTP services, a wizard prompts you for a service name and supplies the preset values that you would otherwise have configured manually.

The procedure for creating entity templates for load balancing virtual servers is different than the AppExpert procedure for creating other entity templates. For more information, see "[Creating an Entity Template](#)."

In addition, the procedure for using the template to create the load balancing virtual server entity is different. For more information, see "[Creating an Entity from a Template](#)."

Configuring an Entity Template

Mar 28, 2012

You can create or modify an entity template either from the AppExpert feature node or from the associated NetScaler feature node for the entity. For example, you can create a content switching virtual server entity template in either the AppExpert feature node or the content switching feature node in the configuration utility.

If you create a template that is not based on an existing entity, you can specify the following options and settings for the template:

- The default value of a parameter.
- Whether the default values are visible to users.
- Whether the default values can be changed by users.
- The number of pages in the entity import wizard, including the page names, text, and available parameters.
- The entities that must be bound to the entity for which the template is being created.

For example, when you are creating a cache redirection virtual server template, you can specify the policies that you want to bind to the cache redirection virtual servers that you create from the template. However, only binding information is included in the template. The bound entities are not included. If the entity template is imported to another NetScaler appliance, the bound entities must exist on the appliance at import time for the binding to succeed. If none of the bound entities exist on the target appliance, the entity (for which the template was configured) is created without any bindings. If only a subset of the bound entities exist on the target appliance, they are bound to the entity that is created from the template.

When you create a template based on an existing entity, the configuration settings of the entity appear in the template. All bound entities are selected by default, but you can modify bindings as necessary. As in the case of a template that is not based on an existing entity, only binding information is included and not the entities. You can either save the template with the existing configuration settings or use the settings as a basis for creating a new configuration for a template.

Creating an Entity Template

Aug 30, 2013

You can create entity templates in either the AppExpert node or the NetScaler feature node that corresponds to the type of entity. For example, you can create a content switching virtual server template from the entity templates tab of the AppExpert feature's Templates node or in the Content Switching node. You can also specify the parameters that you want the template to store, and specify whether you want the template import wizard to prompt the user for certain parameter values.

However, when creating load balancing virtual servers, you do not have the option of specifying parameter values that you want stored in the template. You create a load balancing virtual server template by selecting an existing load balancing virtual server and configuring any variables that you might want to create in existing parameters and bound policies. The variables can be assigned values when you create a load balancing virtual server from the template. The template stores load balancing parameters such as the virtual server's IP address and port number, bound policies, actions, and variable definitions. A deployment file is also created, automatically, from the load balancing configuration. The deployment file stores deployment-specific information, such as information about bound services, service groups, and the name-value pairs of variables. If the bound entities that are included in the template are already configured on the NetScaler appliance to which the template is imported, duplicates are created, with names that are generated automatically in a particular format. The duplicate entities are based on the parameter information stored in the entity template.

When you create a load balancing virtual server template from the AppExpert node, the template is always saved to the `/nsconfig/nstemplates/entities/lb vserver/` folder. If you want to save the template to a different folder, create the template from the Virtual Servers pane in the Load Balancing node. The deployment file is created with the name with which you save the template file, but with the string `_deployment` appended to the name. The deployment file is saved to the `/nsconfig/nstemplates/entities/lb vserver/deployment_files/` folder. For more information about deployment files for load balancing virtual server templates, see "[Understanding Load Balancing Entity Templates and Deployment Files](#)."

Note: You can use either of the first two procedures for creating any template, except for a load balancing virtual server template. For creating a load balancing virtual server template, use the third or fourth procedure.

To create an entity template by using the AppExpert feature node

1. Navigate to AppExpert > Templates.
2. In the details pane, on the Entity Templates tab, do one of the following:
 - To create a new template, click Add. In the Select the Template Type dialog box, select the template type, and then click OK.
 - To create a duplicate of an existing entity template, in the details pane, select the entity template, and then click Add.
3. In the Create...Template dialog box, follow the instructions to create a template.
If you are creating a duplicate of an existing entity template, in the Create...Template dialog box, on the Specify Template Name page, you must change the name of the entity template.
4. Click Finish, and then click Exit.

To create an entity template by using its corresponding feature node

1. Navigate to Traffic Management, and select the feature (for example, Content Switching), and then select the entity (for example, Virtual Servers), for which you want to create the entity template.
2. At the top of the details pane, click Entity Templates, and then click Create Template.

3. In the Create...Template dialog box, follow the instructions to create a template.
4. Click Finish, and then click Exit.

To create a load balancing virtual server template from the AppExpert node

1. Navigate to AppExpert > Templates.
2. In the details pane, on the LB Templates tab, click Add.
3. In the Select Load Balancing Virtual Server dialog box, select the load balancing virtual server whose configuration you want to save to a template file, and then click OK.
4. In the Create Template dialog box, provide the following information:
 - Name. The name of the template.
Note: The Folder field shows the location to which the template will be saved. You cannot modify the path that is displayed.
 - Configure Variables. Configure variables for the load balancing template. For more information, see "[Configuring Variables in Load Balancing Virtual Server Templates.](#)"
 - Introduction Description. A description of the virtual server for which you are creating a template.
 - Summary Description. A summary of the configuration or additional instructions for other administrators, such as a description of any additional steps that need to be followed after the entity is successfully created.
 - Author. The creator of the template.
 - Major. An optional major version number of your choice, to be specified if you want to maintain versions of your template.
 - Minor. An optional minor version number of your choice, to be specified if you want to maintain minor versions of your template.
You can maintain versions by incrementing one or both of the version numbers each time you maintain the template. The Entity Template Wizard concatenates and displays the major and minor version numbers during import. For example, if the major version number is 1 and the minor version is 1, the Entity Template Wizard displays a version number of 1.1.
5. Click OK.

To create a load balancing virtual server template from the Load Balancing Virtual Servers pane

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server on which to base the template,, and then click Create Template. You might have to click the scroll arrow at the bottom right of the pane to bring the Create Template button into view.
3. In the Create Template dialog box, provide the following information:
 - Name. The name of the template.
 - Folder. The location to which the template will be saved.
Note: If you want to save the template to the appliance, you can save it only to the /nsconfig/nstemplates/entities/lb vserver/ directory (the path displayed by default in Folder. If you want to save the template file to a folder on your computer, click the down-arrow on the Browse button, click Local, and then select a folder.
 - Configure Variables. Configure variables for the load balancing template. For more information, see "[Configuring Variables in Load Balancing Virtual Server Templates.](#)"
 - Introduction Description. A description of the virtual server for which you are creating a template.
 - Summary Description. A summary of the configuration or additional instructions for other administrators, such as a description of any additional steps that need to be followed after the entity is successfully created.
 - Author. The creator of the template.
 - Major. An optional major version number of your choice, to be specified if you want to maintain versions of your

template.

- Minor. An optional minor version number of your choice, to be specified if you want to maintain minor versions of your template.

You can maintain versions by incrementing one or both of the version numbers each time you maintain the template.

The Entity Template Wizard concatenates and displays the major and minor version numbers during import. For example, if the major version number is 1 and the minor version is 1, the Entity Template Wizard displays a version number of 1.1.

4. Click OK.

Configuring Variables in Load Balancing Virtual Server Templates

Aug 30, 2013

Load balancing virtual server templates support the declaration of variables in the configured load balancing parameters and in bound policies and actions. The ability to declare variables enables you to replace preconfigured values with values that suit the environment into which you are importing the template. The Entity Template Wizard, which appears when you import a template, includes a Specify Variable Values page on which you can specify appropriate values for the variables that are configured for the entity template. This wizard page appears only when you import a template that is configured with existing variables.

As an example, consider the following expression configured for a policy that is bound to a load balancing virtual server for which you are creating a template. The expression evaluates the value of the Accept-Language header in an HTTP request.

```
HTTP.REQ.HEADER("Accept-Language").CONTAINS("en-us")
```

If you want the value of the header to be configurable at import time, you can specify the string en-us as a variable. When importing the template, you can specify a new value for the variable on the Specify Variable Values page.

After you create a variable, you can do the following:

- Assign additional strings to an existing variable. After you create a variable for a string, you can select and assign other parts of the same or different expression to the variable. The strings you assign to a variable need not be the same. At import time, all the strings that are assigned to the variable are replaced with the value that you provide.
- View the string or strings that are assigned to the variable.
- View a list of all the entities and parameters that use the variable.

To configure variables in a load balancing virtual server template

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, right-click the virtual server that you want to export to a template file, and then click Create Template.
3. In the Create Template dialog box, modify the default template file name if required, specify the location where you want to save the template, and then click Configure Variables.
4. In the Configure Variables dialog box, click the tab that lists the entity for which you want to configure a variable, select the entity, and then click Configure Variables.
5. In the Variables for <Entity Type>: <Entity Name> dialog box, click the  button next to the parameter value or expression in which you want to create a variable.
6. In the Variables for <Field Name> dialog box, do the following:
 - To create a variable, in the text box that displays the configured expression or value, select the string that you want to be configurable at import time, and then click Add. In the Create Variable dialog box, specify a name and a description for the variable, and then click Create.

The name of the variable, its value, and the description you provided appear in the Available Variables listing in the dialog box. The name you provide will be the name of the associated field in the template import wizard, and the description will appear as alt text when the user positions the mouse pointer over the field.

- To modify a variable, in the Available Variables list, click the variable, and then click Open. In the Create Variable dialog

box, modify the value and the description, and then click OK.

The new value that you specify will not replace the text selected in the text box that displays the configured expression or value. However, when you import the template, the new value will be displayed as the default value for the variable in the template import wizard.

- To view all the strings that are assigned to a given variable, in the Available Variables listing, click the name of the variable. The strings that are assigned to the variable are highlighted.
- To view a list of all the parameters, expressions, and actions in which the variable is used, in the Available Variables listing, click the variable whose references you want to view, and then click Show References.
- To assign a string to an existing variable, in the text box that displays the expression you configured, select the string you want to assign to an existing variable, right-click the selection, click Use existing Variable, and then click the name of the variable to which you want to assign the string.

If a variable has multiple strings assigned to it, when you specify a new value for the variable during import, all strings assigned to the variable are replaced with the new value.

7. Click Close.

Modifying an Entity Template

Aug 30, 2013

You can modify only the parameters, bindings, and pages configured for a template. The name and location of the template specified when the template was created cannot be changed. The NetScaler appliance does not provide you with the option of modifying a load balancing virtual server template.

To modify an entity template by using the AppExpert feature node

1. Navigate to AppExpert > Templates.
2. In the details pane, on the Entity Templates tab, select the template you want to change, and then click Open.
3. In the Modify...Template dialog box, follow the instructions to modify a template.
4. Click Finish, and then click Exit.

To modify an entity template by using its corresponding feature node

1. Navigate to Traffic Management, select the feature (for example, Content Switching), and then select the entity (for example, Virtual Servers) for which you want to modify the entity template.
2. At the top of the details pane, click Entity Templates, and then click Manage Template.
3. In the Manage <feature entity name> Entity Templates dialog box, select the template that you want to modify, and then click Modify.
4. In the Modify <template name> Template dialog box, follow the instructions to modify a template.
5. Click Finish, and then click Exit.
6. Click Close.

Deleting an Entity Template

Aug 30, 2013

Deleting an entity template does not affect any objects that have been created by using the template. You can delete a load balancing virtual server template only from the AppExpert feature node.

To delete an entity template by using the AppExpert feature node

1. Navigate to AppExpert > Templates.
2. In the details pane, on the Entity Templates tab, click the template you want to delete, and then click Remove.

To delete an entity template by using its corresponding feature node

1. Navigate to Traffic Management, and select the feature (for example, Content Switching) and then select the entity (for example, Virtual Servers), for which you want to delete the entity template.
2. At the top of the details pane, click Entity Templates, and then click Manage Template.
3. In the Manage...Entity Templates dialog box, select the template that you want to delete, and then click Delete.

Creating an Entity from a Template

Aug 30, 2013

You can create an entity from an entity template either from the AppExpert feature node in the NetScaler configuration utility or from the NetScaler feature node that corresponds to the type of entity that you want to create. For example, you can create a content switching virtual server from a template with either the AppExpert feature node or the content switching feature node in the configuration utility.

The procedure for creating a load balancing virtual server from a template is different than the AppExpert procedure for creating other entities from templates.

After you create an instance of an entity using an entity template, you can configure it in the same way that you would any other object of that type, such as by using the configuration utility or the command line.

To create an entity from a template by using the AppExpert feature node

1. Navigate to AppExpert > Templates.
2. In the details pane, do one of the following:
 1. To create any entity other than a load balancing virtual server from a template, on the Entity Templates tab, click the template that you want to use, and then click Use Template.
 2. To create a load balancing virtual server from a template, on the LB Templates tab, click the template that you want to use, and then click Use Template.
3. In the <Entity Template Name> wizard, follow the instructions to create the entity on the NetScaler.
4. Click Finish, and then click Exit.

To create an entity from a template by using its corresponding feature node

1. Navigate to Traffic Management, and expand a feature node (for example, Content Switching), and then click an entity subnode (for example, Virtual Servers).
2. At the top of the details pane, click Entity Templates, and then click Use Template.
3. Click the name of the template that you want to use.
4. In the Use <template name> Template wizard, follow the instructions to create the entity.
Only templates that match the current context are displayed. For example, in the details pane for content switching virtual servers, only entity templates for content switching virtual servers appear, if configured.
5. Click Finish, and then click Exit.

To create a load balancing virtual server by using a load balancing virtual server template

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Use Template.
3. In the Entity Template Wizard, follow the instructions to create a load balancing virtual server on the NetScaler.
Only templates that match the current context are displayed. For example, when you click Browse (Appliance), only entity templates for load balancing virtual servers appear, if configured.
4. Click Finish, and then click Exit.

Note: The Entity Template Wizard includes a Specify Variable Values page on which you can specify new values for variables. For more information about configuring variables in load balancing virtual server templates, see "[Configuring Variables in Load Balancing Virtual Server Templates](#)."

Managing Entity Template Folders

Aug 30, 2013

You can organize only load balancing virtual server template folders.

To organize load balancing virtual server template folders

1. Navigate to AppExpert > Templates > LB Templates.
2. In the Manage LB Templates dialog box, do one of the following:
 - To change the name of a folder, select the folder and click Rename.

You can also click the folder that you want to rename, and then press F2. You cannot rename the top-level default folder.

- To remove the folder, select the folder and click Delete.

You can also click the folder that you want to remove, and then press the Delete key. You cannot remove the top-level default folder.

3. Click Close.

Uploading and Downloading Entity Templates

Aug 30, 2013

You can import the entity templates that are stored on your local computer. You can also download entity templates from the NetScaler appliance to your local computer and then import them to other NetScaler appliances.

Note: You cannot upload or download load balancing virtual server templates.

To upload an entity template to the NetScaler appliance

1. Navigate to Traffic Management, and expand a feature node (for example, Content Switching), and then click a subnode (for example, Virtual Servers) for which you want to upload an entity template.
2. At the top of the details pane, click Entity Templates, and then click Manage Template.
3. In the Manage...Entity Templates dialog box, click the top-level folder, and then click Upload.
4. In the Upload Entity Template dialog box, navigate to the template file that you want to upload, and then click Select.
5. Click Close.

To download an entity template from the NetScaler appliance

1. Navigate to Traffic Management, and expand a feature node (for example, Content Switching), and then click a subnode (for example, Virtual Servers) for which you want to upload an entity template.
2. At the top of the details pane, click Entity Templates, and then click Manage Template.
3. In the Manage...Entity Templates dialog box, click the template that you want to download, and then click Download.
4. In the Download Entity Template dialog box, navigate to the location at which you want to save the template on your local computer, enter a file name, and then click Save.
5. Click Close.

Understanding Load Balancing Entity Templates and Deployment Files

Mar 28, 2012

Load balancing entity templates are created in the same way that NetScaler application templates are created. When you export a load balancing virtual server to a template file, the following two files are automatically created:

- **Load balancing virtual server template file.** Contains XML elements that store the values of the parameters that are configured for the load balancing virtual server. The file also contains XML elements for storing information about bound policies.
- **Deployment file.** Contains XML elements that store deployment-specific information such as services, service groups, and configured variables.

In the template and deployment files, each unit of configuration information is encapsulated in a specific XML element that is meant for that unit type. For example, the load balancing method parameter, `lbMethod`, is encapsulated within the `<lbmethod>` and `</lbmethod>` tags.

Note: After you export a load balancing virtual server, you can add elements, remove elements, and modify existing elements before importing the configuration information to a NetScaler appliance.

Example of a Load Balancing Virtual Server Template

Following is an example of a template file that was created from a load balancing virtual server called "Lbvip":

```
<?xml version="1.0" encoding="UTF-8" ?>
<template>
  <template_info>
    <entity_name>Lbvip</entity_name>
    <version_major>10</version_major>
    <version_minor>0</version_minor>
    <build_number>40.406</build_number>
  </template_info>
  <entitytemplate>
    <lbvserver_list>
      <lbvserver>
        <name>Lbvip</name>
        <servicetype>HTTP</servicetype>
        <ipv46>0.0.0.0</ipv46>
        <ipmask>*</ipmask>
        <port>0</port>
        <range>1</range>
        <persistencetype>NONE</persistencetype>
        <timeout>2</timeout>
        <persistencebackup>NONE</persistencebackup>
        <backupperstencetimeout>2</backupperstencetimeout>
        <lbmethod>LEASTCONNECTION</lbmethod>
        <persistmask>255.255.255.255</persistmask>
        <v6persistmasklen>128</v6persistmasklen>
        <pq>OFF</pq>
      </lbvserver>
    </lbvserver_list>
  </entitytemplate>
</template>
```

```

<sc>OFF</sc>
<m>IP</m>
<datalength>0</datalength>
<dataoffset>0</dataoffset>
<sessionless>DISABLED</sessionless>
<state>ENABLED</state>
<connfailover>DISABLED</connfailover>
<clttimeout>180</clttimeout>
<somethod>NONE</somethod>
<sopersistence>DISABLED</sopersistence>
<sopersistencetimeout>2</sopersistencetimeout>
<redirectportrewrite>DISABLED</redirectportrewrite>
<downstateflush>DISABLED</downstateflush>
<gt2gb>DISABLED</gt2gb>
<ipmapping>0.0.0.0</ipmapping>
<disableprimaryonshutdown>DISABLED</disableprimaryonshutdown>
<insertvserveripport>OFF</insertvserveripport>
<authentication>OFF</authentication>
<authn401>OFF</authn401>
<push>DISABLED</push>
<pushlabel>none</pushlabel>
<l2conn>OFF</l2conn>
<appflowlog>DISABLED</appflowlog>
<icmpvsrresponse>PASSIVE</icmpvsrresponse>
<lbvserver_cmppolicy_binding_list>
  <lbvserver_cmppolicy_binding>
    <name>Lbvip</name>
    <policyname>NOPOLICY-COMPRESSION</policyname>
    <priority>100</priority>
    <gotopriorityexpression>END</gotopriorityexpression>
    <bindpoint>REQUEST</bindpoint>
  </lbvserver_cmppolicy_binding>
</lbvserver_cmppolicy_binding_list>
</lbvserver>
</lbvserver_list>
</entitytemplate>
</template>

```

Example of a Deployment File

Following is the deployment file associated with the virtual server in the preceding example:

```

<?xml version="1.0" encoding="UTF-8" ?>
<template_deployment>
  <template_info>
    <entity_name>Lbvip</entity_name>
    <version_major>10</version_major>
    <version_minor>0</version_minor>
    <build_number>40.406</build_number>
  </template_info>

```

```
<service_list>
  <service>
    <ip>1.2.3.4</ip>
    <port>80</port>
    <servicetype>HTTP</servicetype>
  </service>
</service_list>
<servicegroup_list>
  <servicegroup>
    <name>svcgrp</name>
    <servicetype>HTTP</servicetype>
    <servicegroup_servicegroupmember_binding_list>
      <servicegroup_servicegroupmember_binding>
        <ip>1.2.3.90</ip>
        <port>80</port>
      </servicegroup_servicegroupmember_binding>
      <servicegroup_servicegroupmember_binding>
        <ip>1.2.8.0</ip>
        <port>80</port>
      </servicegroup_servicegroupmember_binding>
      <servicegroup_servicegroupmember_binding>
        <ip>1.2.8.1</ip>
        <port>80</port>
      </servicegroup_servicegroupmember_binding>
      <servicegroup_servicegroupmember_binding>
        <ip>1.2.9.0</ip>
        <port>80</port>
      </servicegroup_servicegroupmember_binding>
    </servicegroup_servicegroupmember_binding_list>
  </servicegroup>
</servicegroup_list>
</template_deployment>
```

HTTP Callouts

Jan 11, 2013

For certain types of requests, or when certain criteria are met during policy evaluation, you might want to stall policy evaluation briefly, retrieve information from a server, and then perform a specific action that depends on the information that is retrieved. At other times, when you receive certain types of requests, you might want to update a database or the content hosted on a Web server. HTTP callouts enable you to perform all these tasks.

An HTTP callout is an HTTP or HTTPS request that the NetScaler appliance generates and sends to an external application when certain criteria are met during policy evaluation. The information that is retrieved from the server can be analyzed by default syntax policy expressions, and an appropriate action can be performed. You can configure HTTP callouts for HTTP content switching, TCP content switching, rewrite, responder, and for the token-based method of load balancing.

Before you configure an HTTP callout, you must set up an application on the server to which the callout will be sent. The application, which is called the *HTTP callout agent*, must be configured to respond to the HTTP callout request with the required information. The HTTP callout agent can also be a Web server that serves the data for which the NetScaler appliance sends the callout. You must make sure that the format of the response to an HTTP callout does not change from one invocation to another.

After you set up the HTTP callout agent, you configure the HTTP callout on the NetScaler appliance. Finally, to invoke the callout, you include the callout in a default syntax policy in the appropriate NetScaler feature and then bind the policy to the bind point at which you want the policy to be evaluated.

After you have configured the HTTP callout, you must verify the configuration to make sure that the callout is working correctly.

How an HTTP Callout Works

Jan 11, 2013

When the NetScaler appliance receives a client request, the appliance evaluates the request against the policies bound to various bind points. During this evaluation, if the appliance encounters the HTTP callout expression, `SYS.HTTP_CALLOUT(<name>)`, it stalls policy evaluation briefly and sends a request to the HTTP callout agent by using the parameters configured for the specified HTTP callout. Upon receiving the response, the appliance inspects the specified portion of the response, and then either performs an action or evaluates the next policy, depending on whether the evaluation of the response from the HTTP callout agent evaluates to TRUE or FALSE, respectively. For example, if the HTTP callout is included in a responder policy, if the evaluation of the response evaluates to TRUE, the appliance performs the action associated with the responder policy.

If the HTTP callout configuration is incorrect or incomplete, or if the callout invokes itself recursively, the appliance raises an UNDEF condition, and updates the undefined hits counter.

The following figure illustrates the working of an HTTP callout that is invoked from a globally bound responder policy. The HTTP callout is configured to include the IP address of the client that is associated with an incoming request. When the NetScaler appliance receives a request from a client, the appliance generates the callout request and sends it to the callout server, which hosts a database of blacklisted IP addresses and an HTTP callout agent that checks whether the client's IP address is listed in the database. The HTTP callout agent receives the callout request, checks whether the client's IP address is listed, and sends a response that the NetScaler appliance evaluates. If the response indicates that the client's IP address is not blacklisted, the appliance forwards the response to the configured service. If the client's IP address is blacklisted, the appliance resets the client connection.

Figure 1. HTTP Callout Entity Model

- 1: Client request
- 2: HTTP callout request to check whether the client is blacklisted
- 3: Response from HTTP callout agent
- 4: Request forwarded to service if 3 indicates a safe IP address
- 5: Connection RESET if 3 indicates a bad IP address

Notes on the Format of HTTP Requests and Responses

May 21, 2015

The NetScaler appliance does not check for the validity of the HTTP callout request. Therefore, before you configure HTTP callouts, you must know the format of an HTTP request. You must also know the format of an HTTP response, because configuring an HTTP callout involves configuring expressions that evaluate the response from the HTTP callout agent.

This document includes the following details:

- [Format of an HTTP Request](#)
- [Format of an HTTP Response](#)

Format of an HTTP Request

An HTTP request contains a series of lines that each end with a carriage return and a line feed, represented as either <CR><LF> or \r\n.

The first line of a request (the *message line*) contains the HTTP method and target. For example, a message line for a GET request contains the keyword GET and a string that represents the object that is to be fetched, as shown in the following example:

```
GET /mysite/mydirectory/index.html HTTP/1.1\r\n
```

The rest of the request contains HTTP headers, including a required Host header and, if applicable, a message body.

The request ends with a blank line (an extra <CR><LF> or \r\n).

Following is an example of a request:

```
Get /mysite/index.html HTTP/1.1\r\nHost: 10.101.101.10\r\nAccept: */*\r\n\r\n
```

Format of an HTTP Response

An HTTP response contains a status message, response HTTP headers, and the requested object or, if the requested object cannot be served, an error message.

Following is an example of a response:

```
HTTP/1.1 200 OK\r\nContent-Length: 55\r\nContent-Type: text/html\r\nLast-Modified: Wed, 12 Aug 1998 15:03:50 GMT\r\nAccept-Ranges: bytes\r\nETag: "04f97692cbd1:377"\r\nDate: Thu, 19 Jun 2008 19:29:07 GMT\r\n\r\n
```

<55-character response>

Configuring an HTTP Callout

Dec 17, 2013

When configuring an HTTP callout, you specify the type of request (HTTP or HTTPS), destination and format of the request, the expected format of the response, and, finally, the portion of the response that you want to analyze.

For the destination, you either specify the IP address and port of the HTTP callout agent or engage a load balancing, content switching, or cache redirection virtual server to manage the HTTP callout requests. In the first case, the HTTP callout requests will be sent directly to the HTTP callout agent. In the second case, the HTTP callout requests will be sent to the virtual IP address (VIP) of the specified virtual server. The virtual server will then process the request in the same way as it processes a client request. For example, if you expect a large number of callouts to be generated, you can configure instances of the HTTP callout agent on multiple servers, bind these instances (as services) to a load balancing virtual server, and then specify the load balancing virtual server in the HTTP callout configuration. The load balancing virtual server then balances the load on those configured instances as determined by the load balancing algorithm.

For the format of the HTTP callout request, you can specify the individual attributes of the HTTP callout request (an attribute-based HTTP callout), or you can specify the entire HTTP callout request as a default syntax expression (an expression-based HTTP callout).

Note: The appliance does not check for the validity of the request. You must make sure that the request is a valid request. An incorrect or incomplete HTTP callout configuration results in a runtime UNDEF condition that is not associated with an action. The UNDEF condition merely updates the Undefined Hits counter, which enables you to troubleshoot an incorrectly configured HTTP callout. However, the appliance parses the HTTP callout request to enable you to configure certain NetScaler features for the callout. This can lead to an HTTP callout invoking itself. For information about callout recursion and how you can avoid it, see "[Avoiding HTTP Callout Recursion.](#)"

Finally, regardless of whether you use HTTP request attributes or an expression to define the format of the HTTP callout request, you must specify the format of the response from the HTTP callout agent and the portion of the response that you want to evaluate. The response can be a Boolean value, a number, or text. The portion of the response that you want to evaluate is specified by an expression. For example, if you specify that the response contains text, you can use `HTTP.RES.BODY(<unit>)` to specify that the appliance must evaluate only the first <unit> bytes of the response from the callout agent.

At the command line, you first create an HTTP callout by using the `add` command. When you add a callout, all parameters are set to a default value of `NONE`, except the HTTP method, which is set to a default value of `GET`. You then configure the callout's parameters by using the `set` command. The `set` command is used to configure both types of callouts (attribute-based and expression-based). The difference lies in the parameters that are used for configuring the two types of callouts. Accordingly, the command-line instructions that follow include a `set` command for configuring an attribute-based callout and a `set` command for configuring an expression-based callout. In the configuration utility, all of these configuration tasks are performed in a single dialog box.

Note: Before you put an HTTP callout into a policy, you can modify all configured parameters except the return type. Once an HTTP callout is in a policy, you cannot completely modify an expression that is configured in the callout. For example, you cannot change `HTTP.REQ.HEADER("myVal")` to `CLIENT.IP.SRC`. However, you can modify the operators and arguments that are passed to the expression. For example, you can change `HTTP.REQ.HEADER("myVal1")` to `HTTP.REQ.HEADER("myVal2")`, or `HTTP.REQ.HEADER("myVal")` to `HTTP.REQ.HEADER("myVal").AFTER_STR(<string>)`. If the `set` command fails, create a new HTTP callout. HTTP callout configuration involves configuring default syntax expressions. For more information about configuring default syntax expressions, see "[Configuring Default Syntax Expressions: Getting Started.](#)"

To configure an HTTP callout by using the command line interface

At the command prompt, do the following:

1. Create a HTTP callout.

```
add policy httpCallout <name>
```

Example

```
> add policy httpCallout mycallout
```

2. Configure the details of the HTTP callout.

- To configure an attribute-based HTTP callout, type:

```
set policy httpCallout <name> [-IPAddress <ip_addr|ipv6_addr|*>] [-port <port|*>] [-vServer <string>] [-returnType <returnType>] [-httpMethod ( GET | POST )] [-hostExpr <string>] [-urlStemExpr <string>] [-headers <name(value)> ...] [-parameters <name(value)> ...] [-resultExpr <string>]
```

Example

```
> set policy httpCallout mycallout -vserver lbv1 -returnType num -httpMethod GET -hostExpr 'http.req.header("Host")' -urlStemExpr "http.req.url" -parameters Name("My Name") -headers Name("MyHeader") -resultExpr "http.res.body(10000).length"
```

- To configure an expression-based HTTP callout, type:

```
set policy httpCallout <name> [-vServer <string>] [-returnType <returnType>] [-httpMethod ( GET | POST )] [-fullReqExpr <string>] [-resultExpr <string>]
```

Example

```
> set policy httpCallout mycallout1 -vserver lbv1 -returnType num -httpMethod GET -fullReqExpr q{"GET " + http.req.url + "HTTP/" + http.req.version.major + "." + http.req.version.minor.sub(1) + "\r\nHost:10.101.10.10\r\nAccept: */*\r\n\r\n"}
```

3. Verify the configurations of the HTTP callout.

```
show policy httpCallout <name>
```

To configure an HTTP callout by using the configuration utility

1. Navigate to AppExpert > HTTP Callouts.
2. In the details pane, click Add.
3. In the Create HTTP Callout dialog box, configure the parameters of the HTTP callout. For a description of the parameter, hover the mouse cursor over the check box.
4. Click Create and then click Close.

Verifying the Configuration

Aug 30, 2013

For an HTTP callout to work correctly, all the HTTP callout parameters and the entities associated with the callout must be configured correctly. While the NetScaler appliance does not check the validity of the HTTP callout parameters, it indicates the state of the bound entities, namely the server or virtual server to which the HTTP callout is sent. The following table lists the icons and describes the conditions under which the icons are displayed.

Table 1. Icons That Indicate the States of Entities Bound to an HTTP Callout

Icon	Indicates that
	The state of the server that hosts the HTTP callout agent, or the load balancing, content switching, or cache redirection virtual server to which the HTTP callout is sent is UP.
	The state of the server that hosts the HTTP callout agent, or the load balancing, content switching, or cache redirection virtual server to which the HTTP callout is sent is OUT OF SERVICE.
	The state of the server that hosts the HTTP callout agent, or the load balancing, content switching, or cache redirection virtual server to which the HTTP callout is sent is DOWN.

For an HTTP callout to function correctly, the icon must be green at all times. If the icon is not green, check the state of the callout server or virtual server to which the HTTP callout is sent. If the HTTP callout is not working as expected even though the icon is green, check the parameters configured for the callout.

You can also verify the configuration by sending test requests that match the policy from which the HTTP callout is invoked, checking the hits counter for the policy and the HTTP callout, and verifying the responses that the NetScaler appliance sends to the client.

Note: An HTTP callout can sometimes invoke itself recursively a second time. If this happens, the hits counter is incremented by two counts for each callout that is generated by the appliance. For the hits counter to display the correct value, you must configure the HTTP callout in such a way that it does not invoke itself a second time. For more information about how you can avoid HTTP callout recursion, see "[Avoiding HTTP Callout Recursion](#)."

To view the hits counter for an HTTP callout

1. Navigate to AppExpert > HTTP Callouts.
2. In the details pane, click the HTTP callout for which you want to view the hits counter, and then view the hits in the Details area.

Invoking an HTTP Callout

Aug 30, 2013

After you configure an HTTP callout, you invoke the callout by including the `SYS.HTTP_CALLOUT(<name>)` expression in a default syntax policy rule. In this expression, `<name>` is the name of the HTTP callout that you want to invoke.

You can use default syntax expression operators with the callout expression to process the response and then perform an appropriate action. The return type of the response from the HTTP callout agent determines the set of operators that you can use on the response. If the part of the response that you want to analyze is text, you can use a text operator to analyze the response. For example, you can use the `CONTAINS(<string>)` operator to check whether the specified portion of the response contains a particular string, as in the following example:

```
SYS.HTTP_CALLOUT(myCallout).contains("Good IP address")
```

If you use the preceding expression in a responder policy, you can configure an appropriate responder action.

Similarly, if the part of the response that you want to evaluate is a number, you can use a numeric operator such as `GT(int)`. If the response contains a Boolean value, you can use a Boolean operator.

Note: An HTTP callout can invoke itself recursively. HTTP callout recursion can be avoided by combining the HTTP callout expression with a default syntax expression that prevents recursion. For information about how you can avoid HTTP callout recursion, see "[Avoiding HTTP Callout Recursion](#)."

You can also cascade HTTP callouts by configuring policies that each invoke a callout after evaluating previously generated callouts. In this scenario, after one policy invokes a callout, when the NetScaler appliance is parsing the callout before sending the callout to the callout server, a second set of policies can evaluate the callout and invoke additional callouts, which can in turn be evaluated by a third set of policies, and so on. Such an implementation is described in the following example.

First, you could configure an HTTP callout called `myCallout1`, and then configure a responder policy, `Pol1`, to invoke `myCallout1`. Then, you could configure a second HTTP callout, `myCallout2`, and a responder policy, `Pol2`. You configure `Pol2` to evaluate `myCallout1` and invoke `myCallout2`. You bind both responder policies globally.

To avoid HTTP callout recursion, `myCallout1` is configured with a unique custom HTTP header called "Request1." `Pol1` is configured to avoid HTTP callout recursion by using the default syntax expression, `HTTP.REQ.HEADER("Request1").EQ("Callout Request").NOT`.

`Pol2` uses the same default syntax expression, but excludes the `.NOT` operator so that the policy evaluates `myCallout1` when the NetScaler appliance is parsing it. Note that `myCallout2` identifies its own unique header called "Request2," and `Pol2` includes a default syntax expression to prevent `myCallout2` from invoking itself recursively.

Example

```
> add policy httpCallout myCallout1
```

Done

```
> set policy httpCallout myCallout1 -IPAddress 10.102.3.95 -port 80 -returnType TEXT -hostExpr  
"10.102.3.95" -urlStemExpr "/cgi-bin/check_clnt_from_database.pl" -headers Request1  
("Callout Request") -parameters cip(CLIENT.IP.SRC) -resultExpr "HTTP.RES.BODY(100)"
```

Done

```
> add responder policy Pol1 "HTTP.REQ.HEADER(\\"Request1\\").EQ(\\"Callout Request\\").NOT &&
SYS.HTTP_CALLOUT(myCallout1).CONTAINS(\\"IP Matched\\")" RESET
```

Done

```
> bind responder global Pol1 100 END -type OVERRIDE
```

Done

```
> add policy httpCallout myCallout2
```

Done

```
> set policy httpCallout myCallout2 -IPAddress 10.102.3.96 -port 80 -returnType TEXT -hostExpr
\\"10.102.3.96\\" -urlStemExpr \"/cgi-bin/check_clnt_location_from_database.pl\\" -headers Request2
("Callout Request") -parameters cip(CLIENT.IP.SRC) -resultExpr "HTTP.RES.BODY(200)"
```

Done

```
> add responder policy Pol2 "HTTP.REQ.HEADER(\\"Request2\\").EQ(\\"Callout Request\\").NOT &&
HTTP.REQ.HEADER(\\"Request1\\").EQ(\\"Callout Request\\") && SYS.HTTP_CALLOUT(myCallout2).CONTAINS
(\\"APAC\\")" RESET
```

Done

```
> bind responder global Pol2 110 END -type OVERRIDE
```

Done

Avoiding HTTP Callout Recursion

Apr 03, 2013

Even though the NetScaler appliance does not check for the validity of the HTTP callout request, it parses the request once before it sends the request to the HTTP callout agent. This parsing allows the appliance to treat the callout request as any other incoming request, which in turn allows you to configure several useful NetScaler features (such as integrated caching, SureConnect, and Priority Queuing) to work on the callout request.

However, during this parsing, the HTTP callout request can hit the same policy and therefore invoke itself recursively. The appliance detects the recursive invocation and raises an undefined (UNDEF) condition. However, the recursive invocation results in the policy and HTTP callout hit counters being incremented by two counts each instead of one count each.

To prevent a callout from invoking itself, you must identify at least one unique characteristic of the HTTP callout request, and then exclude all requests with this characteristic from being processed by the policy rule that invokes the callout. You can do so by including another default syntax expression in the policy rule. The expression must precede the SYS.HTTP_CALLOUT(<name>) expression so that it is evaluated before the callout expression is evaluated. For example:

```
<Expression that prevents callout recursion> && SYS.HTTP_CALLOUT(<name>)
```

When you configure a policy rule in this way, when the appliance generates the request and parses it, the compound rule evaluates to FALSE, the callout is not generated a second time, and the hit counters are incremented correctly.

One way by which you can assign a unique characteristic to an HTTP callout request is to include a unique custom HTTP header when you configure the callout. Following is an example of an HTTP callout called "myCallout." The callout generates an HTTP request that checks whether a client's IP address is present in a database of blacklisted IP addresses. The callout includes a custom header called "Request," which is set to the value "Callout Request." A globally bound responder policy, "Pol1," invokes the HTTP callout but excludes all requests whose Request header is set to this value, thus preventing a second invocation of myCallout. The expression that prevents a second invocation is HTTP.REQ.HEADER("Request").EQ("Callout Request").NOT.

Example

```
> add policy httpCallout myCallout
Done
```

```
> set policy httpCallout myCallout -IPAddress 10.102.3.95 -port 80 -returnType TEXT -hostExpr ""10.102.3.95"" -urlStemExpr ""/cgi-bin/check_clnt_from_database.pl"" -headers Request("Callout Reque
Done
```

```
> add responder policy Pol1 "HTTP.REQ.HEADER("Request").EQ("Callout Request").NOT && SYS.HTTP_CALLOUT(myCallout).CONTAINS("IP Matched")" RESET
Done
```

```
> bind responder global Pol1 100 END -type OVERRIDE
Done
```

Note: You can also configure an expression to check whether the URL of the request includes the URL stem expression that is configured for the HTTP callout. If you want to implement this scenario, make sure that the HTTP callout agent is dedicated to respond only to HTTP callouts and not to other client requests directed through the appliance. If the HTTP callout agent is an application or Web server that serves other client requests, such an expression will prevent the appliance from processing those client requests. Instead, use a unique custom header as described earlier.

Caching HTTP Callout Responses

Apr 03, 2013

For improved performance while using callouts, you can use the integrated caching feature to cache callout responses. The responses are stored in an integrated caching content group named `calloutContentGroup` for a specified time duration.

Note: To cache callout responses, make sure that the integrated caching feature is enabled.

To set the cache duration by using the command line interface

At the command prompt, type:

```
set policy httpCallout <name> -cacheForSecs <secs>
```

Example

```
> set httpcallout httpcallout1 -cacheForSecs 120
```

To set the cache duration by using the configuration utility

1. Navigate to AppExpert > HTTP Callouts.
2. In the details pane, select the HTTP callout for which you want to set the cache duration and click Open.
3. In the Configure HTTP Callout dialog box, specify the Cache Expiration Time.
4. Verify that you have entered the correct time duration, and then click OK.

Use Case: Filtering Clients by Using an IP Blacklist

May 21, 2015

HTTP callouts can be used to block requests from clients that are blacklisted by the administrator. The list of clients can be a publicly known blacklist, a blacklist that you maintain for your organization, or a combination of both.

The NetScaler appliance checks the IP address of the client against the pre-configured blacklist and blocks the transaction if the IP address has been blacklisted. If the IP address is not in the list, the appliance processes the transaction.

To implement this configuration, you must perform the following tasks:

1. Enable responder on the NetScaler appliance.
2. Create an HTTP callout on the NetScaler appliance and configure it with details about the external server and other required parameters.
3. Configure a responder policy to analyze the response to the HTTP callout, and then bind the policy globally.
4. Create an HTTP callout agent on the remote server.

Enabling Responder

Updated: 2013-08-30

You must enable responder before you can use it.

To enable responder by using the configuration utility

1. Make sure that you have installed the responder license.
2. In the configuration utility, expand AppExpert, and right-click Responder, and then click Enable Responder feature.

Creating an HTTP Callout on the NetScaler Appliance

Updated: 2013-08-30

Create an HTTP callout, HTTP-Callout-1, with the parameter settings shown in the following table. For more information about creating an HTTP callout, see "[Configuring an HTTP Callout](#)."

Table 1. Parameters and Values for HTTP-Callout-1

Parameter	Value
Name	HTTP-Callout-1
Server to receive callout request	
IP Address	10.103.9.95
Port	80
Request to send to the server	
Method	GET
Host Expression	10.102.3.95
URL Stem Expression	"/cgi-bin/check_clnt_from_database.pl"
Headers	

Parameter	Value
Name	Request
Value-expression	Callout Request
Parameters	
Name	Cip
Value-expression	CLIENT.IP.SRC
Server Response	
Return Type	TEXT
Expression to extract data from the response	HTTP.RES.BODY(100)

Configuring a Responder Policy and Binding it Globally

Updated: 2013-08-30

After you configure the HTTP callout, verify the callout configuration, and then configure a responder policy to invoke the callout. While you can create a responder policy in the Policies sub-node and then bind it globally by using the Responder Policy Manager, this demonstration uses the Responder Policy Manager to create the responder policy and bind the policy globally.

To create a responder policy and bind it globally by using the configuration utility

1. Navigate to AppExpert > Responder.
2. In the details pane, under Policy Manager, click Policy Manager.
3. In the Responder Policy Manager dialog box, click Override Global.
4. Click Insert Policy, and then, under Policy Name, click New Policy.
5. In the Create Responder Policy dialog box, do the following:
 1. In Name, type Policy-Responder-1.
 2. In Action, select RESET.
 3. In Undefined-Result Action, select Global undefined-result action.
 4. In Expression, type the following default syntax expression:
"HTTP.REQ.HEADER("Request").EQ("Callout Request").NOT && SYS.HTTP_CALLOUT(HTTP-Callout-1).CONTAINS("IP Matched")"
 5. Click Create, and then click Close.
6. Click Apply Changes, and then click Close.

Creating an HTTP Callout Agent on the Remote Server

You must now create an HTTP callout agent on the remote callout server that will receive callout requests from the NetScaler appliance and respond appropriately. The HTTP callout agent is a script that is different for each deployment and must be written with the server specifications in mind, such as the type of database and the scripting language supported.

Following is a sample callout agent that verifies whether the given IP address is part of an IP blacklist. The agent has been written in the Perl scripting language and uses a MySQL database.

The following CGI script checks for a given IP address on the callout server.

```
#!/usr/bin/perl -w
print "Content-type: text/html\n\n";
```

```

use DBI();
use CGI qw(:standard);
#Take the Client IP address from the request query
my $ip_to_check = param('cip');
# Where a MYSQL database is running
my $dsn = 'DBI:mysql:BAD_CLIENT:localhost';
# Database username to connect with
my $db_user_name = 'dbuser';
# Database password to connect with
my $db_password = 'dbpassword';
my ($id, $password);
# Connecting to the database
my $dbh = DBI->connect($dsn, $db_user_name, $db_password);
my $sth = $dbh->prepare(qq{ select * from bad_clnt });
$sth->execute();
while (my ($ip_in_database) = $sth->fetchrow_array()) {
chomp($ip_in_database);
# Check for IP match
if ($ip_in_database eq $ip_to_check) {
print "\n IP Matched\n";
$sth->finish();
exit;
}
}
print "\n IP Failed\n";
$sth->finish();
exit;

```

Use Case: ESI Support for Fetching and Updating Content Dynamically

May 21, 2015

Edge Side Includes (ESI) is a markup language for edge-level dynamic Web content assembly. It helps in accelerating dynamic Web-based applications by defining a simple markup language to describe cacheable and non-cacheable Web page components that can be aggregated, assembled, and delivered at the network edge. By using HTTP callouts on the NetScaler appliance, you can read through the ESI constructs and aggregate or assemble content dynamically.

To implement this configuration, you must perform the following tasks:

1. Enable rewrite on the NetScaler appliance.
2. Create an HTTP callout on the appliance and configure it with details about the external server and other required parameters.
3. Configure a rewrite action to replace the ESI content with the callout response body.
4. Configure a rewrite policy to specify the conditions under which the action is performed, and then bind the rewrite policy globally.

Enabling Rewrite

Updated: 2013-08-30

Rewrite must be enabled before it is used on the NetScaler appliance. The following procedure describes the steps to enable the rewrite feature.

To enable rewrite by using the configuration utility

1. Make sure that you have installed the rewrite license.
2. In the configuration utility, expand AppExpert, and right-click Rewrite, and then click Enable Rewrite feature.

Creating an HTTP Callout on the NetScaler Appliance

Updated: 2013-08-30

Create an HTTP callout, HTTP-Callout-2, with the parameter settings shown in the following table. For more information about creating an HTTP callout, see "[Configuring an HTTP Callout.](#)"

Table 1. Parameters and Values for HTTP-Callout-2

Parameter	Value
Name	HTTP-Callout-2
Server to receive callout request	
IP Address	10.102.56.51
Port	80

Parameter	Value
Request to send to the server	
Method	GET
Host Expression	10.102.56.51:80
URL Stem Expression	"HTTP.RES.BODY(500).AFTER_STR(\"src=\").BEFORE_STR(\"/>\")"
Headers	
Name	Name
Value-expression	Callout
Server Response	
Return Type	TEXT
Expression to extract data from the response	HTTP.RES.BODY(100)

Configuring the Rewrite Action

Updated: 2013-08-30

Create a rewrite action, Action-Rewrite-1, to replace the ESI content with the callout response body. Use the parameter settings shown in the following table.

Table 2. Parameters and Values for Action-Rewrite-1

Parameter	Value
Name	Action-Rewrite-1
Type	Replace
Expression to choose target text reference	"HTTP.RES.BODY(500).AFTER_STR (\<example>\").BEFORE_STR (\</example>\")"
String expression for replacement text	"SYS.HTTP_CALLOUT(HTTP-Callout-2)"

To configure the rewrite action by using the configuration utility

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, click Add.
3. In the Create Rewrite Action dialog box, in Name, type Action-Rewrite-1.
4. In Type, select REPLACE.
5. In Expression to choose target text reference, type the following default syntax expression:
"HTTP.RES.BODY(500).AFTER_STR("<example>").BEFORE_STR("</example>")"
6. In the String expression for replacement text, type the following string expression:
"SYS.HTTP_CALLOUT(HTTP-Callout-2)"
7. Click Create, and then click Close.

Creating the Rewrite Policy and Binding it Globally

Updated: 2013-08-30

Create a rewrite policy, Policy-Rewrite-1, with the parameter settings shown in the following table. You can create a rewrite policy in the Policies subnode and then bind it globally by using the Rewrite Policy Manager. Alternatively, you can use the Rewrite Policy Manager to perform both these tasks simultaneously. This demonstration uses the Rewrite Policy Manager to perform both tasks.

Table 3. Parameters and Values for Policy-Rewrite-1

Parameter	Value
Name	Policy-Rewrite-1
Action	Action_Rewrite-1
Undefined Result Action	-Global undefined-result action-
Expression	"HTTP.REQ.HEADER("<Name>").CONTAINS("<Callout>").NOT"

To configure a rewrite policy and bind it globally by using the configuration utility

1. Navigate to AppExpert > Rewrite.
2. In the details pane, under Policy Manager, click Rewrite Policy Manager.
3. In the Rewrite Policy Manager dialog box, click Override Global.
4. Click Insert Policy, and then, in the Policy Name column, click New Policy.
5. In the Create Rewrite Policy dialog box, do the following:
 1. In Name, type Policy-Rewrite-1.
 2. In Action, select Action-Rewrite-1.
 3. In Undefined-Result Action, select Global undefined-result action.
 4. In Expression, type the following default syntax expression:
"HTTP.REQ.HEADER("<Name>").CONTAINS("<Callout>").NOT"
 5. Click Create, and then click Close.
6. Click Apply Changes, and then click Close.

Use Case: Access Control and Authentication

May 21, 2015

In high security zones, it is mandatory to externally authenticate the user before a resource is accessed by clients. On the NetScaler appliance, you can use HTTP callouts to externally authenticate the user by evaluating the credentials supplied. In this example, the assumption is that the client is sending the user name and password through HTTP headers in the request. However, the same information could be fetched from the URL or the HTTP body.

To implement this configuration, you must perform the following tasks:

1. Enable the responder feature on the NetScaler appliance.
2. Create an HTTP callout on the appliance and configure it with details about the external server and other required parameters.
3. Configure a responder policy to analyze the response, and then bind the policy globally.
4. Create a callout agent on the remote server.

Enabling Responder

Updated: 2013-08-30

The responder feature must be enabled before it is used on the NetScaler appliance.

To enable responder by using the configuration utility

1. Make sure that the responder license is installed.
2. In the configuration utility, expand AppExpert, and right-click Responder, and then click Enable Responder feature.

Creating an HTTP Callout on the NetScaler Appliance

Updated: 2013-08-30

Create an HTTP callout, HTTP-Callout-3, with the parameter settings shown in the following table. For more information about creating an HTTP callout, see ["Configuring an HTTP Callout."](#)

Table 1. Parameters and Values for HTTP-Callout-3

Parameter	Value
Name	HTTP-Callout-3
Server to receive callout request	
IP Address	10.103.9.95
Port	80
Request to send to the server	
Method	GET
Host Expression	10.102.3.95
URL Stem Expression	"/cgi-bin/authenticate.pl"
Headers	
Name	Request
Value-expression	Callout Request
Parameters	

Parameter Name	Value
Username	HTTP.REQ.HEADER("Username").VALUE(0)
Name	Password
Value-expression	HTTP.REQ.HEADER("Password").VALUE(0)
Server Response	
Return Type	TEXT
Expression to extract data from the response	HTTP.RES.BODY(100)

Creating a Responder Policy to Analyze the Response

Updated: 2013-08-30

Create a responder policy, Policy-Responder-3, that will check the response from the callout server and RESET the connection if the source IP address has been blacklisted. Create the policy with the parameters settings shown in the following table. While you can create a responder policy in the Policies subnode and then bind it globally by using the Responder Policy Manager, this demonstration uses the Responder Policy Manager to create the responder policy and bind the policy globally.

Table 2. Parameters and Values for Policy-Responder-3

Parameter	Value
Name	Policy-Responder-3
Action	RESET
Undefined-Result-Action	-Global undefined-result action-
Expression	"HTTP.REQ.HEADER(\ "Request\ ").EQ(\ "Callout Request\ ").NOT && SYS.HTTP_CALLOUT(HTTP-Callout-3).CONTAINS(\ "Authentication Failed\ ")"

To create a responder policy and bind it globally by using the configuration utility

1. Navigate to AppExpert > Responder.
2. In the details pane, under Policy Manager, click Responder Policy Manager.
3. In the Responder Policy Manager dialog box, click Override Global.
4. Click Insert Policy, and then, in the Policy Name column, click New Policy.
5. In the Create Responder Policy dialog box, do the following:
 1. In Name, type Policy-Responder-3.
 2. In Action, select RESET.
 3. In Undefined-Result Action, select Global undefined-result action.
 4. In the Expression text box, type:
"HTTP.REQ.HEADER(\ "Request\ ").EQ(\ "Callout Request\ ").NOT && SYS.HTTP_CALLOUT(HTTP-Callout-3).CONTAINS(\ "Authentication Failed\ ")"
 5. Click Create, and then click Close.
6. Click Apply Changes, and then click Close.

Creating an HTTP Callout Agent on the Remote Server

You now need to create an HTTP callout agent on the remote callout server. The HTTP callout agent receives callout requests from the NetScaler appliance and responds appropriately. The callout agent is a script that is different for each deployment and must be written with server specifications in mind, such as the type of database and the scripting language supported.

Following is sample callout agent pseudo-code that verifies whether the supplied user name and password are valid. The agent can be implemented in any programming language of your choice. The pseudo-code is to be used only as a guideline for developing the callout agent. You can build additional functionality into the program.

To verify the supplied user name and password by using pseudo-code
