A close-notify is a secure message that indicates the end of SSL data transmission. A close-notify setting is required at the global level. This setting applies to all virtual servers, services, and service groups. For information about the global setting, see [Configuring Advanced SSL Settings](#).

In addition to the global setting, you can set the close-notify parameter at the virtual server, service, or service group level. You therefore have the flexibility of setting the parameter for one entity and unsetting it for another entity. However, make sure that you set this parameter at the global level. Otherwise, the setting at the entity level does not apply.

To configure close-notify at the entity level by using the command line interface

At the command prompt, type any of the following commands to configure close-notify and verify the configuration:

1. To configure close-notify at the virtual server level, type:
  - set ssl vserver <vServerName> -sendCloseNotify ( **YES** | **NO** )
  - show ssl vserver <vServerName>
2. To configure close-notify at the service level, type:
  - set ssl service <serviceName> -sendCloseNotify ( **YES** | **NO** )
  - show ssl service <serviceName>
3. To configure close-notify at the service group level, type:
  - set ssl serviceGroup <serviceGroupName> -sendCloseNotify ( **YES** | **NO** )
  - show ssl serviceGroup <serviceGroupName>

## Example

```
> set ssl vserver sslsvr -sendCloseNotify YES
Done
```

To configure close-notify at the entity level by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Send Close-Notify.

# Configuring ECDHE Ciphers

Jun 20, 2016

The Citrix NetScaler VPX, MPX, and SDX appliances support the ECDHE cipher group in release 10.5 build 53.9 or later. On an SDX appliance, if an SSL chip is assigned to a VPX instance, the cipher support of an MPX appliance applies. Otherwise, the normal cipher support of a VPX instance applies. For a complete list of ciphers supported by the NetScaler appliance, see [Ciphers Supported by the NetScaler Appliance](#).

The following table lists the ciphers supported on VPX instances and MPX appliances.

| Cipher Suite                       | VPX | MPX |
|------------------------------------|-----|-----|
| TLS1-ECDHE-RSA-RC4-SHA             | YES | YES |
| TLS1-ECDHE-RSA-DES-CBC3-SHA        | YES | YES |
| TLS1-ECDHE-RSA-AES128-SHA          | YES | YES |
| TLS1-ECDHE-RSA-AES256-SHA          | YES | YES |
| TLS1.2-ECDHE-RSA-AES128-GCM-SHA256 | NO  | YES |
| TLS1.2-ECDHE-RSA-AES256-GCM-SHA384 | NO  | YES |
| TLS1.2-ECDHE-RSA-AES-128-SHA256    | NO  | YES |
| TLS1.2-ECDHE-RSA-AES-256-SHA384    | NO  | YES |

ECDHE cipher suites use elliptical curve cryptography (ECC). Because of its smaller key size, ECC is especially useful in a mobile (wireless) environment or an interactive voice response environment, where every millisecond is important. Smaller key sizes save power, memory, bandwidth, and computational cost.

A NetScaler appliance supports the following ECC curves:

- P\_256
- P\_384
- P\_224
- P\_521

Note:

- If you upgrade from a build earlier than release 10.1 build 121.10, you must explicitly bind ECC curves to your existing SSL virtual servers or front end services. The curves are bound by default to any virtual servers or front end services that you create after the upgrade.

You can bind an ECC curve to SSL front-end entities only. By default all four curves are bound, in the following order: P\_256,

P\_384,P\_224,P\_521. To change the order, you must first unbind all the curves, and then bind them in the desired order.

To unbind ECC curves and bind an ECC curve to an SSL virtual server by using the command line

At the command prompt, type:

- unbind ssl vserver <vServerName> -eccCurveName ALL
- bind ssl vserver <vServerName> -eccCurveName <eccCurveName>

## Example

```
unbind ssl vs v1 -eccCurveName ALL
bind ssl vserver v1 -eccCurveName P_224
> sh ssl vserver v1
```

Advanced SSL configuration for VServer v1:

DH: DISABLED

Ephemeral RSA: ENABLED Refresh Count: 0

Session Reuse: ENABLED Timeout: 120 seconds

Cipher Redirect: DISABLED

SSLv2 Redirect: DISABLED

ClearText Port: 0

Client Auth: DISABLED

SSL Redirect: DISABLED

Non FIPS Ciphers: DISABLED

SNI: DISABLED

SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: DISABLED TLSv1.2: DISABLED

Push Encryption Trigger: Always

Send Close-Notify: YES

ECC Curve: P\_224

# Configuring a Common Name on an SSL Service or Service Group for Server Certificate Authentication

May 13, 2015

In end-to-end encryption with server authentication enabled, you can include a common name in the configuration of an SSL service or service group. The name that you specify is compared to the common name in the server certificate during an SSL handshake. If the two names match, the handshake is successful. This configuration is especially useful if there are, for example, two servers behind a firewall and one of the servers spoofs the identity of the other. If the common name is not checked, a certificate presented by either server is accepted if the IP address matches.

To configure common-name verification for an SSL service or service group by using the command line interface

At the command prompt, type the following commands to specify server authentication with common-name verification and verify the configuration:

1. To configure common name in a service, type:
  - set ssl service <serviceName> -commonName <string> -serverAuth ENABLED
  - show ssl service <serviceName>
2. To configure common name in a service group, type:
  - set ssl serviceGroup <serviceGroupName> -commonName <string> -serverAuth ENABLED
  - show ssl serviceGroup <serviceGroupName>

## Example

```
> set ssl service svc1 -commonName xyz.com -serverAuth ENABLED
```

```
Done
```

```
> show ssl service svc1
```

```
Advanced SSL configuration for Back-end SSL Service svc1:
```

```
DH: DISABLED
```

```
Ephemeral RSA: DISABLED
```

```
Session Reuse: ENABLED Timeout: 300 seconds
```

```
Cipher Redirect: DISABLED
```

```
SSLv2 Redirect: DISABLED
```

```
Server Auth: ENABLED Common Name: www.xyz.com
```

```
SSL Redirect: DISABLED
```

```
Non FIPS Ciphers: DISABLED
```

```
SNI: DISABLED
```

```
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
```

```
1) CertKey Name: cacert CA Certificate OCSPCheck: Optional
```

```
1) Cipher Name: ALL
```

```
Description: Predefined Cipher Alias
```

```
Done
```

To configure common-name verification for an SSL service or service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services or Navigate to Traffic Management > Load Balancing > Service Groups, and open a service or service group.
2. In the SSL Parameters section, select Enable Server Authentication, and specify a common name.

# Configuring Advanced SSL Settings

Sep 20, 2013

Advanced customization of your SSL configuration addresses specific issues. You can use the `set ssl parameter` command or the configuration utility to specify the following:

- Quantum size to be used for SSL transactions.
- CRL memory size.
- OCSP cache size.
- Deny SSL renegotiation.
- Set the PUSH flag for decrypted, encrypted, or all records.
- Drop requests if the client initiates the handshake for one domain and sends an HTTP request for another domain.
- Set the time after which encryption is triggered.

Note: The time that you specify applies only if you use the `set ssl vserver` command or the configuration utility to set timer-based encryption.

To configure advanced SSL settings by using the command line interface

At the command prompt, type the following commands to configure advanced SSL settings and verify the configuration:

- `set ssl parameter [-quantumSize <quantumSize>] [-crlMemorySizeMB <positive_integer>] [-strictCAChecks (YES | NO)] [-sslTriggerTimeout <positive_integer>] [-sendCloseNotify (YES | NO)] [-encryptTriggerPktCount <positive_integer>] [-denySSLReneg <denySSLReneg>] [-insertionEncoding (Unicode | UTF-8)] [-ocspCacheSize <positive_integer>] [-pushFlag <positive_integer>] [-dropReqWithNoHostHeader (YES | NO)] [-pushEncTriggerTimeout <positive_integer>]`
- `show ssl parameter`

## Example

```
> set ssl parameter -quantumSize 8 -crlMemorySizeMB 256 -strictCAChecks no -sslTriggerTimeout 100 -sendCloseNotify no -encryptTriggerPktCount 45 -denySSLReneg no -insertionEncoding unicode -ocspCacheSize 10 -pushFlag 3 -dropReqWithNoHostHeader YES -pushEncTriggerTimeout 100 ms
Done
```

```
> show ssl parameter
```

Advanced SSL Parameters

```

SSL quantum size: 8 kB
Max CRL memory size: 256 MB
Strict CA checks: NO
Encryption trigger timeout 100 mS
Send Close-Notify NO
Encryption trigger packet count: 45
Deny SSL Renegotiation NO
Subject/Issuer Name Insertion Format: Unicode
OCSP cache size: 10 MB
Push flag: 0x3 (On every decrypted and encrypted record)
Strict Host Header check for SNI enabled SSL sessions: YES
PUSH encryption trigger timeout 100 ms
```

Done

To configure advanced SSL settings by using the configuration utility

Navigate to Traffic Management > SSL and, in the Settings group, select Change advanced SSL settings.

## PUSH Flag-Based Encryption Trigger Mechanism

The encryption trigger mechanism that is based on the PSH TCP flag now enables you to do the following:

- Merge consecutive packets in which the PSH flag is set into a single SSL record, or ignore the PSH flag.
- Perform timer-based encryption, in which the time-out value is set globally by using the set ssl parameter - pushEncTriggerTimeout <positive\_integer> command.

## To configure PUSH flag-based encryption by using the command line interface

At the command prompt, type the following commands to configure PUSH flag-based encryption and verify the configuration:

- set ssl vservers <vServerName> [-pushEncTrigger <pushEncTrigger>]
- show ssl vservers

### Example

Advanced SSL configuration for VServer v1:

```
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
Push Encryption Trigger: Always
```

## To configure PUSH flag-based encryption by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual servers and open an SSL virtual server.
2. In the SSL Parameters section, from the PUSH Encryption Trigger list, select a value.

# Synchronizing Configuration Files in a High Availability Setup

Oct 28, 2013

In a high availability (HA) set up, the primary NetScaler appliance in the HA pair automatically synchronizes with the secondary appliance in the pair. In the synchronization process, the secondary copies the primary's /nsconfig/ssl/ directory, which is the default location for storing the certificates and keys for SSL transactions. Synchronization occurs at one-minute intervals and every time a new file is added to the directory.

To synchronize files in a high availability set up by using the command line interface

At the command prompt, type the following command:

```
sync HA files [<Mode>]
```

## **Example**

```
sync HA files SSL
```

To synchronize files in a high availability set up by using the configuration utility

Navigate to Traffic Management > SSL and, in the Tools group, select Start SSL certificate, key file synchronization for HA.

# Managing Server Authentication

Aug 20, 2013

Since the NetScaler appliance performs SSL offload and acceleration on behalf of a web server, the appliance does not usually authenticate the Web server's certificate. However, you can authenticate the server in deployments that require end-to-end SSL encryption.

In such a situation, the NetScaler becomes the SSL client, carries out a secure transaction with the SSL server, verifies that a CA whose certificate is bound to the SSL service has signed the server certificate, and checks the validity of the server certificate.

To authenticate the server, you must first enable server authentication and then bind the certificate of the CA that signed the server's certificate to the SSL service on the NetScaler. When binding the certificate, you must specify the bind as CA option.

To enable (or disable) server certificate authentication by using the command line interface

At the command prompt, type the following commands to enable server certificate authentication and verify the configuration:

- set ssl service <serviceName> -serverAuth ( ENABLED | DISABLED )
- show ssl service <serviceName>

## Example

```
> set ssl service ssl-service-1 -serverAuth ENABLED
```

```
Done
```

```
> show ssl service ssl-service-1
```

```
Advanced SSL configuration for Back-end SSL Service ssl-service-1:
```

```
DH: DISABLED
```

```
Ephemeral RSA: DISABLED
```

```
Session Reuse: ENABLED Timeout: 300 seconds
```

```
Cipher Redirect: DISABLED
```

```
SSLv2 Redirect: DISABLED
```

```
Server Auth: ENABLED
```

```
SSL Redirect: DISABLED
```

```
Non FIPS Ciphers: DISABLED
```

```
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
```

```
1) Cipher Name: ALL
```

```
Description: Predefined Cipher Alias
```

```
Done
```

To enable (or disable) server certificate authentication by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open an SSL service.
2. In the SSL Parameters section, select Enable Server Authentication, and specify a Common Name.
3. In Advanced Settings, select Certificates, and bind a CA certificate to the service.

To bind the CA certificate to the service by using the command line interface

At the command prompt, type the following commands to bind the CA certificate to the service and verify the configuration:

- bind ssl service <serviceName> -certkeyName <string> -CA
- show ssl service <serviceName>

### Example

```
> bind ssl service ssl-service-1 -certkeyName samplecertkey -CA
Done
> show ssl service ssl-service-1
```

Advanced SSL configuration for Back-end SSL Service ssl-service-1:

DH: DISABLED

Ephemeral RSA: DISABLED

Session Reuse: ENABLED      Timeout: 300 seconds

Cipher Redirect: DISABLED

SSLv2 Redirect: DISABLED

Server Auth: ENABLED

SSL Redirect: DISABLED

Non FIPS Ciphers: DISABLED

SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: samplecertkey    CA Certificate      CRLCheck: Optional

1) Cipher Name: ALL

Description: Predefined Cipher Alias

Done

# Configuring User-Defined Cipher Groups on the NetScaler Appliance

Oct 02, 2013

A cipher group is a set of cipher suites that you bind to an SSL virtual server, service, or service group on the NetScaler appliance. A cipher suite comprises a protocol, a key exchange (Kx) algorithm, an authentication (Au) algorithm, an encryption (Enc) algorithm, and a message authentication code (Mac) algorithm. Your appliance ships with a predefined set of cipher groups. When you create a SSL service or SSL service group, the ALL cipher group is automatically bound to it. However, when you create an SSL virtual server or a transparent SSL service, the DEFAULT cipher group is automatically bound to it. In addition, you can create a user-defined cipher group and bind it to an SSL virtual server, service, or service group.

Note: If your MPX appliance does not have any licenses, then only the EXPORT cipher is bound to your SSL virtual server, service, or service group.

To create a user-defined cipher group, first you create a cipher group and then you bind ciphers or cipher groups to this group. If you specify a cipher alias or a cipher group, all the ciphers in the cipher alias or group are added to the user-defined cipher group. You can also add individual ciphers (cipher suites) to a user-defined group. However, you cannot modify a predefined cipher group. Before removing a cipher group, unbind all the cipher suites in the group.

If you bind a cipher group to an SSL virtual server, service, or service group, the ciphers are appended to the existing ciphers that are bound to the entity. To bind a specific cipher group to the entity, you must first unbind the ciphers or cipher group that is bound to the entity and then bind the specific cipher group. For example, to bind only the AES cipher group to an SSL service, you perform the following steps:

1. Unbind the default cipher group ALL that is bound by default to the service when the service is created.  
`unbind ssl service <service name> -cipherName ALL`
2. Bind the AES cipher group to the service  
`bind ssl service <Service name> -cipherName AE`

If you want to bind the cipher group DES in addition to AES, at the command prompt, type:

- `bind ssl service <service name> -cipherName DES`

Note: The free NetScaler virtual appliance supports only the DH cipher group.

To configure a user-defined cipher group by using the command line interface

At the command prompt, type the following commands to add a cipher group, or to add ciphers to a previously created group, and verify the settings:

- `add ssl cipher <cipherGroupName>`
- `bind ssl cipher <cipherGroupName> -cipherName <string>`
- `show ssl cipher <cipherGroupName>`

Example

```
> add ssl cipher test
Done
> bind ssl cipher test -cipherName SSLv2
Done
> show ssl cipher test
```

```

1) Cipher Name: SSL2-RC2-CBC-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC2(128) Mac=MD5
2) Cipher Name: SSL2-RC4-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC4(128) Mac=MD5
3) Cipher Name: SSL2-DES-CBC3-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=3DES(168) Mac=MD5
4) Cipher Name: SSL2-DES-CBC-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=DES(56) Mac=MD5
5) Cipher Name: SSL2-RC4-64-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC4(64) Mac=MD5
6) Cipher Name: SSL2-EXP-RC4-MD5
Description: SSLv2 Kx=RSA(512) Au=RSA Enc=RC4(40) Mac=MD5 Export
7) Cipher Name: SSL2-EXP-RC2-CBC-MD5
Description: SSLv2 Kx=RSA(512) Au=RSA Enc=RC2(40) Mac=MD5 Export
Done

```

To unbind ciphers from a cipher group by using the command line interface

At the command prompt, type the following commands to unbind ciphers from a user-defined cipher group, and verify the settings:

- show ssl cipher <cipherGroupName>
- unbind ssl cipher <cipherGroupName> -cipherName <string>
- show ssl cipher <cipherGroupName>

## Example

```

> show ssl cipher test
1) Cipher Name: SSL2-RC2-CBC-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC2(128) Mac=MD5
2) Cipher Name: SSL2-RC4-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC4(128) Mac=MD5
3) Cipher Name: SSL2-DES-CBC3-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=3DES(168) Mac=MD5
4) Cipher Name: SSL2-DES-CBC-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=DES(56) Mac=MD5
5) Cipher Name: SSL2-RC4-64-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC4(64) Mac=MD5
6) Cipher Name: SSL2-EXP-RC4-MD5
Description: SSLv2 Kx=RSA(512) Au=RSA Enc=RC4(40) Mac=MD5 Export
7) Cipher Name: SSL2-EXP-RC2-CBC-MD5
Description: SSLv2 Kx=RSA(512) Au=RSA Enc=RC2(40) Mac=MD5 Export
Done

> unbind ssl cipher test -cipherName SSL2-RC2-CBC-MD5

> show ssl cipher test
1) Cipher Name: SSL2-RC4-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC4(128) Mac=MD5
2) Cipher Name: SSL2-DES-CBC3-MD5

```

Description: SSLv2 Kx=RSA Au=RSA Enc=3DES(168) Mac=MD5

3) Cipher Name: SSL2-DES-CBC-MD5

Description: SSLv2 Kx=RSA Au=RSA Enc=DES(56) Mac=MD5

4) Cipher Name: SSL2-RC4-64-MD5

Description: SSLv2 Kx=RSA Au=RSA Enc=RC4(64) Mac=MD5

5) Cipher Name: SSL2-EXP-RC4-MD5

Description: SSLv2 Kx=RSA(512) Au=RSA Enc=RC4(40) Mac=MD5 Export

6) Cipher Name: SSL2-EXP-RC2-CBC-MD5

Description: SSLv2 Kx=RSA(512) Au=RSA Enc=RC2(40) Mac=MD5 Export

Done

To remove a cipher group by using the command line interface

Note: You cannot remove a built-in cipher group. Before removing a user-defined cipher group, make sure that the cipher group is empty.

At the command prompt, type the following commands to remove a user-defined cipher group, and verify the configuration:

- `rm ssl cipher <userDefCipherGroupName> [<cipherName> ...]`
- `show ssl cipher <cipherGroupName>`

## Example

```
> rm ssl cipher test
```

Done

```
> sh ssl cipher test
```

ERROR: No such resource [cipherGroupName, test]

To configure a user-defined cipher group by using the configuration utility

Navigate to Traffic Management > SSL > Cipher Groups, and configure a cipher group.

To bind a cipher group to an SSL virtual server, service, or service group by using the command line interface

At the command prompt, type one of the following:

- `bind ssl vserver <vServerName> -cipherName <string>`
- `bind ssl service <serviceName> -cipherName <string>`
- `bind ssl serviceGroup <serviceGroupName> -cipherName <string>`

## Examples

```
> bind ssl vserver ssl_vserver_test -cipherName test
```

Done

```
bind ssl service nshttps -cipherName test
```

Done

```
> bind ssl servicegroup ssl_svc -cipherName test
```

Done

To bind a cipher group to an SSL virtual server, service, or service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers or navigate to Traffic Management > Load Balancing > Services or navigate to Traffic Management > Load Balancing > Service Groups, and open the virtual server, service, or service group.

2. In Advanced Settings, select SSL Ciphers, and bind a cipher group to the virtual server, service, or service group.

# Configuring SSL Actions and Policies

Jun 03, 2015

An SSL policy evaluates incoming traffic and applies a predefined action to requests that match a rule (expression). You have to configure the actions before creating the policies, so that you can specify an action when you create a policy. To put a policy into effect, you must either bind it to a virtual server on the appliance, so that it applies only to traffic flowing through that virtual server, or bind it globally, so that it applies to all traffic flowing through the appliance.

SSL actions define SSL settings that you can apply to the selected requests. You associate an action with one or more policies. Data in client connection requests or responses is compared to a rule specified in the policy, and the action is applied to connections that match the rule (expression).

You can configure classic policies with classic expressions and default syntax policies with default syntax expressions for SSL.

Note: Users who are not experienced in configuring policies at the NetScaler command line usually find using the configuration utility to be considerably easier.

You can associate a user-defined action or a built-in action to a default syntax policy. Classic policies allow only user-defined actions. In default syntax policy, you can also group policies under a policy label, in which case they are applied only when invoked from another policy.

Common uses of SSL actions and policies include per-directory client authentication, support for Outlook web access, and SSL-based header insertions. SSL-based header insertions contain SSL settings required by a server whose SSL processing has been offloaded to the NetScaler appliance.

To configure SSL actions and policies, see the following sections:

- [Configuring User-Defined Actions for SSL Policies](#)
- [Configuring SSL Policies](#)
- [Configuring an SSL Default Syntax Policy](#)
- [Configuring Built-in Actions for SSL Default Syntax Policies](#)
- [Configuring SSL Policy Labels](#)
- [Configuring Per-Directory Client Authentication](#)
- [Configuring Support for Outlook Web Access](#)
- [Configuring SSL-Based Header Insertion](#)
- [Binding SSL Policies to a Virtual Server](#)
- [Binding SSL Policies Globally](#)

# Configuring User-Defined Actions for SSL Policies

Sep 05, 2013

SSL policies require that you create an action before creating a policy, so that you can specify the actions when you create the policies. In SSL default syntax policies, you can also use the built-in actions. For more information about built-in actions, see [Configuring Built-in SSL Actions](#).

To configure an SSL action by using the command line interface

At the command prompt, type the following commands to configure an action and verify the configuration:

- add SSL action <name> -clientAuth(DOCLIENTAUTH | NOCLIENTAUTH) -clientCert (ENABLED | DISABLED) certHeader <string> -clientHeader <string> -clientCertSerialNumber (ENABLED | DISABLED) -certSerialHeader <string> **-clientCertSubject** (ENABLED | DISABLED) -certSubjectHeader <string> -clientCertHash (ENABLED | DISABLED) -certHashHeader <string> -clientCertIssuer (ENABLED | DISABLED) -certIssuerHeader <string> -sessionID (ENABLED | DISABLED) -sessionIDheader <string> -cipher (ENABLED | DISABLED) -cipherHeader <string> -clientCertNotBefore (ENABLED | DISABLED) **-certNotBeforeHeader** <string> -clientCertNotAfter (ENABLED | DISABLED) -certNotAfterHeader <string> -OWASupport (ENABLED | DISABLED)
- show ssl action [<name>]

## Example

```
> add ssl action Action-SSL-ClientCert -clientCert ENABLED -certHeader "X-Client-Cert"
Done
> show ssl action Action-SSL-ClientCert
1) Name: Action-SSL-ClientCert
 Data Insertion Action:
 Cert Header: ENABLED Cert Tag: X-Client-Cert
Done
```

To configure an SSL action by using the configuration utility

Navigate to Traffic Management > SSL > Policies and, on the Actions tab, click Add.

# Configuring SSL Policies

Sep 26, 2013

Policies on the NetScaler help identify specific connections that you want to process. The processing is based on the actions that are configured for that particular policy. Once you create the policy and configure an action for it, you must either bind it to a virtual server on the NetScaler, so that it applies only to traffic flowing through that virtual server, or bind it globally, so that it applies to all traffic flowing through any virtual server configured on the NetScaler.

The NetScaler SSL feature supports both classic policies and default syntax policies . For a complete description of classic and default syntax expressions, how they work, and how to configure them manually, see <http://docs.citrix.com/en-us/netscaler/10-5/ns-appexpert-con-10/ns-pi-gen-pol-config-wrapper-10-con.html>.

Note: Users who are not experienced in configuring policies at the NetScaler command line will usually find using the configuration utility considerably easier.

# Configuring an SSL Default Syntax Policy

Sep 25, 2014

An SSL default syntax policy defines a control or a data action to be performed on requests. SSL policies can therefore be categorized as control policies and data policies:

- **Control policy.** A control policy uses a control action, such as forcing client authentication.  
Note: In release 10.5 or later, deny SSL renegotiation (denySSLReneg) is set, by default, to ALL. However, control policies, such as CLIENTAUTH, trigger a renegotiation handshake. If you use such policies, you must set denySSLReneg to NO.
- **Data policy.** A data policy uses a data action, such as inserting some data into the request.

The essential components of a policy are an expression and an action. The expression identifies the requests on which the action is to be performed. SSL policies use the default expression syntax or the classic expression syntax. For information about expressions and how to configure them, see .

You can configure a default syntax policy with a built-in action or a user-defined action. You can configure a policy with a built-in action without creating a separate action. However, to configure a policy with a user-defined action, first configure the action and then configure the policy.

You can specify an additional action, called an UNDEF action, to be performed in the event that applying the expression to a request has an undefined result.

To configure an SSL default syntax policy by using the command line interface

At the command prompt, type:

```
add ssl policy <name> -rule <expression> -Action <string> [-undefAction <string>] [-comment <string>]
```

To configure an SSL default syntax policy by using the configuration utility

Navigate to Traffic Management > SSL > Policies and, on the Polices tab, click Add.

# Configuring Built-in Actions for SSL Default Syntax Policies

Aug 20, 2013

Unless you need only the built-in actions in your policies, you have to create the actions before creating the policies, so that you can specify the actions when you create the policies. The built-in actions are of two types, control actions and data actions. You use control actions in control policies, and data actions in data policies.

The built-in control actions are:

- CLIENTAUTH—Perform client certificate authentication.
- NOCLIENTAUTH—Do not perform client certificate authentication.

The built-in data actions are:

- RESET—Close the connection by sending a RST packet to the client.
- DROP—Drop all packets from the client. The connection remains open until the client closes it.
- NOOP—Forward the packet without performing any operation on it.

You can create user-defined data actions. For example, if you enable client authentication, you can create an SSL action to insert client-certificate data into the request header before forwarding the request to the web server. For more information about user-defined actions, see [Configuring User-Defined SSL Actions](#).

If a policy evaluation results in an undefined state, an UNDEF action is performed. For either a data policy or a control policy, you can specify RESET, DROP, or NOOP as the UNDEF action. For a control policy, you also have the option of specifying CLIENTAUTH or NOCLIENTAUTH.

## Examples of built-in actions in a policy

In the following example, if the client sends a cipher other than an EXPORT category cipher, the NetScaler appliance requests client authentication. The client has to provide a valid certificate for a successful transaction.

```
add ssl policy pol1 -rule CLIENT.SSL.CIPHER_EXPORTABLE.NOT -reqAction CLIENTAUTH
```

The following examples assume that client authentication is enabled.

If the version in the certificate provided by the user matches the version in the policy, no action is taken and the packet is forwarded:

```
add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction NOOP
```

If the version in the certificate provided by the user matches the version in the policy, the connection is dropped:

```
add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction DROP
```

If the version in the certificate provided by the user matches the version in the policy, the connection is reset:

```
add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction RESET
```

# Configuring SSL Policy Labels

Aug 20, 2013

Policy labels are holders for policies. A policy label helps in managing a group of policies, called a policy bank, which can be invoked from another policy. SSL policy labels can be control labels or data labels, depending on the type of policies that are included in the policy label. You can add only data policies in a data policy label and only control policies in a control policy label. To create the policy bank, you bind policies to the label and specify the order of evaluation of each policy relative to others in the bank of policies for the policy label. At the NetScaler command line, you enter two commands to create a policy label and bind policies to the policy label. In the configuration utility, you select options from a dialog box. To create an SSL policy label and bind policies to the label by using the command line interface

At the command prompt, type:

- `add ssl policylabel <labelName> -type ( CONTROL | DATA )`
- `bind ssl policylabel <labelName> <policyName> <priority> [<gotoPriorityExpression>] [-invoke (<labelType> <labelName>)]`

## Example

```
add ssl policylabel cpl1 -type CONTROL
```

```
add ssl policylabel dpl1 -type DATA
```

```
bind ssl policylabel cpl1 -policyName ctrlpol -priority 1
```

```
bind ssl policylabel dpl1 -policyName datapol -priority 1
```

To configure an SSL policy label and bind policies to the label by using the configuration utility

Navigate to Traffic Management > SSL > Policy Labels, and configure an SSL policy label.

# Configuring Per-Directory Client Authentication

Aug 20, 2013

If you create an action specifying client-side authentication on a per-directory basis, a client identified by a policy associated with the action is not authenticated as part of the initial SSL handshake. Instead, authentication is carried out every time the client wants to access a specific directory on the web server.

For example, if you have multiple divisions in the company, where each division has a folder in which all its files are stored, and you want to know the identity of each client that tries to access files from a particular directory, such as the finance directory, you can enable per-directory client authentication for that directory.

To enable per-directory client authentication, first configure client authentication as an SSL action, and then create a policy that identifies the directory that you want to monitor. When you create the policy, specify your client-authentication action as the action associated with the policy. Then, bind the policy to the SSL virtual server that will receive the SSL traffic.

To create an SSL action and a policy to enable client authentication by using the command line interface

At the command prompt, type the following commands to create an SSL action to enable to client authentication and verify the configuration:

- add ssl action <name> [-clientAuth ( DOCLIENTAUTH | NOCLIENTAUTH )]
- show ssl action [<name>]
- add ssl policy <name> -rule <expression> [-action <string>] [-undefAction <string>] [-comment <string>]
- show ssl policy [<name>]

## Example

```
> add ssl action ssl-action-1 -clientAuth DOCLIENTAUTH
Done
> show ssl action ssl-action-1
1) Name: ssl-action-1
 Client Authentication Action: DOCLIENTAUTH
 Hits: 0
 Undef Hits: 0
 Action Reference Count: 1
Done
> add ssl policy ssl-pol-1 -rule 'REQ.HTTP.METHOD==GET' -reaction ssl-action-1
> sh ssl policy ssl-pol-1
Name: ssl-pol-1
Rule: REQ.HTTP.METHOD == GET
Action: ssl-action-1
UndefAction: Use Global
Hits: 0
Undef Hits: 0
Done
```

To create an SSL action to enable client authentication by using the configuration utility

1. Navigate to Traffic Management > SSL > Policies and, on the Actions tab, click Add.
2. In the Client Authentication list, select Enabled.

To create and bind an SSL policy to enable client authentication by using the configuration utility

1. Navigate to Traffic Management > SSL and, on the Policies tab, click Add.
2. Navigate to Traffic Management > Load Balancing > Virtual Servers and open an SSL virtual server.  
In Advanced Settings, select SSL Policy, and bind the policy to the virtual server.

# Configuring Support for Outlook Web Access

Aug 20, 2013

If your SSL configuration is offloading SSL transactions from an Outlook Web Access (OWA) server, you must insert a special header field, FRONT-END-HTTPS: ON, in all HTTP requests directed to the OWA servers. This is required for the OWA servers to generate URL links as https:// instead of http://.

When you enable support for OWA on the NetScaler, the header is automatically inserted into the specified HTTP traffic, and you do not need to configure a specific header insertion. Use SSL policies to identify all traffic directed to the OWA server.

Note: You can enable Outlook Web Access support for HTTP-based SSL virtual servers and services only. You cannot apply it to TCP-based SSL virtual servers and services.

To enable OWA support, first configure OWA support as an SSL action, and then create a policy that identifies the virtual servers or services for which you want to enable OWA support. When you create the policy, specify your OWA support action as the action associated with the policy. Then, bind the policy to the SSL virtual server that will receive the SSL traffic.

To create an SSL action and a policy to enable OWA support by using the command line interface

At the command prompt, type the following commands to create an SSL action to enable OWA support and verify the configuration:

- add ssl action <name> -OWASupport ( ENABLED | DISABLED )
- show ssl action [<name>]
- add ssl policy <name> -rule <expression> [-action <string>] [-undefAction <string>] [-comment <string>]
- show ssl policy [<name>]

## Example

```
> add ssl action ssl-action-2 -OWASupport ENABLED
Done
> show ssl action ssl-action-2
1) Name: ssl-action-2
 Type: Data Insertion
 OWA Support: ENABLED
 Hits: 0
 Undef Hits: 0
 Action Reference Count: 1
Done
> add ssl policy ssl-pol -rule 'REQ.HTTP.METHOD == GET' -reqaction ssl-action-2
Done
> sh ssl policy ssl-pol
Name: ssl-pol
Rule: REQ.HTTP.METHOD == GET
Action: ssl-action-2
UndefAction: Use Global
Hits: 0
```

Undef Hits: 0

Done

To create an SSL action to enable OWA support by using the configuration utility

1. Navigate to Traffic Management > SSL > Policies and, on the Actions tab, click Add.
2. In the Outlook Web Access list, select Enabled.

Note: Outlook Web Access support is applicable only for SSL virtual server based configurations and transparent SSL service based configurations and not for SSL configurations with back-end encryption.

To create and bind an SSL policy to enable OWA support by using the configuration utility

Navigate to Traffic Management > SSL > Policies, and add a policy.

In the Action list, select the action that you created earlier. Specify an undefined action, and an expression.

# Configuring SSL-Based Header Insertion

Aug 20, 2013

Because the NetScaler appliance offloads all SSL-related processing from the servers, the servers receive only HTTP traffic. In some circumstances, the server needs certain SSL information. For example, security audits of recent SSL transactions require the client subject name (contained in an X509 certificate) to be logged on the server.

Such data can be sent to the server by inserting it into the HTTP header as a name-value pair. You can insert the entire client certificate, if required, or only the specific fields from the certificate, such as the subject, serial number, issuer, certificate hash, SSL session ID, cipher suite, or the not-before or not-after date used to determine certificate validity.

You can enable SSL-based insertion for HTTP-based SSL virtual servers and services only. You cannot apply it to TCP-based SSL virtual servers and services. Also, client authentication must be enabled on the SSL virtual server, because the inserted values are taken from the client certificate that is presented to the virtual server for authentication.

To configure SSL-based header insertion, first create an SSL action for each specific set of information to be inserted, and then create policies that identify the connections for which you want to insert the information. As you create each policy, specify the action that you want associated with the policy. Then, bind the policies to the SSL virtual servers that will receive the SSL traffic.

The following example uses default syntax policies. In the following example, a control policy (ctrlpol) is created to perform client authentication if a request is received for the URL /testsite/file5.html. A data policy (datapol) is created to perform an action (act1) if client authentication is successful, and an SSL action (act1) is added to insert the certificate details and issuer's name in the request before forwarding the request. For other URLs, client authentication is disabled. The policies are then bound to an SSL virtual server (ssl\_vserver) that receives the SSL traffic.

Command-line example of configuring SSL-based header insertion

## Example

```
> add ssl action act1 -clientCert ENABLED -certHeader mycert -clientcertissuer ENABLED -certIssuerHeader myissuer
> add ssl policy datapol -rule HTTP.REQ.URL.EQ("/testsite/file5.html") -action act1
> add ssl policy ctrlpol -rule HTTP.REQ.URL.EQ("/testsite/file5.html") -action CLIENTAUTH
> bind ssl vserver ssl_vserver -policyName ctrlpol -priority 1
> bind ssl vserver ssl_vserver -policyName datapol -priority 1
Done
```

To configure SSL-based header insertion by using the configuration utility

1. Navigate to Traffic Management > SSL > Policies.
  2. In the details pane, on the Actions tab, click Add.
  3. In the Create SSL Action dialog box, set the following parameters:
    - Name\*
    - Client Certificate
    - Certificate Tag
    - Client Certificate Issuer
    - Issuer Tag
- \* A required parameter

4. Click Create, and then click Close.
5. On the tab, click Add to create a control policy.
6. In the Create SSL Policy dialog box, set the following parameters:
  - Name\*
  - Expression
  - Request Action\* A required parameter
7. Click Create, and then click Close.
8. Create a data policy by repeating steps 5 through 7.
9. In the navigation pane, expand SSL Offload, and then click Virtual Servers.
10. In the details pane, from the list of virtual servers, select the virtual server to which you want to bind the SSL policies, and then click Open.
11. In the Configure Virtual Server (SSL Offload) dialog box, click SSL Settings, and then click SSL Policies.
12. In the Bind/Unbind SSL Policies dialog box, click Insert Policy. Under Policy Name, select the policy that you created in steps 5 through 7.
13. Click OK, and then click Close. A message appears in the status bar, stating that the policy has been bound successfully.
14. Repeat steps 12 and 13 and select the policy that you created in step 8.

# Binding SSL Policies to a Virtual Server

Aug 20, 2013

The SSL policies that are configured on the NetScaler appliance need to be bound to a virtual server that intercepts traffic directed to the virtual server. If the incoming data matches any of the rules configured in the SSL policy, the policy is triggered and the action associated with it is carried out.

You can also bind SSL policies globally or to custom bind points on the NetScaler appliance. For more information about binding policies on the appliance, see .

To bind an SSL policy to a virtual server by using the command line interface

At the command prompt, type the following command to bind an SSL policy to a virtual server and verify the configuration:

- `bind ssl vserver <vServerName> -policyName <string> [-priority <positive_integer>]`
- `show ssl vserver <vServerName>`

## Example

```
> bind ssl vserver vs-server -policyName ssl-policy-1 -priority 10
Done
> show ssl vserver vs-server
```

Advanced SSL configuration for VServer vs-server:

```
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 1000
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 80
Client Auth: DISABLED
SSL Redirect: ENABLED
SSL-REDIRECT Port Rewrite: ENABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
```

```
1) Policy Name: ssl-policy-1 Priority: 10
```

```
1) Cipher Name: DEFAULT
Description: Predefined Cipher Alias
```

```
Done
```

To bind an SSL policy to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open an SSL virtual server.
2. In Advanced Settings, select SSL Policy, Click in the SSL Policy section to bind to the virtual server.

# Binding SSL Policies Globally

Aug 20, 2013

Globally bound policies are evaluated after all policies bound to services, virtual servers, or other NetScaler bind points are evaluated.

To globally bind an SSL policy by using the command line interface

At the command prompt, type the following command to bind a global SSL policy and verify the configuration:

- `bind ssl global - policyName <string> [- priority <positive_integer>]`
- `show ssl global`

Example

```
> bind ssl global -policyName Policy-SSL-2 -priority 90
```

```
Done
```

```
> sh ssl global
```

```
1) Name: Policy-SSL-2 Priority: 90
```

```
2) Name: Policy-SSL-1 Priority: 100
```

```
Done
```

To bind a global SSL policy by using the configuration utility

1. Navigate to Traffic Management > SSL > Policies.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind SSL Policies to Global dialog box, click Insert Policy.
4. In the Policy Name drop-down list, select a policy.
5. Optionally, drag the entry to a new position in the policy bank to automatically update the priority level.
6. Click OK. A message appears in the status bar, stating that the policy has been bound successfully.

# Use Case 1: Configuring SSL Offloading with End-to-End Encryption

May 26, 2015

A simple SSL offloading setup terminates SSL traffic (HTTPS), decrypts the SSL records, and forwards the clear text (HTTP) traffic to the back-end web servers. However, the clear text traffic is vulnerable to being spoofed, read, stolen, or compromised by individuals who succeed in gaining access to the back-end network devices or web servers.

You can, therefore, configure SSL offloading with end-to-end security by re-encrypting the clear text data and using secure SSL sessions to communicate with the back-end Web servers.

Additionally, you can configure the back-end SSL transactions so that the NetScaler appliance uses SSL session multiplexing to reuse existing SSL sessions with the back-end web servers, thus avoiding CPU-intensive key exchange (full handshake) operations. This reduces the overall number of SSL sessions on the server, and therefore accelerates the SSL transaction while maintaining end-to-end security.

To configure SSL Offloading with end-to-end encryption, add SSL based services that represent secure servers with which the NetScaler appliance will carry out end-to-end encryption. Then create an SSL based virtual server, and create and bind a valid certificate-key pair to the virtual server. Bind the SSL services to the virtual server to complete the configuration.

For details on adding SSL based services, see [Configuring Services](#).

For details on adding an SSL virtual server, see [Configuring an SSL Based Virtual Server](#).

For details on creating a certificate-key pair, see [Adding a Certificate-Key Pair](#).

For details on binding a certificate-key pair to a virtual server, see [Binding the Certificate Key Pair to the SSL Based Virtual Server](#).

For details on binding services to a virtual server, see [Binding Services to the SSL Based Virtual Server](#).

## Example

Create two SSL based services, Service-SSL-1 and Service-SSL-2, with IP addresses 10.102.20.30 and 10.102.20.31 and both using port 443.

Then create an SSL based virtual server, Vserver-SSL-2 with an IP address of 10.102.10.20.

Next, create a certificate-key pair, CertKey-1 and bind it to the virtual server.

Bind the SSL services to the virtual server to complete the configuration.

**Table 1. Entities in the SSL Offloading with End-to-End Encryption Example**

| Entity      | Name          | Value        |
|-------------|---------------|--------------|
| SSL Service | Service-SSL-1 | 10.102.20.30 |
|             | Service-SSL-2 | 10.102.20.31 |

| <b>Entity</b>            | <b>Name</b>   | <b>Value</b> |
|--------------------------|---------------|--------------|
| SSL Based Virtual Server | Vserver-SSL-2 | 10.102.10.20 |
| Certificate - Key Pair   | Certkey-1     |              |

# Use Case 2: Configuring Transparent SSL Acceleration

May 26, 2015

Note: You need to enable L2 mode on the NetScaler appliance for transparent SSL acceleration to work.

Transparent SSL acceleration is useful for running multiple applications on a secure server with the same public IP, and also for SSL acceleration without using an additional public IP.

In a transparent SSL acceleration setup, the NetScaler appliance is transparent to the client, because the IP address at which the appliance receives requests is the same as the Web server's IP address.

The NetScaler offloads SSL traffic processing from the Web server and sends either clear text or encrypted traffic (depending on the configuration) to the web server. All other traffic is transparent to the NetScaler and is bridged to the Web server. Therefore, other applications running on the server are unaffected.

There are three modes of transparent SSL acceleration available on the NetScaler:

- Service-based transparent access, where the service type can be SSL or SSL\_TCP.
- Virtual server-based transparent access with a wildcard IP address (\*:443).
- SSL VIP-based transparent access with end-to-end encryption.

Note: An SSL\_TCP service is used for non-HTTPS services (for example SMTPS and IMAPS).

## Service-based Transparent SSL Acceleration

To enable transparent SSL acceleration using the SSL service mode, configure an SSL or an SSL\_TCP service with the IP address of the actual back-end Web server. Instead of a virtual server intercepting SSL traffic and passing it on to the service, the traffic is now directly passed on to the service, which decrypts the SSL traffic and sends clear text data to the back-end server.

The service-based mode allows you to configure individual services with a different certificate, or with a different clear text port. Also, you can also select individual services for SSL acceleration.

You can apply service-based transparent SSL acceleration to data that uses different protocols, by setting the clear text port of the SSL service to the port on which the data transfer between the SSL service and the back-end server occurs.

To configure service-based transparent SSL acceleration, first enable both the SSL and the load balancing features. Then create an SSL based service and configure its clear text port. After the service is created, create and bind a certificate-key pair to this service.

For details on configuring the clear text port for an SSL based service, see "[Configuring Advanced SSL Settings](#)."

For details on creating a certificate-key pair and binding a certificate-key pair to a service, see "[Adding a Certificate-Key Pair](#)."

## Example

Enable SSL offloading and load balancing.

Create an SSL based service, Service-SSL-1 with the IP address 10.102.20.30 using port 443 and configure its clear text port.

Next, create a certificate-key pair, CertKey-1 and bind it to the SSL service.

**Table 1. Entities in the Service-based Transparent SSL Acceleration**

| Entity                 | Name          | Value     |
|------------------------|---------------|-----------|
| SSL Service            | Service-SSL-1 | 102.20.30 |
| Certificate - Key Pair | Certkey-1     |           |

### Virtual Server-based Acceleration with a Wildcard IP Address (\*:443)

You can use an SSL virtual server in the wildcard IP address mode if when you want to enable SSL acceleration for multiple servers that host the secure content of a Web site. In this mode, a single-digital certificate is enough for the entire secure Web site, instead of one certificate per virtual server. This results in significant cost savings on SSL certificates and renewals. The wildcard IP address mode also enables centralized certificate management.

To configure global transparent SSL acceleration on the NetScaler appliance, create a \*:443 virtual server, which is a virtual server that accepts any IP address associated with port 443. Then, bind a valid certificate to this virtual server, and also bind all services to which the virtual server is to transfer. Such a virtual server can use the SSL protocol for HTTP-based data or the SSL\_TCP protocol for non-HTTP-based data.

### To configure virtual server-based acceleration with a wildcard IP address

1. Enable SSL, as described in "[Enabling SSL Processing](#)."
2. Enable load balancing, as described in "[Load Balancing](#)."
3. Add an SSL based virtual server (see "[Configuring an SSL-Based Virtual Server](#)" for the basic settings), and set the clearTextPort parameter (described in "[Configuring Advanced SSL Settings](#)").
4. Add a certificate-key pair, as described in "[Adding a Certificate-Key Pair](#)."

Note: The wildcard server will automatically learn the servers configured on the NetScaler, so you do not need to configure services for a wildcard virtual server.

### Example

After enabling SSL offloading and load balancing, create an SSL based wildcard virtual server with IP address set to \* and port number 443, and configure its clear text port (optional).

If you specify the clear text port, decrypted data will be sent to the backend server on that particular port. Otherwise, encrypted data will be sent to port 443.

Next, create an SSL certificate key pair, CertKey-1 and bind it to the SSL virtual server.

**Table 2. Entities in the Virtual Server-based Acceleration with a Wildcard IP Address Example**

| Entity                   | Name                 | IP Address | Port |
|--------------------------|----------------------|------------|------|
| SSL Based Virtual Server | Vserver-SSL-Wildcard | *          | 443  |
| Certificate - Key Pair   | Certkey-1            |            |      |

## SSL VIP-based Transparent Access with End-To-End Encryption

You can use an SSL virtual server for transparent access with end-to-end encryption if you have no clear text port specified. In such a configuration, the NetScaler terminates and offloads all SSL processing, initiates a secure SSL session, and sends the encrypted data, instead of clear text data, to the web servers on the port that is configured on the wildcard virtual server.

Note: In this case, the SSL acceleration feature runs at the back-end, using the default configuration, with all 34 ciphers available.

To configure SSL VIP based transparent access with end-to-end encryption, Follow instructions for Configuring a Virtual Server-based Acceleration with a Wildcard IP Address (\*:443), but do not configure a clear text port on the virtual server.

# Use Case 3: Configuring SSL Acceleration with HTTP on the Front End and SSL on the Back End

May 26, 2015

In certain deployments, you might be concerned about network vulnerabilities between the NetScaler appliance and the backend servers, or you might need complete end-to-end security and interaction with certain devices that can communicate only in clear text (for example, caching devices).

In such cases, you can set up an HTTP virtual server that receives data from clients that connect to it at the front end and hands the data off to a secure service, which securely transfers the data to the web server.

To implement this type of configuration, you configure an HTTP virtual server on the NetScaler and bind SSL based services to the virtual server. The NetScaler receives HTTP requests from the client on the configured HTTP virtual server, encrypts the data, and sends the encrypted data to the web servers in a secure SSL session.

To configure SSL acceleration with HTTP on the front-end and SSL on the back-end, first enable the load balancing and SSL features on the NetScaler. Then, add SSL based services that represent secure servers to which the NetScaler appliance will send encrypted data. Finally, add an HTTP based virtual server and bind the SSL services to this virtual server.

## Example

Enable load balancing and SSL acceleration on the NetScaler.

After enabling load balancing and SSL acceleration, create two SSL based services, Service-SSL-1 and Service-SSL-2, with IP addresses 10.102.20.30 and 10.102.20.31, and both using port 443.

Then create an HTTP based virtual server, Vserver-HTTP-1, with an IP address of 10.102.10.20.

Bind the SSL services to the virtual server to complete the configuration.

**Table 1. Entities in the SSL Acceleration with HTTP on the Front End and SSL on the Back End Example**

| Entity                    | Name           | Value        |
|---------------------------|----------------|--------------|
| SSL Service               | Service-SSL-1  | 10.102.20.30 |
|                           | Service-SSL-2  | 10.102.20.31 |
| HTTP Based Virtual Server | Vserver-HTTP-1 | 10.102.10.20 |

# Use Case 4: SSL Offloading with Other TCP Protocols

May 26, 2015

In addition to the secure HTTP (HTTPS) protocol, NetScaler appliances support SSL acceleration for other TCP-based secure protocols. However, only simple requests and response-based TCP application protocols are supported. Applications such as FTPS, that insert the server's IP address and port information in their payloads, are not currently supported.

Note: The STARTTLS feature for SMTP is currently not supported.

The NetScaler supports SSL acceleration for Other TCP protocols with and without end-to-end encryption.

To configure SSL offloading with Other TCP protocols, create a virtual server of type SSL\_TCP, bind a certificate-key pair and TCP based services to the virtual server, and configure SSL actions and policies based on the type of traffic expected and the acceleration to be provided.

Follow the instructions in [Configuring SSL Offloading](#), but create an SSL\_TCP virtual server instead of an SSL virtual server, and configure TCP services instead of HTTP services.

## SSL\_TCP Based Offloading with End-to-End Encryption

To configure SSL\_TCP-based offloading with end-to-end encryption, both the virtual server that intercepts secure traffic and the services that it forwards the traffic to must be of type SSL\_TCP.

Configure SSL\_TCP-based offloading as described in [Configuring SSL Offloading with End-to-End Encryption](#), but create an SSL\_TCP virtual server instead of an SSL virtual server.

## Backend Encryption for TCP Based Data

Some deployments might require the NetScaler appliance to encrypt TCP data received as clear text and send the data securely to the back end servers.

To provide SSL acceleration with back-end encryption for clear text TCP traffic arriving from the client, create a TCP based virtual server and bind it to SSL\_TCP based services.

To configure end-to-end encryption for TCP-based data, follow the procedure described in [Configuring the SSL feature with HTTP on the Front-End and SSL on the Back-End](#), but create a TCP virtual server instead of an HTTP virtual server.

# Use Case 5: Configuring SSL Bridging

May 26, 2015

An SSL bridge configured on the NetScaler appliance enables the appliance to bridge all secure traffic between the SSL client and the SSL server. The appliance does not offload or accelerate the bridged traffic, nor does it perform encryption or decryption. Only load balancing is done by the appliance. The SSL server must handle all SSL-related processing. Features such as content switching, SureConnect, and cache redirection do not work, because the traffic passing through the appliance is encrypted.

Because the appliance does not carry out any SSL processing in an SSL bridging setup, there is no need for SSL certificates.

Citrix recommends that you use this configuration only if an acceleration unit (for example, a PCI-based SSL accelerator card) is installed in the web server to handle the SSL processing overhead.

Before you configure SSL bridging, first enable SSL and load balancing on the appliance. Then, create SSL\_Bridge services and bind them to an SSL\_Bridge virtual server. Configure the load balancing feature to maintain server persistency for secure requests.

## Example

After enabling SSL and load balancing, create two servers, s1 and s2. Create two SSL\_Bridge services, sc1 and src2. Create an SSL\_Bridge virtual server and bind the SSL\_Bridge services to the virtual server to complete the configuration. At the command line, type:

```
enable ns feature SSL LB
add server s1 10.102.1.101
add server s2 10.102.1.102
add service src1 s1 SSL_BRIDGE 443
add service src2 s2 SSL_BRIDGE 443
add lb vserver ssl_bridge_vip SSL_BRIDGE 10.102.1.200 443
bind lb vserver ssl_bridge_vip src1
bind lb vserver ssl_bridge_vip src2
```

# Use Case 6: Configuring SSL Monitoring when Client Authentication is Enabled on the Backend Service

May 26, 2015

Consider a scenario in which you need to load balance servers that require SSL client certificates to validate clients. For this deployment, you need to create an SSL service on the NetScaler appliance, add an HTTPS monitor, add a certificate-key pair, bind this certificate-key pair to the SSL service, and then bind the https monitor to this service. You can use this https monitor to perform health checks on the backend services.

To configure SSL monitoring with client certificate

1. Open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on the appliance by using the administrator credentials.
3. Add an SSL service. At the command prompt, type:  
`add service <name> <serverName> <serviceType> <port>`
4. Add an https monitor. At the command prompt, type:  
`add lb monitor <name> <type>`
5. Add the certificate-key pair that is going to be used as the client cert for that SSL service. At the command prompt, type:  
`add ssl certKey <certkeyName> -cert <string> -key <string>`
6. Bind this certkey to the SSL service. At the command prompt, type:  
`bind ssl service <serviceName> -certkeyName <string>`
7. Bind the https monitor to the SSL service. At the command prompt, type:  
`bind lb monitor <monitorName> <serviceName>`

Now, when the appliance tries to probe the backend service on which client authentication is enabled, the backend service will request a certificate as part of the SSL handshake. When the appliance returns the certificate-key bound in step 6 above, the monitor probe will succeed.

## Example

```
add service svc_k 10.102.145.30 SSL 443
add lb monitor sslmon HTTP -respCode 200 -httpRequest "GET /testsite/file5.html" -secure YES
add ssl certKey ctest -cert client_rsa_2048.pem -key client_rsa_2048.ky
bind ssl service svc_k -certkeyName ctest
bind lb monitor sslmon svc_k
> show service svc_k

# Use Case 7: Configuring a Secure Content Switching Server

May 26, 2015

An SSL-based content switching virtual server first decrypts the secure data and then redirects the data to appropriately configured servers as determined by the type of content and the configured content switching policies. The packets sent to the server have a mapped IP address as the source IP address.

The following example shows the steps to configure two address-based virtual servers to perform load balancing on the HTTP services. One virtual server, Vserver-LB-HTML, load balances the dynamic content (cgi, asp), and the other, Vserver-LB-Image, load balances the static content (gif, jpeg). The load-balancing method used is the default, LEASTCONNECTION. A content switching SSL virtual server, Vserver-CS-SSL, is then configured to perform SSL acceleration and switching of HTTPS requests on the basis of configured content switching policies.

## Example

```
> enable ns feature lb cs ssl
> add lb vserver Vserver-LB-HTML http 10.1.1.2 80
> add lb vserver Vserver-LB-Image http 10.1.1.3 80
> add service s1 10.1.1.4 http 80
> add service s2 10.1.1.5 http 80
> add service s3 10.1.1.6 http 80
> add service s4 10.1.1.7 http 80
> bind lb vserver Vserver-LB-HTML s1
> bind lb vserver Vserver-LB-HTML s2
> bind lb vserver Vserver-LB-Image s3
> bind lb vserver Vserver-LB-Image s4
> add cs vserver Vserver-CS-SSL ssl 10.1.1.1 443
> add cs policy pol1 -url "*.cgi"
> add cs policy pol2 -url "*.asp"
> add cs policy pol3 -url "*.gif"
> add cs policy pol4 -url "*.jpeg"
> bind cs vserver Vserver-CS-SSL -policyName pol1 Vserver-LB-HTML
> bind cs vserver Vserver-CS-SSL -policyName pol2 Vserver-LB-HTML
> bind cs vserver Vserver-CS-SSL -policyName pol3 Vserver-LB-Image
> bind cs vserver Vserver-CS-SSL -policyName pol4 Vserver-LB-Image
> add certkey mykey -cert /nsconfig/ssl/ns-root.cert -key /nsconfig/ssl/ns-root.key
> bind certkey Vserver-CS-SSL mykey
>
> show cs vserver Vserver-CS-SSL

# Ciphers Supported by the NetScaler Appliance

May 06, 2016

Your NetScaler appliance ships with a predefined set of cipher groups. To use ciphers that are not part of the DEFAULT cipher group, you have to explicitly bind them to an SSL virtual server. You can also create a user-defined cipher group to bind to the SSL virtual server. For more information about creating a user-defined cipher group, see [Configuring User-Defined Cipher Groups on the NetScaler Appliance](#).

Table 1 lists the NetScaler appliances that support ciphers for the TLS 1.1 and 1.2 protocols.

Table 2 lists the ciphers that are part of the DEFAULT cipher group and are therefore bound by default to an SSL virtual server.

Table 3 lists the other ciphers currently supported by NetScaler appliances.

Table 4 lists additional ciphers, for front-end entities only, supported with TLS 1.2.

Table 1. Support for TLS1.1/1.2 on NetScaler Appliances

|                                                                     | Virtual Server | Front End Service | Internal Service | Backend Service |
|---------------------------------------------------------------------|----------------|-------------------|------------------|-----------------|
| MPX appliances/SDX instances with SSL card                          | yes            | yes               | yes              | yes             |
| MPX-FIPS appliances running firmware version 2.2                    | yes            | yes               | yes              | no              |
| MPX-FIPS appliances running firmware version other than version 2.2 | no             | no                | no               | no              |
| VPX appliances/ SDX instances without SSL card                      | yes            | yes               | yes              | yes             |

Note: FIPS firmware version 2.2 is supported on 10.5.e builds.

Table 2. Ciphers That the NetScaler Appliance Supports by Default

| Cipher Suite      | Protocol | Key Exchange Algorithm | Authentication Algorithm | Encryption Algorithm (Key Size) | Message Authentication Code (MAC) Algorithm | Hex Code | Wireshark Ciphersuite Name   |
|-------------------|----------|------------------------|--------------------------|---------------------------------|---------------------------------------------|----------|------------------------------|
| SSL3-RC4-MD5      | SSLv3    | RSA                    | RSA                      | RC4(128)                        | MD5                                         | 0x0004   | TLS_RSA_WITH_RC4_128_MD5     |
|                   | TLSv1    |                        |                          |                                 |                                             |          |                              |
|                   | TLSv1.1  |                        |                          |                                 |                                             |          |                              |
| SSL3-RC4-SHA      | SSLv3    | RSA                    | RSA                      | RC4(128)                        | SHA1                                        | 0x0005   | TLS_RSA_WITH_RC4_128_SHA     |
|                   | TLSv1    |                        |                          |                                 |                                             |          |                              |

## Note

1. The following curves are supported for ECDHE key exchange algorithms:

- ECDHE 521 curve
- ECDHE 384 curve
- ECDHE 256 curve
- ECDHE 224 curve

For more information about the ECDHE ciphers supported on a NetScaler appliance, see [Configuring ECDHE Ciphers](#).

2. The NetScaler VPX appliance supports only the SHA256 + RSA (Hex code 0x0401) signature hash algorithm in the certificate request message. If you use a different signature algorithm to sign the certificate verify message, the TLSv1.2 handshake fails during client authentication with the error message "Unsupported Certificate."
3. AES-GCM/SHA2 ciphers are supported only on the front end SSL entities on an MPX appliance.

# Cipher/Protocol Support Matrix on the NetScaler Appliance

Apr 27, 2017

From release 10.5 build 56.22, NetScaler MPX appliances support full hardware optimization for all ciphers. In earlier releases, part of ECDHE/DHE cipher optimization was done in software.

For the updated cipher/protocol support matrix, see [http://docs.citrix.com/en-us/netscaler/12/ssl/cipher\\_protocol\\_support\\_matrix.html](http://docs.citrix.com/en-us/netscaler/12/ssl/cipher_protocol_support_matrix.html).

# Server Certificate Support Matrix on the NetScaler Appliance

Apr 27, 2017

For information about the server certificate support matrix, see <http://docs.citrix.com/en-us/netscaler/12/ssl/ssl-server-cert-support-matrix.html>.

# Configuring the MPX 9700/10500/12500/15500 FIPS Appliances

Sep 08, 2016

The Federal Information Processing Standard (FIPS), issued by the US National Institute of Standards and Technologies, specifies the security requirements for a cryptographic module used in a security system. The NetScaler FIPS appliance complies with the second version of this standard, FIPS-140-2.

Note: Henceforth, all references to FIPS imply FIPS-140-2.

The FIPS appliance is equipped with a tamper-proof (tamper-evident) cryptographic module—a Cavium CN1620-NFBE3-2.0-G—designed to comply with the FIPS 140-2 Level-2 specifications. The Critical Security Parameters (CSPs), primarily the server's private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (nsroot) can perform operations on the keys stored inside the HSM.

The following table summarizes the differences between standard NetScaler and NetScaler FIPS appliances.

| Setting        | NetScaler appliance | NetScaler FIPS appliance |
|----------------|---------------------|--------------------------|
| Key storage    | On the hard disk    | On the FIPS card         |
| Cipher support | All ciphers         | FIPS approved ciphers    |
| Accessing keys | From the hard disk  | Not accessible           |

Configuring a FIPS appliance involves configuring the HSM immediately after completing the generic configuration process. You then create or import a FIPS key. After creating a FIPS key, you should export it for backup. You might also need to export a FIPS key so that you can import it to another appliance. For example, configuring FIPS appliances in a high availability (HA) setup requires transferring the FIPS key from the primary node to the secondary node immediately after completing the standard HA setup.

You can upgrade the firmware version on the FIPS card from version 4.6.0 to 4.6.1, and you can reset an HSM that has been locked to prevent unauthorized logon. Only FIPS approved ciphers are supported on a NetScaler FIPS appliance.

This section includes the following details:

- [Configuring the HSM](#)
- [Creating and Transferring FIPS Keys](#)
- [Configuring FIPS Appliances in a High Availability Setup](#)
- [Resetting a Locked HSM](#)
- [FIPS Approved Algorithms and Ciphers](#)

# Configuring the HSM

Aug 30, 2016

Before you can configure the HSM of your NetScaler FIPS appliance, you must complete the initial hardware configuration. For more information, see [Initial Configuration](#).

Configuring the HSM of your NetScaler FIPS appliance erases all existing data on the HSM. To configure the HSM, you must be logged on to the appliance as the superuser (nsroot account). The HSM is preconfigured with default values for the Security Officer (SO) password and User password, which you use to configure the HSM or reset a locked HSM. The maximum length allowed for the password is 14 alphanumeric characters. Symbols are not allowed.

Important: Do not perform the `set ssl fips` command without first resetting the FIPS card and restarting the MPX FIPS appliance.

Although the FIPS appliance can be used with the default password values, you should modify them before using it. The HSM can be configured only when you log on to the appliance as the superuser and specify the SO and User passwords.

Important: Due to security constraints, the appliance does not provide a means for retrieving the SO password. Store a copy of the password safely. Should you need to reinitialize the HSM, you will need to specify this password as the old SO password.

Before initializing the HSM, you can upgrade to the latest build of the software. To upgrade to the latest build, see [Upgrading or Downgrading the System Software](#).

After upgrading, verify that the `/nsconfig/fips` directory has been successfully created on the appliance.

To configure the HSM on an MPX 9700/10500/12500/15500 FIPS appliances by using the command line interface

After logging on to the appliance as the superuser and completing the initial configuration, at the command prompt, type the following commands to configure the HSM and verify the configuration:

1. `show ssl fips`
2. `reset ssl fips`
3. `reboot`
4. `set ssl fips -initHSM Level-2 <newSOPassword> <oldSOPassword> <userPassword> [-hsmLabel <string>]`
5. `save ns config`
6. `reboot`
7. `show ssl fips`

## Example

```
show fips
FIPS Card is not configured
Done
reset fips
reboot
Are you sure you want to restart NetScaler (Y/N)? [N]:y
set ssl fips -initHSM Level-2 sopin12345 so12345 user123 -hsmLabel cavium
This command will erase all data on the FIPS card. You must save the configuration
(saveconfig) after executing this command.
```

```
Do you want to continue?(Y/N)y
Done
save ns config
reboot
Are you sure you want to restart NetScaler (Y/N)? [N]:y
show fips
```

FIPS HSM Info:

```
HSM Label : NetScaler FIPS
Initialization : FIPS-140-2 Level-2
HSM Serial Number : 2.1G1008-IC000021
HSM State : 2
HSM Model : NITROX XL CN1620-NFBE
Firmware Version : 1.1
Firmware Release Date : Jun04,2010
```

```
Max FIPS Key Memory : 3996
Free FIPS Key Memory : 3994
Total SRAM Memory : 467348
Free SRAM Memory : 62564
Total Crypto Cores : 3
Enabled Crypto Cores : 1
```

Done

Note: In release 10.5.e build 55.8007\_e and later, if you upgrade the firmware to version 2.2, the firmware release date is replaced with the firmware build.

```
> show fips
```

FIPS HSM Info:

```
HSM Label : NetScaler FIPS
Initialization : FIPS-140-2 Level-2
HSM Serial Number : 3.0G1235-ICM000264
HSM State : 2
HSM Model : NITROX XL CN1620-NFBE
Hardware Version : 2.0-G
Firmware Version : 2.2
Firmware Build : NFBE-FW-2.2-130009
```

```
Max FIPS Key Memory : 3996
Free FIPS Key Memory : 3958
Total SRAM Memory : 467348
Free SRAM Memory : 50524
Total Crypto Cores : 3
Enabled Crypto Cores : 3
```

Done

To configure the HSM on an MPX 9700/10500/12500/15500 FIPS appliances by using the configuration utility

1. Navigate to Traffic Management > SSL > FIPS.

2. In the details pane, on the FIPS Infotab, click Reset FIPS.
  3. In the navigation pane, click System.
  4. In the details pane, click Reboot.
  5. In the details pane, on the FIPS Info tab, click Initialize HSM.
  6. In the Initialize HSM dialog box, specify values for the following parameters:
    - Security Officer (SO) Password\*—new SO password
    - Old SO Password\*—old SO password
    - User Password\*—user password
    - Level—initHSM (Currently set to Level2 and cannot be changed)
    - HSM Label—hsmLabel
- \*A required parameter
7. Click OK.
  8. In the details pane, click Save.
  9. In the navigation pane, click System.
  10. In the details pane, click Reboot.
  11. Under FIPS HSM Info, verify that the information displayed for the FIPS HSM that you just configured is correct.

# Creating and Transferring FIPS Keys

Nov 04, 2016

After configuring the HSM of your FIPS appliance, you are ready to create a FIPS key. The FIPS key is created in the appliance's HSM. You can then export the FIPS key to the appliance's CompactFlash card as a secured backup. Exporting the key also enables you to transfer it by copying it to the /flash of another appliance and then importing it into the HSM of that appliance. You must enable SIM between two standalone nodes before you export and transfer the keys. In an HA setup, if one of the nodes is replaced with a new appliance, you must enable SIM between this new appliance and the existing appliance of the HA setup before you export or import FIPS keys.

Instead of creating a FIPS key, you can import an existing FIPS key or import an external key as a FIPS key. If you are adding a certificate-key pair of 2048 bits on the MPX 9700/10500/12500/15500 FIPS appliances, make sure that you have the correct certificate and key pair.

Note: If you are planning an HA setup, make sure that the FIPS appliances are configured in an HA setup before creating a FIPS key.

## Creating a FIPS Key

Updated: 2013-08-20

Before creating a FIPS key, make sure that the HSM is configured.

## To create a FIPS key by using the configuration utility

1. Navigate to Traffic Management > SSL > FIPS.
2. In the details pane, on the FIPS Keys tab, click Add.
3. In the Create FIPS Key dialog box, specify values for the following parameters:
  - FIPS Key Name\*—fipsKeyName
  - Modulus\*—modulus
  - Exponent\*—exponent\*A required parameter

Note: In an HA setup, you must enter the user name and password for the secondary node.

4. Click Create, and then click Close.
5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just created are correct.

## To create a FIPS key by using the command line interface

At the command prompt, type the following commands to create a FIPS key and verify the settings:

- `create ssl fipsKey <fipsKeyName> -modulus <positive_integer> [-exponent ( 3 | F4 )]`
- `show ssl fipsKey [<fipsKeyName>]`

### Example

```
create fipskey Key-FIPS-1 -modulus 2048 -exponent 3
show ssl fipsKey Key-FIPS-1
FIPS Key Name: Key-FIPS-1 Modulus: 2048 Public Exponent: 3 (Hex: 0x3)
```

## Exporting a FIPS Key

Updated: 2013-08-20

Citrix recommends that you create a backup of any key created in the FIPS HSM. If a key in the HSM is deleted, there is no way to create the same key again, and all the certificates associated with it are rendered useless.

In addition to exporting a key as a backup, you might need to export a key for transfer to another appliance.

The following procedure provides instructions on exporting a FIPS key to the /nsconfig/ssl folder on the appliance's CompactFlash and securing the exported key by using a strong asymmetric key encryption method.

### To export a FIPS key by using the command line interface

At the command prompt, type:

```
export ssl fipsKey <fipsKeyName> -key <string>
```

#### Example

```
export fipskey Key-FIPS-1 -key Key-FIPS-1.key
```

### To export a FIPS key by using the configuration utility

1. Navigate to Traffic Management > SSL > FIPS
2. In the details pane, on the FIPS Keys tab, click Export.
3. In the Export FIPS key to a file dialog box, specify values for the following parameters:
  - FIPS Key Name\*—fipsKeyName
  - File Name\*—key (To put the file in a location other than the default, you can either specify the complete path or click the Browse button and navigate to a location.)

\*A required parameter
4. Click Export, and then click Close.

## Importing an Existing FIPS Key

Updated: 2013-11-22

To use an existing FIPS key with your FIPS appliance, you need to transfer the FIPS key from the hard disk of the appliance into its HSM.

Note: To avoid errors when importing a FIPS key, make sure that the name of the key imported is the same as the original key name when it was created.

### To import a FIPS key on the MPX 9700/10500/12500/15500 FIPS appliances by using the command line interface

At the command prompt, type the following commands to import a FIPS key and verify the settings:

- import ssl fipsKey <fipsKeyName> -key <string> -inform SIM -exponent (F4 | 3)
- show ssl fipskey <fipsKeyName>

#### Example

```
import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4
```

```
show ssl fipskey key-FIPS-2
```

```
FIPS Key Name: Key-FIPS-2 Modulus: 2048 Public Exponent: F4 (Hex value 0x10001)
```

## To import a FIPS key by using the configuration utility

1. Navigate to Traffic Management > SSL > FIPS
2. In the details pane, on the FIPS Keys tab, click Import.
3. In the Import as a FIPS Key dialog box, select FIPS key file and set values for the following parameters:
  - FIPS Key Name\*
  - Key File Name\*—To put the file in a location other than the default, you can either specify the complete path or click Browse and navigate to a location.
  - Exponent\*\*A required parameter
4. Click Import, and then click Close.
5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just imported are correct.

### Importing External Keys

Updated: 2015-02-09

In addition to transferring FIPS keys that are created within the NetScaler appliance's HSM, you can transfer external private keys (such as those created on a standard NetScaler, Apache, or IIS) to a FIPS NetScaler appliance. External keys are created outside the HSM, by using a tool such as OpenSSL. Before importing an external key into the HSM, copy it to the appliance's flash drive under `/nsconfig/ssl`.

### Importing an external key as a FIPS key on the MPX 9700/10500/12500/15500 FIPS appliances by using the command line interface

On the MPX 9700/10500/12500/15500 FIPS appliances, the `-exponent` parameter in the `import ssl fipskey` command is not required while importing an external key. The correct public exponent is detected automatically when the key is imported, and the value of the `-exponent` parameter is ignored.

The NetScaler FIPS appliance does not support external keys with a public exponent other than 3 or F4.

You do not need a wrap key on the MPX 9700/10500/12500/15500 FIPS appliances.

You cannot import an external, encrypted FIPS key directly to an MPX 9700/10500/12500/15500 FIPS appliance. To import the key you need to first decrypt the key, and then import it. To decrypt the key, at the shell prompt, type:

```
openssl rsa -in <EncryptedKey.key> > <DecryptedKey.out>
```

To import an external key as a FIPS key to an MPX 9700/10500/12500/15500 FIPS appliance by using the command line interface

1. Copy the external key to the appliance's flash drive.
2. If the key is in .pfx format, you must first convert it to PEM format. At the command prompt, type:
  - `convert ssl pkcs12 <output file> -import -pkcs12File <input .pfx file name> -password <password>`
3. At the command prompt, type the following commands to import the external key as a FIPS key and verify the settings:
  - `import ssl fipsKey <fipsKeyName> -key <string> -inform PEM`
  - `show ssl fipskey<fipsKeyName>`

#### Example

```
convert ssl pkcs12 iis.pem -password 123456 -import -pkcs12File iis.pfx
import fipskey Key-FIPS-2 -key iis.pem -inform PEM
```

```
show ssl fipskey key-FIPS-2
```

FIPS Key Name: Key-FIPS-2 Modulus: 0 Public Exponent: F4 (Hex value 0x10001)

Note: The modulus is incorrectly displayed as zero in the above example. The discrepancy does not affect SSL functionality.

## To import an external key as a FIPS key to an MPX 9700/10500/12500/15500 FIPS appliance by using the configuration utility

1. If the key is in .pfx format, you must first convert it to PEM format.
  1. Navigate to Traffic Management > SSL.
  2. In the details pane, under Tools, click Import PKCS#12.
  3. In the Import PKCS12 File dialog box, set the following parameters:
    - Output File Name\*
    - PKCS12 File Name\*—Specify the .pfx file name.
    - Import Password\*
    - Encoding Format\*A required parameter
2. Navigate to Traffic Management > SSL > FIPS
3. In the details pane, on the FIPS Keys tab, click Import.
4. In the Import as a FIPS Key dialog box, select PEM file, and set values for the following parameters:
  - FIPS Key Name\*
  - Key File Name\*—To put the file in a location other than the default, you can either specify the complete path or click Browse and navigate to a location.\*A required parameter
5. Click Import, and then click Close.
6. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just imported are correct.

# Configuring FIPS Appliances in a High Availability Setup

Nov 11, 2013

You can configure two appliances in a high availability (HA) pair as FIPS appliances. For information about configuring an HA setup, see .

Note: Citrix recommends that you use the configuration utility (GUI) for this procedure. If you use the command line (CLI), make sure that you carefully follow the steps as listed in the procedure. Changing the order of steps or specifying an incorrect input file might cause inconsistency that requires that the appliance be restarted. In addition, if you use the CLI, the `create ssl fipskey` command is not propagated to the secondary node. When you execute the command with the same input values for modulus size and exponent on two different FIPS appliances, the keys generated are not identical. You have to create the FIPS key on one of the nodes and then transfer it to the other node. But if you use the configuration utility to configure FIPS appliances in an HA setup, the FIPS key that you create is automatically transferred to the secondary node. The process of managing and transferring the FIPS keys is known as secure information management (SIM).

Important: On the MPX 9700/10500/12500/15500 FIPS appliances, the HA setup should be completed within six minutes. If the process takes longer than six minutes, the internal timer of the FIPS card expires and the following error message appears:

ERROR: Operation timed out or repeated, please wait for 10 mins and redo the SIM/HA configuration steps.

If this message appears, restart the appliance or wait for 10 minutes, and then repeat the HA setup procedure.

In the following procedure, appliance A is the primary node and appliance B is the secondary node.

To configure FIPS appliances in a high availability setup by using the command line interface

1. **On appliance A**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on to the appliance, using the administrator credentials.
3. Initialize appliance A as the source appliance. At the command prompt, type:  
`init ssl fipsSIMsource <certFile>`
4. Copy this <certFile> file to appliance B, in the /nconfig/ssl folder.
5. **On appliance B**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.
6. Log on to the appliance, using the administrator credentials.
7. Initialize appliance B as the target appliance. At the command prompt, type:  
`init ssl fipsSIMtarget <certFile> <keyVector> <targetSecret>`
8. Copy this <targetSecret> file to appliance A.
9. **On appliance A**, enable appliance A as the source appliance. At the command prompt, type:  
`enable ssl fipsSIMSource <targetSecret> <sourceSecret>`
10. Copy this <sourceSecret> file to appliance B.
11. **On appliance B**, enable appliance B as the target appliance. At the command prompt, type:  
`enable ssl fipsSIMtarget <keyVector> <sourceSecret>`
12. **On appliance A**, create a FIPS key, as described in [Creating a FIPS Key](#).
13. Export the FIPS key to the appliance's hard disk, as described in [Exporting a FIPS Key](#).

14. Copy the FIPS key to the hard disk of the secondary appliance by using a secure file transfer utility, such as SCP.
15. **On appliance B**, import the FIPS key from the hard disk into the HSM of the appliance, as described in [Importing an Existing FIPS Key](#).

To configure FIPS appliances in a high availability setup by using the configuration utility

1. On the appliance to be configured as the source appliance, navigate to Traffic Management > SSL > FIPS.
2. In the details pane, on the FIPS Info tab, click Enable SIM.
3. In the Enable HA Pair for SIM dialog box, in the Certificate File Name text box, type the file name, with the path to the location at which the FIPS certificate should be stored on the source appliance.
4. In the Key Vector File Name text box, type the file name, with the path to the location at which the FIPS key vector should be stored on the source appliance.
5. In the Target Secret File Name text box, type the location for storing the secret data on the target appliance.
6. In the Source Secret File Name text box, type the location for storing the secret data on the source appliance.
7. Click OK. The FIPS appliances are now configured in HA mode.
8. Create a FIPS key, as described in [Creating a FIPS Key](#). The FIPS key is automatically transferred from the primary to the secondary.

### Example

In the following example, source.cert is the certificate on the source appliance, stored in the default directory, /nsconfig/ssl. This certificate must be transferred to the same location (/nsconfig/ssl) on the target appliance. The file target.secret is created on the target appliance and copied to the source appliance. The file source.secret is created on the source appliance and copied to the target appliance.

#### On the source appliance

```
init fipsSIMsource /nsconfig/ssl/source.cert
```

#### On the target appliance

```
init fipsSIMtarget /nsconfig/ssl/source.cert /nsconfig/ssl/target.key /nsconfig/ssl/target.secret
```

#### On the source appliance

```
enable fipsSIMsource /nsconfig/ssl/target.secret /nsconfig/ssl/source.secret
```

#### On the target appliance

```
enable fipsSIMtarget /nsconfig/ssl/target.key /nsconfig/ssl/source.secret
```

#### On the source appliance

```
create ssl fipskey fips1 -modulus 2048 -exponent f4
```

```
export fipskey fips1 -key /nsconfig/ssl/fips1.key
```

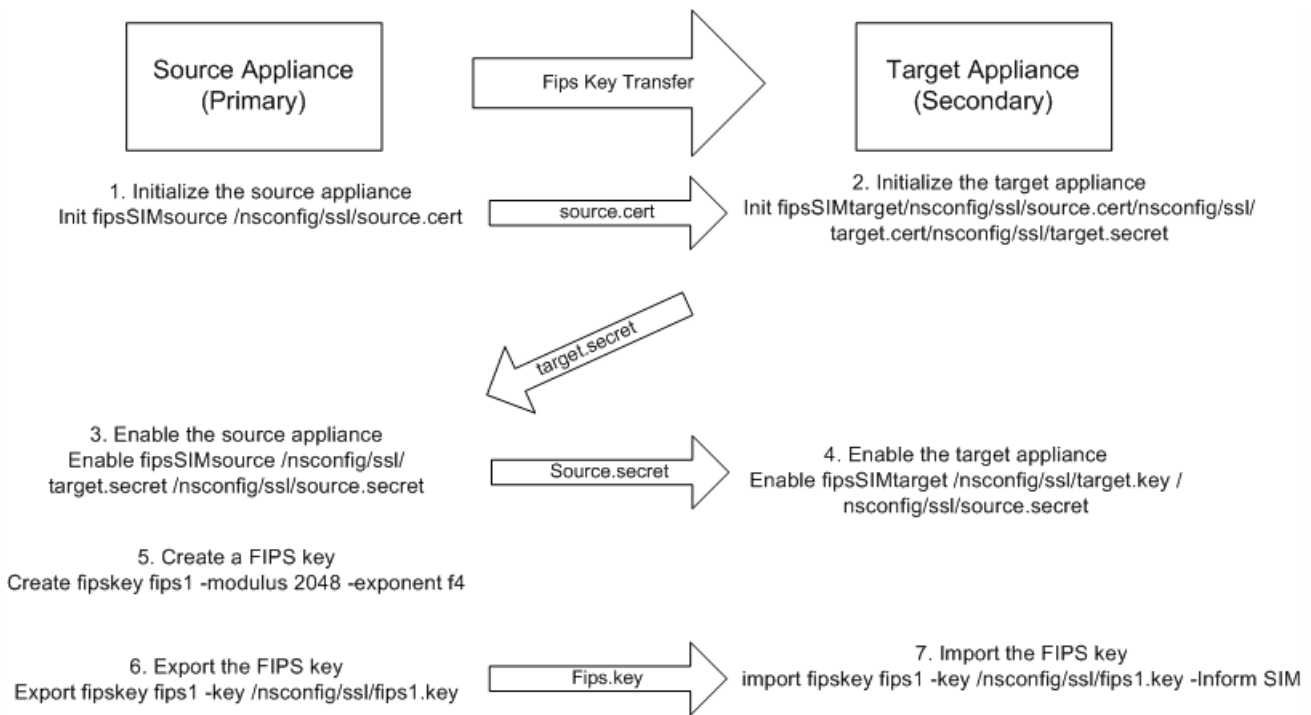

Copy this key into the hard disk of the target appliance.

#### On the target appliance

```
import fipskey fips1 -key /nsconfig/ssl/fips1.key
```

The following diagram summarizes the transfer process.

Figure 1. Transferring the FIPS Key-Summary

# Updating the Firmware to Version 2.2 on a FIPS Card

Apr 25, 2017

Note: This feature is available from release 10.5, build 58.1108.e and is only available in 10.5.e builds.

FIPS firmware version 2.2 supports TLS protocol versions 1.1 and 1.2. From the command line, you can update the firmware version of the FIPS card of a NetScaler MPX 9700/10500/12500/15500 FIPS appliance from version 1.1 to version 2.2.

For successful SIM key propagation from primary to secondary in a high availability (HA) pair, the Cavium firmware version on each appliance should be identical. Perform the firmware update on the secondary appliance first. If executed on the primary appliance first, the long-running update process causes a failover.

## Limitations

- TLS protocol versions 1.1 and 1.2 are supported only on SSL virtual servers and front-end SSL services.
- Secure renegotiation is supported only on SSL virtual servers and front-end SSL services.
- Creating a certificate signing request by using a key that was created on firmware version 1.1 and updated to firmware version 2.2 fails.
- You cannot create a 1024-bit RSA key on firmware version 2.2. However, if you have imported or created a 1024-bit FIPS key on firmware version 1.1 and you then update to firmware version 2.2, you can use that FIPS key on firmware version 2.2.
- 1024-bit RSA keys are not supported.
- Secure renegotiation using SSLv3 protocol is not supported.
- After you upgrade the firmware, TLSv1.1 and TLSv1.2 are disabled by default on the existing virtual servers, internal, and front end services. To use TLS 1.1/1.2, you must explicitly enable these protocols, on the SSL entities, after the upgrade.

## Prerequisites

Download the following files from the download page on [www.citrix.com](http://www.citrix.com). The files must be stored in the /var/nsinstall directory on the appliance.

- FW 2.2 File: FW-2.2-130013
- FW 2.2 Signature File: FW-2.2-130013.sign

FW-2.2-130013 is the recommended firmware version. It includes fixes to improve DRBG.

To update the FIPS firmware to version 2.2 on a standalone appliance

1. Log on to the appliance by using the administrator credentials.
2. At the prompt, type the following command to confirm that the FIPS card is initialized.  
show fips

FIPS HSM Info:

```
HSM Label : NetScaler FIPS
Initialization : FIPS-140-2 Level-2
HSM Serial Number : 3.0G1235-ICM000264
HSM State : 2
HSM Model : NITROX XL CN1620-NFBE
```

```
Hardware Version : 2.0-G
Firmware Version : 1.1
Firmware Release Date : Jun04,2010
```

```
Max FIPS Key Memory : 3996
Free FIPS Key Memory : 3992
Total SRAM Memory : 467348
Free SRAM Memory : 62512
Total Crypto Cores : 3
Enabled Crypto Cores : 1
Done
```

3. Save the configuration. At the prompt, type:  
save config
4. Perform the update. At the prompt, type:  
update ssl fips -fipsFW <path to the extracted contents>/CN16XX-NFBE-FW-2.2-130013

and press Y when the following prompt appears:

This command will update compatible version of the FIPS firmware. You must save the current configuration (saveconfig) before executing this command. You must reboot the system after execution of Done

Note: You only need to specify the firmware file because the firmware signature file is placed in the same location.

The update takes up to ten seconds. The update command is blocking, which means that no other actions are executed until the command finishes. The command prompt reappears when execution of the command is completed.

5. Restart the appliance. At the prompt, type:  
reboot
- Are you sure you want to restart NetScaler (Y/N)? [N]:Y
6. Verify that the update is successful. At the prompt, type:  
show fips

The firmware version displayed in the output should be 2.2. For example:

```
> sh fips
FIPS HSM Info:
HSM Label : NetScaler FIPS
```

Initialization : FIPS-140-2 Level-2  
HSM Serial Number : 2.1G1207-IC002429  
HSM State : 2  
HSM Model : NITROX XL CN1620-NFBE

Hardware Version : 2.0-G  
Firmware Version : 2.2  
Firmware Build : NFBE-FW-2.2-130013  
Max FIPS Key Memory : 3996  
Free FIPS Key Memory : 3982  
Total SRAM Memory : 467348  
Free SRAM Memory : 50472  
Total Crypto Cores : 3  
Enabled Crypto Cores : 1  
Done

To update the FIPS firmware to version 2.2 on appliances in a high availability pair

1. Log on to the secondary node and perform the update as described in [To update the FIPS firmware to version 2.2 on a standalone NetScaler](#).  
Force the secondary node to become primary. At the prompt, type:

force failover

and press Y at the confirmation prompt.

2. Log on to the new secondary node (old primary) and perform the update as described in [To update the FIPS firmware to version 2.2 on a standalone NetScaler](#).
3. Force the new secondary node to become primary again. At the prompt, type:

force failover

and press Y at the confirmation prompt.

# Resetting a Locked HSM

Nov 11, 2013

The HSM becomes locked (no longer operational) if you change the SO password, restart the appliance without saving the configuration, and make three unsuccessful attempts to change the password. This is a security measure for preventing unauthorized access attempts and changes to the HSM settings.

**Important:** To avoid this situation, save the configuration after initializing the HSM.

If the HSM is locked, you must reset the HSM and restart the appliance to restore the default passwords. You can then use the default passwords to access the HSM and configure it with new passwords. When finished, you must save the configuration and restart the appliance.

**Caution:** Do not reset the HSM unless it has become locked.

To reset a locked HSM by using the command line interface

At the command prompt, type the following commands to reset and re-initialize a locked HSM:

- reset ssl fips
- reboot -warm
- set ssl fips -initHSM Level-2 <new SO password> <old SO password> <user password> [-hsmLabel <string>]
- save ns config
- reboot -warm

## Example

```
reset fips
reboot -warm
set fips -initHSM Level-2 newsopin123 sopin123 userpin123 -hsmLabel NSFIPS
saveconfig
reboot -warm
```

Note: The SO and User passwords are the default passwords.

To reset a locked HSM by using the configuration utility

1. Navigate to Traffic Management > SSL > FIPS
2. In the details pane, on the FIPS Info tab, click Reset FIPS.
3. Configure the HSM, as described in [Configuring the HSM](#).
4. In the details pane, click Save.

# FIPS Approved Algorithms and Ciphers

Mar 24, 2017

For the updated FIPS cipher support matrix, see <http://docs.citrix.com/en-us/netscaler/11-1/ssl/ssl-fips-approved-ciphers.html>.

For information about the Cipher/Protocol support matrix, see [http://docs.citrix.com/en-us/netscaler/11-1/ssl/cipher\\_protocl\\_support\\_matrix.html](http://docs.citrix.com/en-us/netscaler/11-1/ssl/cipher_protocl_support_matrix.html).

# Configuring the MPX 14000 FIPS Appliance

Mar 22, 2017

## Important

Configuration steps for NetScaler MPX 14000 FIPS and NetScaler MPX 9700/10500/12500/15500 FIPS appliances are different.

Support for this platform is available only in 10.5-59.1360.e build.

The FIPS appliance is equipped with a tamper-proof (tamper-evident) cryptographic module—a Cavium CNN3560-NFBE-G—designed to comply with the FIPS 140-2 Level-2 specifications. The Critical Security Parameters (CSPs), primarily the server's private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (nsroot) can perform operations on the keys stored inside the HSM.

Before configuring a FIPS appliance, you must first check the state of the FIPS card and then initialize the card. Create a FIPS key and server certificate, and add any additional SSL configuration.

For information about the FIPS ciphers supported, see [FIPS Approved Algorithms and Ciphers](#). The cipher/protocol matrix is available [here](#).

For information about configuring FIPS appliances in a high availability setup, see [Configuring FIPS Appliances in a High Availability Setup](#).

## Limitations

1. SSL renegotiation using the SSLv3 protocol is not supported on the back end of an MPX FIPS appliance.
2. 1024-bit and 4096-bit keys and exponent value of 3 are not supported.

# Configuring the HSM on the MPX 14000 FIPS Appliance

Jun 29, 2016

You must first check the state of your FIPS card to verify that the driver loaded correctly, and then initialize the card.

At the command prompt, type:

```
> show fips
```

```
FIPS Card is not configured
```

```
Done
```

The message “ERROR: Operation not permitted - no FIPS card present in the system” appears if the driver is not loaded correctly.

## Initializing the FIPS Card

The appliance must be restarted three times for proper initialization.

### Important

- Verify that the `/nsconfig/fips` directory is successfully created on the appliance.
- Do not save the configuration before you restart the appliance for the 3rd time.

Perform the following steps to initialize the FIPS card:

1. Reset the FIPS card.
2. Restart the appliance.
3. Set the security officer password for partitions 0 and 1, and the user password for partition 1.  
Note: The set or reset command takes more than 60 seconds to run.
4. Save the configuration.
5. Verify that the password encrypted key for the master partition (`master_pek.key`) is created in the `/nsconfig/fips/` directory.
6. Restart the appliance.
7. Verify that the password encrypted key for the default partition (`master_pek.key`) is created in the `/nsconfig/fips/` directory.
8. Restart the appliance.
9. Verify that the FIPS card is UP.

### To initialize the FIPS card by using the NetScaler command line

At the command prompt, type:

```
> reset fips
```

Done

> **reboot**

> **set fips -initHSM Level-2** so12345 so12345 user123 **-hsmLabel** NSFIPS

This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. Do you want to continue?(Y/N)y

Done

> **saveconfig**

Done

> **reboot**

> **reboot**

> **show fips**

FIPS HSM Info:

HSM Label : NSFIPS

Initialization : FIPS-140-2 Level-2

HSM Serial Number : 3.0G1501-ICM000083

HSM State : 2

HSM Model : No Model Info

Hardware Version : 0.0-G

Firmware Version : 1.0

Firmware Build : NFBE-FW-1.0-39

Max FIPS Key Memory : 102235

Free FIPS Key Memory : 102233

Total SRAM Memory : 557396

Free SRAM Memory : 255456

Total Crypto Cores : 63

Enabled Crypto Cores : 63

Done

# Creating FIPS Keys on the MPX 14000 FIPS Appliance

Jun 29, 2016

You can create a FIPS key on your MPX 14000 FIPS appliance or import an existing FIPS key into the appliance. The MPX 14000 FIPS appliance supports only 2048-bit and 3072-bit keys and an exponent value of F4. For PEM keys, exponent is not required. Verify that the FIPS key is created correctly. Create a certificate signing request and a server certificate. Finally, add the certificate-key pair to your appliance.

## Note

1024-bit and 4096-bit keys and exponent value of 3 are not supported.

### To create a FIPS key by using the NetScaler command line

At the command prompt, type:

```
create ssl fipsKey <fipsKeyName> -modulus <positive_integer> [-exponent (3 | F4)]
```

Example

COPY

```
> create fipsKey f1 -modulus 2048 -exponent F4
```

```
Done
```

### To import a FIPS key by using the NetScaler command line

At the command prompt, type:

```
import ssl fipsKey <fipsKeyName> -key <string> [-inform <inform>] [-wrapKeyName <string>] [-iv<string>]
[-exponent (3 | F4)]
```

Example

COPY

```
>import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4
```

Done

```
>import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform PEM
```

Done

Verify that the FIPS key is created or imported correctly by running the show fipskey command.

Example

COPY

```
> show fipskey
```

```
1) FIPS Key Name: Key-FIPS-2 -key
```

Done

### To create a certificate signing request by using the NetScaler command line

At the command prompt, type:

```
create ssl certReq <reqFile> (-keyFile <input_filename> | -fipsKeyName <string>) [-keyform (DER | PEM)
{-PEMPassPhrase }] -countryName <string> -stateName <string> -organizationName<string>
[-organizationUnit Name <string>] [-localityName <string>] [-commonName <string>] [-emailAddress <string>]
{-challengePassword } [-companyName <string>] [-digestMethod (SHA1 | SHA256)]
```

Example

COPY

```
>create certreq f1.req -fipsKeyName f1 -countryName US -stateName CA -organizationName Citrix -companyName Citrix -commonName
```

Done

### To create a server certificate by using the NetScaler command line

At the command prompt, type:

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile
<input_filename>] [-keyform (DER | PEM) {-PEMPassPhrase }}] [-days
<positive_integer>] [-certForm (DER | PEM)] [-CAcert
<input_filename>] [-CAcertForm (DER | PEM)] [-CAkey <input_filename>]
[-CAkeyForm (DER | PEM)] [-CAserial <output_filename>]
```

Example

COPY

```
> create cert f1.cert f1.req SRVR_CERT -CAcert ns-root.cert -CAkey ns-root.key -CAserial ns-root.srl -days 1000
```

Done

The above example creates a server certificate using a local root CA on the appliance.

### To add a certificate-key pair by using the NetScaler command line

At the command prompt, type:

```
add ssl certKey <certkeyName> (-cert <string> [-password]) [-key
<string> | -fipsKey <string> | -hsmKey <string>] [-inform <inform>]
[-expiryMonitor (ENABLED | DISABLED) [-notificationPeriod
<positive_integer>]] [-bundle (YES | NO)]
```

Example

COPY

```
> add certkey cert1 -cert f1.cert -fipsKey f1
```

Done

After creating the FIPS key and server certificate, you can add the generic SSL configuration. Enable the features that are required for your deployment. Add servers, services, and SSL virtual servers. Bind the certificate-key pair and the service to the SSL virtual server. Save the configuration.

Example

COPY

```
>enable ns feature SSL LB
```

```
Done
```

```
>add server s1 10.217.2.5
```

```
Done
```

```
>add service sr1 s1 HTTP 80
```

```
Done
```

```
>add lb vserver v1 SSL 10.217.2.172 443
```

```
Done
```

```
>bind ssl vserver v1 --certKeyName cert1
```

```
Done
```

```
>bind lb vserver v1 sr1
```

```
Done
```

```
> saveconfig
```

```
Done
```

The basic configuration of your MPX 14000 FIPS appliance is now complete.

For information about configuring secure HTTPS, click [here](#).

For information about configuring secure RPC, click [here](#).

# Support for Thales nShield® HSM

Apr 07, 2017

Note: This feature is available from release 10.5, build 52.1115.e.

A non-FIPS NetScaler appliance stores the server's private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as hardware security module (HSM). Storing a key in the HSM protects it from physical and software attacks. In addition, the keys are encrypted by using special FIPS approved ciphers.

Only the NetScaler MPX 9700/10500/12500/15500 appliances support a FIPS card. Support for FIPS is not available on other MPX appliances, or on the SDX and VPX appliances. This limitation is addressed by supporting a Thales nShield® Connect external HSM on all NetScaler MPX, SDX, and VPX appliances except the MPX 9700/10500/12500/15500 appliances.

Thales nShield Connect is an external FIPS-certified network-attached HSM. With a Thales HSM, the keys are securely stored as application key tokens on a remote file server (RFS) and can be reconstituted inside the Thales HSM only.

If you are already using a Thales HSM, you can now use a NetScaler ADC to optimize, secure, and control the delivery of all enterprise and cloud services.

Note:

- Thales HSMs comply with FIPS 140-2 Level 3 specifications, while the MPX FIPS appliances comply with level 2 specifications.
- You cannot decrypt the trace while using the Thales HSM, because the response from the HSM to the NetScaler appliance is encrypted and only the Hardserver can read it.

This section includes the following details:

- [Architecture Overview](#)
- [Prerequisites](#)
- [Configuring the ADC-Thales Integration](#)
- [Limitations](#)
- [Appendix](#)

# Architecture Overview

Dec 08, 2014

The three entities that are part of a NetScaler-Thales deployment are a Thales nShield Connect module, a remote file server (RFS), and a NetScaler ADC.

The Thales nShield Connect is a network-attached hardware security module. The RFS is used to configure the HSM and to store the encrypted key files.

Hardserver, a proprietary daemon provided by Thales, is used for communication between the client (ADC), the Thales HSM, and the RFS. It uses the IMPATH secure communication protocol. A gateway daemon, called the Hardserver Gateway, is used to communicate between the NetScaler packet engine and the Hardserver.

Note: The terms Thales nShield Connect, Thales HSM, and HSM are used interchangeably in this documentation. The following figure illustrates the interaction between the different components.

In a typical deployment, the RFS is used to securely store keys generated by the HSM. After the keys are generated, you can securely transfer them to the ADC and then use the NetScaler configuration utility or command line to load the keys to the HSM. A virtual server on the ADC uses Thales to decrypt the client key exchange to complete the SSL handshake. Thereafter, all the SSL operations are performed on the ADC.

Note: The terms keys and application key tokens are used interchangeably in this documentation. The following figure illustrates the packet flow in the SSL handshake with the Thales HSM.

Figure 1. SSL Handshake Packets Flow Diagram with NetScaler Using Thales HSM

Note: The communication between the ADC and the HSM uses a Thales proprietary communication protocol, called IMPATH.

# Prerequisites

Dec 08, 2014

Before you can use a Thales nShield Connect with a NetScaler ADC, make sure that the following prerequisites are met:

- A Thales nShield Connect device is installed in the network, ready to use, and accessible to the NetScaler ADC. That is, the NetScaler IP (NSIP) address is added as an authorized client on the HSM.
- A usable Security World exists. Security World is a unique key management architecture used by the Thales nShield line of HSMs. It protects and manages keys as application key tokens, enabling unlimited key capacity, and automatic key backup and recovery. For more information about creating a Security World, see the nShield Connect Quick Start Guide from Thales. You can also find the guide in the CD provided with the Thales HSM module at `CipherTools-linux-dev-xx.xx.xx/document/nShield_Connect_Quick_Start_Guide.pdf`.

Note: Softcard or token/OCS protected keys are currently not supported on the NetScaler ADC.

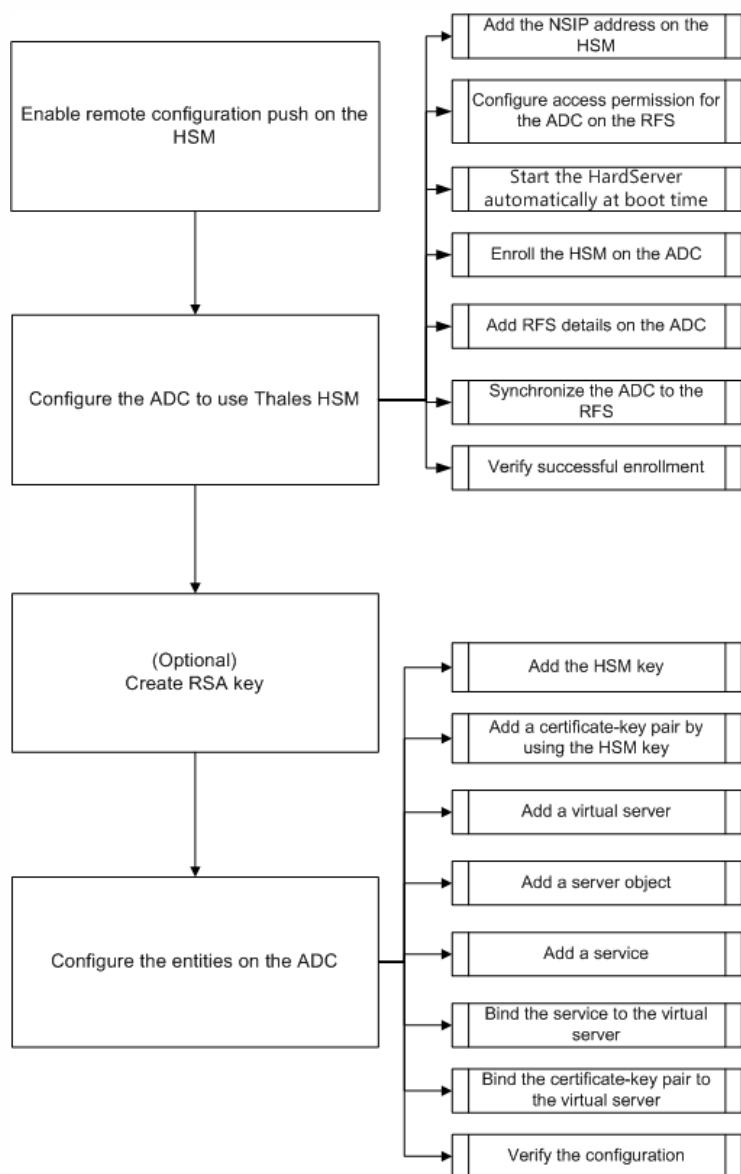

- Licenses are available to support the number of clients that will be connected to the Thales HSM. The ADC and RFS are clients of the HSM.
- A remote file server (RFS) is installed in the network and is accessible to the NetScaler ADC.
- The Thales nShield Connect device, the RFS, and the NetScaler ADC can initiate connections with each other through port 9004.
- You are using NetScaler release 10.5 build 52.1115.e or later.
- The NetScaler appliance does not contain a FIPS Cavium card.

Important: Thales HSM is not supported on the MPX 9700/10500/12500/15500 FIPS appliances.

# Configuring the ADC-Thales Integration

Nov 17, 2015

The following flowchart depicts the tasks that you need to perform to use Thales HSM with a NetScaler ADC:

As shown in the above flowchart, you perform the following tasks:

1. Enable remote configuration push on the HSM.
2. Configure the ADC to use the Thales HSM.
  - Add the NSIP address on the HSM.
  - Configure access permission for the ADC on the RFS.
  - Start the Hardserver.
  - Enroll the HSM on the ADC.
  - Add RFS details on the ADC.
  - Synchronize the ADC to the RFS.
  - Verify that Thales HSM is successfully enrolled on the ADC.
  - Restart the ADC.

3. (Optional) Create an HSM RSA key.
4. Configure the entities on the NetScaler ADC.
  - Add the HSM key.
  - Add a certificate-key pair by using the HSM key.
  - Add a virtual server.
  - Add a server object.
  - Add a service.
  - Bind the service to the virtual server.
  - Bind the certificate-key pair to the virtual server.
  - Verify the configuration.

### Enabling Remote Configuration Push on the HSM

You must specify the IP address of the RFS on the Thales HSM so that it accepts the configuration that the RFS pushes to it. Use the nShield Connect front panel on the Thales HSM to perform the following procedure.

#### To specify the IP address of a remote computer on the Thales HSM

1. Navigate to System Configuration > Config file options > Allow auto push.
2. Select ON, and specify the IP address of the computer (RFS) from which to accept the configuration.

#### Configure the ADC to use the Thales HSM

Sample values used in this documentation:

NSIP address=10.217.2.43

Thales HSM IP address=10.217.2.112

RFS IP address=10.217.2.6

### Add the NetScaler IP (NSIP) Address on the HSM

Typically you use the nShield Connect front panel to add clients to the HSM. For more information, see the nShield Connect Quick Start Guide.

Alternately, use the RFS to add the ADC as a client to the HSM. To do this, you must add the NSIP address in the HSM configuration on the RFS, and then push the configuration to the HSM. Before you can do this, you must know the electronic serial number (ESN) of the HSM.

To get the ESN of your HSM, run the following command on the RFS:

```
root@ns# /opt/nfast/bin/anonkneti <Thales HSM IP address>
```

#### Example

```
root@ns# /opt/nfast/bin/anonkneti 10.217.2.112
```

```
BD17-C807-58D9 5e30a698f7bab3b2068ca90a9488dc4e6c78d822
```

The ESN number is BD17-C807-58D9.

After you have the ESN number, use an editor, such as vi, to edit the HSM configuration file on the RFS.

```
vi /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
```

In the `hs_clients` section, add the following entries:

```
Amount of data in bytes to encrypt with a session key before session key# renegotiation, or 0 for unlimited. (default=1024*1024*8b=8Mb).
datalimit=INT
addr=10.217.2.43
clientperm=unpriv
```

```
keyhash=00
esn=
timelimit=86400
datalimit=8388608

```

Note: Include one or more hyphens as delimiters to add multiple entries in the same section.  
To push the configuration to the HSM, run the following command on the RFS:

```
/opt/nfast/bin/cfg-pushnethsm --address=<Thales HSM IP address> --force /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
```

#### Example

```
/opt/nfast/bin/cfg-pushnethsm --address=10.217.2.112 --force
/opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
```

## Configure Access Permission for the ADC on the RFS

To configure access permission for the ADC on the RFS, run the following command on the RFS:

```
/opt/nfast/bin/rfs-setup --force -g --write-noauth <NetScaler IP address>
```

#### Example

```
[root@localhost bin]# /opt/nfast/bin/rfs-setup --force -g --write-noauth 10.217.2.43
Adding read-only remote_file_system entries
Ensuring the directory /opt/nfast/kmdata/local exists
Adding new writable remote_file_system entries
Ensuring the directory /opt/nfast/kmdata/local/sync-store exists
Saving the new config file and configuring the hardserver
Done
```

Verify that the ADC can reach both the RFS and Thales HSM by using port 9004.

## Start the Hardserver

Change directory to `/var/opt/nfast/scripts/startup`.

To start the Hardserver, run the following command on the ADC:

```
./hardserver &
```

## Enroll the HSM on the ADC

Change directory to `/var/opt/nfast/bin`.

To add HSM details into the ADC configuration, run the following command on the ADC:

```
nethsmenroll --force <Thales_nShield_Connect_ip_address> $(anonkneti <Thales_nShield_Connect_ip_address>)
```

#### Example

```
root@ns# ./nethsmenroll --force 10.217.2.112 $(anonkneti 10.217.2.112)
```

OK configuring hardserver's nethsm imports

This step adds the following entries after the line `# ntoken_esn=ESN` in the `nethsm_imports` section of the `/var/opt/nfast/kmdata/config/config` file.

```
...
local_module=0
remote_ip=10.217.2.112
remote_port=9004
remote_esn=BD17-C807-58D9
keyhash=5e30a698f7bab3b2068ca90a9488dc4e6c78d822
timelimit=86400
```

```
datalimit=8388608
privileged=0
privileged_use_high_port=0
ntoken_esn=
```

Change directory to /var/opt/nfast/bin and run the following command on the ADC:

```
touch "thales_hsm_is_enrolled"
```

Note: To remove an HSM that is enrolled on the ADC, type: ./nethsmenroll --remove <NETHSM-IP>

## Add RFS details on the ADC

To add RFS details, change directory to /var/opt/nfast/bin/ and then run the following command:

```
./rfs-sync --no-authenticate --setup <rfs_ip_address>
```

### Example

```
./rfs-sync --no-authenticate --setup 10.217.2.6
```

No current RFS synchronization configuration.

Configuration successfully written; new config details:

Using RFS at 10.217.2.6:9004: not authenticating.

This step adds the following entries after the # local\_esn=ESN line in the rfs\_sync\_client section of the /var/opt/nfast/kmdata/config/config file.

```
.....
remote_ip=10.217.2.6
remote_port=9004
use_kneti=no
local_esn=
```

Note: To remove an RFS that is enrolled on the ADC, type: ./rfs\_sync --remove

### Example

```
./rfs-sync --no-authenticate --setup 10.217.2.6
```

No current RFS synchronization configuration.

Configuration successfully written; new config details:

Using RFS at 10.217.2.6:9004: not authenticating.

This step adds the following entries after the # local\_esn=ESN line in the rfs\_sync\_client section of the /var/opt/nfast/kmdata/config/config file.

```
.....
remote_ip=10.217.2.6
remote_port=9004
use_kneti=no
local_esn=
```

## Synchronize the ADC to the RFS

To synchronize all the files, change directory to /var/opt/nfast/bin and then run the following command on the ADC:

```
./rfs-sync --update
```

This command fetches all the World files, module files, and key files from the /opt/nfast/kmdata/local directory on the RFS and puts them into the /var/opt/nfast/kmdata/local directory on the ADC. Citrix recommends that you manually copy the World files, the module\_XXXX\_XXXX\_XXXX files, where XXXX\_XXXX\_XXXX is the ESN of the enrolled HSM, and only the required RSA key and certificate files.

## Verify that the Thales HSM is successfully enrolled on the ADC

After you synchronize the ADC to the RFS, do the following:

- Verify that the local Hardserver is UP and running. (nCipher server running).

- Get the state of the configured HSMs, and verify that the values for the `n_modules` (number of modules) field and the `km info` fields are non-zero.
- Verify that the HSM is enrolled correctly and is usable (state `0x2 Usable`) by the ADC.
- Load tests using `sigtest` run properly.

Change directory to `/var/opt/nfast/bin`, and at the shell prompt, run the following commands:

```
root@ns# ./chkserve root@ns# ./nfkminfo root@ns# ./sigtest
```

See [Appendix](#) for an example.

## Restart the ADC

You must restart the ADC for the configuration to take effect. If you have made changes to the configuration, save the configuration before you restart the ADC.

### To restart the ADC by using the command line

At the command prompt, run the following command:

```
reboot
```

### To restart the ADC by using the configuration utility

1. In the configuration utility, click **Reboot** on the home page of the Configuration tab.
2. When prompted to reboot, select **Save configuration** to make sure that you do not lose any configurations.

## Create an HSM RSA Key

Updated: 2014-12-08

Only RSA keys are supported as HSM keys.

Note: Skip this step if keys are already present in the `/opt/nfast/kmdata/local` folder on the RFS.

Create an RSA key, a self-signed certificate, and a Certificate Signing Request (CSR). Send the CSR to a certificate authority to get a server certificate.

The following files are created in the example below:

- Embed RSA key: `key_embed_2ed5428aaeae1e159bdbd63f25292c7113ec2c78`
- Self-Signed Certificate: `example_selfcert`
- Certificate Signing Request: `example_req`

Note: The `generatekey` command is supported in strict FIPS 140-2 Level 3 Security World. An administrator card set (ACS) or an operator card set (OCS) is needed to control many operations, including the creation of keys and OCSs. When you run the `generatekey` command, you are prompted to insert an ACS or OCS card. For more information about strict FIPS 140-2 Level 3 Security World, see the *nShield Connect User Guide*.

The following example uses Level-2 Security World. In the example, the commands are in boldface type.

### Example

```
[root@localhost bin]# ./generatekey embed
size: Key size? (bits, minimum 1024) [1024] > 2048
OPTIONAL: pubexp: Public exponent for RSA key (hex)? []
>
embedsavefile: Filename to write key to? []
> example
plainname: Key name? [] > example
x509country: Country code? [] > US
x509province: State or province? [] > CA
x509locality: City or locality? [] > Santa Clara
x509org: Organisation? [] > Citrix
x509orgunit: Organisation unit? [] > NS
x509dnscommon: Domain name? [] > www.citrix.com
```

```
x509email: Email address? [] > example@citrix.com
nvrAm: Blob in NVRAM (needs ACS)? (yes/no) [no] >
digest: Digest to sign cert req with? (md5, sha1, sha256, sha384, sha512)
[default sha1] > sha512
```

key generation parameters:

```
operation Operation to perform generate
application Application embed
verify Verify security of key yes
type Key type RSA
size Key size 2048
pubexp Public exponent for RSA key (hex)
embedsavefile Filename to write key to example
plainname Key name example
x509country Country code US
x509province State or province CA
x509locality City or locality Santa Clara
x509org Organisation Citrix
x509orgunit Organisation unit NS
x509dnscommon Domain name www.citrix.com
x509email Email address example@citrix.com
nvrAm Blob in NVRAM (needs ACS) no
digest Digest to sign cert req with sha512
```

Key successfully generated.

Path to key: /opt/nfast/kmdata/local/key\_embed\_2ed5428aaeae1e159bdbd63f25292c7113ec2c78

You have new mail in /var/spool/mail/root

## Result

You have created a CSR (example\_req), a self-signed certificate (example\_selfcert), and an application key token file in embed format (/opt/nfast/kmdata/local/key\_embed\_2ed5428aaeae1e159bdbd63f25292c7113ec2c78)

Because the ADC supports keys in simple format only, you must convert the embed key to a simple key.

To convert the embed key to a simple key, run the following command on the RFS:

```
[root@localhost bin]# ./generatekey -r simple
from-application: Source application? (embed, simple) [embed] > embed
from-ident: Source key identifier? (c6410ca00af7e394157518cb53b2db46ff18ce29,
2ed5428aaeae1e159bdbd63f25292c7113ec2c78)
[default c6410ca00af7e394157518cb53b2db46ff18ce29]
> 2ed5428aaeae1e159bdbd63f25292c7113ec2c78
ident: Key identifier? [] > examplersa2048key
plainname: Key name? [] > examplersa2048key
key generation parameters:
operation Operation to perform retarget
application Application simple
verify Verify security of key yes
from-application Source application embed
from-ident Source key identifier 2ed5428aaeae1e159bdbd63f25292c7113ec2c78
ident Key identifier examplersa2048key
plainname Key name examplersa2048key
```

Key successfully retargetted.

Path to key: /opt/nfast/kmdata/local/key\_simple\_examplersa2048key

Important! When prompted for the source key identifier, enter **2ed5428aaeae1e159bdbd63f25292c7113ec2c78** as the embed key.

## Result

A key with the prefix key\_simple (for example key\_simple\_examplersa2048key) is created.

Note: `examp1ersa2048key` is the key identifier (ident) and is referred to as the HSM key name on the ADC. A key identifier is unique. All the simple files have the prefix `key_simple`.

Configure the Entities on the ADC

Updated: 2014-12-08

Before the ADC can process traffic, you must do the following:

1. Enable features.
2. Add a subnet IP (SNIP) address.
3. Add the HSM key to the ADC.
4. Add a certificate-key pair by using the HSM key.
5. Add a virtual server.
6. Add a server object.
7. Add a service.
8. Bind the service to the virtual server.
9. Bind the certificate-key pair to the virtual server.
10. Verify the configuration.

## Enable features on the ADC

Licenses must be present on the ADC before you can enable a feature.

### To enable a feature by using the command line

At the command prompt, run the following commands:

- `enable feature lb`
- `enable feature ssl`

### To enable a feature by using the configuration utility

Navigate to `System > Settings` and, in the Modes and Features group, select `Configure basic features`, and then select `SSL Offloading`.

## Add a subnet IP address

For more information about subnet IP addresses, see [Configuring Subnet IP Addresses](#).

### To add a SNIP address and verify the configuration by using the command line

At the command prompt, run the following commands:

- `add ns ip <IPAddress> <netmask> -type SNIP`
- `show ns ip`

#### Example

```
> add ns ip 192.168.17.253 255.255.248.0 -type SNIP
```

```
Done
```

```
> show ns ip
```

|    | Ipaddress      | Traffic Domain | Type         | Mode   | Arp     | Icmp    | Vserver | State   |
|----|----------------|----------------|--------------|--------|---------|---------|---------|---------|
| 1) | 192.168.17.251 | 0              | NetScaler IP | Active | Enabled | Enabled | NA      | Enabled |
| 2) | 192.168.17.252 | 0              | VIP          | Active | Enabled | Enabled | Enabled | Enabled |
| 3) | 192.168.17.253 | 0              | SNIP         | Active | Enabled | Enabled | NA      | Enabled |

```
Done
```

### To add a SNIP address and verify the configuration by using the configuration utility

Navigate to `System > Network > IPs`, add an IP address, and select the IP Type as Subnet IP.

## Copy the HSM key and certificate to the ADC

Use a secure file transfer utility to securely copy the key (key\_simple\_examplera2048key) to the /var/opt/nfast/kmdata/local folder, and the certificate (example\_selfcert) to the /nsconfig/ssl folder on the ADC.

## Add the key on the ADC

All the keys have a key-simple prefix. When adding the key to the ADC, use the ident as the HSM key name. For example, if the key that you added is key\_simple\_XXXX, the HSM key name is XXXX.

Important:

- The HSM key name must be the same as the ident that you specified when you converted an embed key to a simple key format.
- The keys must be present in the /var/opt/nfast/kmdata/local/ directory on the ADC.

### To add an HSM key by using the command line

At the shell prompt, run the following command:

```
add ssl hsmKey <hsmKeyName> -key <string>
```

#### Example

```
> add ssl hsmKey examplera2048key -key key_simple_examplera2048key
Done
```

### To add an HSM key by using the configuration utility

Navigate to Traffic Management > SSL > HSM, and add an HSM key.

## Add a certificate-key pair on the ADC

For information about certificate-key pairs, see [Adding or Updating a Certificate-Key Pair](#).

### To add a certificate-key pair by using the command line

At the command prompt, run the following command:

```
add ssl certKey <certKeyName> -cert <string> -hsmKey <string>
```

#### Example

```
> add ssl certKey key22 -cert example_selfcert -hsmKey examplera2048key
Done
```

### To add a certificate-key pair by using the configuration utility

Navigate to Traffic Management > SSL > Certificates, and add a certificate-key pair.

## Add a virtual server

For information about a virtual server, see [Configuring an SSL-Based Virtual Server](#).

### To configure an SSL-based virtual server by using the command line

At the command prompt, run the following command:

```
add lb vserver <name> <serviceType> <IPAddress> <port>
```

#### Example

```
> add lb vserver v1 SSL 192.168.17.252 443
```

### To configure an SSL-based virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, create a virtual server, and specify the protocol as SSL.

## Add a server object

Before you can add a server object on the ADC, make sure that you have created a backend server. The following example uses the built-in python HTTP Server module on a Linux system.

## Example

```
%python -m SimpleHTTPServer 80
```

### To add a server object by using the command line

At the command prompt, run the following command:

```
add server <name> <IPAddress>
```

## Example

```
> add server s1 192.168.17.246
```

### To add a server object by using the configuration utility

Navigate to Traffic Management > Load Balancing > Servers, and add a server.

## Add a service

For more information, see [Configuring Services](#).

### To configure a service by using the command line

At the command prompt, run the following command:

```
add service <name> <serverName> <serviceType> <port>
```

## Example

```
> add service sr1 s1 HTTP 80
```

### To configure a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create a service.

## Bind the service to the virtual server

For more information, see [Binding Services to an SSL-Based Virtual Server](#).

### To bind a service to a virtual server by using the command line

At the command prompt, run the following command:

```
bind lb vserver <name> <serviceName>
```

## Example

```
> bind lb vserver v1 sr1
```

### To bind a service to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, and click in the Services pane to bind a service to the virtual server.

## Bind the certificate-key pair to the virtual server on the ADC

For more information, see [Binding the Certificate-Key Pair to the SSL-Based Virtual Server](#).

### To bind a certificate-key pair to a virtual server by using the command line

At the command prompt, run the following command:

```
bind ssl vserver <vServerName> -certkeyName <string>
```

## Example

```
> bind ssl vserver v1 -certkeyName key22
```

Warning: Current certificate replaces the previous binding

## To bind a certificate-key pair to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open an SSL virtual server and, in Advanced Settings, click SSL Certificate.
3. Bind a server certificate to the virtual server.

## Verify the configuration

### To view the configuration by using the command line

At the command prompt, run the following commands:

- show lb vserver <name>
- show ssl vserver <vServerName>

### Example

```
> show lb vserver v1
v1 (192.168.17.252:443) - SSL Type: ADDRESS
State: UP
Last state change was at Wed Oct 29 03:11:11 2014

1) Cipher Name: DEFAULT  
Description: Predefined Cipher Alias

Done

**To view the configuration by using the configuration utility**

Navigate to Traffic Management > Load Balancing > Virtual Servers, and double-click an SSL virtual server to open it and view the configuration.

# Limitations

Jan 25, 2017

- TLS protocol versions 1.1 and 1.2 are not supported with the Thales HSM integration.  
Note: SSL version 3 (SSLv3) is not supported on an MPX appliance but is supported on a VPX virtual appliance. A VPX instance provisioned on an SDX appliance supports SSLv3 only if an SSL chip is not assigned to the instance.
- ECDHE/DHE ciphers and Export ciphers are not supported.
- SSL server key exchange using HSM keys is not supported.
- If you have added or removed keys after you last saved the configuration, you must save the configuration before you perform a warm restart. If you do not save the configuration, there will be a key mismatch between the ADC and the HSM.
- You cannot bind an HSM key to a DTLS virtual server.
- You cannot bind a certificate-key pair that is created by using an HSM key to an SSL service.
- You cannot use the NetScaler configuration utility to enroll the ADC as a client of the HSM or check the status of the HSM from the configuration utility.
- SSL renegotiation is not supported.
- You cannot sign OCSP requests by using a certificate-key pair that is created by using an HSM key.
- A certificate bundle with HSM keys is not supported.
- An error does not appear if the HSM key and certificate do not match. Therefore, while adding a certificate-key pair, you need to make sure that the HSM key and certificate match.
- Clustering and admin partitions are not supported.

# Troubleshooting

Jul 22, 2013

If the SSL feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

## Resources for Troubleshooting

Updated: 2013-07-22

For best results, use the following resources to troubleshoot an SSL issue on a NetScaler appliance:

- The relevant ns.log file
- The latest ns.conf file
- The messages file
- The relevant newnslog file
- Trace files
- A copy of the certificate files, if possible
- A copy of the key file, if possible
- The error message, if any

In addition to the above resources, you can use the Wireshark application customized for the NetScaler trace files to expedite troubleshooting.

## Troubleshooting SSL Issues

Updated: 2013-07-22

To troubleshoot an SSL issue, proceed as follows:

- Verify that the NetScaler appliance is licensed for SSL Offloading and load balancing.
- Verify that SSL Offloading and load balancing features are enabled on the appliance.
- Verify that the status of the SSL virtual server is not displayed as DOWN.
- Verify that the status of the service bound to the virtual server is not displayed as DOWN.
- Verify that a valid certificate is bound to the virtual server.
- Verify that the service is using an appropriate port, preferably port 443.

# Optimization

Aug 06, 2014

The NetScaler optimization features reduce transaction times between the clients and the servers, and they reduce bandwidth consumption. They also enhance server performance by offloading some tasks and making others more efficient.

|                        |                                                                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Client Keep-Alive      | Handles multiple requests on a single client connection. The client does not have to negotiate a new connection for each request to the server.                                            |
| HTTP Compression       | Compresses HTTP responses sent from the servers to compression-aware browsers. The smaller responses reduce download time and save bandwidth.                                              |
| Integrated Caching     | Stores responses to client requests. Subsequent requests for the same content are served from the NetScaler cache instead of being forwarded to the origin server.                         |
| Front End Optimization | Reduces the load and render time of web pages by simplifying and optimizing the content served to the client browser.<br>Note: Supported from NetScaler 10.5 onwards.                      |
| Content Accelerator    | Stores server responses on a Citrix ByteMobile T2100 appliance.<br>Note: Supported from NetScaler 10.1 onwards.                                                                            |
| SPDY (Speedy)          | Acts as a SPDY gateway between clients and your servers, providing SPDY support without the need to configure/upgrade SPDY on the servers.<br>Note: Supported from NetScaler 10.1 onwards. |

# Client Keep-Alive

Aug 06, 2014

The client keep-alive feature enables multiple client requests to be sent on a single client connection. This feature helps in a transaction management environment where typically the server closes the client connection after serving the response. The client then opens a new connection for each request and spends more time on the transaction.

Client keep-alive resolves this issue by keeping the connection between the client and the appliance (client-side connection) open even after the server closes the connection with the appliance. This allows sending multiple client requests using a single connection and saves the round trips associated with opening and closing a connection. Client keep-alive is most beneficial in SSL sessions.

Client keep-alive is also useful under either of the following conditions:

- When the server does not support client keep-alive.
- When the server supports client keep-alive but an application on the server does not support client keep-alive.

Note: Client keep-alive is applicable for HTTP and SSL traffic.

Client-keep alive can be configured globally to be able to handle all traffic. It can also be configured to be active only on specific services.

In client keep-alive environment, the configured services intercept the client traffic and the client request is directed to the origin server. The server sends the response and closes the connection between the server and the appliance. If a "Connection: Close" header is present in the server response, the appliance corrupts this header in the client-side response, and the client-side connection is kept open. As a result, the client does not have to open a new connection for the next request; instead, the connection to the server is reopened.

Note: If a server sends back two "Connection: Close" headers, only one is edited. This results in significant delays on the client rendering of the object because a client does not assume that the object has been delivered completely until the connection is actually closed.

## Configuring Client Keep-Alive

Updated: 2014-08-12

Client keep-alive, by default, is disabled on the NetScaler, both globally and at service level. Therefore, you must enable the feature at the required scope.

Note: If you enable client keep-alive globally, it is enabled for all services, regardless of whether you enable it at the service level.

Additionally, if required, you can configure some HTTP parameters to specify the maximum number of HTTP connections retained in the connection reuse pool, enable connection multiplexing, and enable persistence Etag.

Note: When Persistent ETag is enabled, the ETag header includes information about the server that served the content. This ensures that cache validation conditional requests or browser requests, for that content, always reaches the same server.

## To configure client keep-alive by using the command line interface

At the command prompt, do the following:

1. Enable client keep-alive on the NetScaler.

- At global level  
enable ns mode cka
- At service level  
set service <name> -CKA YES

Note: Client keep-alive can be enabled only for HTTP and SSL services.

2. Configure the required HTTP parameters on the HTTP profile that is bound to the service(s).  
set ns httpProfile <name> -maxReusePool <value> -conMultiplex ENABLED -persistentETag ENABLED

Note: Configure these parameters on the nshttp\_default\_profile HTTP profile, to make them available globally.

## To configure client keep-alive by using the configuration utility

1. Enable client keep-alive on the NetScaler.
  - At global level  
Navigate to System > Settings, click Configure Modes and select Client side Keep Alive.
  - At service level  
Navigate to Traffic Management > Load Balancing > Services, and select the required service. In the Settings grouping, enable Client Keep-Alive.
2. Configure the required HTTP parameters on the HTTP profile that is bound to the service(s).  
Navigate to System > Profiles, and on HTTP Profiles tab, select the required profile and update the required HTTP parameters.

# HTTP Compression

May 20, 2015

For websites with compressible content, the NetScaler HTTP compression feature implements lossless compression to alleviate latency, long download times, and other network-performance problems by compressing the HTTP responses sent from servers to compression-aware browsers. You can improve server performance by offloading the computationally intensive compression task from your servers to the NetScaler appliance.

The following table describes the capabilities of the HTTP compression feature:

| Functionality                         | Description                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Compression Ratio</b>              | Compression ratio depends on the types of files in the responses, but is always significant, noticeably reducing amount of data transmitted over the network.                                                                                                                                                                                                                                            |
| <b>Browser Awareness</b>              | NetScaler serves compressed data to compression aware browsers only, reducing the transaction time between the client and the server. Most modern web browsers support HTTP compression.                                                                                                                                                                                                                 |
| <b>Compression blocking</b>           | You can define content filters to selectively block compression by applying built-in actions.                                                                                                                                                                                                                                                                                                            |
| <b>Compression Caching</b>            | With the integrated caching feature enabled, subsequent requests for the same content are served from the local cache, reducing the number of round trips to the server and improving transaction times.                                                                                                                                                                                                 |
| <b>HTTPS Support</b>                  | Compression is particularly useful on SSL connections, because it reduces the amount of content that has to be encrypted, either on the server or by the NetScaler appliance, and decrypted by the client.                                                                                                                                                                                               |
| <b>Intelligent Response Filtering</b> | The NetScaler compression engine intelligently filters server responses on the basis of defined compression parameters. For example, the compression engine detects zero-content-length responses and compressed responses and does not compress them. The detection of compressed responses enables origin sites to use server-based compression in conjunction with the NetScaler compression feature. |
| <b>Compression Switching</b>          | The NetScaler appliance transparently directs requests from compression aware clients to compression capable servers, so that responses to those clients are compressed, and responses to other clients are not delayed by compression processing.                                                                                                                                                       |

## How Compression Works

A NetScaler ADC can compress both static and dynamically generated data. It applies the GZIP or the DEFLATE compression algorithm to remove extraneous and repetitive information from the server responses and represent the original information in a more compact and efficient format. This compressed data is sent to the client's browser and

uncompressed as determined by the browser's supported algorithm or algorithms (GZIP or DEFLATE).

NetScaler compression treats static and dynamic content differently.

- Static files are compressed only once, and a compressed copy is stored in local memory. Subsequent client requests for cached files are serviced from that memory.
- Dynamic pages are dynamically created each time a client requests them.

When a client sends a request to the server:

1. The client request arrives at the NetScaler ADC. The ADC examines the headers and stores information about what kind of compression, if any, the browser supports.
2. The ADC forwards the request to the server and receives the response.
3. The NetScaler compression engine examines the server response for compressibility by matching it against policies.
4. If the response matches a policy associated with a compression action, and the client browser supports a compression algorithm specified by the action, the NetScaler ADC applies the algorithm and sends the compressed response to the client browser.
5. The client applies the supported compression algorithm to decompress the response.

# Configuring HTTP Compression

May 20, 2015

By default, compression is disabled on the NetScaler ADC. You must enable the feature before configuring it. If the feature is enabled, the ADC compresses server requests specified by compression policies.

To configure HTTP compression, do the following:

- [Configure compression actions](#)
- [Configure compression policies](#)
- [Bind the compression policies to global bind points or to virtual servers](#)
- [Optionally, configure global compression parameters](#)

## Enabling HTTP Compression

Compression can be enabled for HTTP and SSL services only. You can enable it globally, so that it applies to all HTTP and SSL services, or you can enable it just for specific services.

## To enable compression by using the command line interface

At the command prompt, enter one of the following commands to enable compression globally or for a specific service:

- enable ns feature cmp  
OR
- set service <name> -CMP YES

## To configure compression by using the configuration utility

Do one of the following:

- To enable compression globally, navigate to **System > Settings**, click **Configure Basic Features**, and select **HTTP Compression**.
- To enable compression for a specific service, navigate to **Traffic Management > Load Balancing > Services**, select the service, and click **Edit**. In the **Settings** group, click the pencil icon and enable **Compression**.

## Configuring a Compression Action

A compression action specifies the action to take when a request or response matches the rule (expression) in the policy with which the action is associated. For example, you can configure a compression policy that identifies requests that will be sent to a particular server, and associate the policy with an action that compresses the server's response.

There are four built-in compression actions:

- **COMPRESS**: Uses the GZIP algorithm to compress data from browsers that support either GZIP or both GZIP and DEFLATE. Uses the DEFLATE algorithm to compress data from browsers that support only the DEFLATE algorithm. If the browser does not support either algorithm, the browser's response is not compressed.
- **NOCOMPRESS**: Does not compress data.
- **GZIP**: Uses the GZIP algorithm to compress data for browsers that support GZIP compression. If the browser does not support the GZIP algorithm, the browser's response is not compressed.
- **DEFLATE**: Uses the DEFLATE algorithm to compress data for browsers that support the DEFLATE algorithm. If the

browser does not support the DEFLATE algorithm, the browser's response is not compressed. After creating an action, you associate the action with one or more compression policies.

## To create a compression action by using the command line interface

At the command prompt, enter the following command to create a compression action:

```
add cmp action <name> <cmpType> [-addVaryHeader <addVaryHeader> -varyHeaderValue <string>]
```

## To create a compression action by using the configuration utility

Navigate to **Optimization > HTTP Compression > Actions**, click **Add**, and create a compression action to specify the type of compression to be performed on the HTTP response.

### Configuring a Compression Policy

A compression policy contains a rule, which is a logical expression that enables the NetScaler appliance to identify the traffic that should be compressed.

When the NetScaler ADC receives an HTTP response from a server, it evaluates the built-in compression policies and any custom compression policies to determine whether to compress the response and, if so, the type of compression to apply. Priorities assigned to the policies determine the order in which the policies are matched against the requests.

The following table lists the built-in HTTP compression policies. These policies are activated globally when you enable compression.

| Built-in Classic or Default Syntax Policy      | Description                                                                                                                                                                                                            |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ns_nocmp_mozilla_47<br>ns_adv_nocmp_mozilla_47 | Prevents compression of CSS files when a request is sent from a Mozilla 4.7 browser.                                                                                                                                   |

## To create a compression policy by using the command line interface

At the command prompt, enter the following command to create a compression policy:

```
add cmp policy <name> -rule <expression> -resAction <string>
```

## To create a compression policy by using the configuration utility

Navigate to **Optimization > HTTP Compression > Policies**, click **Add**, and create a compression policy by specifying the condition and the corresponding action to be executed.

### Binding a Compression Policy

To put a compression policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the NetScaler ADC, or to a specific virtual server, so that the policy applies only to requests whose destination is the VIP address of that virtual server.

When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

## To bind a compression policy by using the command line interface

At the command prompt, enter one of the following commands to bind a compression policy globally or to a specific virtual server:

- `bind cmp global <policyName> [-priority <positive_integer>] [-state (ENABLED | DISABLED)]..`
- `bind lb vserver <vserverName> -policyName <policyName> -priority <positive_integer>`. Repeat this command for each virtual server to which you want to bind the compression policy.

## To bind a compression policy by using the configuration utility

Do one of the following:

- At global level Navigate to **Optimization > HTTP Compression > Policies**, click **Policy Manager** and bind the required policies by specifying the relevant **Bind Point** and **Connection Type** (Request/Response).
- At virtual server level
  - For load balancing virtual server, Navigate to **Traffic Management > Load Balancing > Virtual Servers**, select the required virtual server, click **Policies**, and bind the relevant policy.
  - For content switching **virtual server**, Navigate to **Traffic Management > Content Switching > Virtual Servers**, select the required virtual server, click **Policies**, and bind the relevant policy.

### Setting the Global Compression Parameters for Optimal Performance

Many users accept the default values for the global compression parameters, but you might be able provide more effective compression by customizing these settings.

The following table describes the compression parameters that you can set on the NetScaler ADC.

| <b>Compression Parameters</b>          | <b>Description</b>                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Quantum size</b>                    | Size, in KB, of the buffer maintained for accumulating server responses. The responses are compressed when the buffer size exceeds this value. For example, if you set the quantum size to 50 KB, the NetScaler ADC compresses the buffer's contents when its size becomes larger than 50 KB. Minimum value: 1. Maximum value: 63488. Default: 57344. |
| <b>Compression level</b>               | Level of compression to apply to server responses. Possible values: Best Speed, Best Compression, optimal.                                                                                                                                                                                                                                            |
| <b>Minimum HTTP response size</b>      | Minimum size, in bytes, of an HTTP response that is compressed. Responses smaller than the value specified by this parameter are sent without being compressed.                                                                                                                                                                                       |
| <b>Bypass compression on CPU usage</b> | NetScaler CPU usage, as a percentage, at or above which no compression is done. Default: 100.                                                                                                                                                                                                                                                         |
| <b>Policy Type*</b>                    | Type of policies used for compression. Possible values: Classic, Default Syntax. Default: Classic.                                                                                                                                                                                                                                                    |
| <b>Allow Server-side compression</b>   | Allow servers to send compressed data to the NetScaler ADC.                                                                                                                                                                                                                                                                                           |
| <b>Compress push packet</b>            | Upon receipt of a packet with a TCP PUSH flag, compress the accumulated packets immediately, without waiting for the quantum buffer to be filled.                                                                                                                                                                                                     |
| <b>External Cache</b>                  | Issue a private response directive indicating that the response message is intended for a single user and must not be cached by a shared or proxy cache.                                                                                                                                                                                              |

## To configure global compression parameters by using the command line interface

At the command prompt, enter the following command to configure compression parameters that apply globally:

```
set cmp parameter -cmpLevel <cmpLevel> -quantumSize <integer> [-addVaryHeader (ENABLED | DISABLED)][-varyHeaderValue <string>]..
```

Note: Vary header parameters are available from NetScaler 10.5 onwards.

## To configure global compression parameters by using the configuration utility

Navigate to **Optimization > HTTP Compression** , click **Change Compression Settings** , and set the relevant parameters.

# Evaluating Your Compression Configuration

Apr 20, 2015

You can view the compression statistics in the dashboard utility or in an SNMP monitor. The dashboard utility displays summary and detailed statistics in a tabular and graphic format.

Optionally, you can also view statistics for a compression policy, including the number of hits that the policy counter increments during the policy based compression.

Note:

- For more information about the statistics and charts, see the Dashboard help on the Citrix NetScaler appliance.
- For more information about SNMP, see [SNMP](#).

## To View Compression Statistics by Using the Command Line Interface

At the command prompt, enter the following commands to display the compression statistics:

1. To display compression statistics summary

```
stat cmp
```

Note: The stat cmp policy command displays statistics for default syntax compression policies only.

2. To display compression policy hits and details

```
show cmp policy <name>
```

3. To display detailed compression statistics

```
stat cmp -detail
```

## To View Compression Statistics by Using the Dashboard

In the Dashboard utility, you can display the following types of compression statistics:

- Select Compression to display a summary of the compression statistics.
- To display detailed compression statistics by protocol type, click the Details
- To display the rate of requests processed by the compression feature, click the Graphical View tab.

## To View Compression Statistics by Using SNMP

You can view the following compression statistics by using the SNMP network management application.

- Number of compression requests (OID: 1.3.6.1.4.1.5951.4.1.1.50.1)
- Number of compressed bytes transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.2)
- Number of compressible bytes received (OID: 1.3.6.1.4.1.5951.4.1.1.50.3)
- Number of compressible packets transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.4)
- Number of compressible packets received (OID: 1.3.6.1.4.1.5951.4.1.1.50.5)
- Ratio of compressible data received and compressed data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.6)
- Ratio of total data received to total data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.7)

## To View Additional Compression Statistics by Using the Configuration Utility

1. To display HTTP compression statistics:

Navigate to Optimization > HTTP Compression and click Statistics.

2. To display statistics of a compression policy

Navigate to Optimization > HTTP Compression > Policies> select the policy, and click Statistics.

3. To display statistics of a compression policy label

Navigate to Optimization > HTTP Compression > Policies> select a policy label, and click Statistics.

# Offloading HTTP Compression to the NetScaler ADC

Nov 04, 2015

Performing compression on a server can affect the server's performance. A NetScaler ADC placed in front of your web servers and configured for HTTP compression offloads compression of both static and dynamic content, saving server CPU cycles and resources.

You can offload compression from the Web servers in either of two ways:

- Disable compression on the web servers, enable the NetScaler Compression feature at a global level, and configure services for compression.
- Leave the compression feature enabled on the web servers and configure the NetScaler appliance to remove the "Accept Encoding" header from all HTTP client requests. The servers then send uncompressed responses. The NetScaler ADC compresses the server responses before sending them to the clients.

Note: The second option does not work if the servers automatically compress all responses. The NetScaler ADC does not attempt to compress a response that is already compressed.

The `Servercmp` parameter enables the Netscaler appliance to handle offload HTTP compression. By default, this parameter is set ON for the server to send compressed data to the Netscaler appliance. To offload HTTP compression, you need to set the `servercmp` parameter to OFF. At the command prompt, enter the following commands:

```
set service <service name> -CMP YES
```

Repeat this command for each service for which you want to enable compression.

```
show service <service name>
```

Repeat this command for each service, to verify that compression is enabled.

Save config

```
set cmp parameter -serverCmp OFF
```

# Integrated Caching

Aug 25, 2016

The integrated cache provides in-memory storage on the Citrix NetScaler appliance and serves Web content to users without requiring a round trip to an origin server. For static content, the integrated cache requires little initial setup. After you enable the integrated cache feature and perform basic setup (for example, determining the amount of NetScaler appliance memory the cache is permitted to use), the integrated cache uses built-in policies to store and serve specific types of static content, including simple Web pages and image files. You can also configure the integrated cache to store and serve dynamic content that is usually marked as non-cacheable by Web and application servers (for example, database records and stock quotes).

**Note:** The term Integrated Cache can be interchangeably used with AppCache; note that from a functionality point of view, both terms mean the same.

When a request or response matches the rule (logical expression) specified in a built-in policy or a policy that you have created, the NetScaler appliance performs the action associated with the policy. By default, all policies store cached objects in and retrieve them from the Default content group, but you can create your own content groups for different types of content.

To enable the NetScaler appliance to find cached objects in a content group, you can configure selectors, which match cached objects against expressions, or you can specify parameters for finding objects in the content group. If you use selectors (which Citrix recommends), configure them first, so that you can specify selectors when you configure content groups. Next, set up any content groups that you want to add, so that they are available when you configure the policies. To complete the initial configuration, create policy banks by binding each policy to a global bind point or a virtual server, or to a label that can be called from other policy banks.

You can tune the performance of the integrated cache, using methods such as pre-loading cached objects before they are scheduled to expire. To manage the handling of cached data once it leaves the NetScaler appliance, you can configure caching-related headers that are inserted into responses. The integrated cache can also act as a forward proxy for other cache servers.

Note: Integrated caching requires some familiarity with HTTP requests and responses. For information about the structure of HTTP data, see *Live HTTP Headers* at "<http://livehttpheaders.mozdev.org/>."

# How the Integrated Cache Works

Sep 04, 2015

The integrated cache monitors HTTP and SQL requests that flow through the Citrix NetScaler appliance and compares the requests with stored policies. Depending on the outcome, the integrated cache feature either searches the cache for the response or forwards the request to the origin server. For HTTP requests, the integrated cache feature can also serve partial content from the cache in response to single byte-range and multi-part byte-range requests.

Cached data can be compressed if the client accepts compressed content. You can configure expiration times for a content group, and you can selectively expire entries in a content group.

Data that is served from the integrated cache is a cache hit, and data served from the origin is a cache miss, as described in the following table.

**Table 1. Cache Hits and Misses**

| <b>Transaction Type</b> | <b>Specifies</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cache Hit               | <p>Responses that the NetScaler appliance serves from the cache, including:</p> <ul style="list-style-type: none"><li>• Static objects, for example, image files and static Web pages</li><li>• 200 OK pages</li><li>• 203 Non-Authoritative Response pages</li><li>• 300 Multiple Choices pages</li><li>• 301 Moved Permanently pages</li><li>• 302 Found pages</li><li>• 304 Not Modified pages</li></ul> <p>These responses are known as positive responses.</p> <p>The NetScaler appliance also caches the following negative responses:</p> <ul style="list-style-type: none"><li>• 307 Temporary Redirect pages</li><li>• 403 Forbidden pages</li><li>• 404 Not Found pages</li><li>• 410 Gone pages</li></ul> <p>To further improve performance, you can configure the NetScaler appliance to cache additional types of content.</p> |
| Storable Cache Miss     | For a storable cache miss, the NetScaler appliance fetches the response from the origin server, and stores the response in the cache before serving it to the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Non-Storable Cache Miss | A non-storable cache miss is inappropriate for caching. By default, any response that contains the following status codes is a non-storable cache miss:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                         |                                                                                                                                                                                     |

|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Note: To integrate dynamic caching with your application infrastructure, use the NITRO API to issue cache commands remotely. For example, you can configure triggers that expire cached responses when a database table is updated. To ensure the synchronization of cached responses with the data on the origin server, you configure expiration methods. When the NetScaler appliance receives a request that matches an expired response, it refreshes the response from the origin server.

Note: Citrix recommends that you synchronize the times on the NetScaler appliance and the back-end server(s).

# Example of Dynamic Caching

Sep 11, 2014

Dynamic caching evaluates HTTP requests and responses based on parameter-value pairs, strings, string patterns, or other data. For example, suppose that a user searches for Bug 31231 in a bug reporting application. The browser sends the following request on the user's behalf:

```
GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&Template=view&TableId=1000
Host: mycompany.net
User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9) Gecko/2008052906 Firefox/3.0
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8
Accept-Language: en-us,en;q=0.5
```

...  
In this example, GET requests for this bug reporting application always contain the following parameters:

- IssuePage
- RecordID
- Template
- TableId

GET requests do not update or alter the data, so you can configure these parameters in caching policies and selectors, as follows:

- You configure a caching policy that looks for the string mybugreportingsystem and the GET method in HTTP requests. This policy directs matching requests to a content group for bugs.
- In the content group for bugs, you configure a hit selector that matches various parameter-value pairs, including IssuePage, RecordID, and so on.

Note that a browser can send multiple GET requests based on one user action. The following is a series of three separate GET requests that a browser issues when a user searches for a bug based on a bug ID.

```
GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&Template=view&TableId=1000
GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=viewbtns&RecordId=31231&TableId=1000
GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=viewbody&RecordId=31231&tableid=1000
```

To fulfill these requests, multiple responses are sent to the user's browser, and the Web page that the user sees is an assembly of the responses.

If a user updates a bug report, the corresponding responses in the cache should be refreshed with data from the origin server. The bug reporting application issues HTTP POST requests when a user updates a bug report. In this example, you configure the following to ensure that POST requests trigger invalidation in the cache:

- A request-time invalidation policy that looks for the string mybugreportingsystem and the POST HTTP request method, and directs matching requests to the content group for bug reports.
- An invalidation selector for the content group for bug reports that expires cached content based on the RecordID parameter. This parameter appears in all of the responses, so the invalidation selector can expire all relevant items in the cache.

The following excerpt shows a POST request that updates the sample bug report.

```
POST /mybugreportingsystem/mybugreport.dll?TransitionForm HTTP/1.1\r\n
User-Agent: Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.0) Opera 7.23 [en]\r\n
Host: mybugreportingsystem\r\n
Cookie:ttSearch.134=%23options%3Afalse%23active%23owner%3Afalse%23unowned%3Afalse%23submitter%3Afalse%23incsub%3Atrue;
Cookie2: $Version=1\r\n
...
\r\n
ProjectId=2&RecordId=31231&TableId=1000&TransitionId=1&Action=Update&CopyProjectId=0&ReloadForm=0&State=&RecordLockId=49873+issues+in+HTTP&F43...
```

When the Citrix NetScaler appliance receives this request, it does the following:

- Matches the request with an invalidation policy.
- Finds the content group that is named in the policy.
- Applies the invalidation selector for this content group and expires all responses that match RecordID=31231.

When a user issues a new request for this bug report, the NetScaler appliance goes to the origin server for updated copies of all the responses that are associated with the report instance, stores the responses in the content group, and serves them to the user's browser, which reassembles the report and displays it.

# Setting Up the Integrated Cache

Oct 13, 2016

To use the integrated cache, you must install the license and enable the feature. After you enable the integrated cache, the Citrix® NetScaler® appliance automatically caches static objects as specified by built-in policies and generates statistics on cache behavior. (Built-in policies have an underscore in the initial position of the policy name.)

Even if the built-in policies are adequate for your situation, you might want to modify the global attributes. For example, you might want to modify the amount of NetScaler appliance memory allocated to the integrated cache.

If you would like to observe cache operation before changing settings, see "[Displaying Cached Objects and Cache Statistics](#)."

Note: The NetScaler cache is an in-memory store that is purged when you restart the appliance.

This section includes the following details:

- [Installing the Integrated Cache License](#)
- [Enabling Integrated Caching](#)
- [Configuring Global Attributes for Caching](#)
- [Built-in Content Group, Pattern Set, and Policies for the Integrated Cache](#)

Updated: 2013-10-28

An integrated cache license is required. For information about licenses, see information about obtaining NetScaler licenses at "<http://support.citrix.com/article/ctx121062>."

## To install the license for the Integrated Caching feature

1. Obtain a license code from Citrix, go to the command line interface, and log in.
2. At the command line interface, copy the license file to the /nsconfig/license folder.
3. Reboot the NetScaler appliance by using the following command:

```
reboot
```

Updated: 2015-05-20

When you enable integrated caching, the NetScaler appliance begins caching server responses. If you have not configured any policies or content groups, the built in policies store cached objects in the Default content group.

## To enable integrated caching by using the command line interface

At the command prompt, type one of the following commands to enable or disable integrated caching:

```
enable ns feature IC
```

## To enable integrated caching by using the configuration utility

Navigate to System > Settings, click Configure Basic Features, and select Integrated Caching.

Updated: 2014-08-08

Global attributes apply to all cached data. You can specify the amount of NetScaler memory allocated to the integrated cache. Via header insertion, a criterion for verifying that a cached object should be served, the maximum length of a POST body permitted in the cache, whether to bypass policy evaluation for HTTP GET requests, and an action to take when a policy cannot be evaluated.

The cache memory capacity is limited only by the memory of the hardware appliance. Also, any packet engine (the central distribution hub of all incoming TCP requests) in the nCore NetScaler appliance is aware of objects cached by other packet engines in the nCore NetScaler appliance.

Note that the default global memory limit is 0. Therefore, even if Integrated Caching is enabled, the NetScaler appliance does not cache any objects. You must explicitly set the global memory limit when integrated caching is enabled.

You can modify the global memory limit configured for caching objects. However, when you update the global memory limit to a value lower than the existing value (for example, from 10 GB to 4 GB), if a higher amount of memory (greater than 4 GB) is already being used to cache objects, the NetScaler continues using that amount of memory.

This means that even though the integrated caching limit is configured to some value, the actual limit used can be higher. This excessive memory is however released when the objects are removed from cache.

The output of the show cache parameter command indicates the configured value (Memory Usage limit) and the actual value being used (Memory usage limit (active value)).

## To configure global settings for caching by using the command line interface

At the command prompt, type:

```
set cache parameter [-memLimit <MBytes>] [-via <string>] [-verifyUsing <criteria>] [-maxPostLen <positiveInteger>] [-prefetchMaxPending <positiveInteger>] [-enableBypass (YES | NO)] [-undefAction (NOCACHE | RESET)]
```

## To configure global settings for caching by using the configuration utility

Navigate to Optimization > Integrated Caching, click Change Cache Settings, and configure the global settings for caching.

Updated: 2013-08-23

The Citrix NetScaler appliance includes a built-in integrated caching configuration that you can use for caching content. The configuration consists of a content group called ctx\_cg\_poc, a pattern set called ctx\_file\_extensions, and a set of integrated cache policies. In the content group ctx\_cg\_poc, only objects that are 500 KB or smaller are cached. The content is cached for 86000 seconds, and the memory limit for the content group is 512 MB. The pattern set is an indexed array of common file extensions for file-type matching.

The following table lists the built-in integrated caching policies. By default, the policies are not bound to any bind point. You must bind them to a bind point if you want the NetScaler appliance to evaluate traffic against the policies. The policies cache objects in the ctx\_cg\_poc content group.

| Integrated caching policy name | Policy rule                                                                                   | Policy action |
|--------------------------------|-----------------------------------------------------------------------------------------------|---------------|
| ctx_images                     | HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).CONTAINS_INDEX("ctx_file_extensions").BETWEEN(101,150) | CACHE         |
| ctx_web_css                    | HTTP.REQ.URL.ENDSWITH(".css")                                                                 | CACHE         |
| ctx_doc_pdf                    | HTTP.REQ.URL.ENDSWITH(".pdf")                                                                 | CACHE         |
| ctx_web_JavaScript             | HTTP.REQ.URL.ENDSWITH(".js")                                                                  | CACHE         |
| ctx_web_JavaScript-Res         | HTTP.RES.HEADER("Content-Type").CONTAINS("application/x-javascript")                          | CACHE         |
| ctx_NOCACHE_Cleanup            | TRUE                                                                                          | NOCACHE       |
| ctx_nonGetReq -rule            | HTTP.REQ.METHOD.eq(GET)                                                                       | NOCACHE       |

|                                 |                                                                                                                                                                                                                    |             |

# Configuring Selectors and Basic Content Groups

Aug 26, 2013

You can configure selectors and apply them to content groups. When you add a selector to one or more content groups, you specify whether the selector is to be used for identifying cache hits or identifying cached objects to be invalidated (expired). Selectors are optional. Alternatively, you can configure content groups to use hit parameters and invalidation parameters. However, Citrix recommends that you configure selectors.

After configuring selectors, or deciding to use parameters instead, you are ready to set up a basic content group. After creating the basic content group, you need to decide how objects should be expired from the cache, and configure cache expiration. You can further modify the cache as described in "[Improving Cache Performance](#)" and "[Configuring Cookies, Headers, and Polling](#)", but you might first want to configure caching policies.

Note: Content group parameters and selectors are used only at request time, and you typically associate them with policies that use MAY\_CACHE or MAY\_NOCACHE actions.

# Advantages of Selectors

Oct 28, 2013

A selector is a filter that locates particular objects in a content group. If you do not configure a selector, the Citrix® NetScaler® appliance looks for an exact match in the content group. This can lead to multiple copies of the same object residing in a content group. For example, a content group that does not have a selector may need to store URLs for `host1.domain.com\mypage.htm`, `host2.domain.com\mypage.htm`, and `host3.domain.com\mypage.htm`. In contrast, a selector can match just the URL (`mypage.html`, using the expression `http.req.url`) and the domain (`.com`, using the expression `http.req.hostname.domain`), allowing the requests to be satisfied by the same URL.

Selector expressions can perform simple matching of parameters (for example, to find objects that match a few query string parameters and their values). A selector expression can use Boolean logic, arithmetic operations, and combinations of attributes to identify objects (for example, segments of a URL stem, a query string, a string in a POST request body, a string in an HTTP header, a cookie). Selectors can also perform programmatic functions to analyze information in a request. For example, a selector can extract text in a POST body, convert the text into a list, and extract a specific item from the list.

For more information about expressions and what you can specify in an expression, see "[Policies and Expressions](#)."

# Using Parameters Instead of Selectors

Jul 10, 2013

Although Citrix recommends the use of selectors with a content group, you can instead configure hit parameters and invalidation parameters. For example, suppose that you configure three hit parameters in a content group for bug reports: BugID, Issuer, and Assignee. If a request contains BugID=456, with Issuer=RohitV and Assignee=Robert, the NetScaler appliance can serve responses that match these parameter-value pairs.

Invalidation parameters in a content group expire cached entries. For example, suppose that BugID is an invalidation parameter and a user issues a POST request to update a bug report. An invalidation policy directs the request to this content group, and the invalidation parameter for the content group expires all cached responses that match the BugID value. (The next time a user issues a GET request for this report, a caching policy can enable the NetScaler appliance to refresh the cached entry for the report from the origin server.)

Note that the same parameter can be used as a hit parameter or an invalidation parameter.

Content groups extract request parameters in the following order:

- URL query
- POST body
- Cookie header

After the first occurrence of a parameter, regardless of where it occurred in the request, all its subsequent occurrences are ignored. For example, if a parameter exists both in the URL query and in the POST body, only the one in the URL query is considered.

If you decide to use hit and invalidation parameters for a content group, configure the parameters when you configure the content group.

Note: Citrix recommends that you use selectors rather than parameterized content groups, because selectors are more flexible and can be adapted to more types of data.

# Configuring a Selector

Aug 07, 2014

A content group can use a hit selector to retrieve cache hits or use an invalidation selector to expired cached objects and fetch new ones from the origin server.

A selector contains a name and a logical expression, called an *advanced expression*.

For more information about advanced expressions, see "[Policies and Expressions](#)."

To configure a selector, you assign it a name and enter one or more expressions. As a best practice, a selector expression should include the URL stem and host, unless there is a strong reason to omit them.

At the command prompt, type:

```
add cache selector <selectorName> (<rule> ...)
```

For information about configuring the expression or expressions, see "[To configure a selector expression by using the command line interface](#)."

## Examples

```
>add cache selector product_selector "http.req.url.query.value(\"ProductId\")" "http.req.url.query.value(\"BatchNum\")" "http.req.url.query.value(\"depotLocation\")"
> add cache selector batch_selector "http.req.url.query.value(\"ProductId\")" "http.req.url.query.value(\"BatchId\")" "http.req.url.query.value(\"depotLocation\")"
> add cache selector product_id_selector "http.req.url.query.value(\"ProductId\")"
> add cache selector batchnum_selector "http.req.url.query.value(\"BatchNum\")" "http.req.url.query.value(\"depotLocation\")"
> add cache selector batchid_selector "http.req.url.query.value(\"depotLocation\")" "http.req.url.query.value(\"BatchId\")"
```

Navigate to Optimization > Integrated Caching > Cache Selectors, and add the cache selector.

# About Content Groups

Mar 16, 2012

A content group is a container for cached objects that can be served in a response. When you first enable the integrated cache, cacheable objects are stored in a content group named Default. You can create new content groups that have unique properties. For example, you can define separate content groups for image data, bug reports, and stock quotes, and you can configure the stock quote content group to be refreshed more often than the other groups.

You can configure expiration of an entire content group or selected entries in a content group.

The data in a content group can be static or dynamic, as follows:

- **Static content groups.** Finds an exact match between the URL stem and host name on the request and the URL stem and host name of the response.
- **Dynamic content groups.** Looks for objects that contains particular parameter-value pairs, arbitrary strings, or string patterns. Dynamic content groups are useful when caching data that is updated frequently (for example, a bug report or a stock quote).

1. A user enters search criteria for an item, such as a bug report, and clicks the Find button in an HTML form.
2. The browser issues one or more HTTP GET requests. These requests contain parameters (for example, the bug owner, bug ID, and so on).
3. When the NetScaler appliance receives the requests, it searches for a matching policy, and if it finds a caching policy that matches these requests, it directs the requests to a content group.
4. The content group looks for appropriate objects in the content group, usually based on criteria that you configure in a selector.

For example, the content group can retrieve responses that match NameField=username and BugID=ID.

5. If it finds matching objects, the NetScaler appliance can serve them to the user's browser, where they are assembled into a complete response (for example, a bug report).

1. A user modifies data (for example, the user modifies the bug report and clicks the Submit button).
2. The browser sends this data in the form of one or more HTTP requests. For example, it can send a bug report in the form of several HTTP POST requests that contain information about the bug owner and bug ID.
3. The NetScaler appliance matches the requests against invalidation policies. Typically, these policies are configured to detect the HTTP POST method.
4. If the request matches an invalidation policy, the NetScaler appliance searches the content group that is associated with this policy, and expires responses that match the configured criteria for invalidation.

For example, an invalidation selector can find responses that match NameField=username and BugID=ID.

5. The next time the NetScaler appliance receives a GET request for these responses, it fetches refreshed versions from the origin server, caches the refreshed responses, and serves these responses to the user's browser, where they are assembled into a complete bug report.

# Setting Up a Basic Content Group

Aug 07, 2014

By default, all cached data is stored in the default content group. You can configure additional content groups and specify these content groups in one or more policies.

You can configure content groups for static content, and you must configure content groups for dynamic content. You can modify the configuration of any content group, including the default group.

At the command prompt, type:

```
add cache contentgroup <name> (-hitSelector <hitSelectorName> -invalSelector <invalidationSelectorName> | -hitParams <hitParamName> -invalParams <invalidationParamName>) -type <type> [-relExpiry <sec> | -relExpiryMilliSec <msec>] [-heurExpiryParam <positiveInteger>]
```

## Examples

```
> add cache contentgroup Products_Details -hitSelector product_selector -invalSelector id_selector
```

```
> add cache contentgroup bugrep -hitParams IssuePage RecordID Template TableId -invalParams RecordID -relExpiry 864000
```

Navigate to Optimization > Integrated Caching > Content Groups, and create the content group.

# Expiring or Flushing Cached Objects

Oct 28, 2013

If a response does not have an Expires header or a Cache-Control header with an expiration time (Max-Age or Smax-Age), you must expire objects in a content group by using one of the following methods:

- Configure content group expiration settings to determine whether and how long to keep the object.
- Configure an invalidation policy and action for the content group. For more information, see "[Configuring Policies for Caching and Invalidation](#)."
- Expire the content group or objects within it manually.

After a cached response expires, the NetScaler appliance refreshes it the next time the client issues a request for the response. By default, when the cache is full, the NetScaler appliance replaces the least recently used response first.

The following list describes methods for expiring cached responses using settings for a content group. Typically, these methods are specified as a percent or in seconds:

- **Manual.** Manually invalidate all responses in a content group or all responses in the cache.
- **Response-based.** Specific expiration intervals for positive and negative responses. Response-based expiry is considered only if the Last-Modified header is missing in the response.
- **Heuristic expiry.** For responses that have a Last-Modified header, heuristic expiry is a percentage of the time since the response was modified (calculated as current time minus the Last-Modified time, multiplied by the heuristic expiry value). For example, if a Last-Modified header indicates that a response was updated 2 hours ago, and the heuristic expiry setting is 10%, cached objects expire after 0.2 hours. This method assumes that frequently updated responses need to be expired more often.
- **Absolute or relative.** Specify an exact (absolute) time when the response expires every day, in HH:MM format, local time or GMT. Local time may not work in all time zones.  
Relative expiration specifies a number of seconds or milliseconds from the time a cache miss causes a trip to the origin server to the expiration of the response. If you specify relative expiration in milliseconds, enter a multiple of 10. This form of expiration works for all positive responses. Last-Modified, Expires, and Cache-Control headers in the response are ignored.

Absolute and relative expiration override any expiration information in the response itself.

- **On download.** The option Expire After Complete Response Received expires a response as soon as it is downloaded. This is useful for frequently updated responses, for example, stock quotes. By default, this option is disabled. Enabling both Flash Cache and Expire After Complete Response Received accelerates the performance of dynamic applications. When you enable both options, the NetScaler appliance fetches only one response for a block of simultaneous requests.

For more information, see "[Queuing Requests to the Cache](#)."

- **Pinned.** By default, when the cache is full the NetScaler appliance replaces the least recently used response first. The NetScaler appliance does not apply this behavior to content groups that are marked as pinned.

If you do not configure expiration settings for a content group, the following are additional options for expiring objects in the group:

- Configure a policy with an INVALID action that applies to the content group.

- Enter the names of content groups when configuring a policy that uses an INVALID action.

Expiration works differently for positive and negative responses. Positive and negative responses are described in the table, *Expiration of Positive and Negative Responses* mentioned below.

The following are rules of thumb for understanding the expiration method that is applied to a content group:

- You can control whether the NetScaler appliance evaluates response headers when deciding whether to expire an object.
- Absolute and relative expiration cause the NetScaler appliance to ignore the response headers (they override any expiration information in the response).
- Heuristic expiration settings and “Weak Positive” and “Weak Negative” expiration (labeled as **Default** values in the configuration utility) cause the NetScaler appliance to examine the response headers. These settings work together as follows:
  - The value in an Expires or Cache-Control header overrides these content group settings.
  - For positive responses that lack an Expires or Cache-Control header but have a Last-Modified header, the NetScaler appliance compares heuristic expiration settings with the header value.
  - For positive responses that lack an Expires, Cache-Control, or Last-Modified header, NetScaler appliance uses the “weak positive” value.
  - For negative responses that lack an Expires or Cache-Control header, NetScaler appliance uses the “weak negative” value.

For a list of expiration parameters see, "[Configuring Periodic Expiration of a Content Group](#)." The following table describes how these methods are applied.

**Table 1. Expiration of Positive and Negative Responses**

| Response Type | Expiration Header Type                 | Content Group Setting                                              | Period the Object Remains in the Cache                                                                                                           |
|---------------|----------------------------------------|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Positive      | any header                             | Expire Content After (relExpiry) with no other settings            | Use the value of the Expire Content After setting.                                                                                               |
| Positive      | any header                             | Expire Content At (absExpiry) with no other settings               | Subtract current date from the value of the Expire Content At setting.                                                                           |
| Positive      | any header                             | Expire Content After (relExpiry) and Expire content at (absExpiry) | Use the smaller of the two values for the content group settings. See the previous rows in this table.                                           |
| Positive      | Last-Modified (with any other headers) | Heuristic (heurExpiry Param) with any other setting                | Subtract the Last-Modified date from the current date, multiply the result by the value of the heuristic expiry setting, and then divide by 100. |

| Response Type | Expiration Header and Type (with any other headers)                                       | Content Group Setting Default (positive) (weakPosRel Expiry) and no other setting                       | Period the Object Remains in the Cache Use the value of the Default (positive) expiry setting.                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Positive      | Expires or Cache-Control: Max-Age header is present<br><br>Last-Modified header is absent | Heuristic (heurExpiry Param), Default (positive) (weakPosRel Expiry), or both                           | Subtract the current date from the Expires or the Cache-Control:Max-Age date.                                                                                                                    |
| Positive      | no caching headers                                                                        | Default (positive) (weakPosRel Expiry) and any other expiration setting.                                | Use the value of the Default (positive) setting.                                                                                                                                                 |
| Positive      | no caching headers                                                                        | Heuristic (heurExpiry Param) is present<br><br>Default (positive) (weakPosRel Expiry) setting is absent | If the Last-Modified header is absent, the response is not cached or it is cached with an Already Expired status.<br><br>If the Last-Modified header is present, use the heuristic expiry value. |
| Negative      | Expires or Cache-Control:Max-Age                                                          | Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings                       | Subtract the current date from the value of the Expires header, or use the value of the Cache-Control:Max-Age header.                                                                            |
| Negative      | Expires or Cache-Control headers are absent                                               | Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings                       | Response is not cached, or is cached with an Already Expired status.                                                                                                                             |
| Negative      | Expires or Cache-Control:Max-Age                                                          | Any setting                                                                                             | Subtract the current date from the Expires or Cache-Control:Max-Age date.                                                                                                                        |
| Negative      | Expires and Cache-Control:Max-Age headers are absent                                      | Default (negative) (weakNegRel Expiry)                                                                  | Use the value of the Default (negative) setting.                                                                                                                                                 |
| Negative      | Expires and Cache-Control:Max-Age                                                         | Any setting other than Default (negative)                                                               | Object is not cached or is cached with an Already Expired status.                                                                                                                                |

|                      |                                         |                                                     |                                               |

# Expiring a Content Group Manually

Aug 04, 2014

You can manually expire all of the entries in a content group.

At the command prompt, type:

```
expire cache contentGroup <name>
```

## To manually expire all responses in a content group by using the configuration utility

Navigate to Optimization > Integrated Caching > Content Groups, select the content group, and click Invalidate to expire all the responses in a content group.

Navigate to Optimization > Integrated Caching > Content Groups, and click Invalidate All to expire all the responses in cache.

# Configuring Periodic Expiration of a Content Group

Aug 08, 2014

You can configure a content group so that it performs selective or full expiration of its entries. The expiration interval can be fixed or relative.

At the command prompt, type:

```
set cache contentgroup <name> (-relExpiry | -relExpiryMilliSec | -absExpiry | -absExpiryGMT | -heurExpiryParam | -weakPosRelExpiry | -weakNegRelExpiry | -expireAtLastBye) <expirationValue>
```

Navigate to Optimization > Integrated Caching > Content Groups, select the content group, and specify expiry method.

Expiring a response forces the NetScaler appliance to fetch a refreshed copy from the origin server. Responses that do not have validators, for example, ETag or Last-Modified headers, cannot be revalidated. As a result, flushing these responses has the same effect as expiring them.

To expire a cached response in a content group for static data, you can specify a URL that must match the stored URL. If the cached response is part of a parameterized content group, you must specify the group name as well as the exact URL stem. The host name and the port number must be the same as in the host HTTP request header of the cached response. If the port is not specified, port 80 is assumed.

## To expire individual responses in a content group by using the command line interface

At the command prompt, type:

```
expire cache object -url <URL> -host <hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET | POST]
```

## To expire individual responses in a content group by using the command line interface (selector-based)

At the command prompt, type the following command:

```
expire cache object -locator <positiveInteger>
```

## To expire a cached response by using the configuration utility

Navigate to Optimization > Integrated Caching > Cached Objects, select the cached response, and expire.

## To expire a response by using the Lookup tool (selector-based)

Navigate to Optimization > Integrated Caching > Cached Objects, click Search and, set the search criteria to find the required cached response and expire.

You can remove, or flush, all responses in a content group, some responses in a group, or all responses in the cache. Flushing

a cached response frees up memory for new cached responses.

Note: To flush responses for more than one object at a time, use the configuration utility method. The command line interface does not offer this option.

## To flush responses from a content group by using the command line interface

At the command prompt, type:

```
flush cache contentGroup <name> [-query <queryString> | [-selectorValue <selectorExpressionIDList> -host <hostName>]]
```

## To flush responses from a content group by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups.
2. In details pane, flush the responses as follows:
  - To flush all responses in all content groups, click Invalidate All, and flush all the responses.
  - To flush responses in a particular content group, select the content group, click Invalidate, and flush all the responses.

Note: If this content group uses a selector, you can selectively flush responses by entering a string in the Selector value text box, entering a host name in the Host text box. Then click Flush and OK. The Selector value can be a query string of up to 2319 characters that is used for parameterized invalidation.

If the content group uses an invalidation parameter, you can selectively flush responses by entering a string in the Query field.

If the content group uses an invalidation parameter and Invalidate objects belonging to target host is configured, enter strings in the Query and Host fields.

## To flush a cached response by using the command line interface

At the command prompt, type:

```
flush cache object -locator <positiveInteger> | -url <URL> -host <hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET | POST]
```

## To flush a cached response by using the configuration utility

Navigate to Optimization > Integrated Caching > Cached Objects, select the cached object, and flush.

You can remove a content group if it is not used by any policy that stores responses in the cache. If the content group is bound to a policy, you must first remove the policy. Removing the content group removes all responses stored in that group.

You cannot remove the Default, BASEFILE, or Deltajs group. The Default group stores cached responses that do not belong in any other content group.

## To delete a content group by using the command line interface

At the command prompt, type:

```
rm cache contentgroup<name>
```

## To delete a content group by using the configuration utility

Navigate to Optimization > Integrated Caching > Content Groups, select the content group, and delete.

# Configuring Policies for Caching and Invalidation

Aug 30, 2013

Policies enable the integrated cache to determine whether to try to serve a response from the cache or the origin. The Citrix NetScaler appliance provides built-in policies for integrated caching, and you can configure additional policies. When you configure a policy, you associate it with an action. An action either caches the objects to which the policy applies or invalidates (expires) the objects. Typically, you based caching policies on information in GET and POST requests. You typically base invalidation policies on the presence of the POST method in requests, along with other information. You can use any information in a GET or POST request in a caching or an invalidation policy.

You can view some of the built-in policies in the integrated cache's Policies node in the configuration utility. The built-in policy names begin with an underscore (\_).

Actions determine what the NetScaler appliance does when traffic matches a policy. The following actions are available:

- **Caching actions.** Policies that you associate with the CACHE action store responses in the cache and serve them from the cache.
- **Invalidation actions.** Policies that you associate with the INVALID action immediately expire cached responses and refresh them from the origin server. Note that for Web-based applications, invalidation policies often evaluate POST requests.
- **“Do not cache” actions.** Policies that you associate with a NOCACHE action never store objects in the cache.
- **“Provisionally cache” actions.** Policies that you associate with a MAYCACHE or MAYNOCACHE action depend on the outcome of additional policy evaluations.

Although the integrated cache does not store objects specified by the LOCK method, you can invalidate cached objects upon receipt of a LOCK request. For invalidation policies only, you can specify LOCK as a method by using the expression `http.req.method.eq("lock")`. Unlike policies for GET and POST requests, you must enclose the LOCK method in quotes because the NetScaler appliance recognizes this method name as a string only.

After you create a policy, you bind it to a particular point in the overall processing of requests and responses. Although you create a policy before binding it, you should understand how the bind points affect the order of processing before you create your policies.

The policies bound to a particular bind point constitute a policy bank. You can use goto expressions to modify the order of execution in a policy bank. You can also invoke policies in other policy banks. In addition, you can create labels and bind policies to them. Such a label is not associated with a processing point, but the policies bound to it can be invoked from other policy banks.

# Actions to Associate with Integrated Caching Policies

Mar 16, 2012

The following table describes actions for integrated caching policies.

**Table 1. Actions That You Can Associate with an Integrated Caching Policy**

| Action      | Specifies                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CACHE       | <p>Serves a response from the cache if the response has not expired. If the response must be fetched from the origin server, the NetScaler appliance caches the response before serving it.</p> <p>Even data that is updated and accessed frequently can be cached. For example, stock quotes are updated frequently, but they can be cached so that they can be served quickly to multiple users. If necessary, cached data can be refreshed immediately after it is downloaded.</p> <p>A CACHE action can be overridden by built-in policies.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| NOCACHE     | <p>Always fetches the response from the origin server and marks the response as non-storable.</p> <p>You typically configure NOCACHE policies for data that is sensitive or personalized.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| MAY_CACHE   | <p>Used in a request-time policy, this setting provisionally enables a response to be stored in a content group, pending evaluation of response-time policies. The following are possible:</p> <ul style="list-style-type: none"> <li>• If a matching response-time policy has a CACHE action but does not specify a content group, the response is stored in the Default group unless built-in policies override this policy.</li> <li>• If a matching response-time policy has a CACHE action and specifies the same content group as the one in the request-time policy, the response is stored in the named content group unless built-in policies override this policy.</li> <li>• If a matching response-time policy has a CACHE action but specifies a different content group from the one in the request-time policy, a NOCACHE action is applied.</li> <li>• If a matching response-time policy has a NOCACHE action, perform a NOCACHE action.</li> <li>• If there is no matching response-time policy, a CACHE action is applied, unless a built-in policy overrides this policy.</li> </ul> |
| MAY_NOCACHE | <p>For a request-time policy, this setting provisionally prevents caching the response. At response time, one of following actions is taken:</p> <ul style="list-style-type: none"> <li>• If no response-time policy matches the request, the final action is NOCACHE.</li> <li>• If a matching response-time policy contains a CACHE action, the final action is CACHE, unless built-in policies override this policy.</li> <li>• If a matching response-time policy contains a NOCACHE action, the final action is NOCACHE.</li> <li>• If a matching response-time policy has a CACHE action but does not specify a content group, the final action is to CACHE the response in the Default content group, unless built-in policies override this policy.</li> </ul>                                                                                                                                                                                                                                                                                                                                   |

| Action  | Specifies                                                                                                                                                                                                                                                                                                                                               |

| INVALID | <p data-bbox="331 219 1469 331">Expires cached responses. Depending on how the policy and the content group are configured, all responses in one or more content groups are expired, or selected objects in the content group are expired.</p> <p data-bbox="331 360 1091 394">Note: You can specify INVALID actions in request-time policies only.</p> |

# Bind Points for a Policy

Oct 28, 2013

You can bind the policy to one of the following bind points:

- **A global policy bank.** These are the request-time default, request-time override, response-time default, and response-time override policy banks, as described in "[Order of Policy Evaluation](#)."
- **A virtual server.** Policies that you bind to a virtual server are processed after the global override policies and before the global default policies, as described in "[Order of Policy Evaluation](#)." Note that when binding a policy to a virtual server, you bind it to either request-time or response-time processing.
- **An ad-hoc policy label.** A policy label is a name assigned to a policy bank. In addition to the global labels, the integrated cache has two built-in custom policy labels:
  - **\_reqBuiltInDefaults.** This policy label, by default, is invoked from the request-time default policy bank.
  - **\_resBuiltInDefaults.** This policy label, by default, is invoked from the response-time default policy bank.You can also define new policy labels. Policies bound to a user-defined policy label must be invoked from within a policy bank for one of the built-in bind points. For more information about creating a policy label, see "[Configuring a Policy Label in the Integrated Cache](#)." For more information about policy label invocation, see "[Configuring a Policy Bank for Caching](#)."

Important: You should bind a policy with an INVALID action to a request-time override or a response-time override bind point. To delete a policy, you must first unbind it.

For an advanced policy to take effect, you must ensure that the policy is invoked at some point during the NetScaler appliance's processing of traffic. To specify the invocation time, you associate the policy with a bind point. The following are the bind points, listed in order of evaluation:

- **Request-time override.** If a request matches a request-time override policy, by default request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Request-time load balancing virtual server.** If policy evaluation cannot be completed after all the request-time override policies are evaluated, the NetScaler appliance processes request-time policies that are bound to load balancing virtual servers. If the request matches one of these policies, evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Request-time content switching virtual server.** Policies that are bound to this bind point are evaluated after request-time policies that are bound to load balancing virtual servers.
- **Request-time default.** If policy evaluation cannot be completed after all request-time, virtual server-specific policies are evaluated, the NetScaler appliance processes request-time default policies. If the request matches a request-time default policy, by default request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Response-time override.** Similar to request-time override policy evaluation.
- **Response-time load balancing virtual server.** Similar to request-time virtual server policy evaluation.
- **Response-time content switching virtual server.** Similar to request-time virtual server policy evaluation.
- **Response-time default.** Similar to request-time default policy evaluation.

You can associate multiple policies with each bind point. To control the order of evaluation of the policies associated with the bind point you configure a priority level. In the absence of any other flow control information, policies are evaluated according to priority level, starting with the lowest numeric priority value.

After all integrated caching policies have been evaluated, if there are conflicting actions specified in request-time and response-time policies, the NetScaler appliance determines the final action as specified in the table, "[Actions That You Can Associate with an Integrated Caching Policy](#)."

Note: Request-time policies for POST data or cookie headers must be invoked during request-time override evaluation, because the built-in request-time policies in the integrated cache return a NOCACHE action for POST requests and a MAY\_NOCACHE action for requests with cookies. Note that you would associate MAY\_CACHE or MAY\_NOCACHE actions with a request-time policy that points to a parameterized content group. The response time policy determines whether the transaction is stored in the cache.

# Configuring a Policy in the Integrated Cache

Aug 07, 2014

You configure new policies to handle data that the built-in policies cannot process. You configure separate policies for caching, preventing caching from occurring, and for invalidating cached data. Following are the main components of a policy for integrated caching:

- Rule: A logical expression that evaluates an HTTP request or response.
- Action: You associate a policy with an action to determine what to do with a request or response that matches the policy rule.
- Content groups: You associate the policy with one or more content groups to identify where the action is to be performed.

At the command prompt, type:

```
add cache policy <policyName> -rule <expression> -action CACHE|MAY_CACHE|NOCACHE|MAY_NOCACHE [-storeInGroup <contentGroupName>] [-undefAction NOCACHE|RESET]
```

## Examples

```
> add cache policy image_cache -rule "http.req.url.contains(".jpg") || http.req.url.contains(".jpeg")" -action CACHE -storeInGroup myImages_group -undefaction NOCACHE
> add cache policy bugReportPolicy -rule "http.req.url.query.contains("IssuePage")" -action CACHE -storeInGroup bugReportGroup
> add cache policy my_form_policy -rule "http.req.header("Host")contains("my.company.com") && http.req.method.eq("GET") && http.req.url.query.contains("v=7")" -action CACHE -storeInGroup my_
> add cache policy viewproducts_policy -rule "http.req.url.contains("viewproducts.aspx")" -action CACHE -storeInGroup Product_Details
```

At the command prompt, type:

```
add cache policy <policyName> -rule <expression> -action INVAL [-invalObjects "<contentGroupName1>[,<selectorName1>"] . .] | [-invalGroup <contentGroupName1>[,<contentGroupName2> . .]] [-undefAction NOCACHE|RESET]
```

## Examples

```
> add cache policy invalidation_events_policy -rule "http.req.header("Host")contains("my.company.com") && http.req.method.eq("GET") && http.req.url.query.contains("v=8")" -action INVAL -invalObjec
> add cache policy inval_all -rule "http.req.method.eq("POST") && http.req.url.contains(".jpeg")" -action INVAL -invalGroups myImages_group myApps_group PDF_group
> add cache policy bugReportInvalidationPolicy -rule "http.req.url.query.contains("TransitionForm")" -action INVAL -invalObjects bugReport
> add cache policy editproducts_policy -rule "http.req.url.contains("editproducts.aspx")" -action INVAL -invalObjects "Product_Details, batchnum_sel" "Products_In_Depots, batchid_sel"
```

Navigate to Optimization > Integrated Caching > Policies, and create the new policy.

# Globally Binding an Integrated Caching Policy

Aug 08, 2014

When you globally bind a policy, it is available to all virtual servers on the NetScaler appliance.

At the command prompt, type:

```
bind cache global <policy> -priority <positiveInteger> [-type
REQ_OVERRIDE | REQ_DEFAULT | RES_OVERRIDE | RES_DEFAULT] [-gotoPriorityExpression <expression>] [-invoke
<labelType> <labelName>]
```

## Example

```
> bind cache global myCachePolicy -priority 100 -type req_default
```

Note that the type argument is optional for globally bound policies, to maintain backward compatibility with policies that you defined using earlier versions of the NetScaler appliance. If you omit the type, the policy is bound to REQ\_DEFAULT or RES\_DEFAULT, depending on whether the policy rule is a response-time or a request-time expression. If the rule contains both request time and response time parameters, it is bound to RES\_DEFAULT. Following is an example of a binding that omits the type.

```
> bind cache global myCache Policy 200
```

Navigate to Optimization > Integrated Caching, click Cache Policy Manager, and bind policies by specifying the relevant bind point and connection type (Request/Response).

# Binding an Integrated Caching Policy to a Virtual Server

Aug 08, 2014

When you bind a policy to a virtual server, it is available only to requests and responses that match the policy and that flow through the relevant virtual server.

When using the configuration utility, you can bind the policy using the configuration dialog box for the virtual server. This enables you to view all of the policies from all NetScaler modules that are bound to this virtual server. You can also use the Policy Manager configuration dialog for the integrated cache. This enables you to view only the integrated caching policies that are bound to the virtual server.

At the command prompt, type:

- `bind lb vserver <name>@ -policyName <policyName> -priority <positiveInteger> -type (REQUEST | RESPONSE)`
- `bind cs vserver <name>@ -policyName <policyName> -priority <positiveInteger> -type (REQUEST | RESPONSE)`
  
- CS Virtual Server - Navigate to **Traffic Management > Content Switching > Virtual Servers**, select the virtual server, and bind relevant cache policies.
- LB Virtual Server - Navigate to **Traffic Management > Load Balancing > Virtual Servers**, select the virtual server, and bind relevant cache policies.

Navigate to **Optimization > Integrated Caching**, click **Cache Policy Manager**, and bind cache policies by specifying the relevant bind point and connection type.

Note: You can bind cache policies to both LB virtual server and CS virtual server by selecting the appropriate bind point.

## Example: Caching Compressed and Uncompressed Versions of a File

Mar 16, 2012

By default, a client that can handle compression can be served uncompressed responses or compressed responses in gzip, deflate, compress, and pack200-gzip format. If the client handles compression, an Accept-Encoding:compression format header is sent in the request. The compression type accepted by the client must match the compression type of the cached object. For example, a cached .gzip file cannot be served in response to a request with an Accept-Encoding:deflate header.

A client that cannot handle compression is served a cache miss if the cached response is compressed.

For dynamic caching, you need to configure two content groups, one for compressed data and one for uncompressed versions of the same data. The following is an example of configuring the selectors, content groups, and policies for serving uncompressed files from the cache to clients that cannot handle compression, and serving compressed versions of the same files to client that can handle compression.

```
add cache selector uncompressed_response_selector http.req.url "http.req.header("Host")"
add cache contentGroup uncompressed_group -hitSelector uncompressed_responst_selector -invalSelector uncomp_resp_sel
add cache policy cache_uncompressed -rule "HTTP.REQ.URL.CONTAINS("xyz")" && !HTTP.REQ.HEADER("Accept-Encoding").EXISTS" -action CACHE -storeInGroup uncompressed_group
bind cache global cache_uncompressed -priority 100 -gotoPriorityExpression END -type REQ_OVERRIDE
add cache selector compressed_response_selector HTTP.REQ.URL "HTTP.REQ.HEADER("Host")" "HTTP.REQ.HEADER("Accept-Encoding")"
add cache contentGroup compressed_group -hitSelector compressed_response_selector
add cache policy cache_compressed -rule "HTTP.REQ.URL.CONTAINS("xyz")" && HTTP.REQ.HEADER("Accept-Encoding").EXISTS" -action CACHE -storeInGroup compressed_group
bind cache global cache_compressed -priority 200 -gotoPriorityExpression END -type REQ_OVERRIDE
```

# Configuring a Policy Bank for Caching

Aug 08, 2014

All of the policies that are associated with a particular bind point are collectively known as a policy bank. In addition to configuring priority levels for policies in a bank, you can modify the order of evaluation order in a bank by configuring Goto expressions. You can further modify the evaluation order by invoking an external policy bank from within the current policy bank. You can also configure new policy banks, to which you assign your own labels. Because such policy banks are not bound to any point in the processing cycle, they can be invoked only from within other policy banks. For convenience, policy banks whose labels do not correspond to a built-in bind point are called policy labels.

In addition to controlling order of policy evaluation by binding the policy and assigning a priority level, as described in "[Binding Policies That Use the Default Syntax](#)", you can establish the flow within a bank of policies by configuring a Goto expression. A Goto expression overrides the flow that is determined by the priority levels. You can also control the evaluation flow by invoking an external policy bank after evaluating an entry in the current bank. Evaluation always returns to the current bank after evaluation has completed for the external bank.

The following table summarizes the entries to control evaluation in a policy bank.

**Table 1. Entries to Control Evaluation Flow in a Policy Bank**

| Attribute       | Specifies                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name            | <p>The name of a policy, or, to invoke another policy bank without evaluating the policy, the keyword NOPOLICY.</p> <p>You can specify NOPOLICY more than once in a policy bank, but you can specify a named policy only once.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Priority        | <p>An integer. The lower the integer, the higher the priority.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Goto Expression | <p>Determines the next policy or policy bank to evaluate. You can provide one of the following values:</p> <ul style="list-style-type: none"><li>• <b>NEXT</b>: Go to the policy with the next higher priority.</li><li>• <b>END</b>: Stop evaluation.</li><li>• <b>USE_INVOCATION_RESULT</b>: Applicable if this entry invokes another policy bank. If the final Goto in the invoked bank has a value of END, evaluation stops. If the final Goto is anything other than END, the current policy bank performs a NEXT.</li><li>• <b>Positive number</b>: Priority number of the next policy to be evaluated.</li><li>• <b>Numeric expression</b>: Expression that produces the priority number of the next policy to be evaluated.</li></ul> <p>The Goto can only proceed forward in a policy bank.</p> <p>Omitting the Goto expression is the same as specifying END.</p> |
| Invocation Type | <p>Designates a policy bank type. The value can be one of the following:</p> <ul style="list-style-type: none"><li>• <b>Request Vserver</b>: Invokes request-time policies that are associated with a virtual server.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                 |                                                                                                                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attribute       | <ul style="list-style-type: none"> <li>• <b>Response Vserver:</b> Invokes response-time policies that are associated with a virtual server.</li> <li>• <b>Policy label:</b> Invokes another policy bank, as identified by the policy label for the bank.</li> </ul> |
| Invocation Name | Name of a virtual server or a policy label, depending on the value that you specified for the Invocation Type.                                                                                                                                                      |

The integrated cache has two built-in policy labels, and you can configure additional policy labels:

- **\_reqBuiltInDefaults:** This policy label is invoked from the request-time default bind point.
- **\_resBuiltInDefaults:** This policy label is invoked from the response-time default bind point.

Note: For information about creating policy labels, see "[Configuring a Policy Label in the Integrated Cache.](#)"

At the command prompt, type:

```
bind cache policylabel <labelName> -policname<policyName> -priority<priority> [-gotoPriorityExpression <gotopriorityExpression>] [-invoke <labelType> <labelName>]
```

1. Navigate to Optimization > Integrated Caching, click Cache policy manager, and specify the relevant bind point (Override Global or Default Global) and connection type to view the list of policies bound to this bind point.
2. If you want to invoke a policy label without evaluating a policy, click NOPOLICY.  
Note: To invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name field, enter the label or virtual server name. See "[Entries to Control Evaluation Flow in a Policy Bank](#)" for details.

At the command prompt, type:

- `bind lb vserver <name>@ -policyName <policyName> |<NOPOLICY-CACHE> -priority <positiveInteger> -gotoPriorityExpression <expression> -type REQUEST | RESPONSE -invoke <labelType> <labelName>`
- `bind cs vserver <name> -policyName <policyName> |<NOPOLICY-CACHE> -priority <positiveInteger> -gotoPriorityExpression <expression> -type REQUEST | RESPONSE -invoke <labelType> <labelName>`

For more information, see "[Entries to Control Evaluation Flow in a Policy Bank.](#)"

1. Navigate to Traffic Management > Load Balancing/Content Switching > Virtual Servers, select the virtual server, and click Policies.
2. If you are configuring an existing entry in this bank, skip this step. If you are adding a new policy to this policy bank, or you want to use the "dummy" NOPOLICY entry, click Add, and do one of the following:
  - To configure a new policy, click Cache and configure the new policy as described in "[Configuring a Policy in the Integrated Cache.](#)"
  - To invoke a policy bank without processing a policy a rule, select the NOPOLICY-CACHE option.

Note: To invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name

field, enter the label or virtual server name. See "[Entries to Control Evaluation Flow in a Policy Bank](#)" for details.

# Configuring a Policy Label in the Integrated Cache

Aug 08, 2014

In addition to configuring policies in a policy bank for one of the built-in bind points or a virtual server, you can create caching policy labels and configure banks of policies for these new labels.

A policy label for the integrated cache can be invoked only from one of the bind points that you can view in the Policy Manager in the **Integrated Caching** details pane (request override, request default, response override, or response default) or the built-in policy labels `_reqBuiltinDefaults` and `_resBuiltinDefaults`. You can invoke a policy label any number of times unlike a policy, which can only be invoked once.

The configuration utility provides an option to rename a policy label. Renaming a policy label does not affect the process of evaluation of the policies bound to the label.

Note: You can use the NOPOLICY “dummy” policy to invoke any policy label from another policy bank. The NOPOLICY entry is a placeholder that does not process a rule.

At the command prompt, type the following command to create a policy label and verify the configuration:

- `add cache policylabel <labelName> -evaluates (REQ|RES)`
- `show cache policylabel <labelName>`

Invoke this policy label from a policy bank. For more information, see "[Configuring a Policy Bank for Caching](#)."

Navigate to Optimization > Integrated Caching > Policy Labels, add a policy label, and bind the cached policies.

Note: To ensure that the NetScaler ADC processes the policy label at the right time, configure an invocation of this label in one of the policy banks that are associated with the built-in bind points

Navigate to Optimization > Integrated Caching > Policy Labels, select the policy label, and rename.

# Unbinding and Deleting an Integrated Caching Policy and Policy Label

Aug 08, 2014

You can unbind a policy from a policy bank, and you can delete it. To delete the policy, you must first unbind it. You can also remove a policy label invocation and delete a policy label. To delete the policy label, you must first remove any invocations that you have configured for the label.

You cannot unbind or delete the labels for the built-in bind points (request default, request override, response default, and response override).

At the command prompt, type:

```
unbind cache global <policy>
```

At the command prompt, type:

```
(unbind lb vserver|unbind cs vserver) <vserverName> -policyName <policyName> -type (REQUEST | RESPONSE)
```

At the command prompt, type:

```
rm cache policy <policyName>
```

Navigate to Optimization > Integrated Caching, click Cache Policy Manager, and unbind policies by specifying the relevant bind point and connection type (Request/Response).

1. Navigate to Optimization > Integrated Caching, click Cache policy manager, and specify the relevant bind point (LB virtual server or CS virtual server) and connection type to view the list of cache policies bound to this virtual server.
2. In the policy Invoke column, clear the entry.

# Caching Support for Database Protocols

Sep 02, 2013

The integrated cache monitors database requests that flow through the Citrix® NetScaler® appliance and caches them as determined by the cache policies. Users have to configure the cache policies for MYSQL and MSSQL protocols, because the NetScaler does not provide any default policies for these protocols. When configuring the protocols, remember that request based policies currently support CACHE and INVALID actions, while response based policies currently support only NOCACHE action. After configuring the policies, bind them to virtual servers. MYSQL and MSSQL policies, both request and response, can be bound only to virtual servers

Before creating a cache policy, create a cache content group of type MYSQL or MSSQL. When you create a MYSQL or MSSQL cache content group, associate at least one hit selector with it. See "[Setting Up a Basic Content Group](#)" for setting up cache content groups.

The following example illustrates the procedure for configuring and verifying cache support for SQL protocols.

```
> enable feature IC
> set cache parameter -memlimit 100
> add cache selector sel1 mssql.req.query.text

> add cache contentgroup cg1 -type "MSSQL" -hitselector "sel1" -invalselector "inval_sel" -relExpiry "500" -maxResSize "100"
> add cache policy cp1 -rule "mssql.req.query.command.contains(\"select\")" -action "CACHE" -storeInGroup "cg1"
> add cache policy cp2 -invalObjects "cg1" -rule "mssql.req.query.text.contains(\"insert\")" -action "INVALID"
> add db user user1 -password "Pass1"
> add service svc_sql_1 10.102.147.70 mssql 64834 -healthMonitor "NO" -downstateflush "ENABLED"
> add lb vserver lb_mssql1 mssql 10.102.147.77 1433 -lbmethod "roundrobin"
> bind lb vserver lb_mssql1 svc_sql_1
> bind lb vserver lb_mssql1 -policyName cp1 -type "REQUEST" -priority "2"
> bind lb vserver lb_mssql1 -policyName cp2 -type "REQUEST" -priority "1"

> show cache selector sel1
 Name:sel1
 Expressions:
 1)mssql.req.query.text
> show cache policy cp1
 Name:cp1
 Rule:mssql.req.query.command.contains("select")
 CacheAction:CACHE
 Stored in group:cg1
 UndefAction:Use Global
 Hits:2
 Undef Hits:0
 Policy is bound to following entities
 1) Bound to:
 REQ VSERVER lb_mssql1
 Priority:2
 GotoPriorityExpression: END
```

Note: The methods for reducing flash crowds, as explained in "[Reducing Flash Crowds](#)", are not supported for MySQL and MSSQL protocols.

# Configuring Expressions for Caching Policies and Selectors

Oct 28, 2013

A request-time expression examines data in request-time transaction, and a response-time expression examines data in a response-time transaction. In a policy for caching, if an expression matches data in a request or response, the Citrix NetScaler appliance takes the action associated with the policy. In a selector, request-time expressions are used to find matching responses that are stored in a content group.

Before configuring policies and selectors for the integrated cache, you need to know, at minimum, the host names, paths, and IP addresses that appear in HTTP request and response URLs. And you probably need to know the format of entire HTTP requests and responses. Programs such as Live HTTP Headers (<http://livehttpheaders.mozdev.org/>) or HTTPFox (<https://addons.mozilla.org/en-US/firefox/addon/6647>) can help you investigate the structure of the HTTP data that your organization works with.

Following is an example of an HTTP GET request for a stock quote program:

```
GET /quote.dll?page=dynamic&mode=data&mode=stock&symbol=CTXS&page=multi&selected=CTXS&random=0.00792039478975548 HTTP/1.1
Host: quotes.mystockquotes.com
User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9) Gecko/2008052906 Firefox/3.0
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8
Accept-Language: en-us,en;q=0.5
Accept-Encoding: gzip,deflate,compress,pack200-gzip
Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7
Keep-Alive: 300
Connection: keep-alive
Referer: http://quotes.mystockquotes.com/quote.dll?mode=stock&symbol=CTXS&page=multi&selected=CTXS
Cookie: __qca=1210021679-72161677-10297606
When configuring an expression, note the following limitations:
```

**Table 1. Restrictions on Request-Time and Response-Time Expressions**

| Expression Type | Restrictions                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Request         | Do not configure request-time expressions in a policy with a CACHE or NOCACHE action. Use MAY_CACHE or MAY_NOCACHE instead.                                                                                                                                                                                                                                                                       |
| Response        | Configure response-time expressions in caching policies only. <ul style="list-style-type: none"><li>• Selectors can use only request-time expressions.</li><li>• Do not configure response-time expressions in a policy with an INVALID action.</li></ul> Do not configure response-time expressions in a policy with a CACHE action and a parameterized content group. Use the MAY_CACHE action. |

Note: For a comprehensive discussion of advanced expressions, see "[Policies and Expression](#)."

## Expression Syntax

Following are basic components of the syntax:

- Separate keywords with periods (.), as follows:  
http.req.url
- Enclose string values in parentheses and quotes, as follows:  
http.req.url.query.contains("this")
- When configuring an expression from the command line, you must escape internal quote marks (the quotes that delimit values in the

expression, as opposed to the quotes that delimit the expression). One method is to use a slash, as follows:

```
"abc\"
```

Selector expressions are evaluated in order of appearance, and multiple expressions in a selector definition are joined by a logical AND. Unlike selector expressions, you can specify Boolean operators and modify the precedence in an advanced expression for a policy rule.

## Configuring an Expression in a Caching Policy or a Selector

Updated: 2014-08-04

Note that on the command line, the syntax for a policy expression is somewhat different from a selector expression. For a comprehensive discussion of advanced expressions, see "[Policies and Expressions](#)."

## To configure a policy expression by using the command line interface

1. Start the policy definition as described in "[Globally Binding an Integrated Caching Policy](#)."
2. To configure the policy rule, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

The following is an example:

```
"http.req.url.contains(\"jpg\")"
```

3. To add Boolean values, insert `&&`, `|`, or `!` operators.

The following are examples:

```
"http.req.url.contains(\"jpg\") || http.req.url.contains(\"jpeg\")"
```

```
"http.req.url.query.contains(\"IssuePage\")"
```

```
"http.req.header(\"Host\")contains(\"my.company.com\") && http.req.method.eq(\"GET\") && http.req.url.query.contains(\"v=7\")"
```

4. To configure an order of evaluation for the constituent parts of a compound

```
"http.req.url.contains(\"jpg\") || (http.req.url.contains(\"jpeg\") && http.req.method.eq(\"GET\"))"
```

## To configure a selector expression by using the command line interface

1. Start the selector definition as described in "[About Content Groups](#)."
2. To configure the selector expression, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

The following is an example:

```
"http.req.url.contains(\"jpg\")"
```

3. You cannot add Boolean values, insert `&&`, `|`, or `!` operators. Enter each expression element delimited in quotes. Multiple expressions in the definition are treated as a compound expression joined by logical ANDs.

The following are examples:

```
"http.req.url.query.value(\"ProductId\") "http.req.url.query.value(\"BatchNum\") "http.req.url.query.value(\"depotLocation\")"
```

## To configure a policy or selector expression by using the configuration utility

1. Start the policy or selector definition as described in "[To configure a policy for caching or invalidation by using the configuration utility](#)" or "[To configure a selector by using the configuration utility](#)."
2. In the Expression field, you can either manually type the default syntax by clicking Switch to Classic Syntax or create new expression using Expression Editor.
3. To insert an operator between two parts of a compound expression, click the Operators button and select the operator type. The following is an example of a configured expression with a Boolean OR (signaled by double vertical bars, `|`):
4. Click Frequently Used Expressions drop-down to insert the commonly used expressions.
5. To test the expression, click the Evaluate. In the Expression Evaluator dialog box, select the Flow Type that matches the expression. In the data field, paste the HTTP request or response that you hope to parse using the expression, and click Evaluate.

# Displaying Cached Objects and Cache Statistics

Oct 12, 2016

You can view particular cached objects, and you can view summary statistics on cache hits, misses, and memory usage. The statistics provide insight on the amount of data that is being served from the cache, what items are responsible for the largest performance benefit, and what you can tune to improve cache performance.

This section includes the following details:

- [Viewing Cached Objects](#)
- [Finding Particular Cached Responses](#)
- [Viewing Cache Statistics](#)

## Viewing Cached Objects

Updated: 2014-08-04

After enabling caching, you can view details for cached objects. For example, you can view the following items:

- Response sizes and header sizes
- Status codes
- Content groups
- ETag, Last-Modified, and Cache-Control headers
- Request URLs
- Hit parameters
- Destination IP addresses
- Request and response times

## To view a list of cached objects by using the command line interface

At the command prompt, type:

```
show cache object
```

**Table 1. Properties of Cached Objects**

| Properties                   | Specifies                                       |
|------------------------------|-------------------------------------------------|
| Response size (bytes)        | The size of the response header and body.       |
| Response header size (bytes) | The size of the header portion of the response. |
| Response status code         | The status code sent with the response.         |

|                        |                                                                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Etag Properties</b> | <b>Specifies</b><br>The ETag header inserted in the response. Typically, this header indicates whether the response has changed recently. |
| Last-Modified          | The Last-Modified header inserted in the response. This header indicates the date that the response was last changed.                     |
| Cache-Control          | The Cache-Control header inserted in the response.                                                                                        |
| Date                   | The Date header that indicates when the response was sent.                                                                                |
| Contentgroup           | The content group where the response is stored.                                                                                           |
| Complex match          | If this object was cached on the basis of parameterized values, this field value is YES.                                                  |
| Host                   | The host specified in the URL that requested this response.                                                                               |
| Host port              | The listen port for the host specified in the URL that requested this response.                                                           |
| URL                    | The URL issued for the stored response.                                                                                                   |
| Destination IP         | The IP address of the server from which this response was fetched.                                                                        |
| Destination port       | The listen port for the destination server.                                                                                               |
| Hit parameters         | If the content group that stores the response uses hit parameters, they are listed in this field.                                         |
| Hit selector           | If this content group uses a hit selector, it is listed in this field.                                                                    |
| Inval selector         | If this content group uses an invalidation selector, it is listed in this field.                                                          |
| Selector Expressions   | If this content group uses a selector, this field displays the expression that defines the selection rule.                                |
| Request time           | The time in milliseconds since the request was issued.                                                                                    |

| Properties                    | Specifies                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Response time                 | Time in milliseconds since the cache started to receive the response.                                                                                                                                                                                                                                                                                                                                                                                           |
| Age                           | Amount of time the object has been in the cache.                                                                                                                                                                                                                                                                                                                                                                                                                |
| Expiry                        | Amount of time after which the object is marked as expired.                                                                                                                                                                                                                                                                                                                                                                                                     |
| Flushed                       | Whether the response has been flushed after expiry.                                                                                                                                                                                                                                                                                                                                                                                                             |
| Prefetch                      | If Prefetch has been configured for this content group, the amount of time before expiry during which the object is fetched from the origin. Prefetch does not apply to negative objects (for example, 404 "object not found" responses).                                                                                                                                                                                                                       |
| Current readers               | Approximately the current number of hits being served. When a response with a Content-Length header object is being downloaded, the current misses and the current readers values are each typically 1. When a chunked response object is being downloaded, the current misses value is typically 1, but the current readers value is typically 0, because the chunked response that is served to the client does not come from the integrated caching buffers. |
| Current misses                | The current number of requests that resulted in a cache miss and fetching from the origin server. This value is typically 0 or 1. If Poll Every Time is enabled for a content group, the count can be greater than 1.                                                                                                                                                                                                                                           |
| Hits                          | The number of cache hits for this object.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Misses                        | The number of cache misses for this object.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Compression format            | The type of compression applied to this object. Compression formats include gzip, deflate, compress, and pack200-gzip.                                                                                                                                                                                                                                                                                                                                          |
| HTTP version in response      | The version of HTTP that was used to send the response.                                                                                                                                                                                                                                                                                                                                                                                                         |
| Weak etag present in response | Strong etag headers change if the bits of an entity change. Strong headers are based on the octet values of an object. Weak etag headers change if the meaning of an entity changes. Weak etag values are based on semantic identity. Weak etags values start with a "W."                                                                                                                                                                                       |
| Negative marker cell          | A marker object is cacheable, but it does not yet meet all the criteria for being cached. For example, the object may exceed the maximum response size for the content group. A marker cell is created for objects of this type. The next time a user sends a request for this object, a cache miss is served.                                                                                                                                                  |

| Properties                                  | Specifications                                                                                                                                                                                                                                                                                |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| marker created                              | Indicates when a marker cell was created (for example, "Waiting for minhit," "Content-length response data is not in group size limit").                                                                                                                                                      |
| Auto poll every time                        | If the integrated cache receives an already expired 200 OK response with validators (either the Last-Modified or the ETag response headers) it stores the response and marks it as Auto-PET (automatically poll every time).                                                                  |
| NetScaler Etag inserted in response         | A variation of the ETag header generated by the NetScaler appliance. A value of YES appears if the NetScaler inserts an Etag in the response.                                                                                                                                                 |
| Full response present in cache              | Indicates whether this is a complete response.                                                                                                                                                                                                                                                |
| Destination IP verified by DNS              | Indicates whether DNS resolution was performed when storing the object.                                                                                                                                                                                                                       |
| Object stored through a cache forward proxy | Indicates whether this response was stored due to a forward proxy that is configured in the integrated cache.                                                                                                                                                                                 |
| Object is a Delta basefile                  | A response that is delta-compressed.                                                                                                                                                                                                                                                          |
| Waiting for minhits                         | Indicates whether this content group requires a minimum number of origin server hits before caching a response.                                                                                                                                                                               |
| Minhit count                                | If this content group requires a minimum number of origin server hits before caching an object, this field displays a count of the number of hits received so far.                                                                                                                            |
| HTTP Request Method                         | The method, GET or POST, used in the request that obtained this object.                                                                                                                                                                                                                       |
| Stored by policy                            | The name of the caching policy that caused this object to be stored. A value of NOT AVAILABLE indicates that the policy has been deactivated or deleted. A value of NONE indicates that the object did not match a visible policy, but was stored according to internal criteria for caching. |

| Properties                                | Specifies                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application firewall metadata exists      | This parameter is used when the application firewall and the integrated cache are both enabled. The application firewall analyzes the contents of a response page, stores its metadata (for example, URLs and forms contained in page), and exports the metadata with the response to the cache. The cache stores the page and the metadata, and when the cache serves the page, it sends the metadata back to the request's session. |
| HTTP callout object, name, type, response | These cells indicate whether this data was stored as a result of an HTTP Callout expression, and provide information about various aspects of the callout and the corresponding response. For more information about HTTP callouts, see " <a href="#">HTTP Callouts</a> ".                                                                                                                                                            |

## To view cached objects by using the configuration utility

Navigate to Optimization > Integrated Caching > Cache Objects. You can view all the cached objects and sort them accordingly as per your requirement.

### Finding Particular Cached Responses

Updated: 2014-08-08

You can find individual items in the cache based on search criteria. There are different methods for finding cached items, depending on whether the content group that contains the data uses hit and invalidation selectors, as follows:

- If the content group uses selectors, you can only conduct the search using the Locator ID for the cached item.
- If the content group does not use selectors, you conduct the search using criteria such as URL, host, content group name, and so on.

When searching for a cached response, you can locate some items by URL and host. If the response is in a content group that uses a selector, you can find it only by using a Locator number (for example, 0x00000000ad7af00000050). To save a Locator number for later use, right-click the entry and select **Copy**. For more information about selectors, see "[Configuring Selectors and Basic Content Groups](#)".

## To display cached responses in content groups that do not have a selector by using the command line interface

At the command prompt, type:

```
show cache object [-locator <positiveInteger>] | [(-url <URL> (-host <hostName> [-port <port>]) [-groupName <contentGroupName>] [-httpMethod GET | POST])] | [-httpStatus<positive integer>] | -group <contentGroupName> | -ignoreMarkerObjects (ON | OFF) | -includeNotReadyObjects (ON | OFF)]
```

## To display cached responses in content groups that have a selector by using the command line interface

At the command prompt, type:

```
show cache object -locator <locatorString> MarkerObjects (ON | OFF) | -includeNotReadyObjects (ON | OFF) | [-httpStatus<positive integer>]
```

## To display cached responses in content groups that do not have a selector by using the configuration utility

Navigate to Optimization > Integrated Caching > Cache Objects, click Search, and set the search criteria to view the required cached response.

If you have not yet configured any content groups, all of the objects are in the Default group.

## To display cached responses in content groups that have a selector by using the configuration utility

Navigate to Optimization > Integrated Caching > Cache Objects, click Search, and set the selector search criteria to view the required cached response.

### Viewing Cache Statistics

Updated: 2013-10-28

The following table summarizes the detailed cache statistics that you can view.

**Table 2. Integrated Cache Statistics**

| Counter           | Specifies                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hits              | Responses that are found in and served from the integrated cache. Includes static objects such as image files, pages with status codes 200, 203, 300, 301, 302, 304, 307, 403, 404, 410, and responses that match a user-defined policy with a CACHE action..                                                                                 |
| Misses            | Intercepted HTTP requests where the response was ultimately fetched from origin server.                                                                                                                                                                                                                                                       |
| Requests          | Total cache hits plus total cache misses.                                                                                                                                                                                                                                                                                                     |
| Non-304 hits      | If the user requests an item more than once, and the item in the cache is unchanged since the last time the NetScaler appliance served it, the NetScaler appliance serves a 304 response instead of the cached object.<br><br>This statistic indicates how many items the NetScaler appliance served from the cache, excluding 304 responses. |
| 304 hits          | Number of 304 (object not modified) responses the NetScaler appliance served from the cache.                                                                                                                                                                                                                                                  |
| 304 hit ratio (%) | Percentage of 304 responses that the NetScaler appliance served, relative to other responses.                                                                                                                                                                                                                                                 |
| Hit ratio (%)     | Percentage of responses that the NetScaler appliance served from the cache (cache hits) relative to responses that could not be served from the cache.                                                                                                                                                                                        |

| Counter                        | Specifies                                                                                                                                                                                                                                                                         |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Origin bandwidth saved (%)     | An estimate of the processing capacity that the NetScaler appliance saved on the origin server due to serving responses from the cache.                                                                                                                                           |
| Bytes served by the NetScaler  | Total number of bytes that the NetScaler appliance served from the origin server and the cache.                                                                                                                                                                                   |
| Bytes served by cache          | Total number of bytes that the NetScaler appliance served from the cache.                                                                                                                                                                                                         |
| Byte hit ratio(%)              | Percentage of data that the NetScaler appliance served from the cache, relative to all of the data in all served responses.                                                                                                                                                       |
| Compressed bytes from cache    | Amount of data, in bytes, that the NetScaler appliance served in compressed form.                                                                                                                                                                                                 |
| Storable misses                | If the NetScaler appliance does not find a requested object in the cache, it fetches the object from the origin server. This is known as a cache miss. A storable cache miss can be stored in the cache.                                                                          |
| Non-storable misses            | A non-storable cache miss cannot be stored in the cache.                                                                                                                                                                                                                          |
| Misses                         | All cache misses.                                                                                                                                                                                                                                                                 |
| Revalidations                  | Max-Age setting in a Cache-Control header determines, in number of seconds, when an intervening cache must revalidate the content with the integrated cache before serving it to the user.<br><br>For more information, see " <a href="#">Inserting a Cache-Control Header</a> ." |
| Successful revalidations       | Number of re-validations that have been performed.<br><br>For more information, see " <a href="#">Inserting a Cache-Control Header</a> ."                                                                                                                                         |
| Conversions to conditional req | A user-agent request for a cached PET object is always converted to a conditional request and sent to the origin server.<br><br>For more information, see " <a href="#">Polling the Origin Server Every Time a Request Is Received</a> ."                                         |
| Storable miss ratio (%)        | Storable cache misses as a percentage of non-storable cache misses.                                                                                                                                                                                                               |

| <b>Counter</b>               | <b>Specifies</b>                                                                                                                                                                                                                                                                                     |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Successful reval ratio (%)   | Successful revalidations as a percentage of all revalidation attempts.<br><br>For more information, see " <a href="#">Inserting a Cache-Control Header.</a> "                                                                                                                                        |
| Expire at last byte          | Number of times that the cache expired content immediately after receiving the last body byte. Only applicable to positive responses, as described in the table " <a href="#">Cache Hits and Misses.</a> "<br><br>For more information, see " <a href="#">Example of Performance Optimization.</a> " |
| Flashcache misses            | If you enable Flash Cache, the cache allows only one request to reach the server, eliminating flash crowds. This statistic indicates the number of Flash Cache requests that were cache misses.<br><br>For more information, " <a href="#">Queuing Requests to the Cache.</a> "                      |
| Flashcache hits              | Number of Flash Cache requests that were cache hits.<br><br>For more information, see " <a href="#">Queuing Requests to the Cache.</a> "                                                                                                                                                             |
| Parameterized inval requests | Requests that match a policy with an invalidation (INVALID) action and a content group that uses an invalidation selector or parameters to selectively expire cached objects in the group.                                                                                                           |
| Full inval requests          | Requests that match an invalidation policy where the invalGroups parameter is configured and expires one or more content groups.                                                                                                                                                                     |
| Inval requests               | Requests that match an invalidation policy and result in expiration of specific cached responses or entire content groups.                                                                                                                                                                           |
| Parameterized requests       | Number of cache requests that were processed using a policy with a parameterized content group.                                                                                                                                                                                                      |
| Parameterized non-304 hits   | Number of cache requests that were processed using a policy with a parameterized content group, where full cached response was found, and the response was not a 304 (object not updated) response.                                                                                                  |
| Parameterized 304 hits       | Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found, and the object was a 304 (object not updated) response.                                                                                                           |
| Total parameterized hits     | Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found.                                                                                                                                                                   |
| Parameterized                | Percentage of 304 (object not updated) responses that were found using a parameterized policy,                                                                                                                                                                                                       |

|                                  |                                                                                                                                                                                                                                                             |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 304 hit ratio Counter (%)        | relative to all cache hits.<br><b>Specifies</b>                                                                                                                                                                                                             |
| Poll every time requests         | If Poll Every Time is enabled, the NetScaler appliance always consults the origin server before serving a stored object.<br><br>For more information, see " <a href="#">Polling the Origin Server Every Time a Request Is Received.</a> "                   |
| Poll every time hits             | Number of times a cache hit was found using the Poll Every Time method.<br><br>For more information, see " <a href="#">Polling the Origin Server Every Time a Request Is Received.</a> "                                                                    |
| Poll every time hit ratio (%)    | Percentage of cache hits using the Poll Every Time method, relative to all searches for cached objects using Poll Every Time.<br><br>For more information, see " <a href="#">Polling the Origin Server Every Time a Request Is Received.</a> "              |
| Maximum memory (KB)              | Maximum amount of memory in the NetScaler appliance that is allocated to the cache. For more information, see " <a href="#">Configuring Global Attributes for Caching.</a> "                                                                                |
| Maximum memory active value (KB) | Maximum amount of memory (active value) that will be set after the memory is actually allocated to the cache. For more information, see " <a href="#">How to Configure the Integrated Caching Feature of a NetScaler Appliance for various Scenarios.</a> " |
| Utilized memory (KB)             | Amount of memory that is actually being used.                                                                                                                                                                                                               |
| Memory allocation failures       | Number of failed attempts to utilize memory for the purpose of storing a response in the cache.                                                                                                                                                             |
| Largest response so far          | Largest response in bytes found in either the cache or the origin server and sent to the client.                                                                                                                                                            |
| Cached objects                   | Number of objects in the cache, including responses that have not yet been fully downloaded and responses that have been expired but not yet flushed.                                                                                                       |
| Marker objects                   | Marker objects are created when a response exceeds the maximum or minimum response size for the content group, or has not yet received the minimum number of hits for the content group.                                                                    |
| Hits being                       | Number of hits that have been served from the cache.                                                                                                                                                                                                        |

| Counter              | Specifies                                                                                                                                                                          |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Misses being handled | Responses that were fetched from the origin server, stored in the cache, and then served. Should approximate the number for storable misses. Does not include non-storable misses. |

## To view summary cache statistics by using the command line interface

At the command prompt, type:

## To view summary cache statistics by using the configuration utility

1. Click the Dashboard tab at the top of the page.
2. Scroll down to the Integrated Caching section of the window.
3. To see detailed statistics, click the More... link at the bottom of the table.

## To view specific cache statistics by using the configuration utility

1. Click the Reporting tab at the top of the page.
2. Under Built-In Reports, expand Integrated Cache, and then click the report with the statistics you want to view.
3. To save the report as a template, click Save As and name the report. The saved report appears under Custom Reports.

# Improving Cache Performance

May 19, 2015

You can improve the performance of integrated cache, including handling simultaneous requests for the same cached data, avoiding delays that are associated with refreshing cached responses from the origin server, and ensuring that a response is requested often enough to be worth caching.

This section includes the following details:

- [Reducing Flash Crowds](#)
- [Caching a Response after a Client Halts a Download](#)
- [Requiring a Minimum Number of Server Hits before Caching](#)
- [Example of Performance Optimization](#)

## Reducing Flash Crowds

Updated: 2015-05-20

Flash crowds occur when many users simultaneously request the same data. All of the requests in a flash crowd can become cache misses if you configured the cache to serve hits only after the entire object is downloaded.

The following techniques can reduce or eliminate flash crowds:

- **PREFETCH:** Refreshes a positive response before it expires to ensure that it never becomes stale or inactive. For more information, see "[Refreshing a Response Prior to Expiration.](#)"
- **Cache buffering:** Starts serving a response to multiple clients as soon as it receives the response header from the origin server, rather than waiting for the entire response to be downloaded. The only limit on the number of clients that can download a response simultaneously is the available system resources.

The Citrix NetScaler appliance downloads and serves responses even if the client that initiated the download halts before the download is complete. If the size of the response exceeds the cache size or if the response is chunked, the cache stops storing the response, but service to the clients is not disrupted.

- **Flash Cache:** Flash Cache queues requests to the cache, and allows only one request to reach the server at a time. For more information, see "[Queuing Requests to the Cache.](#)"

## Refreshing a Response Before Expiration

To ensure that a cached response is fresh whenever it is needed, the PREFETCH option refreshes a response before its calculated expiration time. The prefetch interval is calculated after receiving the first client request. From that point onward, the NetScaler appliance refreshes the cached response at a time interval that you configure in the PREFETCH parameter.

This setting is useful for data that is updated frequently between requests. It does not apply to negative responses (for example, 404 messages).

To configure prefetch for a content group by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -prefetch YES [-prefetchPeriod <seconds> | -prefetchPeriodMilliSec <milliseconds>] [-
```

prefetchMaxPending <positiveInteger>]

To configure prefetch for a content group by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Others tab, in the Flash Crowd and Prefetch group, select Prefetch option, and specify the values in Interval and Maximum number of pending prefetches text boxes.

## Queuing Requests to the Cache

The Flash Cache option queues requests that arrive simultaneously (a flash crowd), retrieves the response, and distributes it to all the clients whose requests are in the queue. If, during this process, the response becomes non-cacheable, the NetScaler appliance stops serving the response from the cache and instead serves the origin server's response to the queued clients. If the response is not available, the clients receive an error message.

Flash Cache is disabled by default. You cannot enable Poll Every Time (PET) and Flash Cache on the same content group.

One disadvantage of Flash Cache is if the server replies with an error (for example, a 404 that is quickly remedied), the error is fanned out to the waiting clients.

Note: If Flash Cache is enabled, in some situations the NetScaler appliance is unable to correctly match the Accept-Encoding header in the client request with the Content-Encoding header in the response. The NetScaler appliance can assume that these headers match and mistakenly serve a hit. As a work-around, you can configure Integrated Caching policies to disallow serving hits to clients that do not have an appropriate Accept-Encoding header.

To enable Flash Cache by using the command line interface

At the command prompt, type:

```
set cache contentgroup <contentGroupName> -flashcache yes
```

To enable Flash Cache by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Others tab, in the Flash Crowd and Prefetch group, select Prefetch option.

## Caching a Response after a Client Halts a Download

Updated: 2014-08-08

You can set the Quick Abort parameter to continue caching a response, even if the client halts a request before the response is in the cache.

If the downloaded response size is less than or equal to the Quick Abort size, the NetScaler appliance stops downloading the response. If you set the Quick Abort parameter to 0, all downloads are halted.

## To configure quick abort size by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -quickAbortSize <integerInKBytes>
```

## To configure quick abort size by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Memory tab, set the relevant value in Quick Abort: Continue caching if more than text box.

## Requiring a Minimum Number of Server Hits before Caching

Updated: 2015-05-19

You can configure the minimum number of times that a response must be found on the origin server before it can be cached. You should consider increasing the minimum hits if the cache memory fills up quickly and has a lower-than-expected hit ratio.

The default value for the minimum number of hits is 0. This value caches the response after the first request.

### To configure the minimum number of hits that are required before caching by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -minhits <positiveInteger>
```

### To configure the minimum number of hits that are required before caching by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Memory tab, set the relevant value in Do not cache, if hits are less than text box.

### Example of Performance Optimization

Updated: 2013-10-28

In this example, a client accesses a stock quote. Stock quotes are highly dynamic. You configure the integrated cache to serve the same stock quote to concurrent clients without sending multiple requests to the origin server. The stock quote expires after it is downloaded to all of the clients, and the next request for a quote for the same stock is fetched from the origin server. This ensures that the quote is always up to date.

The following task overview describes the steps to configure the cache for the stock quote application.

### Task overview: Configuring caching for a stock quote application

1. Create a content group for stock quotes.  
For more information, see "[About Content Groups.](#)"

Configure the following for this content group:

- On the Expiry Method tab, select the Expire after complete response received check box.
  - On the Others tab, select the Flash Cache check box, and click Create.
2. Add a cache policy to cache the stock quotes.  
For more information, see "[Configuring a Policy in the Integrated Cache.](#)"

Configure the following for the policy:

- In the Action and Store in Group lists, select CACHE and select the group that you defined in the previous step.
- Click Add, and in the Add Expression dialog box configure an expression that identifies stock quote requests, for example:  
`http.req.url.contains("cgi-bin/stock-quote.pl")`

3. Activate the policy.

For more information, see "[Globally Binding an Integrated Caching Policy](#)." In this example, you bind this policy to request-time override processing and set the priority to a low value.

# Configuring Cookies, Headers, and Polling

May 20, 2015

This section describes the procedures to configure how the cache manages cookies, HTTP headers, and origin server polling, including modifying default behavior that causes the cache to diverge from documented standards, overriding HTTP headers that might cause cacheable content to not be stored in the cache, and configuring the cache to always poll the origin for updated content under specialized circumstances.

For details, see the following sections:

- [Divergence of Cache Behavior from the Standards](#)
- [Removing Cookies from a Response](#)
- [Inserting HTTP Headers at Response Time](#)
- [Ignoring Cache-Control and Pragma Headers in Requests](#)
- [Polling the Origin Server Every Time a Request Is Received](#)
- [PET and Client-Specific Content](#)
- [PET and Authentication, Authorization, and Auditing](#)

## Divergence of Cache Behavior from the Standards

Updated: 2013-10-28

By default, the integrated cache conforms to the following standards:

- RFC 2616, "Hypertext Transfer Protocol HTTP/1.1"
- The caching behaviors described in RFC 2617, "HTTP Authentication: Basic and Digest Access Authentication"
- The caching behavior described in RFC 2965, "HTTP State Management Mechanism"

The built-in policies and the Default content group attributes ensure conformance with most of these standards.

The default integrated cache behavior diverges from the specifications as follows:

- There is limited support for the Vary header.  
By default, any response containing a Vary header is considered to be non-cacheable unless it is compressed. A compressed response contains Content-Encoding: gzip, Content-Encoding: deflate, or Content-Encoding: pack200-gzip and is cacheable even if it contains the Vary: Accept-Encoding header.
- The integrated cache ignores the values of the headers Cache-Control: no-cache and Cache-Control: private.  
For example, a response that contains Cache-Control: no-cache="Set-Cookie" is treated as if the response contained Cache-Control: no-cache. By default, the response is not cached.
- An image (Content-Type = image/\*) is always considered cacheable even if an image response contains Set-Cookie or Set-Cookie2 headers, or if an image request contains a Cookie header.  
The integrated cache removes Set-Cookie and Set-Cookie2 headers from a response before caching it. This diverges from RFC 2965. You can configure RFC-compliant behavior as follows:

```
add cache policy rfc_compliant_images_policy -rule "http.res.header.set-cookie2.exists || http.res.header.set-cookie.exists" -action NOCACHE
bind cache global rfc_compliant_images_policy -priority 100 -type REQ_OVERRIDE
```

- The following Cache-Control headers in a request force an RFC-compliant cache to reload a cached response from the origin server:

```
Cache-control: max-age=0
```

```
Cache-control: no-cache
```

To guard against Denial of Service attacks, this behavior is not the default. For more information, see "[Inserting a Cache-Control Header](#)."

- By default, the caching module considers a response to be cacheable unless a response header states otherwise.  
To make this behavior RFC 2616 compliant, set -weakPosRelExpiry and -weakNegResExpiry to 0 for all content groups.

## Removing Cookies from a Response

Updated: 2014-08-12

Cookies are often personalized for a user, and typically should not be cached. The Remove Response Cookies parameter removes Set-Cookie and Set-Cookie2 headers before caching a response. By default, the Remove Response Cookies option for a content group prevents caching of responses with Set-Cookie or Set-Cookie2 headers.

Note that when images are cached, the built-in behavior is to remove the Set-Cookie and Set-Cookie2 headers before caching, no matter how the content group is configured.

Note: Citrix recommends that you accept the default Remove Response Cookies for every content group that stores embedded responses, for example, images.

### To configure Remove Response Cookies for a content group by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -removeCookies YES
```

### To configure Remove Response Cookies for a content group by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Others tab, in the Settings group, select Remove response cookies option.

## Inserting HTTP Headers at Response Time

Updated: 2014-08-12

The integrated cache can insert HTTP headers in responses that result from cache hits. The Citrix® NetScaler® appliance does not alter headers in responses that result from cache misses.

The following table describes headers that you can insert in a response.

**Table 1. Different HTTP Headers You Can Insert in a Response That Is Served from the Cache**

| Header | Specifies                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Age    | Provides the age of the response in seconds, calculated from the time the response was generated at the origin server.<br><br>By default, the cache inserts an Age header for every response that is served from the cache.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Via    | Lists protocols and recipients between the start and end points for a request or a response. The NetScaler appliance inserts a Via header in every response that it serves from the cache. The default value of the inserted header is "NS-CACHE-9.2:last octet of the NetScaler IP address."<br><br>For more information, see " <a href="#">Configuring Global Attributes for Caching</a> ."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ETag   | The cache supports response validation using Last-Modified and ETag headers to determine if a response is stale.<br><br>The cache inserts an ETag in a response only if it caches the response and the origin server has not inserted its own ETag header.<br><br>The ETag value is an arbitrary unique number. The ETag value for a response changes if it is refreshed from the origin server, but it stays the same if the server sends a 304 (object not updated) response.<br><br>Origin servers typically do not generate validators for dynamic content because dynamic content is considered non-cacheable. You can override this behavior. With ETag header insertion, the cache is permitted to not serve full responses. Instead, the user agent is required to cache the dynamic response sent by the integrated cache the first time. To force a user agent to cache a |

| Header        | Specifies                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cache-Control | <p>response, you configure the integrated cache to insert an ETag header and replace the origin-provided Cache-Control header.</p> <p>The NetScaler appliance typically does not modify cacheability headers in responses that it serves from the origin server. If the origin server sends a response that is labeled as non-cacheable, the client treats the response as non-cacheable even if the NetScaler appliance caches the response.</p> <p>To cache dynamic responses in a user agent, you can replace Cache-Control headers from the origin server. This applies only to user agents and other intervening caches. They do not affect the integrated cache.</p> <p>For more information, see "<a href="#">Inserting a Cache-Control Header</a>."</p> |

## Inserting an Age, Via, or ETag Header

The following procedures describe how to insert Age, Via, and ETag headers.

To insert an Age, Via, or Etag header by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -insertVia YES -insertAge YES -insertETag YES
```

To insert an Age, Via, or Etag header by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Others tab, in the HTTP Header Insertions group, select the Via, Age, or ETag options, as appropriate.

The values for the other header types are calculated automatically. Note that you configure the Via value in the main settings for the cache.

## Inserting a Cache-Control Header

When the integrated cache replaces a Cache-Control header that the origin server inserted, it also replaces the Expires header. The new Expires header contains an expiration time in the past. This ensures that HTTP/1.0 clients and caches (that do not understand the Cache-Control header) do not cache the content.

To insert a Cache-Control header by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -cacheControl <value>
```

To insert a Cache-Control header by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and
  1. Click Expiry Method tab, clear the heuristic and default expiry settings and set the relevant value in Expire content after text box.
  2. Click Others tab and type the header you want to insert in the Cache-Control text box. Alternatively, click Configure to set the Cache-Control directives in cached responses.

## Ignoring Cache-Control and Pragma Headers in Requests

Updated: 2014-08-12

By default, the caching module processes Cache-Control and Pragma headers. The following tokens in Cache-Control headers are processed as described in RFC 2616.

- max-age
- max-stale
- only-if-cached
- no-cache

A Pragma: no-cache header in a request is treated in the same way as a Cache-Control: no-cache header.

If you configure the caching module to ignore Cache-Control and Pragma headers, a request that contains a Cache-Control: No-Cache header

causes the NetScaler appliance to retrieve the response from the origin server, but the cached response is not updated. If the caching module processes Cache-Control and Pragma headers, the cached response is refreshed.

The following table summarizes the implications of various settings for these headers and the Ignore Browser's Reload Request setting.

**Table 2. Outcome of Settings for Ignoring Reload Requests, Cache-Control, and Pragma Headers**

| Setting for Ignore Cache-Control and Pragma Headers | Setting for Ignore Browser's Reload Request | Outcome                                                                                                                 |
|-----------------------------------------------------|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Yes                                                 | Yes or No                                   | Ignore the Cache-Control and Pragma headers from the client, including the Cache-Control: no-cache directive.           |
| No                                                  | Yes                                         | The Cache-Control: no-cache header produces a cache miss, but a response that is already in the cache is not refreshed. |
| No                                                  | No                                          | A request that contains a Cache-Control: no-cache header causes a cache miss and the stored response is refreshed.      |

## To ignore Cache-Control and Pragma headers in a request by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -ignoreReqCachingHdrs YES
```

## To ignore browser reload requests by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -ignoreReloadReq NO
```

Note that by default, the -ignoreReloadReq parameter is set to YES.

## To ignore Cache-Control and Pragma headers in a request by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Others tab, in the Settings group, select Ignore Cache-control and Pragma Headers in Requests option.

## Example of a Policy to Ignore Cache-Control Headers

In the following example, you configure a request-time override policy to cache responses that contain Content-type: image/\* regardless of the Cache-Control header in the response.

To configure a request-time override policy to cache all responses with image/\*

1. Flush the cache using the Invalidate All option.

For more information, see "[Flushing Responses in a Content Group](#)."

2. Configure a new cache policy, and direct the policy to a particular content group. For more information, see "[Configuring a Policy in the Integrated Cache](#)."
3. Ensure the content group that the policy uses is configured to ignore Cache-Control headers, as described in "[Ignoring Cache-Control and Pragma Headers in Requests](#)."
4. Bind the policy to the request-time override policy bank.

For more information, see "[Globally Binding an Integrated Caching Policy](#)."

Polling the Origin Server Every Time a Request Is Received

Updated: 2014-08-12

You can configure the NetScaler appliance to always consult the origin server before serving a stored response. This is known as Poll Every Time (PET). When the NetScaler appliance consults the origin server and the PET response has not expired, a full response from the origin server does not overwrite cached content. This property is useful when serving client-specific content.

After a PET response expires, the NetScaler appliance refreshes it when the first full response arrives from the origin server.

The Poll Every Time (PET) function works as follows:

- For a cached response that has validators in the form of an ETag or a Last-Modified header, if the response expires it is automatically marked PET and cached.
- You can configure PET for a content group.  
If you configure a content group as PET, every response in the content group is marked PET. The PET content group can store responses that do not have validators. Responses that are automatically marked PET are always expired. Responses that belong to a PET content group can expire after a delay, based on how you configure the content group.

Two types of requests are affected by polling:

- **Conditional Requests:** A client issues a conditional request to ensure that the response that it has is the most recent copy. A user-agent request for a cached PET response is always converted to a conditional request and sent to the origin server. A conditional request has validators in If-Modified-Since or If-None-Match headers. The If-Modified-Since header contains the time from the Last-Modified header. An If-None-Match header contains the response's ETag header value.

If the client's copy of the response is fresh, the origin server replies with 304 Not Modified. If the copy is stale, a conditional response generates a 200 OK that contains the entire response.

- **Non-Conditional Requests:** A non-conditional request can only generate a 200 OK that contains the entire response.

The following table summarizes response types based on the origin server's response

**Table 3. How Responses Are Affected by Poll Every Time**

| Origin Server Response                                                                                                   | Action                                                                                                                                                                                                                                                                                 |
|--------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Send the full response                                                                                                   | The origin server sends the response as-is to the client. If the cached response has expired, it is refreshed.                                                                                                                                                                         |
| 304 Not Modified                                                                                                         | The following header values in the 304 response are merged with the cached response and the cached response is served to the client: <ul style="list-style-type: none"><li>• Date</li><li>• Expires</li><li>• Age</li><li>• Cache-Control header Max-Age and S-Maxage tokens</li></ul> |
| 401 Unauthorized<br>400 Bad Request<br>405 Method Not Allowed<br>406 Not Acceptable<br>407 Proxy Authentication Required | The origin's response is served as-is to the client. The cached response is not changed.                                                                                                                                                                                               |
| Any other error response, for example,                                                                                   | The origin's response is served as-is to the client. The cached response is removed.                                                                                                                                                                                                   |

Note: The Poll Every Time parameter treats the affected responses as non-storable.

## To configure poll every time by using the command line interface

At the command prompt, type:

```
add cache contentgroup <contentGroupName> -pollEveryTime YES
```

## To configure poll every time by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Others tab, in the Settings group, select Poll every time (validate cached content with origin for every request) option.

## PET and Client-Specific Content

The PET function can ensure that content is customized for a client. For example, a Web site that serves content in multiple languages examines the Accept-Language request header to select the language for the content that it is serving. For a multi-language Web site where English is the predominant language, all English language content can be cached in a PET content group. This ensures that every request goes to the origin server to determine the language for the response. If the response is English, and the content has not changed, the origin server can serve a 304 Not Modified to the cache.

The following example shows commands to cache English responses in a PET content group, configure a named expression that identifies English responses in the cache, and configure a policy that uses this content group and named expression. Bold is used for emphasis:

```
add cache contentgroup EnglishLanguageGroup -pollEveryTime YES
add expression containsENExpression -rule "http.res.header("Content-Language").contains("en")"
add cache policy englishPolicy -rule containsENExpression -action CACHE -storeInGroup englishLanguageGroup
bind cache policy englishPolicy -priority 100 -precedeDefRules NO
```

## PET and Authentication, Authorization, and Auditing

Outlook Web Access (OWA) is a good example of dynamically generated content that benefits from PET. All mail responses (\*.EML objects) have an ETag validator that enables them to be stored as PET responses.

Every request for a mail response travels to the origin server, even if the response is cached. The origin server determines whether the requestor is authenticated and authorized. It also verifies that the response exists in the origin server. If all results are positive, the origin server sends a 304 Not Modified response.

# Configuring the Integrated Cache as a Forward Proxy

Aug 08, 2014

The integrated cache can service as a forward proxy device that passes requests to other NetScaler appliances or to other types of cache servers. You configure the integrated cache as a forward proxy by identifying the IP addresses of the cache server or servers. After configuring the forward proxy, the NetScaler appliance sends requests that contain the configured IP address on to the cache server instead of involving the integrated cache.

To configure the NetScaler as a forward cache proxy by using the command line interface

At the command prompt, type:

```
add cache forwardProxy <IPAddress> <port>
```

To configure the NetScaler as a forward cache proxy by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Forward Proxy, and add a forward proxy by specifying the IP address and port number.

# Default Settings for the Integrated Cache

Aug 26, 2013

The Citrix NetScaler integrated cache feature provides built-in policies with default settings as well as initial settings for the Default content group. The information in this section defines the parameters for the built-in policies and Default content group.

## Default Caching Policies

Updated: 2013-08-26

The integrated cache has built-in policies. The NetScaler appliance evaluates the policies in a particular order, as discussed in the following sections.

You can override these built-in policies with a user-defined policy that is bound to a request-time override or response-time override policy bank.

Note that if you configured policies prior to release 9.0 and specified the `-precedeDefRules` parameter when binding the policies, they are automatically assigned to override-time bind points during migration.

## Viewing the Default Policies

The built-in policy names start with an underscore (`_`). You can view the built-in policies from the command line and the administrative console using the `show cache policy` command.

## Default Request Policies

You can override the following built-in request time policies by configuring new policies and binding them to the request-time override processing point. In the following policies, note that the `MAY_NOCACHE` action stipulates that the transaction is cached only when there is a user-configured or built-in `CACHE` directive at response time.

The following policies are bound to the `_reqBuiltinDefaults` policy label. They are listed in priority order.

1. Do not cache a response for a request that uses any method other than GET.

The policy name is `_nonGetReq`. The following is the policy rule:

```
!HTTP.REQ.METHOD.eq(GET)
```

2. Set a `NOCACHE` action for a request with header value that contains `If-Match` or `If-Unmodified-Since`.

The policy name is `_advancedConditionalReq`. The following is the policy rule:

```
HTTP.REQ.HEADER("If-Match").EXISTS || HTTP.REQ.HEADER("If-Unmodified-Since").EXISTS
```

3. Set a `MAY_NOCACHE` action for a request with the following header values: `Cookie`, `Authorization`, `Proxy-authorization` or a request which contains the `NTLM` or `Negotiate` header.

The policy name is `_personalizedReq`. The following is the policy rule:

```
HTTP.REQ.HEADER("Cookie").EXISTS || HTTP.REQ.HEADER("Authorization").EXISTS || HTTP.REQ.HEADER("Proxy-
Authorization").EXISTS || HTTP.REQ.IS_NTLM_OR_NEGOTIATE
```

## Default Response Policies

You can override the following default response-time policies by configuring new policies and binding them to the response-time override processing point.

The following policies are bound to the **\_resBuiltinDefaults** policy label and are evaluated in the order in which they are listed:

1. Do not cache HTTP responses unless they are of type 200, 304, 307, 203 or if the types are between 400 and 499 or between 300 and 302.

The policy name is **\_uncacheableStatusRes**. The following is the policy rule:

```
!((HTTP.RES.STATUS.EQ(200)) || (HTTP.RES.STATUS.EQ(304)) || (HTTP.RES.STATUS.BETWEEN(400,499)) || (HTTP.RES.STATUS.BETWEEN(300, 302)) || (HTTP.RES.STATUS.EQ(307)) || (HTTP.RES.STATUS.EQ(203)))
```

2. Do not cache an HTTP response if it has a Vary header with a value of anything other than Accept-Encoding.

The compression module inserts the Vary: Accept-Encoding header. The name of this expression is

**\_uncacheableVaryRes**. The following is the policy rule:

```
((HTTP.RES.HEADER("Vary").EXISTS) && ((HTTP.RES.HEADER("Vary").INSTANCE(1).LENGTH > 0) || (!HTTP.RES.HEADER("Vary").STRIP_END_WS.SET_TEXT_MODE(IGNORECASE).eq("Accept-Encoding"))))
```

3. Do not cache a response if its Cache-Control header value is No-Cache, No-Store, or Private, or if the Cache-Control header is not valid.

The policy name is **\_uncacheableCacheControlRes**. The following is the policy rule:

```
((HTTP.RES.CACHE_CONTROL.IS_PRIVATE) || (HTTP.RES.CACHE_CONTROL.IS_NO_CACHE) || (HTTP.RES.CACHE_CONTROL.IS_NO_STORE) || (HTTP.RES.CACHE_CONTROL.IS_INVALID))
```

4. Cache responses if the Cache-Control header has one of the following values: Public, Must-Revalidate, Proxy-Revalidate, Max-Age, S-Maxage.

The policy name is **\_cacheableCacheControlRes**. The following is the policy rule:

```
((HTTP.RES.CACHE_CONTROL.IS_PUBLIC) || (HTTP.RES.CACHE_CONTROL.IS_MAX_AGE) || (HTTP.RES.CACHE_CONTROL.IS_MUST_REVALIDATE) || (HTTP.RES.CACHE_CONTROL.IS_PROXY_REVALIDATE) || (HTTP.RES.CACHE_CONTROL.IS_S_MAXAGE))
```

5. Do not cache responses that contain a Pragma header.

The name of the policy is **\_uncacheablePragmaRes**. The following is the policy rule:

```
HTTP.RES.HEADER("Pragma").EXISTS
```

6. Cache responses that contain an Expires header.

The name of the policy is **\_cacheableExpiryRes**. The following is the policy rule:

```
HTTP.RES.HEADER("Expires").EXISTS
```

7. If the response contains a Content-Type header with a value of Image, remove any cookies in the header and cache it.

The name of the policy is **\_imageRes**. The following is the policy rule:

```
HTTP.RES.HEADER("Content-Type").SET_TEXT_MODE(IGNORECASE).STARTSWITH("image/")
```

You could configure the following content group to work with this policy:

```
add cache contentgroup nocookie_group -removeCookies YES
```

8. Do not cache a response that contains a Set-Cookie header.

The name of the policy is **\_personalizedRes**. The following is the policy rule:

```
HTTP.RES.HEADER("Set-Cookie").EXISTS || HTTP.RES.HEADER("Set-Cookie2").EXISTS
```

## Restrictions on Default Policies

You cannot override the following built-in request time policies with user-defined policies.

These policies are listed in priority order.

1. Do not cache any responses if the corresponding HTTP request lacks a GET or POST method.
2. Do not cache any responses for a request if the HTTP request URL length plus host name exceeds 1744 bytes.
3. Do not cache a response for a request that contains an If-Match header.
4. Do not cache a request that contains an If-Unmodified-Since header.  
Note that this is different from the If-Modified-Since header.
5. Do not cache a response if the server does not set an expiry header.

You cannot override the following built-in response time policies. These policies are evaluated in the order in which they are listed:

1. Do not cache responses that have an HTTP response status code of 201, 202, 204, 205, or 206.
2. Do not cache responses that have an HTTP response status code of 4xx, with the exceptions of status codes 403, 404, and 410.
3. Do not cache responses if the response type is FIN terminated, or the response does not have one of the following attributes: Content-Length, or Transfer-Encoding: Chunked.
4. Do not cache the response if the caching module cannot parse its Cache-Control header.

## Initial Settings for the Default Content Group

When you first enable integrated caching, the NetScaler appliance provides one predefined content group named the Default content group. The following table shows the settings for this group.

**Table 1. Predefined Settings for the Default Content Group**

| Parameter               | Description                                                                                                                                                                                                                                                                                | Default Value |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Hit parameters          | The hit parameters contain the parameter names that are significant for generating a response.<br><br>In parameterized hit selection, NetScaler appliance matches the URL stem byte-for-byte, matches normalized values of the hit parameters, and matches the target service information. | none          |
| Invalidation Parameters | These parameters mark a cached object as obsolete during parameterized selection. Specific objects, or all objects in a content group, are selected if the values of the                                                                                                                   | none          |

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                            | Default Value |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Poll Every Time                | invalidation parameters in the object and in the request are same after normalization. The invalidation parameters are a subset of the hit parameters.<br>Poll every time for the objects in this content group.                                                                                                                                       | NO            |
| Ignore reload request          | Specifies whether a request can force the system to reload a cached object from the origin. To guard against Denial of Service attacks, you must set this flag to YES. To get RFC-compliant behavior you should set it to NO.                                                                                                                          | YES           |
| Remove Response Cookies        | If this option is disabled for a content group, and if the response contains cookies, the cookies are stored and served with every cache hit. By default, the remove cookies option is enabled for a content group, to prevent the integrated cache from storing any responses with Set-Cookie or Set-Cookie2 headers unless the response is an image. | YES           |
| Prefetch                       | The Prefetch option refreshes an object when it is about to expire. This ensures that the object remains stale or inactive (and therefore it cannot be served) for a shorter duration of time.                                                                                                                                                         | YES           |
| Prefetch period                | This duration in seconds during which prefetch should be attempted, immediately before the object's calculated expiry time.                                                                                                                                                                                                                            | heuristic     |
| Maximum outstanding prefetches | The number of items that can be subjected to a prefetch at a time.                                                                                                                                                                                                                                                                                     | 4294967295    |
| Flashcache                     | Determines whether to enable queuing of client requests and simultaneous distribution of responses to all clients in the queue.                                                                                                                                                                                                                        | NO            |
| Expire at last byte            | Determines whether to expire a cached response immediately after serving it.                                                                                                                                                                                                                                                                           | NO            |
| Insert Via header              | Defines a string to be inserted in a Via header. By default, a Via header is inserted in all responses served from a content group. The Via header is not inserted for responses that are served by the origin server.                                                                                                                                 | YES           |
| Insert Age header              | The Age header contains information about the age of the object in seconds as calculated by the integrated cache.                                                                                                                                                                                                                                      | YES           |
| Insert ETag header             | With ETag header insertion, the integrated cache does not serve full responses on repeat requests. This is done by forcing the user agent to cache the dynamic response                                                                                                                                                                                | YES           |

| <b>Parameter</b>                  | <b>Description</b>                                                                                                                                                                                                                                                                    | <b>Default Value</b>     |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| Cache-control header              | sent by the cache the first time.<br>You can enable caching of dynamic objects in the user agent by replacing the Cache-Control headers that are inserted by the origin server. You must configure the new Cache-Control header to be inserted in the content group.                  | NONE                     |
| Quick abort size                  | If the size of an object that is being downloaded is less than or equal to the quick abort value, and a client aborts during the download, the cache stops downloading the response. If the object is larger than the quick abort size, the cache continues to download the response. | 4194303 KBytes (maximum) |
| Minimum Response Size             | You can control memory use by setting a minimum response size. Cached objects must be larger than the minimum response size.                                                                                                                                                          | 0 KBytes                 |
| Maximum Response Size             | You can control memory use by setting a maximum response size. Cached objects must be smaller than the maximum response size.                                                                                                                                                         | 80 KBytes                |
| Memory usage limit                | Sets the maximum amount of memory that the cache can use. The effective limit is based on the available memory of the NetScaler appliance. The minimum value is 0 and the maximum value is unlimited.                                                                                 | UNLIMITED                |
| Ignore caching headers in request | Disregards Cache-Control and Pragma headers in HTTP requests.                                                                                                                                                                                                                         | YES                      |
| MinHits configured                | Number of hits that are required to qualify a response for storage in this content group.                                                                                                                                                                                             | 0                        |
| Always evaluate policies          |                                                                                                                                                                                                                                                                                       | NO                       |
| Pinned                            | By default, when the cache is full the NetScaler appliance replaces the least recently used response first. The NetScaler appliance does not apply this behavior to content groups that are marked as pinned.                                                                         | NO                       |
| Lazy DNS resolution               | If set to YES, DNS resolution is performed for responses only if the destination IP address in the request does not match the destination IP address of the cached response.                                                                                                          | YES                      |

# Troubleshooting

Jul 22, 2013

If the integrated cache feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

## Resources for Troubleshooting

Updated: 2013-07-22

For best results, use the following resources to troubleshoot an integrated cache issue on a NetScaler appliance:

- The relevant trace files
- The ns.conf file
- The RFC 2616 document
- A copy of the object, if possible

In addition to the above resources, the following tools expedite troubleshooting:

- The iehttpheaders or a similar utility
- The Wireshark application customized for the NetScaler trace files

## Troubleshooting Integrated Caching Issues

Updated: 2013-08-02

The following are effective steps to troubleshoot the objects that are not cached:

### 1. **Verify that the Integrated Caching feature is enabled.**

Run the following command to verify the feature is enabled:

```
show ns feature
```

Following is sample output of the above command:

```
show ns feature
```

```
Feature status:
```

```
 Web Logging: OFF
 Surge Protection: OFF
 Load Balancing: ON
 Content Switching: ON
 Cache Redirection: OFF
 Sure Connect: OFF
 Compression Control: OFF
 Priority Queuing: OFF
 SSL Offloading: OFF
 Global Server Load Balancing: OFF
 Http DoS Protection: OFF
 Dynamic Routing: OFF
 Content Filtering: OFF
 Integrated Caching: ON
 SSL VPN: OFF
```

```
OSPF Routing: OFF
RIP Routing: OFF
BGP Routing: OFF
```

Done

The entry highlighted in boldface (for reference) in the above output indicates that the integrated caching feature is enabled. If the feature is not enabled, run the following command to enable it:

### **enable ns feature IC**

## 2. **Make sure that sufficient memory is available on the NetScaler appliance.**

Depending on the size of the object to be cached, memory available to store the cacheable object might be insufficient. You can set the memory limit for the integrated cache either globally or for individual content groups.

Run the following command to verify the memory allocated to integrated cache globally:

```
show cache parameter
```

Following is sample output of the above command:

```
show cache parameter
 Integrated cache global configuration:
 Memory usage limit: 256 MBytes
 Via header: NS-CACHE-6.1: 101
 Verify cached object using: HOSTNAME_AND_IP
 Max POST body size to accumulate: 32768
 Current outstanding prefetches: 0
 Max outstanding prefetches: 4294967294
 Treat NOCACHE policies as BYPASS policies: YES
```

Done

The entry highlighted in boldface (for reference) in the preceding output indicates the amount of memory allocated to the integrated cache globally.

Run the following command to verify the memory allocated to an individual content group:

```
show cache contentGroup <Content_Group_Name>
```

Following is sample output of the above command:

```
show cache contentgroup content1
 Name: content1
 Heuristic expiry time parameter: 10 percent
 Weak relative expiry time - Positive responses: 3600 secs
 Weak relative expiry time - Negative responses: 600 secs
 Hit parameters: NONE
 Invalidation Parameters: NONE
 Invalidation restricted to host: NO
 Ignore parameter value case: NO
 Match Request Cookies: NO
 Poll Every Time: NO
 Ignore reload request: YES
```

Remove Response Cookies: YES  
Prefetch: YES  
Prefetch period: heuristic  
Current outstanding prefetches: 0  
Max outstanding prefetches: 4294967294  
Flashcache: NO  
Expire at last byte: NO  
Insert Via header: YES  
Insert Age header: YES  
Insert ETag header: YES  
Cache-control header: NONE  
Quick abort size: 4194303 KBytes (MAXIMUM)  
Minimum Response Size: 0 KBytes  
Maximum Response Size: 80 KBytes  
Memory usage: 0 Bytes  
Memory usage limit: 64 MBytes  
Ignore caching headers in request: YES  
Non-304 hits: 0  
304 hits: 0  
Cached objects: 0  
Number of times expired/flushed: 1  
MinHits configured: 0  
Always evaluate policies: NO  
Pinned: NO

Done

The entry highlighted in boldface (for reference) in the above output indicates the amount of memory allocated to the content group.

### 3. **Verify that cacheable object is small enough to be stored within the configured memory limits.**

Complete the following procedure to make space for the object to be cached:

- Run the following command to flush the cache for the content group to which the object belongs:  
flush cache contentGroup <Content\_Group\_Name>
- Verify that the object is cached. If the object is cached successfully, increase the memory allocated for the content group. Otherwise, run the following command to flush the cache globally:  
flush cache contentGroup ALL
- Verify that the object is cached. If the object is cached successfully, consider increasing the global memory limit. If the object is still not cached, something else is causing the failure to cache the object.

The memory allocated to the integrated cache depends on the NetScaler appliance model. You can allocate approximately half the available memory to the integrated cache. Similarly, the maximum amount of memory you can allocate for a content group cannot be more than the memory allocated for global cache.

To increase the global memory limit for the integrated cache, run the following command:

```
set cache parameter -memLimit <Integer>
```

To increase the memory limit for a content group, run the following command:

```
set cache contentgroup <contentgroup name> -memLimit <Integer>
```

4. **Verify that the cache policy is bound to an appropriate bind point, an appropriate priority is set for the policy, and an appropriate precedeDefRules switch is configured.**

You must activate a caching policy by binding it globally. To verify that the policy is active, run the following command:

```
show cache global
```

Following is sample output of the above command:

```
show cache global
```

```
1) Name: red_pol State: ACTIVE Priority: 1
 Rule: URL CONTAINS red
 Action: NOCACHE
 Precede default HTTP rules: YES
 Hits : 10
```

```
Done
```

In the output, verify the following settings:

- **The policy is bound:** The output should contain all the active cache policies. If the cache policy for the object to be cached is not listed in the output, the policy is not yet bound. Run the following command to bind the policy globally: `bind cache global <Policy_Name> -priority <Integer> [-precedeDefRules YES|NO]`
- **The policy is Active:** If the policy is bound, verify that the state of the policy is displayed as Active. The entry indicating that the policy in the preceding output is active is the first highlighted entry in the sample output of the `show cache global` command, above. The policy is active if it is bound globally and an appropriate priority is set. Otherwise, the status of the policy is showed as Passive.
- **An appropriate priority is assigned to the policy:** The first highlighted entry in the sample output above displays the priority of the policy. If the priority is not set, you can use the `bind` command to set the priority of the policy. Note that the higher the priority number, the lower the priority. The priority assigned to the policy enables the NetScaler appliance to determine the order in which the policy should be evaluated. If evaluation of a particular policy fails, increase the priority of the policy so that it is evaluated before other policies. Caching policies, due to their high granularity, can be very complicated to configure. Therefore, two policies might be contradictory. As a result, only the higher-priority policy takes effect.
- **The precedeDefRules switch setting is correct:** The second highlighted entry in the sample output of the `show cache global` command, above, indicates the `precedeDefRules` switch setting. This setting enables the NetScaler appliance to determine whether the policy should be evaluated before the default built-in policies, which implement the standard HTTP caching behavior, such as basing caching decisions on HTTP header fields (for example, the `If-Modified-Since` and `no-cache` fields). You can set this switch when binding the policy. For certain types of HTTP(S) transactions, you might have to make sure that the policy precedes default HTTP rules, to force objects to be cached. Especially if requests include header fields, such as `If-Modified-Since`, or responses contain the `No-Cache` header field, you might have to make sure that the cache policy overrides the default in order for objects from these transactions to be cached. Force the policy to override default HTTP rules by rebinding the cache policy with the `-precedeDefRules YES` switch.

5. **Verify the size of the object to be cached.**

You can configure a content group with minimum, which by default is 0 KB, and maximum, which by default is 80 KB, response sizes for the objects to be cached. The object does not get cached if its size is not within the configured range. Additionally, verify that the cache expiry times are set to an appropriate value. For example, check for a very small

time limit, such as one second.

Run the following command from the command line interface of the appliance to display the size limits and expiry times for a specific content group:

```
show cache contentGroup <Content_Group_Name>
```

Following is an example of this command's output:

```
show cache contentGroup content1
 Name: content1
 Heuristic expiry time parameter: 10 percent
 Weak relative expiry time - Positive responses: 3600 secs
 Weak relative expiry time - Negative responses: 600 secs
 Hit parameters: NONE
 Invalidation Parameters: NONE
 Invalidation restricted to host: NO
 Ignore parameter value case: NO
 Match Request Cookies: NO
 Poll Every Time: NO
 Ignore reload request: YES
 Remove Response Cookies: YES
 Prefetch: YES
 Prefetch period: heuristic
 Current outstanding prefetches: 0
 Max outstanding prefetches: 4294967294
 Flashcache: NO
 Expire at last byte: NO
 Insert Via header: YES
 Insert Age header: YES
 Insert ETag header: YES
 Cache-control header: NONE
 Quick abort size: 4194303 KBytes (MAXIMUM)
 Minimum Response Size: 0 KBytes
 Maximum Response Size: 80 KBytes
 Memory usage: 0 Bytes
 Memory usage limit: UNLIMITED
 Ignore caching headers in request: YES
 Non-304 hits: 0
 304 hits: 0
 Cached objects: 0
 Number of times expired/flushed: 0
 MinHits configured: 0
 Always evaluate policies: NO
 Pinned: NO
Done
```

In addition to the above steps for troubleshooting integrated caching issues, you can consider using the following troubleshooting techniques:

- Depending on the configuration of a policy, there are virtually an unlimited number of reasons for the policy not getting evaluated. If you have completed the preceding steps to troubleshoot the issue, consider completing the following procedure to troubleshoot the issue further:
  1. Flush the cache.
  2. Verify the value of the hit parameter for the policy by running the following command:

```
show cache global
```

    - 1) Name: home\_pol\_1    State: ACTIVE    Priority: 99  
Rule: URL CONTAINS home  
Action: NOCACHE  
Precede default HTTP rules: NO  
Hits : 29
  3. Send an HTTP request for the related object from a Web browser.
  4. Run the show cache global command again and verify that the value for the hit parameter has incremented. Depending on the policy receiving hits or not, you can determine whether the issue is due to the policy have not been configured correctly or to a more global cache setting.

# Front End Optimization

May 11, 2015

Note: Front end optimization is available if you have an Enterprise or Platinum NetScaler license and are running NetScaler release 10.5 or later.

The HTTP protocols that underlie web applications were originally developed to support transmission and rendering of simple web pages. New technologies such as JavaScript and cascading style sheets (CSS), and new media types such as Flash videos and graphics-rich images, place heavy demands on front-end performance, that is, on performance at the browser level.

The NetScaler front end optimization (FEO) feature addresses such issues and reduces the load time and render time of web pages by:

- Reducing the number of requests required for rendering each page.
- Reducing the number of bytes in page responses.
- Simplifying and optimizing the content served to the client browser.

You can customize your FEO configuration to provide the best results for your users. NetScaler ADCs support numerous web content optimizations for both desktop and mobile users. The following tables describe the front-end optimizations provided by the FEO feature, and the operations performed on different types of files.

## Optimizations Performed by the FEO Feature

| Web Optimization    | Problem                                                                                                                                                                                         | What NetScaler FEO feature does                                         | Benefits                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Inlining</b>     | Client browsers often send multiple requests to servers for loading external CSS, images, and JavaScript associated with the web page.                                                          | CSS inline<br>JavaScript inline<br>CSS combine                          | Loading the external CSS, images, and JavaScript inline with the HTML files improves page-rendering time. This optimization is beneficial for content that will be viewed only once, and for mobile devices that have limited cache sizes. |
| <b>Minification</b> | Data fetched from servers includes inessential characters such as white spaces, comments, and newline characters. The time that browsers spend in processing such data creates website latency. | CSS minification<br>JavaScript minification<br>Removal of HTML comments | Minified files consume less bandwidth and avoid the latency caused by special processing.                                                                                                                                                  |

| Image optimization           | Problem                                                                                                                                                                                                                | What NetScaler does                                                                | Benefits                                                                                                                                    |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
|                              | Mobile browsers often have slow connection speeds and limited cache memory. Downloading images on mobile clients consumes more bandwidth, processing time, and cache space, resulting in web site latency.             | Image shrink-to attributes<br><br>GIF to PNG conversion<br><br>HTML image inlining | Reduces the image to the size indicated in image tag by NetScaler, enabling client browsers to load images faster.                          |
| <b>Repositioning</b>         | Inefficient processing of external CSS, images, and JavaScript increases page-load time.                                                                                                                               | Image lazy loading<br><br>CSS move to Head<br><br>JavaScript move to end           | Repositions HTML elements, to reduce rendering time for web pages and enable client browsers to load the objects faster.                    |
| <b>Connection Management</b> | Many browsers set limits on the number of simultaneous connections that can be established to a single domain. This can cause browsers to download webpage resources one at a time, resulting in higher browsers time. | Domain sharding<br><br>CSS import to link                                          | Overcomes the connection limitation, which improves page-rendering time by enabling client browsers to download more resources in parallel. |

### Web Optimizations performed on different file types

The following table lists the web optimizations that the NetScaler ADC performs on CSS, Images, JavaScript, and HTML:

| Object | Optimization                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CSS    | <ul style="list-style-type: none"> <li>• Minify <sup>*</sup> linked CSS files.</li> <li>• Combine multiple linked CSS files that are present within the &lt;head&gt; tag into a single CSS file.</li> <li>• Convert linked CSS files to inline CSS files.</li> <li>• Convert CSS import rule to linked CSS.</li> </ul> <p>Note: This optimization works if you have not defined the scope and media attributes for the &lt;import&gt; tag and when the &lt;import&gt; tag immediately follows the &lt;style&gt; tag.</p> <ul style="list-style-type: none"> <li>• Within a linked CSS file, convert linked images to inline images.</li> <li>• Move a CSS present within the &lt;body&gt; tag of an HTML page to the &lt;head&gt; tag.</li> </ul> |

| Object     | Optimization                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Images     | <p>Note: The &lt;head&gt; tag must already be present within the HTML script.</p> <ul style="list-style-type: none"> <li>• Optimize JPEG images by removing extraneous bytes.</li> <li>• Reduce image size by weakening the image quality to a value specified in FEO parameters.</li> <li>• Image shrink to attributes.</li> <li>• Convert linked images to inline images.<br/>Note: For animated images in GIF format, only this optimization is supported.</li> <li>• Convert non-animated images in GIF format to PNG format.</li> <li>• Reduce the image size to that specified on the web page, if the size specified on the web page is smaller</li> <li>• Convert images in GIF, PNG, JPEG format to WebP format</li> <li>• Convert images in JPEG format to JPER-XR format</li> <li>• Lazy loading.</li> </ul> |
| JavaScript | <ul style="list-style-type: none"> <li>• Minify* linked JavaScript</li> <li>• Convert linked JavaScript to inline JavaScript.</li> <li>• Move JavaScript present in the &lt;body&gt; tag to the end of the &lt;body&gt; tag.<br/>Note: The size of the &lt;body&gt; tag must be lesser than 64 Kbytes.</li> <li>• Extend cache expiry period.**</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Note: The front end optimization feature supports ASCII characters only. It does not support the unicode character set.  
**How Front End Optimization Works**

After the NetScaler ADC receives the response from the server:

1. Parses the contents of the page, creates an entry in the cache (wherever applicable), and applies the FEO policy.  
 For example, a NetScaler ADC can apply the following optimization rules:
  - Remove white spaces or comments present within a CSS or JavaScript.
  - Combine one or more CSS files to one file.
  - Convert GIF image format to PNG format.
2. Rewrites the embedded objects and saves the optimized content in the cache, with a different signature than the one used for the initial cache entry.
3. For subsequent requests, fetches the optimized objects from the cache, not from the server, and forwards the responses to the client.

\*

Remove extraneous information such as white spaces and comments.

\*

Remove extraneous information such as white spaces and comments.

\*\*

The period during which the browser can use the cached resource without checking to see if fresh content is available on the server.

# Configuring Front End Optimization

Aug 25, 2016

Optionally, you can change the values of the front end optimization global settings. Otherwise, begin by creating actions that specify the optimization rules to be applied to the embedded objects.

After configuring actions, create policies, each with a rule specifying a type of request for which to optimize the response, and associate the actions with the policies.

**Note:** The NetScaler ADC evaluates front end optimization policies at request time only, not at response time.

To put the policies into effect, bind them to bind points. You can bind a policy globally, so that it applies to all traffic that flows through the NetScaler ADC, or you can bind the policy to a load balancing or content switching virtual server of type HTTP or SSL. When you bind a policy, assign it a priority. A lower priority number indicates a higher value. The NetScaler ADC applies the policies in the order of their priorities.

## Prerequisites for Front End Optimization

Front end optimization requires the NetScaler integrated caching feature to be enabled. Additionally, you must perform the following integrated caching configurations:

- Allocate cache memory.
- Set the maximum response size and memory limit for a default cache content group.

For more information on configuring integrated caching, see [Integrated Caching](#).

**Note:** The term Integrated Cache can be interchangeably used with AppCache; note that from a functionality point of view, both terms mean the same.

## To configure front end optimization by using the command line interface

At the command prompt, do the following:

1. Enable the front end optimization feature.  
`enable ns feature FEO`
2. Create one or more front end optimization actions.  
`add feo action <name> [-imgShrinkToAttrib] [-imgGifToPng] ...`

**Example:** To add a front end optimization action for converting images in GIF format to PNG format and to extend cache expiry period:

```
add feo action allact -imgGifToPng -pageExtendCache
```

3. [Optional] Specify non-default values for front end optimization global settings.  
`set feo parameter [-cacheMaxage <integer>] [-jpegQualityPercent <integer>] [-cssInlineThresSize <integer>] [-inlineJsThresSize <integer>] [-inlineImgThresSize <integer>]`

**Example:** To specify the cache maximum expiry period:

```
set feo parameter -cacheMaxage 10
```

4. Create one or more front end optimization policy.  
`add feo policy <name> <rule> <action>`

**Example:** To add a front end optimization policy and associate it with the above specified *allact* action:

```
>add feo policy pol1 TRUE allact
```

```
>add feo policy pol1 "(HTTP.REQ.URL.CONTAINS(\"testsite\"))" allact1
```

5. Bind the policy to a load balancing or content switching virtual server, or bind it globally.  
`bind lb vserver <name> -policyName <string> -priority <num>`

```
bind cs vserver <name> -policyName <string> -priority <num>
```

```
bind feo global <policyName> <priority> -type <type> <gotoPriorityExpression>
```

**Example:** To apply the front end optimization policy to a virtual server named "abc":

```
> bind lb vserver abc -policyName pol1 -priority 1 -type NONE
```

**Example:** To apply the front end optimization policy for all the traffic reaching the ADC:

```
> bind feo global pol1 100 -type REQ_DEFAULT
```

6. Save the configuration.

```
save ns config
```

## Configuring front end optimization by using the configuration utility

1. Enable the front end optimization feature using the command line interface.

2. Create a front end optimization action.

Navigate to Optimization > Front End Optimization > Actions, click Add and create a front end optimization action by specifying the relevant details.

3. [Optional] Specify the front end optimization global settings.

Navigate to Optimization > Front End Optimization, and on the right-pane, under Settings, click Change Front End Optimization settings and specify the front end optimization global settings.

4. Create a front end optimization policy.

Navigate to Optimization > Front End Optimization > Policies, click Add and create a front end optimization policy by specifying the relevant details.

5. Bind the policy to a load balancing or content switching virtual server.

1. Navigate to Optimization > Front End Optimization > Policies.

2. Select a front end optimization policy and click Policy Manager.

3. Under Front End Optimzation Policy Manager, bind the front end optimization policy to a load balancing or content switching virtual server.

## Verifying Front End Optimization Configuration

Updated: 2015-01-12

The dashboard utility displays summary and detailed statistics in tabular and graphic formats. You can view the FEO statistics to evaluate your FEO configuration.

Optionally, you can also display statistics for an FEO policy, including the number of hits that the policy counter increments during policy based FEO.

Note: For more information about statistics and charts, see the Dashboard help on the Citrix NetScaler appliance.

## To View FEO statistics by using the command line interface

At the command prompt, type the following commands to display a summary of FEO statistics, FEO policy hits and details, and detailed FEO statistics, respectively:

- stat feo

Note: The **stat feo policy** command displays statistics only for advanced FEO policies.

- show feo policy <name>
- stat feo -detail

## To view FEO statistics on the Dashboard

In the Dashboard utility, you can:

- Select **Front End Optimization** to display a summary of FEO statistics.
- Click the **Graphical View** tab to display the rate of requests processed by the FEO feature.

# Sample Optimization

Apr 22, 2014

The following table lists some examples of content optimization actions that are applied on HTML content and the embedded objects within the HTML content.

| Optimization rule                         | Sample                                                                                                                                                                                                                            |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Collapse white spaces within an HTML page | Before:<br><title>Hello,  world! </title>                                                                                                                                                                                         |
|                                           | After:<br><title>Hello, world!</title>                                                                                                                                                                                            |
| Combine CSS                               | Before:<br><link rel="stylesheet" type="text/css" href="sheet/abc.css"><br><link rel="stylesheet" type="text/css" href="sheet/xyz.css">                                                                                           |
|                                           | After:<br><link rel="stylesheet" type="text/css" href="sheet/abc.css+xyz.css">                                                                                                                                                    |
| Inline CSS                                | Before<br><html><br><head><br><link rel="sheet" href="abc.css"/><br></head><br><body><br><div class="abc xyz"/><br>Hi!<br></body><br></html><br>Note: abc.css contains<br>.Alice {location: Australia;}<br>.Tom {location: Asia;} |
|                                           | After<br><html><br><head><br><style><br>.Alice {location: Australia;}<br>.Tom {location: Asia;}<br></style><br></head><br><body><br><div class="abc xyz"><br>Hi!<br></div>                                                        |

| Optimization rule                              | Sample<br></body><br></html>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

# Content Accelerator

Nov 27, 2015

## Important

The content accelerator feature is no longer supported on the NetScaler appliance.

Content accelerator is a NetScaler feature that you can use in a Citrix ByteMobile T1100 deployment, to store data on a Citrix ByteMobile T2100 appliance. For more information about Citrix ByteMobile, see [How ByteMobile Works](#).

Storing data on a T2100 appliance saves bandwidth and provides faster response times, because the NetScaler does not have to connect to the server for repeated requests of the same data.

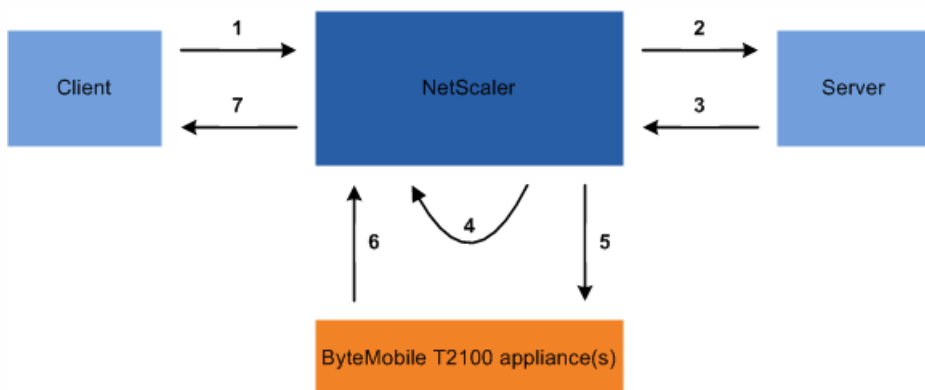

Note: Content accelerator works with a Citrix ByteMobile platinum license. Contact customer support for more information and for obtaining the license.

### How Content Accelerator Works

When a load balancing or content switching virtual server receives a client request, the NetScaler appliance evaluates a content accelerator policy that you have bound to the virtual server. The policy filters the requests to identify the ones to which to apply the content accelerator feature.

Note: For HTTP requests, the content accelerator feature can serve partial content in response to single byte-range requests.

The following figure illustrates the operations that the appliance performs when a client request arrives at a virtual server configured to use the content accelerator feature:

The process flow is as follows:

1. Client sends request.
2. NetScaler forwards the request to the server.
3. Server responds with the predefined size of the response (specified by the `accumResSize` parameter of the `add ca` action command).
4. NetScaler computes a hash of the response sent by the server.
5. NetScaler looks up the hash on the T2100 appliance.

6. A successful lookup indicates that the data is available and the T2100 appliance sends the data to the NetScaler.

Note:

- When a lookup does not succeed, the NetScaler fetches all of the requested data from the server, and simultaneously serves the data to the client and updates the data on the T2100 appliance.
- The T2100 appliance can be configured to specify the number of requests after which to cache the data.

7. NetScaler sends the response to the client.

## Configuring Content Accelerator

Before configuring the content accelerator feature, you must enable it on the NetScaler appliance.

You can configure the content accelerator feature to use one or multiple T2100 appliances. You must add each T2100 appliance as a service and bind these services to a load balancing virtual server that is dedicated to distributing the load between the configured T2100 appliances.

You must also configure a content accelerator action to lookup the data on the T2100 appliance. The action must also specify the T2100 load balancing virtual server and the size of data (in KB) to be fetched from the server to calculate the hash.

The action must be bound to a content accelerator policy that defines the traffic on which to perform content acceleration. The content accelerator policy must be bound to a content switching or load balancing virtual server that receives client traffic. Alternatively, you can bind the policy globally to be applicable to all virtual servers.

## Configuring content accelerator by using the command line interface

At the command prompt, do the following:

1. Enable the content accelerator feature.  
`enable ns feature ca`
2. Identify the T2100 appliances and add each as a service on the NetScaler appliance.  
`add service <name> <IPAddress> <serviceType> <port>`

### Example:

```
> add service T2100-A 10.102.29.61 HTTP 30
```

```
> add service T2100-B 10.102.29.62 HTTP 40
```

```
> add service T2100-C 10.102.29.63 HTTP 50
```

Note: The services must be of type HTTP only.

3. Create a load balancing virtual server for the T2100 appliances. Specify the token load balancing method and the rule shown in the following syntax.  
`add lb vserver <name> <serviceType> <IPAddress> <port> -lbMethod TOKEN -rule "http.req.url.after_str(\"/lookup/\") alt http.req.url.path.SKIP(1).PREFIX(64)"`

### Example:

```
> add lb vserver T2100-lbvserver HTTP 10.102.29.64 99 -lbMethod TOKEN -rule "http.req.url.after_str(\"/lookup/\") alt http.req.url.path.SKIP(1).PREFIX(64)"
```

4. Bind the T2100 services to the load balancing virtual server that you created for them.  
`bind lb vserver <name> <serviceName>`

**Example:**

```
> bind lb vserver T2100-lbvserver T2100-A
> bind lb vserver T2100-lbvserver T2100-B
> bind lb vserver T2100-lbvserver T2100-C
```

5. Define a content accelerator action.

```
add ca action <name> -accumResSize <KBytes> -lbvserver <string> -type lookup
```

**Example:**

```
> add ca action ca_action1 -type lookup -lbvserver T2100-lbvserver -accumResSize 60
```

6. Define a content accelerator policy.

```
add ca policy <name> -rule <expression> -action <name>
```

**Example:** To create a content accelerator policy that caches all video formats.

```
> add ca policy ca_mp4_pol -rule ns_video -action ca_action1
where ns_video is a built-in expression.
```

7. Bind the content accelerator policy to either a virtual server that receives traffic or globally to the NetScaler system.

```
bind lb vserver <name> -policyName <string>
```

```
bind cs vserver <name> -policyName <string>
```

```
bind ca global -policyName <string> -priority <num> -type <type>
```

**Example:** To apply the content accelerator policy to a virtual server named "traf\_rec"

```
> bind lb vserver traf_rec -policyName ca_mp4_pol
```

**Example:** To apply the content accelerator policy for all traffic reaching the NetScaler.

```
> bind ca global -policyName ca_mp4_pol -priority 100 -type RES_DEFAULT
```

8. Save the configuration.

```
save ns config
```

## Configuring content accelerator by using the configuration utility

1. Navigate to System > Settings > Configure Advanced Features and select Content Accelerator.
2. Create a service for each of the T2100 appliances.
  1. Navigate to Traffic Management > Load Balancing > Services.
  2. Click Add and specify the relevant details. In the Server field, make sure you specify the IP address of the T2100 appliance. In the Protocol field select HTTP.
3. Create a virtual server and bind the T2100 services to it.
  1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
  2. Click Add and specify the relevant details.
  3. In the Method and Persistence tab, specify the Method as Token.
  4. In the Policies tab, specify the rule as `http.req.url.after_str("/lookup/") alt http.req.url.path.SKIP(1).PREFIX(64)`.
  5. In the Services tab, select the T2100 services that you want to bind to the virtual server.
4. Create a content accelerator action.
  1. Navigate to Optimization > Content Accelerator > Actions.
  2. Specify the relevant details.
5. Create a content accelerator policy.
  1. Navigate to Optimization > Content Accelerator > Policies.
  2. Click Add, specify the policy rule, and associate the content accelerator action.

6. Bind the content accelerator policy globally or to a virtual server.
  1. Navigate to Optimization > Content Accelerator.
  2. Under the Content Accelerator Policy Manager [REQUEST] or Content Accelerator Policy Manager [RESPONSE] sections, bind the content accelerator policy globally or to a virtual server.

# SPDY (Speedy)

May 20, 2015

Note: Supported from NetScaler 10.1 onwards.

SPDY is an open networking experimental protocol developed by Google to reduce the time taken by a client to load a web page in a browser. An application layer protocol, SPDY changes the way in which HTTP requests and responses are handled. SPDY offers the following advantages compared to a regular HTTP transaction:

- Multiplexed requests and responses—In a single SPDY session, multiple requests from the client can be sent over a single TCP connection to the server. This reduces the number of TCP connections and also optimizes usage of each TCP connection.
- Request prioritization—When requesting services from the server, a client can assign a priority to each request.
- Header Compression—SPDY compresses the HTTP request and response headers, saving bandwidth and reducing latency.
- Server push—The server can send data to the client before the client requests it.
- Security—SPDY is secure by design, because SSL is required for SPDY connections.

NetScaler supports the SPDY/2 and SPDY/3 (from NetScaler 10.5 onwards) versions.

Note: SPDY support depends on the browser version being used.

If you use a NetScaler appliance as a SPDY gateway for your servers, the servers do not have to support SPDY. The NetScaler appliance accepts the incoming SPDY requests, converts them, and sends them to the servers as HTTP requests. It also converts the HTTP responses and sends them to the clients as SPDY responses. While the key value of SPDY is reduced bandwidth consumption and faster communication with clients, an additional benefit of the NetScaler solution is that you avoid the time consuming task of upgrading your web servers and applications to support SPDY.

To use a NetScaler appliance as a SPDY gateway, you must enable SPDY on the appliance.

This document includes the following details:

- [SPDY Requirements](#)
- [How SPDY Works over SSL](#)
- [Configuring SPDY on the NetScaler Appliance](#)
- [Troubleshooting for SPDY](#)

## SPDY Requirements

Both ends of a SPDY connection must support the same version of SPDY. In addition, the clients must meet the following requirements:

- Support ZLIB compression and accept compressed data.
- Support the Next Protocol Negotiation (NPN) TLS extension, because NPN is used in the TLS handshake.

## How SPDY Works over SSL

Updated: 2014-03-13

If SPDY is enabled, when the NetScaler appliance sees TLS ALPN extension with list of supported protocols in the Client Hello message, it responds with either SPDY/3 or SPDY/2 in the ALPN extension in its Server Hello.

NetScaler can also negotiate SPDY over NPN. When NetScaler sees an empty NPN extension in the Client Hello message, it responds with a list of the protocols that it supports. If SPDY is enabled on the NetScaler appliance, the appliance

advertises HTTP/1.1 and SPDY/2 protocols. The client selects one protocol from this list and negotiates the protocol with the server. Because sending the negotiated protocol in plain text would raise security issues, the client sends the Change Cipher Spec notification which defines the details of the encryption for the session, followed by the Next Protocol message, which contains the encrypted protocol that the client has chosen. The client then sends the Finished message. The NetScaler appliance decrypts the Next Protocol message, and then sends a Finished message.

A session is then established, and application data can be exchanged.

Note: The NPN extension is not supported on a NetScaler FIPS appliance, and with TLS protocol versions 1.1 and 1.2.

## Configuring SPDY on the NetScaler Appliance

Updated: 2014-09-15

By default, SPDY is disabled on the NetScaler appliance. After you enable SPDY, the appliance advertises SPDY/2 and/or SPDY/3 along with HTTP/1.1 during an SSL handshake. To enable SPDY on the NetScaler appliance, you must enable SPDY in the HTTP profile bound to the SSL virtual server.

## To configure SPDY by using the command line interface

At the command prompt, do the following:

1. Enable SPDY on a HTTP profile.

```
set ns httpProfile <profileName> -SPDY <options>
```

### Example

```
> set ns httpProfile profile1 -SPDY ENABLED
```

2. Bind the HTTP profile to a SSL virtual server.

```
set lb vserver <ssl-vserver-name> -httpProfileName <httpProfile-with-spdy>
```

### Example

```
> set lb vserver SPDY_LB -httpProfileName profile1
```

Note: To apply SPDY globally, enable SPDY on the global HTTP profile (nshttp\_default\_profile).

You can view the statistics by using the following command:

```
stat protocol http -detail
```

## To configure SPDY by using the configuration utility

1. Navigate to System > Profiles, and in the HTTP Profiles tab, update the profile on which you want to enable SPDY.
2. Navigate to Traffic Management > Load Balancing > Virtual Servers, and associate the HTTP profile to the appropriate SSL virtual server.

## Troubleshooting for SPDY

If SPDY sessions are not enabled even after performing the required steps, check the following conditions.

- If the client is using a Chrome browser, SPDY might not work in some scenarios because Chrome sometimes does not initiate TLS handshake.
- If there is a forward-proxy between the client and the NetScaler appliance, and the forward-proxy doesn't support SPDY, SPDY sessions might not be enabled.
- NetScaler does not support NPN over TLS 1.1/1.2. To use SPDY, the client should disable TLS1.1/1.2 in the browser.

- Similarly, if the client wants to use SPDY, SSL2/3 must be disabled on the browser.

# Security

May 03, 2013

The following topics cover configuration and installation information for NetScaler security features. Most of these features are policy based.

|                                               |                                                                                                                                                                  |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Authentication, Authorization, Auditing (AAA) | Keeps unauthorized users out of the network, denies users access to tasks for which they are not authorized, and tracks the resources used during user sessions. |
| Application Firewall                          | Prevents security breaches, data loss, and possible unauthorized modifications to web sites that access sensitive business or customer information.              |
| Content Filtering                             | Blocks inappropriate HTML requests, preventing the requests from reaching the Web servers.                                                                       |
| HTTP Denial-of-Service Protection             | Prevents hackers from attacking your Web site with large numbers of HTTP requests.                                                                               |
| Priority Queuing                              | Detects high-priority connections and allows those connections to proceed ahead of other connections, guaranteeing unimpeded access to those users.              |
| SureConnect                                   | Serves all incoming connections with either the requested content or a custom Web page that displays information about a delay in the request being serviced.    |
| Surge Protection                              | Detects any rapid rise in connection attempts and adjusts the rate at which connections are allowed to proceed to the server, preventing server overload.        |

# AAA Application Traffic

Sep 18, 2013

Many companies restrict web site access to valid users only, and control the level of access permitted to each user. The AAA feature allows a site administrator to manage access controls with the NetScaler appliance instead of managing these controls separately for each application. Doing authentication on the appliance also permits sharing this information across all web sites within the same domain that are protected by the appliance.

The AAA feature supports authentication, authorization, and auditing for all application traffic. To use AAA, you must configure authentication virtual servers to handle the authentication process and traffic management virtual servers to handle the traffic to web applications that require authentication. You also configure your DNS to assign FQDNs to each virtual server. After configuring the virtual servers, you configure a user account for each user that will authenticate via the NetScaler appliance, and optionally you create groups and assign user accounts to groups. After creating user accounts and groups, you configure policies that tell the appliance how to authenticate users, which resources to allow users to access, and how to log user sessions. To put the policies into effect, you bind each policy globally, to a specific virtual server, or to the appropriate user accounts or groups. After configuring your policies, you customize user sessions by configuring session settings and binding your session policies to the traffic management virtual server. Finally, if your intranet uses client certs, you set up the client certificate configuration.

Before configuring AAA, you should be familiar with and understand how to configure load balancing, content switching, and SSL on the NetScaler appliance.

# How AAA Works

Oct 21, 2015

AAA provides security for a distributed internet environment by allowing any client with the proper credentials to connect securely to protected application servers from anywhere on the Internet. This feature incorporates the three security features of authentication, authorization, and auditing. Authentication enables the NetScaler ADC to verify the client's credentials, either locally or with a third-party authentication server, and allow only approved users to access protected servers. Authorization enables the ADC to verify which content on a protected server it should allow each user to access. Auditing enables the ADC to keep a record of each user's activity on a protected server.

To understand how AAA works in a distributed environment, consider an organization with an intranet that its employees access in the office, at home, and when traveling. The content on the intranet is confidential and requires secure access. Any user who wants to access the intranet must have a valid user name and password. To meet these requirements, the ADC does the following:

- Redirects the user to the login page if the user accesses the intranet without having logged in.
- Collects the user's credentials, delivers them to the authentication server, and caches them in a directory that is accessible through LDAP.
- Verifies that the user is authorized to access specific intranet content before delivering the user's request to the application server.
- Maintains a session timeout after which users must authenticate again to regain access to the intranet. (You can configure the timeout.)
- Logs the user accesses, including invalid login attempts, in an audit log.

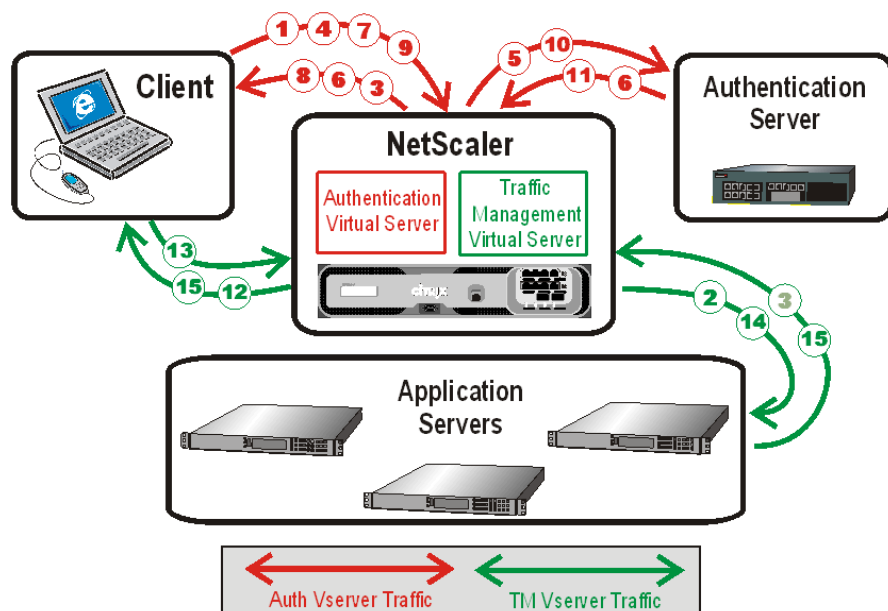

Authentication requires that several entities: the client, the NetScaler appliance, the external authentication server if one is used, and the application server, respond to each other when prompted by performing a complex series of tasks in the correct order. If you are using an external authentication server, this process can be broken down into the following fifteen steps.

1. The client sends a GET request for a URL on the application server.
2. The NetScaler appliance's traffic management virtual server redirects the request to the application server.
3. The application server determines that the client has not been authenticated, and therefore sends an HTTP 200 OK response via the TM vserver to the client. The response contains a hidden script that causes the client to issue a POST request for /cgi/tm.
4. The client sends a POST request for /cgi/tm.
5. The NetScaler appliance's authentication virtual server redirects the request to the authentication server.
6. The authentication server creates an authentication session, sets and caches a cookie that consists of the initial URL and the domain of the traffic management virtual server, and then sends an HTTP 302 response via the authentication virtual server, redirecting the client to /vpn/index.html.
7. The client sends a GET request for /vpn/index.html.
8. The authentication virtual server redirects the client to the authentication server login page.
9. The client sends a GET request for the login page, enters credentials, and then sends a POST request with the credentials back to the login page.
10. The authentication virtual server redirects the POST request to the authentication server.
11. If the credentials are correct, the authentication server tells the authentication virtual server to log the client in and redirect the client to the URL that was in the initial GET request.
12. The authentication virtual server logs the client in and sends an HTTP 302 response that redirects the client to the initially requested URL.

13. The client sends a GET request for their initial URL.
14. The traffic management virtual server redirects the GET request to the application server.
15. The application server responds via the traffic management virtual server with the initial URL.

If you use local authentication, the process is similar, but the authentication virtual server handles all authentication tasks instead of forwarding connections to an external authentication server. The following figure illustrates the authentication process.

Figure 1. Authentication Process Traffic Flow

When an authenticated client requests a resource, the ADC, before sending the request to the application server, checks the user and group policies associated with the client account, to verify that the client is authorized to access that resource. The ADC handles all authorization on protected application servers. You do not need to do any special configuration of your protected application servers.

AAA-TM handles password changes for users by using the protocol-specific method for the authentication server. For most protocols, neither the user nor the administrator needs to do anything different than they would without AAA-TM. Even when an LDAP authentication server is in use, and that server is part of a distributed network of LDAP servers with a single designated domain administration server, password changes are usually handled seamlessly. When an authenticated client of an LDAP server changes his or her password, the client sends a credential modify request to AAA-TM, which forwards it to the LDAP server. If the user's LDAP server is also the domain administration server, that server responds appropriately and AAA-TM then performs the requested password change. Otherwise, the LDAP server sends AAA-TM an LDAP\_REFERRAL response to the domain administration server. AAA-TM follows the referral to the indicated domain administration server, authenticates to that server, and performs the password change on that server.

When configuring AAA-TM with an LDAP authentication server, the system administrator must keep the following conditions and limitations in mind:

- AAA-TM assumes that the domain administration server in the referral accepts the same bind credentials as the original server.
- AAA-TM only follows LDAP referrals for password change operations. In other cases AAA-TM refuses to follow the referral.
- AAA-TM only follows one level of LDAP referrals. If the second LDAP server also returns a referral, AAA-TM refuses to

follow the second referral.

The ADC supports auditing of all states and status information, so you can see the details of what each user did while logged on, in chronological order. To provide this information, the appliance logs each event, as it occurs, either to a designated audit log file on the appliance or to a syslog server. Auditing requires configuring the appliance and any syslog server that you use.

# Enabling AAA

Oct 30, 2013

To use the AAA - Application Traffic feature, you must enable it. You can configure AAA entities—such as the authentication and traffic management virtual servers—before you enable the AAA feature, but the entities will not function until the feature is enabled.

To enable AAA by using the command line interface

At the command prompt, type the following commands to enable AAA and verify the configuration:

- enable ns feature AAA
- show ns feature

## Example

```
> enable feature AAA
```

```
Done
```

```
> show ns feature
```

|     | Feature          | Acronym       | Status    |
|-----|------------------|---------------|-----------|
|     | -----            | -----         | -----     |
| 1)  | Web Logging      | WL            | OFF       |
| 2)  | Surge Protection | SP            | ON        |
| .   |                  |               |           |
| .   |                  |               |           |
| .   |                  |               |           |
| 15) | <b>AAA</b>       | <b>AAA</b>    | <b>ON</b> |
| .   |                  |               |           |
| .   |                  |               |           |
| .   |                  |               |           |
| 23) | HTML Injection   | HTMLInjection | ON        |
| 24) | NetScaler Push   | push          | OFF       |

```
Done
```

To enable AAA by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Authentication, Authorization and Auditing check box.
4. Click OK.

# Setting up AAA Virtual Servers and DNS

Oct 30, 2015

To configure AAA, you first configure an authentication virtual server, which involves binding an SSL certificate-key pair. You then associate the authentication virtual server with a new or existing traffic management virtual server. (Either a load balancing virtual server or a content switching virtual server can serve as a traffic management virtual server.) To complete the initial configuration, you configure DNS to assign hostnames to both the authentication virtual server and the traffic management virtual server, and verify that your virtual servers are UP and configured correctly.

Caution: Both virtual servers must have hostnames in the same domain, or the AAA configuration will not work.

# Configuring the Authentication Virtual Server

Aug 13, 2014

To configure AAA, first configure an authentication virtual server to handle authentication traffic. Next, bind an SSL certificate-key pair to the virtual server to enable it to handle SSL connections. For additional information about configuring SSL and creating a certificate-key pair, see the *Citrix NetScaler Traffic Management Guide* at "[Traffic Management](#)."

To configure an authentication virtual server by using the command line interface

To configure an authentication virtual server and verify the configuration, at the command prompt type the following commands in the order shown:

- add authentication vserver <name> ssl <ipaddress>
- show authentication vserver <name>
- bind ssl certkey <certkeyName>
- show authentication vserver <name>
- set authentication vserver <name> -authenticationDomain <FQDN>
- show authentication vserver <name>

## Example

```
> add authentication vserver Auth-Vserver-2 SSL 10.102.29.77 443
Done
> show authentication vserver Auth-Vserver-2
Auth-Vserver-2 (10.102.29.77:443) - SSL Type: CONTENT
State: DOWN[Certkey not bound]
Client Idle Timeout: 180 sec
Down state flush: DISABLED
Disable Primary Vserver On Down : DISABLED
Authentication : ON
Current AAA Users: 0
Done
> bind ssl certkey Auth-Vserver-2 Auth-Cert-1
Done
> show authentication vserver Auth-Vserver-2
Auth-Vserver-2 (10.102.29.77:443) - SSL Type: CONTENT
State: UP
Client Idle Timeout: 180 sec
Down state flush: DISABLED
Disable Primary Vserver On Down : DISABLED
Authentication : ON
Current AAA Users: 0
Authentication Domain: myCompany.employee.com
Done
> set authentication vserver Auth-Vserver-2 -AuthenticationDomain myCompany.employee.com
Done
> show authentication vserver Auth-Vserver-2
Auth-Vserver-2 (10.102.29.77:443) - SSL Type: CONTENT
State: DOWN[Certkey not bound]
```

Client Idle Timeout: 180 sec  
Down state flush: DISABLED  
Disable Primary Vserver On Down : DISABLED  
Authentication : ON  
Current AAA Users: 0  
Authentication Domain: myCompany.employee.com

Done

## Important

The advantage of using advanced authentication policies configured on a traffic management virtual server helps you to authenticate and redirect the traffic to configured authorization server.

To configure an authentication virtual server by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Virtual Servers.
2. In the details pane, do one of the following:
  - To create a new authentication virtual server, click Add.
  - To modify an existing authentication virtual server, select the virtual server, and then click Edit.The Configuration dialog opens with the Basic Settings area expanded.
3. Specify values for the parameters as follows (asterisk indicates a required parameter):
  - Name\*—name (Cannot be changed for a previously created virtual server)
  - IP Address\*—ipaddress
  - Domain\*—authenticationDomain
  - Failed login timeout—failedLoginTimeout (Seconds allowed before login fails and user must start login process again.)
  - Max login attempts—maxLoginAttempts (Number of login attempts allowed before user is locked out)Note: The authentication virtual server uses only the SSL protocol and port 443, so those options are greyed out. Any options that are not mentioned are not relevant and should be ignored.
4. Click Continue to display the Certificates area.
5. In the Certificates area, configure any SSL certificates you want to use with this virtual server.
  - To configure a CA certificate, click the arrow on the right of CA Certificate to display the CA Cert Key dialog box, select the certificate you want to bind to this virtual server, and click Save.
  - To configure a server certificate, click the arrow on the right of Server Certificate, and follow the same process as for CA certificate.
6. Click Continue to display the Advanced Authentication Policies area.
7. If you want to bind an advanced authentication policy to the virtual server, click the arrow on the right side of the line to display the Authentication Policy dialog box, choose the policy that you want to bind to the server, set the priority, and then click OK.
8. Click Continue to display the Basic Authentication Policies area.
9. If you want to create a basic authentication policy and bind it to the virtual server, click the plus sign to display the Policies dialog box, and follow the prompts to configure the policy and bind it to this virtual server.
10. Click Continue to display the 401-Based Virtual Servers area.
11. In the 401-Based Virtual Servers area, configure any load balancing or content switching virtual servers that you want to bind to this virtual server.
  - To bind a load balancing virtual server, click the arrow to the right of LB virtual server to display the LB Virtual Servers dialog box, and follow the prompts.

- To bind a content switching virtual server, click the arrow to the right of CS virtual server to display the CS Virtual Servers dialog box, and follow the same process as to bind an LB virtual server.
12. If you want to create or configure a group, in the Groups area click the arrow to display the Groups dialog box, and follow the prompts.
  13. Review your settings, and when you are finished, click Done. The dialog box closes. If you created a new authentication virtual server, it now appears in the Configuration window list.

# Configuring a Traffic Management Virtual Server

Aug 19, 2014

After you have created and configured your authentication virtual server, you next create or configure a traffic management virtual server and associate your authentication virtual sever with it. You can use either a load balancing or content switching virtual server for a traffic management virtual server. For more information about creating and configuring either type of virtual server, see the *Citrix NetScaler Traffic Management Guide* at [Traffic Management](#).

Note: The FQDN of the traffic management virtual server must be in the same domain as the FQDN of the authentication virtual server for the domain session cookie to function correctly.

You configure a traffic management virtual server for AAA by enabling authentication and then assigning the FQDN of the authentication server to the traffic management virtual server. You can also configure the authentication domain on the traffic management virtual server at this time. If you do not configure this option, the NetScaler appliance assigns the traffic management virtual server an FQDN that consists of the FQDN of the authentication virtual server without the hostname portion. For example, if domain name of the authentication vserver is tm.xyz.bar.com, the appliance assigns xyz.bar.com. as the authentication domain.

To configure a TM virtual server for AAA by using the command line interface

At the command prompt, type one of the following sets of commands to configure a TM virtual server and verify the configuration:

- set lb vserver <name> -authentication ON -authenticationhost <FQDN> [-authenticationdomain <authdomain>]
- show lb vserver <name>
- set cs vserver <name> -authentication ON -authenticationhost <FQDN> [-authenticationdomain <authdomain>]
- show cs vserver <name>

## Example

```
> set lb vserver vs-cont-sw -Authentication ON -AuthenticationHost mywiki.index.com
```

```
Done
```

```
> show lb vserver vs-cont-sw
```

```
vs-cont-sw (0.0.0.0:0) - TCP Type: ADDRESS
State: DOWN
Last state change was at Wed Aug 19 10:03:15 2009 (+410 ms)
Time since last state change: 5 days, 20:00:40.290
Effective State: DOWN
Client Idle Timeout: 9000 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
No. of Bound Services : 0 (Total) 0 (Active)
Configured Method: LEASTCONNECTION
Mode: IP
Persistence: NONE
Connection Failover: DISABLED
Authentication: ON Host: mywiki.index.com
```

```
Done
```

To configure a TM virtual server for AAA by using the configuration utility

1. In the navigation pane, do one of the following.
  - Navigate to Traffic Management > Load Balancing > Virtual Servers.
  - Navigate to Traffic Management > Content Switching > Virtual ServersThe AAA configuration process for either type of virtual server is identical.
  - In the details pane, select the virtual server on which you want to enable authentication, and then click Edit.
  - In the Domain text box, type the authentication domain.
  - In the Advanced menu on the right, select Authentication.
  - Choose either Form Based Authentication or 401 Based Authentication., and fill in the Authentication information.
    - For Form Based Authentication, enter the Authentication FQDN (the fully-qualified domain name of the authentication server), the Authentication VServer (the IP address of the authentication virtual server), and the Authentication Profile (the profile to use for authentication).
    - For 401 Based Authentication, enter the Authentication VServer and the Authentication Profile only.
  - Click OK. A message appears in the status bar, stating that the vserver has been configured successfully.

# Configuring DNS

Sep 24, 2013

For the domain session cookie used in the authentication process to function correctly, you must configure DNS to assign both the authentication and the traffic management virtual servers to FQDNs in the same domain. For information about how to the configure DNS address records, see the *Citrix NetScalerTraffic Management Guide* at "[Traffic Management](#)"

# Verifying Your Setup for AAA

Sep 18, 2013

After you configure authentication and traffic management virtual servers and before you create user accounts, you should verify that both virtual servers are configured correctly and are in the UP state.

To verify authentication virtual server setup by using the command line interface

At the command prompt, type the following command:

```
show authentication vserver <name>
```

## Example

```
> show authentication vserver Auth-Vserver-2
Auth-Vserver-2 (10.102.29.77:443) - SSL Type: CONTENT
State: UP
Client Idle Timeout: 180 sec
Down state flush: DISABLED
Disable Primary Vserver On Down : DISABLED
Authentication : ON
Current AAA Users: 0
Authentication Domain: myCompany.employee.com
```

Done

To verify your AAA virtual server setup by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Virtual Servers.
2. Review the information in the AAA Virtual Servers pane to verify that your configuration is correct and your authentication virtual server is accepting traffic. You can select a specific virtual server to view detailed information in the details pane.

# Authentication Profile

Aug 13, 2014

An authentication profile specifies the authentication virtual server, authentication host, authentication domain, and authentication level in one location. You can then use the profile to configure authentication for different traffic management virtual servers that use the same authentication virtual server.

To configure an authentication profile by using the command line

To configure an authentication profile, bind that authentication profile to a traffic management virtual server, and verify the configuration, at the command prompt type the following commands:

- `add authentication authnProfile <name> {-authnVsName <string>} {-authenticationHost <string>} {-authenticationDomain <string>} [-authenticationLevel <positive_integer>]`
- `set lb vserver <vserverName> -authnProfile <authnProfileName>`
- `show authentication authnProfile <name>`
- `show authentication vserver <name>`

## Example

```
> add authentication authnProfile authProfile -authnVsName authVS
 -authenticationHost authnVS.example.com -authenticationDomain example.com
 -authenticationLevel 1
```

Done

To configure an authentication profile by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Authentication Profile.
2. In the details pane, do one of the following:
  - To create a new authentication profile, click Add.
  - To modify an existing authentication profile, select the profile, and then click Edit.
3. In the Create Authentication Profile or the Configure Authentication Profile dialog, fill in the fields as described below:
  - Name—Name for the authentication profile. Must begin with a letter, number, or the underscore character (`_`), and must contain only letters, numbers, and the hyphen (`-`), period (`.`) pound (`#`), space (), at (`@`), equals (`=`), colon (`:`), and underscore characters. Can be from 1 to 127 characters long. Cannot be changed for existing authentication profiles.
  - Authentication VServer Name—NetScaler name of the authentication virtual server to which this profile applies.
  - Authentication Host—Hostname of the authentication virtual server.
  - Authentication Domain—Domain of the authentication virtual server.
  - Authentication Level—How many authentication levels this authentication host performs.
4. Click Create or OK.

# Configuring Users and Groups

Aug 19, 2014

After configuring the AAA basic setup, you create users and groups. You first create a user account for each person who will authenticate via the NetScaler appliance. If you are using local authentication controlled by the NetScaler appliance itself, you create local user accounts and assign passwords to each of those accounts.

You also create user accounts on the NetScaler appliance if you are using an external authentication server. In this case, however, each user account must exactly match an account for that user on the external authentication server, and you do not assign passwords to the user accounts that you create on the NetScaler. The external authentication server manages the passwords for users that authenticate with the external authentication server.

If you are using an external authentication server, you can still create local user accounts on the NetScaler appliance if, for example, you want to allow temporary users (such as visitors) to log in but do not want to create entries for those users on the authentication server. You assign a password to each local user account, just as you would if you were using local authentication for all user accounts.

Each user account must be bound to policies for authentication and authorization. To simplify this task, you can create one or more groups and assign user accounts to them. You can then bind policies to groups instead of individual user accounts.

To create a local AAA user account by using the command line interface

At the command prompt, type the following commands to create a local AAA user account and verify the configuration:

- add aaa user <username> [-password <password>]
- show aaa user

## Example

```
> add aaa user user-2 -password emptybag
```

```
Done
```

```
> show aaa user
```

- 1) UserName: user-1
- 2) **UserName: user-2**

```
Done
```

To change the password for an existing AAA local user account by using the command line interface

At the command prompt, type the following command and, when prompted, type the new password:

```
set aaa user <username>
```

## Example

```
> set aaa user user-2
```

```
Enter password:
```

```
Done
```

To configure AAA local users by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Users
2. In the details pane, do one of the following:
  - To create a new user account, click Add.
  - To modify an existing user account, select the user account, and then click Open.

3. In the Create AAA User dialog box, in the User Name text box, type a name for the user.
4. If creating a locally authenticated user account, clear the External Authentication check box and provide a local password that the user will use to log on.
5. Click Create or OK, and then click Close. A message appears in the status bar, stating that the user has been configured successfully.

To create AAA local groups and add users to them by using the command line interface

At the command prompt, type the following commands. Type the first command one time, and type the second command once for each user:

- add aaa group <groupname>
- show aaa group

**Example**

```
> add aaa group group-2
```

```
Done
```

```
> show aaa group
```

```
1) GroupName: group-1
```

```
2) GroupName: group-2
```

```
Done
```

- bind aaa group <groupname> -username <username>

**Example**

```
> bind aaa group group-2 -username user-2
```

```
Done
```

```
> show aaa group group-2
```

```
 GroupName: group-2
```

```
 UserName: user-2
```

```
Done
```

To remove users from an AAA group by using the command line interface

At the command prompt, unbind users from the group by typing the following command once for each user account that is bound to the group:

```
unbind aaa group <groupname> -username <username>
```

**Example**

```
> unbind aaa group group-hr -username user-hr-1
```

```
Done
```

To remove an AAA group by using the command line interface

First remove all users from the group. Then, at the command prompt, type the following command to remove an AAA group and verify the configuration:

- rm aaa group <groupname>
- show aaa group

## Example

```
> rm aaa group group-hr
```

Done

```
> show aaa group
```

```
1) GroupName: group-1
```

```
2) GroupName: group-finance
```

Done

To configure AAA local groups and add users to them by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Groups
2. In the details pane, do one of the following:
  - To create a new group, click Add.
  - To modify an existing group, select the group, and then click Edit.
3. If you are creating a new group, in the Create AAA Group dialog box, in the Group Name text box, type a name for the group.
4. In the Advanced area to the right, click AAA Users.
  1. To add a user to the group, select the user, and then click Add.
  2. To remove a user from the group, select the user, and then click Remove.
  3. To create a new user account and add it to the group, click the Plus icon, and then follow the instructions in “To configure AAA local users by using the configuration utility.”
5. Click Create or OK. The group that you created appears in the AAA Groups page.

# Configuring AAA Policies

Sep 18, 2013

After you set up your users and groups, you next configure authentication policies, authorization policies, and audit policies to define which users are allowed to access your intranet, which resources each user or group is allowed to access, and what level of detail AAA will preserve in the audit logs. An authentication policy defines the type of authentication to apply when a user attempts to log on. If external authentication is used, the policy also specifies the external authentication server. Authorization policies specify the network resources that users and groups can access after they log on. Auditing policies define the audit log type and location.

You must bind each policy to put it into effect. You bind authentication policies to authentication virtual servers, authorization policies to one or more user accounts or groups, and auditing policies both globally and to one or more user accounts or groups.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the NetScaler operating system, policy priorities work in reverse order: the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is performed first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000. The AAA feature implements only the first of each type of policy that a request matches, not any additional policies of that type that a request might also match, so policy priority is important for getting the results you intend.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you bind the policies. You can then add additional policies at any time without having to reassess the priority of an existing policy.

For additional information about binding policies on the NetScaler, see the *Citrix NetScaler Traffic Management Guide* at "[Traffic Management](#)."

# Authentication Policies

Aug 19, 2014

The NetScaler ADC can authenticate users with local user accounts or by using an external authentication server. The appliance supports the following authentication types:

## LOCAL

Authenticates to the NetScaler by using a password, without reference to an external authentication server. User data is stored locally on the NetScaler appliance.

## RADIUS

Authenticate to an external Radius server.

## LDAP

Authenticates to an external LDAP authentication server.

## TACACS

Authenticates to an external Terminal Access Controller Access-Control System (TACACS) authentication server.

After a user authenticates to a TACACS server, the NetScaler ADC connects to the same TACACS server for all subsequent authorizations. When a primary TACACS server is unavailable, this feature prevents delays while the ADC waits for the first TACACS server to time out before resending the authorization request to the second TACACS server.

Note: When authenticating through a TACACS server, AAA-TM logs only successfully executed TACACS commands, to prevent the logs from showing TACACS commands that were entered by users who were not authorized to execute them.

## CERT

Authenticates to the NetScaler appliance by using a client certificate, without reference to an external authentication server.

## NEGOTIATE

Authenticates to a Kerberos authentication server. If there is an error in Kerberos authentication, NetScaler uses NTLM authentication.

## SAML

Authenticates to a server that supports the Security Assertion Markup Language (SAML).

## SAMLIDP

Configures the NetScaler ADC to serve as a Security Assertion Markup Language (SAML) Identity Provider (IdP).

## WEB

Authenticates to a web server, providing the credentials that the web server requires in an HTTP request and analyzing the web server response to determine that user authentication was successful.

An authentication policy is comprised of an expression and an action. Authentication policies use NetScaler expressions.

After creating an authentication action and an authentication policy, bind it to an authentication virtual server and assign a priority to it. When binding it, also designate it as either a primary or a secondary policy. Primary policies are evaluated before secondary policies. In configurations that use both types of policy, primary policies are normally more specific policies while secondary policies are normally more general policies intended to handle authentication for any user accounts that do not meet the more specific criteria.

To add an authentication action by using the command line interface

If you do not use LOCAL authentication, you need to add an explicit authentication action. To do this, at the command prompt, type the following command:

```
add authentication tacacsAction <name> -serverip <IP> [-serverPort <port>] [-authTimeout <positive_integer>] [...]
```

### Example

```
> add authentication tacacsaction Authn-Act-1 -serverip 10.218.24.65 -serverport 1812 -authTimeout 15 -tacacsSecret "minotaur" -authorization OFF -accounting ON -auditFailedCmds
```

To configure an authentication action by using the command line interface

To configure an existing authentication action, at the command prompt, type the following command:

```
set authentication tacacsAction <name> -serverip <IP> [-serverPort <port>] [-authTimeout <positive_integer>] [...]
```

### Example

```
> set authentication tacacsaction Authn-Act-1 -serverip 10.218.24.65 -serverport 1812 -authTimeout 15 -tacacsSecret "minotaur" -authorization OFF -accounting ON -auditFailedCmds
```

To remove an authentication action by using the command line interface

To remove an existing RADIUS action, at the command prompt, type the following command:

```
rm authentication radiusAction <name>
```

### Example

```
> rm authentication tacacsaction Authn-Act-1 Done
```

To configure an authentication server by using the configuration utility

Note: In the configuration utility, the term server is used instead of action, but refers to the same task.

1. Navigate to Security > AAA - Application Traffic > Policies > Authentication.
2. In the details pane, on the Servers tab, do one of the following:
  - To create a new authentication server, click Add.
  - To modify an existing authentication server, select the server, and then click Open.
3. In the Create Authentication Server or Configure Authentication Server dialog box, type or select values for the parameters.
  - Name\*—radiusActionName (Cannot be changed for a previously configured action)
  - Authentication Type\*—authType (Set to RADIUS, cannot be changed)
  - IP Address\*—serverip <IP>
  - IPv6\*—Select the checkbox if the server IP is an IPv6 IP. (No command line equivalent.)
  - Port\*—serverPort
  - Time-out (seconds)\*—authTimeout
4. Click Create or OK, and then click Close. The policy that you created appears in the Authentication Policies and Servers page.

To create and bind an authentication policy by using the command line interface

At the command prompt, type the following commands in the order shown to create and bind an authentication policy and verify the configuration:

- add authentication negotiatePolicy <name> <rule> <reqAction>
- show authentication localPolicy <name>
- bind authentication vserver <name> -policy <policyname> [-priority <priority>] [-secondary]]
- show authentication vserver <name>

#### Example

```
> add authentication localPolicy Authn-Pol-1 ns_true Done > show authentication localPolicy 1) Name: Authn-Pol-1 Rule: ns_true Request action: LOCAL Done > bind authentication vsr
To modify an existing authentication policy by using the command line interface
```

At the command prompt, type the following commands to modify an existing authentication policy:

```
set authentication localPolicy <name> <rule> [-reqlaction <action>]
```

#### Example

```
> set authentication localPolicy Authn-Pol-1 'ns_true' Done
```

To remove an authentication policy by using the command line interface

At the command prompt, type the following command to remove an authentication policy:

```
rm authentication localPolicy <name>
```

#### Example

```
> rm authentication localPolicy Authn-Pol-1 Done
```

To configure and bind authentication policies by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Policies > Authentication, and then select the type of policy that you want to create.
2. In the details pane, on the Policies tab, do one of the following:
  - To create a new policy, click Add.
  - To modify an existing policy, select the action, and then click Edit.
3. In the Create Authentication Policy or Configure Authentication Policy dialog, type or select values for the parameters.
  - Name\*—policyname (Cannot be changed for a previously configured action)
  - Authentication Type\*—authtype
  - Server\*—authVsName
  - Expression\*—rule (You enter expressions by first choosing the type of expression in the leftmost drop-down list beneath the Expression window, and then by typing your expression directly into the expression text area, or by clicking Add to open the Add Expression dialog box and using the drop-down lists in it to construct your expression.)
4. Click Create or OK. The policy that you created appears in the Policies page.
5. Click the Servers tab, and in the details pane do one of the following:
  - To use an existing server, select it, and then click .
  - To create a new server, click Add, and follow the instructions.
6. If you want to designate this policy as a secondary authentication policy, on the Authentication tab, click Secondary. If you want to designate this policy as a primary authentication policy, skip this step.
7. Click Insert Policy.
8. Choose the policy you want to bind to the authentication virtual server from the drop-down list.
9. In the Priority column to the left, modify the default priority as needed to ensure that the policy is evaluated in the proper order.
10. Click OK. A message appears in the status bar, stating that the policy has been configured successfully.

# LDAP Authentication Policies

Aug 13, 2014

As with other types of authentication policies, a Lightweight Directory Access Protocol (LDAP) authentication policy is comprised of an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy. In addition to standard authentication functions, LDAP can search other active directory (AD) servers for user accounts for users that do not exist locally. This function is called referral support or referral chasing.

Normally you configure the NetScaler ADC to use the IP address of the authentication server during authentication. With LDAP authentication servers, you can also configure the ADC to use the FQDN of the LDAP server instead of its IP address to authenticate users. Using an FQDN can simplify an otherwise much more complex AAA configuration in environments where the authentication server might be at any of several IP addresses, but always uses a single FQDN. To configure authentication by using a server's FQDN instead of its IP address, you follow the normal configuration process except when creating the authentication action. When creating the action, you use the **serverName** parameter instead of the **serverIP** parameter, and substitute the server's FQDN for its IP address.

Before you decide whether to configure the ADC to use the IP or the FQDN of your LDAP server to authenticate users, consider that configuring AAA to authenticate to an FQDN instead of an IP address adds an extra step to the authentication process. Each time the ADC authenticates a user, it must resolve the FQDN. If a great many users attempt to authenticate simultaneously, the resulting DNS lookups might slow the authentication process.

LDAP referral support is disabled by default and cannot be enabled globally. It must be explicitly enabled for each LDAP action. You must also make sure that the AD server accepts the same binddn credentials that are used with the referring (GC) server. To enable referral support, you configure an LDAP action to follow referrals, and specify the maximum number of referrals to follow.

If referral support is enabled, and the NetScaler ADC receives an LDAP\_REFERRAL response to a request, AAA follows the referral to the active directory (AD) server contained in the referral and performs the update on that server. First, AAA looks up the referral server in DNS, and connects to that server. If the referral policy requires SSL/TLS, it connects via SSL/TLS. It then binds to the new server with the binddn credentials that it used with the previous server, and performs the operation which generated the referral. This feature is transparent to the user.

Note: These instructions assume that you are already familiar with the LDAP protocol and have already configured your chosen LDAP authentication server.

For more information about setting up authentication policies in general, see "[Authentication Policies](#)". For more information about NetScaler expressions, which are used in the policy rule, see the *Citrix NetScaler Policy Configuration and Reference Guide* at "[Policies and Expressions](#)."

To enable LDAP referral support by using the command line interface

At the command prompt, type the following commands:

- set authentication ldapAction <name> -followReferrals ON
- set authentication ldapAction <name> -maxLDAPReferrals <integer>

## Example

```
> set authentication ldapAction ldapAction-1 -followReferrals ON
```

```
set authentication ldapAction ldapAction-1 -maxLDAPReferrals 2
```

To enable LDAP referral support by using the configuration utility

Note: In the configuration utility, the term server is used instead of action, but refers to the same task.

1. Navigate to Security > AAA - Application Traffic > Policies > LDAP.
2. In the details pane, on the Servers tab, select the LDAP server that you want to configure, and then click Edit.
3. In the Configure Authentication Server dialog, scroll down to the Referrals check box, and select it.
4. In the Maximum Referral Level text box, type the maximum number of referrals to allow.
5. Click OK, and then click Close.

# Negotiate Authentication Policies

Jul 14, 2014

As with other types of authentication policies, a Negotiate authentication policy is comprised of an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy.

In addition to standard authentication functions, the Negotiate Action command can now extract user information from a keytab file instead of requiring you to enter that information manually. If a keytab has more than one SPN, AAA selects the correct SPN. You can configure this feature at the NetScaler command line, or by using the configuration utility..

Note: These instructions assume that you are already familiar with the LDAP protocol and have already configured your chosen LDAP authentication server.

For more information about setting up authentication policies in general, see "[Authentication Policies](#)". For more information about NetScaler expressions, which are used in the policy rule, see the *Citrix NetScaler Policy Configuration and Reference Guide* at "[Policies and Expressions](#)."

To configure AAA to extract user information from a keytab file by using the command line interface

At the command prompt, type the appropriate command:

- add authentication negotiateAction <name> [-keytab <string>]
- set authentication negotiateAction <name> [-keytab <string>]

## Example

```
> set authentication negotiateAction negotiateAction-1 -keytab keytab-1
```

To configure AAA to extract user information from a keytab file by using the configuration utility

Note: In the configuration utility, the term server is used instead of action, but refers to the same task.

1. Navigate to Security > AAA - Application Traffic > Policies > Negotiate.
2. In the details pane, on the Servers tab, do one of the following:
  - If you want to create a new Negotiate action, click Add.
  - If you want to modify an existing Negotiate action, in the data pane select the action, and then click Edit.
3. If you are creating a new Negotiate action, in the Name text box, type a name for your new action. The name can be from one to 127 characters in length and can consist of upper- and lowercase letters, numbers, and the hyphen (-) and underscore (\_) characters. If you are modifying an existing Negotiate action, skip this step. The name is read-only; you cannot change it.
4. Under Negotiate, if the Use Keytab file check box is not already checked, check it.
5. In the Keytab file path text box, type the full path and filename of the keytab file that you want to use.
6. In the Default authentication group text box, type the authentication group that you want to set as default for this user.
7. Click Create or OK to save your changes.

# RADIUS Authentication Policies

Aug 21, 2014

As with other types of authentication policies, a Remote Authentication Dial In User Service (RADIUS) authentication policy is comprised of an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy. However, setting up a RADIUS authentication policy has certain special requirements that are described below.

Normally you configure the NetScaler ADC to use the IP address of the authentication server during authentication. With RADIUS authentication servers, you can now configure the ADC to use the FQDN of the RADIUS server instead of its IP address to authenticate users. Using an FQDN can simplify an otherwise much more complex AAA configuration in environments where the authentication server might be at any of several IP addresses, but always uses a single FQDN. To configure authentication by using a server's FQDN instead of its IP address, you follow the normal configuration process except when creating the authentication action. When creating the action, you substitute the **serverName** parameter for the **serverIP** parameter.

Before you decide whether to configure the ADC to use the IP or the FQDN of your RADIUS server to authenticate users, consider that configuring AAA to authenticate to an FQDN instead of an IP address adds an extra step to the authentication process. Each time the ADC authenticates a user, it must resolve the FQDN. If a great many users attempt to authenticate simultaneously, the resulting DNS lookups might slow the authentication process.

Note: These instructions assume that you are already familiar with the RADIUS protocol and have already configured your chosen RADIUS authentication server.

For more information about setting up authentication policies in general, see "[Authentication Policies](#)." For more information about NetScaler expressions, which are used in the policy rule, see the *Citrix NetScaler Policy Configuration and Reference Guide* at "[Policies and Expressions](#)."

To add an authentication action for a RADIUS server by using the command line interface

If you authenticate to a RADIUS server, you need to add an explicit authentication action. To do this, at the command prompt, type the following command:

```
add authentication radiusAction <name> [-serverip <IP> | -serverName] <FQDN> [-serverPort <port>] [-authTimeout <positive_integer>] [-radKey } [-radNASip (ENABLED | DISABLED)] [-radNASid <string>] [-radVendorID <positive_integer>] [-radAttributeType <positive_integer>] [-radGroupsPrefix <string>] [-radGroupSeparator <string>] [-passEncoding <passEncoding>] [-ipVendorID <positive_integer>] [-ipAttributeType <positive_integer>] [-accounting (ON | OFF)] [-pwdVendorID <positive_integer> [-pwdAttributeType <positive_integer>]] [-defaultAuthenticationGroup <string>] [-callingstationid (ENABLED | DISABLED)]
```

## Example

The following example adds a RADIUS authentication action named **Authn-Act-1**, with the server IP **10.218.24.65**, the server port **1812**, the authentication timeout **15** minutes, the radius key **WareTheLorax**, NAS IP disabled, and NAS ID **NAS1**.

```
> add authentication radiusaction Authn-Act-1 -serverip 10.218.24.65 -serverport 1812
 -authtimeout 15 -radkey WareTheLorax -radNASip DISABLED -radNASid NAS1
```

Done

The following example adds the same RADIUS authentication action, but using the server FQDN **rad01.example.com** instead of the IP.

```
> add authentication radiusaction Authn-Act-1 -serverName rad01.example.com -serverport 1812
 -authtimeout 15 -radkey WareTheLorax -radNASip DISABLED -radNASid NAS1
```

Done

To configure an authentication action for an external RADIUS server by using the command line

To configure an existing RADIUS action, at the NetScaler command prompt, type the following command:

```
set authentication radiusAction <name> [-serverip <IP> | -serverName] <FQDN> [-serverPort <port>] [-authTimeout
<positive_integer>] [-radKey] [-radNASip (ENABLED | DISABLED)] [-radNASid <string>] [-radVendorID <positive_integer>]
[-radAttributeType <positive_integer>] [-radGroupsPrefix <string>] [-radGroupSeparator <string>] [-passEncoding
<passEncoding>] [-ipVendorID <positive_integer>] [-ipAttributeType <positive_integer>] [-accounting (ON | OFF)] [-
pwdVendorID <positive_integer> [-pwdAttributeType <positive_integer>]] [-defaultAuthenticationGroup <string>] [-
callingstationid (ENABLED | DISABLED)]
```

To remove an authentication action for an external RADIUS server by using the command line interface

To remove an existing RADIUS action, at the command prompt, type the following command:

```
rm authentication radiusAction <name>
```

### Example

```
> rm authentication radiusaction Authn-Act-1
```

Done

To configure a RADIUS server by using the configuration utility

Note: In the configuration utility, the term server is used instead of action, but refers to the same task.

1. Navigate to Security > AAA - Application Traffic > Policies > Authentication > Radius
2. In the details pane, on the Servers tab, do one of the following:
  - To create a new RADIUS server, click Add.
  - To modify an existing RADIUS server, select the server, and then click Edit.
3. In the Create Authentication RADIUS Server or Configure Authentication RADIUS Server dialog, type or select values for the parameters. To fill out parameters that appear beneath Send Calling Station ID, expand Details.
  - Name\*—radiusActionName (Cannot be changed for a previously configured action)
  - Authentication Type\*—authtype (Set to RADIUS, cannot be changed)
  - Server Name / IP Address\*—Choose either Server Name or Server IP
    - Server Name\*—serverName <FQDN>
    - IP Address\*—serverIp <IP> If the server is assigned an IPv6 IP address, select the IPv6 check box.
  - Port\*—serverPort
  - Time-out (seconds)\*—authTimeout
  - Secret Key\*—radKey (RADIUS shared secret.)
  - Confirm Secret Key\*—Type the RADIUS shared secret a second time. (No command line equivalent.)
  - Send Calling Station ID—callingstationid
  - Group Vendor Identifier—radVendorID
  - Group Attribute Type—radAttributeType
  - IP Address Vendor Identifier—ipVendorID
  - pwdVendorID—pwdVendorID
  - Password Encoding—passEncoding
  - Default Authentication Group—defaultAuthenticationGroup
  - NAS ID—radNASid
  - Enable NAS IP address extraction—radNASip

- Group Prefix—radGroupsPrefix
  - Group Separator—radGroupSeparator
  - IP Address Attribute Type—ipAttributeType
  - Password Attribute Type—pwdAttributeType
  - Accounting—accounting
4. Click Create or OK. The policy that you created appears in the Servers page.

# SAML Authentication Policies

Sep 09, 2014

The Security Assertion Markup Language (SAML) is an XML-based standard for exchanging authentication and authorization tokens between servers which authenticate users (the *Identity Provider* or *IdP*) and servers that host user applications (*Service Providers*). The NetScaler ADC supports SAML authentication and authorization with HTTP POST-binding, in which the ADC responds to user requests with a 200 OK that contains a form-auto post with the required authentication token.

The NetScaler ADC supports attribute extraction from SAML assertions, and encrypted SAML assertions. The NetScaler implementation of SAML allows signing certificates of less than 2048 bits, but displays a warning message. It also supports the SHA256 hash algorithm for signatures and digests. Citrix recommends that all signing certificates be of at least 2048 bits, and that you use SHA256 as SHA-1 is no longer considered secure.

As with other types of NetScaler authentication policies, a SAML authentication policy is comprised of an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy. However, setting up a SAML authentication policy has certain special requirements that are described below.

Note: These instructions assume that you are already familiar with the SAML protocol and have already configured your chosen SAML authentication server.

For more information about setting up authentication policies in general, see "[Authentication Policies](#)". For more information about NetScaler expressions, which are used in the policy rule, see the *Citrix NetScaler Policy Configuration and Reference Guide* at "[Policies and Expressions](#)".

To add an authentication action for an external SAML server by using the command line

If you authenticate to a SAML server, you need to add an explicit authentication action. To do this, at the command prompt, type the following command:

```
add authentication samlaction <name> [-samlIdPCertName <string>] [-samlSigningCertName <string>] [-samlRedirectUrl <string>] [-samlACSIndex <positive_integer>] [-samlUserField <string>] [-samlRejectUnsignedAssertion (ON | OFF)] [-samlIssuerName <string>] [-samlTwoFactor (ON | OFF)] [-defaultAuthenticationGroup <string>] [-Attribute1 <string>] [-Attribute2 <string>] [-Attribute3 <string>] [-Attribute4 <string>] [-Attribute5 <string>] [-Attribute6 <string>] [-Attribute7 <string>] [-Attribute8 <string>] [-Attribute9 <string>] [-Attribute10 <string>] [-Attribute11 <string>] [-Attribute12 <string>] [-Attribute13 <string>] [-Attribute14 <string>] [-Attribute15 <string>] [-Attribute16 <string>] [-signatureAlg (RSA-SHA1 | RSA-SHA256)] [-digestMethod (SHA1 | SHA256)]
```

## Example

The following example adds a SAML authentication action named Authn-Act-1.

```
> add authentication samlaction Authn-Act-1 -samlIdPCertName samlcert1
 -samlSigningCertName ssigncert1 -samlRedirectUrl https://login.example.com/logon_fail.html
 -samlUserField userfield1 -samlRejectUnsignedAssertion ON -samlIssuerName Issuer
 -samlTwoFactor ON -defaultAuthenticationGroup group -signatureAlg RSA-SHA256
 -digestMethod SHA256
```

Done

To configure an authentication action for an external SAML server by using the command line

To configure an existing SAML action, at the command prompt, type the following command:

```
set authentication samlaction <name> [-samlIdPCertName <string>] [-samlSigningCertName <string>] [-samlRedirectUrl <string>] [-samlUserField <string>] [-samlRejectUnsignedAssertion (ON | OFF)] [-samlIssuerName <string>] [-samlTwoFactor (ON | OFF)] [-defaultAuthenticationGroup <string>] [-Attribute1 <string>] [-Attribute2 <string>] [-Attribute3 <string>] [-Attribute4 <string>] [-Attribute5 <string>] [-Attribute6 <string>] [-Attribute7 <string>] [-Attribute8 <string>] [-Attribute9 <string>] [-Attribute10 <string>] [-Attribute11 <string>] [-Attribute12 <string>] [-Attribute13 <string>] [-Attribute14 <string>] [-Attribute15 <string>] [-Attribute16 <string>] [-signatureAlg (RSA-SHA1 | RSA-SHA256)] [-digestMethod (SHA1 | SHA256)]
```

#### Example

```
> add authentication samlaction Authn-Act-1 -samlIdPCertName samlcert1
 -samlSigningCertName ssigncert1 -samlRedirectUrl https://login.example.com/logon_fail.html
 -samlUserField userfield1 -samlRejectUnsignedAssertion ON -samlIssuerName Issuer
 -samlTwoFactor ON -defaultAuthenticationGroup group -signatureAlg RSA-SHA256
 -digestMethod SHA256
```

Done

To remove an authentication action for an external SAML server by using the command line

To remove an existing SAML action, at the command prompt, type the following command:

```
rm authentication samlaction <name>
```

#### Example

```
> rm authentication samlaction Authn-Act-1
```

Done

To configure a SAML server by using the configuration utility

Note: In the configuration utility, the term server is used instead of action, but refers to the same task.

1. Navigate to AAA - Application Traffic > Policies > Authentication > SAML.
2. In the details pane, on the Servers tab, do one of the following:
  - To create a new SAML server, click Add.
  - To modify an existing SAML server, select the server, and then click Edit.
3. In the Create Authentication Server or Configure Authentication Server dialog box, type or select values for the parameters:
  - Name\*—policyname (Cannot be changed for a previously configured action)
  - Authentication Type\*—authtype (Set to SAML, cannot be changed)
  - IDP Certificate Name\*—samlIDPcertname
  - Redirect URL\*—samlRedirectUrl
  - User Field—samlUserField
  - Signing Certificate Name—samlSigningcertname
  - Issuer Name—samlIssuerName
  - Default Authentication Group—defaultAuthenticationGroup
  - Two Factor—samlTwoFactor
  - Reject Unsigned Assertion—samlRejectUnsignedAssertion
  - ACS Index—samlACSIndex
  - Attribute 1-Attribute 16—attribute1-attribute16 (Used to extract attributes from the SAML assertion.)
4. Click Create or OK. The policy that you created appears in the Servers page.

# SAML IDP Authentication Policies

Aug 19, 2014

As with other types of authentication policies, a Security Assertion Markup Language (SAML) Identity Provider (IdP) authentication policy is comprised of an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy. However, setting up a SAML IdP authentication policy has certain special requirements that are described below.

Note: These instructions assume that you are already familiar with the SAML protocol, understand SAML IdP, and have already configured your chosen SAML authentication server.

For more information about setting up authentication policies in general, see "[Authentication Policies](#)". For more information about NetScaler expressions, which are used in the policy rule, see the *Citrix NetScaler Policy Configuration and Reference Guide* at "[Policies and Expressions](#)".

To configure a SAML IdP authentication policy by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Policies > Authentication > SAML IDP.
2. In the details pane, do one of the following:
  - To add a new policy, click Add.
  - To configure an existing policy, select the policy and the click Edit.The Create SAML IDP Policy or the Configure SAML IDP Policy dialog box opens. The dialog boxes are nearly identical.
3. If you are creating a new policy, in the Create Create SAML IDP Policy dialog box, type a name for your new policy. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (\_) symbols.
4. Select the action (profile) that you want to bind to the policy from the list of available actions, or click the plus sign and create a new action.
5. Add a policy expression (rule) in the Expression window. You enter expressions by first choosing the type of expression in the leftmost drop-down list beneath the Expression window, and then by typing your expression directly into the expression text area, or by clicking Add to open Add Expression dialog box and using the drop-down lists in it to construct your expression.
6. Click Create or OK.

# Web Authentication Policies

Aug 19, 2014

AAA-TM is now able to authenticate a user to a web server, providing the credentials that the web server requires in an HTTP request and analyzing the web server response to determine that user authentication was successful. As with other types of authentication policies, a Web authentication policy is comprised of an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy. |

To set up web-based authentication with a specific web server, first you create a web authentication action. Since authentication to web servers does not use a rigid format, you must specify exactly which information the web server requires and in which format when creating the action. To do this, you create an expression in NetScaler default syntax that contains the following items:

- **Server IP**—The IP address of the authentication Web server.
- **Server Port**—The port of the authentication Web server.
- **Authentication Rule**—An expression in NetScaler default syntax that contains the user's credentials in the format that the Web server expects.
- **Scheme**—HTTP (for unencrypted web authentication) or HTTPS (for encrypted web authentication).
- **Success Rule**—An expression in NetScaler default syntax that matches the web server response string that signifies that the user authenticated successfully.

For all other parameters, follow the normal rules for the add authentication action command.

Next you create a policy associated with that action. The policy is similar to an LDAP policy, and like LDAP policies uses NetScaler classic syntax.

Note: These instructions assume that you are already familiar with the authentication requirements of the web server(s) to which you want to authenticate, and have already configured the web authentication server.

For more information about setting up authentication policies in general, see "[Authentication Policies](#)". For more information about NetScaler expressions, which are used in the policy rule, see the *Citrix NetScaler Policy Configuration and Reference Guide* at "[Policies and Expressions](#)."

To configure a Web authentication action by using the command line interface

To create a web authentication action at the command line, at the command line type the following command:

```
add authentication webAuthAction <name> -serverIP <ip_addr|ipv6_addr|*> -serverPort <port|*> [-fullReqExpr <string>] -
scheme (http | https) -successRule <expression> [-defaultAuthenticationGroup <string>] [-Attribute1 <string>] [-
Attribute2 <string>] [-Attribute3 <string>] [-Attribute4 <string>] [-Attribute5 <string>] [-Attribute6 <string>] [-Attribute7
<string>] [-Attribute8 <string>] [-Attribute9 <string>] [-Attribute10 <string>] [-Attribute11 <string>] [-Attribute12 <string>] [-
Attribute13 <string>] [-Attribute14 <string>] [-Attribute15 <string>] [-Attribute16 <string>]
```

## Example

```
> add authentication webAuthAction webauth1 -serverIP 10.214.56.31 -serverPort 80 -
```

To configure a Web authentication action by using the configuration utility

Note: In the configuration utility, the term server is used instead of action, but refers to the same task.

1. Navigate to Security > AAA - Application Traffic > Policies > LDAP.

2. In the details pane, on the Servers tab, do one of the following:
  - If you want to create a new web authentication action, click Add.
  - If you want to modify an existing web authentication action, in the data pane select the action, and then click Edit.
3. If you are creating a new web authentication action, in the Create Authentication Web server dialog box, Name text box, type a name for the new web authentication action. The name can be from one to 127 characters in length, and can consist of upper- and lowercase letters, numbers, and the hyphen (-) and underscore (\_) characters. If you are modifying an existing web authentication action, skip this step. The name is read-only; you cannot change it.
4. In the Web Server IP Address text box, type the IPv4 or IPv6 IP address of the authentication web server. If the address is an IPv6 IP address, select the IPv6 check box first.
5. In the Port text box, type the port number on which the web server accepts connections.
6. Select HTTP or HTTPS in the Protocol drop-down list.
7. In the HTTP Request Expression text area, type a PCRE-format regular expression that creates the web server request that contains the user's credentials in the exact format expected by the authentication web server.
8. In the Expression to validate the Authentication text area, type a NetScaler default syntax expression that describes the information in the web server response that indicates that user authentication was successful.
9. Fill out the remaining fields as described in the general authentication action documentation.
10. Click OK.

# Configuring Advanced Authentication Policies

Jun 11, 2014

If you know exactly how you want an authentication policy to be configured, you can use the advanced authentication policy dialog to create the policy quickly.

To configure an advanced authentication policy by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies, and then select Policy.
2. In the details pane do one of the following:
  - To create a new policy, click Add.
  - To modify an existing policy, select the policy, and then click Edit.
3. In the Create Authentication Policy or Configure Authentication Policy dialog box, type or select values for the parameters.
  - Name\*—The policy name. Cannot be changed for a previously configured policy.
  - Action Type\*—The policy type: Cert, Negotiate, LDAP, RADIUS, SAML, SAMLIDP, TACACS, or WEBAUTH.
  - Action\*—The authentication action (profile) to associate with the policy. You can choose an existing authentication action, or click the plus and create a new action of the proper type.
  - Log Action—The audit action to associate with the policy. You can choose an existing audit action, or click the plus and create a new action.
  - Expression\*—The rule that selects connections to which you want to apply the action that you specified. The rule can be simple ("true" selects all traffic) or complex. You enter expressions by first choosing the type of expression in the leftmost drop-down list beneath the Expression window, and then by typing your expression directly into the expression text area, or by clicking Add to open Add Expression dialog box and using the drop-down lists in it to construct your expression.)
  - Comment—You can type a comment that describes the type of traffic that this authentication policy will apply to. Optional.
4. Click Create or OK, and then click Close. If you created a policy, that policy appears in the Authentication Policies and Servers page.

# Authorization Policies

Aug 19, 2014

After you create authentication policies, you next create any authorization policies you need. Authorization policies, like other policies, consist of an expression and action. There are only two actions for authorization policies: ALLOW and DENY. ALLOW permits users to access the specified resource; DENY blocks access. The default setting for authorization when no specific policy exists is to deny access to network resources. This means that a user or group can access a particular resource only if an authorization policy explicitly allows access. For optimum security, the best practice is not to change the default setting and to create specific authorization policies for users who need access to specific resources.

Authorization use both default syntax expressions and classic expressions. These expressions are described in detail in the *Citrix NetScaler Policy Configuration and Reference Guide* at "[Policies and Expressions](#)."

After you create an authorization policy, you bind it to the appropriate user accounts or groups to put it into effect.

## To create an authorization policy

At the NetScaler command prompt, type the following commands to create an authorization policy and verify the configuration:

- add authorization policy <name> <rule> <action>
- show authorization policy <name>

### Example

```
> add authorization policy authz-pol-1 "HTTP.REQ.URL.SUFFIX.EQ(\"gif\")" DENY
Done
> show authorization policy authz-pol-1
1) Name: authz-pol-1 Rule: HTTP.REQ.URL.SUFFIX.EQ(\"gif\")
 Action: DENY
Done
>
```

## To modify an authorization policy

At the command prompt, type the following command to modify an authorization policy:  
set authorization policy <name> [-rule <expression>] -action <action>

### Example

```
> set authorization policy authz-pol-1 -rule "HTTP.REQ.URL.SUFFIX.EQ(\"gif\")" -action ALLOW
Done
> show authorization policy authz-pol-1
1) Name: authz-pol-1 Rule: HTTP.REQ.URL.SUFFIX.EQ(\"gif\")
 Action: ALLOW
Done
>
```

## To bind an authorization policy to a user account or group

At the command prompt, type one of the following commands to bind an authorization policy to a user account or group and verify the configuration:

- bind aaa user <userName> [-policy <policyname> [-priority <priority>]] [-intranetApplication <appname>] [-urlName

- `<urlname>] [-intranetIP <intranetip> [<netmask>]]`
- `show aaa user <userName>`
- `bind aaa group <groupName> [-policy <policyname> [-priority <priority>]] [-intranetApplication <appname>] [-urlName <urlname>] [-intranetIP <intranetip> [<netmask>]]`
- `show aaa group <name>`

### Example

```
> bind aaa user user-hr-1 -policy authz-pol-1
Done
> show aaa user user-hr-1
 UserName: user-hr-1
```

```
 Policy: authz-pol-1, Priority: 0
```

```
Done
> bind aaa group group-1 -policy authz-pol-1
Done
> show aaa group group-1
 GroupName: group-1
```

```
 UserName: user-2
```

```
 UserName: user-1
```

```
 Policy: authz-pol-1, Priority: 0
```

Done

To unbind an authorization policy from a user account or group

At the command prompt, type one of the following commands to unbind an authorization policy from a user account or group:

- `unbind aaa user <userName> -policy <policyname>`
- `unbind aaa group <groupName> -policy <policyname>`

### Example

```
> unbind aaa user aaa-user-1 -policy auth-pol-1
Done
```

To remove an authorization policy

First unbind the policy from all user accounts and groups, and then, at the NetScaler command prompt, type the following command to remove an authorization policy:

```
rm authorization policy <name>
```

To configure and bind authorization policies by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Authorization.
2. Navigate to Security > AAA - Application Traffic > Policies > Authorization.
3. In the details pane, do one of the following:
  - To create a new authorization policy, click Add.
  - To modify an existing authorization policy, select the policy, and then click Edit.
4. In the Create Authorization Policy or Configure Authorization Policy dialog, type or select values for the parameters.

- Name\*—policyname(Cannot be changed for a previously configured policy.)
  - Action\*— action
  - Expression\*—rule (By default, the Expression box accepts default syntax policies. To switch to the classic syntax view, click Switch to Classic Syntax.)
5. Click Create or OK. The policy that you created appears on the Authorization Policies page.
  6. To bind an authorization policy to a user account or group, in the navigation pane, under AAA - Application Traffic, click either Users or Groups, as appropriate, and then add that policy to the user account list:
    1. In the details pane, select the appropriate user account, and then click Edit.
    2. In the Advanced menu on the right, click Authorization Policies.
    3. Click the arrow to the right of the list of authorization policies to open the Bind Policy dialog.
    4. Select the policy you want to bind to the user account or group.
    5. In the Priority column, modify the default priority as needed to ensure that the policy is evaluated in the proper order.
    6. Click OK.A message appears in the status bar, stating that the policy has been configured successfully.

# Auditing Policies

Aug 13, 2014

After you create authentication policies, you next create any auditing policies you need. The NetScaler ADC allows auditing of all states and status information, so you can see the event history for any user in chronological order. When you configure auditing on the ADC, you can choose to store the log files locally on the ADC or to send them to a syslog server.

To put your auditing policies into effect, you bind them globally, to a specific authentication virtual server, or to specific user accounts or groups.

To create an auditing policy by using the command line interface

At the command prompt, type the following commands to create an auditing policy and verify the configuration:

- add audit nslogPolicy <name> [-rule <rule>] [-action <action>]
- show audit nslogPolicy

## Example

```
> add audit nslogPolicy audit-1 ns_true audit_server
Done
> show audit nslogPolicy
1) Name: audit-pol Rule: ns_true
 Action: audit_server
2) Name: audit-1 Rule: ns_true
 Action: audit_server
Done
```

To modify an auditing policy by using the command line interface

At the command prompt, type the following commands to modify an auditing policy and verify the configuration:

- set audit nslogPolicy <name> [-rule <expression>] [-action <string>]
- show audit nslogPolicy

## Example

```
> set audit nslogPolicy audit-1 ns_true audit_server
Done
> show audit nslogPolicy
1) Name: audit-pol Rule: ns_true
 Action: audit_server
2) Name: audit-1 Rule: ns_true
 Action: audit_server
Done
```

To globally bind an auditing policy by using the command line interface

At the command prompt, type the following commands to globally bind an auditing policy:

```
bind tm global [-policyName <string> [-priority <positive_integer>]]
```

## Example

```
> bind tm global -policyName Audit-Pol-1 -priority 1000
```

Done

To bind an auditing policy to an authentication virtual server by using the command line interface

At the command prompt, type the following commands to bind an auditing policy to an authentication virtual server and verify the configuration:

- bind authentication vserver <name> [-policy <string> [-priority <positive\_integer>] [-secondary] [-groupExtraction]]
- show authentication vserver [<name>]

### Example

```
> bind authentication Vserver Auth-Vserver-2 -policy Authn-Pol-1
```

Done

```
> show authentication Vserver Auth-Vserver-2
```

```
Auth-Vserver-2 (10.102.29.77:443) - SSL Type: CONTENT
State: UP
Client Idle Timeout: 180 sec
Down state flush: DISABLED
Disable Primary Vserver On Down : DISABLED
Authentication : ON
Current AAA Users: 0
Authentication Domain: myCompany.employee.com
```

```
1) Primary authentication policy name: Authn-Pol-1 Priority: 0
```

Done

To bind an auditing policy to a user account or a group by using the command line interface

At the command prompt, type one of the following commands to bind an auditing policy to a user account or a group:

- bind audit <logtype> user <userName> -policy <polycname> [-priority <priority>]
- bind audit <logtype> user <userName> -policy <polycname> [-priority <priority>]

### Example

```
> bind audit nslogPolicy user aaa-user-1 -policyName Audit-Pol-1 -priority 1000
```

Done

To unbind a globally bound auditing policy by using the command line interface

At the command prompt, type the following commands to unbind a globally-bound auditing policy:

```
unbind audit <logtype> global -policy <polycname>
```

### Example

```
> unbind audit nslogPolicy global -policy Audit-Pol-1
```

Done

To unbind an auditing policy from an authentication virtual server by using the command line interface

At the command prompt, type the following commands to unbind an auditing policy from an authentication virtual server:

```
unbind authentication vserver <name> [-policy <string> [-secondary]][-groupExtraction]]
```

### Example

```
> unbind authentication vserver auth-vserver-1 -policyName Audit-Pol-1
```

Done

To unbind an auditing policy from a user account or a group by using the command line interface

At the command prompt, type one of the following commands to unbind an auditing policy from a user account or a group:

- unbind audit <logtype> user <userName> -policy <policyname>
- unbind audit <logtype> group <groupName> -policy <policyname>

### Example

```
> unbind audit nslogPolicy group aaa-group-1 -policyName Audit-Pol-1
```

Done

To remove an auditing policy by using the command line interface

First unbind the policy from all users and groups, and then, at the command prompt, type the following command to remove an auditing policy:

```
rm audit <logtype> <policyname>
```

To configure and bind auditing policies by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Policies > Auditing.
2. Choose the type of auditing policy that you want to create.
  - To create a policy that logs to syslog, expand Syslog.
  - To create a policy that logs to nslog, expand Nslog.Note: The dialogs for the two types of policies are nearly identical.
3. In the details pane, do one of the following:
  - To create a new auditing policy, click Add.
  - To modify an existing auditing policy, select the policy, and then click Edit.
4. In the Create Audit Policy or Configure Audit Policy dialog, type or select values for the parameters.
  - Name\*—policyname (Cannot be changed for a previously configured policy.)
  - Server\*—actionNote: The Auditing type list box is read-only; you cannot change it.
5. Click Create or OK. The policy that you created appears in the Auditing Policies page.
6. Click OK.
7. To globally bind an auditing policy, in the details pane, click Global Bindings and fill in the Bind/Unbind Audit Policies to Global dialog box.
  1. Select the name of the audit policy you want to globally bind.
  2. Click OK.A message appears in the status bar, stating that the policy has been configured successfully.
8. To bind an auditing policy, select Action > Global Bindings. You can bind an auditing policy to an authentication virtual server, a user account, or a group.

# Session Settings

Apr 18, 2013

After you configure your authentication, authorization, and auditing profiles, you configure session settings to customize your user sessions. The session settings are:

## **The session timeout.**

Controls the period after which the user is automatically disconnected and must authenticate again to access your intranet.

## **The default authorization setting.**

Determines whether the NetScaler appliance will by default allow or deny access to content for which there is no specific authorization policy.

## **The single sign-on setting.**

Determines whether the NetScaler appliance will log users onto all web applications automatically after they authenticate, or will pass users to the web application logon page to authenticate for each application.

## **The credential index setting.**

Determines whether the NetScaler appliance will use primary or the secondary authentication credentials for single signon.

To configure the session settings, you can take one of two approaches. If you want different settings for different user accounts or groups, you create a profile for each user account or group for which you want to configure custom sessions settings. You also create policies to select the connections to which to apply particular profiles, and you bind the policies to users or groups. You can also bind a policy to the authentication virtual server that handles the traffic to which you want to apply the profile.

If you want the same settings for all sessions, or if you want to customize the default settings for sessions that do not have specific profiles and policies configured, you can simply configure the global session settings.

# Session Profiles

Aug 19, 2014

To customize your user sessions, you first create a session profile. The session profile allows you to override global settings for any of the session parameters.

Note: The terms “session profile” and “session action” mean the same thing.

To create a session profile by using the command line interface

At the command prompt, type the following commands to create a session profile and verify the configuration:

- `add tm sessionAction <name> [-sessTimeout <mins>] [-defaultAuthorizationAction ( ALLOW | DENY )] [-SSO ( ON | OFF )] [-ssoCredential ( PRIMARY | SECONDARY )] [-ssoDomain <string>] [-httpOnlyCookie ( YES | NO )] [-persistentCookie ( ENABLED | DISABLED )] [-persistentCookieValidity <minutes>]`
- `show tm sessionAction <name>`

## Example

```
> add tm sessionAction session-profile -sessTimeout 30 -defaultAuthorization ALLOW
```

Done

```
> show tm sessionAction session-profile
```

```
1) Name: session-profile
```

```
 Authorization action : ALLOW
```

```
 Session timeout: 30 minutes
```

Done

To modify a session profile by using the command line interface

At the command prompt, type the following commands to modify a session profile and verify the configuration:

- `set tm sessionAction <name> [-sessTimeout <mins>] [-defaultAuthorizationAction ( ALLOW | DENY )] [-SSO ( ON | OFF )] [-ssoCredential ( PRIMARY | SECONDARY )] [-ssoDomain <string>] [-httpOnlyCookie ( YES | NO )] [-persistentCookie ( ENABLED | DISABLED )] [-persistentCookieValidity <minutes>]`
- `show tm sessionAction`

## Example

```
> set tm sessionAction session-profile -sessTimeout 30 -defaultAuthorization ALLOW
```

Done

```
> show tm sessionAction session-profile
```

```
1) Name: session-profile
```

```
 Authorization action : ALLOW
```

```
 Session timeout: 30 minutes
```

Done

To remove a session profile by using the command line interface

At the command prompt, type the following command to remove a session profile:

```
rm tm sessionAction <name>
```

To configure session profiles by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Session.
2. Navigate to Security > AAA - Application Traffic > Policies > Session.

3. In the details pane, click the Profiles tab.
4. On the Profiles tab, do one of the following:
  - To create a new session profile, click Add.
  - To modify an existing session profile, select the profile, and then click Edit.
5. In the Create TM Session Profile or Configure TM Session Profile dialog, type or select values for the parameters.
  - Name\*—actionname (Cannot be changed for a previously configured session action.)
  - Session Time-out—sesstimeout
  - Default Authorization Action—defaultAuthorizationAction
  - Single Signon to Web Applications—sso
  - Credential Index—ssocredential
  - Single Sign-on Domain—ssoDomain
  - HTTPOnly Cookie—httpOnlyCookie
  - Enable Persistent Cookie—persistentCookie
  - Persistent Cookie Validity—persistentCookieValidity
6. Click Create or OK. The session profile that you created appears in the Session Policies and Profiles pane.

# Session Policies

Aug 19, 2014

After you create one or more session profiles, you create session policies and then bind the policies globally or to an authentication virtual server to put them into effect.

To create a session policy by using the command line interface

At the command prompt, type the following commands to create a session policy and verify the configuration:

- add tm sessionPolicy <name> <rule> <action>
- show tm sessionPolicy <name>

## Example

```
> add tm sessionPolicy session-pol "URL == /*.gif" session-profile
Done
> show tm sessionPolicy session-pol
1) Name: session-pol Rule: URL == /*.gif
 Action: session-profile
Done
```

To modify a session policy by using the command line interface

At the command prompt, type the following commands to modify a session policy and verify the configuration:

- set tm sessionPolicy <name> [-rule <expression>] [-action <action>]
- show tm sessionPolicy <name>

## Example

```
> set tm sessionPolicy session-pol "URL == /*.gif" session-profile
Done
> show tm sessionPolicy session-pol
1) Name: session-pol Rule: URL == /*.gif
 Action: session-profile
Done
```

To globally bind a session policy by using the command line interface

At the command prompt, type the following commands to globally bind a session policy and verify the configuration:

```
bind tm global -policyName <policyname> [-priority <priority>]
```

## Example

```
> bind tm global -policyName session-pol
Done

> show tm sessionPolicy session-pol
1) Name: session-pol Rule: URL == /*.gif
 Action: session-profile
 Policy is bound to following entities
 1) TM GLOBAL PRIORITY : 0
Done
```

To bind a session policy to an authentication virtual server by using the command line interface

At the command prompt, type the following command to bind a session policy to an authentication virtual and verify the configuration:

```
bind authentication vserver <name> -policy <policyname> [-priority <priority>]
```

#### Example

```
> bind authentication vserver auth-vserver-1 -policyName Session-Pol-1 -priority 1000
```

Done

To unbind a session policy from an authentication virtual server by using the command line interface

At the command prompt, type the following commands to unbind a session policy from an authentication virtual server and verify the configuration:

```
unbind authentication vserver <name> -policy <policyname>
```

#### Example

```
> unbind authentication vserver auth-vserver-1 -policyName Session-Pol-1
```

Done

To unbind a globally bound session policy by using the command line interface

At the command prompt, type the following commands to unbind a globally-bound session policy:

```
unbind tm global -policyName <policyname>
```

#### Example

```
> unbind tm global -policyName Session-Pol-1
```

Done

To remove a session policy by using the command line interface

First unbind the session policy from global, and then, at the command prompt, type the following commands to remove a session policy and verify the configuration:

```
rm tm sessionPolicy <name>
```

#### Example

```
> rm tm sessionPolicy Session-Pol-1
```

Done

To configure and bind session policies by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Session.
2. Navigate to Security > AAA - Application Traffic > Policies > Session.
3. In the details pane, on the Policies tab, do one of the following:
  - To create a new session policy, click Add.
  - To modify an existing session policy, select the policy, and then click Edit.
4. In the Create Session Policy or Configure Session Policy dialog, type or select values for the parameters.
  - Name\*—policyname (Cannot be changed for a previously configured session policy.)
  - Request Profile\*—actionname
  - Expression\*—rule (You enter expressions by first choosing the type of expression in the leftmost drop-down list beneath the Expression text area and then typing your expression directly into the expression text area, or by clicking Add to open the Add Expression dialog box and using the drop-down lists in it to construct your expression.)
5. Click Create or OK. The policy that you created appears in the details pane of the Session Policies and Profiles page.

6. To globally bind a session policy, in the details pane, select Global Bindings from the Action drop-down list, and fill in the dialog.
  1. Select the name of the session policy you want to globally bind.
  2. Click OK.
7. To bind a session policy to an authentication virtual server, in the navigation pane, click Virtual Servers, and add that policy to the policies list.
  1. In the details pane, select the virtual server, and then click Edit.
  2. In the Advanced selections to the right of the detail area, click Policies.
  3. Select a policy, or click the plus icon to add a policy.
  4. In the Priority column to the left, modify the default priority as needed to ensure that the policy is evaluated in the proper order.
  5. Click OK.A message appears in the status bar, stating that the policy has been configured successfully.

# Global Session Settings

Aug 13, 2014

In addition to or instead of creating session profiles and policies, you can configure global session settings. These settings control the session configuration when there is no explicit policy overriding them.

To configure the session settings by using the command line interface

At the command prompt, type the following commands to configure the global session settings and verify the configuration:

```
set tm sessionParameter [-sessTimeout <mins>] [-defaultAuthorizationAction (ALLOW | DENY)] [-SSO (ON | OFF)] [-ssoCredential (PRIMARY | SECONDARY)] [-ssoDomain <string>] [-httpOnlyCookie (YES | NO)] [-persistentCookie (ENABLED | DISABLED)] [-persistentCookieValidity <minutes>]
```

## Example

```
> set tm sessionParameter -sessTimeout 30
Done
> set tm sessionParameter -defaultAuthorizationAction DENY
Done
> set tm sessionParameter -SSO ON
Done
> set tm sessionParameter -ssoCredential PRIMARY
Done
```

To configure the session settings by using the configuration utility

1. Navigate to Security > AAA - Application Traffic
2. In the details pane, under Settings, click Change global settings.
3. In the Global Session Settings dialog, type or select values for the parameters.
  - Session Time-out— sessTimeout
  - Default Authorization Action— defaultAuthorizationAction
  - Single Sign-on to Web Applications— sso
  - Credential Index— ssoCredential
  - Single Sign-on Domain— ssoDomain
  - HTTPOnly Cookie— httpOnlyCookie
  - Enable Persistent Cookie— persistentCookie
  - Persistent Cookie Validity (minutes)— persistentCookieValidity
  - Home Page— homepage
4. Click OK.

# Traffic Settings

Sep 24, 2013

If you use forms-based or SAML single sign-on (SSO) for your protected applications, you configure that feature in the Traffic settings. SSO enables your users to log on once to access all protected applications, rather than requiring them to log on separately to access each one.

Forms-based SSO allows you to use a web form of your own design as the sign-on method instead of a generic pop-up window. You can therefore put your company logo and other information you might want your users to see on the logon form. SAML SSO allows you to configure one NetScaler appliance or virtual appliance instance to authenticate to another NetScaler appliance on behalf of users who have authenticated with the first appliance.

To configure either type of SSO, you first create a forms or SAML SSO profile. Next, you create a traffic profile and link it to the SSO profile you created. Next, you create a policy, link it to the traffic profile. Finally, you bind the policy globally or to an authentication virtual server to put your configuration into effect.

# Traffic Profiles

Aug 19, 2014

After creating at least one forms or SAML sso profile, you must next create a traffic profile.

Note: In this feature, the terms “profile” and “action” mean the same thing.

To create a traffic profile by using the command line interface

At the command prompt, type:

```
add tm trafficAction <name> [-appTimeout <mins>] [-SSO (ON | OFF)] [-formSSOAction <string>]] [-persistentCookie (ENABLED | DISABLED)] [-InitiateLogout (ON | OFF)]
```

## Example

```
add tm trafficAction Traffic-Prof-1 -appTimeout 10 -SSO ON -formSSOAction SSO-Prof-1
```

To modify a session profile by using the command line interface

At the command prompt, type:

```
set tm trafficAction <name> [-appTimeout <mins>] [-SSO (ON | OFF)] [-formSSOAction <string>]] [-persistentCookie (ENABLED | DISABLED)] [-InitiateLogout (ON | OFF)]
```

## Example

```
set tm trafficAction Traffic-Prof-1 -appTimeout 10 -SSO ON -formSSOAction SSO-Prof-1
```

To remove a session profile by using the command line interface

At the command prompt, type:

```
rm tm trafficAction <name>
```

## Example

```
rm tm trafficAction Traffic-Prof-1
```

To configure traffic profiles by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Traffic.
2. Navigate to Security > AAA - Application Traffic > Policies > Traffic.
3. In the details pane, click the Profiles tab.
4. On the Profiles tab, do one of the following:
  - To create a new traffic profile, click Add.
  - To modify an existing traffic profile, select the profile, and then click Edit.
5. In the Create Traffic Profile or Configure Traffic Profile dialog box, specify values for the parameters.
  - Name\*—name (Cannot be changed for a previously configured session action.)
  - AppTimeout—appTimeout
  - Single Sign-On—SSO
  - Form SSO Action—formSSOAction
  - SAML SSO Action—samlSSOAction
  - Enable Persistent Cookie—persistentCookie
  - Initiate Logout—InitiateLogout
6. Click Create or OK. The traffic profile that you created appears in the Traffic Policies, Profiles, and either the Form SSO

Profiles or SAML SSO Profiles pane, as appropriate.

# Traffic Policies

Aug 19, 2014

After you create one or more form SSO and traffic profiles, you create traffic policies and then bind the policies, either globally or to a traffic management virtual server, to put them into effect.

To create a traffic policy by using the command line interface

At the command prompt, type:

```
add tm trafficPolicy <name> <rule> <action>
```

## Example

```
add tm trafficPolicy Traffic-Pol-1 "HTTP.REQ.HEADER("Cookie").CONTAINS("login=true)" Traffic-Prof-1
```

To modify a traffic policy by using the command line interface

At the command prompt, type:

```
set tm trafficPolicy <name> <rule> <action>
```

## Example

```
set tm trafficPolicy Traffic-Pol-1 "HTTP.REQ.HEADER("Cookie").CONTAINS("login=true)" Traffic-Prof-1
```

To globally bind a traffic policy by using the command line interface

At the command prompt, type:

```
bind tm global -policyName <string> [-priority <priority>]
```

## Example

```
bind tm global -policyName Traffic-Pol-1
```

To bind a traffic policy to a load balancing or content switching virtual server by using the command line interface

At the command prompt, type one of the following commands:

- `bind lb vserver <name> -policy <policyName> [-priority <priority>]`
- `bind cs vserver <name> -policy <policyName> [-priority <priority>]`

## Example

```
bind authentication vserver auth-vserver-1 -policyName Traffic-Pol-1 -priority 1000
```

To unbind a globally bound traffic policy by using the command line interface

At the command prompt, type:

```
unbind tm global -policyName <policyname>
```

## Example

```
unbind tm global -policyName Traffic-Pol-1
```

To unbind a traffic policy from a load balancing or content switching virtual server by using the command line interface

At the command prompt, type one of the following commands:

- `unbind lb vserver <name> -policy <policyname>`
- `unbind cs vserver <name> -policy <policyname>`

## Example

```
unbind authentication vserver auth-vserver-1 -policyName Traffic-Pol-1
```

To remove a traffic policy by using the command line interface

First unbind the session policy from global, and then, at the command prompt, type:

```
rm tm trafficPolicy <name>
```

## Example

```
rm tm trafficPolicy Traffic-Pol-1
```

To configure and bind traffic policies by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Traffic.
2. Navigate to Security > AAA - Application Traffic > Policies > Traffic.
3. In the details pane, do one of the following:
  - To create a new session policy, click Add.
  - To modify an existing session policy, select the policy, and then click Edit.
4. In the Create Traffic Policy or Configure Traffic Policy dialog, specify values for the parameters.
  - Name\*—policyName (Cannot be changed for a previously configured session policy.)
  - Profile\*—actionName
  - Expression—rule (You enter expressions by first choosing the type of expression in the leftmost drop-down list beneath the Expression text area and then typing your expression directly into the expression text area, or by clicking Add to open the Add Expression dialog box and using the drop-down lists in it to construct your expression.)
5. Click Create or OK. The policy that you created appears in the details pane of the Session Policies and Profiles page.

# Form SSO Profiles

Jun 08, 2015

To enable and configure forms-based SSO, you first create an SSO profile.

Note:

- Forms-based single sign-on does not work if the form is customized to include Javascript.
- In this feature, the terms “profile” and “action” mean the same thing.

To create a form SSO profile by using the command line interface

At the command prompt, type:

- `add tm formSSOAction <name> -actionURL <URL> -userField <string> -passwdField <string> -ssoSuccessRule <expression> [-nameValuePair <string>] [-responsesize <positive_integer>] [-nvtype ( STATIC | DYNAMIC )] [-submitMethod ( GET | POST )`
- `show tm formSSOAction [<name>]`

## Example

```
add tm formSSOAction SSO-Prof-1 -actionURL "/logon.php"
-userField "loginID" -passwdField "passwd"
-nameValuePair "loginID passwd" -responsesize "9096"
-ssoSuccessRule "HTTP.RES.HEADER("Set-Cookie").CONTAINS("LogonID")"
-nvtype STATIC -submitMethod GET
-sessTimeout 10 -defaultAuthorizationAction ALLOW
```

To modify a form SSO by using the command line interface

At the command prompt, type:

```
set tm formSSOAction <name> -actionURL <URL> -userField <string> -passwdField <string> -ssoSuccessRule <expression>
[-nameValuePair <string>] [-responsesize <positive_integer>] [-nvtype (STATIC | DYNAMIC)] [-submitMethod (GET | POST
)]
```

## Example

```
set tm formSSOAction SSO-Prof-1 -actionURL "/logon.php"
-userField "loginID" -passwdField "passwd"
-ssoSuccessRule "HTTP.RES.HEADER("Set-Cookie").CONTAINS("LogonID")"
-nameValuePair "loginID passwd" -responsesize "9096"
-nvtype STATIC -submitMethod GET
-sessTimeout 10 -defaultAuthorizationAction ALLOW
```

To remove a form SSO profile by using the command line interface

At the command prompt, type:

```
rm tm formSSOAction <name>
```

## Example

```
rm tm sessionAction SSO-Prof-1
```

To configure form SSO profiles by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Policies > Traffic.
2. In the details pane, click the Form SSO Profiles tab.
3. On the Form SSO Profiles tab, do one of the following:
  - To create a new form SSO profile, click Add.
  - To modify an existing form SSO profile, select the profile, and then click Edit.
4. In the Create Form SSO Profile or Configure Form SSO Profile dialog, specify values for the parameters:
  - Name\*—name (Cannot be changed for a previously configured session action.)
  - Action URL\*—actionURL
  - User Name Field\*—userField
  - Password Field\*—passField
  - Expression\*—ssoSuccessRule
  - Name Value Pair—nameValuePair
  - Response Size—responsesize
  - Extraction—nvtype
  - Submit Method—submitMethod
5. Click Create or OK, and then click Close. The form SSO profile that you created appears in the Traffic Policies, Profiles, and Form SSO Profiles pane.

# SAML SSO Profiles

Jun 12, 2014

To enable and configure SAML-based SSO, you first create a SAML SSO profile.

To create a SAML SSO profile by using the command line interface

At the command prompt, type:

```
add tm samlSSOProfile <name> -samlSigningCertName <string> -assertionConsumerServiceURL <URL> -relaystateRule <expression> -sendPassword (ON | OFF) [-samlIssuerName <string>]
```

## Example

```
add tm samlSSOProfile saml-SSO-Prof-1 -samlSigningCertName "Example, Inc." -assertionConsumerServiceURL "https://service.example.com" -relaystateRule "true" -sendPassword "ON" -samlIssuerName
```

To modify a SAML SSO by using the command line interface

At the command prompt, type:

```
set tm samlSSOProfile <name> -samlSigningCertName <string> -assertionConsumerServiceURL <URL> -relaystateRule <expression> -sendPassword (ON | OFF) [-samlIssuerName <string>]
```

## Example

```
set tm samlSSOProfile saml-SSO-Prof-1 -samlSigningCertName "Example, Inc." -assertionConsumerServiceURL "https://service.example.com" -relaystateRule "true" -sendPassword "ON" -samlIssuerName
```

To remove a SAML SSO profile by using the command line interface

At the command prompt, type:

```
rm tm samlSSOProfile <name>
```

## Example

```
rm tm sessionAction saml-SSO-Prof-1
```

To configure a SAML SSO profile by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Policies > Traffic.
2. In the details pane, click the SAML SSO Profiles tab.
3. On the SAML SSO Profiles tab, do one of the following:
  - To create a new SAML SSO profile, click Add.
  - To modify an existing SAML SSO profile, select the profile, and then click OpenEdit.
4. In the Create SAML SSO Profiles or the Configure SAML SSO Profiles dialog box, set the following parameters:
  - Name\*
  - Signing Certificate Name\*
  - ACS URL\*
  - Relay State Rule\*
  - Send Password
  - Issuer Name
5. Click Create or OK, and then click Close. The SAML SSO profile that you created appears in the Traffic Policies, Profiles, and SAML SSO Profiles pane.

# Session Timeout for OWA 2010

Jun 06, 2014

You can now force OWA 2010 connections to time out after a specified period of inactivity. OWA sends repeated keepalive requests to the server to prevent timeouts. Keeping the connections open can interfere with single sign-on.

To force OWA 2010 to timeout after a specified period by using the command line interface

At the command prompt, type the following commands:

- `add tm trafficAction <actname> [-forcedTimeout <forcedTimeout> -forcedTimeoutVal <mins> ]`  
For <actname>, substitute a name for your traffic policy. For <mins>, substitute the number of minutes after which to initiate a forced timeout. For <forcedTimeout>, substitute one of the following values:
  - **START**—Starts the timer for forced timeout if a timer has not already been started. If a running timer exists, has no effect.
  - **STOP**—Stops a running timer. If no running timer is found, has no effect.
  - **RESET**—Restarts a running timer. If no running timer is found, starts a timer just as if the **START** option had been used.
- `add tm trafficPolicy <polname> <rule> <actname>`  
For <polname>, substitute a name for your traffic policy. For <rule>, substitute a rule in NetScaler default syntax.
- `bind lb vserver <vservname> -policyName <name> -priority <number>`  
For <vservname>, substitute the name of the AAA traffic management virtual server. For <priority>, substitute an integer that designates the policy's priority.

## Example

```
add tm trafficAction act-owa2010timeout -forcedTimeout RESET -forcedTimeoutVal 10
add tm trafficPolicy pol-owa2010timeout true act-owa2010timeout
bind lb vserver vs-owa2010 -policyName pol-owa2010timeout -priority 10
```

# Authenticating with Client Certificates

Aug 13, 2014

Web sites that contain sensitive content, such as online banking websites or websites with employee personal information, sometimes require client certificates for authentication. To configure AAA to authenticate users on the basis of client-side certificate attributes, you first enable client authentication on the traffic management virtual server and bind the root certificate to the authentication virtual server. Then, you implement one of two options. You can configure the default authentication type on the authentication virtual server as CERT, or you can create a certificate action that defines what the NetScaler ADC must do to authenticate users on the basis of a client certificate. In either case, your authentication server must support CRLs. You configure the ADC to extract the user name from the SubjectCN field or another specified field in the client certificate.

When the user tries to log on to an authentication virtual server for which an authentication policy is not configured, and a global cascade is not configured, the user name information is extracted from the specified field of the certificate. If the required field is extracted, the authentication succeeds. If the user does not provide a valid certificate during the SSL handshake, or if the user name extraction fails, authentication fails. After it validates the client certificate, the ADC presents a logon page to the user.

The following procedures assume that you have already created a functioning AAA configuration, and therefore they explain only how to enable authentication by using client certificates. These procedures also assume that you have obtained your root certificate and client certificates and have placed them on the ADC in the /nsconfig/ssl directory.

To configure the AAA client certificate parameters by using the command line interface

At the command prompt, type the following commands, in the order shown, to configure the certificate and verify the configuration:

- add ssl certKey <certkeyName> -cert <certFile> -key <keyFile> -password -inform <inform> -expiryMonitor <expiryMonitor> -notificationPeriod <notificationPeriod>
- bind ssl certKey <certkeyName> -vServer <certkeyName> -CA -crlCheck Mandatory
- show ssl certKey [<certkeyName>]
- set aaa parameter -defaultAuthType CERT
- show aaa parameter
- set aaa certParams -userNameField "Subject:CN"
- show aaa certParams

To configure the AAA client certificate parameters by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Virtual Servers.
2. In the details pane, select the virtual server that you want to configure to handle client certificate authentication, and then click Edit.
3. On the Configuration page, under Certificates, click the right arrow (>) to open the CA Cert Key installation dialog.
4. In the CA Cert Key dialog box, click Insert.
5. In the CA Cert Key - SSL Certificates dialog box, click Install.
6. In the Install Certificate dialog box, set the following parameters, whose names correspond to the CLI parameter names as shown:
  - Certificate-Key Pair Name\*— certkeyName
  - Certificate File Name— certFile
  - Key File Name— keyFile

- Certificate Format—inform
  - Password—password
  - Certificate Bundle—bundle
  - Notify When Expires—expiryMonitor
  - Notification Period—notificationPeriod
7. Click Install, and then click Close.
  8. In the CA Cert Key dialog box, in the Certificate list, select the root certificate.
  9. Click Save.
  10. Click Back to return to the main configuration screen.
  11. Navigate to Security > AAA - Application Traffic > Policies > Authentication > CERT.
  12. In the details pane, select the policy you want to configure to handle client certificate authentication, and then click Edit.
  13. In the Configure Authentication CERT Policy dialog, Server drop-down list, select the virtual server you just configured to handle client certificate authentication.
  14. Click OK. A message appears in the status bar, stating that the configuration completed successfully.

# Client Certificate Pass-Through

Jul 30, 2014

The NetScaler ADC can now be configured to pass client certificates through to protected applications that require client certificates for user authentication. The ADC first authenticates the user, then inserts the client certificate into the request and sends it to the application. This feature is configured by adding appropriate SSL policies.

The exact behavior of this feature when a user presents a client certificate depends upon the configuration of the VPN virtual server.

- If the VPN virtual server is configured to accept client certificates but not require them, the ADC inserts the certificate into the request and then forwards the request to the protected application.
- If the VPN virtual server has client certificate authentication disabled, the ADC renegotiates the authentication protocol and reauthenticates the user before it inserts the client certificate in the header and forwards the request to the protected application.
- If the VPN virtual server is configured to require client certificate authentication, the ADC uses the client certificate to authenticate the user, then inserts the certificate in the header and forwards the request to the protected application.

In all of these cases, you configure client certificate pass-through as follows.

To create and configure client certificate pass-through by using the command line interface

At the command prompt, type the following commands:

- `add vpn vserver <name> SSL <IP> 443`  
For <name>, substitute a name for the virtual server. The name must contain from one to 127 ASCII characters, beginning with a letter or underscore (`_`), and containing only letters, numbers, and the underscore, hash (`#`), period (`.`), space, colon (`:`), at (`@`), equals (`=`), and hyphen (`-`) characters. For <IP>, substitute the IP address assigned to the virtual server.
- `set ssl vserver <name> -clientAuth ENABLED -clientCert <clientcert>`  
For <name>, substitute the name of the virtual server that you just created. For <clientCert>, substitute one of the following values:
  - `disabled`—disables client certificate authentication on the VPN virtual server.
  - `mandatory`—configures the VPN virtual server to require client certificates to authenticate.
  - `optional`—configures the VPN virtual server to allow client certificate authentication, but not to require it.
- `bind vpn vserver <name> -policy local`  
For <name>, substitute the name of the VPN virtual server that you created.
- `bind vpn vserver <name> -policy cert`  
For <name>, substitute the name of the VPN virtual server that you created.
- `bind ssl vserver <name> -certKeyName <certkeyname>`  
For <name>, substitute the name of the virtual server that you created. For <certKeyName>, substitute the client certificate key.
- `bind ssl vserver <name> -certKeyName <cacertkeyname> -CA -ocspCheck Optional`  
For <name>, substitute the name of the virtual server that you created. For <cacertKeyName>, substitute the CA certificate key.
- `add ssl action <actname> -clientCert ENABLED -certHeader CLIENT-CERT`  
For <actname>, substitute a name for the SSL action.

- add ssl policy <polname> -rule true -action <actname>  
For <polname>, substitute a name for your new SSL policy. For <actname>, substitute the name of the SSL action that you just created.
- bind ssl vserver <name> -policyName <polname> -priority 10  
For <name>, substitute the name of the VPN virtual server.

## Example

```
add vpn vserver vs-certpassthru SSL 10.121.250.75 443
set ssl vserver vs-certpassthru -clientAuth ENABLED -clientCert optional
bind vpn vserver vs-certpassthru -policy local
bind vpn vserver vs-certpassthru -policy cert
bind ssl vserver vs-certpassthru -certkeyName mycertKey
bind ssl vserver vs-certpassthru -certkeyName mycertKey -CA -ocspCheck Optional
add ssl action act-certpassthru -clientCert ENABLED -certHeader CLIENT-CERT
add ssl policy pol-certpassthru -rule true -action act-certpassthru
bind ssl vserver vs-certpassthru -policyName pol-certpassthru -priority 10
```

# Configuring AAA with Commonly Used Protocols

Mar 15, 2013

Configuring the NetScaler for Authentication, Authorization, and Auditing (AAA) needs a specific setup on the NetScaler and clients' browsers. The configuration varies with the protocol used for AAA.

For more information about configuring the NetScaler for Kerberos authentication, see [Handling Authentication, Authorization and Auditing with Kerberos/NTLM](#).

# Handling Authentication, Authorization and Auditing with Kerberos/NTLM

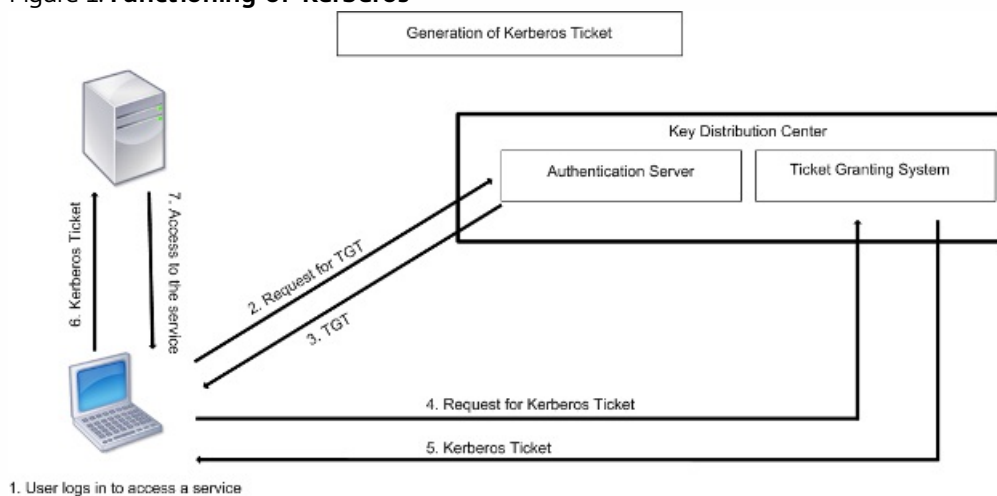

Mar 27, 2012

Kerberos, a computer network authentication protocol, provides secure communication over the Internet. Designed primarily for client-server applications, it provides for mutual authentication by which the client and server can each ensure the other's authenticity. Kerberos uses a trusted third party, referred to as Key Distribution Center (KDC). A KDC consists of an Authentication Server (AS), which authenticates a user, and a Ticket Granting Server (TGS).

Each entity on the network (client or server) has a secret key that is known only to itself and the KDC. The knowledge of this key implies authenticity of the entity. For communication between two entities on the network, the KDC generates a session key, referred to as the Kerberos ticket or service ticket. The client makes a request to the AS for credentials for a specific server. The client then receives a ticket, referred to as Ticket Granting Ticket (TGT). The client then contacts the TGS, using the TGT it received from the AS to prove its identity, and asks for a service. If the client is eligible for the service, the TGS issues a Kerberos ticket to the client. The client then contacts the server hosting the service (referred to as the service server), using the Kerberos ticket to prove that it is authorized to receive the service. The Kerberos ticket has a configurable lifetime. The client authenticates itself with the AS only once. If it contacts the physical server multiple times, it reuses the AS ticket.

The following figure shows the basic functioning of the Kerberos protocol.

Figure 1. **Functioning of Kerberos**

**Kerberos authentication has the following advantages:**

- Faster authentication. When a physical server gets a Kerberos ticket from a client, the server has enough information to authenticate the client directly. It does not have to contact a domain controller for client authentication, and therefore the authentication process is faster.
- Mutual authentication. When the KDC issues a Kerberos ticket to a client and the client uses the ticket to access a service, only authenticated servers can decrypt the Kerberos ticket. If the virtual server on the NetScaler is able to decrypt the Kerberos ticket, you can conclude that both the virtual server and client are authenticated. Thus, the authentication of the server happens along with the authentication of the client.
- Single sign-on between Windows and other operating systems that support Kerberos.

**Kerberos authentication may have the following disadvantages:**

- Kerberos has strict time requirements; the clocks of the involved hosts must be synchronized with the Kerberos server clock to ensure that the authentication does not fail. You can mitigate this disadvantage by using the Network Time Protocol daemons to keep the host clocks synchronized. Kerberos tickets have an availability period, which you can configure.
- Kerberos needs the central server to be available continuously. When the Kerberos server is down, no one can log on. You can mitigate this risk by using multiple Kerberos servers and fallback authentication mechanisms.
- Because all the authentication is controlled by a centralized KDC, any compromise in this infrastructure, such as the user's password for a local workstation being stolen, can allow an attacker to impersonate any user. You can mitigate this risk to some extent by using only a desktop machine or laptop that you trust, or by enforcing preauthentication by means of a hardware-token.

To use Kerberos authentication, you must configure it on the NetScaler appliance and on each client.

# How NetScaler Implements Kerberos for Client Authentication

Jun 12, 2014

Note: Kerberos/NTLM authentication is supported only in the NetScaler 9.3 nCore release or later, and it can be used only for AAA traffic management (AAA-TM) virtual servers.

NetScaler handles the components involved in Kerberos authentication in the following way:

## **Key Distribution Center (KDC)**

In the Windows 2000 Server or later versions, the Domain Controller and KDC are part of the Windows Server. If the Windows Server is UP and running, it indicates that the Domain Controller and KDC are configured. The KDC is also the Active Directory server.

Note: All Kerberos interactions are validated with the Windows Kerberos Domain Controller.

## **Authentication Service and Protocol Negotiation**

A NetScaler appliance supports Kerberos authentication on the AAA-TM authentication virtual servers. If the Kerberos authentication fails, the NetScaler uses the NTLM authentication.

By default, Windows 2000 Server and later Windows Server versions use Kerberos for AAA. If you create an authentication policy with NEGOTIATE as the authentication type, the NetScaler attempts to use the Kerberos protocol for AAA and if the client's browser fails to receive a Kerberos ticket, the NetScaler uses the NTLM authentication. This process is referred to as negotiation.

The client may fail to receive a Kerberos ticket in any of the following cases:

- Kerberos is not supported on the client.
- Kerberos is not enabled on the client.
- The client is in a domain other than that of the KDC.
- The Access Directory on the KDC is not accessible to the client.

For Kerberos/NTLM authentication, the NetScaler does not use the data that is present locally on the NetScaler appliance.

## **Authorization**

The traffic management virtual server can be a load balancing virtual server or a content switching virtual server.

## **Auditing**

The NetScaler appliance supports auditing of Kerberos authentication with the following audit logging:

- Complete audit trail of the traffic management end-user activity
- SYSLOG and high performance TCP logging
- Complete audit trail of system administrators
- All system events
- Scriptable log format

## **Supported Environment**

Kerberos authentication does not need any specific environment on the NetScaler. The client (browser) must provide support for Kerberos authentication.

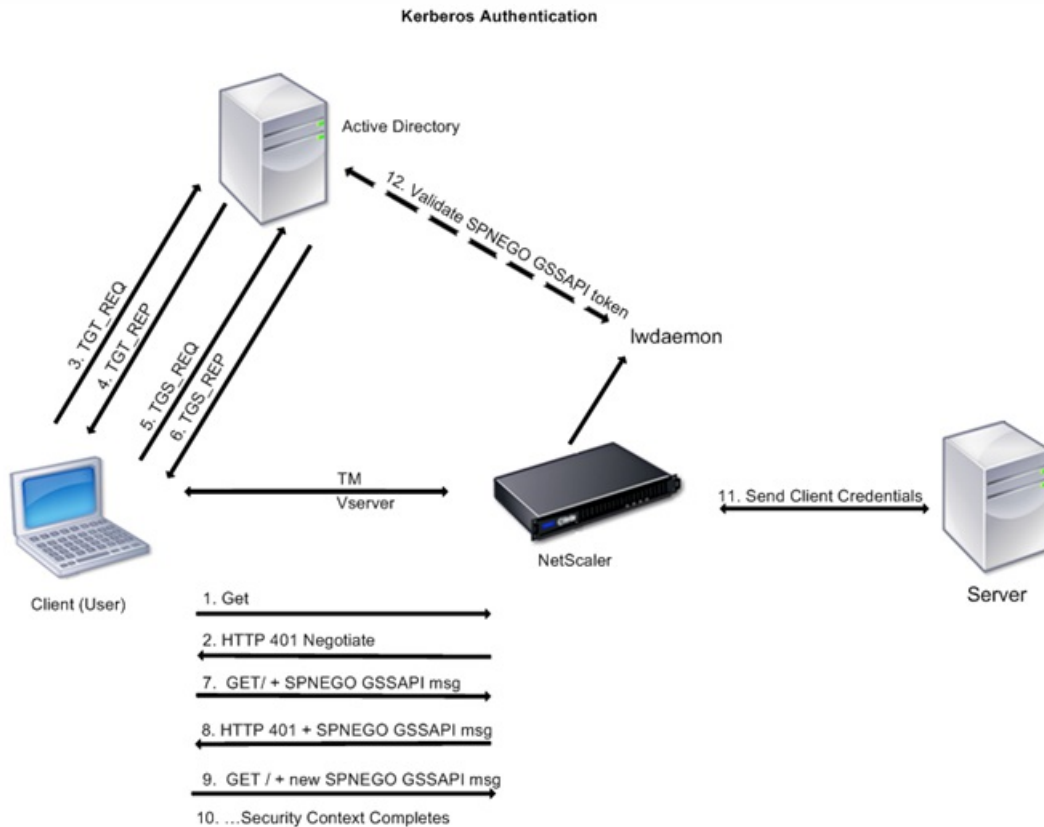

### High Availability

In a high availability setup, only the active NetScaler joins the domain. In case of a failover, the NetScaler lwagent daemon joins the secondary NetScaler appliance to the domain. No specific configuration is required for this functionality.

### Kerberos Authentication Process

The following figure shows a typical process for Kerberos authentication in the NetScaler environment.

Figure 1. Kerberos Authentication Process on NetScaler

The Kerberos authentication occurs in the following stages:

#### Client authenticates itself to the KDC.

1. The NetScaler appliance receives a request from a client.
2. The traffic management (load balancing or content switching) virtual server on the NetScaler sends a challenge to the client.
3. To respond to the challenge, the client gets a Kerberos ticket.
  - The client sends the Authentication Server of the KDC a request for a ticket-granting ticket (TGT) and receives the TGT. (See 3, 4 in the figure, Kerberos Authentication Process.)
  - The client sends the TGT to the Ticket Granting Server of the KDC and receives a Kerberos ticket. (See 5, 6 in the figure, Kerberos Authentication Process.)

Note: The above authentication process is not necessary if the client already has a Kerberos ticket whose lifetime has not expired. In addition, clients such as Web Services, .NET, or J2EE, which support SPNEGO, get a Kerberos ticket for the target server, create an SPNEGO token, and insert the token in the HTTP header when they send an HTTP request. They do not

go through the client authentication process.

**Client requests a service.**

1. The client sends the Kerberos ticket containing the SPNEGO token and the HTTP request to the traffic management virtual server on the NetScaler. The SPNEGO token has the necessary GSSAPI data.
2. The NetScaler establishes a security context between the client and the NetScaler. If the NetScaler cannot accept the data provided in the Kerberos ticket, the client is asked to get a different ticket. This cycle repeats till the GSSAPI data is acceptable and the security context is established. The traffic management virtual server on the NetScaler acts as an HTTP proxy between the client and the physical server.

**NetScaler completes the authentication.**

1. After the security context is complete, the traffic management virtual server validates the SPNEGO token.
2. From the valid SPNEGO token, the virtual server extracts the user ID and GSS credentials, and passes them to the authentication daemon.
3. A successful authentication completes the Kerberos authentication.

# Kerberos Authentication - Configuration on the NetScaler Appliance

Mar 27, 2012

To configure Kerberos authentication on the NetScaler appliance, perform the following tasks:

1. Enable the Authentication, Authorization, and Auditing (AAA) feature on the NetScaler appliance.
2. On the Active Directory, add a user for Kerberos authentication, map the HTTP service to this user, and generate a keytab file and import it to the NetScaler appliance. You can map more than one service if the Kerberos authentication is required for more than one service. The keytab file should contain entries for every service that is bound to the traffic management virtual server on the NetScaler. The keytab file is necessary for decrypting the secret received from the client during Kerberos authentication. The authentication details of all the services are stored in a single keytab file on the NetScaler.
3. Add a DNS server.  
Note: The NetScaler must obtain the IP address of the domain controller from the fully qualified domain name (FQDN). Therefore, Citrix recommends configuring the NetScaler with a DNS server. A less preferred alternative is to create a static DNS entry.
4. Create an authentication negotiation policy with a negotiation action.
5. Configure an authentication server and bind the authentication policy to the authentication virtual server.
6. Configure an authentication service and a traffic management virtual server, and bind the service to the virtual server. You can use either a load balancing or a content switching virtual server.
7. Verify the configuration.

# Enabling AAA on the NetScaler

Oct 30, 2013

Enable authentication of the traffic on the NetScaler appliance.

To enable Authentication, Authorization, and Auditing (AAA) by using the command line interface

At the command prompt, type the following commands to enable AAA and verify the configuration:

- enable ns feature AAA
- show ns feature

## Example

```
> enable feature aaa
```

```
Done
```

```
> show ns feature
```

```
Feature Acronym Status
```

```

```

```
1) Web Logging WL ON
```

```
...
```

```
3) Load Balancing LB ON
```

```
4) Content Switching CS ON
```

```
5) Cache Redirection CR ON
```

```
...
```

```
14) SSL VPN SSLVPN ON
```

```
15) AAA AAA ON
```

```
...
```

```
26) CloudBridge CloudBridge OFF
```

```
Done
```

To enable Authentication, Authorization, and Auditing (AAA) on NetScaler by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure basic features.
3. In the Configure Basic Features dialog box, select the Authentication, Authorization and Auditing check box.
4. Click OK.
5. In the confirmation dialog box, click Yes. A message appears in the status bar to indicate that the feature is enabled.

# Adding a Keytab file

Nov 14, 2013

The keytab file contains information about services necessary for Kerberos authentication. The keytab file is necessary for decrypting the secret received from the client during Kerberos authentication. You can map more than one service if the Kerberos authentication is required for more than one service. The keytab file should contain entries for every service that is bound to the traffic management virtual server on the NetScaler. The authentication details of all the services are stored in a single keytab file on the NetScaler.

To generate a keytab file and import it to the NetScaler appliance, follow the procedure described below:

Note: You can generate the keytab file and import it onto the NetScaler only from the command line.

1. Log onto the Active Directory server and create a user for Kerberos authentication.

For example, type the following command:

```
net user Kerb-SVC-Account freebsd!@#456 /add
```

2. In the User Properties section, ensure the following settings:

- The Change password at next logon option is not selected.
- The Password does not expire option is selected.

3. Map the HTTP service to the above user and export the keytab file. For example, run the following command on the Active Directory server:

```
ktpass /out keytabfile /princ HTTP/owa.newacp.com@NEWACP.COM /pass freebsd!@#456 /mapuser newacp\dummy /ptype KRB5_NT_PRINCIPAL
```

Note: If you want to map more services, repeat the above command for every service. You can give the same name or different names for the output file.

4. Transfer the keytab file to the NetScaler by using the unix ftp command or any other file transfer utility of your choice.
5. Log onto the NetScaler appliance, and run the ktutil utility to verify the keytab file. The keytab file has an entry for the HTTP service after it is imported.

## Example

```
root@ns# ktutil
ktutil: rkt /var/keytabfile
ktutil: list
slot KVNO Principal
```

```

ktutil: wkt /etc/ krb5.keytab
ktutil: list
slot KVNO Principal
```

```

1 2 HTTP/owa.newacp.com@NEWACP.COM
ktutil: quit
```

# Adding a DNS Server

Oct 30, 2013

The NetScaler appliance should obtain the IP address of the domain controller from the fully qualified domain name (FQDN). Therefore, Citrix recommends configuring the NetScaler with a DNS server. A less preferred alternative is to create a static DNS entry.

To add a DNS server by using the command line interface

At the command prompt, type the following command:

```
add dns nameserver <IP>
```

Note: Alternatively, you can add static host entries or use any other means so that the NetScaler can resolve the FQDN name of the domain controller to an IP address.

## Example

```
add dns nameserver 1.2.3.4
```

To add a DNS server by using the NetScaler configuration utility

1. Navigate to Traffic Management > DNS > Name Servers.
2. In the details pane, click Add.
3. In the IP Address box, type the IP address.
4. Click Create, and then Close.
5. Verify that the details pane shows the newly added DNS server.

# Creating an Authentication Negotiation Policy

Nov 14, 2013

Create a negotiation policy with a negotiation action for Kerberos authentication of services.

To create an authentication negotiation policy by using the command line interface

At the command prompt, type the following commands:

- add authentication negotiateAction <name> -domain <domainName> -domainUser <domainUsername> -domainUserPasswd <domainUserPassword> -encrypted
- add authentication negotiatePolicy <name> <rule> <reqAction>

## Example

```
add authentication negotiateAction negact -domain newacp.com -domainUser Administrator -domainUserPasswd skp5sep
```

```
add authentication negotiatePolicy negopol ns_true negact
```

To create an authentication negotiation policy by using the NetScaler configuration utility

1. Navigate to Security > AAA-Application Traffic > Policies > Authentication.
2. In the details pane, on the Policies tab, click Add.
3. In the Create Authentication Policy dialog box, set the following parameters:
  - Name
  - Authentication Type - Select NEGOTIATE.
  - Server - Select an existing server from the dropdown list. To add a new authentication server, click New..., and in the Create Authentication Server dialog box, set the following parameters:
    - Domain Name
    - User Name
    - Password
    - Confirm Password - Retype the password.
  - Expression - In the Named Expression list, select General and select True Value from the dropdown list, and then click Add Expression.
4. Click Create, and then click Close.
5. Verify that the policy you created appears in the Authentication Policies and Servers pane.

# Creating an Authentication Virtual Server

Oct 30, 2013

Configure an authentication virtual server and bind the authentication negotiation policy to the authentication virtual server. To create an authentication virtual server and bind the negotiation policy by using the command line interface

At the command prompt, type the following commands:

- add authentication vserver <name> SSL <ipAuthVserver> 443 -authenticationDomain <domainName>
- bind authentication vserver <name> -policy <negotiatePolicyName>

## Example

```
add authentication vserver authen1 SSL 10.102.113.166 443 -authenticationDomain newacp.com
add ssl certKey cert1 -cert "/nsconfig/ssl/complete/server/server_rsa_2048.pem" -key "/nsconfig/ssl/complete/server/server_rsa_2048.key"
bind ssl vserver authen1 -certKeyName cert1
bind authentication vserver authen1 -policy negopol
```

To create an authentication virtual server and bind the negotiation policy by using the NetScaler configuration utility

1. Navigate to Security > AAA-Application Traffic > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Authentication) dialog box, set the following parameters:
  - Name
  - IP Address
  - Protocol - Select SSL
  - Domain - Type the fully qualified domain name added while creating the keytab file.

Note: For AAA, the protocol must be SSL protocol and port must be 443. Therefore, these options are not provided.
4. On the Authentication tab, click Insert Policy. In the Authentication Policies group, from the Policy Name dropdown list, select the negotiate authentication policy you added for Kerberos authentication.
5. On the Certificates tab, select an SSL certificate from the list of available certificates, and then click Add. If the certificate you want to bind is not displayed in the Available Certificates list, click Install..., and then select the certificate file.
6. Click Create, and then click Close. The new authentication virtual server appears in the Authentication Virtual Servers pane.

# Configuring a Traffic Management Virtual Server

Oct 30, 2013

Configure an authentication service and a traffic management virtual server, and bind the service to the virtual server. You can use either a load balancing or a content switching virtual server.

To create a traffic management virtual server and service, and bind the service by using the command line interface

At the command prompt, type the following commands:

- `add service <name>@ <ipBackendWebserver> HTTP 80`
- `add lb vserver <name>@ SSL <ipAddressLbVserver> 443 -authn401 ON -authnVsName <authVserverName>`
- `bind lb vserver <name>@ <serviceName>`

Note: Use a similar procedure for using a content switching virtual server as the traffic management virtual server.

## Example

```
add service svc1 10.217.28.92 HTTP 80
add lb vserver v2 HTTP 10.102.113.164 80 -persistenceType NONE -cltTimeout 180 -authn401 ON -authnVsName authen1
bind lb vserver v2 svc1
```

To create a traffic management virtual server and service, and bind the service by using the NetScaler configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, set the following parameters:
  - Service Name
  - Server
  - Protocol - Select HTTP.
  - Port - Select 80.
4. In the navigation pane, expand Load Balancing and click Virtual Servers.
5. In the details pane, click Add.
6. In the Create Virtual Server (Load balancing) dialog box, set values for the following parameters:
  - Name
  - IP Address
  - Protocol
  - Port
7. In the Create Virtual Server (Load balancing) dialog box, on the Services tab, select the service you created in Step 3 to Step 5.
8. In the Create Virtual Server (Load balancing) dialog box, on the Advanced tab, expand Authentication Settings, and then select the 401 Based Authentication check box.
9. Click Create, and then click Close. The new load balancing virtual server appears in the Load Balancing Virtual Servers pane.
10. In the details pane, verify the settings of the virtual server.

Note: Use a similar procedure to create a content switching virtual server.

Note: For more information, see [Setting up basic load balancing](#).

# Verifying the configuration for Kerberos Authentication

Mar 27, 2012

Ensure that you completed the following tasks and verify whether the configuration is complete and correct.

- Enable the AAA feature
- Import the keytab file
- Configure the DNS server
- Configure negotiation policies and actions
- Configure authentication virtual server
- Configure traffic management virtual server

To verify the configuration:

1. Access the load balancing virtual server, using the FQDN. For example, <http://owa.newacp.com>.
2. View the AAA session on the NetScaler. `show aaa session`

## Example

```
ClientIp (ClientPort) ->ServerIp(ServerPort)
```

```

```

```
PE id : 4
```

```
User name: john.smith@NEWACP.COM Session Type: TM
```

```
Done
```

# Configuration of Kerberos Authentication on a Client

Mar 27, 2012

Kerberos support must be configured on the browser to use Kerberos for authentication. You can use any Kerberos-compliant browser. Instructions for configuring Kerberos support on Internet Explorer and Mozilla Firefox follow. For other browsers, see the documentation of the browser.

## To configure Internet Explorer for Kerberos authentication

1. In the Tools menu select Internet Options.
2. On the Security tab, click Local Intranet, and then click Sites.
3. In the Local Intranet dialog box, make sure that the Automatically detect intranet network option is selected, and then click Advanced.
4. In the Local Intranet dialog box, add the web sites of the domains of the traffic management virtual server on the NetScaler. The specified sites become local intranet sites.
5. Click Close or OK to close the dialog boxes.

## To configure Mozilla Firefox for Kerberos authentication

1. Make sure that you have Kerberos properly configured on your computer.
2. Type `about:config` in the URL bar.
3. In the filter text box, type `network.negotiate`.
4. Change `network.negotiate-auth.delegation-uris` to the domain that you want to add.
5. Change `network.negotiate-auth.trusted-uris` to the domain that you want to add.  
Note: If you are running Windows, you also need to enter `sspi` in the filter text box and change the `network.auth.use-sspi` option to False.

# Offloading Kerberos Authentication from Physical Servers

Nov 14, 2013

The NetScaler appliance can offload authentication tasks from servers. Instead of the physical servers authenticating the requests from clients, the Netscaler authenticates all the client requests before it forwards them to any of the physical servers bound to it. The user authentication is based on Active Directory tokens.

There is no authentication between the NetScaler and the physical server, and the authentication offload is transparent to the end users. After the initial logon to a Windows computer, the end user does not have to enter any additional authentication information in a pop-up or on a logon page.

In the current NetScaler release, Kerberos authentication is available only for Authentication, Authorization, and Auditing (AAA) Traffic Management Virtual Servers. Kerberos authentication is not supported for SSL VPN in the NetScaler Gateway Enterprise Edition appliance or for NetScaler appliance management.

Kerberos authentication requires configuration on the NetScaler appliance and on client browsers.

To configure Kerberos authentication on the NetScaler appliance

1. Create a user account on Active Directory. When creating a user account, verify the following options in the User Properties section:

- Make sure that you do not select the Change password at next logon option.
- Be sure to select the Password does not expire option.

2. On the NetScaler appliance, at the CLI command prompt, type:

- `ktpass -princ HTTP/kerberos.crete.lab.net@crete.lab.net -ptype KRB5_NT_PRINCIPAL -mapuser kerbuser@crete.lab.net -mapop set -pass Citrix1 -out C:\kerbtabfile.txt`

Note: Be sure to type the above command on a single line. The output of the above command is written into the C:\kerbtabfile.txt file.

3. Upload the kerbtabfile.txt file to the /etc directory of the NetScaler appliance by using a Secure Copy (SCP) client.

4. Run the following command to add a DNS server to the NetScaler appliance.

- `add dns nameserver 1.2.3.4`

The NetScaler appliance cannot process Kerberos requests without the DNS server. Be sure to use the same DNS server that is used in the Microsoft Windows domain.

5. Switch to the shell prompt and run the following commands from the shell prompt:

- `ktutil # rkt /etc/kerbtabfile.txt`
- `# wkt /etc/krb5.keytab`
- `# list`

The list command displays the user account details that you created in the Active Directory. A sample screen of the output of the list command is shown below.

Figure 1. Sample Output of the list Command

```

> shell

root@ns# cd /etc
root@ns# ls -la *.txt
-rw-r--r-- 1 root wheel 82 Apr 4 00:43 kerbtabfile.txt
root@ns# ktutil
ktutil: rkt /etc/kerbtabfile.txt
ktutil: wkt /etc/krb5.keytab
ktutil: list
slot KVNO Principal

 1 3 HTTP/kerberos.crete.example.com@crete.example.com
ktutil: quit
root@ns#

```

6. Switch to the command line interface of NetScaler.
7. Run the following command to create a Kerberos authentication server:
  - add authentication negotiateAction KerberosServer -domain "crete.lab.net" -domainUser kerbuser -domainUserPasswd Citrix1
8. Run the following command to create a negotiation policy:
  - add authentication negotiatePolicy Kerberos-Policy "REQ.IP.DESTIP == 192.168.17.200" KerberosServer
9. Run the following command to create an authentication virtual server.
  - add authentication vserver Kerb-Auth SSL 192.168.17.201 443 -AuthenticationDomain crete.example.com
10. Run the following command to bind the Kerberos policy to the authentication virtual server:
  - bind authentication vserver Kerb-Auth -policy Kerberos-Policy -priority 100
11. Run the following command to bind an SSL certificate to the authentication virtual server. You can use one of the test certificates, which you can install from the GUI NetScaler appliance. Run the following command to use the ServerTestCert sample certificate.
  - bind ssl vserver Kerb-Auth -certkeyName ServerTestCert
12. Create an HTTP load balancing virtual server with the IP address, 192.168.17.200. Ensure that you create a virtual server from the command line interface for NetScaler 9.3 releases if they are older than 9.3.47.8.
13. Run the following command to configure an authentication virtual server:
  - set lb vserver <name>-authn401 ON -authnVsName Kerb-Auth
14. Enter the host name http://www.crete.example.com in the address bar of the Web browser. The Web browser displays an authentication dialog box because the Kerberos authentication is not set up in the browser.
 

Note: Kerberos authentication requires a specific configuration on the client. Ensure that the client can resolve the hostname, which results in the Web browser connecting to an HTTP virtual server.
15. Configure Kerberos on the Web browser of the client computer.
  - For configuring on Internet Explorer, see "[Configuring Internet Explorer for Kerberos authentication.](#)"
  - For configuring on Mozilla Firefox, see "[Configuring Mozilla Firefox for Kerberos authentication.](#)"
16. Verify whether you can access the backend physical server without authentication.

### To configure Internet Explorer for Kerberos authentication

1. Select Internet Options from the Tools menu.
2. Activate the Security tab.
3. Select Local Intranet from the Select a zone to view change security settings section.
4. Click Sites.

5. Click Advanced.
6. Specify the URL, <http://www.crete.example.com> and click Add.
7. Restart Internet Explorer.

To configure Mozilla Firefox for Kerberos authentication

1. Enter `about:config` in the address bar of the browser.
2. Click the warning disclaimer.
3. Type `Network.Negotiate-auth.trusted-uris` in the Filter box.
4. Double click `Network.Negotiate-auth.trusted-uris`. A sample screen is shown below.

The screenshot shows the Firefox `about:config` page. The filter box contains `network.negotia`. A table lists several preferences, with `network.negotiate-auth.trusted-uris` highlighted. The table has columns for Preference Name, Status, Type, and Value.

| Preference Name                                     | Status  | Type    | Value |
|-----------------------------------------------------|---------|---------|-------|
| <code>network.negotiate-auth.allow-proxies</code>   | default | boolean | tr    |
| <code>network.negotiate-auth.delegation-uris</code> | default | string  |       |
| <code>network.negotiate-auth.gsslib</code>          | default | string  |       |
| <code>network.negotiate-auth.trusted-uris</code>    | default | string  |       |

5. In the Enter String Value dialog box, specify `www.crete.example.com`.
6. Restart Firefox.

# NetScaler Kerberos Single Sign-On

Oct 11, 2013

NetScaler appliances now support single sign-on (SSO) using the Kerberos 5 protocol. Users log on to a proxy, the Application Delivery Controller (ADC), which then provides access to protected resources.

The NetScaler Kerberos SSO implementation requires the user's password for SSO methods that rely on basic, NTLM, or forms-based authentication. The user's password is not required for Kerberos SSO, although if Kerberos SSO fails and the NetScaler appliance has the user's password, it uses the password to attempt NTLM SSO.

If the user's password is available, the KCD account is configured with a realm, and no delegated user information is present, the NetScaler Kerberos SSO engine impersonates the user to obtain access to authorized resources. Impersonation is also called unconstrained delegation.

The NetScaler Kerberos SSO engine can also be configured to use a delegated account to obtain access to protected resources on the user's behalf. This configuration requires delegated user credentials, a keytab, or a delegated user certificate and matching CA certificate. Configuration that uses a delegated account is called constrained delegation.

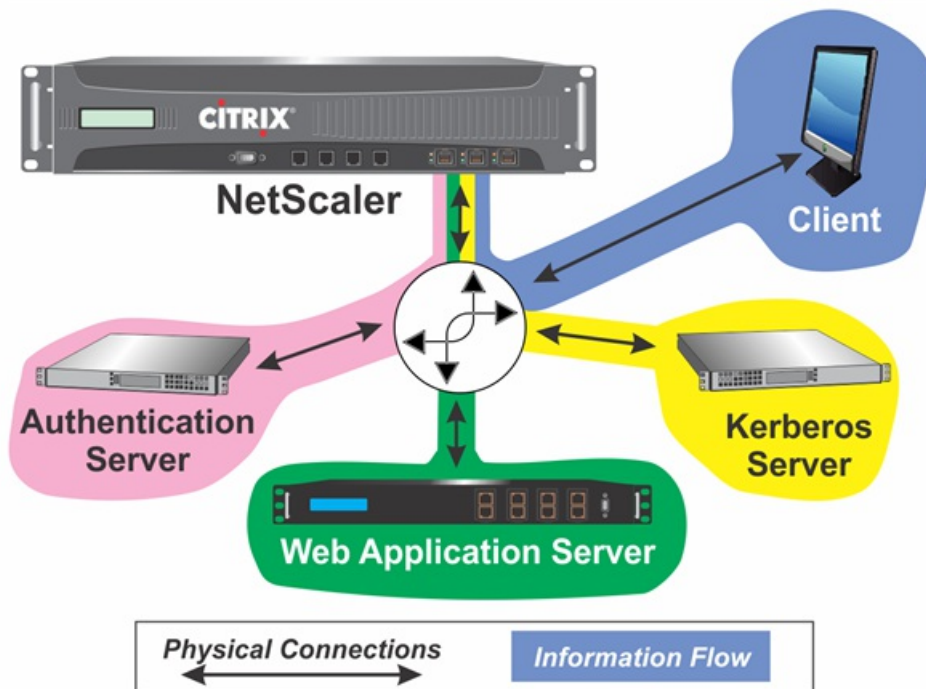

# An Overview of NetScaler Kerberos SSO

Oct 14, 2013

To use the NetScaler Kerberos SSO feature, users first authenticate with Kerberos or a supported third-party authentication server. Once authenticated, the user requests access to a protected web application. The web server responds with a request for proof that the user is authorized to access that web application. The user's browser contacts the Kerberos server, which verifies that the user is authorized to access that resource, and then provides the user's browser with a service ticket that provides proof. The browser resends the user's request to the web application server with the service ticket attached. The web application server verifies the service ticket, and then allows the user to access the application.

AAA-TM implements this process as shown in the following diagram. The diagram illustrates the flow of information through the NetScaler appliance and AAA-TM, on a secure network with LDAP authentication and Kerberos authorization. AAA-TM environments that use other types of authentication have essentially the same information flow, although they might differ in some details.

Figure 1. A Secure Network with LDAP and Kerberos

NetScaler AAA-TM authentication and authorization in a Kerberos environment requires that the following actions take place.

1. The client sends a request for a resource to the traffic management virtual server on the NetScaler appliance.
2. The traffic management virtual server passes the request to the authentication virtual server, which authenticates the client and then passes the request back to the traffic management virtual server.
3. The traffic management virtual server sends the client's request to the web application server.
4. The web application server responds to the traffic management virtual server with a 401 Unauthorized message that requests Kerberos authentication, with fallback to NTLM authentication if the client does not support Kerberos.
5. The traffic management virtual server contacts the Kerberos SSO daemon.

6. The Kerberos SSO daemon contacts the Kerberos server and obtains a ticket-granting ticket (TGT) allowing it to request service tickets authorizing access to protected applications.
7. The Kerberos SSO daemon obtains a service ticket for the user and sends that ticket to the traffic management virtual server.
8. The traffic management virtual server attaches the ticket to the user's initial request and sends the modified request back to the web application server.
9. The web application server responds with a 200 OK message.

These steps are transparent to the client, which just sends a request and receives the requested resource.

All AAA-TM authentication mechanisms support NetScaler Kerberos SSO. AAA-TM supports the Kerberos SSO mechanism with the Kerberos, CAC (Smart Card) and SAML authentication mechanisms with any form of client authentication to the NetScaler appliance. It also supports the HTTP-Basic, HTTP-Digest, Forms-based, and NTLM (versions 1 and 2) SSO mechanisms if the client uses either HTTP-Basic or Forms-Based authentication to log on to the NetScaler appliance.

The following table shows each supported client-side authentication method, and the supported server-side authentication method for that client-side method.

**Table 1. Supported Authentication Methods**

|                                    | Basic/Digest/NTLM | Kerberos Constrained Delegation | User Impersonation |
|------------------------------------|-------------------|---------------------------------|--------------------|
| CAC (Smart Card): at SSL/TLS Layer |                   | X                               | X                  |
| Forms-Based (LDAP/RADIUS/TACACS)   | X                 | X                               | X                  |
| HTTP Basic (LDAP/RADIUS/TACACS)    | X                 | X                               | X                  |
| Kerberos                           |                   | X                               |                    |
| NTLM v1/v2                         |                   | X                               | X                  |
| SAML                               |                   | X                               |                    |
| SAML Two-Factor                    | X                 | X                               | X                  |
| Certificate Two-Factor             | X                 | X                               | X                  |

# Setting up NetScaler SSO

Oct 08, 2013

You can configure NetScaler SSO to work in one of two ways: by impersonation or by delegation. SSO by impersonation is a simpler configuration than SSO by delegation, and is therefore usually preferable when your configuration allows it. To configure NetScaler SSO by impersonation, you must have the user's user name and password.

To configure NetScaler SSO by delegation, you must have the delegated user's credentials in one of the following formats: the user's user name and password, the keytab configuration that includes the user name and an encrypted password, or the delegated user certificate and the matching CA certificate.

# Prerequisites

Mar 30, 2015

Before you configure NetScaler SSO, you need to have your NetScaler appliance fully configured to manage traffic to and authentication for your web application servers. Therefore, you must configure either load balancing or content switching, and then AAA, for these web application servers. You should also verify routing between the appliance, your LDAP server, and your Kerberos server.

If your network is not already configured in this manner, perform the following configuration tasks:

- Configure a server and service for each web application server.
- Configure a traffic management virtual server to handle traffic to and from your web application server.

Following are brief instructions and examples for performing each of these tasks from the NetScaler command line. For further assistance, see "" and "[Setting up AAA Virtual Servers and DNS.](#)"

For NetScaler SSO to obtain a TGS (service ticket) for a service, either the FQDN assigned to the server entity on the NetScaler appliance must match the FQDN of the web application server, or the server entity name must match the NetBios name of the web application server. You can take either of the following approaches:

- Configure the NetScaler server entity by specifying the FQDN of the web application server.
- Configure the NetScaler server entity by specifying the IP address of the web application server, and assign the server entity the same name as the NetBios name of the web application server.

At the command prompt, type the following commands:

- add server name <serverFQDN>
- add service name serverName serviceType port

For the variables, substitute the following values:

- **serverName**—A name for the NetScaler appliance to use to refer to this server.
- **serverFQDN**—The FQDN of the server. If the server has no domain assigned to it, use the server's IP address and make sure that the server entity name matches the NetBios name of the web application server.
- **serviceName**—A name for the NetScaler appliance to use to refer to this service.
- **type**—The protocol used by the service, either HTTP or MSSQLSVC.
- **port**—The port on which the service listens. HTTP services normally listen on port 80. Secure HTTPS services normally listen on port 443.

The following examples add server and service entries on the NetScaler appliance for the web application server was1.example.com. The first example uses the FQDN of the web application server; the second uses the IP address.

To add the server and service using the web application server FQDN, was1.example.com, you would type the following commands:

```
add server was1 was1.example.com
```

```
add service was1service was1 HTTP 80
```

To add the server and service using the web application server IP and NetBios name, where the web application server IP is 10.237.64.87 and its NetBios name is WAS1, you would type the following commands:

```
add server WAS1 10.237.64.87
```

```
add service was1service WAS1 HTTP 8
```

The traffic management virtual server manages traffic between the client and the web application server. You can use either a load balancing or a content switching virtual server as the traffic management server. The SSO configuration is the same for either type.

To create a load balancing virtual server, at the command prompt, type the following command:

```
add lb vserver <vserverName> <type> <IP> <port>
```

For the variables, substitute the following values:

- **vserverName**—A name for the NetScaler appliance to use to refer to this virtual server.
- **type**—The protocol used by the service, either HTTP or MSSQLSVC.
- **IP**—The IP address assigned to the virtual server. This would normally be an IANA-reserved, non-public IP address on your LAN.
- **port**—The port on which the service listens. HTTP services normally listen on port 80. Secure HTTPS services normally listen on port 443.

To add a load balancing virtual server called `tmvserver1` to a configuration that manages HTTP traffic on port 80, assigning it a LAN IP address of 10.217.28.20 and then binding the load balancing virtual server to the `wasservice1` service, you would type the following commands:

```
add lb vserver tmvserver1 HTTP 10.217.28.20 80
```

```
bind lb vserver tmvserver1 wasservice1
```

The authentication virtual server manages authentication traffic between the client and the authentication (LDAP) server. To create an authentication virtual server, at the command prompt type the following commands:

- `add authentication vserver <authvserverName> SSL <IP> 443`
- `set authentication vserver <authvservername> -authenticationdomain <domain>`

For the variables, substitute the following values:

- **authvserverName** —A name for the NetScaler appliance to use to refer to this authentication virtual server. Must begin with a letter, number, or the underscore character (`_`), and must contain only letters, numbers, and the hyphen (`-`), period (`.`) pound (`#`), space (), at (`@`), equals (`=`), colon (`:`), and underscore characters. Can be changed after the authentication virtual server is added by using the `rename authentication vserver` command.
- **IP**—The IP address assigned to the authentication virtual server. As with the traffic management virtual server, this address would normally be an IANA-reserved, non-public IP on your LAN.
- **domain**—The domain assigned to the virtual server. This would usually be the domain of your network. It is customary, though not required, to enter the domain in all capitals when configuring the authentication virtual server.

To add an authentication virtual server called `authvserver1` to your configuration and assign it the LAN IP `10.217.28.21` and the domain `EXAMPLE.COM`, you would type the following commands:

```
add authentication vserver authvserver1 SSL 10.217.28.21 443
set authentication vserver authvserver1 -authenticationdomain EXAMPLE.COM
```

The authentication virtual server can be configured to handle authentication for a single domain or for multiple domains. If it is configured to support authentication for multiple domains, you must also specify the domain for NetScaler SSO by creating an authentication profile, and then configuring the traffic management virtual server to use that authentication profile.

Note: The traffic management virtual server can be either a load balancing (`lb`) or content switching (`cs`) virtual server. The following instructions assume that you are using a load balancing virtual server. To configure a content switching virtual server, simply substitute `set cs vserver` for `set lb vserver`. The procedure is otherwise the same.

To create the authentication profile, and then configure the authentication profile on a traffic management virtual server, type the following commands:

- `add authentication authnProfile <authnProfileName> {-authvserverName <string>} {-authenticationHost <string>} {-authenticationDomain <string>}`
- `set lb vserver <vserverName> -authnProfile <authnprofileName>`

For the variables, substitute the following values:

- **authnprofileName**—A name for the authentication profile. Must begin with a letter, number, or the underscore character (`_`), and must consist of from one to thirty-one alphanumeric or hyphen (`-`), period (`.`), pound (`#`), space (), at (`@`), equals (`=`), colon (`:`), and underscore characters.
- **authvserverName**—The name of the authentication virtual server that this profile uses for authentication.
- **authenticationHost**—Host name of the authentication virtual server.
- **authenticationDomain**—Domain for which NetScaler SSO handles authentication. Required if the authentication virtual server performs authentication for more than one domain, so that the correct domain is included when the NetScaler appliance sets the traffic management virtual server cookie.

To create an authentication profile named `authnProfile1` for authentication of the `example.com` domain, and to configure the load balancing virtual server `vserver1` to use the authentication profile `authnProfile1`, you would type the following commands:

```
add authentication authnProfile authnProfile1 -authnvsName authvsesrver1
 -authenticationHost authvsesrver1 -authenticationDomain example.com
set lb vserver vserver1 -authnProfile authnProfile1
```

# Configuring SSO

Oct 13, 2013

Configuring NetScaler SSO to authenticate by impersonation is simpler than configuring than SSO to authenticate by delegation, and is therefore usually preferable when your configuration allows it. You just create a KCD account. You can use the user's password.

If you do not have the user's password, you can configure NetScaler SSO to authenticate by delegation. Although somewhat more complex than configuring SSO to authenticate by impersonation, the delegation method provides flexibility in that a user's credentials might not be available to the NetScaler appliance in all circumstances.

For either impersonation or delegation, you must also enable integrated authentication on the web application server.

# Enabling Integrated Authentication on the Web Application Server

Oct 14, 2013

To set up NetScaler Kerberos SSO on each web application server that Kerberos SSO will manage, use the configuration interface on that server to configure the server to require authentication. Select Kerberos (negotiate) authentication by preference, with fallback to NTLM for clients that do not support Kerberos.

Following are instructions for configuring Microsoft Internet Information Server (IIS) to require authentication. If your web application server uses software other than IIS, consult the documentation for that web server software for instructions.

1. Log on to the IIS server and open Internet Information Services Manager.
2. Select the web site for which you want to enable integrated authentication. To enable integrated authentication for all IIS web servers managed by IISM, configure authentication settings for the Default Web Site. To enable integrated authentication for individual services (such as Exchange, Exadmin, ExchWeb, and Public), configure these authentication settings for each service individually.
3. Open the Properties dialog box for the default web site or for the individual service, and click the Directory Security tab.
4. Beside Authentication and Access Control, select Edit.
5. Disable anonymous access.
6. Enable Integrated Windows authentication (only). Enabling integrated Windows authentication should automatically set protocol negotiation for the web server to Negotiate, NTLM, which specifies Kerberos authentication with fallback to NTLM for non-Kerberos capable devices. If this option is not automatically selected, manually set protocol negotiation to Negotiate, NTLM.

# Setting Up SSO by Impersonation

Mar 18, 2015

You can configure the KCD account for NetScaler SSO by impersonation. In this configuration, the NetScaler appliance obtains the user's username and password when the user authenticates to the authentication server and uses those credentials to impersonate the user to obtain a ticket-granting ticket (TGT). If the user's name is in UPN format, the appliance obtains the user's realm from UPN. Otherwise, it obtains the user's name and realm by extracting it from the SSO domain used during initial authentication, or from the session profile.

When configuring the KCD account, you must set the realm parameter to the realm of the service that the user is accessing. The same realm is also used as the user's realm if the user's realm cannot be obtained from authentication with the Netscaler appliance or from the session profile.

At the command prompt, type the following command:

```
add aaa kcdaccount <accountname> -realmStr <realm>
```

For the variables, substitute the following values:

- **accountname**—The KCD account name.
- **realm**—The domain assigned to NetScaler SSO.

## Example:

To add a KCD account named `kcdccount1`, and use the keytab named `kcdvserver.keytab`, you would type the following command:

```
add aaa kcdAccount kcdaccount1 -keytab kcdvserver.keytab
```

# Configuring SSO by Delegation

Oct 13, 2013

To configure SSO by Delegation, you need to perform the following tasks:

- If you are configuring delegation by delegated user certificate, install the matching CA certificates on the NetScaler appliance and add them to the NetScaler configuration.
- Create the KCD account on the appliance. The appliance uses this account to obtain service tickets for your protected applications.
- Configure the Active Directory server.

If you are configuring NetScaler SSO with a client certificate, you must copy the matching CA certificate for the client certificate domain (the client CA certificate) to the NetScaler appliance, and then install the CA certificate. To copy the client CA certificate, use the file transfer program of your choice to transfer the certificate and private-key file to the NetScaler appliance, and store the files in `/nsconfig/ssl`.

## To install the client CA certificate on the NetScaler appliance

At the command prompt, type the following command:

```
add ssl certKey <certKeyName> -cert <cert> [(-key <key> [-password]) | -fipsKey <fipsKey>] [-inform (DER | PEM)] [-expiryMonitor (ENABLED | DISABLED | UNSET) [-notificationPeriod <positive_integer>]] [-bundle (YES | NO)]
```

For the variables, substitute the following values:

- **certKeyName**—A name for the client CA certificate. Must begin with an ASCII alphanumeric or underscore ( `_` ) character, and must consist of from one to thirty-one characters. Allowed characters include the ASCII alphanumerics, underscore, hash ( `#` ), period ( `.` ), space, colon ( `:` ), at ( `@` ), equals ( `=` ), and hyphen ( `-` ) characters. Cannot be changed after the certificate-key pair is created. If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my cert" or 'my cert').
- **cert**—Full path name and file name of the X509 certificate file used to form the certificate-key pair. The certificate file must be stored on the NetScaler appliance, in the `/nsconfig/ssl/` directory.
- **key**—Full path name and file name of the file that contains the private key to the X509 certificate file. The key file must be stored on the NetScaler appliance in the `/nsconfig/ssl/` directory.
- **password**—If a private key is specified, the passphrase used to encrypt the private key. Use this option to load encrypted private keys in PEM format.
- **fipsKey**—Name of the FIPS key that was created inside the Hardware Security Module (HSM) of a FIPS appliance, or a key that was imported into the HSM.  
Note: You can specify either a `key` or a `fipsKey`, but not both.
- **inform**—Format of the certificate and private-key files, either PEM or DER.
- **passplain**—Pass phrase used to encrypt the private key. Required when adding an encrypted private-key in PEM format.
- **expiryMonitor**—Configure the NetScaler appliance to issue an alert when the certificate is about to expire. Possible values: ENABLED, DISABLED, UNSET.
- **notificationPeriod**—If `expiryMonitor` is ENABLED, number of days before the certificate expires to issue an alert.
- **bundle**—Parse the certificate chain as a single file after linking the server certificate to its issuer's certificate within the file. Possible values: YES, NO.

The following example adds the specified delegated user certificate `customer-cert.pem` to the NetScaler configuration along with the key `customer-key.pem`, and sets the password, certificate format, expiration monitor, and notification period.

To add the delegated user certificate, you would type the following commands:

```
add ssl certKey customer -cert "/nsconfig/ssl/customer-cert.pem"
 -key "/nsconfig/ssl/customer-key.pem" -password "dontUseDefaultPWs!"
 -inform PEM -expiryMonitor ENABLED [-notificationPeriod 14
```

If you are configuring NetScaler SSO by delegation, you can configure the KCD account to use the user's log-on name and password, to use the user's log-on name and keytab, or to use the user's client certificate. If you configure SSO with user name and password, the NetScaler appliance uses the delegated user account to obtain a Ticket Granting Ticket (TGT), and then uses the TGT to obtain service tickets for the specific services that each user requests. If you configure SSO with keytab file, the NetScaler appliance uses the delegated user account and keytab information. If you configure SSO with a delegated user certificate, the NetScaler appliance uses the delegated user certificate.

## To create the KCD account for SSO by delegation with a password

At the command prompt, type the following commands:

```
add aaa kcdaccount <accountname> -delegatedUser root -kcdPassword <password> -realmStr <realm>
```

For the variables, substitute the following values:

- **accountname**—A name for the KCD account.
- **password**—A password for the KCD account.
- **realm**—The realm of the KCD account, usually the domain for which SSO is active.

To add a KCD account named `kcdaccount1` to the NetScaler appliance configuration with a password of `password1` and a realm of `EXAMPLE.COM`, specifying the delegated user account in UPN format (as `root`), you would type the following commands:

```
add aaa kcdaccount kcdaccount1 -delegatedUser root
-kcdPassword password1 -realmStr EXAMPLE.COM
```

To add a KCD account named `kcdaccount1` to the NetScaler appliance configuration with a password of `password1` and a realm of `EXAMPLE.COM`, specifying the delegated user account in SPN format, you would type the following commands:

```
add aaa kcdAccount kcdaccount1 -realmStr EXAMPLE.COM
-delegatedUser "host/kcdvserver.example.com" -kcdPassword password1
```

## Creating the KCD account for SSO by delegation with a keytab

If you plan to use a keytab file for authentication, first create the keytab. You can create the keytab file manually by logging onto the AD server and using the `ktpass` utility, or you can use the NetScaler configuration utility to create a batch script, and then run that script on the AD server to generate the keytab file. Next, use FTP or another file transfer program to transfer the keytab file to the NetScaler appliance and place it in the `/nsconfig/krb` directory. Finally, configure the KCD account for NetScaler SSO by delegation and provide the path and file name of the keytab file to the NetScaler appliance.

Log on to the AD server command line and, at the command prompt, type the following command:

```
ktpass /princ <SPN> /ptype KRB5_NT_PRINCIPAL /mapuser <DOMAIN>\<username> /pass <password> -out <File_Path>
```

For the variables, substitute the following values:

- **SPN**—The service principal name for the KCD service account.
- **DOMAIN**—The domain of the Active Directory server.
- **username**—The KSA account username.
- **password**—The KSA account password.
- **path**— The full path name of the directory in which to store the keytab file after it is generated.

1. Navigate to Security > AAA - Application Traffic
2. In the data pane, under Kerberos Constrained Delegation, click Batch file to generate Keytab.
3. In the Generate KCD (Kerberos Constrained Delegation) Keytab Script dialog box, set the following parameters:
  - **Domain User Name**—The KSA account username.
  - **Domain Password**—The KSA account password.
  - **Service Principal**—The service principal name for the KSA.
  - **Output File Name**—The full path and file name to which to save the keytab file on the AD server.
4. Clear the Create Domain User Account check box.
5. Click Generate Script.
6. Log on to the Active Directory server and open a command line window.
7. Copy the script from the Generated Script window and paste it directly into the Active Directory server command-line window. The keytab is generated and stored in the directory under the file name that you specified as **Output File Name**.
8. Use the file transfer utility of your choice to copy the keytab file from the Active Directory server to the NetScaler appliance and place it in the `/nsconfig/krb` directory.

At the command prompt, type the following command:

```
add aaa kcdaccount <accountname> -keytab <keytab>
```

Example:

To add a KCD account named `kcdaccount1`, and use the keytab named `kcdvserver.keytab`, you would type the following commands:

```
add aaa kcdaccount kcdaccount1 -keytab kcdvserver.keytab
```

## To create the KCD account for SSO by delegation with a delegated user cert

At the command prompt, type the following command:

```
add aaa kcdaccount <accountname> -realmStr <realm> -delegatedUser <user_name/SPN> -usercert <cert> -cacert <cacert>
```

For the variables, substitute the following values:

- **accountname**—A name for the KCD account.

- **realmStr**—The realm for the KCD account, usually the domain for which SSO is configured.
- **delegatedUser**—The delegated user name, in SPN format.
- **usercert**—The full path and name of the delegated user certificate file on the NetScaler appliance. The delegated user certificate must contain both the client certificate and the private key, and must be in PEM format. If you use smart card authentication, you might need to create a smart card certificate template to allow certificates to be imported with the private key.
- **cacert**—The full path to and name of the CA certificate file on the NetScaler appliance.

To add a KCD account named `kcdaccount1`, and use the keytab named `kcdvserver.keytab`, you would type the following command:

```
add aaa kcdaccount kcdaccount1 -realmStr EXAMPLE.COM
 -delegatedUser "host/kcdvserver.example.com" -usercert /certs/usercert
 -cacert /cacerts/cacert
```

When you configure SSO by delegation, in addition to creating the KCDAccount on the NetScaler appliance, you must also create a matching Kerberos Service Account (KSA) on your LDAP active directory server, and configure the server for SSO. To create the KSA, use the account creation process on the active directory server. To configure SSO on the active directory server, open the properties window for the KSA. In the Delegation tab, enable the following options: Trust this user for delegation to specified services only and Use any Authentication protocol. (The Kerberos only option does not work, because it does not enable protocol transition or constrained delegation.) Finally, add the services that NetScaler SSO will manage.

Note: If the Delegation tab is not visible in the KSA account properties dialog box, before you can configure the KSA as described, you must use the Microsoft `setspn` command-line tool to configure the active directory server so that the tab is visible.

## To configure delegation for the Kerberos service account

1. In the LDAP account configuration dialog box for the Kerberos service account that you created, click the Delegation tab.
2. Choose "Trust this user for delegation to the specified services only".
3. Under "Trust this user for delegation to the specified services only," choose "Use any authentication protocol".
4. Under "Services to which this account can present delegated credentials," click Add.
5. In the Add Services dialog box, click Users or Computers, choose the server that hosts the resources to be assigned to the service account, and then click OK.

Note: Constrained delegation does not support services hosted in domains other than the domain assigned to the account, even though Kerberos might have a trust relationship with other domains

6. Back in the Add Services dialog box, in the Available Services list, choose the services assigned to the service account. NetScaler SSO supports the HTTP and MSSQLSVC services.
7. Click OK.

# Generating the KCD Keytab Script

Aug 13, 2014

The KCD Keytab Script dialog box generates the keytab script, which in turn generates the keytab file necessary to configure KCD on the NetScaler ADC.

1. Navigate to Security > AAA - Application Traffic
2. In the details pane, under Kerberos Constrained Delegation, click Batch file to generate keytab.
3. In the Generate KCD (Kerberos Constrained Delegation) Keytab Script dialog box, fill out the fields as described below.
  - **Domain User Name:** The name of the domain user.
  - **Domain Password:** The password for the domain user.
  - **Service Principal:** The service principal.
  - **Output File Name:** A filename for the KCD script file.
  - **Create Domain User Account:** Select this check box to create the specified domain user account.
4. Click Generate Script to generate the script. The script is generated, and appears in the Generated Script text box below the Generate Script button.
5. Copy the script, and save it as a file on your AD domain controller. You must now run this script on the domain controller to generate the keytab file, and then copy the keytab file to the /nsconfig/krb/ directory on the NetScaler appliance.
6. Click OK.

# SAML IdP

Jun 03, 2015

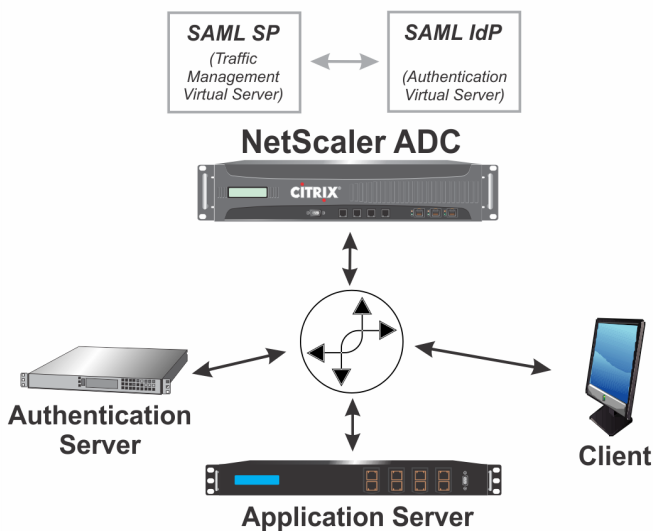

The NetScaler ADC can now act as a SAML identity provider (IdP). As an IdP, the ADC accepts SAML requests from users that request access to a protected application, redirecting users to the logon page to authenticate. After the user authenticates, the ADC generates a SAML assertion that grants access to the protected resource and redirects the user to the resource that requested authentication. When the user logs out or is logged out by any SP, the ADC sends logout requests to all other SPs that the user accessed during the current session and terminates the session.

**Note:** From NetScaler 10.5 onwards, the SAML IdP can be configured to encrypt the assertions that are sent to the SAML SP. It is recommended to encrypt assertions as they can include sensitive information. The assertions are encrypted by using the public key of the SAML SP. To encrypt assertions, you must enable encryption and specify the encryption algorithm, in the SAML IdP profile.

The SAML protocol supports a variety of bindings (profiles) which handle the authentication and authorization process in different ways. The NetScaler ADC currently supports only the SP-initiated model with POST binding. An SP-initiated SAML flow usually occurs when a protected resource redirects an unauthenticated client's request to the SAML SP. The SP evaluates the client's request and, if the client has not already authenticated, redirects the request to the IdP.

The NetScaler ADC supports every authentication method with SAML IdP that it supports with traditional logins. It supports both single-factor and two-factor authentication, and also supports SAML authentication with external SPs. The ADC supports attribute extraction from SAML assertions, and encrypted SAML assertions. The NetScaler implementation of SAML allows signing certificates of less than 2048 bits, but displays a warning message. It also supports the SHA256 hash algorithm for signatures and digests. Citrix recommends that all signing certificates be of at least 2048 bits, and that you use SHA256 as SHA-1 is no longer considered secure.

In any SAML configuration of the ADC, the load balancing virtual server functions as the SP. When the NetScaler ADC is configured to serve as the IdP, the authentication virtual server functions as the IdP. In this configuration, most of the SAML conversation takes place entirely within the ADC, as illustrated in the following diagram.

The authentication process occurs in the following sequence:

1. The client requests a protected application.
2. The traffic management virtual server receives the request, and responds to the client with HTTP 200 OK and a request for a SAML assertion.
3. If the client does not have a SAML assertion, the client requests to authenticate.
4. The traffic management virtual server sends an authentication request to the authentication virtual server by posting it to /saml/login, including the following two XML-based attachments and signing it:
  - **SAMLRequest**. Standard SAML authentication request with appropriate information.
  - **RelayState**. Internal NetScaler information.
5. The authentication virtual server receives the signed SAML authentication request and performs the following steps:
  1. Evaluates its SAML IdP policies to choose the correct profile.
  2. Uses that profile to validate the SAML authentication request.
  3. Responds with HTTP 302 Found, and then loads the logon page.
6. The client types his or her credentials into the logon form, and sends them to the authentication virtual server.
7. The authentication virtual server sends the credentials to the authentication server.
8. The authentication server authenticates the client to the authentication virtual server.

9. The authentication virtual server generates a SAML assertion, signs it, and sends the assertion to the client.
10. The client resends the initial request with the SAML assertion.
11. The traffic management virtual server responds with HTTP 302 found and loads the requested resource.

When the ADC is configured to authenticate users with an external IdP, the conversation described above changes slightly. If the ADC is configured to authenticate all users with the external IdP, after the authentication virtual server validates the authentication request it redirects the request to the external IdP, which displays its own login page. If the ADC is configured for fallback authentication, it displays its own logon page and redirects the user to the external IdP only when the user fails to authenticate locally.

When the ADC is configured to use two-factor authentication, it first authenticates the user with the IdP. After the user successfully authenticates with the IdP and the authentication virtual server has validated the SAML assertion, it redirects the user to the second authentication logon page.

Configuring the NetScaler ADC to serve as SAML IdP requires adding a SAML IdP profile and policy to the standard SAML configuration. As with most NetScaler commands, with the following commands you can substitute "set" for "add" to modify an existing SAML IdP profile or policy.

At the command prompt, type:

```
add authentication samldpProfile <name> -samlSigningCertName <samlSigningCertName> -samldpCertName <samldpCertName>
-assertionConsumerServiceURL <URL> [-sendPassword (ON | OFF)] [-samlIssuerName <string>]
```

### Example:

```
> add authentication samldpProfile act-auth-samlidp -samlSigningCertName myCert -samldpCertName myIdPCert - assertionConsumerServiceURL /auth/saml
```

1. Navigate to Security > AAA - Application Traffic > Policies > Authentication > Basic Policies > SAML IDP.
2. In the details pane, click the Profiles tab.
3. On the Profiles tab, do one of the following:
  - To create a new SAML IDP profile, click Add.
  - To modify an existing SAML IDP profile, select the profile, and then click Edit.
4. In the Create Authentication SAML IDP Profile or the Configure Authentication SAML IDP Profile dialog box, specify values for the required parameters.
5. Click Create or OK, and then click Close.

# Application Firewall

Mar 28, 2012

The following topics cover installation and configuration of the Citrix Application Firewall feature.

|                               |                                                                                                                                                                                                   |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Introduction                  | An overview of web application security and how the application firewall works.                                                                                                                   |
| Configuration                 | How to configure the application firewall to protect a web site, a web service, or a web 2.0 site.                                                                                                |
| Signatures                    | A detailed description of the signatures feature and how to configure the signatures, add signatures from a supported vulnerability scanning tool, and define your own signatures, with examples. |

| Profiles                      | A description of how profiles are configured and used in the application firewall.                                                                                                                |
| Policies                      | A description of how policies are used when configuring the application firewall, with examples of useful policies.                                                                               |
| Imports                       | A description of how the application firewall uses different types of imported files, and how to import and export files.                                                                         |
| Global Configuration          | A description of application firewall features that apply to all profiles, and how to configure them.                                                                                             |
| Use Cases                     | Extended examples that demonstrate how to set up the application firewall to best protect specific types of more complex web sites and web services.                                              |
| Logs, Statistics, and Reports | How to access and use the application firewall logs, the statistics, and the reports to assist in configuring the application firewall.                                                           |

# Introduction

Oct 08, 2014

The Citrix NetScaler Application Firewall prevents security breaches, data loss, and possible unauthorized modifications to web sites that access sensitive business or customer information. It does so by filtering both requests and responses, examining them for evidence of malicious activity, and blocking those that exhibit such activity. Your site is protected not only from common types of attacks, but also from new, as yet unknown attacks. In addition to protecting web servers and web sites from unauthorized access and misuse by hackers and malicious programs, the application firewall provides protection against security vulnerabilities in legacy CGI code or scripts, other web frameworks, web server software, and the underlying operating systems.

The NetScaler Application Firewall is available as a stand-alone appliance, or as a feature on a Citrix NetScaler application delivery controller (ADC) or Citrix NetScaler virtual appliance (VPX). In the application firewall documentation, the term NetScaler ADC refers to the platform on which the application firewall is running, regardless of whether that platform is a dedicated firewall appliance, a NetScaler ADC on which other features have also been configured, or a NetScaler VPX.

To use the application firewall, you must create at least one security configuration to block connections that violate the rules that you set for your protected web sites. The number of security configurations that you might want to create depends on the complexity of your web site. In some cases, a single configuration is sufficient. In other cases, particularly those that include interactive web sites, web sites that access database servers, online stores with shopping carts, you might need several different configurations to best protect sensitive data without wasting significant effort on content that is not vulnerable to certain types of attacks. You can often leave the defaults for the global settings, which affect all security configurations, unchanged. However, you can change the global settings if they conflict with other parts of your configuration or you prefer to customize them.

# Web Application Security

Oct 08, 2014

Web application security is network security for computers and programs that communicate by using the HTTP and HTTPS protocols. This is an extremely broad area in which security flaws and weaknesses abound. Operating systems on both servers and clients have security issues and are vulnerable to attack. Web server software and web site enabling technologies such as CGI, Java, JavaScript, PERL and PHP have underlying vulnerabilities. Browsers and other client applications that communicate with web-enabled applications also have vulnerabilities. Web sites that use any technology but the simplest of HTML, including any site that allows interaction with visitors, often have vulnerabilities of their own.

In the past, a breach in security was often just an annoyance, but today that is seldom the case. For example, attacks in which a hacker gained access to a web server and made unauthorized modifications to (defaced) a web site used to be common. They were usually launched by hackers who had no motivation beyond demonstrating their skills to fellow hackers or embarrassing the targeted person or company. Most current security breaches, however, are motivated by a desire for money. The majority attempt to accomplish one or both of the following goals: to obtain sensitive and potentially valuable private information, or to obtain unauthorized access to and control of a web site or web server.

Certain forms of web attacks focus on obtaining private information. These attacks are often possible even against web sites that are secure enough to prevent an attacker from taking full control. The information that an attacker can obtain from a web site can include customer names, addresses, phone numbers, social security numbers, credit card numbers, medical records, and other private information. The attacker can then use this information or sell it to others. Much of the information obtained by such attacks is protected by law, and all of it by custom and expectation. A breach of this type can have extremely serious consequences for customers whose private information is compromised. At best, these customers will have to exercise vigilance to prevent others from abusing their credit cards, opening unauthorized credit accounts in their name, or appropriating their identities outright (identity theft). At worst, the customers may face ruined credit ratings or even be blamed for criminal activities in which they had no part.

Other web attacks are aimed at obtaining control of (or *compromising*) a web site or the server on which it operates, or both. A hacker who gains control of a web site or server can use it to host unauthorized content, act as a proxy for content hosted on another web server, provide SMTP services to send unsolicited bulk email, or provide DNS services to support such activities on other compromised web servers. Most web sites that are hosted on compromised web servers promote questionable or outright fraudulent businesses. For example, the majority of phishing web sites and child exploitation web sites are hosted on compromised web servers.

Protecting your web sites and web services against these attacks requires a multilayered defense capable of both blocking known attacks with identifiable characteristics and protecting against unknown attacks, which can often be detected because they look different from the normal traffic to your web sites and web services.

Updated: 2014-10-08

The first line of defense for your web sites is protection against the large number of attacks that are known to exist and have been observed and analyzed by web security experts. Common types of attacks against HTML-based web sites include:

- **Buffer overflow attacks.** Sending an extremely long URL, extremely long cookie, or other extremely long bit of information to a web server in hopes of causing it or the underlying operating system to hang, crash, or provide the

attacker with access to the underlying operating system. A buffer overflow attack can be used to gain access to unauthorized information, to compromise a web server, or both.

- **Cookie security attacks.** Sending a modified cookie to a web server, usually in hopes of obtaining access to unauthorized content by using falsified credentials.
- **Forceful browsing.** Accessing URLs on a web site directly, without navigating to the URLs by means of hyperlinks on the home page or other common start URLs on the web site. Individual instances of forceful browsing may simply indicate a user who bookmarked a page on your web site, but repeated attempts to access nonexistent content, or content that users should never access directly, often represent an attack on web site security. Forceful browsing is normally used to gain access to unauthorized information, but can also be combined with a buffer overflow attack in an attempt to compromise your server.
- **Web form security attacks.** Sending inappropriate content to your web site in a web form. Inappropriate content can include modified hidden fields, HTML or code in a field intended for alphanumeric data only, an overly long string in a field that accepts only a short string, an alphanumeric string in a field that accepts only an integer, and a wide variety of other data that your web site does not expect to receive in that web form. A web form security attack can be used either to obtain unauthorized information from your web site or to compromise the web site outright, usually when combined with a buffer overflow attack.

Two specialized types of attacks on web form security deserve special mention:

- **SQL injection attacks.** Sending an active SQL command or commands in a web form or as part of a URL, with the goal of causing an SQL database to execute the command or commands. SQL injection attacks are normally used to obtain unauthorized information.
- **Cross-site scripting attacks.** Using a URL or a script on a web page to violate the same-origin policy, which forbids any script from obtaining properties from or modifying any content on a different web site. Since scripts can obtain information and modify files on your web site, allowing a script access to content on a different web site can provide an attacker the means to obtain unauthorized information, to compromise a web server, or both.

Attacks against XML-based web services normally fall into at least one of the following two categories: attempts to send inappropriate content to a web service, or attempts to breach security on a web service. Common types of attacks against XML-based web services include:

- **Malicious code or objects.** XML requests that contain code or objects that can either directly obtain sensitive information or can give an attacker control of the web service or underlying server.
- **Badly-formed XML requests.** XML requests that do not conform to the W3C XML specification, and that can therefore breach security on an insecure web service.
- **Denial of service (DoS) attacks.** XML requests that are sent repeatedly and in high volume, with the intent of overwhelming the targeted web service and denying legitimate users access to the web service.

In addition to standard XML-based attacks, XML web services and Web 2.0 sites are also vulnerable to SQL injection and cross-site scripting attacks, as described below:

- **SQL injection attacks.** Sending an active SQL command or commands in an XML-based request, with the goal of causing an SQL database to execute that command or commands. As with HTML SQL injection attacks, XML SQL injection attacks are normally used to obtain unauthorized information.
- **Cross-site scripting attacks.** Using a script included in an XML based application to violate the same-origin policy, which does not allow any script to obtain properties from or modify any content on a different application. Since scripts can obtain information and modify files by using your XML application, allowing a script access to content belonging to a different application can give an attacker the means to obtain unauthorized information, to compromise the

application, or both.

Known web attacks can usually be stopped by filtering web site traffic for specific characteristics (signatures) that always appear for a specific attack and should never appear in legitimate traffic. This approach has the advantages of requiring relatively few resources and posing relatively little risk of false positives. It is therefore a valuable tool in fighting attacks on web sites and web services, and configuring basic signature protections that intercept most known web attacks is easy to do.

The greatest threat against web sites and applications does not come from known attacks, but from unknown attacks. Most unknown attacks fall into one of two categories: newly-launched attacks for which security firms have not yet developed an effective defense (zero-day attacks), and carefully-targeted attacks on a specific web site or web service rather than many web sites or web services (spear attacks). These attacks, like known attacks, are usually intended to obtain sensitive private information, compromise the web site or web service and allow it to be used for further attacks, or both of those goals.

Zero-day attacks are a major threat to all users. These attacks are usually of the same types as known attacks; zero-day attacks often involve injected SQL, a cross-site script, a cross-site request forgery, or another type of attack similar to known attacks. In most cases, they target vulnerabilities that the developers of the targeted software, web site, or web service either are unaware of or have just learned about. Security firms have therefore usually not developed defenses against these attacks, and even if they have, users have usually not obtained and installed the patches or performed the workarounds necessary to protect against these attacks. The time between discovery of a zero-day attack and availability of a defense (the vulnerability window) is shrinking, but perpetrators can still count on hours or even days in which many web sites and web services lack any specific protection against the attack.

Spear attacks are a major threat, but to a more select group of users. A common type of spear attack, a spear phish, is usually targeted at customers of a specific bank or financial institution, or (less commonly) at employees of a specific company or organization. Unlike other phishes, which are often crudely written forgeries that a user with any familiarity with the actual communications of that bank or financial institution can recognize, spear phishes are letter perfect and extremely convincing. They can contain information specific to the individual that, at first look, no stranger should know or be able to obtain. The spear phisher is therefore able to convince his or her target to provide the requested information, which the phisher can then use to loot accounts, to process illegitimately obtained money from other sources, or to gain access to other, even more sensitive information.

Both of these types of attack have certain characteristics that can usually be detected, although not by using static patterns that look for specific characteristics, as do standard signatures. Detecting these types of attacks requires more sophisticated and more resource-intensive approaches, such as heuristic filtering and positive security model systems. Heuristic filtering looks, not for specific patterns, but for patterns of behaviors. Positive security model systems model the normal behavior of the web site or web service that they are protecting, and then block connections that do not fit within that model of normal use. URL based and web-form based security checks profile normal use of your web sites, and then control how users interact with your web sites, using both heuristics and positive security to block anomalous or unexpected traffic. Both heuristic and positive security, properly designed and deployed, can catch most attacks that signatures miss. However, they require considerably more resources than do signatures, and you must spend some time configuring them properly to avoid false positives. They are therefore usually used, not as the primary line of defense, but as backups to signatures or other less resource-intensive approaches.

By configuring these advanced protections in addition to signatures, you create a hybrid security model, which enables the application firewall to provide comprehensive protection against both known and unknown attacks.

# How The Application Firewall Works

Sep 03, 2013

When you install the application firewall, you create an initial security configuration, which consists of a policy, a profile, and a signatures object. The policy is a rule that identifies the traffic to be filtered, and the profile identifies the patterns and types of behavior to allow or block when the traffic is filtered. The simplest patterns, which are called signatures, are not specified within the profile, but in a signatures object that is associated with the profile.

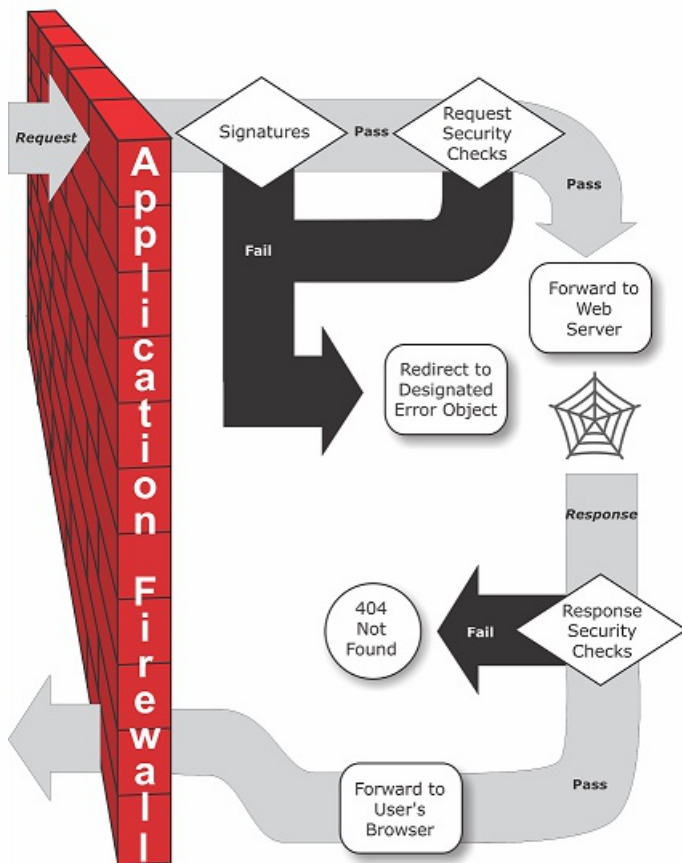

A signature is a string or pattern that matches a known type of attack. The application firewall contains over a thousand signatures in seven categories, each directed at attacks on specific types of web servers and web content. Citrix updates the list with new signatures as new threats are identified. During configuration, you specify the signature categories that are appropriate for the web servers and content that you need to protect. Signatures provide good basic protection with low processing overhead. If your applications have special vulnerabilities or you detect an attack against them for which no signature exists, you can add your own signatures.

The more advanced protections are called security checks. A security check is a more rigorous, algorithmic inspection of a request for specific patterns or types of behavior that might indicate an attack or constitute a threat to your protected web sites and web services. It can, for example, identify a request that attempts to perform a certain type of operation that might breach security, or a response that includes sensitive private information such as a social security number or credit card number. During configuration, you specify the security checks that are appropriate for the web servers and content that you need to protect. The security checks are restrictive. Many of them can block legitimate requests and responses if you do not add the appropriate exceptions (relaxations) when configuring them. Identifying the needed exceptions is not difficult if you use the adaptive learning feature, which observes normal use of your web site and creates recommended exceptions.

The application firewall can be installed as either a Layer 3 network device or a Layer 2 network bridge between your servers and your users, usually behind your company's router or firewall. It must be installed in a location where it can intercept traffic between the web servers that you want to protect and the hub or switch through which users access those web servers. You then configure the network to send requests to the application firewall instead of directly to your web servers, and responses to the application firewall instead of directly to your users. The application firewall filters that traffic before forwarding it to its final destination, using both its internal rule set and your additions and modifications. It blocks or renders harmless any activity that it detects as harmful, and then forwards the remaining traffic to the web server. The following figure provides an overview of the filtering process.

Note: The figure omits the application of a policy to incoming traffic. It illustrates a security configuration in which the policy is to process all requests. Also, in this configuration, a signatures object has been configured and associated with the profile, and security checks have been configured in the profile.

Figure 1. A Flowchart of Application Firewall Filtering

As the figure shows, when a user requests a URL on a protected web site, the application firewall first examines the request to ensure that it does not match a signature. If the request matches a signature, the application firewall either displays the error object (a web page that is located on the application firewall appliance and which you can configure by using the imports feature) or forwards the request to the designated error URL (the error page). Signatures do not require as many resources as do security checks, so detecting and stopping attacks that are detected by a signature before running any of the security checks reduces the load on the server.

If a request passes signature inspection, the application firewall applies the request security checks that have been enabled. The request security checks verify that the request is appropriate for your web site or web service and does not contain material that might pose a threat. For example, security checks examine the request for signs indicating that it might be of an unexpected type, request unexpected content, or contain unexpected and possibly malicious web form data, SQL commands, or scripts. If the request fails a security check, the application firewall either sanitizes the request and then sends it back to the NetScaler appliance (or NetScaler virtual appliance), or displays the error object. If the request passes the security checks, it is sent back to the NetScaler appliance, which completes any other processing and forwards the request to the protected web server.

When the web site or web service sends a response to the user, the application firewall applies the response security checks that have been enabled. The response security checks examine the response for leaks of sensitive private information, signs of web site defacement, or other content that should not be present. If the response fails a security check, the application firewall either removes the content that should not be present or blocks the response. If the response passes the security checks, it is sent back to the NetScaler appliance, which forwards it to the user.

Updated: 2013-09-03

The basic application firewall features are policies, profiles, and signatures, which provide a hybrid security model as described in "[Known Web Attacks](#)," "[Unknown Web Attacks](#)," and "[How the Application Firewall Works](#)." Of special note is the learning feature, which observes traffic to your protected applications and recommends appropriate configuration settings for certain security checks.

The imports feature manages files that you upload to the application firewall. These files are then used by the application firewall in various security checks, or when responding to a connection that matches a security check.

You can use the logs, statistics, and reports features to evaluate the performance of the application firewall and identify possible needs for additional protections.

# The Application Firewall Configuration Interfaces

Oct 09, 2014

All hardware and virtual versions of the Citrix NetScaler application delivery controller (ADC) can be configured and managed from the Citrix NetScaler command line interface or the web-based configuration utility. All features of most NetScaler features can be configured using either of these tools. The Citrix Application Firewall is an exception: not all application firewall configuration tasks can be performed at the command line. Inexperienced users also find the configuration utility easier to use. In particular, the application firewall wizard considerably reduces the complexity of configuring the application firewall. Unlike most NetScaler wizards, the application firewall wizard can serve as your primary interface to the application firewall.

The command line interface is a modified UNIX shell based on the FreeBSD bash shell. To configure the application firewall from the command line interface, you type commands at the prompt and press the Enter key, just as you do with any other Unix shell. For instructions for using the command line interface, see "[Command Reference](#)."

The configuration utility is a web-based GUI interface to the ADC. The application firewall configuration section is found under Security > Application Firewall. Figure 1 shows the navigation pane expanded to display the application firewall screens, and in the detail pane the main application firewall screen.

The configuration utility has two main areas on all screens. The panel on the left, called the navigation pane, contains a navigation tree, with which you navigate to the screens on which you configure the features that are installed on your appliance. The screens to which you navigate appear to the right of the navigation pane, in the details pane.

When you access the configuration utility, the details pane displays the System Overview screen. If, in the navigation pane,

you click plus sign next to the application firewall folder, the Application Firewall node expands to include the main application firewall elements that you can configure. If you click the first element, Profiles, the details pane displays the configured profiles, if any profiles have been configured. At the bottom of the details pane, you can click Add to configure a new profile. Other buttons at the bottom of the details pane are grayed out until you select an existing profile. Screens for the other elements work in the same way.

If, instead of expanding the application firewall node, you click the node itself, the details pane displays different options, one of which is the application firewall wizard, as shown in Figure 1. Citrix recommends that you use the wizard for initial configuration, and many users use it almost exclusively. It includes most of the functionality that is available elsewhere in the configuration utility.

For information and instructions on accessing the configuration utility, see "[Citrix NetScaler Getting Started Guide](#)."

# Configuring the Application Firewall

Oct 09, 2014

You can configure the Citrix Application Firewall (application firewall) by using any of the following methods:

- **Application Firewall Wizard.** A dialog box consisting of a series of screens that step you through the configuration process.
- **Citrix Web Interface AppExpert Template.** A NetScaler AppExpert template (a set of configuration settings) that are designed to provide appropriate protection for web sites. This AppExpert template contains appropriate Application Firewall configuration settings for protecting many web sites.
- **Citrix NetScaler Configuration Utility.** The NetScaler web-based configuration interface.
- **Citrix NetScaler Command Line Interface.** The NetScaler command line configuration interface.

Citrix recommends that you use the Application Firewall Wizard. Most users will find it the easiest method to configure the application firewall, and it is designed to prevent mistakes. If you have a new Citrix NetScaler ADC or VPX that you will use primarily to protect web sites, you may find the Web Interface AppExpert template a better option because it provides a good default configuration, not just for the application firewall, but for the entire appliance. Both the configuration utility and the command line interface are intended for experienced users, primarily to modify an existing configuration or use advanced options.

The application firewall wizard is a dialog box that consists of several screens that prompt you to configure each part of a simple configuration. The application firewall then creates the appropriate configuration elements from the information that you give it. This is the simplest and, for most purposes, the best way to configure the application firewall.

To use the wizard, connect to the configuration utility with the browser of your choice. When the connection is established, verify that the application firewall is enabled, and then run the application firewall wizard, which prompts you for configuration information. You do not have to provide all of the requested information the first time you use the wizard. Instead, you can accept default settings, perform a few relatively straightforward configuration tasks to enable important features, and then allow the application firewall to collect important information to help you complete the configuration.

For example, when the wizard prompts you to specify a rule for selecting the traffic to be processed, you can accept the default, which selects all traffic. When it presents you with a list of signatures, you can enable the appropriate categories of signatures and turn on the collection of statistics for those signatures. For this initial configuration, you can skip the advanced protections (security checks). The wizard automatically creates the appropriate policy, signatures object, and profile (collectively, the security configuration), and binds the policy to global. The application firewall then begins filtering connections to your protected web sites, logging any connections that match one or more of the signatures that you enabled, and collecting statistics about the connections that each signature matches. After the application firewall processes some traffic, you can run the wizard again and examine the logs and statistics to see if any of the signatures that you have enabled are matching legitimate traffic. After determining which signatures are identifying the traffic that you want to block, you can enable blocking for those signatures. If your web site or web service is not complex, does not use SQL, and does not have access to sensitive private information, this basic security configuration will probably provide adequate protection.

You may need additional protection if, for example, your web site is dynamic. Content that uses scripts may need protection against cross-site scripting attacks. Web content that uses SQL—such as shopping carts, many blogs, and most

content management systems—may need protection against SQL injection attacks. Web sites and web services that collect sensitive private information such as social security numbers or credit card numbers may require protection against unintentional exposure of that information. Certain types of web-server or XML-server software may require protection from types of attacks tailored to that software. Another consideration is that specific elements of your web sites or web services may require different protection than do other elements. Examining the application firewall logs and statistics can help you identify the additional protections that you might need.

After deciding which advanced protections are needed for your web sites and web services, you can run the wizard again to configure those protections. Certain security checks require that you enter exceptions (relaxations) to prevent the check from blocking legitimate traffic. You can do so manually, but it is usually easier to enable the adaptive learning feature and allow it to recommend the necessary relaxations. You can use the wizard as many times as necessary to enhance your basic security configuration and/or create additional security configurations.

The wizard automates some tasks that you would have to perform manually if you did not use the wizard. It automatically creates a policy, a signatures object, and a profile, and assigns them the name that you provided when you were prompted for the name of your configuration. The wizard also adds your advanced-protection settings to the profile, binds the signatures object to the profile, associates the profile with the policy, and puts the policy into effect by binding it to Global.

A few tasks cannot be performed in the wizard. You cannot use the wizard to bind a policy to a bind point other than Global. If you want the profile to apply to only a specific part of your configuration, you must manually configure the binding. You cannot configure the engine settings or certain other global configuration options in the wizard. While you can configure any of the advanced protection settings in the wizard, if you want to modify a specific setting in a single security check, it may be easier to do so on the manual configuration screens in the configuration utility.

For more information on using the Application Firewall Wizard, see "[The Application Firewall Wizard](#)."

AppExpert Templates are a different and simpler approach to configuring and managing complex enterprise applications. The AppExpert display in the configuration utility consists of a table. Applications are listed in the left-most column, with the NetScaler features that are applicable to that application appearing each in its own column to the right. (In the AppExpert interface, those features that are associated with an application are called *application units*.) In the AppExpert interface, you configure the interesting traffic for each application, and turn on rules for compression, caching, rewrite, filtering, responder and the application firewall, instead of having to configure each feature individually.

The Web Interface AppExpert Template contains rules for the following application firewall signatures and security checks:

- "[Deny URL check](#)." Detects connections to content that is known to pose a security risk, or to any other URLs that you designate.
- "[Buffer Overflow check](#)." Detects attempts to cause a buffer overflow on a protected web server.
- "[Cookie Consistency check](#)." Detects malicious modifications to cookies set by a protected web site.
- "[Form Field Consistency check](#)." Detects modifications to the structure of a web form on a protected web site.
- "[CSRF Form Tagging check](#)." Detects cross-site request forgery attacks.
- "[Field Formats check](#)." Detects inappropriate information uploaded in web forms on a protected web site.
- "[HTML SQL Injection check](#)." Detects attempts to inject unauthorized SQL code.
- "[HTML Cross-Site Scripting check](#)." Detects cross-site scripting attacks.

For information on installing and using an AppExpert Template, see "[AppExpert Applications and Templates](#)."

The NetScaler configuration utility is a web-based interface that provides access to all configuration options for the application firewall feature, including advanced configuration and management options that are not available from any other configuration tool or interface. Specifically, many advanced Signatures options can be configured only in the configuration utility. You can review recommendations generated by the learning feature only in the configuration utility. You can bind policies to a bind point other than Global only in the configuration utility.

For a description of the configuration utility, see "[The Application Firewall Configuration Interfaces](#)." For more information on using the configuration utility to configure the application firewall, see "[Manual Configuration By Using the Configuration Utility](#)."

For instructions on configuring the application firewall by using the configuration utility, see "[Manual Configuration By Using the Configuration Utility](#)." For information on the Citrix NetScaler Configuration Utility, see "[The Application Firewall Configuration Interfaces](#)."

The Citrix NetScaler command line interface is a modified UNIX shell based on the FreeBSD bash shell. To configure the Application Firewall from the command line interface, you type commands at the prompt and press the Enter key, just as you do with any other Unix shell. You can configure most parameters and options for the application firewall by using the NetScaler command line. Exceptions are the signatures feature, many of whose options can be configured only by using the configuration utility or the Application Firewall wizard, and the learning feature, whose recommendations can only be reviewed in the configuration utility.

For instructions on configuring the application firewall by using the NetScaler command line, see "[Manual Configuration By Using the Command Line Interface](#)."

# Enabling the Application Firewall

Oct 09, 2014

Before you can create an application firewall security configuration, you must make sure that the application firewall feature is enabled.

- If you are configuring a dedicated Citrix Application Firewall ADC or are upgrading an existing Citrix NetScaler ADC or VPX, the feature is already enabled. You do not have to perform either of the procedures described here.
- If you have a new NetScaler ADC or VPX, you need to enable the application firewall feature before you configure it.
- If you are upgrading a NetScaler ADC or VPX from a previous version of the NetScaler operating system to the current version, you might need to enable the application firewall feature before you configure it.

Note: If you are upgrading a NetScaler ADC or VPX from a previous version, you might also need to update the licenses on your ADC or VPX before you can enable the application firewall. Check with your Citrix representative or reseller to obtain the correct license.

You can enable the application firewall by using the command line or the configuration utility.

At the command prompt, type the following command:

```
enable ns feature AppFW
```

1. Navigate to System > Settings.
2. In the details pane, click Configure Basic Features.
3. In the Configure Basic Features dialog box, check the Application Firewall check box.
4. Click OK.

# The Application Firewall Wizard

Oct 01, 2013

Unlike most wizards, the Application Firewall wizard is designed not just to simplify the initial configuration process, but also to modify previously created configurations and to maintain your Application Firewall setup. A typical user runs the wizard multiple times, skipping some of the screens each time.

To run the Application Firewall wizard, first open the configuration utility. Next, in the navigation pane, expand Application Firewall, and then in the details pane click Application Firewall Wizard. (For more information about the configuration utility, see "[The Application Firewall User Interfaces.](#)") Then:

1. Navigate to Security > Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard. The first screen of the wizard appears.
3. To advance to the next screen, click Next.

The Application Firewall wizard displays the following screens, in the following order:

1. **Introduction screen.** Provides an introduction to the Application Firewall wizard. There is nothing that you can configure on this screen.
2. **Specify Name screen.** On this screen, when creating a new security configuration, you specify the name that the wizard is to assign to the configuration. The name can begin with a letter, number, or the underscore symbol, and can consist of from 1 to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (\_) symbols. Choose a name that makes it easy for others to tell what content your new security configuration protects.

Note: Because the wizard uses this name for both the policy and the profile, it is limited to 31 characters. Manually created policies can have names up to 127 characters in length.

When creating an existing configuration, you select Modify Existing Configuration and then, in the Name drop-down list, select the name of the existing configuration that you want to modify.

Note: Only policies that are bound to global or to a bind point appear in this list; you cannot modify an unbound policy by using the Application Firewall wizard. You must either manually bind it to Global or a bind point, or modify it manually. (For manual modification, in the configuration utility's Application Firewall --> Policies --> Firewall pane, select the policy and click Open).

You also select a profile type on this screen. The profile type determines the types of advanced protection (security checks) that can be configured. Because certain kinds of content are not vulnerable to certain types of security threats, restricting the list of available checks saves time during configuration. The types of Application Firewall profiles are:

- **Web Application (HTML).** Any HTML-based Web site that does not use XML or Web 2.0 technologies.
- **XML Application (XML, SOAP).** Any XML-based Web service.
- **Web 2.0 Application (HTML, XML, REST).** Any Web 2.0 site that combines HTML and XML-based content, such as an ATOM-based site, a blog, an RSS feed, or a wiki.

Note: If you are unsure which type of content is used on your Web site, you can choose Web 2.0 Application to ensure that you protect all types of Web application content.

3. **Specify Rule screen.** On this screen, you specify the policy rule (*expression*) that defines the traffic to be examined by this security configuration. If you are creating an initial configuration to protect your Web sites and Web services, you can simply accept the default value, true, which selects all web traffic .

If you want this security configuration to examine, not all HTTP traffic that is routed through the appliance, but specific traffic, you can write a policy rule specifying the traffic that you want it to examine. Rules are written in Citrix NetScaler expressions language, which is a fully functional object-oriented programming language.

- For a simple description of using the NetScaler expressions syntax to create Application Firewall rules, and a list of useful rules, see "[Firewall Policies](#)."
- For a detailed explanation of how to create policy rules in NetScaler expressions syntax, see "[Policies and Expressions](#)."

Note: In addition to the default expressions syntax, for backward compatibility the NetScaler operating system supports the NetScaler classic expressions syntax on NetScaler Classic and nCore appliances and virtual appliances. Classic expressions are not supported on NetScaler Cluster appliances and virtual appliances. Current users who want to migrate their existing configurations to the NetScaler cluster must migrate any policies that contain classic expressions to the default expressions syntax.

4. **Select Signature Protections screen.** On this screen, you select the categories of signatures that you want to use to protect your web sites and web services. The default categories are:

- **CGI.** Protection against attacks on web sites that use CGI scripts in any language, including PERL scripts, Unix shell scripts, and Python scripts.
- **Cold Fusion.** Protection against attacks on web sites that use the Adobe Systems® ColdFusion® Web development platform.
- **FrontPage.** Protection against attacks on web sites that use the Microsoft® FrontPage® Web development platform.
- **PHP.** Protection against attacks on web sites that use the PHP open-source Web development scripting language.
- **Client side.** Protection against attacks on client-side tools used to access your protected web sites, such as Microsoft Internet Explorer, Mozilla Firefox, the Opera browser, and the Adobe Acrobat Reader.
- **Microsoft IIS.** Protection against attacks on Web sites that run the Microsoft Internet Information Server (IIS).
- **Miscellaneous.** Protection against attacks on other server-side tools, such as Web servers and database servers.

If you are creating a new security configuration, the signature categories that you select are enabled, and by default they are recorded in a new signatures object. The new signatures object is assigned the same name that you entered on the Specify name screen as the name of the security configuration.

If you have previously configured signatures objects and want to use one of them as the signatures object associated with the security configuration that you are creating, click Select Existing Signature and select a signatures object from the Signatures list.

If you are modifying an existing security configuration, you can click Select Existing Signature and assign a different signatures object to the security configuration.

5. **Select Signature Actions screen.** On this screen, you select the actions associated with the signature categories that you selected on the Select signature protections screen. If you are creating an initial configuration, you might want

to accept the defaults, which enable the Log and Stats actions but not the Block action. You can decide later, after reviewing the collected logs and statistics, which signatures you should use to block traffic, and then enable the Block action for those signatures. Signatures are designed to catch specific known attacks on your web sites, and therefore they have extremely low false positive rates. However, with any new configuration, you should probably observe how the settings you chose are working before you use them to block traffic.

If you select More for one of the signature categories, the Configure Actions for Signatures dialog box appears. Its contents are the same as the contents of the Modify Signatures Object dialog box, as described in "[To Configure a Signatures Object](#)."

If the signatures object has already logged connections, you can click Logs to display the Syslog Viewer with the logs, as described in "[Logs, Statistics, and Reports](#)." If a signature is blocking legitimate access to your protected web site or web service, you can create and implement a relaxation for that signature by selecting a log that shows the unwanted blocking, and then clicking Deploy.

6. **Select Advanced Protections screen.** On this screen, you choose the advanced protections (also called *security checks* or simply *checks*) that you want to use to protect your web sites and web services. The checks are divided into categories. Which categories are available (and which checks are available within a category) depends on the profile type that you chose on the Specify Name screen. All checks are available for Web 2.0 Application profiles. If you chose that profile type, the Select advanced protections screen displays the following categories of security checks:

- Top--level protections (Some checks appear at the top level, not in any category.)
- Data Leak Prevention Protections
- Advanced Form Protections
- URL Protections
- XML Protections

To display the individual checks in a category, click the icon to the left of the category. To apply a security check to your filtered data, select the check box next to the name of the security check. For descriptions of the security checks see "[Advanced Protections](#)" and its subtopics.

7. **Select Advanced Actions screen.** On this screen, you configure the actions for the advanced protections that you have enabled.

Note: If no advanced protections are enabled, the Wizard skips the Advanced Actions screen and goes directly to the Summary screen.

The actions that you can configure are:

- **Block.** Block connections that match the signature. Disabled by default.
- **Log.** Log connections that match the signature for later analysis. Enabled by default.
- **Stats.** Maintain statistics, for each signature, that show how many connections it matched and provide certain other information about the types of connections that were blocked. Disabled by default.
- **Learn.** Observe traffic to this Web site or Web service, and use connections that repeatedly violate this check to generate recommended exceptions to the check, or new rules for the check. Available only for some checks.

To enable or disable an action for a check, in the list, select or clear the check box for that action to the right of that check.

To configure other parameters for those checks that have them, in the list, click the blue chevron to the far right of that check. In the dialog box that appears, configure the parameters. These vary from check to check. You can also select a check and, at the bottom of the dialog box, click Open to display a dialog box for modifying any of the options for that check. These dialog boxes also vary from check to check. Most of them include a Checks tab and a General tab. If the check supports relaxations, the Checks tab includes an Add button, which opens yet another dialog box, in which you can specify a relaxation for the check. A relaxation is a rule for exempting specified traffic from the check.

For information about the settings available for a check, see the detailed description of that check.

To review the recommendations generated by the learning engine for a specific check, select that check and then click Learned Violations to open the Manage Learned Rules dialog box for that check. For more information on how learning works and how to configure exceptions (relaxations) or deploy learned rules for a check, see "[Manual Configuration By Using the Configuration Utility](#)" under To configure and use the learning feature

To view all logs for a specific check, select that check, and then click Logs to display the Syslog Viewer, as described in "[Logs, Statistics, and Reports](#)." If a security check is blocking legitimate access to your protected web site or web service, you can create and implement a relaxation for that security check by selecting a log that shows the unwanted blocking, and then clicking Deploy.

8. **Summary screen.** On this screen, you review your configuration choices to verify that they are what you want. If you want to make changes, you click Back until you have returned to the appropriate screen, and make your changes. If the configuration is as you want it, you click Finish to save it, and then click Exit to close the Application Firewall wizard.

Following are four procedures that show how to perform specific types of configuration by using the Application Firewall wizard.

1. Navigate to Security > Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard.
3. On the Application Firewall wizard, Introduction screen, in the lower right-hand corner, click Next.
4. On the Specify Name screen, in the Name text box, type a name for your new security configuration, and from the Type drop-down list, select the type of security configuration. Then, click Next.
5. On the Specify Rule screen, click Next again.  
Note: The default rule, true, protects all Web traffic that is sent via your NetScaler appliance or virtual appliances. You can create specific security configurations to protect specific parts of your Web sites or Web applications later.
6. On the Select Signature Protections screen, select check boxes to specify the groups of signatures that are appropriate for protecting the content on your protected web sites, and then click Next.  
For more information about signatures, see "[Signatures](#)."
7. On the Select Signature Actions screen, select or clear the associated check boxes to choose the signature actions that you want for each signature category that you selected in the previous step, and then click Next.
8. On the Select Advanced Protections screen, click Next again.  
You typically do not need to configure the security checks during initial configuration.
9. On the Summary screen, review your choices to verify that they are what you want. Then, click Finish, or click Back to return to a previous screen and make changes. When you are finished, click Exit to close the Application Firewall wizard.

1. Navigate to Security > Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard.
3. On the Application Firewall wizard, Introduction screen, in the lower right-hand corner, click Next.
4. On the Specify Name screen, select Modify Existing Configuration and, in the Name drop-down list, choose the security configuration that you created during simple configuration, and then click Next.
5. In the Specify Rule screen, click Next again.
6. In the Select Signature Protections screen, click Next again.

7. In the Select Signature Actions screen, enable blocking for your chosen signatures by selecting the Block check box to the left of each of those signature.  
For more information about which signatures to consider for blocking and how to determine when you can safely enable blocking for a signature, see "[Signatures](#)."
8. In the Select advanced protections screen, click Next.
9. On the Summary screen, review your choices to verify that they appear correct. Then, click Finish, or click Back to return to the Select Signature Actions screen and make changes. When you are finished, click Exit to close the Application Firewall wizard.

1. Navigate to Security > Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard.
3. On the Application Firewall wizard, Introduction screen, in the lower right-hand corner, click Next.
4. On the Specify Name screen, select Modify Existing Configuration and, in the Name drop-down list, choose the security configuration that you created during simple configuration. Then, click Next.
5. On the Specify Rule screen, click Next again.
6. On the Select Signature Protections screen, click Next.
7. On the Select Signature Actions screen, click Next again.
8. On the Select advanced protections screen, select the check box beside each security check that you want to enable, and then click Next.  
For information about the security checks, see "[Advanced Protections](#)" and its subtopics.
9. On the Select Deep Actions screen, select check boxes to specify the actions that you want the Application Firewall to perform for each security check, and then click Next.  
For general information about the actions, see "[Advanced Protections](#)" and its subtopics. For information about the learning feature, which is available for some security checks, see "[To configure and use the Learning feature](#)."
10. On the Summary screen, review your choices to verify that they appear correct. Then, click Finish, or click Back to return to the Select Signature Actions screen and make changes. When you are finished, click Exit to close the Application Firewall wizard.

The following procedure describes how to use the Application Firewall wizard to create a specialized security configuration to protect only specific content. In this case, you create a new security configuration instead of modifying the initial configuration. This type of security configuration requires a custom rule, so that the policy applies the configuration to only the selected Web traffic.

1. Navigate to Security > Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard.
3. On the Application Firewall wizard, Introduction screen, in the lower right-hand corner, click Next.
4. On the Specify Name screen, type a name for your new security configuration in the Name text box, select the type of security configuration from the Type drop-down list, and then click Next.
5. On the Specify Rule screen, enter a rule that matches only that content that you want this Web application to protect, and then click Next.  
For a description of policies and policy rules, see "[Policies](#)."
6. On the Select Signature Protections screen, choose the appropriate groups of signatures to protect the content on

your protected web sites by selecting the check box beside each group of signatures, and then click Next.  
For detailed information about signatures, see "[Signatures](#)."

7. On the Select Signature Actions screen, select or clear the associated check boxes to choose the signature actions that you want for each signature category that you selected in the previous step, and then click Next. For a detailed description of actions, see "[Signatures](#)."
8. In the Select Advanced Protections screen, select the check box beside each security check that you want to enable, and then click Next.  
For detailed information about the security checks, see "[Advanced Protections](#)" and its subtopics.
9. In the Select Advanced Actions screen, select check boxes to specify the actions that you want the Application Firewall to perform for each security check. Then, click Next.  
For information about each security check to help you determine which actions to enable, see the [Advanced Protections](#) section.
10. On the Summary screen, review your choices to verify that they appear correct. Then, click Finish, or click Back to return to the Select Signature Actions screen and make changes. When you are finished, click Exit to close the wizard.

# Manual Configuration

Mar 28, 2012

If you want to bind a profile to a bind point other than Global, you must manually configure the binding. Also, certain security checks require that you either manually enter the necessary exceptions or enable the learning feature to generate the exceptions that your Web sites and Web services need. Some of these tasks cannot be performed by using the application firewall wizard.

If you are familiar with how the application firewall works and prefer manual configuration, you can manually configure a signatures object and a profile, associate the signatures object with the profile, create a policy with a rule that matches the web traffic that you want to configure, and associate the policy with the profile. You then bind the policy to Global, or to a bind point, to put it into effect, and you have created a complete security configuration.

For manual configuration, you can use the configuration utility (a graphical interface) or the command line. Citrix recommends that you use the configuration utility. Not all configuration tasks can be performed at the command line. Certain tasks, such as enabling signatures and reviewing learned data, must be done in the configuration utility. Most other tasks are easier to perform in the configuration utility.

# Manual Configuration By Using the Configuration Utility

Sep 03, 2013

If you need to configure the Application Firewall feature manually, Citrix recommends that you use the configuration utility. For a description of the configuration utility, see "[The Application Firewall User Interfaces](#)."

Before you can configure the signatures, you must create a new signatures object from the appropriate default signatures object template. Assign the copy a new name, and then configure the copy. You cannot configure or modify the default signatures objects directly. The following procedure provides basic instructions for configuring a signatures object. For more detailed instructions, see "[Manually Configuring the Signatures Feature](#)." If you need to create your own, user defined signatures, see "[The Signatures Editor](#)."

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to use as a template, and then click Add.  
Your choices are:
  - \* **Default Signatures**. Contains the signatures rules, the SQL injection rules, and the cross-site scripting rules.
  - \* **XPath Injection**. Contains all of the items in the \* Default Signatures, and in addition contains the XPath injection rules.
3. In the Add Signatures Object dialog box, type a name for your new signatures object, click OK, and then click Close. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), and underscore ( ) symbols.
4. Select the signatures object that you created, and then click Open.
5. In the Modify Signatures Object dialog box, set the Display Filter Criteria options at the left to display the filter items that you want to configure.  
As you modify these options, the results that you specify are displayed in the Filtered Results window at the right. For more information about the categories of signatures, see "[Signatures](#)."
6. In the Filtered Results area, configure the settings for a signature by selecting and clearing the appropriate check boxes.
7. When finished, finished, click Close.

Creating an application firewall profile requires that you specify only a few configuration details.

1. Navigate to Security > Application Firewall > Profiles.
2. In the details pane, click Add.
3. In the Create Application Firewall Profile dialog box, type a name for your profile.  
The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore ( ) symbols.
4. Choose the profile type from the drop-down list.
5. Click Create, and then click Close.

1. Navigate to Security > Application Firewall > Profiles.
2. In the details pane, select the profile that you want to configure, and then click Edit.
3. In the Configure Application Firewall Profile dialog box, on the Security Checks tab, configure the security checks.
  - To enable or disable an action for a check, in the list, select or clear the check box for that action.
  - To configure other parameters for those checks that have them, in the list, click the blue chevron to the far right of that check. In the dialog box that appears, configure the parameters. These vary from check to check.

You can also select a check and, at the bottom of the dialog box, click Open to display the Configure Relaxation dialog box or Configure Rule dialog box for that check. These dialog boxes also vary from check to check. Most of them include a Checks tab and a General tab. If the check supports relaxations or user-defined rules, the Checks tab includes an Add button, which opens yet another dialog box, in which you can specify a relaxation or rule for the check. (A relaxation is a rule for exempting specified traffic from the check.) If relaxations have already been configured, you can select one and click Open to modify it.
  - To review learned exceptions or rules for a check, select the check, and then click Learned Violations. In the Manage Learned Rules dialog box, select each learned exception or rule in turn.
    - To edit the exception or rule, and then add it to the list, click Edit & Deploy.
    - To accept the exception or rule without modification, click Deploy.
    - To remove the exception or rule from the list, click Skip.
  - To refresh the list of exceptions or rules to be reviewed, click Refresh.
  - To open the Learning Visualizer and use it to review learned rules, click Visualizer.
  - To review the log entries for connections that matched a check, select the check, and then click Logs. You can use this information to determine which checks are matching attacks, so that you can enable blocking for those checks. You can also use this information to determine which checks are matching legitimate traffic, so that you can configure an appropriate exemption to allow those legitimate connections. For more information about the logs, see "[Logs, Statistics, and Reports](#)."
  - To completely disable a check, in the list, clear all of the check boxes to the right of that check.
4. On the Settings tab, configure the profile settings.
  - To associate the profile with the set of signatures that you previously created and configured, under Common Settings, choose that set of signatures in the Signatures drop-down list.

Note: You may need to use the scroll bar on the right of the dialog box to scroll down to display the Common Settings section.
  - To configure an HTML or XML Error Object, select the object from the appropriate drop-down list.

Note: You must first upload the error object that you want to use in the Imports pane. For more information about importing error objects, see "[Imports](#)."
  - To configure the default XML Content Type, type the content type string directly into the Default Request and Default Response text boxes, or click Manage Allowed Content Types to manage the list of allowed content types.

">[More](#)...."
5. If you want to use the learning feature, click Learning, and configure the learning settings for the profile, as described in "[Configuring and Using the Learning Feature](#)".
6. Click OK to save your changes and return to the Profiles pane.

Updated: 2014-06-12

You configure two different types of information in this dialog box, depending upon which security check you are configuring. In the majority of cases, you configure an exception (or relaxation) to the security check. If you are configuring the Deny URL check or the Field Formats check, you configure an addition (or rule). The process for either of these is the

same.

## To configure a relaxation or rule by using the configuration utility

1. Navigate to Security > Application Firewall > Profiles.
2. In the Profiles pane, select the profile you want to configure, and then click Edit.
3. In the Configure Application Firewall Profile dialog box, click the Security Checks tab. The Security Checks tab contains the complete list of application firewall security checks, also called *advanced protections* in some places.
4. In the Security Checks tab, click the check that you want to configure, and then click Open. The Modify Check dialog box for the check that you chose is displayed, with the Checks tab selected. The Checks tab contains a list of existing relaxations or rules for this check. The list might be empty if you have not either manually added any relaxations or approved any relaxations that were recommended by the learning engine. Beneath the list is a row of buttons that allow you to add, modify, delete, enable, or disable the relaxations on the list.
5. To add or modify a relaxation or a rule, do one of the following:
  - To add a new relaxation, click Add.
  - To modify an existing relaxation, select the relaxation that you want to modify, and then click Open.The Add Check Relaxation or Modify Check Relaxation dialog box for the selected check is displayed. Except for the title, these dialog boxes are identical.
6. Fill in the dialog box as described below. The dialog boxes for each check are different; the list below covers all elements that might appear in any dialog box.
  - **Enabled check box**—Select to place this relaxation or rule in active use; clear to deactivate it.
  - **Attachment Content Type**—The Content-Type attribute of an XML attachment. In the text area, enter a regular expression that matches the Content-Type attribute of the XML attachments to allow.
  - **Action URL**—In the text area, enter a PCRE-format regular expression that defines the URL to which data entered into the web form is delivered.
  - **Cookie**—In the text area, enter a PCRE-format regular expression that defines the cookie.
  - **Field Name**—A web form field name element may be labeled Field Name, Form Field, or another similar name. In the text area, enter a PCRE-format regular expression that defines the name of the form field.
  - **Form Origin URL**—In the text area, enter a PCRE-format regular expression that defines the URL that hosts the web form.
  - **Form Action URL**—In the text area, enter a PCRE-format regular expression that defines the URL to which data entered into the web form is delivered.
  - **Name**—An XML element or attribute name. In the text area, enter a PCRE-format regular expression that defines the name of the element or attribute.
  - **URL**—A URL element may be labeled Action URL, Deny URL, Form Action URL, Form Origin URL, Start URL, or simply URL. In the text area, enter a PCRE-format regular expression that defines the URL.
  - **Format**—The format section contains multiple settings that include list boxes and text boxes. Any of the following can appear:
    - **Type**—Select a field type in the Type drop-down list. To add a new field type definition, click Manage—
    - **Minimum Length**—Type a positive integer that represents the minimum length in characters if you want to force

users to fill in this field. Default: 0 (Allows field to be left blank.)

- **Maximum length**—To limit the length of data in this field, type a positive integer that represents the maximum length in characters. Default: 65535
- **Location**—Choose the element of the request that your relaxation will apply to from the drop-down list. For HTML security checks, the choices are:
  - FORMFIELD—Form fields in web forms.
  - HEADER—Request headers.
  - COOKIE—Set-Cookie headers.

For XML security checks, the choices are:

- ELEMENT—XML element.
- ATTRIBUTE—XML attribute.
- **Maximum Attachment Size**—The maximum size in bytes allowed for an XML attachment.
- **Comments**—In the text area, type a comment. Optional.

Note: For any element that requires a regular expression, you can type the regular expression, use the Regex Tokens menu to insert regular expression elements and symbols directly into the text box, or click Regex Editor to open the Add Regular Expression dialog box, and use it to construct the expression.

7. To remove a relaxation or rule, select it, and then click Remove.
8. To enable a relaxation or rule, select it, and then click Enable.
9. To disable a relaxation or rule, select it, and then click Disable.
10. To configure the settings and relationships of all existing relaxations in an integrated interactive graphic display, click Visualizer, and use the display tools.

Note: The Visualizer button does not appear on all check relaxation dialog boxes.

11. To review learned rules for this check, click Learning and perform the steps in "[To configure and use the Learning feature.](#)"
12. Click OK.

1. Navigate to Security > Application Firewall > Profiles.
2. In the Profiles pane, select the profile, and then click Edit.
3. Click the Learning tab. At the top of the Learning tab is list of the security checks that are available in the current profile and that support the learning feature.
4. To configure the learning thresholds, select a security check, and then type the appropriate values in the following text boxes:
  - **Minimum number threshold.** Depending on which security check's learning settings you are configuring, the minimum number threshold might refer to the minimum number of total user sessions that must be observed, the minimum number of requests that must be observed, or the minimum number of times a specific form field must be observed, before a learned relaxation is generated. Default: 1
  - **Percentage of times threshold.** Depending on which security check's learning settings you are configuring, the percentage of times threshold might refer to the percentage of total observed user sessions that violated the security check, the percentage of requests, or the percentage of times a form field matched a particular field type, before a learned relaxation is generated. Default: 0
5. To remove all learned data and reset the learning feature, so that it must start its observations again from the beginning, click Remove All Learned Data.

Note: This button removes only learned recommendations that have not been reviewed and either approved or skipped. It does not remove learned relaxations that have been accepted and deployed.

6. To restrict the learning engine to traffic from a specific set of IPs, click Trusted Learning Clients, and add the IP addresses that you want to use to the list.
  1. To add an IP address or IP address range to the Trusted Learning Clients list, click Add.
  2. In the Add Trusted Learning Clients dialog box, Trusted Clients IP list box, type the IP address or an IP address range in CIDR format.
  3. In the Comments text area, type a comment that describes this IP address or range.
  4. Click Create to add your new IP address or range to the list.
  5. To modify an existing IP address or range, click the IP address or range, and then click Open. Except for the name, the dialog box that appears is identical to the Add Trusted Learning Clients dialog box.
  6. To disable or enable an IP address or range, but leave it on the list, click the IP address or range, and then click Disable or Enable, as appropriate.
  7. To remove an IP address or range completely, click the IP address or range, and then click Remove.
7. Click Close to return to the Configure Application Firewall Profile dialog box.
8. Click Close to close the Configure Application Firewall Profile dialog box, and return to the Application Firewall Profile screen.

1. Navigate to Security > Application Firewall > Policies.
2. In the details pane, do one of the following:
  - To create a new firewall policy, click Add. The Create Application Firewall Policy is displayed.
  - To edit an existing firewall policy, select the policy, and then click Edit. The Create Application Firewall Policy or Configure Application Firewall Policy is displayed.
3. If you are creating a new firewall policy, in the Create Application Firewall Policy dialog box, Policy Name text box, type a name for your new policy.

The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 128 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (\_) symbols.

If you are configuring an existing firewall policy, this field is read-only. You cannot modify it.
4. Select the profile that you want to associate with this policy from the Profile drop-down list. You can create a new profile to associate with your policy by clicking New, and you can modify an existing profile by clicking Modify.
5. In the Expression text area, create a rule for your policy.
  - You can type a rule directly into the text area.
  - You can click Prefix to select the first term for your rule, and follow the prompts. See "[To Create an Application Firewall Rule \(Expression\)](#)" for a complete description of this process.
  - You can click Add to open the Add Expression dialog box, and use it to construct the rule. See "[The Add Expression Dialog Box](#)" for a complete description of this process.
6. Click Create or OK, and then click Close.

The policy rule, also called the *expression*, defines the web traffic that the application firewall filters by using the profile associated with the policy. Like other NetScaler policy rules (or *expressions*), application firewall rules use NetScaler expressions syntax. This syntax is powerful, flexible, and extensible. It is too complex to describe completely in this set of instructions. You can use the following procedure to create a simple firewall policy rule, or you can read it as an overview of the policy creation process.

1. If you have not already done so, navigate to the appropriate location in the Application Firewall wizard or the NetScaler configuration utility to create your policy rule:
  - If you are configuring a policy in the Application Firewall wizard, in the navigation pane, click Application Firewall, then in the details pane click Application Firewall Wizard, and then navigate to the Specify Rule screen.
  - If you are configuring a policy manually, in the navigation pane, expand Application Firewall, then Policies, and then Firewall. In the details pane, to create a new policy, click Add. To modify an existing policy, select the policy, and then click Open.
2. On the Specify Rule screen, the Create Application Firewall Profile dialog box, or the Configure Application Firewall Profile dialog box, click Prefix, and then choose the prefix for your expression from the drop-down list. Your choices are:
  - **HTTP**. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
  - **SYS**. The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
  - **CLIENT**. The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
  - **SERVER**. The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

After you choose a prefix, the application firewall displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom.

3. Choose your next term.

If you chose HTTP as your prefix, your only choice is REQ, which specifies the Request/Response pair. (The application firewall operates on the request and response as a unit instead of on each separately.) If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

When you have decided which term you want, double-click it to insert it into the Expression window.

4. Type a period after the term you just chose. You are then prompted to choose your next term, as described in the previous step. When a term requires that you type a value, fill in the appropriate value. For example, if you choose HTTP.REQ.HEADER(""), type the header name between the quotation marks.
5. Continue choosing terms from the prompts and filling in any values that are needed, until your expression is finished. Following are some examples of expressions for specific purposes.

- **Specific web host**. To match traffic from a particular web host:

```
HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
```

For shopping.example.com, substitute the name of the web host that you want to match.

- **Specific web folder or directory**. To match traffic from a particular folder or directory on a Web host:

```
HTTP.REQ.URL.STARTSWITH("https://www.example.com/folder")
```

For www.example.com, substitute the name of the web host. For folder, substitute the folder or path to the content that you want to match. For example, if your shopping cart is in a folder called /solutions/orders, you substitute that string for folder.

- **Specific type of content: GIF images**. To match GIF format images:

```
HTTP.REQ.URL.ENDSWITH(".gif")
```

To match other format images, substitute another string in place of .gif.

- **Specific type of content: scripts.** To match all CGI scripts located in the CGI-BIN directory:

```
HTTP.REQ.URL.STARTSWITH("https://www.example.com/CGI-BIN")
```

To match all JavaScripts with .js extensions:

```
HTTP.REQ.URL.ENDSWITH(".js")
```

For more information about creating policy expressions, see "[Policies and Expressions](#)."

Note: If you use the command line to configure a policy, remember to escape any double quotation marks within NetScaler expressions. For example, the following expression is correct if entered in the configuration utility:

```
HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
```

If entered at the command line, however, you must type this instead:

```
HTTP.REQ.HEADER(\"Host\").EQ(\"shopping.example.com\")
```

The Add Expression dialog box (also referred to as the Expression Editor) helps users who are not familiar with the NetScaler expressions language to construct a policy that matches the traffic that they want to filter.

1. If you have not already done so, navigate to the appropriate location in the Application Firewall wizard or the NetScaler configuration utility:
  - If you are configuring a policy in the Application Firewall wizard, in the navigation pane, click Application Firewall, then in the details pane click Application Firewall Wizard, and then navigate to the Specify Rule screen.
  - If you are configuring a policy manually, in the navigation pane, expand Application Firewall, then Policies, and then Firewall. In the details pane, to create a new policy, click Add. To modify an existing policy, select the policy, and then click Open.
2. On the Specify Rule screen, in the Create Application Firewall Profile dialog box, or in the Configure Application Firewall Profile dialog box, click Add.
3. In the Add Expression dialog box, in the Construct Expression area, in the first list box, choose one of the following prefixes:
  - **HTTP**. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol. The default choice.
  - **SYS**. The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
  - **CLIENT**. The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
  - **SERVER**. The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.
4. In the second list box, choose your next term. The available terms differ depending on the choice you made in the previous step, because the dialog box automatically adjusts the list to contain only those terms that are valid for the context. For example, if you selected HTTP in the previous list box, the only choice is REQ, for requests. Because the application firewall treats requests and associated responses as a single unit and filters both, you do not need to specify responses separately. After you choose your second term, a third list box appears to the right of the second. The Help window displays a description of the second term, and the Preview Expression window displays your expression.
5. In the third list box, choose the next term. A new list box appears to the right, and the Help window changes to display a description of the new term. The Preview Expression window updates to display the expression as you have specified it to that point.

6. Continue choosing terms, and when prompted filling in arguments, until your expression is complete. If you make a mistake or want to change your expression after you have already selected a term, you can simply choose another term. The expression is modified, and any arguments or additional terms that you added after the term that you modified are cleared.
7. When you have finished constructing your expression, click OK to close the Add Expression dialog box. Your expression is inserted into the Expression text area.

1. Do one of the following:
  - Navigate to Security > Application Firewall, and in the details pane, click Application Firewall policy manager.
  - Navigate to Security > Application Firewall > Policies > Firewall Policies, and in the details pane, click Policy Manager.
2. In the Application Firewall Policy Manager dialog, choose the bind point to which you want to bind the policy from the drop-down list. The choices are:
  - **Override Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance, and are applied before any other policies.
  - **LB Virtual Server.** Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.
  - **CS Virtual Server.** Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.
  - **Default Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance.
  - **Policy Label.** Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.
  - **None.** Do not bind the policy to any bind point.
3. Click Continue. A list of existing application firewall policies appears.
4. Select the policy you want to bind by clicking it.
5. Make any additional adjustments to the binding.
  - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
  - To modify the policy expression, double click that field to open the Configure Application Firewall Policy dialog box, where you can edit the policy expression.
  - To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
  - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression
6. Repeat steps 3 through 6 to add any additional application firewall policies you want to globally bind.
7. Click OK. A message appears in the status bar, stating that the policy has been successfully bound.

# Manual Configuration By Using the Command Line Interface

Dec 17, 2013

You can configure many application firewall features from the NetScaler command line. There are important exceptions, however. You cannot enable signatures from the command line. There are over 1,000 default signatures in seven categories; the task is simply too complex for the command line interface. You can configure the check actions and parameters for security checks from the command line, but cannot enter manual relaxations. While you can configure the adaptive learning feature and enable learning from the command line, you cannot review learned relaxations or learned rules and approve or skip them. The command line interface is intended for advanced users who are thoroughly familiar with the NetScaler appliance and the application firewall feature.

To manually configure the application firewall by using the NetScaler command line, use a telnet or secure shell client of your choice to log on to the NetScaler command line.

To create a profile by using the command line interface

At the command prompt, type the following commands:

- add appfw profile <name> [-defaults ( **basic** | **advanced** )]
- set appfw profile <name> -type ( **HTML** | **XML** | **HTML XML** )
- save ns config

## Example

The following example adds a profile named pr-basic, with basic defaults, and assigns a profile type of HTML. This is the appropriate initial configuration for a profile to protect an HTML Web site.

```
add appfw profile pr-basic -defaults basic
set appfw profile pr-basic -type HTML
save ns config
```

To configure a profile by using the command line interface

At the command prompt, type the following commands:

- set appfw profile <name> <arg1> [<arg2> ...] where <arg1> represents a parameter and <arg2> represents either another parameter or the value to assign to the parameter represented by <arg1>. For descriptions of the parameters to use when configuring specific security checks, see [Advanced Protections](#) and its subtopics. For descriptions of the other parameters, see "Parameters for Creating a Profile."
- save ns config

## Example

The following example shows how to configure an HTML profile created with basic defaults to begin protecting a simple HTML-based Web site. This example turns on logging and maintenance of statistics for most security checks, but enables blocking only for those checks that have extremely low false positive rates and require no special configuration. It also turns on transformation of unsafe HTML and unsafe SQL, which prevents attacks but does not block requests to your Web sites. With logging and statistics enabled, you can later review the logs to determine whether to enable blocking for a

specific security check.

```
set appfw profile -startURLAction log stats
set appfw profile -denyURLAction block log stats
set appfw profile -cookieConsistencyAction log stats
set appfw profile -crossSiteScriptingAction log stats
set appfw profile -crossSiteScriptingTransformUnsafeHTML ON
set appfw profile -fieldConsistencyAction log stats
set appfw profile -SQLInjectionAction log stats
set appfw profile -SQLInjectionTransformSpecialChars ON
set appfw profile -SQLInjectionOnlyCheckFieldsWithSQLChars ON
set appfw profile -SQLInjectionParseComments checkall
set appfw profile -fieldFormatAction log stats
set appfw profile -bufferOverflowAction block log stats
set appfw profile -CSRFtagAction log stats
save ns config
```

To create and configure a policy

At the command prompt, type the following commands:

- add appfw policy <name> <rule> <profile>
- save ns config

## Example

The following example adds a policy named pl-blog, with a rule that intercepts all traffic to or from the host blog.example.com, and associates that policy with the profile pr-blog. This is an appropriate policy to protect a blog hosted on a specific hostname.

```
add appfw policy pl-blog "HTTP.REQ.HOSTNAME.DOMAIN.EQ("blog.example.com")" pr-blog
```

To bind an Application Firewall policy

At the command prompt, type the following commands:

- bind appfw global <policyName> <priority>
- save ns config

## Example

The following example binds the policy named pl-blog and assigns it a priority of 10.

```
bind appfw global pl-blog 10
save ns config
```

# Signatures

May 02, 2013

The application firewall signatures function provides specific, configurable rules that protect your web sites against known attacks. A signature represents a pattern that is a component of a known attack on an operating system, a web server, a web site, an XML-based web service, or any other server that is connected to a web site or web service. A signature can be used to check either requests or responses. A signature can consist of a literal string or a PCRE-compliant regular expression.

To specify how the application firewall is to use signatures, you configure a signatures object, which specifies the signatures to apply to your traffic and the actions to be taken when the signatures match the traffic. A signatures object also contains the SQL injection and cross-site scripting patterns, and may also contain XPath injection patterns. These patterns are not actually signatures but are used by some of the advanced protection checks. The SQL Injection and Cross-Site Scripting patterns contain the SQL special symbols and keywords, the cross-site scripting allowed tags and attributes, and the denied patterns for the HTML and XML SQL Injection and Cross-Site Scripting checks. The XPath injection patterns contain the XPath (XML Path Language) denied patterns.

Note: If you use the wizard to configure signatures, the signatures object is created automatically.

The application firewall examines requests to your protected web sites and web services to determine whether a request matches a signature. Matching requests are handled as you specify when configuring the Signatures actions. By default, matching requests are logged so that you can examine them later. If you enabled blocking, the application firewall displays an error page or error object. If you enabled statistics, the application firewall also includes the request in the statistics that it maintains about requests that match an application firewall signature or security check.

If you want to configure signatures manually, you must create a signatures object from a template or import a signatures object file. There are two default templates that you can use: the \*Default Signatures template and the \*XPath Injection template. The \*Default Signatures template contains over 1,000 signatures, in addition to the complete list of SQL injection and cross-site scripting allowed and denied patterns. The \*XPath Injection template contains all of those, and in addition contains 57 XPath keywords and special strings.

In addition to using its native signatures format, the application firewall can create a signatures object by using a built-in template for any supported external signatures format, or by importing an external signatures file in a supported format. The supported formats are as follows:

- **Cenzic**—Signatures files, produced by Cenzic products, that use Cenzic Hailstorm technology.
- **IBM AppScan**—Signatures files produced by IBM AppScan Enterprise and IBM AppScan Standard.
- **Qualys**—Qualys WAS signatures files produced by QualysGuard products. Only Qualys WAS 1.0 files are supported for importing as signatures. WAS 2.0 is not supported.

Note: Qualys classifies a single SQL special character in a URL as a security threat, even when no SQL keywords are present. The SQL injection check does not consider the presence of a single SQL special character a threat unless an SQL keyword is present. For that reason, a Qualys scanner continues to report such requests as containing SQL injection vulnerabilities, but the application firewall does not detect or block these requests because they pose no actual threat to your protected web sites and web services.

- **Trend Micro**—Signatures files produced by the Trend Micro Vulnerability Scanner (TMVS).

- **Whitehat**—WASC 1.0, WASC 2.0, and best practices signatures produced by Whitehat Sentinel products.

WASC signatures include information about many vulnerabilities. The application firewall generates blocking signatures from all WASC vulnerabilities. However, only certain vulnerabilities are appropriate for the web application firewall environment. For a list of appropriate Whitehat signatures, see [Whitehat WASC Signature Types for WAF Use](#).

Once you have created a signatures object, you can configure all parts of it, including the signatures rules, the XML SQL Injection and Cross-Site Scripting rules, and the Xpath injection rules. You can manually create and modify your own custom signatures in the signatures editor. You can also add new SQL injection, cross-site scripting, and XPath injection patterns, modify existing patterns, and remove patterns.

Regardless of whether you use the wizard for initial configuration or configure your signatures object manually, you should regularly apply the Citrix updates to keep your signatures current. Citrix regularly updates the default application firewall signatures. You can apply those updates manually, or you can enable automatic signature updates so that the application firewall can update the signatures from the Cloud-based application firewall updates service. You can obtain the correct URL for either type of updates from your Citrix service representative or reseller.

# Manually Configuring the Signatures Feature

Sep 03, 2013

To use signatures to protect your web sites, you must review the rules, and enable and configure the ones that you want to apply. The rules are disabled by default. Citrix recommends that you enable all rules that are applicable to the type of content that your web site uses.

To manually configure the signatures feature, use a browser to connect to the configuration utility. Then, create a signatures object from a built-in template, an existing signatures object, or by importing a file. Next, configure the new signatures object.

Note: The following procedures do not address adding user-defined signatures to a signatures object. To create your own signatures, see "[The Signatures Editor](#)."

# Adding or Removing a Signatures Object

Oct 06, 2014

You can add a new signatures object to the application firewall by:

- Copying a built-in template.
- Copying an existing signatures object.
- Importing a signatures object from an external file.

You must use the configuration utility to copy a template or existing signatures object. You can use either the configuration utility or the command line to import a signatures object. You can also use either the configuration utility or the command line to remove a signatures object.

To create a signatures object from a template

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to use as a template.

Your choices are:

- **\* Default Signatures.** Contains the signatures rules, the SQL injection rules, and the cross-site scripting rules.
- **\* XPath Injection.** Contains the XPath injection patterns.
- **Any existing signatures object.**

Attention: If you do not choose a signatures type to use as a template, the application firewall will prompt you to create signatures from scratch.

3. Click Add.
4. In the Add Signatures Object dialog box, type a name for your new signatures object, and then click OK. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), and underscore (\_) symbols.
5. Click Close.

To create a signatures object by importing a file

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, click Add.
3. In the Add Signatures Object dialog box, select the format of the signatures you want to import.
  - To import a NetScaler format signatures file, select the Native Format tab.
  - To import an external signatures format file, select the External Format tab.
4. Choose the file that you want to use to create your new signatures object.
  - To import a native NetScaler format signatures file, in the Import section select either Import from Local File or Import from URL, then type or browse to the path or URL to the file.
  - To import a Cenzic, IBM AppScan, Qualys, or Whitehat format file, in the XSLT section select Use Built-in XSLT File, Use Local File, or Reference from URL. Next, if you chose Use Built-in XSLT File, select the appropriate file format from the drop-down list. If you chose Use Local File or Reference from URL, then type or browse to the path or URL to the file.
5. Click Add, and then click Close.

To create a signatures object by importing a file by using the command line

At the command prompt, type the following commands:

- import appfw signatures <src> <name> [-xslt <string>] [-comment <string>] [-overwrite] [-merge] [-sha1 <string>]
- save ns config

## Example #1

The following example creates a new signatures object from a file named signatures.xml and assigns it the name MySignatures.

```
import appfw signatures signatures.xml MySignatures
save ns config
```

To remove a signatures object by using the configuration utility

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to remove.
3. Click Remove.

To remove a signatures object by using the command line

At the command prompt, type the following commands:

- rm appfw signatures <name>
- save ns config

# Configuring or Modifying a Signatures Object

Oct 06, 2014

You configure a signatures object after creating it, or modify an existing signatures object, to enable or disable signature categories or specific signatures, and configure how the application firewall responds when a signature matches a connection.

To configure or modify a signatures object

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to configure, and then click Open.
3. In the Modify Signatures Object dialog box, set the Display Filter Criteria options at the left to display the filter items that you want to configure.

As you modify these options, the results that you requested are displayed in the Filtered Results window at the right.

- To display only selected categories of signatures, check or clear the appropriate signature-category check boxes. The signature categories are:

| Name        | Type of Attack that this Signature Protects Against                    |
|-------------|------------------------------------------------------------------------|
| cgi         | CGI scripts. Includes Perl and UNIX shell scripts.                     |
| client      | Browsers and other clients.                                            |
| coldfusion  | Web sites that use the Adobe Systems ColdFusion application server.    |
| frontpage   | Web sites that use Microsoft's FrontPage server.                       |
| iis         | Web sites that use the Microsoft Internet Information Server (IIS).    |
| misc        | Miscellaneous attacks.                                                 |
| php         | Web sites that use PHP                                                 |
| web-activex | Web sites that contain ActiveX controls.                               |
| web-struts  | Web sites that contain Apache struts, which are java-ee based applets. |

- To display only signatures that have specific check actions enabled, select the ON check box for each of those actions, clear the ON check boxes for the other actions, and clear all of the OFF check boxes. To display only signatures that have a specific check action disabled, select their respective OFF check boxes and clear all of the ON check boxes. To display signatures regardless of whether they have a check action enabled or disabled, select or clear both the ON and the OFF check boxes for that action. The check actions are:

| Criterion | Description                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------|
| Enabled   | The signature is enabled. The application firewall checks only for signatures that are enabled when it processes traffic.        |
| Block     | Connections that match this signature are blocked.                                                                               |
| Log       | A log entry is produced for any connection that matches this signature.                                                          |
| Stats     | The application firewall includes any connection that matches this signature in the statistics that it generates for that check. |

- To display only signatures that contain a specific string, type the string into the text box under the filter criteria, and then click Search.
  - To reset all display filter criteria to the default settings and display all signatures, click Show All.
4. For information about a specific signature, select the signature, and then click the blue double arrow in the More field. The Signature Rule Vulnerability Detail message box appears. It contains information about the purpose of the signature and provides links to external web-based information about the vulnerability or vulnerabilities that this signature addresses. To access an external link, click the blue double arrow to the left of the description of that link.
  5. Configure the settings for a signature by selecting the appropriate check boxes.
  6. If you want to add a local signature rule to the signatures object, or modify an existing local signature rule, see "[The Signatures Editor](#)."
  7. If you have no need for SQL injection, cross-site scripting, or Xpath injection patterns, click OK, and then click Close. Otherwise, in the lower left-hand corner of the details pane, click Manage SQL/XSS Patterns.
  8. In the Manage SQL/XSS Patterns dialog box, Filtered Results window, navigate to the pattern category and pattern that you want to configure. For information about the SQL injection patterns, see "[HTML SQL Injection Check](#)." For information about the cross-site scripting patterns, see "[HTML Cross-Site Scripting Check](#)."
  9. To add a new pattern:
    1. Select the branch to which you want to add the new pattern.
    2. Click the Add button directly below the lower section of the Filtered Results window.
    3. In the Create Signature Item dialog box, fill in the Element text box with the pattern that you want to add. If you are adding a transformation pattern to the transform rules branch, under Elements, fill in the From text box with the pattern that you want to change and the To text box with the pattern to which you want to change the previous pattern.
    4. Click OK.
  10. To modify an existing pattern:
    1. In the Filtered Results window, select the branch that contains the pattern that you want to modify.
    2. In the detail window beneath the Filtered Results window, select the pattern that you want to modify.
    3. Click Modify.
    4. In the Modify Signature Item dialog box, Element text box, modify the pattern. If you are modifying a transformation pattern, you can modify either or both patterns under Elements, in the From and the To text boxes.
    5. Click OK.
  11. To remove a pattern, select the pattern that you want to remove, then click the Remove button below the details pane beneath the Filtered Results window. When prompted, confirm your choice by clicking Close.
  12. To add the patterns category to the XSS branch:

1. Select the branch to which you want to add the patterns category.
2. Click the Add button directly below the Filtered Results window.  
Note: Currently you can add only one category, named patterns, to the XSS branch, so after you click Add, you must accept the default choice, which is patterns.
3. Click OK.
13. To remove a branch, select that branch, and then click the Remove button directly below the Filtered Results window. When prompted, confirm your choice by clicking OK.  
Note: If you remove a default branch, you remove all of the patterns in that branch. Doing so can disable the security checks that use that information.
14. When you are finished modifying the SQL injection, cross-site scripting, and XPath injection patterns, click OK, and then click Close to return to the Modify Signatures Object dialog box.
15. Click OK at any point to save your changes, and when you are finished configuring the signatures object, click Close.

# Updating a Signatures Object

Oct 03, 2014

You should update your signatures objects frequently to ensure that your application firewall is providing protection against current threats. You should regularly update both the default application firewall signatures and any signatures that you import from a supported vulnerability scanning tool.

Citrix regularly updates the default signatures for the application firewall. You can update the default signatures manually or automatically. In either case, ask your Citrix representative or Citrix reseller for the URL to access the updates. You can enable automatic updates of the Citrix native format signatures in the "Engine Settings" and "Signature Auto Update Settings" dialog boxes.

Most makers of vulnerability scanning tools regularly update the tools. Most web sites also change frequently. You should update your tool and rescan your web sites regularly, exporting the resulting signatures to a file and importing them into your application firewall configuration.

Note: When you update the application firewall signatures from the NetScaler command line, you must first update the default signatures, and then issue additional update commands to update each custom signatures file that is based on the default signatures. If you do not update the default signatures first, a version mismatch error prevents updating of the custom signatures files.

To update the application firewall signatures from the source by using the command line

At the command prompt, type the following commands:

- `update appfw signatures <name> [-mergedefault]`
- `save ns config`

## Example

The following example updates the signatures object named `MySignatures` from the default signatures object, merging new signatures in the default signatures object with the existing signatures. This command does not overwrite any user-created signatures or signatures imported from another source, such as an approved vulnerability scanning tool.

```
update appfw signatures MySignatures -mergedefault
save ns config
```

Updating a Signatures Object from a Citrix Format File

Updated: 2014-10-06

Citrix regularly updates the signatures for the Application Firewall. You should regularly update the signatures on your Application Firewall to ensure that your Application Firewall is using the most current list. Ask your Citrix representative or Citrix reseller for the URL to access the updates.

## To update a signatures object from a Citrix format file by using the command line

At the command prompt, type the following commands:

- `update appfw signatures <name> [-mergeDefault]`
- `save ns config`

## To update a signatures object from a Citrix format file by using the configuration utility

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to update.
3. In the Action drop-down list, select Merge.
4. In the Update Signatures Object dialog box, choose one of the following options.
  - **Import from URL**—Choose this option if you download signature updates from a web URL.
  - **Import from Local File**—Choose this option if you import signature updates from a file on your local hard drive, network hard drive, or other storage device.
5. In the text area, type the URL, or type or browse to the local file.
6. Click Update. The update file is imported, and the Update Signatures dialog box changes to a format nearly identical to that of the Modify Signatures Object dialog box. The Update Signatures Object dialog box displays all branches with new or modified signature rules, SQL injection or cross-site scripting patterns, and XPath injection patterns if there are any.
7. Review and configure the new and modified signatures.
8. When you are finished, click OK, and then click Close.

### Updating a Signatures Object from a Supported Vulnerability Scanning Tool

Updated: 2014-01-17

Note: Before you update a signatures object from a file, you must create the file by exporting signatures from the vulnerability scanning tool.

### To import and update signatures from a vulnerability scanning tool

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to update, and then click Merge.
3. In the Update Signatures Object dialog box, on the External Format tab, Import section, choose one of the following options.
  - **Import from URL**—Choose this option if you download signature updates from a Web URL.
  - **Import from Local File**—Choose this option if you import signature updates from a file on your local or a network hard drive or other storage device.
4. In the text area, type the URL, or browse or type the path to the local file.
5. In the XSLT section, choose one of the following options.
  - **Use Built-in XSLT File**—Choose this option if you want to use a built-in XSLT files.
  - **Use Local File**—Choose this option to use an XSLT file on your local computer.
  - **Reference from URL**—Choose this option to import an XSLT file from a web URL.
6. If you chose Use Built-in XSLT File, in the Built-In XSLT drop-down list choose the built-in XSLT file that you want to use.
  - To use the Cenzip XSLT file, select Cenzip.
  - To use the IBM AppScan Standard XSLT file, select IBM AppScan Standard.
  - To use the IBM AppScan Enterprise XSLT file, select IBM AppScan Enterprise.
  - To use the Qualys XSLT file, select Qualys.
  - To use the Trend Microsystems XSLT file, select Trend Micro.
  - To use the Whitehat XSLT file, select Whitehat.
7. Click Update. The update file is imported, and the Update Signatures dialog box changes to a format nearly identical to that of the Modify Signatures Object dialog box, which is described in "[Configuring or Modifying a Signatures Object.](#)"

The Update Signatures Object dialog box displays all branches with new or modified signature rules, SQL injection or cross-site scripting patterns, and XPath injection patterns if there are any.

8. Review and configure the new and modified signatures.
9. When you are finished, click OK, and then click Close.

# Exporting a Signatures Object to a File

Oct 06, 2014

You export a signatures object to a file so that you can import it to another NetScaler ADC.

To export a signatures object to a file

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to configure.
3. In the Actions drop-down list, select Export.
4. In the Export Signatures Object dialog box, Local File text box, type the path and name of the file to which you want to export the signatures object, or use the Browse dialog to designate a path and name.
5. Click OK.

# The Signatures Editor

Oct 14, 2014

You can use the signatures editor, which is available in the configuration utility, to add a new user-defined (local) signature rule to an existing signatures object, or to modify a previously configured local signature rule. Except that it is defined by the user (you), a local signature rule has the same attributes as a default signature rule from Citrix, and it functions in the same way. You enable or disable it, and configure the signature actions for it, just as you do for a default signature.

Add a local rule if you need to protect your web sites and services from a known attack that the existing signatures do not match. For example, you might discover a new type of attack and determine its characteristics by examining the logs on your web server, or you might obtain third-party information about a new type of attack.

At the heart of a signature rule are the rule *patterns*, which collectively describe the characteristics of the attack that the rule is designed to match. Each pattern can consist of a simple string, a PCRE-format regular expression, or the built-in SQL injection or cross-site scripting patterns.

You might want to modify a signature rule by adding a new pattern or modifying an existing pattern to match an attack. For example, you might find out about changes to an attack, or you might determine a better pattern by examining the logs on your web server, or from third-party information.

To add or modify a local signature rule by using the Signatures Editor

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to edit, and then click Open.
3. In the Modify Signatures Object dialog box, in the middle of the screen beneath the Filtered Results window, do one of the following:
  - To add a new local signature rule, click Add.
  - To modify an existing local signature rule, select that rule, and then click Open.
4. In the Add Local Signature Rule or the Modify Local Signature Rule dialog box, configure the actions for a signature by selecting the appropriate check boxes.
  - **Enabled.** Enables the new signature rule. If you do not select this, this new signature rule is added to your configuration, but is inactive.
  - **Block.** Blocks connections that violate this signature rule.
  - **Log.** Logs violations of this signature rule to the NetScaler log.
  - **Stat.** Includes violations of this signature rule in the statistics.
  - **Remove.** Strips information that matches the signature rule from the response. (Applies only to response rules.)
  - **X-Out.** Masks information that matches the signature rule with the letter X. (Applies only to response rules.)
  - **Allow Duplicates.** Allows duplicates of this signature rule in this signatures object.
5. Choose a category for the new signature rule from the Category drop-down list.

You can also create a new category by clicking the icon to the right of the list and using the Add Signature Rule Category dialog box to add a new category to the list, The rule you are modifying is automatically added to the new category. For instructions, see "[To add a signature rule category.](#)"
6. In the **LogString** text box, type a brief description of the signature rule to be used in the logs.
7. In the **Comment** text box, type a comment. (Optional)
8. Click More..., and modify the advanced options.
  1. To strip HTML comments before applying this signature rule, in the Strip Comments drop-down list choose All or

Exclude Script Tag.

2. To set CSRF Referer Header checking, in the CSRF Referer Header checking radio button array, select either the If Present or Always radio button.
  3. To manually modify the Rule ID assigned to this local signature rule, modify the number in the Rule ID text box. The ID must be a positive integer between 1000000 and 1999999 that has not already been assigned to a local signature rule.
  4. To assign a version number to the new signature rule, modify the number in the Version Number text box.
  5. To assign a Source ID, modify the string in the Source ID text box.
  6. To specify the source, choose Local or Snort from the Source drop-down list, or click the Add icon to the right of the list and add a new source.
  7. To assign a harm score to violations of this local signature rule, type a number between 1 and 10 in the Harm Score text box.
  8. To assign a severity rating to this local signature rule, in the Severity drop-down list choose High, Medium, or Low, or click the Add icon to the right of the list and add a new severity rating.
  9. To assign a violation type to this local signature rule, in the Type drop-down list choose Vulnerable or Warning, or click the Add icon to the right of the list and add a new violation type.
  9. In the **Patterns** list, add or edit a pattern.
    - To add a pattern, click Add. In the Create New Signature Rule Pattern dialog box, add one or more patterns for your signature rule, and then click OK.
    - To edit a pattern, select the pattern, and then click Open. In the Edit Signature Rule Pattern dialog box, modify the pattern, and then click OK.
- For more information about adding or editing patterns, see "[Signature Rule Patterns](#)."
10. Click OK.

# To add a signature rule category

Sep 03, 2013

Putting signature rules into a category enables you to configure the actions for a group of signatures instead of for each individual signature. You might want to do so for the following reasons:

- **Ease of selection.** For example, assume that all of signature rules in a particular group protect against attacks on a specific type of web server software or technology. If your protected web sites use that software or technology, you want to enable them all. If they do not, you do not want to enable any of them.
- **Ease of initial configuration.** It is easiest to set defaults for a group of signatures as a category, instead of one-by-one. You can then make any changes to individual signatures as needed.
- **Ease of ongoing configuration.** It is easier to configure signatures if you can display only those that meet specific criteria, such as belonging to a specific category.

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select that signatures object that you want to configure, and then click Open.
3. In the Modify Signatures Object dialog box, in the middle of the screen, beneath the Filtered Results window, click Add.
4. In the Add Local Signature Rule dialog box, click the icon to the right of the Category drop-down list.
5. In the Add Signature Rule Category dialog box, New Category text box, type a name for your new signature category. The name can consist of from one to 64 characters.
6. Click **OK**.

# Signature Rule Patterns

Aug 20, 2014

You can add a new pattern to a signature rule or modify an existing pattern of a signature rule to specify a string or expression that characterizes an aspect of the attack that the signature matches. To determine which patterns an attack exhibits, you can examine the logs on your web server, use a tool to observe connection data in real time, or obtain the string or expression from a third-party report about the attack.

**Caution:** Any new pattern that you add to a signature rule is in an AND relationship with the existing patterns. Do not add a new pattern to an existing signature rule if you do not want a potential attack to have to match all of the patterns in order to match the signature.

Each pattern can consist of a simple string, a PCRE-format regular expression, or the built-in SQL injection or cross-site scripting pattern. Before you attempt to add a pattern that is based on a regular expression, you should make sure that you understand PCRE-format regular expressions. PCRE expressions are complex and powerful; if you do not understand how they work, you can unintentionally create a pattern that matches something that you did not want (a *false positive*) or that fails to match something that you did want (a *false negative*).

If you are not already familiar with PCRE-format regular expressions, you can use the following resources to learn the basics, or for help with some specific issue:

- — "*Mastering Regular Expressions*"  
, Third Edition. Copyright (c) 2006 by Jeffrey Friedl. O'Reilly Media, ISBN: 9780596528126
- — "*Regular Expressions Cookbook*"  
. Copyright (c) 2009 by Jan Goyvaerts and Steven Levithan. O'Reilly Media, ISBN: 9780596520687
- **PCRE Man page/Specification** (text/official): "<http://www.pcre.org/pcre.txt>"
- **PCRE Man Page/Specification** (html/gammon.edu.au): "<http://www.gammon.com.au/pcre/index.html>"
- **Wikipedia PCRE entry**: "<http://en.wikipedia.org/wiki/PCRE>"
- **PCRE Mailing List** (run by exim.org): "<http://lists.exim.org/mailman/listinfo/pcre-dev>"

If you need to encode non-ASCII characters in a PCRE-format regular expression, the NetScaler platform supports encoding of hexadecimal UTF-8 codes. For more information, see "[PCRE Character Encoding Format](#)."

To configure a signature rule pattern

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select that signatures object that you want to configure, and then click **Open**.
3. In the Modify Signatures Object dialog box, in the middle of the screen beneath the Filtered Results window, either click Add to create a signature rule, or select an existing signature rule and click Open.  
Note: You can modify only signature rules that you added. You cannot modify the default signature rules.  
Depending on your action, either the Add Local Signature Rule or the Modify Local Signature Rule dialog box appears. Both dialog boxes have the same contents.
4. Under the Patterns window in the dialog box, either click Add to add a new pattern, or select an existing pattern from the list beneath the Add button and click Open. Depending on your action, either the Create New Signature Rule Pattern or the Edit Signature Rule Pattern dialog box appears. Both dialog boxes have the same contents.
5. In the Pattern Type drop-down list, choose the type of connection that the pattern is intended to match.
  - If the pattern is intended to match request elements or features, such as injected SQL code, attacks on web forms, cross-site scripts, or inappropriate URLs, choose **Request**.
  - If the pattern is intended to match response elements or features, such as credit card numbers or safe objects,

choose **Response**.

6. In the Location area, define the elements to examine with this pattern.

The Location area describes what elements of the HTTP request or response to examine for this pattern. The choices that appear in the Location area depend upon the chosen pattern type. If you chose Request as the pattern type, items relevant to HTTP requests appear; if you chose Response, items relevant to HTTP responses appear.

In addition, as you choose a value from the Area drop-down list, the remaining parts of the Location area change interactively. Following are all configuration items that might appear in this section.

### Area

Drop-down list of elements that describe a particular portion of the HTTP connection. The choices are as follows:

- **HTTP\_ANY**. All parts of the HTTP connection.
- **HTTP\_COOKIE**. All cookies in the HTTP request headers after any cookie transformations are performed.  
Note: Does not search HTTP response "Set-Cookie:" headers.
- **HTTP\_FORM\_FIELD**. Form fields and their contents, after URL decoding, percent decoding, and removal of excess whitespace. You can use the <Location> tag to further restrict the list of form field names to be searched.
- **HTTP\_HEADER**. The value portions of the HTTP header after any cross-site scripting or URL decoding transformations.
- **HTTP\_METHOD**. The HTTP request method.
- **HTTP\_ORIGIN\_URL**. The origin URL of a web form.
- **HTTP\_POST\_BODY**. The HTTP post body and the web form data that it contains.
- **HTTP\_RAW\_COOKIE**. All HTTP request cookie, including the "Cookie:" name portion.  
Note: Does not search HTTP response "Set-Cookie:" headers.
- **HTTP\_RAW\_HEADER**. The entire HTTP header, with individual headers separated by linefeed characters (\n) or carriage return/line-feed strings (\r\n).
- **HTTP\_RAW\_RESP\_HEADER**. The entire response header, including the name and value parts of the response header after URL transformation has been done, and the complete response status. As with HTTP\_RAW\_HEADER, individual headers are separated by linefeed characters (\n) or carriage return/line-feed strings (\r\n).
- **HTTP\_RAW\_SET\_COOKIE**. The entire Set-Cookie header after any URL transformations have been performed.  
Note: URL transformation can change both the domain and path parts of the Set-Cookie header.
- **HTTP\_RAW\_URL**. The entire request URL before any URL transformations are performed, including any query or fragment parts.
- **HTTP\_RESP\_HEADER**. The value part of the complete response headers after any URL transformations have been performed.
- **HTTP\_RESP\_BODY**. The HTTP response body.
- **HTTP\_SET\_COOKIE**. All "Set-Cookie" headers in the HTTP response headers.
- **HTTP\_STATUS\_CODE**. The HTTP status code.
- **HTTP\_STATUS\_MESSAGE**. The HTTP status message.
- **HTTP\_URL**. The value portion of the URL in the HTTP headers, excluding any query or fragment parts, after conversion to the UTF-\* character set, URL decoding, stripping of whitespace, and conversion of relative URLs to absolute. Does not include HTML entity decoding.

### URL

Examines any URLs found in the elements specified by the Area setting. Select one of the following settings.

- **Any**. Checks all URLs.
- **Literal**. Checks URLs that contain a literal string. After you select Literal, a text box is displayed. Type the literal string that you want in the text box.
- **PCRE**. Checks URLs that match a PCRE-format regular expression. After you select this choice, the regular expression

window is displayed. Type the regular expression in the window. You can use the **Regex Tokens** to insert common regular expression elements at the cursor, or you can click **Regex Editor** to display the Regular Expression Editor dialog box, which provides more assistance in constructing the regular expression that you want.

- **Expression.** Checks URLs that match a NetScaler default expression.

#### **Field Name**

Examines any form field names found in the elements specified by the Area selection.

- **Any.** Checks all URLs.
- **Literal.** Checks URLs that contain a literal string. After you select **Literal**, a text box is displayed. Type the literal string that you want in the text box.
- **PCRE.** Checks URLs that match a PCRE-format regular expression. After you select this choice, the regular expression window is displayed. Type the regular expression in the window. You can use the **Regex Tokens** to insert common regular expression elements at the cursor, or you can click **Regex Editor** to display the Regular Expression Editor dialog box, which provides more assistance in constructing the regular expression that you want.
- **Expression.** Checks URLs that match a NetScaler default expression.

7. In the **Pattern** area, define the pattern. A pattern is a literal string or PCRE-format regular expression that defines the pattern that you want to match. The **Pattern** area contains the following elements:

#### **Match**

A drop-down list of search methods that you can use for the signature. This list differs depending on whether the pattern type is **Request** or **Response**.

#### **Request Match Types**

- **Literal.** A literal string.
- **PCRE.** A PCRE-format regular expression.  
**NOTE:** When you choose PCRE, the regular expression tools beneath the **Pattern** window are enabled. These tools are not useful for most other types of patterns.
- **Injection.** Directs the application firewall to look for injected SQL in the specified location. The **Pattern** window disappears, because the application firewall already has the patterns for SQL injection.
- **CrossSiteScripting.** Directs the application firewall to look for cross-site scripts in the specified location. The **Pattern** window disappears, because the application firewall already has the patterns for cross-site scripts.
- **Expression.** An expression in the NetScaler default expressions language. This is the same expressions language that is used to create application firewall policies and other policies on the NetScaler appliance. Although the NetScaler expressions language was originally developed for policy rules, it is a highly flexible general purpose language that can also be used to define a signature pattern.

When you choose **Expression**, the NetScaler Expression Editor appears beneath **Pattern** window. For more information about the Expression Editor and instructions on how to use it, see "[To add a firewall rule \(expression\) by using the Add Expression dialog box.](#)" For more information about NetScaler expressions, see "[Policies and Expressions.](#)"

#### **Response Match Types**

- **Literal.** A literal string.
- **PCRE.** A PCRE-format regular expression.  
**NOTE:** When you choose PCRE, the regular expression tools beneath the **Pattern** window are enabled. These tools are not useful for most other types of patterns.
- **Credit Card.** A built-in pattern to match one of the six supported types of credit card number.

Note: The Expression match type is not available for Response-side signatures.

### Pattern Window (unlabeled)

In this window, type the pattern that you want to match, and fill in any additional data.

- **Literal.** Type the string you want to search for in the text area.
- **PCRE.** Type the regular expression in the text area. Use the **Regex Editor** for more assistance in constructing the regular expression that you want, or the Regex Tokens to insert common regular expression elements at the cursor. To enable UTF-8 characters, click UTF-8.
- **Expression.** Type the NetScaler advanced expression in the text area. Use Prefix to choose the first term in your expression, or Operator to insert common operators at the cursor. Click **Add** to open the Add Expression dialog box for more assistance in constructing the regular expression that you want. Click Evaluate to open the Advanced Expression Evaluator to help determine what effect your expression has.
- **Offset.** The number of characters to skip over before starting to match on this pattern. You use this field to start examining a string at some point other than the first character.
- **Depth.** How many characters from the starting point to examine for matches. You use this field to limit searches of a large string to a specific number of characters.
- **Min-Length.** The string to be searched must be at least the specified number of bytes in length. Shorter strings are not matched.
- **Max-Length.** The string to be searched must be no longer than the specified number of bytes in length. Longer strings are not matched.
- **Search method.** A check box labeled fastmatch. You can enable fastmatch only for a literal pattern, to improve performance.

8. Click OK.

9. Repeat the previous four steps to add or modify additional patterns.

10. When finished adding or modifying patterns, click OK to save your changes and return to the Signatures pane.

Caution: Until you click **OK** in the **Add Local Signature Rule** or **Modify Local Signature Rule** dialog box, your changes are not saved. Do not close either of these dialog boxes without clicking **OK** unless you want to discard your changes.

# Overview of Security checks

Sep 03, 2013

The application firewall advanced protections (security checks) are a set of filters designed to catch complex or unknown attacks on your protected web sites and web services. The security checks use heuristics, positive security, and other techniques to detect attacks that may not be detected by signatures alone. You configure the security checks by creating and configuring an application firewall profile, which is a collection of user-defined settings that tell the application firewall which security checks to use and how to handle a request or response that fails a security check. A profile is associated with a signatures object and with a policy to create a security configuration.

The application firewall provides twenty security checks, which differ widely in the types of attacks that they target and how complex they are to configure. The security checks are organized into the following categories:

- **Common security checks.** Checks that apply to any aspect of web security that either does not involve content or is equally applicable to all types of content.
- **HTML security checks.** Checks that examine HTML requests and responses. These checks apply to HTML-based web sites and to the HTML portions of Web 2.0 sites, which contain mixed HTML and XML content.
- **XML security checks.** Checks that examine XML requests and responses. These checks apply to XML-based web services and to the XML portions of Web 2.0 sites.

The security checks protect against a wide range of types of attack, including attacks on operation system and web server software vulnerabilities, SQL database vulnerabilities, errors in the design and coding of web sites and web services, and failures to secure sites that host or can access sensitive information.

All security checks have a set of configuration options, the check actions, which control how the application firewall handles a connection that matches a check. Three check actions are available for all security checks. They are:

- **Block.** Block connections that match the signature. Disabled by default.
- **Log.** Log connections that match the signature, for later analysis. Enabled by default.
- **Stats.** Maintain statistics, for each signature, that show how many connections it matched and provide certain other information about the types of connections that were blocked. Disabled by default.

A fourth check action, **Learn**, is available for more than half of the check actions. It observes traffic to a protected Web site or web service and uses connections that repeatedly violate the security check to generate recommended exceptions (relaxations) to the check, or new rules for the check. In addition to the check actions, certain security checks have parameters that control the rules that the check uses to determine which connections violate that check, or that configure the application firewall's response to connections that violate the check. These parameters are different for each check, and they are described in the documentation for each check.

To configure security checks, you can use the application firewall wizard, as described in "[The Application Firewall Wizard](#)," or you can configure the security checks manually, as described in "[Manual Configuration By Using the Configuration Utility](#)." Some tasks, such as manually entering relaxations or rules or reviewing learned data, can be done only by using the configuration utility, not the command line. Using the wizard is usually best configuration method, but in some cases manual configuration might be easier if you are thoroughly familiar with it and simply want to adjust the configuration for a single security check.

Regardless of which method you use to configure the security checks, each security check requires that certain tasks be performed. Many checks require that you specify exceptions (relaxations) to prevent blocking of legitimate traffic before

you enable blocking for that security check. You can do this manually, by observing the log entries after a certain amount of traffic has been filtered and then creating the necessary exceptions. However, it is usually much easier to enable the learning feature and let it observe the traffic and recommend the necessary exceptions.

# Top-Level Protections

Oct 01, 2013

Four of the application firewall protections are especially effective against common types of Web attacks, and are therefore more commonly used than any of the others. They are:

- **HTML Cross-Site Scripting.** Examines requests and responses for scripts that attempt to access or modify content on a different Web site than the one on which the script is located. When this check finds such a script, it either renders the script harmless before forwarding the request or response to its destination, or it blocks the connection.
- **HTML SQL Injection.** Examines requests that contain form field data for attempts to inject SQL commands into an SQL database. When this check detects injected SQL code, it either blocks the request or renders the injected SQL code harmless before forwarding the request to the Web server.

Note: If both of the following conditions apply to your configuration, you should make certain that your Application Firewall is correctly configured:

- If you enable the HTML Cross-Site Scripting check or the HTML SQL Injection check (or both), and
- Your protected Web sites accept file uploads or contain Web forms that can contain large POST body data.

For more information about configuring the Application Firewall to handle this case, see "[Configuring the Application Firewall](#)."

- **Buffer Overflow.** Examines requests to detect attempts to cause a buffer overflow on the Web server.
- **Cookie Consistency.** Examines cookies returned with user requests to verify that they match the cookies your Web server set for that user. If a modified cookie is found, it is stripped from the request before the request is forwarded to the Web server.

The Buffer Overflow check is simple; you can usually enable blocking for it immediately. The other three top-level checks are considerably more complex and require configuration before you can safely use them to block traffic. Citrix strongly recommends that, rather than attempting to configure these checks manually, you enable the learning feature and allow it to generate the necessary exceptions.

# HTML Cross-Site Scripting Check

Jan 19, 2015

## HTML Cross-Site Scripting Check

The HTML Cross-Site Scripting check examines both the headers and the POST bodies of user requests for possible cross-site scripting attacks. If it finds a cross-site script, it either modifies (transforms) the request to render the attack harmless, or blocks the request.

To prevent misuse of the scripts on your protected web sites to breach security on your web sites, the HTML Cross-Site Scripting check blocks scripts that violate the same origin rule, which states that scripts should not access or modify content on any server but the server on which they are located. Any script that violates the same origin rule is called a cross-site script, and the practice of using scripts to access or modify content on another server is called cross-site scripting. The reason cross-site scripting is a security issue is that a web server that allows cross-site scripting can be attacked with a script that is not on that web server, but on a different web server, such as one owned and controlled by the attacker.

Unfortunately, many companies have a large installed base of JavaScript-enhanced web content that violates the same origin rule. If you enable the HTML Cross-Site Scripting check on such a site, you have to generate the appropriate exceptions so that the check does not block legitimate activity.

If you use the wizard or the configuration utility, in the Modify HTML Cross-Site Scripting Check dialog box, on the General tab you can enable or disable the Block, Log, Learn, and Statistics actions, and in addition the following parameters:

- **Transform.** If enabled, the application firewall makes the following changes to requests that match the HTML Cross-Site Scripting check:
  - Left angle bracket (<) to HTML character entity equivalent (&lt;)
  - Right angle bracket (>) to HTML character entity equivalent (&gt;)This ensures that browsers do not interpret unsafe html tags, such as <script>, and thereby execute malicious code. If you enable both request-header checking and transformation, any special characters found in request headers are also modified as described above. If scripts on your protected web site contain cross-site scripting features, but your web site does not rely upon those scripts to operate correctly, you can safely disable blocking and enable transformation. This configuration ensures that no legitimate web traffic is blocked, while stopping any potential cross-site scripting attacks.
- **Check complete URLs.** If checking of complete URLs is enabled, the application firewall examines entire URLs for HTML cross-site scripting attacks instead of checking just the query portions of URLs.
- **Check Request headers.** If Request header checking is enabled, the application firewall examines the headers of requests for HTML cross-site scripting attacks, instead of just URLs. If you use the configuration utility, you can enable this parameter in the **Settings** tab of the application firewall profile.

If you use the command-line interface, you can enter the following commands to configure the HTML Cross-Site Scripting Check:

- set appfw profile <name> -crossSiteScriptingAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -crossSiteScriptingTransformUnsafeHTML ([**ON**] | [**OFF**])
- set appfw profile <name> -crossSiteScriptingCheckCompleteURLs ([**ON**] | [**OFF**])
- set appfw profile <name> -checkRequestHeaders ([**ON**] | [**OFF**])

To specify relaxations for the HTML Cross-Site Scripting check, you must use the configuration utility. On the Checks tab of the Modify HTML Cross-Site Scripting Check dialog box, click Add to open the Add HTML Cross-Site Scripting Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify HTML Cross-Site Scripting Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation, as described in "[Manual Configuration By Using the Configuration Utility](#)."

Following are examples of HTML Cross-Site Scripting check relaxations:

### Web Form Field Expressions

- **Logon Fields.** The following expression exempts all fields beginning with the string logon\_ followed by a string of upper- and lower-case letters or numbers that is at least two characters long and no more than fifteen characters long:

```
^logon_[0-9A-Za-z]{2,15}$
```

- **Name Fields.** The following expression exempts form fields with names beginning with Name\_ followed by a string beginning with a letter or number and consisting of from one to twenty letters, numbers, or the apostrophe or hyphen symbol:

```
^Name_[0-9A-Za-z][0-9A-Za-z'-]{0,20}$
```

- **Name Fields (Special Characters).** If your web site has Turkish-speaking customers whose first names may contain special characters, you might have a form field that begins with the string Turkish-Name\_ on their logon page. In addition, the customers may use the same special characters in their names. The special characters in both of these strings must be represented as encoded UTF-8 strings. The following expression exempts form fields beginning with Turkish-Name\_ and containing Turkish special characters:

```
^T\xC3\xBCrk\xC3\xA7e-Name_([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])+$
```

- **Session-ID Fields.** The following expression exempts all fields beginning with the string sessionid- followed by a ten-digit number:

```
^sessionid-[0-9]{10,10}$
```

### URL Expressions

- **URLs using JavaScript.** You can use a single expression to exempt all URLs that end with a filename that follows a specified pattern. The following expression exempts all URLs that end with the string query\_ followed by a string of upper- and lower-case letters or numbers that is at least two characters long and no more than forty characters long, and ending with the string .js:

```
query_[0-9A-Za-z]{2,40}[.]js$
```

- **URLs containing a Specified String.** You can use an expression to exempt all URLs that contain a specific string. The following expression exempts all URLs that contain the string prodinfo:

```
^https?:/(((0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])|((0-9A-Za-z_-]|\\x[0-9A-Fa-f][0-9A-Fa-f])+[a-z]{2,6})/[^<>?]*\?prodinfo[^\<>?]*$
```

In the above expression, each character class has been grouped with the string `\\x[0-9A-Fa-f][0-9A-Fa-f]`, which matches all properly constructed character encoding strings but does not allow stray backslash characters that are not associated with a UTF-8 character encoding string. The double backslash (`\\`) is an escaped backslash, which tells the application firewall to interpret it as a literal backslash. If you included only one backslash, the application firewall would interpret the following left square bracket (`[`) as a literal character instead of as the opening of a character class, which would break the expression.

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.\* ) metacharacter/wildcard combination, can have results you do not want or expect, such as blocking access to web content that you did not intend to block or allowing an attack that the HTML Cross-Site Scripting check would otherwise have blocked.

# HTML SQL Injection Check

Jul 25, 2015

The HTML SQL Injection check provides special defenses against injection of unauthorized SQL code that might break security. It examines both the headers and the POST bodies of requests for injected SQL code. If the application firewall detects unauthorized SQL code in a user request, it either transforms the request, to render the SQL code inactive, or blocks the request.

Many web applications have web forms that use SQL to communicate with relational database servers. Often, the scripts that pass web form information to the database do not validate the information provided by the user before sending it to the database. Malicious code or a hacker can use the insecure web form to send SQL commands to the web server.

The application firewall HTML SQL Injection check provides special defenses against injection of unauthorized SQL code that might break security. If the application firewall detects unauthorized SQL code in a user request, it either transforms the request, to render the SQL code inactive, or blocks the request. The application firewall examines the request payload for injected SQL code in three locations: 1) POST body, 2) headers, and 3) cookies.

A default set of keywords and special characters provides known keywords and special characters that are commonly used to launch SQL attacks. You can add new patterns, and you can edit the default set to customize the SQL check inspection. The application firewall offers various action options for implementing SQL Injection protection. In addition to the **Block**, **Log**, **Stats** and **Learn** actions, the application firewall profile also offers the option to **transform SQL special characters** to render an attack harmless.

In addition to actions, there are several parameters that can be configured for SQL injection processing. You can check for **SQL wildcard characters**. You can change the SQL Injection type and select one of the 4 options (**SQLKeyword**, **SQLSpIChar**, **SQLSpICharANDKeyword**, **SQLSpICharORKeyword**) to indicate how to evaluate the SQL keywords and SQL special characters when processing the payload. The **SQL Comments Handling** parameter gives you an option to specify the type of comments that need to be inspected or exempted during SQL Injection detection.

You can deploy relaxations to avoid false positives. The application firewall learning engine can provide recommendations for configuring relaxation rules.

Following options are available for configuring an optimized SQL Injection protection for your application:

- **Block**—If you enable block, the block action is triggered only if the input matches the SQL injection type specification. For example, if **SQLSpICharANDKeyword** is configured as the SQL injection type, a request is not blocked if it contains no key words, even if SQL special characters are detected in the input. Such a request is blocked if the SQL injection type is set to either **SQLSpIChar**, or **SQLSpICharORKeyword**.
- **Log**—If you enable the log feature, the SQL Injection check generates log messages indicating the actions that it takes. If block is disabled, a separate log message is generated for each input field in which the SQL violation was detected. However, only one message is generated when the request is blocked. Similarly, one log message per request is generated for the transform operation, even when SQL special characters are transformed in multiple fields. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.
- **Stats**—If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you need to configure new relaxation rules or modify the existing ones.
- **Learn**—If you are not sure which SQL relaxation rules might be ideally suited for your application, you can use the learn

feature to generate recommendations based on the learned data. The application firewall learning engine monitors the traffic and provides SQL learning recommendations based on the observed values. To get optimal benefit without compromising performance, you might want to enable the learn option for a short time to get a representative sample of the rules, and then deploy the rules and disable learning.

- **Transform SQL special characters**—The application firewall considers three characters, Single straight quote ('), Backslash (\), and Semicolon (;) as special characters for SQL security check processing. The SQL Transformation feature modifies the SQL Injection code in an HTML request to ensure that the request is rendered harmless. The modified HTML request is then sent to the server. All default transformation rules are specified in the `/netscaler/default_custom_settings.xml` file.

The transform operation renders the SQL code inactive by making the following changes to the request:

Single straight quote (') to double straight quote (").

Backslash (\) to double backslash (\\).

Semicolon (;) is dropped completely.

These three characters (special strings) are necessary to issue commands to an SQL server. Unless an SQL command is prefaced with a special string, most SQL servers ignore that command. Therefore, the changes that the application firewall performs when transformation is enabled prevent an attacker from injecting active SQL. After these changes are made, the request can safely be forwarded to your protected web site. When web forms on your protected web site can legitimately contain SQL special strings, but the web forms do not rely on the special strings to operate correctly, you can disable blocking and enable transformation to prevent blocking of legitimate web form data without reducing the protection that the application firewall provides to your protected web sites.

The transform operation works independently of the SQL Injection Type setting. If transform is enabled and the SQL Injection type is specified as SQL keyword, SQL special characters are transformed even if the request does not contain any keywords.

**Note:** You normally enable either transformation or blocking, but not both. If the block action is enabled, it takes precedence over the transform action. If you have blocking enabled, enabling transformation is redundant.

In addition to configuring the actions, in the HTML SQL Injection Settings pane, you can also configure the following parameters:

- **Check for SQL Wildcard Characters**—Wild card characters can be used to broaden the selections of a structured query language (SQL-SELECT) statement. These wild card operators can be used in conjunction with LIKE and NOT LIKE operators to compare a value to similar values. The percent (%), and underscore (\_) characters are frequently used as wild cards. The percent sign is analogous to the asterisk (\*) wildcard character used with MS-DOS and to match zero, one, or multiple characters in a field. The underscore is similar to the MS-DOS question mark (?) wildcard character. It matches a single number or character in an expression.

For example, you can use the following query to do a string search to find all customers whose names contain the D character.

```
SELECT * from customer WHERE name like "%D%"
```

The following example combines the operators to find any salary values that have 0 in the second and third place.

```
SELECT * from customer WHERE salary like '_00%'
```

Different DBMS vendors have extended the wildcard characters by adding extra operators. The NetScaler application firewall can protect against attacks that are launched by injecting these wildcard characters. The 5 default Wildcard characters are percent (%), underscore (\_), caret (^), opening square bracket ([), and closing square bracket (]). This protection applies to both HTML and XML profiles.

The default wildcard chars are a list of literals specified in the **\*Default Signatures:**

```
<wildchar type="LITERAL">%</wildchar>
```

```
<wildchar type="LITERAL">_</wildchar>
```

```
<wildchar type="LITERAL">^</wildchar>
```

```
<wildchar type="LITERAL">[</wildchar>
```

```
<wildchar type="LITERAL">]</wildchar>
```

Wildcard characters in an attack can be PCRE, like `[^A-F]`. The application firewall also supports PCRE wildcards, but the literal wildcard chars above are sufficient to block most attacks.

**Note:** The SQL wildcard character check is different from the SQL special character check. This option must be used with caution to avoid false positives.

- **Check Request Containing SQL Injection Type**—The application firewall provides 4 options to implement the desired level of strictness for SQL Injection inspection, based on the individual need of the application. The request is checked against the injection type specification for detecting SQL violations. The 4 SQL injection type options are:
    - **SQL Special Character and Keyword**—Both an SQL keyword and an SQL special character must be present in the input to trigger SQL violation. This least restrictive setting is also the default setting.
    - **SQL Special Character**—At least one of the special characters must be present in the input to trigger SQL violation.
    - **SQL key word**—At least one of the specified SQL keywords must be present in the input to trigger an SQL violation. Do not select this option without due consideration. To avoid false positives, make sure that none of the keywords are expected in the inputs.
    - **SQL Special Character or Keyword**—Either the key word or the special character string must be present in the input to trigger the security check violation.
  - **SQL comments handling.** By default, the application firewall checks all SQL comments for injected SQL commands. Many SQL servers ignore anything in a comment, however, even if it is preceded by an SQL special character. For faster processing, if your SQL server ignores comments, you can configure the application firewall to skip comments when examining requests for injected SQL. The SQL comments handling options are:
    - **ANSI.** Skip ANSI-format SQL comments, which are normally used by UNIX-based SQL databases.
    - **Nested.** Skip nested SQL comments, which are normally used by Microsoft SQL Server.
    - **ANSI/Nested.** Skip comments that adhere to both the ANSI and nested SQL comment standards. Comments that match only the ANSI standard, or only the nested standard, are still checked for injected SQL.
    - **Check all Comments.** Check the entire request for injected SQL, without skipping anything. The default setting.
- Caution:** In most cases, you should not choose the Nested or the ANSI/Nested option unless your back-end database runs on Microsoft SQL Server. Most other types of SQL server software do not recognize nested comments. If nested comments appear in a request directed to another type of SQL server, they may indicate an attempt to breach security on that server.
- **Check Request headers.** Examine the headers of requests for HTML SQL Injection attacks, instead of just URLs. If you

use the configuration utility, you can enable this parameter in the Advanced Settings -> Profile Settings pane of the application firewall profile.

**Caution:** If you enable both request header checking and transformation, any SQL special characters found in headers are also transformed. The Accept, Accept-Charset, Accept-Encoding, Accept-Language, Expect, and User-Agent headers normally contain semicolons (;), so enabling both Request header checking and transformation simultaneously may cause errors.

**If you use the command-line interface, you can enter the following commands to configure the HTML SQL Injection Check:**

- **set appfw profile <name> -SQLInjectionAction** ([[block] [learn] [log] [stats]] | [none])
- **set appfw profile <name> -SQLInjectionTransformSpecialChars** (ON | OFF)
- **set appfw profile <name> -SQLInjectionCheckSQLWildChars** (ON | OFF)
- **set appfw profile <name> -SQLInjectionType** ([SQLKeyword] | [SQLSplChar] | [SQLSplCharANDKeyword] | [SQLSplCharORKeyword])
- **set appfw profile <name> -SQLInjectionParseComments** ([checkall] | [ansi| nested] | [ansinested])
- **set appfw profile <name> -CheckRequestHeaders** (ON | OFF)

**To configure or modify the SQL Injection check by using the configuration utility**

- Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
- In the Advanced Settings pane, click **Security Checks**.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

If you just want to enable or disable **Block, Log, Stats, and Learn** actions for **HTML SQL Injection**, you can select or clear check boxes in the table, click **OK**, and then click **Save and Close** to close the Security Check pane.

If you want to configure additional options for this security check, double click **HTML SQL Injection**, or select the row and click Action Settings, to display the following options:

**Transform SQL Special character**—Transform any SQL Special characters in the request.

**Check for SQL Wildcard Characters**—Consider SQL Wildcard characters in the payload to be attack patterns.

**Check Request Containing**—Type of SQL injection (**SQLKeyword, SQLSplChar, SQLSplCharANDKeyword, or SQLSplCharORKeyword**) to check.

**SQL Comments Handling**—Type of comments (**Check All Comments, ANSI, Nested, or ANSI/Nested**) to check.

After changing any of the above settings, click **OK** to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click **OK** to save all the changes you have made in the Security Checks section, and then click **Save and Close** to close the Security Check pane.

- To enable or disable the **Check request Header** setting, in the Advanced Settings pane, click **Profile Settings**. In Common Settings, Select or clear the Check Request Headers check box. Click **OK**. You can either use the X icon at the top right hand side of the Profile Settings pane to close this section or, if you have finished configuring this profile, you can click **Done** to return to the **Application Firewall > Profile**.

## To configure an SQL Injection relaxation rule by using the configuration utility

- Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
- In the Advanced Settings pane, click **Relaxation Rules**.
- In the Relaxation Rules table, double-click the **HTML SQL Injection** entry, or select it and click **Edit**.
- In the HTML SQL Injection Relaxation Rules dialogue box, perform **Add**, **Edit**, **Delete**, **Enable**, or **Disable** operations for relaxation rules.

Following are examples of HTML SQL Injection check relaxations:

### Web Form Field Name Expressions

- **Logon Fields.** The following expression exempts all fields beginning with the string `logon_` followed by a string of letters or numbers that is at least two characters long and no more than fifteen characters long:

```
^logon_[0-9A-Za-z]{2,15}$
```

- **Name Fields.** The following expression exempts form fields with names beginning with `Name_` followed by a string beginning with a letter or number and consisting of from one to twenty letters, numbers, or the apostrophe or hyphen symbol:

```
^Name_[0-9A-Za-z][0-9A-Za-z'-]{0,20}$
```

- **Name Fields (Special Characters).** If your web site has Turkish-speaking customers whose first names may contain special characters, you might have a form field that begins with the string `Turkish-Name_` on their logon page. In addition, the customers may use the same special characters in their names. The special characters in both of these strings must be represented as encoded UTF-8 strings. The following expression exempts form fields beginning with `Turkish-Name_` and containing Turkish special characters:

```
^T\xC3\xBCrk\xC3\xA7e-Name_([0-9A-Za-z][\x[0-9A-Fa-f][0-9A-Fa-f])+$
```

- **Session-ID Fields.** The following expression exempts all fields beginning with the string `sessionid-` followed by a ten-digit number:

```
^sessionid-[0-9]{10,10}$
```

### Action URL Expressions

- **URLs using JavaScript.** You can use a single expression to exempt all URLs that end with a filename that follows a specified pattern. The following expression exempts all URLs that end with the string `query_` followed by a string of upper- and lower-case letters or numbers that is at least two characters long and no more than forty characters long, and that end with the string `.js`:

```
query_[0-9A-Za-z]{2,40}[.]*js$
```

- **URLs containing a Specified String.** You can use an expression to exempt all URLs that contain a specific string. The following expression exempts all URLs that contain the string `prodinfo`:

```
^https?:/(((0-9A-Za-z)[\x[0-9A-Fa-f][0-9A-Fa-f])((0-9A-Za-z_-)[\x[0-9A-Fa-f][0-9A-Fa-f]+[.])+[a-z]{2,6})/[^<>?]*\?prodinfo[^\<>?]*$
```

In the expression above, each character class has been grouped with the string `\x[0-9A-Fa-f][0-9A-Fa-f]`, which matches all properly constructed character encoding strings but does not allow stray backslash characters that are not associated with a UTF-8 character encoding string. The double backslash (`\\`) is an escaped backslash, which tells the application firewall to interpret it as a literal backslash. If you included only one backslash, the application firewall would interpret the following left square bracket (`[`) as a literal character instead of as the opening of a character class, which

would break the expression.

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.\*  
metacharacter/wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the HTML SQL Injection check would otherwise have blocked.

# Buffer Overflow Check

Feb 03, 2014

The Buffer Overflow check detects attempts to cause a buffer overflow on the web server. If the application firewall detects that the URL, cookies or header are longer than the specified maximum length in a request, it blocks that request because it might be an attempt to cause a buffer overflow.

The Buffer Overflow check prevents attacks against insecure operating-system or web-server software that can crash or behave unpredictably when it receives a data string that is larger than it can handle. Proper programming techniques prevent buffer overflows by checking incoming data and either rejecting or truncating overlong strings. Many programs, however, do not check all incoming data and are therefore vulnerable to buffer overflows. This issue especially affects older versions of web-server software and operating systems, many of which are still in use.

If you use the wizard or the configuration utility, in the Modify Buffer Overflow Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions. On the Checks tab, you can set the following parameters:

- **Maximum URL Length.** The maximum length the application firewall allows in a requested URL. Requests with longer URLs are blocked. Possible Values: 0-65536. Default: 1024
- **Maximum Cookie Length.** The maximum length the application firewall allows for all cookies in a request. Excess cookies are stripped from requests before those requests are forwarded to your protected web server. Possible Values: 0-65536. Default: 4096
- **Maximum Header Length.** The maximum length the application firewall allows for HTTP headers. Requests with longer headers are blocked. Possible Values: 0-65536. Default: 4096

If you use the command-line interface, you can add the following Buffer Overflow Check arguments to the set appfwl profile <profileName> command:

- -bufferOverflowAction [ **block** ] [ **log** ] [ **stats** ]
- -bufferOverflowMaxURLLength <positiveInteger>
- -bufferOverflowMaxCookieLength <positiveInteger>
- -bufferOverflowMaxHeaderLength <positiveInteger>

# Cookie Consistency Check

Feb 03, 2014

The Cookie Consistency check examines cookies returned by users, to verify that they match the cookies that your web site set for that user. If a modified cookie is found, it is stripped from the request before the request is forwarded to the web server. You can also configure the Cookie Consistency check to transform all of the server cookies that it processes, by encrypting the cookies, proxying the cookies, or adding flags to the cookies. This check applies to requests and responses.

An attacker would normally modify a cookie to gain access to sensitive private information by posing as a previously authenticated user, or to cause a buffer overflow. The Buffer Overflow check protects against attempts to cause a buffer overflow by using a very long cookie. The Cookie Consistency check focuses on the first scenario.

If you use the wizard or the configuration utility, in the Modify Cookie Consistency Check dialog box, on the General tab you can enable or disable the following actions:

- Block
- Log
- Learn
- Statistics
- Transform. If enabled, the Transform action modifies all cookies as specified in the following settings:
  - **Encrypt Server Cookies.** Encrypt cookies set by your web server, except for any listed in the Cookie Consistency check relaxation list, before forwarding the response to the client. Encrypted cookies are decrypted when the client sends a subsequent request, and the decrypted cookies are reinserted into the request before it is forwarded to the protected web server. Specify one of the following types of encryption:
    - **None.** Do not encrypt or decrypt cookies. The default.
    - **Decrypt only.** Decrypt encrypted cookies only. Do not encrypt cookies.
    - **Encrypt session only.** Encrypt session cookies only. Do not encrypt persistent cookies. Decrypt any encrypted cookies.
    - **Encrypt all.** Encrypt both session and persistent cookies. Decrypt any encrypted cookies.  
Note: When encrypting cookies, the application firewall adds the **HttpOnly** flag to the cookie. This flag prevents scripts from accessing and parsing the cookie. The flag therefore prevents a script-based virus or trojan from accessing a decrypted cookie and using that information to breach security. This is done regardless of the Flags to Add in Cookies parameter settings, which are handled independently of the Encrypt Server Cookies parameter settings.
  - **Proxy Server Cookies.** Proxy all non-persistent (session) cookies set by your web server, except for any listed in the Cookie Consistency check relaxation list. Cookies are proxied by using the existing application firewall session cookie. The application firewall strips session cookies set by the protected web server and saves them locally before forwarding the response to the client. When the client sends a subsequent request, the application firewall reinserts the session cookies into the request before forwarding it to the protected web server. Specify one of the following settings:
    - **None.** Do not proxy cookies. The default.
    - **Session only.** Proxy session cookies only. Do not proxy persistent cookies.  
Note: If you disable cookie proxying after having enabled it (set this value to None after it was set to Session only), cookie proxying is maintained for sessions that were established before you disabled it. You can therefore safely disable this feature while the application firewall is processing user sessions.
  - **Flags to Add in Cookies.** Add flags to cookies during transformation. Specify one of the following settings:
    - **None.** Do not add flags to cookies. The default.
    - **HTTP only.** Add the HttpOnly flag to all cookies. Browsers that support the HttpOnly flag do not allow scripts to

access cookies that have this flag set.

- **Secure.** Add the Secure flag to cookies that are to be sent only over an SSL connection. Browsers that support the Secure flag do not send the flagged cookies over an insecure connection.
- **All.** Add the HttpOnly flag to all cookies, and the Secure flag to cookies that are to be sent only over an SSL connection.

If you use the command-line interface, you can enter the following commands to configure the Cookie Consistency Check:

- set appfw profile <name> -cookieConsistencyAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -cookieTransforms ([**ON**] | [**OFF**])
- set appfw profile <name> -cookieEncryption ([**none**] | [**decryptOnly**] | [**encryptSession**] | [**encryptAll**])
- set appfw profile <name> -cookieProxying ([**none**] | [**sessionOnly**])
- set appfw profile <name> -addCookieFlags ([**none**] | [**httpOnly**] | [**secure**] | [**all**])

To specify relaxations for the Cookie Consistency check, you must use the configuration utility. On the Checks tab of the Modify Cookie Consistency Check dialog box, click Add to open the Add Cookie Consistency Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Cookie Consistency Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

Following are examples of Cookie Consistency check relaxations:

- **Logon Fields.** The following expression exempts all form fields beginning with the string logon\_ followed by a string of letters or numbers that is at least two characters long and no more than fifteen characters long:

```
^logon_[0-9A-Za-z]{2,15}$
```

- **Logon Fields (special characters).** The following expression exempts all form fields beginning with the string türkçe-logon\_ followed by a string of letters or numbers that is at least two characters long and no more than fifteen characters long:

```
^türkçe-logon_[0-9A-Za-z]{2,15}$
```

- **Arbitrary strings.** Allow cookies that contain the string sc-item\_, followed by the ID of an item that the user has added to his shopping cart ([0-9A-Za-z]+), a second underscore (\_), and finally the number of these items he wants ([1-9][0-9]?), to be user-modifiable:

```
^sc-item_[0-9A-Za-z]+_[1-9][0-9]?$
```

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.\*?) metacharacter/wildcard combination, can have results you do not want or expect, such as blocking access to web content that you did not intend to block or allowing an attack that the Cookie Consistency check would otherwise have blocked.

# Application Firewall Support for Google Web Toolkit

Mar 23, 2015

**Note:** This feature is available in NetScaler release 10.5.e.

Web servers following Google Web Toolkit (GWT) Remote Procedure Call (RPC) mechanisms can be secured by the NetScaler application firewall without a need for any specific configuration to enable the GWT support.

## What is GWT

The GWT is used for building and optimizing complex high-performance web applications by people who do not have expertise in XMLHttpRequest, and JavaScript. This open source, free development toolkit is used extensively for developing small and large scale applications and is quite frequently used for displaying browser based data such as search results for flights, hotels, and so on. The GWT provides a core set of Java APIs and widgets for writing optimized JavaScript scripts that can run on most browsers and mobile devices. The GWT RPC framework makes it easy for the client and server components of the web application to exchange Java objects over HTTP. GWT RPC services are not the same as web services based on SOAP or REST. They are simply a lightweight method for transferring data between the server and the GWT application on the client. GWT handles serialization of the Java objects exchanging the arguments in the method calls and the return value.

For popular websites that use GWT, see

<https://www.quora.com/What-web-applications-use-Google-Web-Toolkit-%28GWT%29>

## How a GWT Request Works

The GWT RPC request is pipe delimited and has variable number of arguments. It is carried as a payload of HTTP POST and has the following values:

1. Content-type = text/x-gwt-rpc. Charset can be any value.
2. Method = POST.

The following example shows a valid payload for a GWT request:

```
5|0|8|http://localhost:8080/test/16878339F02B83818D264AE430C20468| com.test.client.TestService|testMethod|java.lang.String|java.lang.Integer|myInput1|java.lang.Integer/3438268394|1|2|3|4|2|5|6|7|8|1|
```

The request can be divided into three parts:

### a) Header: 5|0|8|

The first 3 digits "5|0|8|" in the above request, represent "version, subversion, and size of table", respectively. These must be positive integers.

### b) String Table:

```
http://localhost:8080/test/16878339F02B83818D264AE430C20468| com.test.client.TestService|testMethod|java.lang.String|java.lang.Integer|myInput1|java.lang.Integer/3438268394|
```

The members of the above pipe delimited string table contain the user-provided inputs. These inputs are parsed for the application firewall checks and are identified as follows:

- 1st : http://localhost:8080/test/  
This is the Request URL. It should not contain the query part, because the GET method is not allowed.
- 2nd : 16878339F02B83818D264AE430C20468  
Unique HEX identifier. A request is considered malformed if this string has non-hex characters.
- 3rd : com.test.client.TestService  
Service Class name
- 4th : testMethod  
Service method name
- 5th onwards: java.lang.String|java.lang.Integer|myInput1|java.lang.Integer/3438268394  
Data-types and data. Non-primitive data-types are specified as  
<container>.<sub-cntnr>.name/<integer\_identifier>

### c) Payload: 1|2|3|4|2|5|6|7|8|1|

The payload consists of references to the elements in the string table. These integer values cannot be larger than the number of elements in the string table.

Application firewall protection for GWT applications

The application firewall understands and interprets GWT RPC requests, inspects the payload for security check violations, and takes specified actions.

The application firewall headers and cookies checks for GWT requests are similar to those for other request formats. After appropriate URL decoding and charset conversion, all the parameters in the string table are inspected. The GWT request body does not contain field names, just the field values. The input values can be validated against the specified format by using the application firewall Field Format check, which can also be used to control the length of the input. The **Cross-site Scripting** and **SQL Injection** attacks in the inputs can be easily detected and thwarted by the application firewall.

**Learning and relaxation rules:** Learning and deployment of relaxation rules are supported for GWT requests. Application firewall rules are in the form of <actionURL> <fieldName> mapping. The GWT request format does not have the field names and thus requires special handling. The application firewall inserts dummy field names in the learned rules that can be deployed as relaxation rules. The -isRegex flag works as it does for non-GWT rules.

#### **Action URL:**

Multiple services responding to an RPC can be configured on the same web server. The HTTP request has the URL of the web server, not of the actual service handling the RPC. Therefore, relaxation is not applied on the basis of the HTTP request URL, because that would relax all the services on that URL for the target field. For GWT requests, the application firewall uses the URL of the actual service found in the GWT payload, in the fourth field in the string table.

#### **Field name:**

Since the GWT request body contains only field values, the application firewall inserts dummy field names such as 1, 2, and so on when recommending learned rules.

#### **Example of a GWT learned rule**

```
POST /abcd/def/gh HTTP/1.1
Content-type: text/x-gwt-rpc
Host: 10.217.222.75
Content-length: 157
```

```
5|0|8|http://localhost:8080/acdtest|16878339F02Baf83818D264AE430C20468|
com.test.client.TestService|testMethod|java.lang.String%3b|java.lang.Integer|onblur|
```

The learn data will be as follows:

```
> sh learningdata pr1 crossSiteScripting
Profile: pr1 SecurityCheck: crossSiteScripting
1) Url: http://localhost:8080/acdtest/ >> From GWT Payload.
Field: 10
Hits: 1
Done
```

#### **Example of a GWT relaxation rule**

```
bind appfw profile pr1 -crossSiteScripting 1 abcd -isregex NOTREGEX
```

**Log Messages:** The application firewall generates log messages for the security check violations that are detected in the GWT requests. A log message generated by a malformed GWT request contains the string "GWT" for easy identification.

#### **Example of a Log message for malformed GWT request**

```
Dec 5 21:48:02 <local0.notice> 10.217.31.247 12/05/2014:21:48:02 GMT ns 0-PPE-0 : APPFW Message 696 0 : "GWT RPC request with malformed payload.
<blocked>"
```

#### **Difference in processing of GWT vs non-GWT requests**

The same payload can trigger different application firewall security check violations for different Content-types. Consider the following example:

```
5|0|8|http://localhost:8080/acdtest|16878339F02Baf83818D264AE430C20468|com.test.client.TestService|testMethod|java.lang.String%3b|java.lang.Integer|select|
```

#### **Content-type: application/x-www-form-urlencoded**

A request sent with this content type results in a SQL violation if the SQL Injection Type is configured to use any of the four available options: SQLSpICharANDKeyword, SQLSpICharORKeyword, SQLKeyword, or SQLSpIChar. The application firewall considers '&' to be the field separator and '=' to be the name-value separator when processing the above payload. Since neither of these characters appears anywhere in the post body, the entire content is treated as a single field name. The field name in this request contains both an SQL special character (;) and an SQL Keyword (select). Therefore violations are caught for all four SQL Injection type options.

#### **Content-type: text/x-gwt-rpc**

A request sent with this content type triggers an SQL violation only if the SQL injection type is set to one of the following three options: SQLSpICharORKeyword, SQLKeyword, or SQLSpIChar. No violation is triggered if the SQL injection type is set to SQLSpICharANDKeyword, which is the

default option. The application firewall considers the vertical bar ' | ' to be the field separator for the above payload in the GWT request. Therefore, the post body is divided into various form-field values, and form-field names are added (in accordance with the convention described earlier). Because of this splitting, the SQL special character and SQL keyword become parts of separate form fields.

Form field 8: java.lang.String%3b -> %3b is the (;) char

Form Field 10: select

As a result, when SQL Injection Type is set to **SQLSpIChar**, field 8 indicates the SQL violation. For **SQLKeyword**, field 10 indicates the violation. Either of these two fields can indicate a violation if the SQL Inject type is configured with the **SQLSpICharORKeyword** option, which looks for the presence of either a keyword or a special character. No violation is caught for the default **SQLSpICharANDKeyword** option, because there is no single field that has a value that contains both **SQLSpIChar** and **SQLKeyword** together.

**Tips:**

- No special application firewall configuration is needed to enable GWT support.
- The Content-type must be text/x-gwt-rpc.
- Learning and deploying of the relaxation rules for all the pertinent application firewall security checks applied to GWT payload works the same as it does for the other supported content-types.
- Only POST requests are considered valid for GWT. All other request methods are blocked if the content-type is text/x-gwt-rpc.
- GWT requests are subject to the configured POST body limit of the profile.
- The sessionless setting for the security checks is not applicable and will be ignored.
- CEF log format is supported for the GWT log messages.

# Data Leak Prevention Checks

Mar 28, 2012

The data-leak-prevention checks filter responses to prevent leaks of sensitive information, such as credit card numbers and social security numbers, to unauthorized recipients.

# Credit Card Check

Feb 03, 2014

The Credit Card check provides special handling for credit card numbers. A web application does not usually send a credit card number in a response to a user request, even when the user supplies a credit card number in the request. The application firewall examines web server responses, including headers, for credit card numbers. If it finds a credit card number in the response, and the administrator has not configured it to allow credit card numbers to be sent, it responds in one of two ways:

- It blocks the response.
- It replaces all but the final group of digits in the credit card with x's. For example, a credit card number of 9876-5432-1234-5678 would be rendered xxxx-xxxx-xxxx-5678.

The Credit Card check prevents attackers from exploiting a security flaw in your web server software or on your web site to obtain credit card numbers of your customers. If your web sites do not have access to credit card information, you do not need to configure this check. If you have a shopping cart or other application that can access credit card numbers, or your web sites have access to database servers that contain credit card numbers, you should configure protection for each type of credit card that you accept.

Note: A web site that does not access an SQL database usually does not have access to sensitive private information such as credit card numbers.

If you use the wizard or the configuration utility, in the Credit Card Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions, and the following actions:

- **X-Out.** Mask any credit card number detected in a response by replacing each digit, except the digits in the final group, with the letter "X."
- **Maximum credit cards allowed per page.** Allow up to the specified number of credit card numbers per page in responses without masking the credit card numbers or blocking the response. The Maximum is set to zero (0) by default. Web pages do not usually contain unmasked credit card numbers, but occasionally a web page might legitimately contain a credit card number or even a list of credit card numbers. To allow one or more credit card numbers to appear in a web page before masking the numbers or blocking the response, change the value in the "Maximum credit cards allowed per page" text box to the number of credit cards that you want to allow.

To configure the types of credit cards to be protected, in the Modify Credit Card Check dialog box, select each credit card type that you want to protect, and then click Protect. If you want to cancel protection for a credit card type, select that credit card type and then click Unprotect. You can hold down your Shift or Ctrl key while choosing credit card types, and then enable or disable several credit card types at once by clicking the Protect or Unprotect button while multiple credit card types are selected.

If you use the command-line interface, you can enter the following commands to configure the Credit Card Check:

- set appfw profile <name> -creditCardAction [**block**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -creditCard (**VISA** | **MASTERCARD** | **DISCOVER** | **AMEX** | **JCB** | **DINERSCLUB**)
- set appfw profile <name> -creditCardMaxAllowed <integer>
- set appfw profile <name> -creditCardXOut (**[ON]** | **[OFF]**)

# Safe Object Check

Feb 03, 2014

The Safe Object check provides user-configurable protection for sensitive business information, such as customer numbers, order numbers, and country-specific or region-specific telephone numbers or postal codes. A user-defined regular expression or custom plug-in tells the application firewall the format of this information and defines the rules to be used to protect it. If a string in a user request matches a safe object definition, the application firewall either blocks the response, masks the protected information, or removes the protected information from the response before sending it to the user, depending on how you configured that particular safe object rule.

The Safe Object check prevents attackers from exploiting a security flaw in your web server software or on your web site to obtain sensitive private information, such as company credit card numbers or social security numbers. If your web sites do not have access to these types of information, you do not need to configure this check. If you have a shopping cart or other application that can access such information, or your web sites have access to database servers that contain such information, you should configure protection for each type of sensitive private information that you handle and store.

Note: A web site that does not access an SQL database usually does not have access to sensitive private information. The Safe Object Check dialog box is unlike that for any other check. Each safe object expression that you create is the equivalent of a separate security check, similar to the Credit Card check, for that type of information. If you use the wizard or the configuration utility, you add a new expression by clicking Add and configuring the expression in the Add Safe Object dialog box. You modify an existing expression by selecting it, then clicking Open, and then configuring the expression in the Modify Safe Object dialog box.

In the Safe Object dialog box for each safe object expression, you can configure the following:

- **Safe Object Name.** A name for your new safe object. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 255 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (\_) symbols.
- **Actions.** Enable or disable the Block, Log, and Statistics actions, and the following actions:
  - **X-Out.** Mask any information that matches the safe object expression with the letter “X”.
  - **Remove.** Remove any information that matches the safe object expression.
- **Regular Expression.** Enter a PCRE-compatible regular expression that defines the safe object. You can create the regular expression in one of three ways: by typing the regular expression directly into the text box, by using the **Regex Tokens** menu to enter regular expression elements and symbols directly into the text box, or by opening the Regular Expressions Editor and using it to construct the expression. The regular expression must consist of ASCII characters only. Do not cut and paste characters that are not part of the basic 128-character ASCII set. If you want to include non-ASCII characters, you must manually type those characters in PCRE hexadecimal character encoding format.  
Note: Do not use start anchors (^) at the beginning of Safe Object expressions, or end anchors (\$) at the end of Safe Object expressions. These PCRE entities are not supported in Safe Object expressions, and if used, will cause your expression not to match what it was intended to match.
- **Maximum Match Length.** Enter a positive integer that represents the maximum length of the string that you want to match. For example, if you want to match U.S. social security numbers, enter the number eleven (11) in this field. That allows your regular expression to match a string with nine numerals and two hyphens. If you want to match California driver's license numbers, enter the number eight (8).  
Caution: If you do not enter a maximum match length in this field, the application firewall uses a default value of one (1) when filtering for strings that match your safe object expressions. As a result, most safe object expressions fail to match their target strings.

You cannot use the command-line interface to configure the Safe Object check. You must configure it by using either the application firewall wizard or the configuration utility.

Following are examples of Safe Object check regular expressions:

- Look for strings that appear to be U.S. social security numbers, which consist of three numerals (the first of which must not be zero), followed by a hyphen, followed by two more numerals, followed by a second hyphen, and ending with a string of four more numerals:  
`[1-9][0-9]{2,2}-[0-9]{2,2}-[0-9]{4,4}`
- Look for strings that appear to be California driver's license IDs, which start with a letter and are followed by a string of exactly seven numerals:  
`[A-Za-z][0-9]{7,7}`
- Look for strings that appear to be Example Manufacturing customer IDs which, consist of a string of five hexadecimal characters (all the numerals and the letters A through F), followed by a hyphen, followed by a three-letter code, followed by a second hyphen, and ending with a string of ten numerals:  
`[0-9A-Fa-f]{5,5}-[A-Za-z]{3,3}-[0-9]{10,10}`

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write to ensure that they define exactly the type of string you want to add as a safe object definition, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.\* ) metacharacter/wildcard combination, can have results you did not want or expect, such as blocking access to web content that you did not intend to block.

# Advanced Form Protection Checks

Mar 28, 2012

The advanced Form Protection checks examine web form data to prevent attackers from compromising your system by modifying the web forms on your web sites or sending unexpected types and quantities of data to your web site in a form.

# Field Formats Check

Sep 28, 2017

The Field Formats check verifies the data that users send to your web sites in a web form. It examines both the length and type of data to ensure that it is appropriate for the form field in which it appears. If the application firewall detects inappropriate web form data in a user request, it blocks the request. This check applies to HTML requests only. It does not apply to XML requests.

By preventing an attacker from sending inappropriate web form data to your web site, the Field Formats check prevents certain types of attacks on your web site and database servers. For example, if a particular field expects the user to enter a phone number, the Field Formats check examines the user's response to ensure that the data matches the format for a phone number. If a particular field expects a first name, the Field Formats check ensures that the data in that field is of a type and length appropriate for a first name. It does the same thing for each form field that you configure it to protect.

The Field Formats check provides a different type of protection than does the Form Field Consistency check. The Form Field Consistency check verifies that the structure of the web forms returned by users is intact, that data format restrictions configured in the HTML are respected, and that data in hidden fields has not been modified. It can do this without any specific knowledge about your web forms other than what it derives from the web form itself. The Field Formats check verifies that the data in each form field matches the specific formatting restrictions that you configured manually, or that the learning feature generated and you approved. In other words, the Form Field Consistency check enforces general web form security, while the Field Formats check enforces the specific rules that you set for your web forms.

## Note

Field format rules are tightening rules. Adding them to relaxation list from learned data acts as a blocking rule.

To relax field format rules, please remove particular "fieldname" from the fieldformat relaxations list.

Before it can protect your web forms, the Field Formats check requires that you configure the application firewall to recognize the type and length of data expected in each form field on each web form that you want to protect.

If you use the wizard or the configuration utility, in the Modify Field Formats Check dialog box, on the General tab you can enable or disable the Block, Log, Learn, and Statistics actions and the following parameters:

- **Field Type.** Assign a default field type to form fields in web forms that do not have a field type. This parameter is not set by default. You can assign any field type that is defined on your application firewall as the default field type.  
Caution: If you set a restrictive default field type and do not disable blocking until you are certain that the field types assigned to your form fields are correct, users may be unable to use your web forms.
- **Minimum Length.** The default minimum data length assigned to form fields in web forms that do not have an explicit setting. This parameter is set to 0 by default, which allows the user to leave the field blank. Any higher setting forces users to fill in the field.
- **Maximum Length.** The default maximum data length assigned to form fields in web forms that do not have an explicit setting. This parameter is set to 65535 by default.

If you use the command-line interface, you can enter the following commands to configure the Field Formats Check:

- set appfw profile <name> -fieldFormatAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -defaultFieldFormatType <string>
- set appfw profile <name> -defaultFieldFormatMinLength <integer>
- set appfw profile <name> -defaultFieldFormatMaxLength <integer>

To specify relaxations for the Field Formats check, you must use the configuration utility. On the Checks tab of the Modify Field Formats Check dialog box, click Add to open the Add Field Formats Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Field Formats Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

Following are examples of Field Formats check relaxations:

- Choose form fields with the name FirstName:

```
^FirstName$
```

- Choose form fields with names that begin with Name\_ and are followed by a string beginning with a letter or number and consisting of from one to twenty letters, numbers, or the apostrophe or hyphen symbol:

```
^Name_[0-9A-Za-z][0-9A-Za-z'-]{0,20}$
```

- Choose form fields with names that begin with Turkish-FirstName\_ and are otherwise the same as the previous expression, except that they can contain Turkish special characters throughout:

```
^T\xC3\xBCrk\xC3\xA7e-FirstName_[0-9A-Za-z]\x[0-9A-Fa-f][0-9A-Fa-f]+$
```

- Choose form field names that begin with a letter or number, consist of a combination of letters and/or numbers only, and that contain the string Num anywhere in the string:

```
^[0-9A-Za-z]*Num[0-9A-Za-z]*$
```

# Form Field Consistency Check

Feb 05, 2014

The Form Field Consistency check examines the web forms returned by users of your web site, and verifies that web forms were not modified inappropriately by the client. This check applies only to HTML requests that contain a web form, with or without data. It does not apply to XML requests.

The Form Field Consistency check prevents clients from making unauthorized changes to the structure of the web forms on your web site when they fill out and submit a form. It also ensures that the data a user submits meets the HTML restrictions for length and type, and that data in hidden fields is not modified. This prevents an attacker from tampering with a web form and using the modified form to gain unauthorized access to web site, redirect the output of a contact form that uses an insecure script and thereby send unsolicited bulk email, or exploit a vulnerability in your web server software to gain control of the web server or the underlying operating system. Web forms are a weak link on many web sites and attract a wide range of attacks.

The Form Field Consistency check verifies all of the following:

- If a field is sent to the user, the check ensures that it is returned by the user.
- The check enforces HTML field lengths and types.  
Note: The Form Field Consistency check enforces HTML restrictions on data type and length but does not otherwise validate the data in web forms. You can use the Field Formats check to set up rules that validate data returned in specific form fields on your web forms.
- If your web server does not send a field to the user, the check does not allow the user to add that field and return data in it.
- If a field is a read-only or hidden field, the check verifies that the data has not changed.
- If a field is a list box or radio button field, the check verifies that the data in the response corresponds to one of the values in that field.

If a web form returned by a user violates one or more of the Form Field consistency checks, and you have not configured the application firewall to allow that web form to violate the Form Field Consistency checks, the request is blocked.

If you use the wizard or the configuration utility, in the Modify Form Field Consistency Check dialog box, on the General tab you can enable or disable the Block, Log, Learn, and Statistics actions.

You also configure Sessionless Field Consistency in the General tab. If Sessionless Field Consistency is enabled, the application firewall checks only the web form structure, dispensing with those parts of the Form Field Consistency check that depend upon maintaining session information. This can speed the Form Field Consistency check with little security penalty for web sites that use many forms. To use Sessionless Field Consistency on all web forms, select On. To use it only for forms submitted with the HTTP POST method, select postOnly

If you use the command-line interface, you can enter the following command to configure the Form Field Consistency Check:

- `set appfw profile <name> -fieldConsistencyAction [block] [learn] [log] [stats] [none]`

To specify relaxations for the Form Field Consistency check, you must use the configuration utility. On the Checks tab of the Modify Form Field Consistency Check dialog box, click Add to open the Add Form Field Consistency Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Form Field Consistency Check Relaxation

dialog box. Either dialog box provides the same options for configuring a relaxation, as described in "[Manual Configuration By Using the Configuration Utility](#)."

Following are examples of Form Field Consistency check relaxations:

### Form Field Names

- Choose form fields with the name UserType:

```
^UserType$
```

- Choose form fields with names that begin with UserType\_ and are followed by a string that begins with a letter or number and consists of from one to twenty-one letters, numbers, or the apostrophe or hyphen symbol:

```
^UserType_[0-9A-Za-z][0-9A-Za-z']{0,20}$
```

- Choose form fields with names that begin with Turkish-UserType\_ and are otherwise the same as the previous expression, except that they can contain Turkish special characters throughout:

```
^T\xC3\xBCrk\xC3\xA7e-UserType_([0-9A-Za-z][\x0-9A-Fa-f][0-9A-Fa-f])+$
```

Note: See "[PCRE Character Encoding Format](#)" for a complete description of supported special characters and how to encode them properly.

- Choose form field names that begin with a letter or number, consist of a combination of letters and/or numbers only, and that contain the string Num anywhere in the string:

```
^[0-9A-Za-z]*Num[0-9A-Za-z]*$
```

### Form Field Action URLs

- Choose URLs beginning with http://www.example.com/search.pl? and containing any string after the query except for a new query:

```
^http://www[.]example[.]com/search[.]pl\?[^\?]*$
```

- Choose URLs that begin with http://www.example-español.com and have paths and filenames that consist of upper-case and lower-case letters, numbers, non-ASCII special characters, and selected symbols in the path. The ñ character and any other special characters are represented as encoded UTF-8 strings containing the hexadecimal code assigned to each special character in the UTF-8 charset:

```
^http://www[.]example-espa\xC3\xB1ol[.]com/((([0-9A-Za-z][\x0-9A-Fa-f][0-9A-Fa-f])
([0-9A-Za-z_][\x0-9A-Fa-f][0-9A-Fa-f])*)*([0-9A-Za-z][\x0-9A-Fa-f][0-9A-Fa-f])
([0-9A-Za-z_][\x0-9A-Fa-f][0-9A-Fa-f])*[.](asp|http|php|s?html?))$
```

- Choose all URLs that contain the string /search.cgi?:

```
^[^\?<>]*/search[.]cgi\?[^\?<>]*$
```

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.\* ) metacharacter/wildcard combination, can have results you do not want or expect, such as blocking access to web content that you did not intend to block or allowing an attack that the Cookie Consistency check would otherwise have blocked.

# CSRF Form Tagging Check

Feb 05, 2014

The Cross Site Request Forgery (CSRF) Form Tagging check tags each web form sent by a protected web site to users with a unique and unpredictable FormID, and then examines the web forms returned by users to ensure that the supplied FormID is correct. This check protects against cross-site request forgery attacks. This check applies only to HTML requests that contain a web form, with or without data. It does not apply to XML requests.

The CSRF Form Tagging check prevents attackers from using their own web forms to send high volume form responses with data to your protected web sites. This check requires relatively little CPU processing capacity compared to certain other security checks that analyze web forms in depth. It is therefore able to handle high volume attacks without seriously degrading the performance of the protected web site or the application firewall itself.

Before you enable the CSRF Form Tagging check, you should be aware of the following:

- You need to enable form tagging. The CSRF check depends on form tagging and does not work without it.
- You should disable the Citrix NetScaler Integrated Caching feature for all web pages containing forms that are protected by that profile. The Integrated Caching feature and CSRF form tagging are not compatible.
- You should consider enabling Referer checking. Referer checking is part of the Start URL check, but it prevents cross-site request forgeries, not Start URL violations. Referer checking also puts less load on the CPU than does the CSRF Form Tagging check. If a request violates Referer checking, it is immediately blocked, so the CSRF Form Tagging check is not invoked.
- The CSRF Form Tagging check does not work with web forms that use different domains in the form-origin URL and form-action URL. For example, CSRF Form Tagging cannot protect a web form with a form-origin URL of `http://www.example.com/` and a form action URL of `http://www.example.org/form.pl`, because `example.com` and `example.org` are different domains.

If you use the wizard or the configuration utility, in the Modify CSRF Form Tagging Check dialog box, on the General tab you can enable or disable the Block, Log, Learn and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the CSRF Form Tagging Check:

- `set appfw profile <name> -fieldConsistencyAction [block] [log] [learn] [stats] [none]`

To specify relaxations for the CSRF Form Tagging check, you must use the configuration utility. On the Checks tab of the Modify CSRF Form Tagging Check dialog box, click Add to open the Add CSRF Form Tagging Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify CSRF Form Tagging Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

Following are examples of CSRF Form Tagging check relaxations:

Note: The following expressions are URL expressions that can be used in both the Form Origin URL and Form Action URL roles.

- Choose URLs beginning with `http://www.example.com/search.pl?` and containing any string after the query, except for a new query:

```
^http://www[.]example[.]com/search[.]pl\?[^\?]*$
```

- Choose URLs that begin with `http://www.example-español.com` and have paths and filenames that consist of upper-case and lower-case letters, numbers, non-ASCII special characters, and selected symbols in the path. The ñ character

and any other special characters are represented as encoded UTF-8 strings containing the hexadecimal code assigned to each special character in the UTF-8 charset:

```
^http://www[.]example-espa\xC3xB1o[.]com/((([0-9A-Za-z])\x[0-9A-Fa-f][0-9A-Fa-f])
([0-9A-Za-z_])\x[0-9A-Fa-f][0-9A-Fa-f])*)*([0-9A-Za-z])\x[0-9A-Fa-f][0-9A-Fa-f]
([0-9A-Za-z_])\x[0-9A-Fa-f][0-9A-Fa-f]*[.](asp|htp|php|s?html?)$
```

- Choose all URLs that contain the string /search.cgi?:

```
^[^?<>]*/search[.]cgi\^[^?<>]*$
```

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.\* ) metacharacter/wildcard combination, can have results you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the check would otherwise have blocked.

# Managing CSRF Form Tagging Check Relaxations

Sep 03, 2013

You configure an exception (or relaxation) to the CSRF Form Tagging security check in the Add Cross-Site Request Forgery Tagging Check Relaxation dialog box or the Modify Cross-Site Request Forgery Tagging Check Relaxation dialog box.

1. Navigate to Security > Application Firewall > Profiles.
2. In the Profiles pane, select the profile you want to configure, and then click Open.
3. In the Configure Application Firewall Profile dialog box, click the Security Checks tab. The Security Checks tab contains the list of application firewall security checks.
4. In the Security Checks window, click CSRF Form Tagging, and then click Open. The Modify Cross-Site Request Forgery Tagging Check dialog box is displayed, with the Checks tab selected. The Checks tab contains a list of existing CSRF relaxations. The list might be empty if you have not either manually added any relaxations or approved any relaxations that were recommended by the learning engine. Beneath the list is a row of buttons that allow you to add, modify, delete, enable, or disable the relaxations on the list.
5. To add or modify a CSRF relaxation, do one of the following:
  - To add a new relaxation, click Add.
  - To modify an existing relaxation, select the relaxation that you want to modify, and then click Open. The Add Cross-Site Request Forgery Tagging Check Relaxation or Modify Cross-Site Request Forgery Tagging Check Relaxation dialog box is displayed. Except for the title, these dialog boxes are identical.
6. Fill in the dialog box as described below.
  - **Enabled check box**—Select to place this relaxation or rule in active use; clear to deactivate it.
  - **Form Origin URL**—In the text area, enter a PCRE-format regular expression that defines the URL that hosts the form.
  - **Form Action URL**—In the text area, enter a PCRE-format regular expression that defines the URL to which data entered into the form is delivered.
  - **Comments**—In the text area, type a comment. Optional.  
Note: For any element that requires a regular expression, you can type the regular expression, use the Regex Tokens menu to insert regular expression elements and symbols directly into the text box, or click Regex Editor to open the Add Regular Expression dialog box, and use it to construct the expression.
7. Click OK. The Add Cross-Site Request Forgery Tagging Check Relaxation or Modify Cross-Site Request Forgery Tagging Check Relaxation dialog box closes and you return to the Modify Cross-Site Request Forgery Tagging Check dialog box.
8. To remove a relaxation or rule, select it, and then click Remove.
9. To enable a relaxation or rule, select it, and then click Enable.
10. To disable a relaxation or rule, select it, and then click Disable.
11. To configure the settings and relationships of all existing relaxations in an integrated interactive graphic display, click Visualizer, and use the display tools.
12. To review and configure learned rules for the CSRF check, click Learning and perform the steps in "[To configure and use the Learning feature.](#)"
13. Click OK.

# URL Protection Checks

Mar 28, 2012

The URL Protection checks examine request URLs to prevent attackers from aggressively attempting to access multiple URLs (forceful browsing) or using a URL to trigger a known security vulnerability in web server software or web site scripts.

# Start URL Check

Feb 07, 2017

The Start URL check examines the URLs in incoming requests and blocks the connection attempt if the URL does not meet the specified criteria. To meet the criteria, the URL must match an entry in the Start URL list, unless the Enforce URL Closure parameter is enabled. If you enable this parameter, a user who clicks a link on your Web site is connected to the target of that link.

The primary purpose of the Start URL check is to prevent repeated attempts to access random URLs on a Web site, (forceful browsing). Forceful browsing can be used to trigger a buffer overflow, find content that users were not intended to access directly, or find a back door into secure areas of your Web server.

If you use the wizard or the configuration utility, in the Modify Start URL Check dialog box, on the General tab you can enable or disable Block, Log, Statistics, Learn actions, and the following parameters:

- **Enforce URL Closure.** Allow users to access any web page on your web site by clicking a hyperlink on any other page on your web site. Users can navigate to any page on your web site that can be reached from the home page or any designated start page by clicking hyperlinks.

Note: The URL closure feature allows any query string to be appended to and sent with the action URL of a web form submitted by using the HTTP GET method. If your protected web sites use forms to access an SQL database, make sure that you have the SQL injection check enabled and properly configured.

- **Sessionless URL Closure.** From the client's point of view, this type of URL closure functions in exactly the same way as standard, session-aware URL Closure, but uses a token embedded in the URL instead of a cookie to track the user's activity, which consumes considerably fewer resources.

Note: When enabling sessionless (Sessionless URL Closure), you must also enable regular URL closure (Enforce URL Closure) or sessionless URL closure does not work.

- **Validate Referrer Header.** Verify that the Referrer header in a request that contains web form data from your protected web site instead of another web site. This action verifies that your web site, not an outside attacker, is the source of the web form. Doing so protects against cross-site request forgeries (CSRF) without requiring form tagging, which is more CPU-intensive than header checks. The application firewall can handle the HTTP Referrer header in one of the following three ways, depending on which option you select in the drop-down list:

- **Off.** Do not validate the Referrer header.
- **If-Present.** Validate the Referrer header if a Referrer header exists. If an invalid Referrer header is found, the request generates a referer-header violation. If no Referrer header exists, the request does not generate a referer-header violation. This option enables the application firewall to perform Referrer header validation on requests that contain a Referrer header, but not block requests from users whose browsers do not set the Referrer header or who use web proxies or filters that remove that header.
- **Always.** Always validate the Referrer header. If there is no Referrer header, or if the Referrer header is invalid, the request generates a referer-header violation.

Note: Although the referer header check and Start URL security check share the same action settings, it is possible to violate the referer header check without violating the Start URL check. The difference is visible in the logs, which log referer header check violations separately from Start URL check violations.

One Start URL setting, Exempt Closure URLs from Security Checks, is not configured in the Modify Start URL Check dialog box, but in the Settings tab of the Configure Application Firewall Profile dialog box. If enabled, this setting directs the application firewall not to run further security checks on URLs that meet the URL Closure criteria.

If you use the command-line interface, you can enter the following commands to configure the Start URL Check:

- set appfw profile <name> -startURLAction [block] [learn] [log] [stats] [none]
- set appfw profile <name> -startURLClosure ([ON] | [OFF])
- set appfw profile <name> -sessionlessURLClosure ([ON] | [OFF])
- set appfw profile <name> -exemptClosureURLsFromSecurityChecks ([ON] | [OFF])
- set appfw profile <name> -RefererHeaderCheck ([OFF] | [if-present] | [AlwaysExceptStartURLs] | [AlwaysExceptFirstRequest])

To specify relaxations for the Start URL check, you must use the configuration utility. On the Checks tab of the Modify Start URL Check dialog box, click Add to open the Add Start URL Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Start URL Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

Following are examples of Start URL check relaxations:

- Allow users to access the home page at [www.example.com](http://www.example.com):

```
^http://www[.]example[.]com$
```

- Allow users to access all static HTML (.htm and .html), server-parsed HTML (.htp and .shtml), PHP (.php), and Microsoft ASP (.asp) format web pages at [www.example.com](http://www.example.com):

```
^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_]*)*
[0-9A-Za-z][0-9A-Za-z_]*[.](asp|htp|php|s?html)?$
```

- Allow users to access web pages with pathnames or file names that contain non-ASCII characters at [www.example-español.com](http://www.example-español.com):

```
^http://www[.]example-espa\xC3\xB1ol[.]com/((([0-9A-Za-z]\\x[0-9A-Fa-f][0-9A-Fa-f])([0-9A-Za-z_]\\x[0-9A-Fa-f][0-9A-Fa-f])*
)/)*
([0-9A-Za-z]\\x[0-9A-Fa-f][0-9A-Fa-f])([0-9A-Za-z_]\\x[0-9A-Fa-f][0-9A-Fa-f])*[.](asp|htp|php|s?html)?$
```

Note: In the above expression, each character class has been grouped with the string `\\x[0-9A-Fa-f][0-9A-Fa-f]`, which matches all properly-constructed character encoding strings but does not allow stray backslash characters that are not associated with a UTF-8 character encoding string. The double backslash (`\\`) is an escaped backslash, which tells the application firewall to interpret it as a literal backslash. If you included only one backslash, the application firewall would instead interpret the following left square bracket (`[`) as a literal character instead of the opening of a character class, which would break the expression.

- Allow users to access all GIF (.gif), JPEG (.jpg and .jpeg), and PNG (.png) format graphics at [www.example.com](http://www.example.com):

```
^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_]*)*
[0-9A-Za-z][0-9A-Za-z_]*[.](gif|jpe?g|png)$
```

- Allow users to access CGI (.cgi) and PERL (.pl) scripts, but only in the CGI-BIN directory:

```
^http://www[.]example[.]com/CGI-BIN/[0-9A-Za-z][0-9A-Za-z_]*[.](cgi|pl)$
```

- Allow users to access Microsoft Office and other document files in the docsarchive directory:

```
^http://www[.]example[.]com/docsarchive/[0-9A-Za-z][0-9A-Za-z_]*[.](doc|xls|pdf|ppt)$
```

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions that you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk ( `.*` ) metacharacter/wildcard combination, can have results you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the Start URL check would otherwise have blocked.

# Deny URL Check

Feb 03, 2014

The Deny URL check examines and blocks connections to URLs that are commonly accessed by hackers and malicious code. This check contains a list of URLs that are common targets of hackers or malicious code and that rarely if ever appear in legitimate requests. You can also add URLs or URL patterns to the list. The Deny URL check prevents attacks against various security weaknesses known to exist in web server software or on many web sites.

The Deny URL check takes priority over the Start URL check, and thus denies malicious connection attempts even when a Start URL relaxation would normally allow a request to proceed.

In the Modify Deny URL Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the Deny URL Check:

- `set appfw profile <name> -denyURLAction [block] [log] [stats] [none]`

To create and configure your own deny URLs, you must use the configuration utility. On the Checks tab of the Modify Deny URL Check dialog box, click Add to open the Add Deny URL dialog box, or select an existing user-defined deny URL and click Open to open the Modify Deny URL dialog box. Either dialog box provides the same options for creating and configuring a deny URL.

Following are examples of Deny URL expressions:

- Do not allow users to access the image server at images.example.com directly:

```
^http://images[.]example[.]com$
```

- Do not allow users to access CGI (.cgi) or PERL (.pl) scripts directly:

```
^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*)*
[0-9A-Za-z][0-9A-Za-z_-]*[.](cgi|pl)$
```

- Here is the same deny URL, modified to support non-ASCII characters:

```
^http://www[.]example[.]com/(([0-9A-Za-z]\\x[0-9A-Fa-f][0-9A-Fa-f])
([0-9A-Za-z_-]\\x[0-9A-Fa-f][0-9A-Fa-f])*)*([0-9A-Za-z]\\x[0-9A-Fa-f][0-9A-Fa-f])
([0-9A-Za-z_-]\\x[0-9A-Fa-f][0-9A-Fa-f])*[.](cgi|pl)$
```

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL or pattern that you want to block, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.\* ) metacharacter/wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block.

# XML Protection Checks

Mar 28, 2012

The XML Protection checks examine requests for XML-based attacks of all types.

Caution: The XML security checks apply only to content that is sent with an HTTP content-type header of text/xml. If the content-type header is missing, or is set to a different value, all XML security checks are bypassed. If you plan to protect XML or Web 2.0 web applications, the webmasters of each web server that hosts those applications should ensure that the proper HTTP content-type header is sent.

# XML Format Check

Feb 20, 2014

The XML Format check examines the XML format of incoming requests and blocks those requests that are not well formed or that do not meet the criteria in the XML specification for properly-formed XML documents. Some of those criteria are:

- An XML document must contain only properly-encoded Unicode characters that match the Unicode specification.
- No special XML syntax characters—such as <, > and &—can be included in the document except when used in XML markup.
- All begin, end, and empty-element tags must be correctly nested, with none missing or overlapping.
- XML element tags are case-sensitive. All beginning and end tags must match exactly.
- A single root element must contain all the other elements in the XML document.

A document that does not meet the criteria for well-formed XML does not meet the definition of an XML document. Strictly speaking, it is not XML. However, not all XML applications and web services enforce the XML well-formed standard, and not all handle poorly-formed or invalid XML correctly. Inappropriate handling of a poorly-formed XML document can cause security breaches. The purpose of the XML Format check is to prevent a malicious user from using a poorly-formed XML request to breach security on your XML application or web service.

If you use the wizard or the configuration utility, in the Modify XML Format Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the XML Format Check:

- `set appfw profile <name> -xmlFormatAction [block] [log] [stats] [none]`

You cannot configure exceptions to the XML Format check. You can only enable or disable it.

# XML Denial-of-Service Check

Nov 14, 2013

The XML Denial of Service (XML DoS or XDoS) check examines incoming XML requests to determine whether they match the characteristics of a denial-of-service (DoS) attack, and blocks those requests that do. The purpose of the XML DoS check is to prevent an attacker from using XML requests to launch a denial-of-service attack on your web server or web site.

If you use the wizard or the configuration utility, in the Modify XML Denial-of-Service Check dialog box, on the General tab you can enable or disable the Block, Log, Statistics, and Learn actions:

If you use the command-line interface, you can enter the following command to configure the XML Denial-of-Service check:

- `set appfw profile <name> -xmlDoSAction [block] [log] [learn] [stats] [none]`

To configure individual XML Denial-of-Service rules, you must use the configuration utility. On the Checks tab of the Modify XML Denial-of-Service Check dialog box, select a rule and click Open to open the Modify XML Denial-of-Service dialog box for that rule. The individual dialog boxes differ for the different rules but are extremely simple. Some only allow you to enable or disable the rule; others allow you to modify a number by typing a new value in a text box.

The individual XML Denial-of-Service rules are:

## Maximum Element Depth

Restrict the maximum number of nested levels in each individual element to 256. If this rule is enabled, and the application firewall detects an XML request with an element that has more than the maximum number of allowed levels, it blocks the request. You can modify the maximum number of levels to any value from one (1) to 65,535.

## Maximum Element Name Length

Restrict the maximum length of each element name to 128 characters. This includes the name within the expanded namespace, which includes the XML path and element name in the following format:

```
{http://prefix.example.com/path/}target_page.xml
```

The user can modify the maximum name length to any value between one (1) character and 65,535.

## Maximum # Elements

Restrict the maximum number of any one type of element per XML document to 65,535. You can modify the maximum number of elements to any value between one (1) and 65,535.

## Maximum # Element Children

Restrict the maximum number of children (including other elements, character information, and comments) each individual element is allowed to have to 65,535. You can modify the maximum number of element children to any value between one (1) and 65,535.

## Maximum # Attributes

Restrict the maximum number of attributes each individual element is allowed to have to 256. You can modify the maximum number of attributes to any value between one (1) and 256.

## Maximum Attribute Name Length

Restrict the maximum length of each attribute name to 128 characters. You can modify the maximum attribute name

length to any value between one (1) and 2,048.

#### **Maximum Attribute Value Length**

Restrict the maximum length of each attribute value to 2048 characters. You can modify the maximum attribute name length to any value between one (1) and 2,048.

#### **Maximum Character Data Length**

Restrict the maximum character data length for each element to 65,535. You can modify the length to any value between one (1) and 65,535.

#### **Maximum File Size**

Restrict the size of each file to 20 MB. You can modify the maximum file size to any value.

#### **Minimum File Size**

Require that each file be at least 9 bytes in length. You can modify the minimum file size to any positive integer representing a number of bytes.

#### **Maximum # Entity Expansions**

Limit the number of entity expansions allowed to the specified number. Default: 1024.

#### **Maximum Entity Expansion Depth**

Restrict the maximum number of nested entity expansions to no more than the specified number. Default: 32.

#### **Maximum # Namespaces**

Limit the number of namespace declarations in an XML document to no more than the specified number. Default: 16.

#### **Maximum Namespace URI Length**

Limit the URL length of each namespace declaration to no more than the specified number of characters. Default: 256.

#### **Block Processing Instructions**

Block any special processing instructions included in the request. This rule has no user-modifiable values.

#### **Block DTD**

Block any document type definitions (DTD) included with the request. This rule has no user-modifiable values.

#### **Block External Entities**

Block all references to external entities in the request. This rule has no user-modifiable values.

#### **SOAP Array Check**

Enable or disable the following SOAP array checks:

- **Maximum SOAP Array Size.** The maximum total size of all SOAP arrays in an XML request before the connection is blocked. You can modify this value. Default: 20000000.
- **Maximum SOAP Array Rank.** The maximum rank or dimensions of any single SOAP array in an XML request before the connection is blocked. You can modify this value. Default: 16.

# XML Cross-Site Scripting Check

Jan 15, 2015

The XML Cross-Site Scripting check examines the user requests for possible cross-site scripting attacks in the XML payload. If it finds a possible cross-site scripting attack, it blocks the request.

To prevent misuse of the scripts on your protected web services to breach security on your web services, the XML Cross-Site Scripting check blocks scripts that violate the same origin rule, which states that scripts should not access or modify content on any server but the server on which they are located. Any script that violates the same origin rule is called a cross-site script, and the practice of using scripts to access or modify content on another server is called cross-site scripting. The reason cross-site scripting is a security issue is that a web server that allows cross-site scripting can be attacked with a script that is not on that web server, but on a different web server, such as one owned and controlled by the attacker.

Unfortunately, many companies have a large installed base of JavaScript-enhanced web content that violates the same origin rule. If you enable the XML Cross-Site Scripting check on such a site, you have to generate the appropriate exceptions so that the check does not block legitimate activity.

**Actions:** If you use the wizard or the configuration utility, in the XML Cross-Site Scripting Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the actions for the XML Cross-Site Scripting Check:

- set appfw profile <name> -XMLXSSAction [block [log] [stats] [none]]

**Relaxations:** You can use the configuration utility to specify relaxations for the XML Cross-Site Scripting check. On the Checks tab of the Modify XML Cross-Site Scripting Check dialog box, click Add to open the Add XML Cross-Site Scripting Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify XML Cross-Site Scripting Check Relaxation dialog box to edit an existing rule. Either dialog box provides the same options for configuring a relaxation, as described in "[Manual Configuration By Using the Configuration Utility](#)."

The XML Cross-Site Scripting check relaxation rules have the following parameters :

- **Name:** You can use literal strings or Regular Expressions to configure the name. The following expression exempts all elements beginning with the string name\_ followed by a string of upper- and lower-case letters or numbers that is at least two characters long and no more than fifteen characters long:

```
^name_[0-9A-Za-z]{2,15}$
```

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the name that you want to add as an exception, and nothing else. Careless use of Regular Expressions can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the XML Cross-Site Scripting check would otherwise have blocked.

- **Location** You can specify the Location of the Cross-site Scripting Check exception in your XML payload. The option ELEMENT is selected by Default. You can change it to select ATTRIBUTE.
- **Comment** This is an optional field. You can use up to a 255 character long string to describe the purpose of this relaxation Rule.

# XML SQL Injection Check

Dec 16, 2013

The XML SQL Injection check examines both the headers and the bodies of user requests for possible XML SQL Injection attacks. If it finds injected SQL, it blocks the request.

To prevent misusing the scripts on your protected web services to breach security on your web services, the XML SQL Injection check blocks scripts that violate the same origin rule, which states that scripts should not access or modify content on any server but the server on which they are located. Any script that violates the same origin rule is called a cross-site script, and the practice of using scripts to access or modify content on another server is called XML SQL Injection. The reason XML SQL Injection is a security issue is that a web server that allows XML SQL Injection can be attacked with a script that is not on that web server, but on a different web server, such as one owned and controlled by the attacker.

Unfortunately, many companies have a large installed base of JavaScript-enhanced web content that violates the same origin rule. If you enable the XML SQL Injection check on such a site, you have to generate the appropriate exceptions so that the check does not block legitimate activity. In addition, to prevent blocking of legitimate requests, this check ignores cookies that were set by the server, even if they contain elements that the Cookie Consistency check would otherwise block. You should keep this in mind when configuring this check.

Note: To prevent blocking of legitimate requests, this check ignores cookies that were set by the server, even if they contain elements that the Cookie Consistency check would otherwise block.

If you use the wizard or the configuration utility, in the Modify XML SQL Injection Check dialog box, on the General tab you can enable or disable Block, Log, and Statistics actions, and the following parameters:

- **Restrict checks to fields containing SQL special characters.** If you configure the application firewall to check only fields that contain SQL special strings, the application firewall skips web form fields that do not contain special characters. Since most SQL servers do not process SQL commands that are not preceded by a special character, enabling this parameter can significantly reduce the load on the application firewall and speed up processing without placing your protected web sites at risk.
- **SQL comments handling.** By default, the application firewall checks all SQL comments for injected SQL commands. Many SQL servers ignore anything in a comment, however, even if it is preceded by an SQL special character. For faster processing, if your SQL server ignores comments, you can configure the application firewall to skip comments when examining requests for injected SQL. The SQL comments handling options are:
  - **ANSI.** Skip ANSI-format SQL comments, which are normally used by UNIX-based SQL databases.
  - **Nested.** Skip nested SQL comments, which are normally used by Microsoft SQL Server.
  - **ANSI/Nested.** Skip comments that adhere to both the ANSI and nested SQL comment standards. Comments that match only the ANSI standard, or only the nested standard, are checked for injected SQL.

Caution: In most cases, you should not choose the Nested or the ANSI/Nested option unless your database runs on Microsoft SQL Server. Most other types of SQL server software do not recognize nested comments. If nested comments appear in a request directed to another type of SQL server, they may indicate an attempt to breach security on that server.
- **Check all Comments.** Check the entire request for injected SQL, without skipping anything. The default setting.
- **Check Request headers.** If Request header checking is enabled, the application firewall examines the headers of requests for XML SQL Injection attacks, instead of just URLs.

Caution: If you enable both request header checking and transformation, any SQL special characters found in headers

are also transformed. The Accept, Accept-Charset, Accept-Encoding, Accept-Language, Expect, and User-Agent headers normally contain semicolons (;), so enabling both Request header checking and transformation simultaneously may cause errors.

If you use the command-line interface, you can enter the following commands to configure the XML SQL Injection Check:

- set appfw profile <name> -XMLSQLInjectionAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -XMLSQLInjectionOnlyCheckFieldsWithSQLChars (**ON** | **OFF** )]
- set appfw profile <name> -XMLSQLInjectionParseComments ([**checkall**] | [**ansi** | **nested**] | [**ansinested**])

You configure the exceptions to the XML SQL Injection check by opening the Modify XML SQL Injection Check dialog box, Checks tab. An exception can consist of either a literal string or a PCRE-format regular expression. For information about adding, modifying, removing, enabling, or disabling exceptions, see "[Manual Configuration By Using the Configuration Utility](#)."

Following are examples of XML SQL Injection check relaxations:

- **Name element or attribute.** The following expression exempts all elements beginning with the string name\_ followed by a string of upper- and lower-case letters or numbers that is at least two characters long and no more than fifteen characters long:

```
^name_[0-9A-Za-z]{2,15}$
```

- **URL element or attribute.** The following expression exempts URLs with hostnames of web.example.com, with a path up to four levels deep followed by an optional file name and extension, but no HTML or query symbols :

```
^https?://web[.]example[.]com(/[^\<>?]{1,30}){0,4}(/[^\<>?]{1,30})*$
```

- **URL element or attribute (special characters).** The following expression exempts URLs with hostnames of web.türkçe-example.com, with the same path and file restrictions as above:

```
^https?://web[.]t\xC3\xBCrk\xC3\xA7e-example[.]com(/[^\<>?]{1,30}){0,4}(/[^\<>?]{1,30})*$
```

# XML Attachment Check

Feb 20, 2014

The XML Attachment check examines incoming requests for malicious attachments, and it blocks those requests that contain attachments that might breach applications security. The purpose of the XML Attachment check is to prevent an attacker from using an XML attachment to breach security on your server.

If you use the wizard or the configuration utility, in the Modify XML Attachment Check dialog box, on the General tab you can enable or disable the Block, Learn, Log, Statistics, and Learn actions:

If you use the command-line interface, you can enter the following command to configure the XML Attachment Check:

- `set appfw profile <name> -xmlAttachmentAction [block] [learn] [log] [stats] [none]`

You must configure the other XML Attachment check settings in the configuration utility. In the Modify XML Attachment Check dialog box, on the Checks tab, you can configure the following settings:

- **Maximum Attachment Size.** Allow attachments that are no larger than the maximum attachment size you specify. To enable this option, first select the Enabled check box, and then type the maximum attachment size in bytes in the Size text box.
- **Attachment Content Type.** Allow attachments of the specified content type. To enable this option, first select the Enabled check box, and then enter a regular expression that matches the Content-Type attribute of the attachments that you want to allow.
  - You can type the URL expression directly in the text window. If you do so, you can use the Regex Tokens menu to enter a number of useful regular expressions at the cursor instead of typing them manually.
  - You can click Regex Editor to open the Add Regular Expression dialog box and use it to construct the URL expression.

# Web Services Interoperability Check

Oct 30, 2013

The Web Services Interoperability (WS-I) check examines both requests and responses for adherence to the WS-I standard, and blocks those requests and responses that do not adhere to this standard. The purpose of the WS-I check is to block requests that might not interact with other XML appropriately. An attacker can use inconsistencies in interoperability to launch an attack on your XML application.

If you use the wizard or the configuration utility, in the Modify Web Services Interoperability Check dialog box, on the General tab you can enable or disable the Block, Log, Statistics, and Learn actions.

If you use the command-line interface, you can enter the following command to configure the Web Services Interoperability check:

- `set appfw profile <name> -xmlWSIAction [block] [log] [learn] [stats] [none]`

To configure individual Web Services Interoperability rules, you must use the configuration utility. On the Checks tab of the Modify Web Services Interoperability Check dialog box, select a rule and click Enable or Disable to enable or disable the rule. You can also click Open to open the Web Services Interoperability Detail message box for that rule. The message box displays read-only information about the rule. You cannot modify or make other configuration changes to any of these rules.

# XML Message Validation Check

Feb 20, 2014

The XML Message Validation check examines requests that contain XML messages to ensure that they are valid. If a request contains an invalid XML message, the application firewall blocks the request. The purpose of the XML Validation check is to prevent an attacker from using specially constructed invalid XML messages to breach the security of your application.

If you use the wizard or the configuration utility, in the Modify XML Message Validation Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the XML Message Validation Check:

- `set appfw profile <name> -xmlValidationAction [block] [log] [stats] [none]`

You must use the configuration utility to configure the other XML Validation check settings. In the Modify XML Message Validation Check dialog box, on the Checks tab, you can configure the following settings:

- **XML Message Validation.** Use one of the following options to validate the XML message:
  - **SOAP Envelope.** Validate only the SOAP envelope of XML messages.
  - **WSDL.** Validate XML messages by using an XML SOAP WSDL. If you choose WSDL validation, in the WSDL Object drop-down list you must choose a WSDL. If you want to validate against a WSDL that has not already been imported to the application firewall, you can click the Import button to open the Manage WSDL Imports dialog box and import your WSDL. See "[WSDL](#)" for more information.
    - If you want to validate the entire URL, leave the Absolute radio button in the End Point Check button array selected. If you want to validate only the portion of the URL after the host, select the Relative radio button.
    - If you want the application firewall to enforce the WSDL strictly, and not allow any additional XML headers not defined in the WSDL, you must clear the Allow additional headers not defined in the WSDL check box.  
Caution: If you uncheck the Allow Additional Headers not defined in the WSDL check box, and your WSDL does not define all XML headers that your protected XML application or Web 2.0 application expects or that a client sends, you may block legitimate access to your protected service.
  - **XML Schema.** Validate XML messages by using an XML schema. If you choose XML schema validation, in the XML Schema Object drop-down list you must choose an XML schema. If you want to validate against an XML schema that has not already been imported to the application firewall, you can click the Import button to open the Manage XML Schema Imports dialog box and import your WSDL. See "[WSDL](#)" for more information.
- **Response Validation.** By default, the application firewall does not attempt to validate responses. If you want to validate responses from your protected application or Web 2.0 site, select the Validate Response check box. When you do, the Reuse the XML Schema specified in request validation check box and the XML Schema Object drop-down list are activated.
  - Check the Reuse XML Schema check box to use the schema you specified for request validation to do response validation as well.  
Note: If you check this check box, the XML Schema Object drop-down list is grayed out.
  - If you want to use a different XML schema for response validation, use the XML Schema Object drop-down list to select or upload that XML schema .

# XML SOAP Fault Filtering Check

Oct 30, 2013

The XML SOAP Fault Filtering check examines responses from your protected web services and filters out XML SOAP faults. This prevents leaking of sensitive information to attackers.

If you use the wizard or the configuration utility, in the Modify XML SOAP Fault Filtering Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions, and the Remove action, which removes SOAP faults before forwarding the response to the user.

If you use the command-line interface, you can enter the following command to configure the XML SOAP Fault Filtering Check:

```
set appfw profile <name> -XMLSOAPFaultAction [block] [log] [stats] [none]
```

You cannot configure exceptions to the XML SOAP Fault Filtering check. You can only enable or disable it.

# Managing Content Types

Jun 12, 2014

Web servers usually add a Content-Type header that contains a MIME/type definition for the type of content in each file that the web server serves to users. Web servers serve many different types of content. For example, standard HTML is assigned the "text/html" MIME type. JPG images are assigned the "image/jpeg" or "image/jpg" content type. A normal web server can serve dozens or hundreds of different types of content, all defined in the Content Type header by an assigned MIME/type.

Many application firewall filtering rules are designed to filter specific types of content. Because filtering rules that apply to one type of content (such as HTML) are often inappropriate when filtering a different type of content (such as images), the application firewall attempts to determine the content type of requests and responses before it filters them. When a web server or browser does not add a Content-Type header to a request or response, the application firewall applies a default content type to the connection and filters the content accordingly.

The default content type is normally "application/octet-stream", the most generic MIME/type definition. This MIME/type is appropriate for any type of content that a web server is likely to serve, but also does not provide much information to the application firewall to allow it to choose appropriate filtering. If a protected web server on your network is configured to add accurate content type headers to the content it serves, or serves only one type of content, you can create a profile for that web server and assign a different default content type to it to improve both the speed and the accuracy of filtering.

You can also configure a list of allowed response content types for a specific profile. When this feature is configured, if the application firewall filters a response that does not match one of the allowed content types, it blocks the response.

Requests must always be of either the "application/x-www-form-urlencoded" or "multipart/form-data" types. The application firewall bypasses any request that has any other content type designated.

Note: You cannot include the "application/x-www-form-urlencoded" or "multipart/form-data" content types on the allowed response content types list.

At the command prompt, type the following commands:

- set appfw profile <name> -requestContentType <type>
- save ns config

## Example

The following example sets the "text/html" content type as the default for the specified profile:

```
set appfw profile profile1 -requestContentType "text/html"
save ns config
```

At the command prompt, type the following commands:

- unset appfw profile <name> -requestContentType <type>
- save ns config

## Example

The following example unsets the default content type of "text/html" for the specified profile, allowing the type to revert to "application/octet-stream":

```
unset appfw profile profile1 -requestContentType "text/html"
save ns config
```

At the command prompt, type the following commands:

- set appfw profile <name> -responseContentType <type>
- save ns config

## Example

The following example sets the "text/html" content type as the default for the specified profile:

```
set appfw profile profile1 -responseContentType "text/html"
save ns config
```

At the command prompt, type the following commands:

- unset appfw profile <name> -responseContentType <type>
- save ns config

## Example

The following example unsets the default content type of "text/html" for the specified profile, allowing the type to revert to "application/octet-stream":

```
unset appfw profile profile1 -responseContentType "text/html"
save ns config
```

At the command prompt, type the following commands:

- bind appfw profile <name> -ContentType <contentTypeName>
- save ns config

## Example

The following example adds the "text/shtml" content type to the allowed content types list for the specified profile:

```
bind appfw profile profile1 -contentType "text/shtml"
save ns config
```

At the command prompt, type the following commands:

- unbind appfw profile <name> -ContentType <contentTypeName>

- save ns config

## Example

The following example removes the "text/shtml" content type from the allowed content types list for the specified profile:

```
unbind appfw profile profile1 -contentType "text/shtml"
save ns config
```

1. Navigate to Security > Application Firewall > Profiles.
2. In the details pane, select the profile that you want to configure, and then click Edit. The Configure Application Firewall Profile dialog box is displayed.
3. In the Configure Application Firewall Profile dialog box, click the Settings tab
4. On the Settings tab, scroll down about halfway to the Content Type area.
5. In the Content Type area, configure the default request or response content type:
  - To configure the default request content type, type the MIME/type definition of the content type you want to use in the Default Request text box.
  - To configure the default response content type, type the MIME/type definition of the content type you want to use in the Default Response text box.
  - To create a new allowed content type, click Add. The Add Allowed Content Type dialog box is displayed.
  - To edit an existing allowed content type, select that content type, and then click Open. The Modify Allowed Content Type dialog box is displayed.
6. To manage the allowed content types, click Manage Allowed Content Types.
7. To add a new content type or modify an existing content type, click Add or Open, and in the Add Allowed Content Type or Modify Allowed Content Type dialog box, do the following steps.
  1. Select/clear the Enabled check box to include the content type in, or exclude it from, the list of allowed content types.
  2. In the Content Type text box, type a regular expression that describes the content type that you want to add, or change the existing content type regular expression.  
Content types are formatted exactly as MIME type descriptions are.

Note: You can include any valid MIME type on the allowed contents type list. Since many types of document can contain active content and therefore could potentially contain malicious content, you should exercise caution when adding MIME types to this list.

3. In the Comments text box, add an optional comment that describes the reason for adding this particular MIME type to the allowed contents type list.
4. Click Create or OK to save your changes.
8. Click Close to close the Manage Allowed Content Types dialog box and return to the Settings tab.
9. Click OK to save your changes.

# Profiles

Feb 03, 2014

A profile is a collection of security settings that are used to protect specific types of web content or specific parts of your web site. In a profile, you determine how the application firewall applies each of its filters (or checks) to requests to your web sites, and responses from them. The application firewall supports two types of profile: four built-in (default) profiles that do not require further configuration, and user-defined profiles that do require further configuration.

The four application firewall built-in profiles provide simple protection for applications and web sites that either do not require protection, or that should not be directly accessed by users at all. These profile types are:

- **APFW\_BYPASS**. Skips all application firewall filtering and sends the unmodified traffic to the protected application or web site, or to the client.
- **APFW\_RESET**. Resets the connection, requiring that the client re-establish his or her session by visiting a designated start page.
- **APFW\_DROP**. Drops all traffic to or from the protected application or web site, and sends no response of any kind to the client.
- **APFW\_BLOCK**. Blocks traffic to or from the protected application or web site.

You use the built-in profiles exactly as you do user-defined profiles, by configuring a policy that selects the traffic to which you want to apply the profile and then associating the profile with your policy. Since you do not have to configure a built-in policy, it provides a quick way to allow or block specified types of traffic or traffic that is sent to specific applications or web sites.

User-defined profiles are profiles that are build and configured by users. Unlike the default profiles, you must configure a user-defined profile before it will be of use filtering traffic to and from your protected applications.

There are three types of user-defined profile:

- **HTML**. Protects HTML-based web pages.
- **XML**. Protects XML-based web services and web sites.
- **Web 2.0**. Protects Web 2.0 content that combines HTML and XML content, such as ATOM feeds, blogs, and RSS feeds.

The application firewall has a number of security checks, all of which can be enabled or disabled, and configured in a number of ways in each profile. Each profile also has a number of settings that control how it handles different types of content. Finally, rather than manually configuring all of the security checks, you can enable and configure the learning feature. This feature observes normal traffic to your protected web sites for a period of time, and uses those observations to provide you with a tailored list of recommended exceptions (*relaxations*) to some security checks, and additional rules for other security checks.

During initial configuration, whether by using the Application Firewall Wizard or manually, you normally create one general purpose profile to protect all content on your web sites that is not covered by a more specific profile. After that, you can create as many specific profiles as you want to protect more specialized content.

The Profiles pane consists of a table that contains the following elements:

**Name.** Displays all the application firewall profiles configured in the appliance.

**Bound signature.** Displays the signatures object that is bound to the profile in the previous column, if any.

**Policies.** Displays the application firewall policy that invokes the profile in the leftmost column of that row, if any.

**Comments.** Displays the comment associated with the profile in the leftmost column of that row, if any.

**Profile Type.** Displays the type of profile. Types are Built-In, HTML, XML, and Web 2.0.

Above the table is a row of buttons and a drop-down list that allow you to create, configure, delete, and view information about your profiles:

- **Add.** Add a new profile to the list.
- **Edit.** Edit the selected profile.
- **Delete.** Delete the selected profile from the list.
- **Statistics.** View the statistics for the selected profile.
- **Action.** Drop-down list that contains additional commands. Currently allows you to import a profile that was exported from another application firewall configuration.

# Creating Application Firewall Profiles

Jun 12, 2014

You can create an application firewall profile in one of two ways: by using the command line, and by using the configuration utility. Creating a profile by using the command line requires that you specify options on the command line. The process is similar to that of [configuring an existing profile](#), and with a few exceptions the two commands take the same parameters.

Creating a profile by using the configuration utility requires that you specify only two options. You specify basic or advanced *defaults*, the default configuration for the various security checks and settings that are part of a profile, and choose the profile *type* to match the type of content that the profile is intended to protect. You can also, optionally, add a comment. After you create the profile, you must then configure it by selecting it in the data pane, and then clicking Edit.

If you plan to use the learning feature or to enable and configure a large number of advanced protections, you should choose advanced defaults. In particular, if you plan to configure either of the SQL injection checks, either of the cross-site scripting checks, any check that provides protection against Web form attacks, or the cookie consistency check, you should plan to use the learning feature. Unless you include the proper exceptions for your protected Web sites when configuring these checks, they can block legitimate traffic. Anticipating all of the necessary exceptions without creating any that are too broad is difficult. The learning feature makes this task much easier. Otherwise, basic defaults are quick and should provide the protection that your web applications need.

There are three profile types:

- **HTML**. Protects standard HTML-based web sites.
- **XML**. Protects XML-based web services and web sites.
- **Web 2.0 (HTML XML)**. Protects sites that contain both HTML and XML elements, such as ATOM feeds, blogs, and RSS feeds.

There are also a few restrictions on the name that you can give to a profile. A profile name cannot be the same as the name assigned to any other profile or action in any feature on the NetScaler appliance. Certain action or profile names are assigned to built-in actions or profiles, and can never be used for user profiles. A complete list of disallowed names can be found in the Application Firewall Profile [Supplemental Information](#). If you attempt to create a profile with a name that has already been used for an action or a profile, an error message is displayed and the profile is not created.

At the command prompt, type the following commands:

- `add appfw profile <name> [-defaults ( basic | advanced )]`
- `set appfw profile <name> -type ( HTML | XML | HTML XML )`
- `set appfw profile <name> -comment "<comment>"`
- `save ns config`

## Example

The following example adds a profile named `pr-basic`, with basic defaults, and assigns a profile type of HTML. This is the appropriate initial configuration for a profile to protect an HTML Web site.

```
add appfw profile pr-basic -defaults basic -comment "Simple profile for web sites."
set appfw profile pr-basic -type HTML
```

save ns config

Creating an application firewall profile requires that you specify only a few configuration details.

1. Navigate to Security > Application Firewall > Profiles.
2. In the details pane, click Add.
3. In the Create Application Firewall Profile dialog box, type a name for your profile.  
The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore ( ) symbols.
4. Choose the profile type from the drop-down list.
5. Click Create, and then click Close.

# Configuring Application Firewall Profiles

Jun 12, 2014

To configure a user-defined application firewall profile, first configure the security checks, which are called *deep protections* or *advanced protections* in the application firewall wizard. Certain checks require configuration if you are to use them at all. Others have default configurations that are safe but limited in scope; your web sites might need or benefit from a different configuration that takes advantage of additional features of certain security checks.

After you have configured the security checks, you can also configure a number of other settings that control the behavior, not of a single security check, but the application firewall feature. The default configuration is sufficient to protect most web sites, but you should review them to make sure that they are right for your protected web sites.

For more information about the application firewall security checks, see "[Advanced Protections](#)."

To configure an application firewall profile by using the command line

At the command prompt, type the following commands:

- set appfw profile <name> <arg1> [<arg2> ...]

where:

- <arg1> = a parameter and any associated options.
- <arg2> = a second parameter and any associated options.
- ... = additional parameters and options.

For descriptions of the parameters to use when configuring specific security checks, see "[Advanced Protections](#)."

- save ns config

## Example

The following example shows how to enable blocking for the HTML SQL Injection and HTML Cross-Site Scripting checks in a profile named pr-basic. This command enables blocking for those actions while making no other changes to the profile.

```
set appfw profile pr-basic -crossSiteScriptingAction block
-SQLInjectionAction block
```

To configure an application firewall profile by using the configuration utility

1. Navigate to Security > Application Firewall > Profiles.
2. In the details pane, select the profile that you want to configure, and then click Edit.
3. In the Configure Application Firewall Profile dialog box, on the Security Checks tab, configure the security checks.
  - To enable or disable an action for a check, in the list, select or clear the check box for that action.
  - To configure other parameters for those checks that have them, in the list, click the blue chevron to the far right of that check. In the dialog box that appears, configure the parameters. These vary from check to check.You can also select a check and, at the bottom of the dialog box, click Open to display the Configure Relaxation dialog box or Configure Rule dialog box for that check. These dialog boxes also vary from check to check. Most of them include a Checks tab and a General tab. If the check supports relaxations or user-defined rules, the Checks tab includes an Add button, which opens yet another dialog box, in which you can specify a relaxation or rule for the check. (A relaxation is a rule for exempting specified traffic from the check.) If relaxations have already been configured, you can select one and click Open to modify it.

- To review learned exceptions or rules for a check, select the check, and then click Learned Violations. In the Manage Learned Rules dialog box, select each learned exception or rule in turn.
    - To edit the exception or rule, and then add it to the list, click Edit & Deploy.
    - To accept the exception or rule without modification, click Deploy.
    - To remove the exception or rule from the list, click Skip.
  - To refresh the list of exceptions or rules to be reviewed, click Refresh.
  - To open the Learning Visualizer and use it to review learned rules, click Visualizer.
  - To review the log entries for connections that matched a check, select the check, and then click Logs. You can use this information to determine which checks are matching attacks, so that you can enable blocking for those checks. You can also use this information to determine which checks are matching legitimate traffic, so that you can configure an appropriate exemption to allow those legitimate connections. For more information about the logs, see "[Logs, Statistics, and Reports](#)."
  - To completely disable a check, in the list, clear all of the check boxes to the right of that check.
4. On the Settings tab, configure the profile settings.
    - To associate the profile with the set of signatures that you previously created and configured, under Common Settings, choose that set of signatures in the Signatures drop-down list.  
Note: You may need to use the scroll bar on the right of the dialog box to scroll down to display the Common Settings section.
    - To configure an HTML or XML Error Object, select the object from the appropriate drop-down list.  
Note: You must first upload the error object that you want to use in the Imports pane. For more information about importing error objects, see "[Imports](#)."
    - To configure the default XML Content Type, type the content type string directly into the Default Request and Default Response text boxes, or click Manage Allowed Content Types to manage the list of allowed content types.  
">>More...."
  5. If you want to use the learning feature, click Learning, and configure the learning settings for the profile, as described in "[Configuring and Using the Learning Feature](#)".
  6. Click OK to save your changes and return to the Profiles pane.

# Changing an Application Firewall Profile Type

Jun 12, 2014

If you chose the wrong profile type for an application firewall profile, or the type of content on the protected web site has changed, you can change the profile type.

Note: When you change the profile type, you lose all configuration settings and learned relaxations or rules for the features that the new profile type does not support. For example, if you change the profile type from Web 2.0 to XML, you lose any configuration options for Start URL, Form Field Consistency Check, and the other HTML-specific security checks. The configuration for any options that is supported by both the old and the new profile types remains unchanged. To change an application firewall profile type by using the command line interface

At the command prompt, type the following commands:

- set appfw profile <name> -type ( **HTML** | **XML** | **HTML XML** )
- save ns config

## Example

The following example changes the type of a profile named pr-basic, from HTML to HTML XML, which is equivalent to the Web 2.0 type in the configuration utility.

```
set appfw profile pr-basic -type HTML XML
save ns config
```

To change an application firewall profile type by using the configuration utility.

1. Navigate to Security > Application Firewall > Policies.
2. In the details pane, click Action, and then Change Profile Type.
3. In the Change Application Firewall Profile Type dialog box, Profile Type drop-down list, select a new profile type.
4. Click OK to save your changes and return to the Profiles pane.

# Exporting and Importing an Application Firewall Profile

Oct 07, 2014

You can export application firewall profiles to your local computer as files, and import previously exported profile files. You might want to configure an application firewall in a test bed configuration and then export the profile or profiles so that you can import the profile configuration to your production NetScaler ADCs. You might also want to export a profile to back up your configuration before making changes so that you can easily roll the configuration back to a known state if necessary.

To export an application firewall profile by using the command line interface

At the command prompt, type the following commands:

- `archive appfw profile <name> <archiveName>`

Make the following substitutions:

- `name`—Name of the profile to archive.
- `archiveName`—Name of the archive file to create.
- `export appfw archive <archiveName> <target>`

Make the following substitutions:

- `archiveName`—Name of the archive to export. (The same name as in the previous step.)
- `target`—Full path and filename of the exported file on your local computer. Enclose in straight double quotation marks if the path or filename contains spaces.

## Example

Assuming that your local computer uses the Windows 7 operating system, and you are logged onto your local computer as "jsmith", the following example exports a profile named `pr-basic` to the home directory.

```
archive appfw profile pr-basic pr-basic.tgz
```

```
export appfw pr-basic.tgz "C:\Users\jsmith\Documents\pr-basic.tgz"
```

To export an application firewall profile by using the configuration utility

1. Navigate to Security > Application Firewall > Profiles.
2. In the details pane, select a profile to export, and then click Actions and select Export.
3. Choose the local path and filename for the exported file.
  - You can accept the default choice, which consists of the path to your home directory or folder and a filename of the profile name plus the extension `.tgz`, which indicates a Unix-style tar archive that is compressed by gzip.
  - You can type a new path and/or file name. The path must exist, and the filename must be a valid filename in your local computer's operating system. If you do not specify the `.tgz` extension, it is added automatically.
  - You can use the Browse dialog to locate the path and save the file under the default filename. (Recommended)
4. Click Export. The profile is exported and saved to your computer under the path and file name that you designated.

To import an application firewall profile by using the command line interface

At the command prompt, type the following command:

- `import appfw archive <source> <archiveName>`

Make the following substitutions:

- `source`— Full path and filename of the archive file to be imported from your local computer. Enclose in straight double quotation marks if the path or filename contains spaces.
- `archiveName`— Name of the archive file on the NetScaler ADC.
- `restore appfw profile <archiveName>`

## Example

Assuming that your local computer uses the Windows 7 operating system, and you are logged onto your local computer as "jsmith", the following example imports a profile named `pr-basic.tgz`, located in your home directory, to the application firewall and installs it as a profile named `pr-basic`.

```
import appfw archive "C:\Users\jsmith\Documents\pr-basic.tgz" pr-basic.tgz
restore appfw profile pr-basic.tgz
```

# Configuring and Using the Learning Feature

Sep 28, 2017

The learning feature is a repetitive pattern filter that observes activity on a web site or application protected by the application firewall, to determine what constitutes normal activity on that web site or application. It then generates a list of up to 2,000 suggested rules or exceptions (relaxations) for each security checks that includes support for the learning feature. Users normally find it easier to configure relaxations by using the learning feature than by entering the necessary relaxations manually.

The security checks that support the learning feature are:

- Start URL check
- Cookie Consistency check
- Form Field Consistency check
- Field Formats check
- CSRF Form Tagging check
- HTML SQL Injection check
- HTML Cross-Site Scripting check
- XML Denial-of-Service check
- XML Attachment check
- Web Services Interoperability check

You perform two different types of activities when using the learning feature. First, you enable and configure the feature to use it. You can use learning on all traffic to your protected web applications, or you can configure a list of IPs (called the *Add Trusted Learning Clients* list) from which the learning feature should generate recommendations. Second, after the feature has been enabled and has processed a certain amount of traffic to your protected web sites, you review the list of suggested rules and relaxations (learned rules) and mark each with one of the following designations:

- **Edit & Deploy.** The rule is pulled into the Edit dialog box so that you can modify it, and the modified form is deployed.
- **Deploy.** The unmodified learned rule is placed on the list of rules or relaxations for this security check.
- **Skip.** The learned rule is placed on a list of rules or relaxations that are not deployed. The learned rule is removed when skipped. However, as they are not added to relaxations, they might get learned again.

Learning is not performed only when relaxations are in place, except for field format rules. When rules are skipped, they are only removed from learned database. As relaxations are not added, they might get learned again. When rules are deployed, they are removed from learned database and also relaxations are added for the rules. As relaxations are added, they would not be learned again. For fieldformat protection, learning is performed irrespective of relaxations.

Although you can use the command line interface for basic configuration of the learning feature, the feature is designed primarily for configuration through the Application Firewall wizard or the configuration utility. You can perform only limited configuration of the learning feature by using the command line.

The wizard integrates configuration of learning features with configuration of the application firewall as a whole, and is therefore the easiest method for configuring this feature on a new NetScaler appliance or when managing a simple application firewall configuration. The configuration utility visualizer and manual interface both provide direct access to all learned rules for all security checks, and are therefore often preferable when you must review learned rules for a large number of security checks.

The learning database is limited to 20 MB in size, which is reached after approximately 2,000 learned rules or relaxations are generated per security check for which learning is enabled. If you do not regularly review and either approve or ignore learned rules and this limit is reached, an error is logged to the NetScaler log and no more learned rules are generated until you review the existing learned rules and relaxations.

If learning stops because the database has reached its size limit, you can restart learning either by reviewing the existing learned rules and relaxations or by resetting the learning data. After learned rules or relaxations are approved or ignored, they are removed from the database. After you reset the learning data, all existing learning data is removed from the database and it is reset to its minimum size. When the database falls below 20 MB in size, learning restarts automatically.

To configure the learning settings by using the command line interface

Specify the application firewall profile to be configured and, for each security check that you want to include in that profile, specify the minimum threshold or the percent threshold. The minimum threshold is an integer representing the minimum number of user sessions that the application firewall must process before it learns a rule or relaxation (default: 1). The percent threshold is an integer representing the percentage of user sessions in which the application firewall must observe a particular pattern (URL, cookie, field, attachment, or rule violation) before it learns a rule or relaxation (default: 0). Use the following commands:

- `set appfw learningsettings <profileName> [-startURLMinThreshold <positive_integer>] [-startURLPercentThreshold <positive_integer>] [-cookieConsistencyMinThreshold <positive_integer>] [-cookieConsistencyPercentThreshold <positive_integer>] [-CSRFtagMinThreshold <positive_integer>] [-CSRFtagPercentThreshold <positive_integer>] [-fieldConsistencyMinThreshold <positive_integer>] [-fieldConsistencyPercentThreshold <positive_integer>] [-crossSiteScriptingMinThreshold <positive_integer>] [-crossSiteScriptingPercentThreshold <positive_integer>] [-SQLInjectionMinThreshold <positive_integer>] [-SQLInjectionPercentThreshold <positive_integer>] [-fieldFormatMinThreshold <positive_integer>] [-fieldFormatPercentThreshold <positive_integer>] [-XMLWSIMinThreshold <positive_integer>] [-XMLWSIPercentThreshold <positive_integer>] [-XMLAttachmentMinThreshold <positive_integer>] [-XMLAttachmentPercentThreshold <positive_integer>]`
- `save ns config`

## Example

The following example enables and configures the learning settings in the profile `pr-basic` for the HTML SQL Injection security check. This is an appropriate initial test bed learning configuration, where you have complete control over the traffic that is sent to the application firewall.

```
set appfw learningsettings pr-basic -SQLInjectionMinThreshold 10
set appfw learningsettings pr-basic -SQLInjectionPercentThreshold 70
save ns config
```

To reset learning settings to their defaults by using the command line interface

To remove any custom configuration of the learning settings for the specified profile and security check, and return the learning settings to their defaults, at the command prompt type the following commands:

- `unset appfw learningsettings <profileName> [-startURLMinThreshold ] [-startURLPercentThreshold ] [-cookieConsistencyMinThreshold ] [-cookieConsistencyPercentThreshold ] [-CSRFtagMinThreshold ] [-CSRFtagPercentThreshold ] [-fieldConsistencyMinThreshold ] [-fieldConsistencyPercentThreshold ] [-crossSiteScriptingMinThreshold ] [-crossSiteScriptingPercentThreshold ] [-SQLInjectionMinThreshold ] [-SQLInjectionPercentThreshold ] [-fieldFormatMinThreshold ] [-fieldFormatPercentThreshold ] [-XMLWSIMinThreshold ] [-XMLWSIPercentThreshold ] [-XMLAttachmentMinThreshold ] [-XMLAttachmentPercentThreshold ]`

XMLWSIPercentThreshold ] [-XMLAttachmentMinThreshold ] [-XMLAttachmentPercentThreshold]

- save ns config

To display the learning settings for a profile by using the command line interface

At the command prompt, type the following command:

```
show appfw learningsettings <profileName>
```

To display unreviewed learned rules or relaxations for a profile by using the command line interface

At the command prompt, type the following command:

```
show appfw learningdata <profileName> <securityCheck>
```

To remove specific unreviewed learned rules or relaxations from the learning database by using the command line interface

At the command prompt, type the following command:

```
rm appfw learningdata <profileName> (-startURL <expression> | -cookieConsistency <string> | (-fieldConsistency <string> <formActionURL>) | (-crossSiteScripting <string> <formActionURL>) | (-SQLInjection <string> <formActionURL>) | (-fieldFormat <string><formActionURL>) | (-CSRFTag <expression> <CSRFFormOriginURL>) | -XMLDoSCheck <expression> | -XMLWSICheck <expression> | -XMLAttachmentCheck <expression>) [-TotalXMLRequests]
```

## Example

The following example removes all unreviewed learned relaxations for the pr-basic profile, HTML SQL Injection security check, that apply to the LastName form field.

```
rm appfw learningdata pr-basic -SQLInjection LastName
```

To remove all unreviewed learned data by using the command line interface

At the command prompt, type the following command:

```
reset appfw learningdata
```

To export learning data by using the command line interface

At the command prompt, type the following command:

```
export appfw learningdata <profileName> <securitycheck>[-target <string>]
```

## Example

The following example exports learned relaxations for the pr-basic profile and the HTML SQL Injection security check to a comma-separated values (CSV) format file in the /var/learn\_data/ directory under the filename specified in the -target parameter.

```
export appfw learningdata pr-basic SQLInjection -target sqli_Id
```

To configure the Learning feature by using the configuration utility

1. Navigate to Security > Application Firewall > Profiles.
2. In the Profiles pane, select the profile, and then click Edit.
3. Click the Learning tab. At the top of the Learning tab is list of the security checks that are available in the current profile and that support the learning feature.
4. To configure the learning thresholds, select a security check, and then type the appropriate values in the following text

boxes:

- **Minimum number threshold.** Depending on which security check's learning settings you are configuring, the minimum number threshold might refer to the minimum number of total user sessions that must be observed, the minimum number of requests that must be observed, or the minimum number of times a specific form field must be observed, before a learned relaxation is generated. Default: 1
  - **Percentage of times threshold.** Depending on which security check's learning settings you are configuring, the percentage of times threshold might refer to the percentage of total observed user sessions that violated the security check, the percentage of requests, or the percentage of times a form field matched a particular field type, before a learned relaxation is generated. Default: 0
5. To remove all learned data and reset the learning feature, so that it must start its observations again from the beginning, click Remove All Learned Data.  
Note: This button removes only learned recommendations that have not been reviewed and either approved or skipped. It does not remove learned relaxations that have been accepted and deployed.
  6. To restrict the learning engine to traffic from a specific set of IPs, click Trusted Learning Clients, and add the IP addresses that you want to use to the list.
    1. To add an IP address or IP address range to the Trusted Learning Clients list, click Add.
    2. In the Add Trusted Learning Clients dialog box, Trusted Clients IP list box, type the IP address or an IP address range in CIDR format.
    3. In the Comments text area, type a comment that describes this IP address or range.
    4. Click Create to add your new IP address or range to the list.
    5. To modify an existing IP address or range, click the IP address or range, and then click Open. Except for the name, the dialog box that appears is identical to the Add Trusted Learning Clients dialog box.
    6. To disable or enable an IP address or range, but leave it on the list, click the IP address or range, and then click Disable or Enable, as appropriate.
    7. To remove an IP address or range completely, click the IP address or range, and then click Remove.
  7. Click Close to return to the Configure Application Firewall Profile dialog box.
  8. Click Close to close the Configure Application Firewall Profile dialog box, and return to the Application Firewall Profile screen.

To review learned rules or relaxations by using the configuration utility

1. Navigate to Security > Application Firewall > Profiles.
2. Select the security check for which you want to review learned rules or relaxations, and then click Manage Rules.
3. In the Manage Learned Rules dialog box, choose how you want to review the learned rules.
  - To review the actual learned patterns as displayed in the window, do nothing and proceed to the next step.
  - To review the learned data hierarchically as a branching tree, enabling you to choose general patterns that match many of the learned patterns, click Visualizer.
4. If you have chosen to review actual learned patterns, perform the following steps.
  1. Select the first learned relaxation and choose how to handle it.
    - To modify and then accept the relaxation, click Edit & Deploy, edit the relaxation regular expression, and then click OK.
    - To accept the relaxation without modifications, click Deploy.
    - To remove the relaxation from the list without deploying it, click Skip.
  2. Repeat the previous step to review each additional learned relaxation.

5. If you have chosen to use the Learning Visualizer, perform the following steps.
  1. In the branching hierarchical display, select a node that contains a learned pattern, and choose how to handle it. The screen area beneath the tree structure, under Regex of Selected Node, displays a generalized expression that matches all of the patterns in that node. If you want to display an expression that matches just one of the branches or just one of the leaves, select that branch or leaf.
    - To modify and then accept the learned relaxation, click Edit & Deploy, edit the relaxation regular expression, and then click OK.
    - To accept the relaxation without modifications, click Deploy.
    - To remove the modification from the list without deploying it, click Skip.
  2. Repeat the previous step to review other portions of the display.
  3. Click Close to return to the Manage Learned Rules dialog box.
6. Click Close to return to the Configure Application Firewall Profile dialog box.
7. Click Close to close the Configure Application Firewall Profile dialog box, and return to the Application Firewall Profile screen.

# Supplemental Information about Profiles

Oct 01, 2013

Following is supplemental information about particular aspects of application firewall profiles. This information explains how to include special characters in a security check rule or relaxation, and how to use variables when configuring profiles.

## Configuration Variable Support

Instead of using static values, to configure the application firewall's security checks and settings, you can now use standard NetScaler named variables. By creating variables, you can more easily export and then import configurations to new NetScaler appliances, or update existing NetScaler appliances from a single set of configuration files. This simplifies updates when you use a test bed setup to develop a complex application firewall configuration that is tuned for your local network and servers and then transfer that configuration to your production NetScaler appliances.

You create application firewall configuration variables in the same manner as you do any other NetScaler named variables, following standard NetScaler conventions. To create a named expression variable by using the configuration utility, you use the "[Add Expression dialog box](#)." To create a named expression variable by using the NetScaler command line, you use the add expression command followed by the appropriate parameter.

The following URLs and expressions can be configured with variables instead of static values:

- **Start URL** (-starturl)
- **Deny URL** (-denyurl)
- **Form Action URL** for *Form Field Consistency Check* (-fieldconsistency)
- **Action URL** for *XML SQL Injection Check* (-xmlSQLInjection)
- **Action URL** for *XML Cross-Site Scripting Check* (-xmlXSS)
- **Form Action URL** for *HTML SQL Injection Check* (-sqlInjection)
- **Form Action URL** for *Field Format Check* (-fieldFormat)
- **Form Origin URL** and **Form Action URL** for *Cross-Site Request Forgery (CSRF) Check* (-csrfTag)
- **Form Action URL** for *HTML Cross-Site Scripting Check* (-crossSiteScripting)
- **Safe Object** (-safeObject)
- **Action URL** for *XML Denial-of-Service (XDoS) check* (-XMLDoS)
- **URL** for *Web Services Interoperability check* (-XMLWSIURL)
- **URL** for *XML Validation check* (-XMLValidationURL)
- **URL** for *XML Attachment check* (-XMLAttachmentURL)

For more information, see "[Policies and Expressions](#)."

To use a variable in the configuration, you enclose the variable name between two at (@) symbols and then use it exactly as you would the static value that it replaces. For example, if you are configuring the Deny URL check by using the configuration utility and want to add the named expression variable myDenyURL to the configuration, you would type @myDenyURL@ into the Add Deny URL dialog box, Deny URL text area. To do the same task by using the NetScaler command line, you would type add appfw profile <name> -denyURLAction @myDenyURL@.

## PCRE Character Encoding Format

The NetScaler operating system supports direct entry of characters in the printable ASCII character set only—characters with hexadecimal codes between HEX 20 (ASCII 32) and HEX 7E (ASCII 127). To include a character with a code outside that range in your application firewall configuration, you must enter its UTF-8 hexadecimal code as a PCRE regular

expression.

A number of character types require encoding using a PCRE regular expression if you include them in your application firewall configuration as a URL, form field name, or Safe Object expression. They include:

- **Upper-ASCII characters.** Characters with encodings from HEX 7F (ASCII 128) to HEX FF (ASCII 255). Depending on the character map used, these encodings can refer to control codes, ASCII characters with accents or other modifications, non-Latin alphabet characters, and symbols not included in the basic ASCII set. These characters can appear in URLs, form field names, and safe object expressions.
- **Double-Byte characters.** Characters with encodings that use two 8-byte words. Double-byte characters are used primarily for representing Chinese, Japanese, and Korean text in electronic format. These characters can appear in URLs, form field names, and safe object expressions.
- **ASCII control characters.** Non-printable characters used to send commands to a printer. All ASCII characters with hexadecimal codes less than HEX 20 (ASCII 32) fall into this category. These characters should never appear in a URL or form field name, however, and would rarely if ever appear in a safe object expression.

The NetScaler appliance does not support the entire UTF-8 character set, but only the characters found in the following eight charsets:

- **English US (ISO-8859-1).** Although the label reads, “English US,” the application firewall supports all characters in the ISO-8859-1 character set, also called the Latin-1 character set. This character set fully represents most modern western European languages and represents all but a few uncommon characters in the rest.
- **Chinese Traditional (Big5).** The application firewall supports all characters in the BIG5 character set, which includes all of the Traditional Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in Hong Kong, Macau, Taiwan, and by many people of Chinese ethnic heritage who live outside of mainland China.
- **Chinese Simplified (GB2312).** The application firewall supports all characters in the GB2312 character set, which includes all of the Simplified Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in mainland China.
- **Japanese (SJIS).** The application firewall supports all characters in the Shift-JIS (SJIS) character set, which includes most characters (ideographs) commonly used in modern Japanese.
- **Japanese (EUC-JP).** The application firewall supports all characters in the EUC-JP character set, which includes all characters (ideographs) commonly used in modern Japanese.
- **Korean (EUC-KR).** The application firewall supports all characters in the EUC-KR character set, which includes all characters (ideographs) commonly used in modern Korean.
- **Turkish (ISO-8859-9).** The application firewall supports all characters in the ISO-8859-9 character set, which includes all letters used in modern Turkish.
- **Unicode (UTF-8).** The application firewall supports certain additional characters in the UTF-8 character set, including those used in modern Russian.

When configuring the application firewall, you enter all non-ASCII characters as PCRE-format regular expressions using the hexadecimal code assigned to that character in the UTF-8 specification. Symbols and characters within the normal ASCII character set, which are assigned single, two-digit codes in that character set, are assigned the same codes in the UTF-8

character set. For example, the exclamation point (!), which is assigned hex code 21 in the ASCII character set, is also hex 21 in the UTF-8 character set. Symbols and characters from another supported character set have a paired set of hexadecimal codes assigned to them in the UTF-8 character set. For example, the letter a with an acute accent (á) is assigned UTF-8 code C3 A1.

The syntax you use to represent these UTF-8 codes in the application firewall configuration is “\xNN” for ASCII characters; “\xNN\xNN” for non-ASCII characters used in English, Russian, and Turkish; and “\xNN\xNN\xNN” for characters used in Chinese, Japanese, and Korean. For example, if you want to represent a ! in an application firewall regular expression as a UTF-8 character, you would type \x21. If you want to include an á, you would type \xC3\xA1.

Note: Normally you do not need to represent ASCII characters in UTF-8 format, but when those characters might confuse a web browser or an underlying operating system, you can use the character’s UTF-8 representation to avoid this confusion. For example, if a URL contains a space, you might want to encode the space as \x20 to avoid confusing certain browsers and web server software.

Below are examples of URLs, form field names, and safe object expressions that contain non-ASCII characters that must be entered as PCRE-format regular expressions to be included in the application firewall configuration. Each example shows the actual URL, field name, or expression string first, followed by a PCRE-format regular expression for it.

- A URL containing extended ASCII characters.

Actual URL: <http://www.josénuñez.com>

Encoded URL: `^http://www[.]j[os]\xC3\xA9nu\xC3\xB1ez[.]com$`

- Another URL containing extended ASCII characters.

Actual URL: <http://www.example.de/trömsö.html>

Encoded URL: `^http://www[.]example[.]de/tr\xC3\xB6msö[.]html$`

- A form field name containing extended ASCII characters.

Actual Name: nome\_do\_usuario

Encoded Name: `^nome_do_usu\xC3\xA1rio$`

- A safe object expression containing extended ASCII characters.

Unencoded Expression `[A-Z]{3,6}¥[1-9][0-9]{6,6}`

Encoded Expression: `[A-Z]{3,6}\xC2\xA5[1-9][0-9]{6,6}`

You can find a number of tables that include the entire Unicode character set and matching UTF-8 encodings on the Internet. A useful web site that contains this information is located at the following URL:

<http://www.utf8-chartable.de/unicode-utf8-table.pl>

For the characters in the table on this web site to display correctly, you must have an appropriate Unicode font installed on your computer. If you do not, the visual display of the character may be in error. Even if you do not have an appropriate font installed to display a character, however, the description and the UTF-8 and UTF-16 codes on this set of web pages will be correct.

Inverted PCRE Expressions

In addition to matching content that contains a pattern, you can match content that does not contain a pattern by using an inverted PCRE expression. To invert an expression, you simply include an exclamation point (!) followed by white space as the first character in the expression.

Note: If an expression consists only of an exclamation point with nothing following, the exclamation point is treated as a literal character, not syntax indicating an inverted expression.

The following application firewall commands support inverted PCRE expressions:

- Start URL (URL)
- Deny URL (URL)
- Form Field Consistency (form action URL)
- Cookie Consistency (form action URL)
- Cross Site Request Forgery (CSRF) (form action URL)
- HTML Cross-site Scripting (form action URL)
- Field Format (form action URL)
- Field Type (type)
- Confidential Field (URL)

Note: If the security check contains an isRegex flag or check box, it must be set to YES or checked to enable regular expressions in the field. Otherwise the contents of that field are treated as literal and no regular expressions (inverted or not) are parsed.

#### Disallowed Names for Application Firewall Profiles

The following names are assigned to built-in actions and profiles on the NetScaler appliance, and cannot be used as names for a user-created application firewall profile.

- AGRESSIVE
- ALLOW
- BASIC
- CLIENTAUTH
- COMPRESS
- CSSMINIFY
- DEFLATE
- DENY
- DNS-NOP
- DROP
- GZIP
- HTMLMINIFY
- IMGOPTIMIZE
- JSMINIFY
- MODERATE
- NOCLIENTAUTH
- NOCOMPRESS
- NONE
- NOOP
- NOREWRITE
- RESET
- SETASLEARNNSLOG\_ACT

- SETNSLOGPARAMS\_ACT
- SETSYSLOGPARAMS\_ACT
- SETTMSESSPARAMS\_ACT
- SETVPNPARAMS\_ACT
- SET\_PREAUTHPARAMS\_ACT
- default\_DNS64\_action
- dns\_default\_act\_Cachebypass
- dns\_default\_act\_Drop
- nshttp\_default\_profile
- nshttp\_default\_strict\_validation
- nstcp\_default\_Mobile\_profile
- nstcp\_default\_XA\_XD\_profile
- nstcp\_default\_profile
- nstcp\_default\_tcp\_interactive\_stream
- nstcp\_default\_tcp\_lan
- nstcp\_default\_tcp\_lan\_thin\_stream
- nstcp\_default\_tcp\_lfp
- nstcp\_default\_tcp\_lfp\_thin\_stream
- nstcp\_default\_tcp\_lnp
- nstcp\_default\_tcp\_lnp\_thin\_stream
- nstcp\_internal\_apps

# Policy Labels

Nov 19, 2013

A policy label consists of a set of policies, other policy labels, and virtual server-specific policy banks. The application firewall evaluates each policy bound to the policy label in order of priority. If the policy matches, it filters the connection as specified in the associated profile. Then it does whatever the Goto parameter specifies, which can be to terminate policy evaluation, go to the next policy, or go to the policy with the specified priority. If the Invoke parameter is set, it terminates processing of the current policy label and begins to process the specified policy label or virtual server.

To create an application firewall policy label by using the command line

At the command prompt, type the following commands:

- add appfw policylabel <labelName> http\_req
- save ns config

## Example

The following example creates a policy label named policylbl1.

```
add appfw policylabel policylbl1 http_req
save ns config
```

To bind a policy to a policy label by using the command line

At the command prompt, type the following commands:

- bind appfw policylabel <labelName> <policyName> <priority> [<gotoPriorityExpression>] [-invoke (<labelType> <labelName>)]
- save ns config

## Example

The following example binds the policy policy1 to the policy label policylbl1 with a priority of 1.

```
bind appfw policylabel policylbl1 policy1 1
save ns config
```

To configure an application firewall policy label by using the configuration utility

1. Navigate to Security > Application Firewall > Policy Labels.
2. In the details pane, do one of the following:
  - To add a new policy label, click Add.
  - To configure an existing policy label, select the policy label and the click Open.The Create Application Firewall Policy Label or the Configure Application Firewall Policy Label dialog box opens. The dialog boxes are nearly identical.
3. If you are creating a new policy label, in the Create Application Firewall Policy Label dialog box, type a name for your new policy label.

The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (\_) symbols.

4. Select Insert Policy to insert a new row and display a drop-down list with all existing application firewall policies.
5. Select the policy you want to bind to the policy label, or select New Policy to create a new policy and follow the instructions in [To create and configure a policy by using the configuration utility](#). The policy that you selected or created is inserted into the list of globally bound application firewall policies.
6. Make any additional adjustments.
  - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
  - To modify the policy expression, double click that field to open the Configure Application Firewall Policy dialog box, where you can edit the policy expression.
  - To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
  - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression
7. Repeat steps 5 through 7 to bind any additional application firewall policies you want to the policy label.
8. Click Create or OK, and then click Close. A message appears in the status bar, stating that you have successfully created or modified the policy label.

# Policies

Mar 28, 2012

The application firewall uses two types of policies: firewall policies and auditing policies. Firewall policies control which traffic is sent to the application firewall. Auditing policies control the log server to which application firewall logs are sent.

Firewall policies can be complex because the policy rule can consist of multiple expressions in the NetScaler expressions language, which is a full-fledged object oriented programming language capable of defining with extreme precision exactly which connections to filter. Because firewall policies operate within the context of the application firewall, they must meet certain criteria that are connected to how the application firewall functions and what traffic is appropriately filtered by it. As long as you keep these criteria in mind, however, firewall policies are similar to policies for other NetScaler features. The instructions here do not attempt to cover all aspects of writing firewall policies, but only provide an introduction to policies and cover those criteria that are unique to the application firewall.

Auditing policies are simple because the policy rule is always `ns_true`. You need only specify the log server that you want to send logs to, the logging levels that you want to use, and a few other criteria that are explained in detail.

# Firewall Policies

Oct 01, 2013

A firewall policy is a rule associated with a profile. The rule is an expression or group of expressions that defines the types of request/response pairs that the application firewall is to filter by applying the profile. Firewall policy expressions are written in the NetScaler expressions language, an object-oriented programming language with special features to support specific NetScaler functions. The profile is the set of actions that the application firewall is to use to filter request/response pairs that match the rule.

Firewall policies enable you to assign different filtering rules to different types of web content. Not all web content is alike. A simple web site that uses no complex scripting and accesses and handles no private data might require only the level of protection provided by a profile created with basic defaults. Web content that contains JavaScript-enhanced web forms or accesses an SQL database probably requires more tailored protection. You can create a different profile to filter that content, and create a separate firewall policy that can determine which requests are attempting to access that content. You then associate the policy expression with a profile you created and globally bind the policy to put it into effect.

The application firewall processes only HTTP connections, and therefore uses a subset of the overall NetScaler expressions language. The information here is limited to topics and examples that are likely to be useful when configuring the application firewall. Following are links to additional information and procedures for firewall policies:

- For procedures that explain how to create and configure a policy, see "[Creating and Configuring Application Firewall Policies.](#)"
- For a procedure that explains in detail how to create a policy rule (expression), see "[To create or configure an Application Firewall rule \(expression\).](#)"
- For a procedure that explains how to use the Add Expression dialog box to create a policy rule, see "[To add a firewall rule \(expression\) by using the Add Expression dialog box.](#)"
- For a procedure that explains how to view the current bindings for a policy, see "[Viewing a Firewall Policy's Bindings.](#)"
- For procedures that explain how to bind an application firewall policy, see "[Binding Application Firewall Policies.](#)"
- For detailed information about the NetScaler expressions language, see "[Policies and Expressions.](#)"

# Creating and Configuring Application Firewall Policies

Jun 12, 2014

A firewall policy consists of two elements: a *rule*, and an associated *profile*. The rule selects the HTTP traffic that matches the criteria that you set, and sends that traffic to the application firewall for filtering. The profile contains the filtering criteria that the application firewall uses.

The policy rule consists of one or more expressions in the NetScaler expressions language. The NetScaler expressions syntax is a powerful, object-oriented programming language that enables you to precisely designate the traffic that you want to process with a specific profile. For users who are not completely familiar with the NetScaler expressions language syntax, or who prefer to configure their NetScaler appliance by using a web-based interface, the configuration utility provides two tools: the Prefix menu and the Add Expression dialog box. Both help you to write expressions that select exactly the traffic that you want to process. Experienced users who are thoroughly familiar with the syntax may prefer to use the NetScaler command line to configure their NetScaler appliances.

Note: In addition to the default expressions syntax, for backward compatibility the NetScaler operating system supports the NetScaler classic expressions syntax on NetScaler Classic and nCore appliances and virtual appliances. Classic expressions are not supported on NetScaler Cluster appliances and virtual appliances. Current NetScaler users who want to migrate existing configurations to the NetScaler Cluster must migrate any policies that contain classic expressions to the default expressions syntax.

For detailed information about the NetScaler expressions languages, see "[Policies and Expressions](#)."

You can create a firewall policy by using the configuration utility or the NetScaler command line.

To create and configure a policy by using the command line interface

At the command prompt, type the following commands:

- add appfw policy <name> <rule> <profileName>
- save ns config

## Example

The following example adds a policy named pi-blog, with a rule that intercepts all traffic to or from the host blog.example.com, and associates that policy with the profile pr-blog. This is an appropriate policy to protect a blog hosted on a specific hostname.

```
add appfw policy pi-blog "HTTP.REQ.HOSTNAME.DOMAIN.EQ("blog.example.com")" pr-blog
```

To create and configure a policy by using the configuration utility

1. Navigate to Security > Application Firewall > Policies.
2. In the details pane, do one of the following:
  - To create a new firewall policy, click Add. The Create Application Firewall Policy is displayed.
  - To edit an existing firewall policy, select the policy, and then click Edit. The Create Application Firewall Policy or Configure Application Firewall Policy is displayed.
3. If you are creating a new firewall policy, in the Create Application Firewall Policy dialog box, Policy Name text box, type a name for your new policy.

The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 128 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (\_) symbols.

If you are configuring an existing firewall policy, this field is read-only. You cannot modify it.

4. Select the profile that you want to associate with this policy from the Profile drop-down list. You can create a new profile to associate with your policy by clicking New, and you can modify an existing profile by clicking Modify.
5. In the Expression text area, create a rule for your policy.
  - You can type a rule directly into the text area.
  - You can click Prefix to select the first term for your rule, and follow the prompts. See "[To Create an Application Firewall Rule \(Expression\)](#)" for a complete description of this process.
  - You can click Add to open the Add Expression dialog box, and use it to construct the rule. See "[The Add Expression Dialog Box](#)" for a complete description of this process.
6. Click Create or OK, and then click Close.

### To create or configure an Application Firewall rule (expression)

The policy rule, also called the *expression*, defines the web traffic that the application firewall filters by using the profile associated with the policy. Like other NetScaler policy rules (or *expressions*), application firewall rules use NetScaler expressions syntax. This syntax is powerful, flexible, and extensible. It is too complex to describe completely in this set of instructions. You can use the following procedure to create a simple firewall policy rule, or you can read it as an overview of the policy creation process.

1. If you have not already done so, navigate to the appropriate location in the Application Firewall wizard or the NetScaler configuration utility to create your policy rule:
  - If you are configuring a policy in the Application Firewall wizard, in the navigation pane, click Application Firewall, then in the details pane click Application Firewall Wizard, and then navigate to the Specify Rule screen.
  - If you are configuring a policy manually, in the navigation pane, expand Application Firewall, then Policies, and then Firewall. In the details pane, to create a new policy, click Add. To modify an existing policy, select the policy, and then click Open.
2. On the Specify Rule screen, the Create Application Firewall Profile dialog box, or the Configure Application Firewall Profile dialog box, click Prefix, and then choose the prefix for your expression from the drop-down list. Your choices are:
  - **HTTP**. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
  - **SYS**. The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
  - **CLIENT**. The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
  - **SERVER**. The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

After you choose a prefix, the application firewall displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom.

3. Choose your next term.

If you chose HTTP as your prefix, your only choice is REQ, which specifies the Request/Response pair. (The application firewall operates on the request and response as a unit instead of on each separately.) If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

When you have decided which term you want, double-click it to insert it into the Expression window.

4. Type a period after the term you just chose. You are then prompted to choose your next term, as described in the

previous step. When a term requires that you type a value, fill in the appropriate value. For example, if you choose HTTP.REQ.HEADER(""), type the header name between the quotation marks.

5. Continue choosing terms from the prompts and filling in any values that are needed, until your expression is finished. Following are some examples of expressions for specific purposes.

- **Specific web host.** To match traffic from a particular web host:

```
HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
```

For shopping.example.com, substitute the name of the web host that you want to match.

- **Specific web folder or directory.** To match traffic from a particular folder or directory on a Web host:

```
HTTP.REQ.URL.STARTSWITH("https://www.example.com/folder")
```

For www.example.com, substitute the name of the web host. For folder, substitute the folder or path to the content that you want to match. For example, if your shopping cart is in a folder called /solutions/orders, you substitute that string for folder.

- **Specific type of content: GIF images.** To match GIF format images:

```
HTTP.REQ.URL.ENDSWITH(".gif")
```

To match other format images, substitute another string in place of .gif.

- **Specific type of content: scripts.** To match all CGI scripts located in the CGI-BIN directory:

```
HTTP.REQ.URL.STARTSWITH("https://www.example.com/CGI-BIN")
```

To match all JavaScripts with .js extensions:

```
HTTP.REQ.URL.ENDSWITH(".js")
```

For more information about creating policy expressions, see "[Policies and Expressions.](#)"

Note: If you use the command line to configure a policy, remember to escape any double quotation marks within NetScaler expressions. For example, the following expression is correct if entered in the configuration utility:

```
HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
```

If entered at the command line, however, you must type this instead:

```
HTTP.REQ.HEADER(\"Host\").EQ(\"shopping.example.com\")
```

To add a firewall rule (expression) by using the Add Expression dialog box

The Add Expression dialog box (also referred to as the Expression Editor) helps users who are not familiar with the NetScaler expressions language to construct a policy that matches the traffic that they want to filter.

1. If you have not already done so, navigate to the appropriate location in the Application Firewall wizard or the NetScaler configuration utility:
  - If you are configuring a policy in the Application Firewall wizard, in the navigation pane, click Application Firewall, then in the details pane click Application Firewall Wizard, and then navigate to the Specify Rule screen.
  - If you are configuring a policy manually, in the navigation pane, expand Application Firewall, then Policies, and then Firewall. In the details pane, to create a new policy, click Add. To modify an existing policy, select the policy, and then click Open.
2. On the Specify Rule screen, in the Create Application Firewall Profile dialog box, or in the Configure Application Firewall Profile dialog box, click Add.

3. In the Add Expression dialog box, in the Construct Expression area, in the first list box, choose one of the following prefixes:
  - **HTTP**. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol. The default choice.
  - **SYS**. The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
  - **CLIENT**. The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
  - **SERVER**. The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.
4. In the second list box, choose your next term. The available terms differ depending on the choice you made in the previous step, because the dialog box automatically adjusts the list to contain only those terms that are valid for the context. For example, if you selected HTTP in the previous list box, the only choice is REQ, for requests. Because the application firewall treats requests and associated responses as a single unit and filters both, you do not need to specify responses separately. After you choose your second term, a third list box appears to the right of the second. The Help window displays a description of the second term, and the Preview Expression window displays your expression.
5. In the third list box, choose the next term. A new list box appears to the right, and the Help window changes to display a description of the new term. The Preview Expression window updates to display the expression as you have specified it to that point.
6. Continue choosing terms, and when prompted filling in arguments, until your expression is complete. If you make a mistake or want to change your expression after you have already selected a term, you can simply choose another term. The expression is modified, and any arguments or additional terms that you added after the term that you modified are cleared.
7. When you have finished constructing your expression, click OK to close the Add Expression dialog box. Your expression is inserted into the Expression text area.

# Binding Application Firewall Policies

Jun 12, 2014

After you have configured your application firewall policies, you bind them to Global or a bind point to put them into effect. After binding, any request or response that matches an application firewall policy is transformed by the profile associated with that policy.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the NetScaler OS, policy priorities work in reverse order - the higher the number, the lower the priority.

Because the application firewall feature implements only the first policy that a request matches, not any additional policies that it might also match, policy priority is important for achieving the results that you intend. If you give your first policy a low priority (such as 1000), you configure the application firewall to perform it only if other policies with a higher priority do not match a request. If you give your first policy a high priority (such as 1), you configure the application firewall to perform it first, and skip any other policies that might also match. You can leave yourself plenty of room to add other policies in any order, without having to reassign priorities, by setting priorities with intervals of 50 or 100 between each policy when you bind your policies.

For more information about binding policies on the NetScaler appliance, see "[Policies and Expressions](#)."

To bind an application firewall policy by using the command line interface

At the command prompt, type the following commands:

- `bind appfw global <policyName> <priority>`
- `save ns config`

## Example

The following example binds the policy named pl-blog and assigns it a priority of 10.

```
bind appfw global pl-blog 10
save ns config
```

To bind an application firewall policy by using the configuration utility

1. Do one of the following:
  - Navigate to Security > Application Firewall, and in the details pane, click Application Firewall policy manager.
  - Navigate to Security > Application Firewall > Policies > Firewall Policies, and in the details pane, click Policy Manager.
2. In the Application Firewall Policy Manager dialog, choose the bind point to which you want to bind the policy from the drop-down list. The choices are:
  - **Override Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance, and are applied before any other policies.
  - **LB Virtual Server.** Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.
  - **CS Virtual Server.** Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this

policy.

- **Default Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance.
  - **Policy Label.** Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.
  - **None.** Do not bind the policy to any bind point.
3. Click Continue. A list of existing application firewall policies appears.
  4. Select the policy you want to bind by clicking it.
  5. Make any additional adjustments to the binding.
    - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
    - To modify the policy expression, double click that field to open the Configure Application Firewall Policy dialog box, where you can edit the policy expression.
    - To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
    - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression
  6. Repeat steps 3 through 6 to add any additional application firewall policies you want to globally bind.
  7. Click OK. A message appears in the status bar, stating that the policy has been successfully bound.

# Viewing a Firewall Policy's Bindings

Jun 12, 2014

You can quickly check to determine what bindings are in place for any firewall policy by viewing the bindings in the configuration utility.

To view bindings for an application firewall policy

1. Navigate to Security > Application Firewall > Policies > Firewall Policies
2. In the details pane, select the policy that you want to check, and then click Show Bindings. The Binding Details for Policy: Policy message box is displayed, with a list of bindings for the selected policy.
3. Click Close.

# Supplemental Information about Application Firewall Policies

Jun 07, 2012

Following is supplemental information about particular aspects of application firewall policies that system administrators who manage the application firewall might need to know.

## Correct but Unexpected Behavior

Web application security and modern web sites are complex. In a number of scenarios, a NetScaler policy might cause the application firewall to behave differently in certain situations than a user who is familiar with policies would normally expect. Following are a number of cases where the application firewall may behave in an unexpected fashion.

- **Request with a missing HTTP Host header and an absolute URL.** When a user sends a request, in the majority of cases the request URL is relative. That is, it takes as its starting point the Referer URL, the URL where the user's browser is located when it sends the request. If a request is sent without a Host header, and with a relative URL, the request is normally blocked both because it violates the HTTP specification and because a request that fails to specify the host could under some circumstances constitute an attack. If a request is sent with an absolute URL, however, even if the Host header is missing, the request bypasses the application firewall and is forwarded to the web server. Although such a request violates the HTTP specification, it poses no possible threat because an absolute URL contains the host.

# Auditing Policies

Jun 12, 2014

Auditing policies determine the messages that are generated and logged during an Application Firewall session. These messages are logged in SYSLOG format to the local NSLOG server or to an external logging server. Different types of messages are logged on the basis of the level of logging selected.

To create an auditing policy, you must first create either an NSLOG server or a SYSLOG server. After specifying the server, you create the policy and specify the type of log and the server to which logs are sent.

To create an auditing server by using the command line interface

You can create two different types of auditing server: an NSLOG server or a SYSLOG server. The command names are different, but the parameters for the commands are the same.

To create an auditing server, at the NetScaler command prompt, type the following commands:

- add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> ... [-dateFormat ( **MMDDYYYY** | **DDMMYYYY** )] [-logFacility <logFacility>] [-tcp ( **NONE** | **ALL** )] [-acl ( **ENABLED** | **DISABLED** )] [-timeZone ( **GMT\_TIME** | **LOCAL\_TIME** )] [-userDefinedAuditlog ( **YES** | **NO** )] [-appflowExport ( **ENABLED** | **DISABLED** )]
- save ns config

## Example

The following example creates a syslog server named syslog1 at IP 10.124.67.91, with loglevels of emergency, critical, and warning, log facility set to LOCAL1, that logs all TCP connections:

```
add audit syslogAction syslog1 10.124.67.91 -logLevel emergency critical warning -logFacility LOCAL1 -tcp ALL
save ns config
```

To modify or remove an auditing server by using the command line interface

- To modify an auditing server, type the set audit <type> command, the name of the auditing server, and the parameters to be changed, with their new values.
- To remove an auditing server, type the rm audit <type> command and the name of the auditing server.

## Example

The following example modifies the syslog server named syslog1 to add errors and alerts to the log level:

```
set audit syslogAction syslog1 10.124.67.91 -logLevel emergency critical warning alert error -logFacility LOCAL1 -tcp ALL
save ns config
```

To create or configure an auditing server by using the configuration utility

1. Navigate to Security > Application Firewall > Policies > Auditing.
2. In the details pane, click the Server tab.
3. Do one of the following:
  - To add a new auditing server, click Add.
  - To modify an existing auditing server, select the server, and then click Edit.

4. In the Create Auditing Server or Configure Auditing Server dialog box, set the following parameters:

- Name
- Auditing Type
- IP Address
- Port
- Log Levels
- Log Facility
- TCP Logging
- ACL Logging
- User-Configurable Log Messages
- AppFlow Logging
- Date Format
- Time Zone

5. Click Create or OK.

To create an auditing policy by using the command line interface

You can create an NSLOG policy or a SYSLOG policy. The type of policy must match the type of server. The command names for the two types of policy are different, but the parameters for the commands are the same.

At the command prompt, type the following commands:

- `add audit syslogPolicy <name> [-rule <expression>] [-action <string>]`
- `save ns config`

## Example

The following example creates a policy named syslogP1 that logs application firewall traffic to a syslog server named syslog1.

```
add audit syslogPolicy syslogP1 -rule "ns_true" -action syslog1
save ns config
```

To configure an auditing policy by using the command line interface

At the command prompt, type the following commands:

- `set audit syslogPolicy <name> [-rule <expression>] [-action <string>]`
- `save ns config`

## Example

The following example modifies the policy named syslogP1 to log application firewall traffic to a syslog server named syslog2.

```
set audit syslogPolicy syslogP1 -rule "ns_true" -action syslog2
save ns config
```

To configure an auditing policy by using the configuration utility

1. Navigate to Security > Application Firewall > Policies > Auditing.
2. In the details pane, do one of the following:
  - To add a new policy, click Add.

- To modify an existing policy, select the policy, and then click Edit.
3. In the Create Auditing Policy or Configure Auditing Policy dialog box, set the following parameters:
    - Name
    - Auditing Type
    - Server
  4. Click Create or OK.

# Imports

Mar 28, 2012

Several application firewall features make use of external files that you upload to the application firewall when configuring it. Using the configuration utility, you manage those files in the Imports pane, which has four tabs corresponding to the four types of files you can import: HTML error objects, XML error objects, XML schemas, and Web Services Description Language (WSDL) files. Using the NetScaler command line, you can import these types of files, but you cannot export them.

## HTML Error Object

When a user's connection to an HTML or Web 2.0 page is blocked, or a user asks for a non-existent HTML or Web 2.0 page, the application firewall sends an HTML-based error response to the user's browser. When configuring which error response the application firewall should use, you have two choices:

- You can configure a redirect URL, which can be hosted on any Web server to which users also have access. For example, if you have a custom error page on your Web server, 404.html, you can configure the application firewall to redirect users to that page when a connection is blocked.
- You can configure an HTML error object, which is an HTML-based Web page that is hosted on the application firewall itself. If you choose this option, you must upload the HTML error object to the application firewall. You do that in the Imports pane, on the HTML Error Object tab.

The error object must be a standard HTML file that contains no non-HTML syntax except for application firewall error object customization variables. It cannot contain any CGI scripts, server-parsed code, or PHP code. The customization variables enable you to embed troubleshooting information in the error object that the user receives when a request is blocked. While most requests that the application firewall blocks are illegitimate, even a properly configured application firewall can occasionally block legitimate requests, especially when you first deploy it or after you make significant changes to your protected Web sites. By embedding information in the error page, you provide the user with the information that he or she needs to give to the technical support person so that any issues can be fixed.

The application firewall error page customization variables are:

- `$(NS_TRANSACTION_ID)`. The transaction ID that the application firewall assigned to this transaction.
- `$(NS_APPFW_SESSION_ID)`. The application firewall session ID.
- `$(NS_APPFW_VIOLATION_CATEGORY)`. The specific application firewall security check or rule that was violated.
- `$(NS_APPFW_VIOLATION_LOG)`. The detailed error message associated with the violation.
- `$(COOKIE("<CookieName>"))`. The contents of the specified cookie. For `<CookieName>`, substitute the name of the specific cookie that you want to display on the error page. If you have multiple cookies whose contents you want to display for troubleshooting, you can use multiple instances of this customization variable, each with the appropriate cookie name.  
Note: If you have blocking enabled for the Cookie Consistency Check, any blocked cookies are not displayed on the error page because the application firewall blocks them.

To use these variables, you embed them in the HTML or XML of the error page object as if they were an ordinary text string. When the error object is displayed to the user, for each customization variable the application firewall substitutes the information to which the variable refers. An example HTML error page that uses custom variables is shown below.

```
<!doctype html public "-//w3c//dtd html 4.0/en"> <html> <head> <title>Page Not Accessible</title> </head> <body> <h1>Page Not Accessible</h1> <p>The page that you accessed is not available. You
To use this error page, copy it into a text or HTML editor. Substitute the appropriate local information for the following variables, which are enclosed in square brackets to distinguish them from the
NetScaler variables. (Leave those unchanged):
```

- **[homePage]**. The URL for your web site's home page.
- **[helpDeskEmailAddress]**. The email address that you want users to use to report blocking incidents.
- **[helpDeskPhoneNumber]**. The phone number that you want users to call to report blocking incidents.
- **[cookieName]**. The name of the cookie whose contents you want to display on the error page.

## XML Error Object

When a user's connection to an XML page is blocked, or a user asks for a nonexistent XML application, the application firewall sends an XML-based error response to the user's browser. You configure the error response by uploading an XML-based error page to the application firewall in the Imports Pane, on the XML Error Object tab. All XML error responses are hosted on the application firewall. You cannot configure a redirect URL for XML applications.

Note: You can use the same customization variables in an XML error object as in an HTML error object.

## XML Schema

When the application firewall performs a validation check on a user's request for an XML or Web 2.0 application, it can validate the request against the XML schema or design type document (DTD) for that application and reject any request that does not follow the schema or DTD. Both an XML schema and a DTD are standard XML configuration files that describe the structure of a specific type of XML document.

## WSDL

When the application firewall performs a validation check on a user's request for an XML SOAP-based web service, it can validate the request against the web services type definition (WSDL) file for that web service. A WSDL file is a standard XML SOAP configuration file that defines the elements of a specific XML SOAP web service.

# Importing and Exporting Files

Oct 02, 2014

You can import HTML or XML error objects, XML schemas, DTDs, and WSDLs to the application firewall by using the configuration utility or the command line. You can edit any of these files in a web-based text area after importing them, to make small changes directly on the NetScaler ADC instead of having to make them on your computer and then reimport them. Finally, you can export any of these files to your computer, or delete any of these files, by using the configuration utility.

Note: You cannot delete or export an imported file by using the command line.

To import a file by using the command line interface

At the command prompt, type the following commands:

- `import appfw htmlerrorpage <src> <name>`
- `save ns config`

## Example

The following example imports an HTML error object from a file named `error.html` and assigns it the name `HTMLError`.

```
import htmlerrorpage error.html HTMLError
```

```
save ns config
```

To import a file by using the configuration utility

Before you attempt to import an XML schema, DTD, or WSDL file, or an HTML or XML error object from a network location, verify that the NetScaler ADC can connect to the Internet or LAN computer where the file is located. Otherwise, you cannot import the file or object.

1. Navigate to Security > Application Firewall > Imports.
2. Navigate to Application Firewall > Imports.
3. In the Application Firewall Imports pane, select the tab for the type of file you want to import, and then click Add. The tabs are HTML Error Page, XML Error Page, XML Schema or WSDL. The upload process is identical on all four tabs from the user point of view.
4. Fill in the dialog fields.
  - **Name**—A name for the imported object.
  - **Import From**—Choose the location of the HTML file, XML file, XML schema or WSDL that you want to import in the drop-down list:
    - **URL**: A web URL on a website accessible to the ADC.
    - **File**: A file on a local or networked hard disk or other storage device.
    - **Text**: Type or paste the text of the custom response directly into a text field in the configuration utility. The third text box changes to the appropriate value. The three possible values are provided below.
  - **URL**—Type the URL into the text box.
  - **File**—Type the path and filename to the HTML file directly, or click Browse and browse to the HTML file.
  - **Text**—The third field is removed, leaving a blank space.
5. Click Continue. The File Contents dialog is displayed. If you chose URL or File, the File Contents text box contains the HTML file that you specified. If you chose Text, the File Contents text box is empty.

6. If you chose Text, type or copy and paste the custom response HTML that you want to import.
7. Click Done.
8. To delete an object, select the object, and then click Delete.

### To export a file by using the configuration utility

Before you attempt to export an XML schema, DTD, or WSDL file, or an HTML or XML error object, verify that the application firewall appliance can access the computer where the file is to be saved. Otherwise, you cannot export the file.

1. Navigate to Security > Application Firewall > Imports.
2. In the Application Firewall Imports pane, select the tab for the type of file you want to export.  
The export process is identical on all four tabs from the user point of view.
3. Select the file that you want to export.
4. Expand the Action drop-down list, and select Export.
5. In the dialog box, choose Save File and click OK.
6. In the Browse dialog box, navigate to the local file system and directory where you want to save the exported file, and click Save.

### To edit an HTML or XML Error Object in the configuration utility

You edit the text of HTML and XML error objects in the configuration utility without exporting and then reimporting them.

1. Navigate to Security > Application Firewall > Imports, and then select the tab for the type of file that you want to modify.
2. Navigate to Application Firewall > Imports, and then select the tab for the type of file that you want to modify.
3. Select the file that you want to modify, and then click Edit.  
The text of the HTML or XML error object is displayed in a browser text area. You can modify the text by using the standard browser-based editing tools and methods for your browser.

Note: The edit window is designed to allow you to make minor changes to your HTML or XML error object. To make extensive changes, you may prefer to export the error object to your local computer and use standard HTML or XML web page editing tools.

4. Click OK, and then click Close.

# Global Configuration

Sep 12, 2013

The application firewall global configuration affects all profiles and policies. The Global Configuration items are:

- **Engine Settings.** A collection of global settings—session cookie name, session time-out, maximum session lifetime, logging header name, undefined profile, default profile, and import size limit—that pertain to all connections that the application firewall processes, rather than to a specific subset of connections.
- **Confidential Fields.** A set of form fields in web forms that contain sensitive information that should not be logged to the application firewall logs. Form fields such as password fields on a logon page or credit card information on a shopping cart checkout form are normally designated as confidential fields.
- **Field Types.** The list of web form field types used by the Field Formats security check. Each of these field types is defined by a PCRE-compliant regular expression that defines the type of data and the minimum/maximum length of data that should be allowed in that type of form field.
- **XML Content Types.** The list of content types recognized as XML and subjected to XML-specific security checks. Each of these content types is defined by a PCRE-compliant regular expression that defines the exact MIME type assigned to that content.
- **JSON Content Types.** The list of content types recognized as JSON and subjected to JSON-specific security checks. Each of these content types is defined by a PCRE-compliant regular expression that defines the exact MIME type assigned to that content.

# Engine Settings

Oct 07, 2014

The engine settings affect all requests and responses that the application firewall processes. They include the following items:

- **Cookie name**—The name of the cookie that stores the NetScaler session ID.
- **Session timeout**—The maximum inactive period allowed. If a user session shows no activity for this length of time, the session is terminated and the user is required to reestablish it by visiting a designated start page.
- **Cookie post-encrypt prefix**—The string that precedes the encrypted portion of any encrypted cookies.
- **Maximum session lifetime**—The maximum amount of time, in seconds, that a session is allowed to remain live. After this period is reached, the session is terminated and the user is required to reestablish it by visiting a designated start page. This setting cannot be less than the session timeout. To disable this setting, so that there is no maximum session lifetime, set the value to zero (0).
- **Logging header name**—The name of the HTTP header that holds the Client IP, for logging.
- **Undefined profile**—The profile applied when the corresponding policy action evaluates as undefined.
- **Default profile**—The profile applied to connections that do not match a policy.
- **Import size limit**—The maximum cumulative total byte count of all files imported to the ADC, including signatures, WSDLs, schemas, HTML and XML error pages. During an import, if the size of the imported object would cause the cumulative total sizes of all imported files to exceed the configured limit, the import operation fails and the ADC displays the following error message: *ERROR: Import failed - exceeding the configured total size limit on the imported objects.*
- **Learn message rate limit**—The maximum number of requests and responses per second that the learning engine is to process. Any additional requests or responses over this limit are not sent to the learning engine.
- 
- **Log malformed request**—Enable logging of malformed HTTP requests.
- **Use configurable secret key**—Use a configurable secret key for application firewall operations.
- **Reset learned data**—Remove all learned data from the application firewall. Restarts the learning process by collecting fresh data.
- 
- 

Two settings, *Reset Learned Data* and *Signatures Auto-Update*, are found in different places depending on whether you use the command line or the configuration utility to configure your application firewall. When using the command line, you configure Reset Learned Data by using the `reset appfw learningdata` command, which takes no parameters and has no other functions. You configure Signatures Auto-Update in the `set appfw settings` command: the `-signatureAutoUpdate` parameter enables or disables auto-updating of the signatures, and `-signatureUrl` configures the URL which hosts the updated signatures file.

When using the configuration utility, you configure Reset Learned Data in Security > Application Firewall > Engine Settings; the Reset Learned Data button is at the bottom of the dialog box. You configure Signatures Auto-Update for each set of signatures in Security > Application Firewall > Signatures, by selecting the signatures file, clicking the right mouse button and selecting Auto Update Settings.

Normally, the default values for the application firewall settings are correct. If the default settings cause a conflict with other servers or cause premature disconnection of your users, however, you might need to modify them.

To configure engine settings by using the command line interface

At the command prompt, type the following commands:

- set appfw settings [-sessionCookieName <name>] [-sessionTimeout <positiveInteger> ] [-sessionLifetime <positiveInteger>] [-clientIPLoggingHeader <headerName> ] [-undefaction <profileName> ] [-defaultProfile <profileName>] [-importSizeLimit <positiveInteger>] [-logMalformedReq ( ON | OFF )] [-signatureAutoUpdate ( ON | OFF )] [-signatureUrl <expression>] [-cookiePostEncryptPrefix <string>] [-useConfigurableSecretKey ( ON | OFF )] [-learnRateLimit <positiveInteger>]
- save ns config

## Example

```
set appfw settings -sessionCookieName citrix-appfw-id -sessionTimeout 3600
-sessionLifetime 14400 -clientIPLoggingHeader NS-AppFW-Client-IP -undefaction APPFW_RESET
-defaultProfile APPFW_RESET -importSizeLimit 4096
save ns config
```

To configure engine settings by using the configuration utility

1. Navigate to Security > Application Firewall
2. In the details pane, click Change Engine Settings.
3. In the Application Firewall Engine Settings dialog box, set the following parameters:
  - Cookie Name
  - Session Timeout
  - Cookie Post Encrypt Prefix
  - Maximum Session Lifetime
  - Logging Header Name
  - Undefined Profile
  - Default Profile
  - Import Size Limit
  - Learn Messages Rate Limit
  - 
  - Entity Decoding
  - Log Malformed Request
  - Use Secret Key
  - Learn Message Rate Limit
  - Signatures Auto Update
4. Click OK.

# Confidential Fields

Jun 12, 2014

You can designate web-form fields as confidential to protect the information users type into them. Normally, any information a user types into a web form on one of your protected web servers is logged in the NetScaler logs. The information typed into a web-form field designated as confidential, however, is not logged. That information is saved only where the web site is configured to save such data, normally in a secure database.

Common types of information that you may want to protect with a confidential field designation include:

- Passwords
- Credit card numbers, validation codes, and expiration dates
- Social security numbers
- Tax ID numbers
- Home addresses
- Private telephone numbers

In addition to being good practice, proper use of confidential field designations may be necessary for PCI-DSS compliance on ecommerce servers, HIPAA compliance on servers that manage medical information in the United States, and compliance with other data protection standards.

Important: In the following two cases, the Confidential Field designation does not function as expected:

- If a Web Form has either a confidential field or an action URL longer than 256 characters, the field or action URL is truncated in the NetScaler logs.
- With certain SSL transactions, the logs are truncated if either the confidential field or the action URL is longer than 127 characters.

In either of these cases, the application firewall masks a fifteen-character string with the letter "x," instead of the normal eight character string. To ensure that any confidential information is removed, the user must use form field name and action URL expressions that match the first 256, or (in cases where SSL is used) the first 127 characters.

To configure your application firewall to treat a web-form field on a protected web site as confidential, you add that field to the Confidential Fields list. You can enter the field name as a string, or you can enter a PCRE-compatible regular expression specifying one or more fields. You can enable the confidential-field designation when you add the field, or you can modify the designation later.

To add a confidential field by using the command line interface

At the command prompt, type the following commands:

- `add appfw confidField <fieldName> <url> [-isRegex ( REGEX | NOTREGEX )] [-comment "<string>"] [-state ( ENABLED | DISABLED )]`
- `save ns config`

## Example

The following example adds all web form fields whose names begin with Password to the confidential fields list.

```
add appfw confidField Password "https?://www[.]example[.]com/[^<>]*[^\a-z]password[0-9a-z_-]*[.](asp|cgi|htm|html|http|js|php)" -isRegex REGEX -state ENABLED
save ns config
```

To modify a confidential field by using the command line interface

At the command prompt, type the following commands:

- `set appfw confidField <fieldName> <url> [-isRegex ( REGEX | NOTREGEX )] [-comment "<string>"] [-state ( ENABLED | DISABLED )]`
- `save ns config`

## Example

The following example modifies the confidential field designation to add a comment.

```
set appfw confidField Password "https?://www[.]example[.]com/[^<>]*[^\a-z]password[0-9a-z_-]*[.](asp|cgi|htm|html|http|js|php)" -comment "Protect password fields." -isRegex REGEX -state ENABLED
save ns config
```

To remove a confidential field by using the command line interface

At the command prompt, type the following commands:

- `rm appfw confidField <fieldName> <url>`
- `save ns config`

To configure a confidential field by using the configuration utility

1. Navigate to Security > Application Firewall.
2. In the details pane, under Settings, click Manage Confidential Fields.
3. In the Manage Confidential Fields dialog box, do one of the following:

- To add a new form field to the list, click Add.
- To change an existing confidential field designation, select the field, and then click Edit.

The Application Firewall Confidential Fields dialog box appears.

Note: If you select an existing confidential field designation and then click Add, the Create Confidential Form Field dialog box displays the information for that confidential field. You can modify that information to create your new confidential field.

4. In the dialog box, fill out the elements. They are:

- **Enabled check box.** Select or clear to enable/disable this confidential field designation.
- **Is form field name a regular expression check box.** Select or clear to enable PCRE-format regular expressions in the form field name.
- **Field Name.** Enter a literal string or PCRE-format regular expression that either represents a specific field name or that matches multiple fields with names that follow a pattern.
- **Action URL.** Enter a literal URL or a regular expression that defines one or more URLs of the web page(s) on which the web form(s) that contains the confidential field are located.
- **Comments.** Enter a comment. Optional.

5. Click Create or OK.
6. To remove a confidential field designation from the confidential fields list, select the confidential field listing you want to remove, then click Remove to remove it, and then click OK to confirm your choice.
7. When you have finished adding, modifying, and removing confidential field designations, click Close.

## Examples

Following are some regular expressions that define form field names that you might find useful:

- `^passwd_` (Applies confidential-field status to all field names that begin with the "passwd\_" string.)
- `^(((0-9a-zA-Z_~)*|\x[0-9A-Fa-f][0-9A-Fa-f]+)?passwd_` (Applies confidential-field status to all field names that begin with the string passwd\_, or that contain the string -passwd\_ after another string that might contain non-ASCII special characters.)

Following are some regular expressions that define specific URL types that you might find useful. Substitute your own web host(s) and domain(s) for those in the examples.

- If the web form appears on multiple web pages on the web host `www.example.com`, but all of those web pages are named `logon.pl?`, you could use the following regular expression:  
`https?://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*)logon[.]pl?`
- If the web form appears on multiple web pages on the web host `www.example-español.com`, which contains the n-tilde (ñ) special character, you could use the following regular expression, which represents the n-tilde special character as an encoded UTF-8 string containing C3 B1, the hexadecimal code assigned to that character in the UTF-8 charset:  
`https?://www[.]example-espaa\xC3\xB1ol[.]com/([0-9A-Za-z][0-9A-Za-z_-]*)logon[.]pl?`
- If the web form containing `query.pl` appears on multiple web pages on different hosts within the `example.com` domain, you could use the following regular expression:  
`https?://([0-9A-Za-z][0-9A-Za-z_-]*[.])*example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*)logon[.]pl?`
- If the web form containing `query.pl` appears on multiple web pages on different hosts in different domains, you could use the following regular expression:  
`https?://([0-9A-Za-z][0-9A-Za-z_-]*[.])*[0-9A-Za-z][0-9A-Za-z_-].[a-z]{2,6}/([0-9A-Za-z][0-9A-Za-z_-]*)logon[.]pl?`
- If the web form appears on multiple web pages on the web host `www.example.com`, but all of those web pages are named `logon.pl?`, you could use the following regular expression:  
`https?://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*)logon[.]pl?`

# Field Types

Jun 12, 2014

A field type is a PCRE-format regular expression that defines a particular data format and minimum/maximum data lengths for a form field in a web form. Field types are used in the Field Formats check.

The application firewall comes with several default field types, which are:

- **integer.** A string of any length consisting of numbers only, without a decimal point, and with an optional preceding minus sign (-).
- **alpha.** A string of any length consisting of letters only.
- **alphanum.** A string of any length consisting of letters and/or numbers.
- **nohtml.** A string of any length consisting of characters, including punctuation and spaces, that does not contain HTML symbols or queries.
- **any.** Anything at all.

Important: Assigning the any field type as the default field type, or to a field, allows active scripts, SQL commands, and other possibly dangerous content to be sent to your protected web sites and applications in that form field. You should use the any type sparingly, if you use it at all.

You can also add your own field types to the Field Types list. For example, you might want to add a field type for a social security number, postal code, or phone number in your country. You might also want to add a field type for a customer identification number or store credit card number.

To add a field type to the Field Types list, you enter the field name as a literal string or PCRE-format regular expression.

To add a field type by using the command line interface

At the command prompt, type the following commands:

- `add appfw fieldType <name> <regex> <priority> [-comment "<string>"]`
- `save ns config`

## Example

The following example adds a field type named SSN that matches US Social Security numbers to the Field Types list, and sets its priority to 1.

```
add appfw fieldType SSN "^[1-9][0-9]{2,2}-[0-9]{2,2}-[0-9]{4,4}$" 1
save ns config
```

To modify a field type by using the command line interface

At the command prompt, type the following commands:

- `set appfw fieldType <name> <regex> <priority> [-comment "<string>"]`
- `save ns config`

## Example

The following example modifies the field type to add a comment.

```
set appfw fieldType SSN "^[1-9][0-9]{2,2}-[0-9]{2,2}-[0-9]{4,4}$" 1 -comment "US Social Security Number"
save ns config
```

To remove a field type by using the command line interface

At the command prompt, type the following commands:

- `rm appfw fieldType <name>`
- `save ns config`

To configure a field type by using the configuration utility

1. Navigate to Security > Application Firewall.
2. In the details pane, under Settings, click Manage Field Types.
3. In the Manage Field Types dialog box, do one of the following:
  - To add a new field type to the list, click Add.
  - To change an existing field type, select the field type, and then click Edit.

The Configure Field Type dialog box appears.

Note: If you select an existing field type designation and then click Add, the dialog box displays the information for that field type. You can modify that information to create your new field type.

4. In the dialog box, fill out the elements. They are:
  - Name
  - Regular Expression
  - Priority
  - Comment
5. Click Create or OK.
6. To remove a field type from the Field Types list, select the field type listing you want to remove, then click Remove to remove it, and then click OK to confirm your choice.
7. When you have finished adding, modifying, and removing field types, click Close.

## Examples

Following are some regular expressions for field types that you might find useful:

- `^[1-9][0-9]{2,2}-[0-9]{2,2}-[0-9]{4,4}$` U.S. Social Security numbers
- `^[A-C][0-9]{7,7}$` California driver's license numbers.
- `^[+][0-9]{1,3} [0-9() -]{1,40}$` International phone numbers with country codes.
- `^[0-9]{5,5}-[0-9]{4,4}$` U.S. ZIP code numbers.
- `^[0-9A-Za-z][0-9A-Za-z+_-]{0,25}@([0-9A-Za-z][0-9A-Za-z_-]*[.])\{1,4\}[A-Za-z]{2,6}$` Email addresses.

# XML Content Types

Jun 12, 2014

By default, the application firewall treats files that follow certain naming conventions as XML. You can configure the application firewall to examine web content for additional strings or patterns that indicate that those files are XML files. This can ensure that the application firewall recognizes all XML content on your site, even if certain XML content does not follow normal XML naming conventions, ensuring that XML content is subjected to XML security checks.

To configure the XML content types, you add the appropriate patterns to the XML Content Types list. You can enter a content type as a string, or you can enter a PCRE-compatible regular expression specifying one or more strings. You can also modify the existing XML content types patterns.

To add an XML content type pattern by using the command line interface

At the command prompt, type the following commands:

- `add appfw XMLContentType <XMLContenttypevalue> [-isRegex ( REGEX | NOTREGEX )]`
- `save ns config`

## Example

The following example adds the pattern `.*xml` to the XML Content Types list and designates it as a regular expression.

```
add appfw XMLContentType ".*xml" -isRegex REGEX
```

To remove an XML content type pattern by using the command line interface

At the command prompt, type the following commands:

- `rm appfw XMLContentType <XMLContenttypevalue>`
- `save ns config`

To configure the XML content type list by using the configuration utility

1. Navigate to Security > Application Firewall.
2. In the details pane, under Settings, click Manage XML Content Types.
3. In the Manage XML Content Types dialog box, do one of the following:
  - To add a new XML content type, click Add.
  - To modify an existing XML content type, select that type and then click Edit.The Configure Application Firewall XML Content Type dialog appears.  
Note: If you select an existing XML content type pattern and then click Add, the dialog box displays the information for that XML content type pattern. You can modify that information to create your new XML content type pattern.
4. In the dialog box, fill out the elements. They are:
  - **IsRegex.** Select or clear to enable PCRE-format regular expressions in the form field name.
  - **XML Content Type** Enter a literal string or PCRE-format regular expression that matches the XML content type pattern that you want to add.
5. Click Create.
6. To remove an XML content type pattern from the list, select it, then click Remove to remove it, and then click OK to confirm your choice.
7. When you have finished adding and removing XML content type patterns, click Close.

# JSON Content Types

Jun 12, 2014

By default, the application firewall treats files with the content type "application/json" as JSON files. The default setting enables the application firewall to recognize JSON content in requests and responses, and to handle that content appropriately.

You can configure the application firewall to examine web content for additional strings or patterns that indicate that those files are JSON files. This can ensure that the application firewall recognizes all JSON content on your site, even if certain JSON content does not follow normal JSON naming conventions, ensuring that JSON content is subjected to JSON security checks.

To configure the JSON content types, you add the appropriate patterns to the JSON Content Types list. You can enter a content type as a string, or you can enter a PCRE-compatible regular expression specifying one or more strings. You can also modify the existing JSON content types patterns.

To add a JSON content type pattern by using the command line interface

At the command prompt, type the following commands:

- add appfw JSONContentType <JSONContenttypevalue> [-isRegex ( REGEX | NOTREGEX )]
- save ns config

## Example

The following example adds the pattern `.*json` to the JSON Content Types list and designates it as a regular expression.

```
add appfw JSONContentType ".*json" -isRegex REGEX
```

To configure the JSON content type list by using the configuration utility

1. Navigate to Security > Application Firewall.
2. In the details pane, under Settings, click Manage JSON Content Types.
3. In the Manage JSON Content Types dialog box, do one of the following:
  - To add a new JSON content type, click Add.
  - To modify an existing JSON content type, select that type and then click Edit.

The Configure Application Firewall JSON Content Type dialog appears.

Note: If you select an existing JSON content type pattern and then click Add, the dialog box displays the information for that JSON content type pattern. You can modify that information to create your new JSON content type pattern.

4. In the dialog box, fill out the elements. They are:
  - **IsRegex.** Select or clear to enable PCRE-format regular expressions in the form field name.
  - **JSON Content Type** Enter a literal string or PCRE-format regular expression that matches the JSON content type pattern that you want to add.
5. Click Create or OK.
6. To remove a JSON content type pattern from the list, select it, then click Remove to remove it, and then click OK to confirm your choice.
7. When you have finished adding and removing XML content type patterns, click Close.

# Logs, Statistics, and Reports

Sep 03, 2013

The information maintained in the logs and statistics, and displayed in the reports, provides important guidance for configuring and maintaining the application firewall.

## The Application Firewall Logs

The logs provide information about the requests and responses that the application firewall has observed while protecting your web sites and applications. Most important, it logs each connection that matches a signature or a security check. You can observe the logs to determine which connections are matching a signature or security check. You can then use this information, along with your own knowledge about your protected web sites and applications, to determine whether the connections that each signature or check is matching are valid (false positives). If they are, you can either remove the signature or check from your configuration, or take appropriate measures to mitigate the false positives before you enable blocking for that signature or security check.

## NetScaler Format Logs

When configured to use NetScaler format logs, the application firewall produces logs that follow the same format as other NetScaler features. Each log contains the following fields:

- **Timestamp.** The date and time when the connection occurred.
- **Severity.** The severity level of the log.
- **Module.** The NetScaler module that generated the log entry.
- **Event Type.** The type of event, such as signature violation or security check violation.
- **Event ID.** The ID assigned to the event.
- **Client IP.** The IP address of the user whose connection was logged.
- **Transaction ID.** The ID assigned to the transaction that caused the log.
- **Session ID.** The ID assigned to the user session that caused the log.
- **Message.** The log message. Contains information identifying the signature or security check that triggered the log entry.

You can search on any of these fields, or any combination of information from different fields, to select logs to display, limited only by the capabilities of the tools you use to view the logs. You can observe the signatures by using the application firewall wizard to access the NetScaler syslog viewer, or manually by logging onto the NetScaler appliance or NetScaler virtual appliance.

## Viewing the Application Firewall Logs

You can view the logs by using the syslog viewer, or by logging onto the NetScaler appliance, opening a Unix shell, and using the Unix text editor of your choice.

- **Viewing by using the syslog viewer.** You invoke the syslog viewer from one of two locations: the Select Signature Actions page or the Select Advanced Actions page in the Application Firewall Wizard. To invoke the syslog viewer for a signature, in the Select Signature Actions pane click the logs link to the right of that signature. To invoke the syslog viewer for a security check, in the Select Advanced Actions page, security checks list, select that security check, and then beneath the list click the Logs button. Either procedure causes the configuration utility to download the current ns.log file and then display the entries that are relevant to that signature or security check.

The syslog viewer contains the following elements:

- *Module list box*. The NetScaler module whose logs you want to view. Always set to APPFW for application firewall logs.
  - *Event Type list box*. The type of event. For signatures, this is always APPFW\_SIGNATURE\_MATCH. For security checks, this is the specific security check that you selected.
  - *Severity*. It lets you specify only logs of a specific severity level. Leave blank to see all logs.
  - *Find Now button*. Search the nslog.file, using the current criteria, and display the logs that match.
  - *Clear button*. Resets your settings to the defaults.
  - *Logs display window*. Displays the logs that meet the current criteria. Log information is displayed in several columns that correspond to the log fields for the log format that the application firewall is currently configured to maintain, with an additional column, Deploy, to the extreme left. You can sort the display by clicking a column heading. You can create and implement a relaxation for a signature or security check that is blocking legitimate use of a protected web site or web service by selecting a log that shows the unwanted blocking, and then clicking Deploy.
  - *Log directory*. The directory where the logs are stored. If you have archived logs stored in a different directory and want to view those, you can click Browse and browse to that directory to display those logs in the Log files list.
  - *Log files list*. A list of the log files in the Log directory. To download and uncompress an archived log file, select the file, and then click Download. To refresh the display, click Refresh.
  - *Search in list box*. Searches in a particular section of logs when selecting logs to display in the Logs display window. To search something other than the log message, select a different choice.
  - *Search string*. Search for the specified string or regular expression to choose the logs to display in the Logs display window. This field is filled out by the application firewall wizard for you with the appropriate value to display the logs relevant to the signature or security check that you selected. You can modify the string to choose logs based on different criteria.
  - *Case Sensitive check box*. Select if the Search string is case sensitive.
  - *Regular Expression check box*. Select if the Search string is a regular expression.
  - *Clear button*. Resets the syslog viewer to its default settings.
  - *Go button*. Uses the new search criteria to search the ns.log file and displays the results in the Logs display window.
- For more information about the Application Firewall Wizard, see "[The Application Firewall Wizard](#)."
- **Viewing from the command line**. Log onto the application firewall appliance, and then type the following command at the NetScaler command prompt:

```
shell
```

After the Unix shell is displayed, type the following command to navigate to the directory where the logs are stored:

```
cd /var/log
```

You can use the vi editor, or any Unix text editor or text search tool of your choice to view and filter the logs for specific entries.

Note: If the text editor or text search tool is not installed by default on the NetScaler appliance, you must first install it before you can use it to view and filter the logs.

## The Application Firewall Statistics

When you enable the statistics action for application firewall signatures or security checks, the application firewall maintains information about connections that match that signature or security check. You can view the accumulated statistics information on the Monitoring tab of the main logon page of your application firewall appliance by selecting one of the following choices in the Select Group list box:

- **Application Firewall.** A summary of all statistics information gathered by your application firewall appliance for all profiles.
- **Application Firewall (per profile).** The same information, but displayed per-profile rather than summarized.

You can use this information to monitor how your application firewall is operating and determine whether there is any abnormal activity or abnormal amounts of hits on a signature or security check. If you see such a pattern of abnormal activity, you can check the logs for that signature or security check, to diagnose the issue, and then take corrective action.

## The Application Firewall Reports

The application firewall reports provide information about your application firewall configuration and how it is handling traffic for your protected web sites.

## The PCI DSS Report

The Payment Card Industry (PCI) Data Security Standard (DSS), version 1.2, consists of twelve security criteria that most credit card companies require businesses who accept online payments via credit and debit cards to meet. These criteria are designed to prevent identity theft, hacking, and other types of fraud. If an internet service provider or online merchant does not meet the PCI DSS criteria, that ISP or merchant risks losing authorization to accept credit card payments through its web site.

ISPs and online merchants prove that they are in compliance with PCI DSS by having an audit conducted by a PCI DSS Qualified Security Assessor (QSA) Company. The PCI DSS report is designed to assist them both before and during the audit. Before the audit, it shows which application firewall settings are relevant to PCI DSS, how they should be configured, and (most important) whether your current application firewall configuration meets the standard. During the audit, the report can be used to demonstrate compliance with relevant PCI DSS criteria.

The PCI DSS report consists of a list of those criteria that are relevant to your application firewall configuration. Under each criterion, it lists your current configuration options, indicates whether your current configuration complies with the PCI DSS criterion, and explains how to configure the application firewall so that your protected web site(s) will be in compliance with that criterion.

The PCI DSS report is located under System > Reports. To generate the report as an Adobe PDF file, click Generate PCI DSS Report. Depending on your browser settings, the report is displayed in the pop-up window or you are prompted to save it to your hard disk.

Note: To view this and other reports, you must have the Adobe Reader program installed on your computer.

The PCI DSS report consists of the following sections:

- **Description.** A description of the PCI DSS Compliance Summary report.
- **Firewall License and Feature Status.** Tells you whether the application firewall is licensed and enabled on your NetScaler appliance.
- **Executive Summary.** A table that lists the PCI DSS criteria and tells you which of those criteria are relevant to the application firewall.
- **Detailed PCI DSS Criteria Information.** For each PCI DSS criterion that is relevant to your application firewall configuration, the PCI DSS report provides a section that contains information about whether your configuration is currently in compliance and, if it is not, how to bring it into compliance.

- **Configuration.** Data for individual profiles, which you access either by clicking Application Firewall Configuration at the top of the report, or directly from the Reports pane. The Application Firewall Configuration report is the same as the PCI DSS report, with the PCI DSS-specific summary omitted, and is described below.

## The Application Firewall Configuration Report

The Application Firewall Configuration report is located under System > Reports. To display it, click Generate Application Firewall Configuration Report. Depending on your browser settings, the report is displayed in the pop-up window or you are prompted to save it to your hard disk.

The Application Firewall Configuration report starts with a Summary page, which consists of the following sections:

- **Application Firewall Policies.** A table that lists your current application firewall policies, showing the policy name, the content of the policy, the action (or profile) it is associated with, and global binding information.
- **Application Firewall Profiles.** A table that lists your current application firewall profiles and indicates which policy each profile is associated with. If a profile is not associated with a policy, the table displays INACTIVE in that location.

To download all report pages for all policies, at the top of the Profiles Summary page click Download All Profiles. You display the report page for each individual profile by selecting that profile in the table at the bottom of the screen. The Profile page for an individual profile shows whether each check action is enabled or disabled for each check, and the other configuration settings for the check.

To download a PDF file containing the PCI DSS report page for the current profile, click Download Current Profile at the top of the page. To return to the Profiles Summary page, click Application Firewall Profiles. To go back to the main page, click Home. You can refresh the PCI DSS report at any time by clicking Refresh in the upper right corner of the browser. You should refresh the report if you make changes to your configuration.

# Configuring the Application Firewall Logs

Sep 03, 2013

You can configure the application firewall logs by using the configuration utility or the NetScaler command line. You can configure the application firewall to produce logs in either native NetScaler format, or in Common Event Format (CEF).

To configure the Application Firewall logs by using the command line interface

At the command prompt, type the following commands:

- set appfw settings -CEFLogging ( **ON** | **OFF** )
- save ns config

## Example

The following example configures the application firewall to use CEF logs.

```
set appfw settings -CEFLogging ON
save ns config
```

The following example disables CEF logs and returns the application firewall configuration to using native NetScaler format logs.

```
set appfw settings -CEFLogging OFF
save ns config
```

# Appendices

Sep 30, 2013

The following supplemental material provides additional detail about complex or peripheral application firewall tasks.

# PCRE Character Encoding Format

Mar 28, 2012

The NetScaler operating system supports direct entry of characters in the printable ASCII character set only—characters with hexadecimal codes between HEX 20 (ASCII 32) and HEX 7E (ASCII 127). To include a character with a code outside that range in your application firewall configuration, you must enter its UTF-8 hexadecimal code as a PCRE regular expression.

A number of character types require encoding using a PCRE regular expression if you include them in your application firewall configuration as a URL, form field name, or Safe Object expression. They include:

- **Upper-ASCII characters.** Characters with encodings from HEX 7F (ASCII 128) to HEX FF (ASCII 255). Depending on the character map used, these encodings can refer to control codes, ASCII characters with accents or other modifications, non-Latin alphabet characters, and symbols not included in the basic ASCII set. These characters can appear in URLs, form field names, and safe object expressions.
- **Double-Byte characters.** Characters with encodings that use two 8-byte words. Double-byte characters are used primarily for representing Chinese, Japanese, and Korean text in electronic format. These characters can appear in URLs, form field names, and safe object expressions.
- **ASCII control characters.** Non-printable characters used to send commands to a printer. All ASCII characters with hexadecimal codes less than HEX 20 (ASCII 32) fall into this category. These characters should never appear in a URL or form field name, however, and would rarely if ever appear in a safe object expression.

The NetScaler appliance does not support the entire UTF-8 character set, but only the characters found in the following eight charsets:

- **English US (ISO-8859-1).** Although the label reads, “English US,” the application firewall supports all characters in the ISO-8859-1 character set, also called the Latin-1 character set. This character set fully represents most modern western European languages and represents all but a few uncommon characters in the rest.
- **Chinese Traditional (Big5).** The application firewall supports all characters in the BIG5 character set, which includes all of the Traditional Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in Hong Kong, Macau, Taiwan, and by many people of Chinese ethnic heritage who live outside of mainland China.
- **Chinese Simplified (GB2312).** The application firewall supports all characters in the GB2312 character set, which includes all of the Simplified Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in mainland China.
- **Japanese (SJIS).** The application firewall supports all characters in the Shift-JIS (SJIS) character set, which includes most characters (ideographs) commonly used in modern Japanese.
- **Japanese (EUC-JP).** The application firewall supports all characters in the EUC-JP character set, which includes all characters (ideographs) commonly used in modern Japanese.
- **Korean (EUC-KR).** The application firewall supports all characters in the EUC-KR character set, which includes all characters (ideographs) commonly used in modern Korean.
- **Turkish (ISO-8859-9).** The application firewall supports all characters in the ISO-8859-9 character set, which includes all letters used in modern Turkish.

- **Unicode (UTF-8).** The application firewall supports certain additional characters in the UTF-8 character set, including those used in modern Russian.

When configuring the application firewall, you enter all non-ASCII characters as PCRE-format regular expressions using the hexadecimal code assigned to that character in the UTF-8 specification. Symbols and characters within the normal ASCII character set, which are assigned single, two-digit codes in that character set, are assigned the same codes in the UTF-8 character set. For example, the exclamation point (!), which is assigned hex code 21 in the ASCII character set, is also hex 21 in the UTF-8 character set. Symbols and characters from another supported character set have a paired set of hexadecimal codes assigned to them in the UTF-8 character set. For example, the letter a with an acute accent (á) is assigned UTF-8 code C3 A1.

The syntax you use to represent these UTF-8 codes in the application firewall configuration is “\xNN” for ASCII characters; “\xNN\xNN” for non-ASCII characters used in English, Russian, and Turkish; and “\xNN\xNN\xNN” for characters used in Chinese, Japanese, and Korean. For example, if you want to represent a ! in an application firewall regular expression as a UTF-8 character, you would type \x21. If you want to include an á, you would type \xC3\xA1.

Note: Normally you do not need to represent ASCII characters in UTF-8 format, but when those characters might confuse a web browser or an underlying operating system, you can use the character’s UTF-8 representation to avoid this confusion. For example, if a URL contains a space, you might want to encode the space as \x20 to avoid confusing certain browsers and web server software.

Below are examples of URLs, form field names, and safe object expressions that contain non-ASCII characters that must be entered as PCRE-format regular expressions to be included in the application firewall configuration. Each example shows the actual URL, field name, or expression string first, followed by a PCRE-format regular expression for it.

- A URL containing extended ASCII characters.

Actual URL: <http://www.josénuñez.com>

Encoded URL: `^http://www[.]j[os\xC3xA9nu\xC3xB1ez[.]com$`

- Another URL containing extended ASCII characters.

Actual URL: <http://www.example.de/trömsö.html>

Encoded URL: `^http://www[.]example[.]de/tr\xC3xB6msö[.]html$`

- A form field name containing extended ASCII characters.

Actual Name: nome\_do\_usuário

Encoded Name: `^nome_do_usu\xC3xA1rio$`

- A safe object expression containing extended ASCII characters.

Unencoded Expression `[A-Z]{3,6}¥[1-9][0-9]{6,6}`

Encoded Expression: `[A-Z]{3,6}\xC2xA5[1-9][0-9]{6,6}`

You can find a number of tables that include the entire Unicode character set and matching UTF-8 encodings on the Internet. A useful web site that contains this information is located at the following URL:

<http://www.utf8-chartable.de/unicode-utf8-table.pl>

For the characters in the table on this web site to display correctly, you must have an appropriate Unicode font installed on your computer. If you do not, the visual display of the character may be in error. Even if you do not have an appropriate font installed to display a character, however, the description and the UTF-8 and UTF-16 codes on this set of web pages will be correct.

# Whitehat WASC Signature Types for WAF Use

May 02, 2013

The Citrix NetScaler Application Firewall accepts and generates blocking rules for all vulnerability types that the Whitehat scanners generate. However, certain vulnerabilities are most applicable to a web application firewall. Following are lists of those vulnerabilities, categorized by whether they are addressed by WASC 1.0, WASC 2.0, or best practices signature types.

## WASC 1.0 Signature Types

- HTTP Request Smuggling
- HTTP Response Splitting
- HTTP Response Smuggling
- Null Byte Injection
- Remote File Inclusion
- URL Redirector Abuse

## WASC 2.0 Signature Types

- Abuse of Functionality
- Brute Force
- Content Spoofing
- Denial of Service
- Directory Indexing
- Information Leakage
- Insufficient Anti-automation
- Insufficient Authentication
- Insufficient Authorization
- Insufficient Session Expiration
- LDAP Injection
- Session Fixation

## Best Practices

- Autocomplete Attribute
- Insufficient Cookie Access Control
- Insufficient Password Strength
- Invalid HTTP Method Usage
- Non-HttpOnly Session Cookie
- Persistent Session Cookie
- Personally Identifiable Information
- Secured Cachable HTTP Messages
- Unsecured Session Cookie

# Streaming Support for Request Processing

Jan 16, 2015

Note: This feature is available in NetScaler release 10.5.e.

The Citrix application firewall now uses request side streaming, which results in a significant performance boost. Instead of buffering the entire request before processing it, the application firewall now looks at the incoming data, field by field, to inspect the input of each field for any configured security check violation (SQL, XSS, Field Consistency, Field Formats, etc.). As soon as the processing of the data for a field is completed, it is forwarded to the backend while the evaluation continues for the remaining fields. This significantly improves the processing time specially when handling large posts where the forms have large number of fields.

Although the streaming process is transparent to the users, minor configuration adjustments are required due to the following changes:

**RegEx Pattern Match:** RegEx pattern match is now restricted to 4K for contiguous character string match.

**Field Name Match:** Application firewall learning engine can only distinguish the first 128 bytes of the name for learning. If a form has multiple fields with names that have identical string match for the first 128 bytes, the learning engine may not be able to distinguish between them. Similarly, the deployed relaxation rule might inadvertently relax all such fields.

Removing white spaces, percent decoding, unicode decoding, and charset conversion which is done during canonicalization is carried out prior to security check inspection. The 128 byte limit is applicable to the canonicalized representation of the field name in UTF-8 character format. The ASCII characters are 1 byte but the UTF-8 representation of the characters in some international languages may range from 1-4 bytes. If each character in the name takes 4 bytes when converted to UTF-8 format, only first 32 characters in the name may be distinguished by the learned rule for such a language.

**Field Consistency Check:** When the field Consistency check is enabled, all the forms in the session are now stored based on the "as\_fid" tag inserted by the application firewall without consideration for the "action\_url."

- **Mandatory Form tagging for Form Field consistency:** When the field consistency check is enabled, the form tag must be enabled also. The Field Consistency protection might not work if form tagging is turned off.
- **Sessionless Form Field Consistency:** The application firewall no longer carries out the "GET" to "POST" conversion of forms when sessionless field consistency parameter is enabled. The form tag is required for sessionless field consistency also.
- **Tampering of as\_fid:** If a form is submitted after tampering as\_fid, it now triggers field consistency violation even if no other field was tampered. In non-streaming requests, this was allowed because the forms could be validated using the "action\_url" stored in the session.

**Signatures:** The signatures now have the following specifications:

- **Location:** It is now a mandatory requirement that location must be specified for each pattern. All patterns in the rule **MUST** have a <Location> tag.
- **Fast Match:** All signature rules must have a fast match pattern. If there is no fast match pattern, an attempt will be made to select one if possible. Fast match must be a literal string but some PCRE's can be used for fast match if they contain a usable literal string.
- **Deprecated Locations:** Following locations are no longer supported in signature rules.
  - HTTP\_ANY
  - HTTP\_RAW\_COOKIE
  - HTTP\_RAW\_HEADER
  - HTTP\_RAW\_RESP\_HEADER

- HTTP\_RAW\_SET\_COOKIE

**XSS/SQL Transform:** Raw data is used for transformation because the SQL special characters ( single quote('), backslash (\), and semicolon (;), and XSS tags (<) and(>)) are same in all languages and do not need canonicalization of data. All representations of these characters, such as HTML entity encoding, percent encoding, or ASCII are evaluated for transform operation.

The application firewall no longer inspects both the attribute name and value for the XSS transform operation. Now only XSS attribute names are transformed when streaming is engaged.

**RAW POST Body:** The security check inspections are always done on RAW POST body.

**Form ID:** The application firewall inserted "as\_fid" tag, which is a computed hash of the form, will no longer be unique for the user session. It will now have an identical value for a specific form irrespective of the user or the session.

**Charset:** If a request does not have a charset, the default charset specified in the application profile is used when processing the request.

#### **Counters:**

Counters with prefix "se\_" and "appfwreq\_" are added to track the streaming engine and the application firewall streaming engine request counters respectively.

nsconsmg -d statswt0 -g se\_err\_

nsconsmg -d statswt0 -g se\_tot\_

nsconsmg -d statswt0 -g se\_cur\_

nsconsmg -d statswt0 -g appfwreq\_err\_

nsconsmg -d statswt0 -g appfwreq\_tot\_

nsconsmg -d statswt0 -g appfwreq\_cur\_

\_err counters: indicate the rare event which should have succeeded but failed due to either memory allocation problem or some other resource crunch.

\_tot counters: ever increasing counters.

\_cur counters: counters indicating current values that keep changing based on usage from current transactions.

#### **Tips:**

- The application firewall security checks should work exactly the same as before.
- There is no set ordering for the processing of the security checks.
- The response side processing is not affected and remains unchanged.
- Streaming is not engaged if CVPN is used.

# Trace HTML Requests with Security Logs

Jan 16, 2015

Note: This feature is available in NetScaler release 10.5.e.

Troubleshooting a problem, which requires analysis of data received in the client request can be quite challenging specially when there is heavy traffic flowing through the box. Diagnosing issues which may affect the functionality or security of the application require a quick response.

The NetScaler now offers the option to isolate traffic for a specific application firewall profile and collect nstrace for the HTML requests that trigger a log or block action or malformed requests that might be causing reset or aborts. The nstrace collected in –appfw mode will include details of the entire request including the application firewall generated log messages. You can use “Follow TCP stream” in the trace to view the details of the individual transaction including headers, payload, as well as the corresponding log message, together in the same screen.

This gives you a comprehensive overview regarding your traffic. Having a detailed view of the request, payload, and associated log records can be very useful to analyze security check violation. You can easily identify the pattern that is triggering the violation. If the pattern should be allowed, you can take a decision to modify the configuration and/or add a relaxation rule.

This enhancement helps in troubleshooting the NetScaler ADC and offers the following benefits:

1. **Isolate traffic for specific profile:** This enhancement can be quite useful when you need to isolate traffic for only one profile or specific transactions of a profile for troubleshooting. You no longer have to skim through the entire data collected in the trace or need special filters to isolate requests that are of interest to you which can be tedious especially with heavy traffic. You now have the option to view only the data that you are interested in.
2. **Collect data for specific requests:** The trace can be collected for a specified duration. You can collect trace for only a couple of requests to isolate, analyze, and debug specific transactions if needed.
3. **Identify resets or aborts:** Unexpected closing of connections are not easily visible. The trace collected in –appfw mode captures a reset or an abort, triggered by the application firewall. This allows a quicker isolation of issue when you do not see a security check violation message. Malformed requests or other non-RFC compliant requests terminated by application firewall will now be easier to identify.
4. **View decrypted SSL traffic:** HTTPS traffic is captured in plain text to allow for easier troubleshooting.
5. **Provides comprehensive view:** Allows you to look at the entire request at the packet level, check the payload, look at the logs to check what security check violation is being triggered and identify the match pattern in the payload. If the payload consists of any unexpected data, junk strings, or non-printable characters (null character, \r or \n etc), they are easy to discover in the trace.
6. **Modify configuration:** The debugging can provide useful information to decide if the observed behavior is the correct behavior or the configuration should be modified.
7. **Expedite response time:** Faster debugging on target traffic can improve the response time to provide explanations and/or root cause analysis by Citrix engineering and support team.

Please see any task topic in eDocs for documenting tasks. <http://support.citrix.com/proddocs/topic/ns-security-10-5-map/appfw-config-manual-cli-tsk.html>

## To configure debug tracing for a profile by using the command line interface

Step 1. Enable tracing for the profile. You can use the show command to verify the configured setting.

- set appfw profile <profile> -trace ON

Step 2. Start collecting trace. You can continue to use all the options which are applicable for the nstrace command.

- start nstrace -mode APPFW

Stop collecting the trace

- stop nstrace

**Location of the trace:** The nstrace is stored in a time-stamped folder which is created in the /var/nstrace directory and can be viewed using wireshark. You can tail the /var/log/ns.log to see the log messages providing details regarding the location of the new trace.

#### Tips:

- When -appfw mode option is used, the nstrace will only collect the data for the profile(s) for which "trace" was enabled.
- Enabling trace on the profile will not automatically start collecting the traces till you explicitly execute the "start nstrace" command to collect the trace.
- Although, enabling trace on a profile may not have any adverse effect on the performance of the application firewall but you may want to enable this feature only for the duration for which you want to collect the data. It is recommended that you turn the -trace flag off after you have collected the trace. This will prevent the risk of inadvertently getting data from profiles for which you had enabled this flag in the past.
- The Block or Log action must be enabled for the security check for the transaction record to be included in the nstrace.
- Resets and aborts will be logged independently of security checks actions when trace is "On" for the profile(s).
- This feature is only applicable for troubleshooting the requests received from the client. The traces in -appfw mode do not include the responses received from the server.
- You can continue to use all the options which are applicable for the nstrace command. For example, "start nstrace -tcpdump enabled -size 0 -mode appFW"
- If a request triggers multiple violations, the nstrace for that record will include all the corresponding log messages.
- CEF log message format is supported for this functionality.
- Signature violations triggering block and/or log action for request side checks will also be included in the trace.
- Only HTML (non-XML) requests are collected in the trace.

#### Example of a Log record in the trace:

# Content Filtering

Sep 03, 2013

Content filtering can do some of the same tasks as the Citrix NetScaler Application Firewall, and is a less CPU-intensive tool. It is limited, however, to examining the header portion of the HTTP request or response and to performing a few simple actions on connections that match. If you have a complex Web site that makes extensive use of scripts and accesses back-end databases, the Application Firewall may be the better tool for protecting that Web site. For more information about the Citrix NetScaler Application Firewall, see the *Citrix Application Firewall Guide* at <http://support.citrix.com/article/CTX132360>.

Content filtering is based on regular expressions that you can apply to either HTTP requests or HTTP responses. To block requests from a particular site, for example, you could use an expression that compares each request's URL to the URL specified in the expression. The expression is part of a policy, which also specifies an action to be performed on requests or responses that match the expression. For example, an action might drop a request or reset the connection.

Following are some examples of things you can do with content filtering policies:

- Prevent users from accessing certain parts of your Web sites unless they are connecting from authorized locations.
- Prevent inappropriate HTTP headers from being sent to your Web server, possibly breaching security.
- Redirect specified requests to a different server or service.

To configure content filtering, once you have made sure that the feature is enabled, you configure filtering actions for your servers to perform on selected connections (unless the predefined actions are adequate for your purposes). Then you can configure policies to apply the actions to selected connections. Your policies can use predefined expressions, or you can create your own. To activate the policies you configured, you bind them either globally or to specific virtual servers.

To configure content filtering, do the following:

1. [Enabling Content Filtering](#)
2. [Configuring a Content Filtering Action](#)
3. [Configuring a Content Filtering Policy](#)
4. [Binding a Content Filtering Policy](#)

# Enabling Content Filtering

Oct 31, 2013

By default, content filtering is enabled on NetScaler appliances running the NetScaler operating system 8.0 or above. If you are upgrading an existing appliance from an operating system version earlier than 8.0, you must update the licenses before you can use content filtering, and you may need to enable the content filtering feature itself manually.

To enable content filtering by using the command line interface

At the command prompt, type the following commands to enable content filtering and verify the configuration:

- enable ns feature ContentFiltering
- show ns feature

## Example

```
> enable ns feature ContentFiltering
```

```
Done
```

```
> show ns feature
```

|     | Feature                  | Acronym       | Status    |
|-----|--------------------------|---------------|-----------|
|     | -----                    | -----         | -----     |
| 1)  | Web Logging              | WL            | ON        |
| 2)  | Surge Protection         | SP            | OFF       |
| .   |                          |               |           |
| .   |                          |               |           |
| .   |                          |               |           |
| .   |                          |               |           |
| 11) | Http DoS Protection      | HDOSP         | OFF       |
| 12) | <b>Content Filtering</b> | <b>CF</b>     | <b>ON</b> |
| .   |                          |               |           |
| .   |                          |               |           |
| 23) | HTML Injection           | HTMLInjection | ON        |
| 24) | NetScaler Push           | push          | OFF       |

```
Done
```

To enable content by filtering by using the configuration utility

1. In the navigation pane, expand **System**, and then select **Settings**.
2. In the details pane, click **Configure basic features**.
3. In the Configure Basic Features dialog box, select the **Content Filter** check box, and then click **OK**.

# Configuring a Content Filtering Action

Sep 03, 2013

After you enable the content filtering feature, you create one or more actions to tell your NetScaler appliance how to handle the connections it receives.

Content filter **Qualifier\*** drop-down list allows you to select the **action** to be performed. Following options are available:

## Reset

Terminates the connection, sending the appropriate termination notice to the user's browser.

## Add

Adds the specified HTTP header before sending the request to the Web server.

## Corrupt

Modifies the designated HTTP header in a manner that prevents it from performing the function it was intended to perform, then sends the request to the server.

## Forward

Redirects the request to the designated service.

## ErrorCode

Returns the designated HTTP error code to the user's browser with an option to configure a **Response page**.

## Drop

Silently deletes the request, without sending a response to the user's browser.

To configure a content filtering action by using the command line interface

At the command prompt, type the following commands to configure a Content Filtering action and verify the configuration:

- add filter action <name> <qualifier> [<serviceName>] [<value>] [<respCode>] [<page>]
- show filter action <name>

## Example

```
> add filter action act_drop Drop
```

```
Done
```

```
> show filter action act_drop
```

```
1) Name: act_drop Filter Type: drop
```

```
Done
```

To configure a content filtering action by using the configuration utility

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, do one of the following:
  - To create a new filter action, in the **Filter Actions** Tab, click **Add**.
  - To modify an existing action, select the action, and then click **Edit**.
3. In the Add Filter Action or Configure Filter Action dialog box, specify values for the parameters:
  - Action Name\*—name
  - Qualifier\*—qualifier ( Determines which of the following parameters you can configure)
  - Service Name—servicename
  - HeaderName:Value—value

- Response Code—respcode
  - Response Page—page
4. Fill in any other required information. For example, if you are configuring an action to send an HTTP error code, you must choose the appropriate error code from a drop-down list. If necessary, you can then modify the text of the error message, which is displayed beneath the drop-down list.
  5. Click Create or OK, and then click Close. The Actions list displays the action you configured, and a message in the status bar indicates that your action has been created.

# Configuring a Content Filtering Policy

Sep 03, 2013

To implement content filtering, you must configure at least one policy to tell your NetScaler appliance how to distinguish the connections you want to filter. You must first have configured at least one filtering action, because when you configure a policy, you associate it with an action.

Content filtering policies examine a combination of one or more of the following elements to select requests or responses for filtering:

## **URL**

The URL in the HTTP request.

## **URL query**

Only the query portion of the URL, which is the portion after the query (?) symbol.

## **URL token**

Only the tokens in the URL, if any, which are the parts that begin with an ampersand (&) and consist of the token name, followed by an equals sign (=), followed by the token value.

## **HTTP method**

The HTTP method used in the request, which is usually GET or POST, but can be any of the eight defined HTTP methods.

## **HTTP version**

The HTTP version in the request, which is usually HTTP 1.1.

## **Standard HTTP header**

Any of the standard HTTP headers defined in the HTTP 1.1 specification.

## **Standard HTTP header value**

The value portion of the HTTP header, which is the portion after the colon and space (:).

## **Custom HTTP header**

A non-standard HTTP header issued by your Web site or that appears in a user request.

## **Custom header value**

The value portion of the custom HTTP header, which (as with the standard HTTP header) is the portion after the colon and space (:).

## **Client Source IP**

The IP from which the client request was sent.

Content filtering policies use the simpler of two NetScaler expressions languages, called classic expressions. For a complete description of classic expressions, how they work, and how to configure them manually, see "[Policies and Expressions](#)."

Note: Users who are not experienced in configuring policies at the NetScaler command line will usually find using the configuration utility considerably easier.

To configure a content filtering policy by using the command line interface

At the command prompt, type the following commands to configure a content filtering policy and verify the configuration:

- add filter policy <name> -rule <expression> (-reqAction <action> | -resAction <string>)
- show filter policy <name>

### Example

```
> add filter policy cf-pol -rule "REQ.HTTP.URL CONTAINS http://abc.com" -reqaction DROP
```

Done

```
> show filter policy cf-pol
```

```
1) Name: cf-pol Rule: REQ.HTTP.URL CONTAINS http://abc.com
 Request action: DROP
 Response action:
 Hits: 0
```

Done

To configure a content filtering policy by using the configuration utility

1. Navigate to Security > Protection Features > Filter.
2. Navigate to Protection Features > Filter.
3. In the details pane, to create a new policy, click Add.
4. If you are creating a new policy, in the Create Filter Policy dialog box, in the Filter Name text box, type a name for your new policy.
5. Select either Request Action or Response Action to activate the drop-down list to the right of that item.
6. Click the down arrow to the right of the drop-down list and select the action to be performed on the request or response. The default choices are RESET and DROP. Any other actions you have created will also appear in this list.  
Note: You can also click New to create a new Content Filtering action, or Modify to modify an existing Content Filtering action. You can only modify actions you created; the default actions are read-only.
7. If you want to use a predefined expression (or named expression) to define your policy, choose one from the Named Expressions list.
  1. Click the down arrow to the right of the first Named Expressions drop-down list, and choose the category of named expressions that contains the named expression you want to use.
  2. Click the down arrow to the right of the second Named Expressions drop-down list, and choose the named expression you want. As you choose a named expression, the regular expression definition of that named expression appears in the Preview Expression pane beneath the Named Expression list boxes.
  3. Click Add Expression to add that named expression to the Expression list.  
Note: You should perform either this step or step 7, but not both.
8. If you want to create a new expression to define your policy, use the Expression Editor.
  1. Click the Add button. The Add Expression dialog box appears.
  2. In the Add Expression dialog box, choose the type of connection you want to filter. The Flow Type is set to REQ by default, which tells the NetScaler appliance to look at incoming connections, or requests. If you want to filter outgoing connections (responses), you click the right arrow beside the drop-down list and choose RES.
  3. If the Protocol is not already set to HTTP, click the down arrow to the right of the Protocol drop-down list and choose HTTP.  
Note: In the NetScaler classic expressions language, "HTTP" includes HTTPS requests, as well.
  4. Click the down arrow to the right of the Qualifier drop-down list, and then choose a qualifier for your expression. Your choices are:

#### **METHOD**

The HTTP method used in the request.

#### **URL**

The contents of the URL header.

**URLTOKENS**

The URL tokens in the HTTP header.

**VERSION**

The HTTP version of the connection.

**HEADER**

The header portion of the HTTP request.

**URLLEN**

The length of the contents of the URL header.

**URLQUERY**

The query portion of the contents of the URL header.

**URLQUERYLEN**

The length of the query portion of the URL header.

The contents of the remaining list boxes change to the choices appropriate to the Qualifier you pick. For example, if you choose HEADER, a text field labeled Header Name\* appears below the Flow Type list box.

5. Click the down arrow to the right of the Operator drop-down list, and choose an operator for your expression. Your choices will vary depending on the Protocol you chose in the preceding step. The following list includes all of the operators:

**==**

Matches the following text string exactly.

**!=**

Does not exactly match the following text string.

**>**

Is greater than the following integer.

**CONTAINS**

Contains the following text string.

**CONTENTS**

The contents of the designated header, URL, or URL query.

**EXISTS**

The specified header or query exists.

**NOTCONTAINS**

Does not contain the following text string.

**NOTEXISTS**

The specified header or query does not exist.

6. If the Value text box is visible, type the appropriate string or number. If you are testing a string in any way, type the string into the Value text box. If you are testing an integer in any way, type the integer into the Value text box.
7. If you chose HEADER as the Protocol, type the header you want in the Header Name\* text box.
8. Click OK to add your expression to the Expressions list.
9. Repeat steps B through H to create any additional expressions you want for your profile.

10. Click Close to close the Expressions Editor.
9. If you created a new expression, in the Expression frame select an option from the Match Any Expression drop-down list. Your choices are:
  - Match Any Expression. If a request matches any expression in the Expressions list, the request matches this policy.
  - Match All Expressions. If a request matches all expressions in the Expressions list, the request matches this policy. If it does not match all of them, it does not match this policy.
  - Tabular Expression Switches the Expressions list to a tabular format with three columns. In the first column you can place a BEGIN [ ] operator. The second column contains the expressions you have selected or created. In the third column, you can place any of the other operators in the following list, to create complex policy groups in which each group can be configured for match any expression or match all expressions.
  - The AND [ && ] operator tells the appliance to require that a request match both the current expression and the following expression.
  - The OR [ | ] operator tells the appliance to require that a request match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.
  - The END [ ] operator tells the appliance that this is the last expression in this expression group or policy.  
Note: The Tabular format allows you to create a complex policy that contains both “Match Any Expression” and “Match All Expressions” on a per-expression basis. You are not limited to just one or the other.
  - Advanced Free-Form Switches off the Expressions Editor entirely and modifies the Expressions list into a text area. In the text area, you can type the PCRE-format regular expression of your choice to define this policy. This is both the most powerful and the most difficult method of creating a policy, and is recommended only for those thoroughly familiar with the NetScaler appliance and PCRE-format regular expressions.  
Caution: If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression editing mode unless you are sure that is what you want.
10. Repeat steps 6 through 8 to add any additional expressions you want to the Expressions list. You can mix named expressions and expressions created in the Expressions Editor. To the NetScaler appliance, they are all the same.
11. Click Create to create your new policy. Your new policy appears in the Policies pane list.
12. Click Close. To create additional Content Filtering policies, repeat the previous procedure. To remove a Content Filtering policy, select the policy in the Policies tab and click Remove.

# Binding a Content Filtering Policy

Oct 31, 2013

You must bind each content filtering policy to put it into effect. You can bind policies globally or to a particular virtual server. Globally bound policies are evaluated each time traffic directed to any virtual server matches the policy. Policies bound to a specific vserver are evaluated only when that vserver receives traffic that matches the policy.

To bind a policy to a virtual server by using the command line interface

At the command prompt, type the following commands to bind a policy to a virtual server and verify the configuration:

- `bind lb vserver <name>@ -policyName <string> -priority <positive_integer>`
- `show lb vserver <name>`

## Example

```
> bind lb vserver vs-loadbal -policyName policyTwo -priority 100
Done
> show lb vserver vs-loadbal
1) vs-loadbal (10.102.29.20:80) - HTTP Type: ADDRESS
 State: OUT OF SERVICE
 Last state change was at Wed Aug 19 09:05:47 2009 (+211 ms)
 Time since last state change: 2 days, 00:58:03.260
 Effective State: DOWN
 Client Idle Timeout: 180 sec
 Down state flush: ENABLED
 Disable Primary Vserver On Down : DISABLED
 Port Rewrite : DISABLED
 No. of Bound Services : 0 (Total) 0 (Active)
 Configured Method: LEASTCONNECTION
 Mode: IP
 Persistence: NONE
 Vserver IP and Port insertion: OFF
 Push: DISABLED Push VServer:
 Push Multi Clients: NO
 Push Label Rule: none
```

Done

To globally bind a policy by using the command line interface

At the command prompt, type the following commands to globally bind a policy and verify the configuration:

- `bind filter global (<policyName> [-priority <positive_integer>]) [-state ( ENABLED | DISABLED )]`
- `show filter global`

## Example

```
bind filter global cf-pol -priority 1
Done show filter global
```

1) Policy Name: cf-pol Priority: 1

Done

To bind a policy to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server to which you want to bind the content filtering policy from the list, and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab, and then select the check box in the Active column of the filter policy that you want to bind to the virtual server.
4. Click OK. The policies you have bound display a check mark and the word Yes in the Policies Bound column of the Policies tab.

To globally bind a policy by using the configuration utility

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, in the Policies tab, select the policy that you want to bind, and then click Global Bindings.
3. In the Bind/Unbind Filter Policies dialog box, in the Policy Name drop-down list, select a policy, and then click Add. The policy is added to the Configured list.  
Note: To select multiple policies from the list, press and hold the Ctrl key, then click each policy you want.
4. Click OK, and then click Close. The policies you have bound display a check mark and the word Yes in the Globally Bound column of the Policies tab.

# Configuring Content Filtering for a Commonly Used Deployment Scenario

Oct 31, 2013

This example provides instructions for using the configuration utility to implement a content filtering policy in which, if a requested URL contains root.exe or cmd.exe, the content filtering policy filter-CF-nimda is evaluated and the connection is reset.

To configure this content filtering policy, you must do the following:

- Enable content filtering
- Configure content filtering policy
- Bind content filtering policy globally or to a virtual server
- Verify the configuration

Note: Since this example uses a default content filtering action, you do not need to create a separate content filtering action.

To enable content filtering

1. In the navigation pane, expand System, and click Settings.
2. In the details pane, under Modes & Features, click Change Basic Features.
3. In the Configure Basic Features dialog box, select the Content Filtering check box, and then click OK.
4. In the Enable/Disable feature(s) dialog box, click Yes. A message appears in the status bar, stating that the selected feature is enabled.

To configure the content filtering policy filter-CF-nimda

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, click Add. The Create Filter Policy dialog box appears.
3. In the Create Filter Policy dialog box, in the Filter Name text box, type the name filter-CF-nimda.
4. Select the Request Action option, and in the drop-down list, select RESET.
5. In the Expression frame, select Match Any Expression from the drop-down list, and then click Add.
6. In the Add Expression dialog box, Expression Type drop-down list, select General.
7. In the Flow Type drop-down list, select REQ.
8. In the Protocol drop-down list, select HTTP.
9. In the Qualifier drop-down list, select URL.
10. In the Operator drop-down list, select CONTAINS.
11. In the Value text box, type cmd.exe, and then click OK. The expression is added in the Expression text box.
12. To create another expression, repeat Steps 7 through 11, but in the Value text box, type root.exe. Then click OK, and finally click Close.
13. Click Create on the Create Filter Policy dialog box. The filter policy filter-CF-nimda appears in the Filter list.
14. Click Close.

To globally bind the content filtering policy

1. Navigate to Security > Protection Features > Filter. The Filter page appears in the right pane.
2. In the details pane, Policies tab, select the policy that you want to bind and click Global Bindings. The Bind/Unbind Filter Policies dialog box appears.

3. In the Bind/Unbind Filter Policies dialog box, in the Policy Name drop-down list, select the policy filter-CF-nimda, and click Add. The policy is added to the Configured list.
4. Click OK, and then click Close. The policy you have bound displays a check mark and Yes in the Globally Bound column of the Policies tab.

To bind the content filtering policy to a virtual server

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane virtual servers list, select vserver-CF-1 to which you want to bind the content filtering policy and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab.
4. In the Active column, select the check box for the policy filter-CF-nimda, and then click OK. Your content filtering policy is now active, and should be filtering requests. If it is functioning correctly, the Hits counter is incremented every time there is a request for a URL containing either root.exe or cmd.exe. This allows you to confirm that your content filtering policy is working. The content filtering policy is bound to the virtual server.

To verify the content filtering configuration by using the command line interface

At the command prompt, type the following command to verify the content filtering configuration:

```
show filter policy filter-CF-nimda
```

**Example**

```
sh filter policy filter-CF-nimda
```

```
 Name: filter-CF-nimda Rule: REQ.HTTP.URL CONTAINS cmd.exe || REQ.HTTP.URL CONTAINS root.exe
```

```
 Request action: RESET
```

```
 Response action:
```

```
 Hits: 0
```

```
Done
```

Note: The Hits counter displays an integer that denotes the number of times the filter-CF-nimda policy is evaluated. In the preceding steps, the Hits counter is set to zero because no requests for a URL containing either cmd.exe or root.exe have been made yet. If you want to see the counter increment in real time, you can simply request a URL that contains either of these strings.

To verify the content filtering configuration by using the configuration utility

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, select the filter policy filter-CF-nimda. The bottom of the pane should display the following:

**Request Action:**

```
RESET
```

**Rule:**

```
REQ.HTTP.URL CONTAINS cmd.exe | | REQ.HTTP.URL CONTAINS root.exe
```

**Hits:**

```
0
```

# Troubleshooting

Jul 22, 2013

If the content filtering feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

## Resources for Troubleshooting

Updated: 2013-07-22

You can use the following tools and resources to troubleshoot most Content Filtering issues on a NetScaler appliance:

- The Wireshark application customized for the NetScaler trace files
- Trace files recorded when accessing the resource
- The configuration files
- The ns.log file
- The iehttphheaders, or a Fiddler trace or a similar utility

## Troubleshooting Content Filtering Issues

Updated: 2013-08-02

To troubleshoot a content filtering issue, proceed as follows:

- Verify that the feature is enabled.
- Verify that the content filtering policy is configured correctly. Pay special attention to the expression that evaluates the incoming requests.  
Note: Most content filtering issues are caused by incorrect configuration, and the error is most often in the policy configuration.
- Check the policy's Hits counter to verify that it is incrementing. If it is not, the policy is not getting evaluated.
- If the policy is getting evaluated and the required filtering is still not performed, you need to look into the policy expressions and action.
- If the policy's expression seems valid, test it by assigning a simple NSTRUE value to see if the evaluation of the expression is creating any issue.
- Reevaluate whether the filtering should be based on the request or the response.
- Verify that the action is configured correctly. For example, if a custom action is used to corrupt a header in the request, verify that the header name in the action is correct. If you are not sure about the header name, start a browser with iehttphheaders or a similar utility, and then verify the headers in the request. When this feature is used, you can use nstrace to find out if appropriate action is performed when the packets leave NetScaler appliance.
- An iehttphheaders or Fiddler trace can help you find header options and names, client-side request headers, and response headers recorded on the client.
- To check the modifications made to the request header, record an nstrace on the NetScaler appliance or a Wireshark trace on the server.
- If none of the above measures resolves the issue, verify that the connection has not become untrackable, which can happen in certain circumstances. If a connection becomes untrackable, the appliance does not perform any application-level processing of the requests. In that event, contact Citrix Technical Support.

# HTTP Denial-of-Service Protection

Mar 16, 2012

Internet hackers can bring down a site by sending a surge of GET requests or other HTTP-level requests. HTTP Denial-of-Service (HTTP DoS) Protection provides an effective way to prevent such attacks from being relayed to your protected Web servers. The HTTP DoS feature also ensures that a NetScaler appliance located between the internet cloud and your Web servers is not brought down by an HTTP DoS attack.

Most attackers on the Internet use applications that discard responses to reduce computation costs, and minimize their size to avoid detection. The attackers focus on speed, devising ways to send attack packets, establish connections or send HTTP requests as rapidly as possible.

Real HTTP clients such as Internet Explorer, Firefox, or NetScape browsers can understand HTML Refresh meta tags, Java scripts, and cookies. In standard HTTP the clients have most of these features enabled. However, the dummy clients used in DoS attacks cannot parse the response from the server. If malicious clients attempt to parse and send requests intelligently, it becomes difficult for them to launch the attack aggressively.

When the NetScaler appliance detects an attack, it responds to a percentage of incoming requests with a Java or HTML script containing a simple refresh and cookie. (You configure that percentage by setting the Client Detect Rate parameter.) Real Web browsers and other Web-based client programs can parse this response and then resend a POST request with the cookie. DoS clients drop the NetScaler appliance's response instead of parsing it, and their requests are therefore dropped as well.

Even when a legitimate client responds correctly to the NetScaler appliance's refresh response, the cookie in the client's POST request may become invalid in the following conditions:

- If the original request was made before the NetScaler appliance detected the DoS attack, but the resent request was made after the appliance had come under attack.
- When the client's think time exceeds four minutes, after which the cookie becomes invalid.

Both of these scenarios are rare, but not impossible. In addition, the HTTP DoS protection feature has the following limitations:

- Under an attack, all POST requests are dropped, and an error page with a cookie is sent.
- Under an attack, all embedded objects without a cookie are dropped, and an error page with a cookie is sent.

The HTTP DoS protection feature may affect other NetScaler features. Using DoS protection for a particular content switching policy, however, creates additional overhead because the policy engine must find the policy to be matched. There is some overhead for SSL requests due to SSL decryption of the encrypted data. Because most attacks are not on a secure network, though, the attack is less aggressive.

If you have implemented priority queuing, while it is under attack a NetScaler appliance places requests without proper cookies in a low-priority queue. Although this creates overhead, it protects your Web servers from false clients. HTTP DoS protection typically has minimal effect on throughput, since the test JavaScript is sent for a small percentage of requests only. The latency of requests is increased, because the client must re-issue the request after it receives the JavaScript. These requests are also queued

To implement HTTP DoS protection, you enable the feature and define a policy for applying this feature. Then you configure your services with the settings required for HTTP DoS. You also bind a TCP monitor to each service and bind your

policy to each service to put it into effect.

# Layer 3-4 SYN Denial-of-Service Protection

May 18, 2017

Any NetScaler appliance with system software version 8.1 or later automatically provides protection against SYN DoS attacks.

To mount such an attack, a hacker initiates a large number of TCP connections but does not respond to the SYN-ACK messages sent by the victimized server. The source IP addresses in the SYN messages received by the server are typically spoofed. Because new SYN messages arrive before the half-open connections initiated by previous SYN messages time out, the number of such connections increases until the server no longer has enough memory available to accept new connections. In extreme cases, the system memory stack can overflow.

A NetScaler appliance defends against SYN flood attacks by using SYN cookies instead of maintaining half-open connections on the system memory stack. The appliance sends a cookie to each client that requests a TCP connection, but it does not maintain the states of half-open connections. Instead, the appliance allocates system memory for a connection only upon receiving the final ACK packet, or, for HTTP traffic, upon receiving an HTTP request. This prevents SYN attacks and allows normal TCP communications with legitimate clients to continue uninterrupted.

SYN DoS protection on the NetScaler appliance ensures the following:

- The memory of the NetScaler is not wasted on false SYN packets. Instead, memory is used to serve legitimate clients.
- Normal TCP communications with legitimate clients continue uninterrupted, even when the Web site is under SYN flood attack.

In addition, because the NetScaler appliance allocates memory for HTTP connection state only after it receives an HTTP request, it protects Web sites from idle connection attacks.

SYN DoS protection on your NetScaler appliance requires no external configuration. It is enabled by default.

## Disabling SYN Cookies

SYN cookies are enabled by default on a NetScaler appliance to prevent SYN attacks. If your deployment requires you to disable SYN cookies, for example, for server-initiated data connections or in cases where a connection is not established because the first packet is dropped or reordered, use one of the following methods to disable SYN cookies.

### To disable SYN cookies by using the NetScaler command line

At the command prompt, type:

```
set nstcpprofile nstcp_default_profile -synCookie DISABLED
```

### Arguments

synCookie

Enable or disable the SYNCOOKIE mechanism for TCP handshake with clients. Disabling SYNCOOKIE prevents SYN attack protection on the NetScaler appliance.

Possible values: ENABLED, DISABLED

Default: ENABLED

## To disable SYN cookies by using the NetScaler GUI

1. Navigate to **System > Profiles > TCP Profiles**.
2. Select a profile and click **Edit**.
3. Clear the **TCP SYN Cookie** check box.
4. Click **OK**.

# Enabling HTTP DoS Protection

Sep 03, 2013

To configure HTTP DoS protection, you must first enable the feature.

To enable HTTP DoS protection by using the command line interface

At the command prompt, type the following commands to enable HTTP DoS protection and verify the configuration:

- enable ns feature HttpDoSProtection
- show ns feature

## Example

```
> enable ns feature HttpDoSProtection
```

```
Done
```

```
> show ns feature
```

|            | Feature                      | Acronym       | Status    |
|------------|------------------------------|---------------|-----------|
|            | -----                        | -----         | -----     |
| 1)         | Web Logging                  | WL            | ON        |
| 2)         | Surge Protection             | SP            | OFF       |
| .          |                              |               |           |
| .          |                              |               |           |
| .          |                              |               |           |
| 10)        | Global Server Load Balancing | GSLB          | ON        |
| <b>11)</b> | <b>Http DoS Protection</b>   | <b>HDOSP</b>  | <b>ON</b> |
| 12)        | Content Filtering            | CF            | ON        |
| .          |                              |               |           |
| .          |                              |               |           |
| 23)        | HTML Injection               | HTMLInjection | ON        |
| 24)        | NetScaler Push               | push          | OFF       |

```
Done
```

```
>
```

To enable HTTP DoS protection by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, click Configure Advanced Features.
3. In the Configure Advanced Features dialog box, select the HTTP DoS Protection check box.
4. Click OK.

# Defining an HTTP DoS Policy

Sep 03, 2013

After you enable HTTP DoS protection, you next create a policy.

Note: Before changing the default setting for Client Detect Rate, see "[Tuning the Client Detection/JavaScript Challenge Response Rate.](#)"

To configure a HTTP DoS policy by using the command line interface

At the command prompt, type one of the following commands to configure an HTTP DoS policy and verify the configuration:

- `add dos policy <name> -qDepth <positive_integer> [-cltDetectRate <positive_integer>]`
- `set dos policy <name> -qDepth <positive_integer> [-cltDetectRate <positive_integer>]`

## Example

```
> add dos policy pol-HTTP-DoS -qDepth 30
Done
> set dos policy pol-HTTP-DoS -qDepth 40
Done
> show dos policy
1) Policy: pol-HTTP-DoS QDepth: 40
Done
>
```

To configure an HTTP DoS policy by using the configuration utility

1. Navigate to Security > Protection Features > HTTP DoS.
2. In the details pane, do one of the following:
  - To create a new policy, click Add.
  - To modify an existing policy, select the policy, and then click Open.
3. In the Create HTTP DoS Policy or Configure HTTP DoS Policy dialog box, specify values for the parameters:
  - Name\*—name (You cannot change the name of an existing policy.)
  - QDepth\*—qdepth
  - Client Detect Rate—cltDetectRate (Before changing the default setting for cltDetectRate, see "[Tuning the Client Detection/JavaScript Challenge Response Rate.](#)")
4. Click OK to create your new policy. The policy that you created appears in the details pane, and the status bar displays a message indicating that the DoS policy is successfully configured.

# Configuring an HTTP DoS Service

Sep 03, 2013

After you configure an HTTP DoS policy, you must configure a service for your policy. The service accepts HTTP traffic that is protected by the HTTP DoS policy.

To configure an HTTP DoS service by using the command line interface

At the command prompt, type one of the following commands to configure an HTTP DoS service and verify the configuration:

- add service <name>@ (<IP>@ | <serverName>@) HTTP <port> [-maxClient <positive\_integer>] [-maxReq <positive\_integer>] -state ENABLED
- set service <name>@ (<IP>@ | <serverName>@) HTTP <port> [-maxClient <positive\_integer>] [-maxReq <positive\_integer>] -state ENABLED

## Example

```
> add service ser-HTTP-Dos1 10.102.29.40 HTTP 87
Done
> set service ser-HTTP-Dos1 -maxReq 20
Done
> show service
1) srv-http-10 (10.102.29.30:80) - HTTP
 State: DOWN
 Last state change was at Wed Jul 8 07:49:52 2009
 Time since last state change: 34 days, 00:48:18.700
 Server Name: 10.102.29.30
 Server ID : 0 Monitor Threshold : 0
 Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
 Use Source IP: NO
 Client Keepalive(CKA): NO
 Access Down Service: NO
 TCP Buffering(TCPB): NO
 HTTP Compression(CMP): NO
 Idle timeout: Client: 180 sec Server: 360 sec
 Client IP: DISABLED
 Cacheable: NO
 SC: OFF
 SP: OFF
 Down state flush: ENABLED
 .
 .
 .

5) ser-HTTP-Dos1 (10.102.29.40:87) - HTTP
 State: DOWN
 Last state change was at Tue Aug 11 08:23:40 2009
 Time since last state change: 0 days, 00:14:30.300
```

**Server Name: 10.102.29.40**  
**Server ID : 0 Monitor Threshold : 0**  
**Max Conn: 0 Max Req: 20 Max Bandwidth: 0 kbits**  
**Use Source IP: NO**  
**Client Keepalive(CKA): NO**  
**Access Down Service: NO**  
**TCP Buffering(TCPB): NO**  
**HTTP Compression(CMP): YES**  
**Idle timeout: Client: 180 sec Server: 360 sec**  
**Client IP: DISABLED**  
**Cacheable: NO**  
**SC: OFF**  
**SP: OFF**  
**Down state flush: ENABLED**

Done

>

To configure an HTTP DoS service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, do one of the following:
  - To create a new service, click Add.
  - To modify an existing service, select the service, and then click Open.
3. In the Create Server or Configure Server dialog box, specify values for the following parameters, which correspond to the descriptions in "Parameters for configuring an HTTP DoS service" as follows (asterisk indicates a required parameter):
  - Service Name\*—name (You cannot change the name of an existing service.)
  - Server\*—IP or serverName (Specify one or the other, not both.)
  - Port\*—port
4. If the Enable Service check box is not selected, select it.
5. Select the Advanced tab, and select the Override Global check box to enable those choices.
6. Specify values for the following parameters.
  - Max Clients\*—maxClient
  - Max Requests\*—maxReq
7. Click Create or OK, and then click Close. The service appears in the list of services.

# Binding an HTTP DoS Monitor and Policy

Sep 03, 2013

To put HTTP DoS protection into effect after you have configured an HTTP DoS service, you must bind the monitor, and then bind the service to the HTTP DoS policy.

To bind the monitor to the service by using the command line interface

At the command prompt, type the following commands to bind the monitor to the service and verify the configuration:

- bind lb monitor <monitorName> <serviceName>
- show lb monitor

## Example

```
> bind lb monitor tcp ser-HTTP-DoS
Done
> show lb monitor
1) Name.....: ping-default Type.....: PING State....ENABLED
2) Name.....: tcp-default Type.....: TCP State....ENABLED
3) Name.....: ping Type.....: PING State....ENABLED
4) Name.....: tcp Type.....: TCP State....ENABLED
5) Name.....: http Type.....: HTTP State....ENABLED
.
.
.
17) Name.....: ldns-dns Type.....: LDNS-DNS State....ENABLED
Done
```

To bind the policy to the service by using the command line interface

At the command prompt, type the following commands to bind the policy to the service and verify the configuration:

```
bind service <serviceName> -policyName <policyname>
```

## Example

```
> bind service ser-HTTP-DoS -policyName pol-HTTP-DoS
Done
> show service
1) srv-http-10 (10.102.29.30:80) - HTTP
 State: DOWN
 Last state change was at Wed Jul 8 07:49:52 2009
 Time since last state change: 34 days, 01:24:58.510
 Server Name: 10.102.29.30
 Server ID : 0 Monitor Threshold : 0
 Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
 Use Source IP: NO
 Client Keepalive(CKA): NO
 Access Down Service: NO
 TCP Buffering(TCPB): NO
 HTTP Compression(CMP): NO
```

Idle timeout: Client: 180 sec Server: 360 sec  
Client IP: DISABLED  
Cacheable: NO  
SC: OFF  
SP: ON  
Down state flush: ENABLED  
. . .

4) **ser-HTTP-Dos (10.102.29.18:88) - HTTP**

**State: DOWN**  
**Last state change was at Tue Aug 11 08:19:45 2009**  
**Time since last state change: 0 days, 00:55:05.40**  
**Server Name: 10.102.29.18**  
**Server ID : 0 Monitor Threshold : 0**  
**Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits**  
**Use Source IP: NO**  
**Client Keepalive(CKA): NO**  
**Access Down Service: NO**  
**TCP Buffering(TCPB): NO**  
**HTTP Compression(CMP): YES**  
**Idle timeout: Client: 180 sec Server: 360 sec**  
**Client IP: DISABLED**  
**Cacheable: NO**  
**SC: OFF**  
**SP: ON**  
**Down state flush: ENABLED**

5) **ser-HTTP-Dos1 (10.102.29.40:87) - HTTP**

**State: DOWN**  
**Last state change was at Tue Aug 11 08:23:40 2009**  
**Time since last state change: 0 days, 00:51:10.110**  
**Server Name: 10.102.29.40**  
**Server ID : 0 Monitor Threshold : 0**  
**Max Conn: 0 Max Req: 20 Max Bandwidth: 0 kbits**  
**Use Source IP: NO**  
**Client Keepalive(CKA): NO**  
**Access Down Service: NO**  
**TCP Buffering(TCPB): NO**  
**HTTP Compression(CMP): YES**  
**Idle timeout: Client: 180 sec Server: 360 sec**  
**Client IP: DISABLED**  
**Cacheable: NO**  
**SC: OFF**  
**SP: OFF**  
**Down state flush: ENABLED**

Done

>

To bind the monitor and policy to the service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service that you want to bind, and then click Open.
3. In the Configure Service dialog box, select the Monitor tab, click the name of the monitor you want in the Monitors list, and then click Add. The selected monitor is added to the Configured frame.
4. Select the Policies tab, then select the HTTP DoS tab.
5. Select a policy from the Available Policies list, and then click Add. The policy appears in the Configured Policies list.
6. Click OK, and then click Close. A message appears in the status bar, stating that the service has been configured.

# Tuning the Client Detection/JavaScript Challenge Response Rate

Sep 03, 2013

After you have enabled and configured HTTP DoS protection, if more than the maximum specified number of clients are waiting in the NetScaler surge queue for the HTTP DoS service, the HTTP DoS protection function is triggered. The default rate of challenged JavaScript responses sent to the client is one percent of the server response rate. The default response rate is inadequate in many real attack scenarios, however, and may need to be tuned.

For example, assume that the Web server is capable of a maximum of 500 responses/sec, but is receiving 10,000 Gets/sec. If 1% of the server responses are sent as JavaScript challenges, responses are reduced to almost none: 5 client (500 \* 0.01) JavaScript responses, for 10000 waiting client requests. Only about 0.05% of the real clients receive JavaScript challenge responses. However, if the client detection/JavaScript challenge response rate is very high (for example, 10%, generating 1000 challenge JavaScript responses per second), it may saturate the upstream links or harm the upstream network devices. Exercise care when modifying the default **Client Detect Rate** value.

If the configured triggering surge queue depth is, for example, 200, and the surge queue size is toggling between 199 and 200, the NetScaler toggles between the "attack" and "no-attack" modes, which is not desirable. The HTTP DoS feature includes a window mechanism is provided. When the surge queue size reaches the designated queue depth value, triggering "attack" mode, the surge queue size must fall for the NetScaler to enter "no-attack" mode. In the scenario just described, if the value of WINDOW\_SIZE is set to 20, the surge queue size must fall below 180 before the NetScaler enters "no-attack" mode. During configuration, you must specify a value more than the WINDOW\_SIZE for the **QDepth** parameter when adding a DoS policy or setting a DoS policy.

The triggering surge queue depth should be configured on the basis of previous observations of traffic characteristics. For more information about setting up a correct configuration, see "[Guidelines for HTTP DoS Protection Deployment](#)."

# Guidelines for HTTP DoS Protection Deployment

Mar 16, 2012

Citrix recommends you to deploy the HTTP DoS protection feature in a tested and planned manner and closely monitor its performance after the initial deployment. Use the following information to fine-tune the deployment of HTTP DoS Protection.

- The maximum number of concurrent connections supported by your servers.
- The average and normal values of the concurrent connections supported by your servers.
- The maximum output rate (responses/sec) that your server can generate.
- The average traffic that your server handles.
- The typical bandwidth of your network.
- The maximum bandwidth available upstream.
- The limits affecting bandwidth (such as external links, a particular router, or other critical devices on the path that may suffer from a traffic surge).
- Whether allowing a greater number of clients to connect is more important than protecting upstream network devices.

To determine the characteristics of a HTTP DoS attack, you should consider the following issues.

- What is the rate of incoming fake requests that you have experienced in the past?
- What types of requests have you received (complete posts, incomplete gets)?
- Did previous attacks saturate your downstream links? If not, what was the bandwidth?
- What types of source IP addresses and source ports did the HTTP requests have (e.g., IP addresses from one subnet, constant IP, ports increasing by one).
- What types of attacks do you expect in future? What type have you seen in the past?
- Any or all information that can help you tune DoS attack protection.

# Priority Queuing

Sep 03, 2013

The priority queuing feature lets you filter incoming HTTP traffic on the basis of categories that you create and define, and prioritize those HTTP requests accordingly. Priority queuing directs high-priority requests to the server ahead of low-priority requests, so that users who need resources for important business uses receive expedited access to your protected Web servers.

Note: The priority queuing feature is not supported in NetScaler 9.2 nCore.

To implement priority queuing, you create priority queuing policies that specify a priority, weight, threshold, and implicit action. When an incoming request matches a priority queuing policy, the request is processed as the associated action indicates. For example, you can create a priority queuing policy that places all matching requests above a certain threshold in a surge queue, while giving priority treatment to other requests.

You can bind up to three priority queuing policies to a single load balancing virtual server. The priority levels are:

## Level 1

A Level 1 policy processes priority requests.

## Level 2

A Level 2 policy processes requests that should receive responses as soon as Level 1 requests have been cleared from the queue.

## Level 3

A Level 3 policy processes non-priority requests that receive responses only after requests in the first two queues have been cleared.

You can use weighted queuing to adjust the relative priority of each of these queues. Weights can range from 0 to 101. A weight of 101 tells the NetScaler appliance to clear all requests in that queue before forwarding any requests in the lower-priority queues to the Web server. A weight of 0 tells the appliance to send requests in that queue to the Web server only when there are no requests waiting in any of the other queues.

You must assign a unique name to each priority queuing policy. Policy names can be up to 127 characters. Multiple policies bound to the same load balancing virtual server cannot have the same priority level. No two virtual servers that have one or more common underlying physical services can have priority queuing configured or enabled on both virtual servers simultaneously.

To configure priority queuing the NetScaler, you perform the following steps:

- Enable the load balancing feature
- Define a server and service
- Define a load balancing virtual server
- Bind the service to the load balancing virtual server
- Enable the priority queuing feature
- Create the priority queuing policies
- Bind the priority queuing policies to the load balancing virtual server
- Enable priority queuing on load balancing virtual server

For information about enabling load balancing, creating servers, creating virtual servers and services, and binding these servers and services, see the *Citrix NetScaler Traffic Management Guide* at <http://support.citrix.com/article/CTX132359>.

For complete information about policies and expressions, see the *Citrix NetScaler Policy Configuration and Reference Guide* at <http://support.citrix.com/article/CTX132362>.

# Enabling Priority Queuing

Sep 03, 2013

To use the priority queuing feature the NetScaler appliance, you must first enable it.

To enable priority queuing by using the command line interface

At the command prompt, type the following commands to enable priority queuing and verify the configuration:

- enable ns feature PriorityQueuing
- show ns feature

## Example

```
> enable ns feature PriorityQueuing
```

```
Done
```

```
> show ns feature
```

|           | Feature                 | Acronym       | Status    |
|-----------|-------------------------|---------------|-----------|
|           | -----                   | -----         | -----     |
| 1)        | Web Logging             | WL            | ON        |
| 2)        | Surge Protection        | SP            | OFF       |
| 3)        | Load Balancing          | LB            | ON        |
| .         |                         |               |           |
| .         |                         |               |           |
| .         |                         |               |           |
| <b>8)</b> | <b>Priority Queuing</b> | <b>PQ</b>     | <b>ON</b> |
| .         |                         |               |           |
| 23)       | HTML Injection          | HTMLInjection | ON        |
| 24)       | NetScaler Push          | push          | OFF       |

```
Done
```

To enable priority queuing by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, click Configure advanced features.
3. In the Configure Advanced Features dialog box, select the Priority Queuing check box.
4. Click OK.

# Configuring a Priority Queuing Policy

Sep 03, 2013

To configure a priority queuing policy, you can use either the configuration utility or the command line.

Note: For more information about using the command line, see "[Command Reference](#)."

To configure a priority queuing policy by using the command line interface

At the command prompt, type the following command to configure a priority queuing policy and verify the configuration:  
add pq policy <policyName> -rule <expression> -priority <positive\_integer> [-weight <positive\_integer>] [-qDepth <positive\_integer> | -polqDepth <positive\_integer>]

## Example

```
> add pq policy pol_cgibin -rule "URL == '/cgi-bin/'" -priority 1
Done
> show pq policy pol_cgibin
1) Policy: pol_cgibin Rule: URL == '/cgi-bin/' Priority: 1 Weight: 10
 Hits: 0
Done
```

To configure a priority queuing policy by using the configuration utility

1. Navigate to Security > Protection Features > Priority Queuing.
2. In the details pane, do one of the following:
  - To create a new policy, click Add.
  - To modify an existing policy, select the policy, and then click Open.
3. If you are creating a new policy, in the Create PQ Policy dialog box, in the Name text box, type a name for your new policy.

The name can consist of from one to 127 letters, numbers and the hyphen and underscore symbol.

If you are modifying an existing policy, skip this step. You cannot change the name of an existing policy.

4. In the Rule text box, either enter the policy expression directly, or click New to create a policy expression. If you click New, perform the following steps:
  1. In the Create Expression dialog box, click Add.
  2. In the Add Expression dialog box, leave Expression Type set to General, and in the Flow Type drop-down list, select a Flow Type. Your choices are REQ (for requests) and RES (for responses).
  3. In the Protocol drop-down list, select a protocol. If you selected REQ in the previous step, your choices are HTTP (Web-based connections), SSL (secure Web connections), TCP and IP. If you selected RES in the previous step, your choices are HTTP, TCP and IP.
  4. In the Qualifier drop-down list, select a qualifier.  
Your choices depend upon your selections in the previous step. Common choices are HTTP VERSION (the version of the HTTP connection), HTTP HEADER (the specified HTTP header), TCP SOURCEPORT/ DESTPORT (the source or destination port of a TCP connection), and IP SOURCEIP/DESTIP (the source or destination IP of the connection).

If you choose HTTP HEADER, the Header text box appears beneath the original row of text boxes. You fill in the name of the HTTP header you want.

For a complete description of the available choices, see "[Policies and Expressions](#)."

5. In the Operator drop-down list, select an operator.  
For a complete description of the available choices, see "[Policies and Expressions](#)."
6. In the Value text box, type the value you want to test for.  
This may be a text string or a number, depending upon the context. For a complete description of values appropriate to the specific context, see "[Policies and Expressions](#)."
7. Click OK. The expression is added in the Expression text box.
8. Click Create. The expression appears in the Rule text box.
5. In the Priority and Weight text boxes, type numeric values, for example, 1 and 30. For more information about Priority and Weight, see "[Setting Up Weighted Queuing](#)."
6. Enter a numeric value for either Queue Depth or Policy Queue Depth, for example 234, and click Create.
  - Queue Depth Defines the total number of waiting clients or requests on the virtual server to which the policy is bound.
  - Policy Queue Depth Defines the total number of waiting clients or requests belonging to the policy.The policy is created and appears in the Priority Queuing page.  
Note: To create additional priority queuing policies, repeat the procedure in the preceding section, and click Close after you finish.

# Binding a Priority Queuing Policy

Sep 03, 2013

After you create a priority queuing policy, you must bind it to the appropriate virtual server to put it into effect. To bind a priority queuing policy by using the command line interface

At the command prompt, type the following commands to bind a policy and verify the configuration:

- bind lb vserver <name> -policyName <policyname>
- show lb vserver <name>

## Example

```
> bind lb vserver lbvip -policyname pol_cgibin
Done
> show lb vserver lbvip
 lbvip (8.7.6.6:80) - HTTP Type: ADDRESS
 State: DOWN
 Last state change was at Wed Jul 15 05:54:24 2009 (+782 ms)
 Time since last state change: 26 days, 05:44:37.370
 Effective State: DOWN
 Client Idle Timeout: 180 sec
 Down state flush: ENABLED
 Disable Primary Vserver On Down : DISABLED
 Port Rewrite : DISABLED
 No. of Bound Services : 0 (Total) 0 (Active)
 Configured Method: LEASTCONNECTION
 Mode: IP
 Persistence: NONE
 Vserver IP and Port insertion: OFF
 Push: DISABLED Push VServer:
 Push Multi Clients: NO
 Push Label Rule: none
```

1) Policy : ns\_cmp\_msapp Priority:0

1) Priority Queuing Policy : pol\_cgibin

Done

>

To bind a priority queuing policy by using the configuration utility

1. In the navigation pane, locate and select the virtual server to which you want to bind the priority queuing policy.
  - To select a load balancing virtual server, expand Traffic Management > Load Balancing > Virtual Servers, then select the load balancing virtual server that you want..
  - To select a content switching virtual server, expand Traffic Management > Content Switching > Virtual Servers, then select the content switching virtual server that you want..
2. In the Configure Virtual Server dialog box, select the Policies tab.

3. Click the double right-arrow (») symbol to display the complete list of policy types, and then select Priority Queuing from the drop-down list.
4. Click Insert Policy.
5. In the Policy Name row, select the policy that you want to bind from the drop-down list.
6. ClickOK to save your changes.

# Setting Up Weighted Queuing

Sep 03, 2013

When priority queuing is implemented, lower-priority requests are typically kept on hold while higher-priority requests are served. The lower-priority requests may therefore be delayed if there is a constant flow of higher-priority requests.

To prevent delays for low-priority requests across multiple priority levels, you can configure weighted queuing for serving requests. The default weights for the priorities are:

- Gold - Priority 1 - Weight 3
- Silver - Priority 2 - Weight 2
- Bronze - Priority 3 - Weight 1

You assign the minimum weight, zero (0), to requests that the NetScaler appliance should send to the server only if no requests are stored in any of the other queues. You assign the maximum weight, 101, to requests that the appliance should send to the server immediately, ahead of any requests stored in any of the other queues. Weights between these two set the relative priority of a particular queue in relation to the other queues. Queues with a higher weight are processed first; queues with a lower weight after the others have been processed. To assign the weights, see "[Configuring a Priority Queuing Policy](#)."

Note: The weight assigned to a higher-priority queue must be larger than the weight assigned to a lower-priority queue. For example, the weight assigned to The Gold (Priority 1) queue must be greater than the weight assigned to the Silver (Priority 2) queue.

# SureConnect

Sep 03, 2013

You can use the SureConnect feature of the Citrix NetScaler appliance to service all incoming connections with either the requested content or a custom Web page that displays information about a delay in the request being serviced.

When servers are overloaded with the requests, the servers might either respond slowly or not at all. The SureConnect feature enables the NetScaler appliance to detect and compensate such conditions by ensuring that every client request gets serviced in some way, such as either a custom Web page or actual content is sent to the client.

SureConnect is activated when the response time or maximum server connections to a client request exceeds a limit that you have set. The SureConnect browser window displays one of the following:

- A progress bar with the amount of time remaining until the requested content will be available.
- Alternate Web content of your choice (alternate page).
- Both a progress bar and alternate page.
- Complete custom content of your choice.

You can configure whether the SureConnect progress bar alone is displayed or both the progress bar and the alternate page are displayed.

When the server becomes responsive again, the original request for content is served. If the user chooses, the alternate content window can remain in focus.

Subsequent requests from the same user within the same session are served immediately. This can be configured using the settings described later in this section.

SureConnect can be activated when a response is delayed, and when the number of user connections to a given URL exceeds a specified threshold.

SureConnect works with all standard browsers, including Microsoft Internet Explorer, Netscape Navigator, and Mozilla Firefox.

SureConnect is advantageous in the following situations:

- **Full server queue**

The server can respond fast, but there are too many users. This results in the server's queue being full and unable to process additional client requests.

**SureConnect Solution:** In this situation, the SureConnect window is displayed, showing the time left until the content will be available. The alternate page is displayed under the progress bar, if an alternate page has been configured.

- **Large response delay**

The server response is slow. Typically, if a Web server does not respond to a client request quickly, the user will leave the site.

**SureConnect Solution:** When the predicted delay reaches a configured time threshold, the SureConnect window displays the progress bar and the optional alternate page in the client browser.

- **Client time-out**

When the client requests content from a very slow Web site, a time-out message displays in the client browser, and the content is not delivered. The user may leave the site.

**SureConnect Solution:** The appliance stores the request until the server is no longer busy and delivers the requested content to the client.

- **Server experiencing a traffic surge**

The server typically responds quickly, but the current load of open connections is greater than the server capacity to serve them. Therefore, the server response is delayed.

**SureConnect Solution:** A SureConnect window is displayed in the client browser, showing the time left. The alternate page from the server is also displayed if it has been configured.

# Installing SureConnect

Mar 21, 2012

SureConnect files must be installed on the alternate content server, which can be the same as the primary server.

On a Windows server, extract the `sc_xx.exe` file (where `xx` is the build number), or on a UNIX server, extract the `sc_xx.tar` file (where `xx` is the build number).

Note: You must install SureConnect in the default Web root directory.

If the alternate content server is the same as the primary server, place the SureConnect and alternate content files in any directory under the Web root directory. Specify this path when you add a policy to configure SureConnect. By default, SureConnect files are installed in the `/Citrix NetScaler appliance` directory under the default Web root directory.

If the alternate content server is different than the primary server, the SureConnect and alternate content files must be in a unique directory under the Web root directory. By default, this unique directory is the `/Citrix NetScaler system` directory. Specify this path when you add a policy to configure SureConnect.

The following files are extracted:

- Alternate content files (`progressbar.htm`, `alternatepage.htm`, and `barandpage.htm`)
- `System-Logo.gif`
- `Customer-Logo.gif`
- `Sample.gif`
- `README.txt`.

## Installing on UNIX

This section describes how to install SureConnect alternate content on a UNIX server. The following are the prerequisites:

- The UNIX server is running the Apache server.
- The shell with the `#` prompt is in use.
- Apache is installed in the default location.
- The `sc_xx.tar` file is downloaded from the organization's Web site into the `/var/ftp/incoming` directory.

## To install SureConnect

1. At the command prompt, navigate to the `htdocs` directory:

```
cd /usr/local/apache/htdocs
```

2. Type the following command:

```
tar xvpf/var/ftp/incoming/sc_xx.tar
```

The output from the `.tar` file is displayed. A `/Citrix NetScaler system` directory is created under the specified path and the SureConnect files are installed.

## Installing on Windows

Updated: 2013-09-03

This section describes how to install SureConnect alternate content on a Windows server. The following are the prerequisites:

- The server is running the Microsoft Internet Information Server.
- The DOS prompt is being used.

- The SureConnect zip (self-extracting) file is downloaded from the organization Web site using FTP into the C:\inetpub\wwwroot directory.

## To install SureConnect on Windows

Do one of the following:

- At the command prompt, navigate to the wwwroot directory:  
cd c:\inetpub\wwwroot
- Type the name of the executable file:  
sc\_xx.exe
- Double-click the sc\_xx.exe icon from the Microsoft Windows Explorer Web browser, extract from the compressed file into the default path (for example, the c:\inetpub\wwwroot directory).

Output from the zip file is displayed. A /Citrix NetScaler system directory is created under the specified path, and the SureConnect files are installed.

# Configuring SureConnect

Sep 03, 2013

The following topics describe how to configure SureConnect for scenarios involving alternate server failure.

- ["Configuring the Response for Alternate Server Failure"](#)
- ["Configuring the SureConnect Policies"](#)
- ["Customizing the Alternate Content File"](#)
- ["Configuring SureConnect for Citrix NetScaler Features"](#)

## Configuring the Response for Alternate Server Failure

Updated: 2013-09-03

If the alternate server fails, and the primary server cannot immediately deliver the requested content to the client, SureConnect does not display alternate content from the failed alternate server in the client Web browser.

The Citrix NetScaler appliance automatically sends a response to the client browser. You can customize the server response to display information suited to your needs.

The default response is:

Your Request is being processed... Estimated Time: \_\_\_\_\_ Secs

## Customizing the Default Response

The NetScaler appliance automatically sends the response to the client if the alternate server fails, or if the appliance is configured to send the default response.

To customize the default response of the appliance, create a vsr.htm file (a sample is provided in this section) as follows:

- The file can contain any valid HTML statements other than embedded objects.
- The file size cannot exceed 800 bytes.
- The file must reside on the NetScaler appliance. If you have a high availability (HA) setup, the file must reside on the primary and secondary nodes. Any changes made to the file on the primary node must also be applied to the file on the secondary node.
- Put vsr.htm file in the /etc directory.

To customize the default response

Change any of the contents between the </HEAD> and </HTML> tags in the vsr.htm file. Following is the sample content from vsr.htm file. The sections that you can edit are in bold text.

```
HTTP/1.1 200 OK
Server: NS_WS3.0
Content-Type: text/html
Cache-control: no-cache
Pragma: no-cache
Set-Cookie: NSC_BP_IP=@@SID@@; path=/
<HTML> <HEAD> <META HTTP-EQUIV="Refresh" CONTENT="0">
```

</HEAD> <font color=blue size=5>Your request is being processed...

<br>Estimated Delay: @@DELAY@@ Sec </font> </HTML>

Note: Include @@DELAY@@ to display the predicted delayed response time in seconds.

## SureConnect with In-Memory response (NS action)

Updated: 2013-09-03

When defining the SureConnect policy by using the add sc policy command, you can configure the NetScaler Appliance to serve alternative content to the client.

To enable SureConnect and configure the in-memory response, perform the following tasks:

- Enable the SureConnect feature on the appliance by using the enable feature SC command
- Define the services by using the add service <servicename> <IP address> <servicetype> <port> command. This identifies the original server for which the SureConnect is configured and the types of services.
- Add a SureConnect policy by using the add sc policy command. You can configure a URL-based policy or a rule-based policy. The incoming requests are validated against the URL or rule you specify in the policy.

Note: You can configure the SureConnect feature on a load balancing virtual server. In that case, perform the following additional actions:

- Enable Load Balancing by using the enable feature LB command.
- Enable SureConnect feature on the virtual server by using the set lb vserver <vservername> -sc ON command.
- Bind services to the virtual server by using the bind lb vserver <name> <serviceName> command.
- Bind policies to the virtual server by using the bind lb vserver <name> -policyname <name> command.

The following example illustrates how to configure SureConnect for the load balancing feature so that SureConnect will display alternative content from the NetScaler appliance.

In this example, two physical servers, with IP addresses, 10.101.3.187 and 10.101.3.188 are load balanced by the NetScaler appliance. The appliance has one configured virtual server, vs-NSact, whose IP address is 10.101.3.201. The file that contains the alternative content is vsr.htm. It is copied from the file system into system memory. Services are loaded until the SureConnect policy triggers, and the appliance supplies the alternate content.

```
enable feature SC LB
add service psvc1 10.101.3.187 http 80
add service psvc2 10.101.3.188 http 80
add lb vserver vs-NSact HTTP 10.101.3.201 80
bind lb vserver vs-NSact psvc1
bind lb vserver vs-NSact psvc2
add sc policy policyNS -url /cgi-bin/*.cgi -delay 400000
-action NS
set sc parameter -vsr /nsconfig/ssl/vsr.htm
bind lb vserver vs-NSact -policyName policyNS
set lb vserver vs-NSact -sc ON
save config
```

Table 1. Parameter values used in this example

Service	
---------	--

Name	psvc1, psvc2
Server	10.101.3.187, 10.101.3.188
Protocol	HTTP
Port	80
Load Balancing Virtual Server	
Name	vs-NSact
IP Address	10.101.3.201
Protocol	HTTP
Port	80
SureConnect Policy	
Name	policyNS
URL	/cgi-bin/*.cgi
Delay(microseconds)	400000
SC Parameter	
VSR File Name	vsr.htm

To configure this example by using the configuration utility

- In the In the navigation pane, navigate to System > Settings. In the Modes and Features pane, perform the following actions:
  - Click Configure Basic Features, select Load Balancing, and Click Go.
  - Click Configure Advanced Features, select SureConnect, and Click Go.
- In the navigation pane, navigate to Security > Protection Features > SureConnect. In the details pane, click Parameters. In the Configure SureConnect Parameters window, browse and select the VSR filename.
- Navigate to Traffic Management > Load Balancing > Services. In the details pane, click Add. In the **Create Services** window, enter the paramter values as shown in Table 5-1, and click **OK**.
- Navigate to Traffic Management > Load Balancing > Virtual servers. In the details pane, click Add. In the Create Virtual

Server (Load Balancing) dialog box, enter the values shown in Table 5.1 for the Load Balancing Virtual Server parameters and click OK.

5. In the navigation pane, navigate to Traffic Management > Load Balancing > Virtual servers. Select the virtual server vs-NSact and click Open in the details pane. The Configure Virtual system (Load Balancing) dialog box, displays the list of configured services. Select services psvc1 and psvc2 and click OK.
6. In the navigation pane, expand Security > Protection Features > SureConnect. In the details pane, click Add. Create the policy with the values as given in the parameters table.
7. In the navigation pane, navigate to Traffic Management > Load Balancing > Virtual servers. Select the virtual server vs-NSact and click Open in the details pane. In the Configure Virtual system (Load Balancing) dialog box, click the Policies tab. Click >> to expand the features. Select **SureConnect**. When the list of SureConnect polices appear, select policyNS and click OK.
8. In the navigation pane, navigate to Traffic Management > Load Balancing > Virtual servers. Select the virtual server vs-NSact and click Open in the details pane. In the Configure Virtual system (Load Balancing) dialog box, on the Advanced tab, select SC and click OK.

## Configuring the SureConnect Policies

You can configure the following SureConnect policies. The NetScaler appliance matches incoming requests in the order the policies are configured:

- Exact URL-based policies
- Wildcard rule-based policies

## Configuring Exact URL Based Policies

Updated: 2013-09-03

When you configure an exact URL based policy, the NetScaler appliance matches the incoming request against the URL that has been configured in the policy. URL based policies take precedence over rule based policies.

To configure an exact URL based policy by using the command line interface

At the command prompt, type:

```
add sc policy <name> [-url <URL> | -rule <expression>] [-delay <usecs>] [-maxConn <positive_integer>] [-action (ACS
<altContentSvcName> <altContentPath>) | NS | NOACTION]]
```

To configure an exact URL based policy by using the configuration utility

1. Navigate to Security > Protection Features > SureConnect.
2. In the details pane, click Add.
3. In the Create SureConnect Policy dialog box, set the following parameters:
  - Name\*
  - URL (Make sure that the URL check box is selected)
  - Value\*
  - Delay (microseconds)\*
  - Maximum Client Connections
  - Action (Select from the Choose Action list.)
  - Alternate Service Name (if you select ACS as the Action)
  - Alternate Content Path (if you select ACS as the Action)\*A required parameter
4. Click Create, and click Close. The URL based policy appears in the right pane, and a message displays in the status bar

that the policy is successfully configured.

## Configuring Wildcard Rule-Based Policies

Updated: 2013-09-03

SureConnect matches the incoming requests to a defined rule, if you configure a rule-based policy. To configure a SureConnect policy based on a wildcard rule by using the command line interface

1. Create the expression(s).  
Use the add expression command to create each expression.

2. Create the rule(s).

Use the add sc policy command with the -rule expression\_logic argument to specify the rule(s). In the -rule expression\_logic argument, refer to the expression(s) you created in step 1.

Repeat this command to create and name each rule.

The following example creates a rule "rule = = /\*.cgi":

```
add vsrver vs-lb http 1.1.1.1 80
add expression expr1 url == /cgi-bin/*.cgi
add expression expr2 url == /index.html
add sc policy surecpolicy1 -rule (expr1||expr2) -delay 1000000 -action NS
bind lb vsrver vs-lb -policyName surecpolicy1
```

To complete the SureConnect configuration, you will need to enter additional commands, beyond those shown in the example.

To configure a wildcard rule-based policy by using the configuration utility

1. Navigate to Security > Protection Features > SureConnect.
2. In the details pane, click Add.
3. In the Create SureConnect Policy dialog box, in the Name text box, type the name of the policy.
4. Under What to Monitor, click Expression, and then click Configure.
5. In the Create Expression dialog box, click Add.
6. In the Add Expression dialog box, enter an expression. For example, you can select an Expression Type of General, a Flow Type of REQ, a Protocol of HTTP, a Qualifier of URLQUERY, an Operator of CONTAINS, and in the Value text box, type AA. For more information about expressions, see "[Policies and Expressions.](#)"
7. Click OK, and click Close.
8. In the Create Expression dialog box, click Create.

Examples of wildcard rules:

"/sports/\*" matches all URLs under /sports

"/sports\*" matches all URLs whose prefix matches "/sports", starting at the beginning of the URL.

/\*.jsp" matches all URLs whose file extension is ".jsp"

When configuring rule-based policies, first add the more specific rule-based policies, before adding more generic rules (for

example, add /cgi-bin/sports\*.cgi before adding /cgi-bin/\*.cgi).

## Displaying the Configured SureConnect Policy

To view the SureConnect policy that you have configured, at the NetScaler command prompt, enter the show sc policy command.

### Customizing the Alternate Content File

When SureConnect activates, it can display alternate content from one of the following files that you have configured:

- **progressbar.htm**. Displays the progress information.
- **alternatepage.htm**. Displays an alternate page.
- **barandpage.htm**. Displays both the progress information and an alternate page.

The alternate content files are JavaScript files. During SureConnect installation, these files are copied onto the server that contains the alternate content. These files can contain alternate content (including an alternate page) or references to other files that contain the alternate content.

This section describes the changes you can make to the alternate content file provided by the appliance.

```
**** DEFINE YOUR VALUES HERE ****
var alt_url = "/Citrix NetScaler system /sample.gif";
var alt_url = "http://www.DomainName.com";
var Citrix NetScaler system _logo = "netscaler_logo.gif";
var our_logo = "netscaler_logo.gif";
var height = 450;
var width = 550;
var top = 200;
var left = 200;
var popunder = "no"; //specify yes for pop-under & no for pop-up
var shift_focus = "yes" //if you want to send pop-up to background on getting primary content else specify no
**** YOUR DEFINITIONS ENDS HERE ****
```

You can make these changes:

- **var alt\_url**. Specify the URL for the alternate content if a file provides the alternate content. For example:  
var alt\_url = "/Citrix NetScaler system/sports.htm"  
Note: The alternate content file must be present in the /Citrix NetScaler system directory under the documents root of the Web server.
- **var our\_logo**. Specify the image file of your organization logo.
- **var height**. Specify the height of the SureConnect window.
- **var width**. Specify the width of the SureConnect window.
- **var top and var left**. Specify the position of the SureConnect window.
- **var popunder**. Specifies the position of the alternate content window. Specify the value as NO to place the alternate content window above the original window. Specify the value as YES to place the alternate content window beneath the original window.
- **var shift\_focus**. Specify the focus of the alternate content window. YES places the pop-up window in the background when getting the primary content. NO always keeps the pop-up window in focus, even when getting the primary content.

Note: For more information, see the README.txt file provided by the appliance with other alternate content files.

### Configuring SureConnect for Citrix NetScaler Features

Updated: 2013-09-03

This section describes how SureConnect works in combination with the load balancing, content switching, cache redirection, and high availability features of the NetScaler appliance.

## Configuring SureConnect for Load Balancing

You can use SureConnect in environments where the primary servers use the load balancing feature, with or without alternate servers. If the load balancing virtual server configured for SureConnect fails, the backup virtual server (if there is one) handles the traffic. Backup virtual servers do not support SureConnect policies.

Note: For information about load balancing, see "[Load Balancing](#)."

## Configuring SureConnect for Cache Redirection

You can use SureConnect in environments where cache redirection is configured. The primary server is a load balancing virtual server bound to the cache redirection virtual server. Regardless of any rules configured for the cache redirection feature:

- You can configure any URL for SureConnect.
- Once SureConnect is activated for a client, requests from the client are always sent to the origin server.

## Configuring SureConnect for High Availability

SureConnect is compatible with NetScaler appliances operating in high availability mode.

Note: If the optional vsr.htm file is used, it must be present in both nodes (primary and secondary) and must use the same name and directory.

# Activating SureConnect

Sep 03, 2013

You can set the Citrix NetScaler appliance to activate SureConnect if either of two criteria match. Both criteria are arguments to the add sc policy command, as described here:

- -delay <microseconds>

The first time the client requests the URL, the appliance records how long the server takes to respond. The appliance will not activate SureConnect until the second time the URL is requested. The first and second requests may be from the same or different clients.

If you set -delay argument, SureConnect will be activated the second time the delay reaches the threshold you set.

- -maxConn <positive\_integer>

When the appliance receives a request, it checks the number of connections to the server for the configured URL. SureConnect is activated if the number of connections is greater than or equal to the value that you set for the -maxConn argument.

If you will be providing alternate content to be displayed in the client's Web browser, you should configure the -action argument of the add sc policy command. This specifies for the NetScaler appliance whether the alternate content is coming from a dedicated alternate server (-action ACS) or the appliance (-action NS).

When SureConnect is activated by the -maxConn argument, the SureConnect window and progress bar are displayed in the client's browser (with an alternate page, if configured).

# SureConnect Environments

Sep 03, 2013

The following topics describe SureConnect environments.

- ["Primary and Alternate Servers"](#)
- ["Configuration Checklist"](#)
- ["Example Configurations"](#)

## Primary and Alternate Servers

The SureConnect environment uses a dedicated server to provide alternate content when the requested content is not available. The alternate content may include an alternate page, plus optional components such as frame set, organization logo, and so on. The alternate and primary servers can be the same server.

You can configure SureConnect to display a progress bar when the requested content is not available (or the progress bar and an alternate page).

The following figure illustrates the SureConnect environment.

Figure 1. SureConnect - Primary and Alternate Servers

## Configuration Checklist

Updated: 2013-09-03

Complete the following checklist before you start configuration:

**Table 1. Configuration Checklist**

<p>- The same builds are running for the appliance and for the SureConnect files as suggested by appliance staff.</p> <p>Appliance Build Number: _____</p> <p>SureConnect (sc_xx.exe) Build Number: _____</p>
---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<ul style="list-style-type: none"> <li>▫ The latest SureConnect files (style files) are extracted to: <ul style="list-style-type: none"> <li>● All primary servers (required for NS action).</li> <li>● The alternate content server (required for ACS action).</li> </ul> </li> </ul>
<ul style="list-style-type: none"> <li>▫ All customizations to the latest style and vsr.htm files are applied.</li> </ul>
<ul style="list-style-type: none"> <li>▫ The alternate content server is accessible from the Internet (required for ACS action).</li> </ul>
<ul style="list-style-type: none"> <li>▫ If the -redirectURL URL argument of the add vserver CLI command needs to be specified: <ul style="list-style-type: none"> <li>● The URL is up and running.</li> <li>● This URL is not on the configured servers.</li> <li>● This URL does not match any content in the vserver (that is, do not redirect a missing URL to itself). Redirecting a missing URL to itself can send some browsers into an infinite loop.</li> </ul> </li> </ul>
<ul style="list-style-type: none"> <li>▫ All URLs to be configured for SureConnect are top-level URLs only. (Only the URLs that occupy the whole window or frame can be configured, not the embedded objects).</li> </ul>

Following are the steps to configure SureConnect in a setup with a primary server and a dedicated alternate server:

- Enable the SureConnect feature
- Add the SureConnect policy
- Bind the SureConnect policy

You can optionally configure the following:

- Redirect the client to another URL if the primary server fails, or send a customized response to the client if the alternate server fails.
- If the servers do not provide alternate content, send a default or customized response.

## To redirect the client to another URL

1. Enable the SureConnect feature.
2. Define the primary server and its service.

You must identify the original server for which SureConnect support is being configured. At the NetScaler command prompt, type the following command:

```
add service <serviceName> <IP> HTTP <port>
```

where <serviceName> assigns a name for the service; <IP> is the server's IP address; and <port> is the port number that the service will use.

Repeat use of the add service CLI command for each service that is to be added.

You can also configure SureConnect on a load balancing virtual server. At the NetScaler command prompt, type the following command:

```
add vserver <name> HTTP <IP> <port>
```

3. Define and bind the SureConnect policy as follows. If you are configuring a rule-based policy, perform this step as described in "[Configuring Wildcard Rule-Based Policies](#)." To configure a URL-based policy, at the NetScaler command prompt, type the following command:

```
add sc policy <name> [-url <URL>] [-delay <microsec>] [-maxConn <positiveInteger>]
```

For a detailed description of the add sc policy command, see "[Command Reference](#)."

To bind the SureConnect policy, at the NetScaler command prompt, type the following command:

```
bind service <serviceName> -policyname <string>
```

where <serviceName> is the name of the service defined in step 2, and <string> is the name of the SureConnect policy.

Repeat the bind service command for each policy created.

You must include the alternate content page in the altContSvcName argument, and in the altContPath argument of the add sc policy command.

In the following example, the name of the alternate content file is /Citrix NetScaler system /barandpage.htm, and this file resides in svc2.

4. To save the configuration, at the NetScaler command prompt, type the following command:

```
save config
```

## Example Configurations

Updated: 2013-09-03

The following examples illustrate various SureConnect configurations.

The examples assume that monitoring of physical services is enabled. If the alternate system is down, SureConnect will deliver the alternate content from the system itself.

### Example 1 - SureConnect Progress Bar and Alternate Page

You can configure SureConnect to display both the progress bar and an alternate page to the user.

To bind a SureConnect policy to a load balancing virtual server, at the command prompt, type the following commands:

```
bind lb vserver <virtualServerName> -policyName <string>
```

where <virtualServerName> is the name of the load balancing virtual server defined in step 2 of the configuration process, and <string> is the name of the SureConnect policy defined in step 3.

Figure 2. SureConnect Configuration - Example 1

At the NetScaler command prompt, type the following commands:

```
enable feature SC
show ns info
add service svc2 192.2.3.6 HTTP 9002
show server
show service svc2
add service svc9 192.2.3.5 HTTP 8002
add sc policy policy8 -url /cgi-bin/slow.asp
-delay 3000000 -action ACS svc2 /NetScaler 9000 system barandpage.htm
bind service svc9 -policyname policy8
set service svc9 -sc ON
save config
```

After you configure SureConnect, you can enter commands that show information to verify what you have configured.

## Example 2 - SureConnect Progress Bar Only

In this example, SureConnect will display only the progress bar. The server orgsvr with IP address 10.101.8.187 has service orgsvc. This server is connected to the appliance. The service is bound to the appliance. The progressbar.htm file specifies that only the progress bar will be displayed.

At the NetScaler command prompt, type the following commands:

```
enable feature SC
add service orgsvc 10.101.3.187 HTTP 80
add sc policy policy9 -url /cgi-bin/slow.asp
-delay 4000000 -action ACS orgsvc /NetScaler 9000 system /progressbar.htm
bind service orgsvc -policyname policy9
set service orgsvc -sc ON
save config
```

## Example 3 - SureConnect with Load Balancing

This example illustrates how to configure the load balancing feature so that SureConnect will display alternate contents from the primary server. For information about load balancing, see "[Load Balancing](#)."

In this example, two physical servers with IP 10.101.3.187 and 10.101.3.188 are being load balanced by the appliance. The name and location of the alternate page file is specified in the file `alternatepage.htm`, which resides on both servers.

The appliance has one configured virtual server address: 10.101.3.201. At the NetScaler command prompt, type the following commands:

```
enable feature SC LB
add service psvc1 10.101.3.187 HTTP 80
add service psvc2 10.101.3.188 HTTP 80
add vserver vs-SureC HTTP 10.101.3.201 80
bind lb vserver vs-SureC psvc1
bind lb vserver vs-SureC psvc2
add sc policy policy9 -url /cgi-bin/slow.asp -delay 4000000
-action ACS vs-SureC /NetScaler system /alternatepage.htm
bind lb vserver vs-SureC -policyName policy9
set lb vserver vs-SureC -sc ON
save config
```

## Example 4 - SureConnect with Load Balancing (ACS Action)

This example illustrates how to configure the NetScaler appliance load balancing feature so that SureConnect will display alternate content from the alternate server. For information about load balancing, see "[Load Balancing](#)."

In this case, there are two physical servers, IP 10.101.3.187 and 10.101.3.188. Both are being load balanced by the appliance.

The name and location of the alternate page file are specified in file `barandpage.htm`, which resides on a third server not being load balanced.

The third server's IP address is 10.101.3.189. Because `barandpage.htm` is specified, the progress bar and alternate page will both be displayed.

The appliance has one configured virtual server "vsvr" whose IP address (Virtual Server) is 10.101.3.200.

At the NetScaler command prompt, type the following commands:

```
enable feature SC LB
add service psvc1 10.101.3.187 HTTP 80
add service psvc2 10.101.3.188 HTTP 80
add service alt-cont-svc 10.101.3.189 HTTP 80
add vserver vsvr HTTP 10.101.3.200 80
bind lb vserver vsvr psvc1
bind lb vserver vsvr psvc2
add sc policy policy10 -url /cgi-bin/slow.asp
-delay 4000000 -action ACS alt-cont-svc
```

```

/NetScaler 9000 system /barandpage.htm
bind lb vsvr -policyName policy10
set lb vsvr vsvr -sc ON
save config

```

## Example 5 - SureConnect with Content Switching

This example illustrates how to configure SureConnect where the NetScaler content switching and load balancing features are being used. SureConnect is configured on a load balancing virtual server bound to a content switching virtual server.

The alternate content is distributed under the content switching virtual server according to the content switching rules. For more information about load balancing and content switching, see "[Load Balancing](#)" and "[Content Switching](#)."

In this case, three physical services with IP addresses 10.100.100.104, 10.100.100.105, and 10.100.100.106 are bound to three load balancing virtual servers with IP addresses 10.100.100.101, 10.100.100.102, and 10.100.100.103. These three load balancing virtual servers are bound to a content switching virtual server with IP address 10.100.100.100.

In this setup, lbvip1 contains .cgi content, lbvip2 contains .gif content, and .lbvip3 contains .html content.

The name and location of the alternate page file is specified in the file alternatepage.htm, which resides on lbvip3. The embedded objects in this file must be distributed according to the content switching rules (any embedded gif will reside on lbvip2, any embedded htm will reside on lbvip3, and so on).

Figure 3. SureConnect Configuration - Example 5

At the NetScaler command prompt, type the following commands:

```

enable feature CS LB SC
add vsvr cswvip HTTP 10.100.100.100 80 -type CONTENT
add vsvr lbvip1 HTTP 10.100.100.101 80 -type ADDRESS

```

```
add vserver lbvip2 HTTP 10.100.100.102 80 -type ADDRESS
add vserver lbvip3 HTTP 10.100.100.103 80 -type ADDRESS
add service psvc1 10.100.100.104 HTTP 80
add service psvc2 10.100.100.105 HTTP 80
add service psvc3 10.100.100.106 HTTP 80
bind lb vserver lbvip1 psvc1
bind lb vserver lbvip2 psvc2
bind lb vserver lbvip3 psvc3
add cs policy CSWpolicy1 -url /*.cgi
bind cs vserver cswvip lbvip1 -policyName CSWpolicy1
add cs policy CSWpolicy2 -url /*.gif
bind cs vserver cswvip lbvip2 -policyName CSWpolicy2
add cs policy CSWpolicy3 -url /*.htm
bind cs vserver cswvip lbvip3 -policyName CSWpolicy3
add sc policy SCpol -url /cgi-bin/delay.cgi -delay 4000000 -action ACS cswvip /alternatepage.htm
bind lb vserver lbvip1 -policyName SCpol
set lb vserver lbvip1 -sc ON
save config
```

# Surge Protection

Mar 21, 2012

When a surge in client requests overloads a server, server response becomes slow, and the server is unable to respond to new requests. The Surge Protection feature ensures that connections to the server occur at a rate that the server can handle. The response rate depends on how surge protection is configured. The NetScaler appliance also tracks the number of connections to the server, and uses that information to adjust the rate at which it opens new server connections.

Surge protection is enabled by default. If you do not want to use surge protection, as will be the case with some special configurations, you must disable it.

The default surge protection settings are sufficient for most uses, but you can configure surge protection to tune it for your needs. First, you can set the throttle value to tell it how aggressively to manage connection attempts. Second you can set the base threshold value to control the maximum number of concurrent connections that the NetScaler appliance will allow before triggering surge protection. (The default base threshold value is set by the throttle value, but after setting the throttle value you can change it to any number you want.)

The following figure illustrates how surge protection is configured to handle traffic to a Web site.

Figure 1. A Functional Illustration of NetScaler Surge Protection

Note: If the NetScaler appliance is installed at the edge of the network, where it interacts with network devices on the client side of the Internet, the surge protection feature must be disabled. Surge protection must also be disabled if you enable USIP (Using Source IP) mode on your appliance.

The following example and illustration show the request and response rates for two cases. In one case, surge protection is disabled, and in the other it is enabled.

When surge protection is disabled and a surge in requests occurs, the server accepts as many requests as it can process concurrently, and then begins to drop requests. As the server becomes more overloaded, it goes down and the response rate is reduced to zero. When the server recovers from the crash, usually several minutes later, it sends resets for all pending requests, which is abnormal behavior, and also responds to new requests with resets. The process repeats for each surge in requests. Therefore, a server that is under DDoS attack and receives multiple surges of requests can become unavailable to legitimate users.

When surge protection is enabled and a surge in requests occurs, surge protection manages the rate of requests to the server, sending requests to the server only as fast as the server can handle those requests. This enables the server to respond to each request correctly in the order it was received. When the surge is over, the backlogged requests are cleared.

as fast as the server can handle them, until the request rate matches the response rate.

The following figure compares the request and response scenarios when surge protection is enabled to that when it is disabled.

Figure 2. Request/Response Rate with and without Surge Protection

# Disabling and Reenabling Surge Protection

Sep 03, 2013

The surge protection feature is enabled by default. When surge protection is enabled, it is active for any service that you add.

To disable or reenabling surge protection by using the command line interface

At the command prompt, type one of the following sets of commands to disable or reenabling surge protection and verify the configuration:

- disable ns feature SurgeProtection
- show ns feature
  
- enable ns feature SurgeProtection
- show ns feature

## Example

```
disable ns feature SurgeProtection
```

```
Done show ns feature
```

	Feature	Acronym	Status
	-----	-----	-----
1)	Web Logging	WL	ON
2)	<b>Surge Protection</b>	<b>SP</b>	<b>OFF</b>
.			
.			
.			
23)	HTML Injection	HTMLInjection	ON
24)	NetScaler Push	push	OFF

```
Done
```

```
enable ns feature SurgeProtection
```

```
Done
```

```
> show ns feature
```

	Feature	Acronym	Status
	-----	-----	-----
1)	Web Logging	WL	ON
2)	<b>Surge Protection</b>	<b>SP</b>	<b>ON</b>
.			
.			
.			
23)	HTML Injection	HTMLInjection	ON
24)	NetScaler Push	push	OFF

```
Done
```

```
>
```

To disable or reenabling surge protection by using the configuration utility

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Change Advanced Features.
3. In the Configure Advanced Features dialog box, clear the selection from the Surge Protection check box to disable the surge protection feature, or select the check box to enable the feature.
4. Click OK.
5. In the Enable/Disable Feature(s) dialog box, click Yes. A message appears in the status bar, stating that the feature has been enabled or disabled.

To disable or reenable surge protection for a particular service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services. The list of configured services is displayed in the details pane.
2. In the details pane, select the service for which you want to disable or reenable the surge protection feature, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab and scroll down.
4. In the Others frame, clear the selection from the Surge Protection check box to disable the surge protection feature, or select the check box to enable the feature.
5. Click OK. A message appears in the status bar, stating that the feature has been enabled or disabled.

Note: Surge protection works only when both the feature and the service setting are enabled.

# Setting Thresholds for Surge Protection

May 14, 2012

To set the rate at which the NetScaler appliance opens connections to the server, you must configure the threshold and throttle values for surge protection.

The following figure shows the surge protection curves that result from setting the throttle rate to relaxed, normal, or aggressive. Depending on the configuration of the server capacity, you can set base threshold values to generate appropriate surge protection curves.

Figure 1. Surge Protection Curves

Your configuration settings affect the behavior of surge protection in the following manner:

- If you do not specify a throttle rate, it is set to normal (the default value), and the base threshold is set to 200, as shown in the preceding figure.
- If you specify a throttle rate (aggressive, normal, or relaxed) without specifying a base threshold, the curve reflects the default values of the base threshold for that throttle rate. For example, if you set the throttle rate to relaxed, the resulting curve will have the base threshold value of 500.
- If you specify only the base threshold, the entire surge protection curve shifts up or down, depending on the value you specify, as shown in the figure that follows.
- If you specify both a base threshold and a throttle rate, the resulting surge protection curve is based on the set throttle rate and adjusted according to the value set for the base threshold.

In the following figure, the lower curve (Aggressive 1) results when the throttle rate is set to aggressive but the base threshold is not set. The upper curve (Aggressive 2) results when the base threshold is set to 500, but the throttle rate is not set. The second upper curve (Aggressive 2) also results when the base threshold is set to 500, and the throttle rate is set to aggressive.

Figure 2. Aggressive Rate with the Default or a Set Base Threshold

### To set the threshold for surge protection by using the configuration utility

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Global System Settings.
3. If you want to set a base threshold different from the default for the throttle rate, in the Configure Global Settings dialog box, Base Threshold text box, enter the maximum number of concurrent server connections allowed before surge protection is triggered. The base threshold is the maximum number of server connections that can be open before surge protection is activated. The maximum value for this setting is 32,767 server connections. The default setting for this value is controlled by the throttle rate you choose in the next step.

Note: If you do not set an explicit value here, the default value will be used.

4. In the Throttle drop-down list, select a throttle rate. The throttle is the rate at which the NetScaler appliance allows connections to the server to be opened. The throttle can be set to the following values:

#### **Aggressive**

Choose this option when the connection-handling and surge-handling capacity of the server is low and the connection needs to be managed carefully. When you set the throttle to aggressive, the base threshold is set to a default value of 16, which means that surge protection is triggered whenever there are 17 or more concurrent connections to the server.

#### **Normal**

Choose this option when there is no external load balancer behind the NetScaler appliance or downstream. The base threshold is set to a value of 200, which means that surge protection is triggered whenever there are 201 or more concurrent connections to the server. Normal is the default throttle option.

#### **Relaxed**

Choose this option when the NetScaler appliance is performing load balancing between a large number of Web servers, and can therefore handle a high number of concurrent connections. The base threshold is set to a value of 500, which means that surge protection is triggered only when there are 501 or more concurrent connections to the server.

5. Click OK. A message appears in the status bar, stating that the global settings are configured.

# Flushing the Surge Queue

Dec 04, 2013

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the NetScaler appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.

Note: Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

To flush a surge queue by using the command line interface

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]
```

## Examples

1.

```
flush ns surgeQ --name SVC1ANZGB --serverName 10.10.10.1 80
```

The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10

2.

```
flush ns surgeQ
```

The above command flushes all the surge queues on the appliance.

To flush a surge queue by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Flush Surge Queue.

# NITRO API

Oct 15, 2015

Click [here](#) for NITRO documentation for NetScaler versions 11.0 and 10.5.

# Obtaining the NITRO Package

Jun 03, 2014

The NITRO package is available as a tar file on the Downloads page of the NetScaler appliance's configuration utility. You must download and un-tar the file to a folder on your local system. This folder is referred to as <NITRO\_SDK\_HOME> in this documentation.

The folder contains the NITRO libraries in the lib subfolder. The libraries must be added to the client application classpath to access NITRO functionality. The <NITRO\_SDK\_HOME> folder also provides samples and documentation that can help you understand the NITRO SDK.

Note:

- The REST package contains only documentation for using the REST interfaces.
- For the Python SDK, the library must be installed on the client path. For installation instructions, read the <NITRO\_SDK\_HOME>/README.txt file.

# How NITRO Works

Jun 03, 2014

The NITRO infrastructure consists of a client application and the NITRO Web service running on a NetScaler appliance. The communication between the client application and the NITRO web service is based on REST architecture using HTTP or HTTPS.

Figure 1. NITRO execution flow

As shown in the above figure, a NITRO request is executed as follows:

1. The client application sends REST request message to the NITRO web service. When using the SDKs, an API call is translated into the appropriate REST request message.
2. The web service processes the REST request message.
3. The NITRO web service returns the corresponding REST response message to the client application. When using the SDKs, the REST response message is translated into the appropriate response for the API call.

To minimize traffic on the NetScaler network, you retrieve the whole state of a resource from the server, make modifications to the state of the resource locally, and then upload it back to the server in one network transaction. For example, to update a load balancing virtual server, you must retrieve the object, update the properties, and then upload the changed object in a single transaction.

Note: Local operations on a resource (changing its properties) do not affect its state on the server until the state of the object is explicitly uploaded.

NITRO APIs are synchronous in nature. This means that the client application waits for a response from the NITRO web service before executing another NITRO API.

# REST Web Services

Mar 30, 2015

REST (REpresentational State Transfer) is an architectural style based on simple HTTP requests and responses between the client and the server. REST is used to query or change the state of objects on the server side. In REST, the server side is modeled as a set of entities where each entity is identified by a unique URL.

NITRO URLs are formed as follows:

- **For configurations.** `http://<netscaler-ip-address>/nitro/v1/config/<resource-type>`
- **For retrieving statistics.** `http://<netscaler-ip-address>/nitro/v1/stat/<resource-type>`

For example, for a load balancing virtual server, `<resource-type>` can be replaced by `lbvserver`.

For more information on the REST objects and the usage, see the documentation provided in the `<NITRO_SDK_HOME>/index.html` file.

## Some points to remember

- In addition to the CRUD operations (Create, Read, Update, and Delete), resources (such as `lbvserver`) can support other operations or actions. These operations use the HTTP POST method, with the URL specifying the operation to be performed and the request body specifying the parameters for that operation.
- Content-Type to be used is `"application/vnd.com.citrix.netscaler.<resource-type>+json"`. However, content types such as `"application/x-www-form-urlencoded"` that were supported in NetScaler 9.3 and earlier versions can also be used. You must make sure that the payload is the same as used in earlier versions. The payloads provided in this documentation are only applicable if the content-type is `"application/vnd.com.citrix.netscaler.<resource-type>+json"`.
- All NITRO operations are logged in the `/var/log/nitro.log` file on the NetScaler appliance.

# Connecting to the NetScaler Appliance

Apr 10, 2015

The first step towards using NITRO is to establish a session with the NetScaler appliance and then authenticate the session by using the NetScaler administrator's credentials. You must specify the username and password in the login object. The session ID that is created must be specified in the request header of all further operations in the session.

Note:

- You must have a user account on the appliance to log on to it. The configuration operations that you can perform are limited by the administrative roles assigned to your account.
- Instead of creating a NITRO session, you can logon to the NetScaler appliance while performing individual operations. To do this, you must specify the username and password in the **request header** of the NITRO request as follows:

```
X-NITRO-USER:<username>
```

```
X-NITRO-PASS:<password>
```

```
Content-Type:application/vnd.com.citrix.netscaler.lbvserver+json
```

For example, to connect and create a session with a NetScaler appliance with NSIP address 10.102.29.60 by using the HTTP protocol:

- **Request:**

**HTTP Method**

```
POST
```

**URL**

```
http://10.102.29.60/nitro/v1/config/login
```

**Request Headers**

```
Content-Type:application/vnd.com.citrix.netscaler.login+json
```

**Request Payload**

```
{
 "login":
 {
 "username": "<username>",
 "password": "<password>"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

```
200 OK
```

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

**Response Header**

Set-Cookie:

```
NITRO_AUTH_TOKEN=<tokenvalue>;
```

```
path=/nitro/v1
```

## Modifying the Session Timeout

You can modify the timeout period by specifying a new timeout period (in seconds) in the login object. For example, to modify the timeout period to 60 minutes:

```
{
 "login":
 {
 "username":"<username>",
 "password":"<password>",
 "timeout":"3600"
 }
}
```

Some points to note with regards to session timeout for NetScaler 10.5 and later versions:

- When restricted timeout param is enabled, NITRO, by default, uses the timeout value that is configured for the logged in user. You can customize this value but it must be limited to the value specified for the user. If no value is specified for the user, the default timeout value of 15 minutes is used.
- When restricted timeout param is not enabled, NITRO uses the default value of 30 minutes as session timeout.

# Enabling NetScaler Features and Modes

Apr 10, 2015

Some NetScaler features and modes are disabled by default and therefore must be enabled before they can be configured. To enable a NetScaler feature or mode, specify the action as "enable" in the URL query string, and in the request payload, specify the feature or mode to be enabled.

For example, to enable the load balancing and content switching features:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/nsfeature?action=enable

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.nsfeature+json

**Request Payload**

```
{
 "nsfeature":
 {
 "feature":
 [
 "LB",
 "CS"
]
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

For example, to enable the L2 and fast ramp modes:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/nsmode?action=enable

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.nsmode+json

#### Request Payload

```
{
 "nsmode":
 {
 "mode":
 [
 "L2",
 "FR"
]
 }
}
```

- **Response:**

#### HTTP Status Code on Success

200 OK

#### HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Note: To disable a feature or mode, in the URL query string, specify the action as "disable".

# Saving NetScaler Configurations

Apr 10, 2015

To make sure that the configurations persist on rebooting the appliance, you must save the NetScaler configurations. To save the configurations, specify the action as "save" in the URL query string.

To save the configurations:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/nsconfig?action=save

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.nsconfig+json

**Request Payload**

```
{
 "nsconfig":
 {}
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# General API Usage

Apr 01, 2015

A NetScaler appliance has multiple features, and each feature has multiple resources. Each NetScaler resource, depending on the operation to be performed on it, has a unique URL associated with it. URLs for configuration operations have the following format:

`http://<netscaler-ip-address>/nitro/v1/config/<resource_type>/<resource_name>.`

For example, to access the lbserver named MyFirstLbVServer on a NetScaler with IP 10.102.29.60, the URL is:

`http://10.102.29.60/nitro/v1/config/lbserver/MyFirstLbVServer.`

This section explains, in general, the different types of operations that can be performed on the NetScaler appliance by using NITRO API.

Before going into the details of these operations, you must be aware of the following functionality:

- You can use the "action" query parameter in the URL to perform operations such as save, enable, disable, and kill sessions.
- You can use the "attrs", "filter", "args", "count" and other query parameters when retrieving NetScaler resources. For more information, see [Retrieving Details of NetScaler Resources](#).
- You can perform bulk operations and thus minimize network traffic. To perform a bulk operation, specify the required parameters in the same request payload. You can also control the behavior of a bulk operation in case of failure of some operations. To do this, in the request header, specify the appropriate value for the X-NITRO-ONERROR parameter. For more information, see [Performing Bulk Operations](#).
- NetScaler NITRO clearly shows the errors so that corrective actions can be taken. For more information, see [Error Handling](#).

# Adding a NetScaler Resource

Apr 10, 2015

To create a new resource (for example, an lbserver) on the appliance, specify the resource name and other related arguments in the specific resource object.

For example, to create an load balancing virtual server named MyFirstLbVServer:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/lbserver

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.lbserver+json

**Request Payload**

```
{
 "lbserver":
 {
 "name":"MyFirstLbVServer",
 "servicetype":"http"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 Created

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# Enabling a NetScaler Resource

Apr 10, 2015

To enable a resource on the NetScaler appliance, specify the action as "enable" in the URL query string, and in the request payload, specify the resource to be enabled.

For example, to enable a load balancing virtual server named MyFirstLbVServer:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/lbserver?action=enable

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.lbserver+json

**Request Payload**

```
{
 "lbserver":
 {
 "name":"MyFirstLbVServer"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Note: To disable a resource, in the URL query string, specify the action as "disable".

# Getting the Count of NetScaler Resources

Apr 10, 2015

To get a count of a specific resource type, in the URL specify the count query parameter as "yes".

For example, to get a count of all the load balancing virtual servers:

- **Request:**

**HTTP Method**

GET

**URL**

http://<netscaler-ip-address>/nitro/v1/config/lbserver?count=yes

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Accept:application/vnd.com.citrix.netscaler.lbserver+json

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

**Response Header**

Content-Type:application/vnd.com.citrix.netscaler.lbserver+json

**Response Payload**

```
{
 "lbserver":
 [
 {
 "__count": 4
 }
]
}
```

# Retrieving Details of NetScaler Resources

Apr 10, 2015

NITRO provides multiple approaches using which you can retrieve resources and their relevant details. The following table explains each of these approaches with the required URL.

Note: A sample format of the request and response is provided below the table.

<b>Retrieving all details of all resources of a specific type</b>	<p>In the URL, specify the type of resource for which you want to retrieve the details.</p> <p>For example, to retrieve all details of load balancing virtual servers available on a NetScaler appliance.</p> <p><code>http://&lt;netscaler-ip-address&gt;/nitro/v1/config/lbserver</code></p>
<b>Retrieving all details of a specific resource</b>	<p>In the URL, specify the name of resource for which you want to retrieve the details.</p> <p>For example, to retrieve all details of a load balancing virtual server named MyFirstLbVServer:</p> <p><code>http://&lt;netscaler-ip-address&gt;/nitro/v1/config/lbserver/MyFirstLbVServer</code></p>
<b>Retrieving summary or detailed view of resources</b>	<p>In the URL, use the "view" query parameter to specify whether you want to view the summary (mandatory parameters) or detail (all parameters).</p> <p>For example, to view the mandatory parameters for all load balancing virtual servers:</p> <p><code>http://&lt;netscaler-ip-address&gt;/nitro/v1/config/lbserver?view=summary</code> Note: By default, the retrieved results are displayed in detail view (?view=detail).</p>
<b>Retrieving all details of resources that have multiple unique identifiers</b>	<p>In the URL, specify the type of resource and use the "args" query parameter to specify the unique attributes and the values for those attributes.</p> <p>For example, to get the application firewall profiles that have unique identifiers "name" and "starturl" as appfw1 and aa respectively.</p> <p><code>http://&lt;netscaler-ip-address&gt;/nitro/v1/config/appfwprofile?args=name:appfw1,starturl:aa</code></p>
<b>Retrieving specific details of all resources of a specific type</b>	<p>In the URL, specify the type of the resource and use the "attrs" query parameter to specify the resource details that you want to retrieve.</p> <p>For example, to retrieve the "name" and "lbmethod" of all load balancing virtual servers:</p> <p><code>http://&lt;netscaler-ip-address&gt;/nitro/v1/config/lbserver?attrs=name,lbmethod</code></p>
<b>Retrieving specific details of a specific</b>	<p>In the URL, specify the type and name of the resource and use the "attrs" query parameter to specify the resource details that you want to retrieve.</p>

<b>resource</b>	<p>For example, to retrieve the "name" and "lbmethod" of a load balancing virtual server named "MyFirstLbVServer":</p> <p>http://&lt;netscaler-ip-address&gt;/nitro/v1/config/lbserver/MyFirstLbVServer?attrs=name,lbmethod</p>
<b>Filtering the retrieved resources</b>	<p>In the URL, specify the type of resource and use the "filter" query parameter to specify the attribute(s) and the value(s) of the attributes. The resources fetched will be filtered based on the filter criteria.</p> <p>Note: The filter query parameter supports the use of PCRE regular expressions. For example, to filter the load balancing virtual servers where the "lbmethod" is ROUNDROBIN.</p> <p>http://&lt;netscaler-ip-address&gt;/nitro/v1/config/lbserver?filter=lbmethod:ROUNDROBIN</p>
<b>Retrieving resources in paginated manner</b>	<p>If the request is likely to result in a large number of resources, you can divide the results into pages and retrieve them page by page (paginated). For example, if you are retrieving all the 53 load balancing virtual servers of a NetScaler appliance, instead of retrieving all 53 in one response, you can configure the results to be divided into 6 pages each having 10 results.</p> <p>In the URL, specify the name of the resource and use the following query parameters:</p> <ul style="list-style-type: none"> <li>• "pageno" - The page number to be displayed.</li> <li>• "pagesize" - The number of resources to be displayed in each page.</li> </ul> <p>For example, to retrieve the load balancing virtual servers in a paginated form, first get a count (using the "count" query parameter shown in below row) of the load balancing virtual servers. Then, accordingly specify the number of results for each page and then specify the page number to be displayed.</p> <p>http://&lt;netscaler-ip-address&gt;/nitro/v1/config/lbserver?pagesize=10&amp;pageno=3</p>

For example, to retrieve only the name and load balancing method of all load balancing virtual servers on a NetScaler:

• **Request:**

**HTTP Method**

GET

**URL**

http://<netscaler-ip-address>/nitro/v1/config/lbserver?attrs=name,lbmethod

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Accept:application/vnd.com.citrix.netscaler.lbserver\_list+json

Note: If the operation returns a list of objects, the Accept header does not require the resource type to be appended by "\_list".

• **Response:**

## HTTP Status Code on Success

200 OK

## HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

## Response Header

Content-Type:application/vnd.com.citrix.netscaler.lbvserver\_list+json

Note: For a single object, the Content-Type header does not require the resource type to be appended by "\_list".

## Response Payload

```
{
 lbvserver:
 {
 name: "test",
 lbmethod: "LEASTCONNECTION"
 }
 {
 name: "test1",
 lbmethod: "LEASTCONNECTION"
 }
}
```

# Retrieving Statistics of NetScaler Resources

Apr 10, 2015

The NetScaler appliance collects statistics about the usage of its features and the corresponding resources. NITRO can retrieve these statistics.

- To get statistics of a feature, the URL format must be: *http://<netscaler-ip-address>/nitro/v1/stat/<feature\_name>*.
- To get statistics of a resource, the URL format must be: *http://<netscaler-ip-address>/nitro/v1/stat/<resource\_type>/<resource\_name>*.
- [From NetScaler 10.5 Build 58.x] To get statistics of the services and service groups that are bound to a load balancing virtual server, the URL format must be: *http://<netscaler-ip-address>/nitro/v1/stat/lbserver/<name>?statbindings=yes*.

For example, to get the statistics of a load balancing virtual server named MyFirstLbVServer:

- **Request:**

**HTTP Method**

GET

**URL**

*http://<netscaler-ip-address>/nitro/v1/stat/lbserver/MyFirstLbVServer*

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Accept:application/vnd.com.citrix.netscaler.lbserver+json

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

**Response Header**

Content-Type:application/vnd.com.citrix.netscaler.lbserver+json

**Response Payload**

```
{
 "lbserver":
 [
 {
 "name":"MyFirstLbVServer",
 "establishedconn":0,
 "vslbhealth":0,
 "primaryipaddress":"0.0.0.0",
 ...
 }
]
}
```

Note: Not all NetScaler features and resources have statistic objects associated with them.

# Resetting Properties of a NetScaler Resource

Apr 10, 2015

To unset the value of an attribute of a NetScaler object or reset it to its default value (similar to the "unset" NetScaler CLI commands), specify the action as "unset" in the URL query string, and in the request payload, specify the value of the attributes to be unset as "true" (boolean).

For example, to unset the load balancing method and the comments attributes of a load balancer virtual server named MyFirstLbVServer:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/lbserver?action=unset

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.lbserver+json

**Request Payload**

```
{
 "lbserver":
 {
 "name":"MyFirstLbVServer",
 "lbmethod":"true",
 "comment":"true"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# Renaming a NetScaler Resource

Apr 10, 2015

To change the name of an existing resource, specify the action as "rename" in the URL query string, and in the request payload, specify the existing name and the new name.

For example, to change the name of a load balancing virtual server from MyFirstLbVServer to MyServer:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/lbserver?action=rename

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.lbserver+json

**Request Payload**

```
{
 "lbserver":
 {
 "name":"MyFirstLbVServer",
 "newname":"MyServer"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# Updating a NetScaler Resource

Apr 10, 2015

To update the details of an existing resource on the NetScaler appliance, specify the name of the resource in the URL, and in the request payload, within the specific resource object, specify the name and the updated details of the resource.

For example, to change the load balancing method to ROUNDROBIN and update the comment property for a load balancing virtual server named MyFirstLbVServer:

- **Request:**

**HTTP Method**

PUT

**URL**

http://<netscaler-ip-address>/nitro/v1/config/lbserver/MyFirstLbVServer

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.lbserver+json

**Request Payload**

```
{
 "lbserver":
 {
 "name":"MyFirstLbVServer",
 "lbmethod":"ROUNDROBIN",
 "comment":"Updated comments"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# Binding NetScaler Resources

Apr 15, 2015

NetScaler resources form relationships with each other through the process of binding. This is how services are associated with a load balancing virtual server, or how policies are bound to a load balancing virtual server. Each binding relationship is represented by its own object. A binding resource has properties representing the name of each NetScaler resource in the binding relationship. It can also have other properties related to that relationship (for example, the weight of the binding between an lbvserver resource and a service resource).

Read through the following examples to get a better understanding of the bind and unbind operation.

**Example 1:** To bind a service named "svc\_prod" to a load balancing virtual server named "MyFirstLbVServer" and specify a weight for the binding:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/lbvserver\_service\_binding

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.lbvserver\_service\_binding+json

**Request Payload**

```
{
 "lbvserver_service_binding":
 {
 "servicename":"svc_prod",
 "weight":"20",
 "name":"MyFirstLbVServer"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

201 Created

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

**Example 2:** To bind a policy to a policy label:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/authenticationpolicylabel\_authenticationpolicy\_binding

## Request Headers

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.authenticationpolicylabel\_authenticationpolicy\_binding

## Request Payload

```
{
 "authenticationpolicylabel_authenticationpolicy_binding":
 {
 "policyname":"p1",
 "priority":"100",
 "gotopriorityexpression":"END",
 "labelname":"pl1"
 }
}
```

- **Response:**

### HTTP Status Code on Success

201 Created

### HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

To unbind a resource, use the DELETE method and specify an "args" query string parameter in the URL that contains the attribute name and value in the relationship resource that designates the secondary resource.

For example, to unbind the service "svc\_prod" from the load balancing virtual server "MyFirstLbVServer":

- **Request:**

### HTTP Method

DELETE

### URL

http://<netscaler-ip-address>/nitro/v1/config/lbserver\_service\_binding/MyFirstLbVServer?args=servicename:svc\_prod

### Request Header

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

- **Response:**

### HTTP Status Code on Success

200 OK

### HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# Globally Binding NetScaler Resources

Apr 10, 2015

Some NetScaler resources can be bound globally to affect the whole system. For example, if a compression policy is bound to an load balancing virtual server, the policy affects only the traffic on that virtual server. However, if bound globally, it can affect any traffic on the NetScaler appliance regardless of the virtual server that handles the traffic.

The names of NITRO resources that can be used to bind resources globally have the pattern `<featurename>global_<resourcetype>_binding`. For example, the object `aaaglobal_aaapreauthenticationpolicy_binding` is used to bind preauthentication policies globally.

For example, to bind the policy named `preautpol1` globally at priority 200:

- **Request:**

**HTTP Method**

POST

**URL**

`http://<netscaler-ip-address>/nitro/v1/config/aaaglobal_aaapreauthenticationpolicy_binding/preautpol1`

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.aaaglobal\_aaapreauthenticationpolicy\_binding+json

**Request Payload**

```
{
 "aaaglobal_aaapreauthenticationpolicy_binding":
 {
 "policy":"preautpol1",
 "priority":"200"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

To unbind a global resource, in the URL use the `args` query parameter to specify the resource to be unbound.

For example, to unbind the policy named `preautpol1`:

- **Request:**

**HTTP Method**

DELETE

**URL**

`http://<netscaler-ip-address>/nitro/v1/config/aaaglobal_aaapreauthenticationpolicy_binding?args=policy:preautpol1`

## Request Header

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

- **Response:**

### HTTP Status Code on Success

200 OK

### HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# Deleting a NetScaler Resource

Apr 10, 2015

To delete a NetScaler resource, specify the resource name in the URL.

For example, to delete a load balancing virtual server named MyFirstLbVServer:

- **Request:**

**HTTP Method**

DELETE

**URL**

http://<netscaler-ip-address>/nitro/v1/config/lbserver/MyFirstLbVServer

**Request Header**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# Performing Bulk Operations

Jun 21, 2017

You can create and update multiple resources simultaneously and thus minimize network traffic. For example, you can add/enable/disable multiple load balancing virtual servers in the same operation. To perform a bulk operation, specify the required parameters in the same request payload.

To account for the failure of some operations within the bulk operation, NITRO allows you to configure one of the following behaviors:

- **Exit.** When the first error is encountered, the execution stops. The NITRO operations that were executed before the error are committed. This is the default behavior.
- **Rollback.** When the first error is encountered, the execution stops. The NITRO operations that were executed before the error are rolled back. Rollback is only supported for add and bind NITRO operations.
- **Continue.** All the NITRO operations in the list are executed even if some operations fail.

You must specify the behavior of the bulk operation in the request header using the X-NITRO-ONERROR parameter.

For example, to add two load balancing virtual servers in one operation, and continue even if one of the add operation fails:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/lbserver

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.lbserver\_list+json

X-NITRO-ONERROR:continue

**Request Payload**

```
{
 "lbserver":
 [
 {
 "name":"new_lbserver1",
 "servicetype":"http"
 },
 {
 "name":"new_lbserver2",
 "servicetype":"http"
 }
]
}
```

- **Response:**

**HTTP Status Code on Success**

201 Created for the add operation and 200 OK for the update operation.

#### HTTP Status Code on Failure

207 Multi Status with error details in the response payload. For more information, see [Error Handling](#).

### Example for enabling multiple load balancing virtual servers in the same operation

- Request:

#### HTTP Method

POST

#### URL

http://<netscaler-ip-address>/nitro/v1/config/lbserver?action=enable

#### Request Headers

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/json

#### Request Payload

```
{
 "lbserver":
 [
 {
 "name":"v1",
 },
 {
 "name":"v2",
 }
]
}
```

- Response:

#### HTTP Status Code on Success

201 Created for the add operation and 200 OK for the update operation.

#### HTTP Status Code on Failure

207 Multi Status with error details in the response payload. For more information, see [Error Handling](#).

# Performing File Operations

Aug 28, 2015

NetScaler operations such as configuring SSL certificates requires the input files to be available locally on the NetScaler appliance. NITRO allows you to perform file operations such as uploading file to the NetScaler, retrieving a list of files and the file content from the NetScaler, and also delete files from the NetScaler. These operations can be performed for files of type: txt, cert, req, xml, lic, and key.

Note:

- File size must be less than or equal to 2 MB.
- Use the "BASE64" value for the fileencoding attribute in the request payload. This is the only valid encoding currently supported.
- The filelocation path must be URL encoded. For example, if the path is /nsconfig/ssl, encode the / and use the file location as %2Fnsconfig%2Fssl

## Uploading a File to the NetScaler

To upload a file to the NetScaler, specify a name for the file, the location where the file must be created on the NetScaler, and the content of the file.

For example, to upload a file named cert1.crt in the /nsconfig/ssl/ directory:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/systemfile

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.systemfile+json

**Request Payload**

```
{
 "systemfile":
 {
 "filename": "cert1.crt",
 "filelocation": "/nsconfig/ssl/",
 "filecontent": "VGhpcyBpcyBteSBmaWxl",
 "fileencoding": "BASE64"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

## Retrieving the Files from a NetScaler Directory

To retrieve the files from a specific NetScaler directory, specify the directory path in the URL.

For example, to retrieve the files from the /nsconfig/ssl directory.

- **Request:**

### HTTP Method

GET

### URL

http://<netscaler-ip-address>/nitro/v1/config/systemfile?args=filelocation:%2Fnsconfig%2Fssl

### Request Header

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

- **Response:**

### HTTP Status Code on Success

200 OK

### HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

### Response Header

Content-Type:application/vnd.com.citrix.netscaler.systemfile\_list+json

### Response Payload

```
{
 "systemfile":
 [
 {
 "filename": "ns-root.key",
 "filelocation": "/nsconfig/ssl",
 "fileaccesstime": "Tue Jan 14 19:27:01 2014",
 "filemodifiedtime": "Tue Nov 5 17:16:00 2013"
 },
 {
 "filename": "ns-root.req",
 "filelocation": "/nsconfig/ssl",
 "fileaccesstime": "Tue Jan 14 19:27:01 2014",
 "filemodifiedtime": "Tue Nov 5 17:16:00 2013"
 }
]
}
```

## Retrieving Contents of a Specific File

To retrieve the contents of a file, specify the filename and its directory path in the URL.

For example, to retrieve the contents of the ns-root.key file from the /nsconfig/ssl directory.

- **Request:**

**HTTP Method**

GET

**URL**

http://<netscaler-ip-address>/nitro/v1/config/systemfile/ns-root.key?args=filelocation:%2Fnsconfig%2Fssl

**Request Header**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

**Response Header**

Content-Type:application/vnd.com.citrix.netscaler.systemfile+json

**Response Payload**

```
{
 "systemfile":
 [
 {
 "filename": "ns-root.key",
 "filelocation": "/nsconfig/ssl",
 "filecontent": "LS0tLS1CRUdJTiBSU0EgUFJJKFV0tLQo=",
 "fileencoding": "BASE64",
 "fileaccesstime": "Tue Jan 14 19:27:01 2014",
 "filemodifiedtime": "Tue Nov 5 17:16:00 2013"
 }
]
}
```

## Deleting a File from the NetScaler

To delete a file from the NetScaler appliance, specify the filename and the directory path in the URL.

For example, to delete the ns-root.key file from the /nsconfig/ssl directory.

- **Request:**

**HTTP Method**

DELETE

**URL**

`https://<netscaler-ip-address>/nitro/v1/config/systemfile/ns-root.key?args=filelocation:%2Fnsconfig%2Fssl`

#### **Request Header**

`Cookie:NITRO_AUTH_TOKEN=<tokenvalue>`

- **Response:**

#### **HTTP Status Code on Success**

200 OK

#### **HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# Killing a System Session

Apr 10, 2015

A NetScaler administrator can kill any system session by specifying the action as "kill" in the URL query string and by specifying the required system session ID in the request payload.

For example, to kill a system session that has ID as 311:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/systemsession?action=kill

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.systemsession+json

**Request Payload**

```
{
 "systemsession":
 {
 "sid":"311"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# Disconnecting from the NetScaler Appliance

Apr 10, 2015

Before disconnecting (logging out) from the NetScaler appliance, make sure that you have saved the NetScaler configurations.

To logout of the NetScaler appliance:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/logout

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.logout+json

**Request Payload**

```
{
 "logout":{}
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# Usage Scenarios

Mar 30, 2015

In this section, we provide NITRO API specific to certain resources and scenarios. We will be adding more scenarios in future updates to this documentation.

# Configuring a NetScaler Cluster

Apr 10, 2015

You can use NITRO to add or create and manage a NetScaler cluster.

## Cluster Instance Operations

All operations on a cluster instance must be performed on the clusterinstance object.

For example, to create a cluster instance with ID 1, connect to the NetScaler appliance that you are first adding to the cluster:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/clusterinstance

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.clusterinstance+json

**Request Payload**

```
{
 "clusterinstance":
 {
 "clid":1,
 "preemption":"ENABLED"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

201 Created

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

## Cluster Node Operations

All operations on a cluster node must be performed on the clusternode object.

For example, to add a NetScaler appliance with NSIP address 10.102.29.60 to the cluster:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/clusternode

#### Request Headers

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.clusternode+json

#### Request Payload

```
{
 "clusternode":
 {
 "nodeid":1,
 "ipaddress":"10.102.29.60",
 "state":"ACTIVE",
 "backplane":"1/1/2"
 }
}
```

- **Response:**

#### HTTP Status Code on Success

201 Created

#### HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

### Add a Cluster IP Address

To define a cluster IP address, specify the required parameters in the nsip object.

For example, to configure a cluster IP address:

- **Request:**

#### HTTP Method

POST

#### URL

http://<netscaler-ip-address>/nitro/v1/config/nsip

#### Request Headers

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.nsip+json

#### Request Payload

```
{
 "nsip":
 {
 "ipaddress":"10.102.29.61",
 "netmask":"255.255.255.255",
 "type":"CLIP"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

201 Created

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

## Add a Spotted IP Address

To configure an IP address as spotted, specify the required parameters in the nsip object. This configuration must be done on the cluster IP address.

For example, to configure a spotted SNIP address on a node with ID 1:

- **Request:**

**HTTP Method**

POST

**URL**

http://<cluster-ip-address>/nitro/v1/config/nsip

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.nsip+json

**Request Payload**

```
{
 "nsip":
 {
 "ipaddress":"10.102.29.77",
 "netmask":"255.255.255.0",
 "type":"SNIP",
 "ownernode":1
 }
}
```

- **Response:**

**HTTP Status Code on Success**

201 Created

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

## Join NetScaler Appliance to Cluster

To join an appliance to a cluster, specify the required parameters in the cluster object.

For example, to join a NetScaler appliance to a cluster:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/cluster

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.cluster+json

**Request Payload**

```
{
 "cluster":
 {
 "clip":"10.102.29.61",
 "password":"verysecret"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

## Linkset Operations

To configure a linkset, do the following:

1. Create a linkset by specifying the required parameters in the linkset object.

For example, to add a linkset LS/1:

- **Request:**

**HTTP Method**

POST

**URL**

http://<cluster-ip-address>/nitro/v1/config/linkset

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.linkset+json

**Request Payload**

```
{
 "linkset":
 {
 "id":"LS/1"
 }
}
```

```
}
```

- **Response:**

**HTTP Status Code on Success**

201 Created

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

2. Bind the required interfaces to the linkset by specifying the interfaces in the linkset\_interface\_binding object.

For example, to bind interfaces 1/1/2 and 2/1/2 to linkset LS/1:

- **Request:**

**HTTP Method**

PUT

**URL**

http://<cluster-ip-address>/nitro/v1/config/linkset\_interface\_binding/LS%2F1?action=bind

Note: The linkset name (LS/1), must be URL encoded as LS%2F1.

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.linkset\_interface\_binding+json

**Request Payload**

```
{
 "linkset_interface_binding":
 {
 "id":"LS/1",
 "ifnum":"1/1/2 2/1/2"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# Configuring Admin Partitions

Apr 10, 2015

To create an admin partition, you must perform a set of operations on the default partition. To understand this procedure, let us consider a company that has two departments each of which has an application that requires the NetScaler functionality. The NetScaler admin wants to have a different partition for each department so that there is isolation of users and configurations. The NetScaler admin must do the following (the sample shows configurations only for a single admin partition):

Note: For detailed information and best practices, see [Admin Partitions](#).

1. Create a partition and allocate the required resources to that partition.

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/nspartition

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.nspartition+json

**Request Payload**

```
{
 "nspartition":
 {
 "partitionname":"partition-dept1",
 "maxbandwidth":"10240",
 "minbandwidth":"10240",
 "maxconn":"1024",
 "maxmemlimit":"10"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 Created

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

2. Associate the appropriate users with the partition.

- **Request:**

**HTTP Method**

PUT

**URL**

http://<netscaler-ip-address>/nitro/v1/config/systemuser\_nspartition\_binding/user1

#### Request Headers

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.systemuser\_nspartition\_binding+json

#### Request Payload

```
{
 "systemuser_nspartition_binding":
 {
 "username":"user1",
 "partitionname":"partition-dept1"
 }
}
```

- **Response:**

#### HTTP Status Code on Success

200 OK

#### HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

### 3. Associate an appropriate command policy to the admin partition user.

- **Request:**

#### HTTP Method

PUT

#### URL

http://<netscaler-ip-address>/nitro/v1/config/systemuser\_systemcmdpolicy\_binding/user1

#### Request Headers

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.systemuser\_systemcmdpolicy\_binding+json

#### Request Payload

```
{
 "systemuser_systemcmdpolicy_binding":
 {
 "username":"user1",
 "policyname":"partition-admin",
 "priority":"1"
 }
}
```

- **Response:**

#### HTTP Status Code on Success

200 OK

#### HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides

details of the error.

4. Specify the VLANs or bridgegroups to be associated with the partition. This step ensures network isolation of the traffic. Traffic received on the interfaces of the VLAN or bridgegroup is isolated from the traffic of other partitions.

- **Request:**

**HTTP Method**

PUT

**URL**

http://<netscaler-ip-address>/nitro/v1/config/nspartition\_vlan\_binding/partition-dept1

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.nspartition\_vlan\_binding+json

**Request Payload**

```
{
 "nspartition_vlan_binding":
 {
 "partitionname":"partition-dept1",
 "vlan":"2"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

5. Save the configurations.

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/nsconfig?action=save

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.nsconfig+json

**Request Payload**

```
{
 "nsconfig":
 {
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

The admin partition is created.

6. Now, to configure this admin partition, you must logout of the default partition and logon again. You are automatically taken to the admin partition to which you were first bound and once there you can configure the NetScaler.

Note: If you want to configure another admin partition, perform the switch operation given in the next step before performing this step.

7. [Optional] If you are associated with multiple admin partitions, you can switch to the required partition.

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/nspartition?action=Switch

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.nspartition+json

**Request Payload**

```
{
 "nspartition":
 {
 "partitionname":"partition-dept2"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

8. View the partitions that are available on the NetScaler appliance. If a user is associated with more than one partition, the response payload includes the "partitiontype" attribute the value of which indicates the partition to which the user is currently logged on.

- **Request:**

**HTTP Method**

GET

**URL**

http://<netscaler-ip-address>/nitro/v1/config/nspartition

#### Request Headers

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Accept:application/vnd.com.citrix.netscaler.nspartition+json

- **Response:**

#### HTTP Status Code on Success

200 OK

#### HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

#### Response Header

Content-Type:application/vnd.com.citrix.netscaler.nspartition+json

#### Response Payload

```
{
 "nspartition":
 {
 "partitionname":"partition-dept1",
 "partitionid": "2",
 "partitiontype": "Current Partition",
 "maxbandwidth":"10240",
 "minbandwidth":"10240",
 "maxconn":"1024",
 "maxmemlimit":"10"
 }
}
```

# Managing AppExpert Applications

Apr 10, 2015

To export an AppExpert application, specify the parameters needed for the export operation in the `apptemplateinfo` object. Optionally, you can specify basic information about the AppExpert application template, such as the author of the configuration, a summary of the template functionality, and the template version number, in the `template_info` object. This information is stored as part of the template file that is created.

For example, to export an AppExpert application named MyApp1:

- **Request:**

**HTTP Method**

POST

**URL**

`http://<netscaler-ip-address>/nitro/v1/config/apptemplateinfo?action=export`

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.apptemplateinfo+json

**Request Payload**

```
{
 "apptemplateinfo":
 {
 "appname":"MyApp1",
 "apptemplatefilename":"BizAp.xml",
 "template_info":
 {
 "templateversion_major":"2",
 "templateversion_minor":"1",
 "author":"XYZ",
 "introduction":"Intro",
 "summary":"Summary"
 }
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

To import an AppExpert application, specify the parameters needed for the import operation in the `apptemplateinfo` object.

For example, to import an AppExpert application named MyApp1:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/apptemplateinfo?action=import

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.apptemplateinfo+json

**Request Payload**

```
{
 "apptemplateinfo":
 {
 "apptemplatefilename":"BizAp.xml",
 "deploymentfilename":"BizAp_deployment.xml",
 "appname":"MyApp1"
 }
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

To import an AppExpert application by specifying different deployment settings:

- **Request:**

**HTTP Method**

POST

**URL**

http://<netscaler-ip-address>/nitro/v1/config/apptemplateinfo?action=import

**Request Headers**

Cookie:NITRO\_AUTH\_TOKEN=<tokenvalue>

Content-Type:application/vnd.com.citrix.netscaler.apptemplateinfo+json

**Request Payload**

```
{
 "apptemplateinfo":
 {
 "apptemplatefilename":"BizAp.xml",
 "appname":"Myapp2",
 "deploymentinfo":
 {
 "appendpoint":
 [
```

```
{
 "ipv46":"11.2.3.8",
 "port":80,
 "servicetype":"HTTP"
},
"service":
[
 {
 "ip":"12.3.3.15",
 "port":80,
 "servicetype":"SSL"
 },
 {
 "ip":"14.5.5.16",
 "port":443,
 "servicetype":"SSL"
 }
]
}
}
```

- **Response:**

**HTTP Status Code on Success**

200 OK

**HTTP Status Code on Failure**

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

# Error Handling

Apr 10, 2015

In case of a failed request, NITRO provides the required information through the HTTP status code and in the response header and response payload.

- [Error in a Single Resource Operation](#)
- [Error in a Bulk Operations](#)
- [Warnings](#)

## Error in a Single Resource Operation

The response of a single erroneous operation is as follows:

### HTTP Status Code

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors)

### Response Header

Content-Type:application/vnd.com.citrix.netscaler.error+json

### Response Payload

```
{
 errorcode: <Error code>
 message: "<Error message>"
 severity: "ERROR"
}
```

## Error in a Bulk Operation

When there is a failure in one of the bulk operations, the response payload gives a combination of success and failure (depends on the value set for X-NITRO-ONERROR in the request header).

### HTTP Status Code

207 Multi Status

### Response Header

Content-Type:application/vnd.com.citrix.netscaler.error\_list+json

### Response Payload when X-NITRO-ONERROR is set to continue

When the first operation fails, the request is not terminated. The response payload shows the error details of the failed operation and the success status of the other operations.

```
{
 "errorcode": 1243,
 "message": "Bulk operation failed",
 "severity": "ERROR",
 "response":
 [
 {
 "errorcode": 273,
 "message": "Resource already exists",
 "severity": "ERROR"
 }
]
}
```

```

 },
 {
 "errorcode": 0,
 "message": "Done",
 "severity": "NONE"
 }
]
}

```

### Response Payload when X-NITRO-ONERROR is set to exit

When the first operation fails, the request is terminated. The response payload only shows the error details of the failed operation.

```

{
 "errorcode": 1243,
 "message": "Bulk operation failed",
 "severity": "ERROR",
 "response":
 [
 {
 "errorcode": 273,
 "message": "Resource already exists",
 "severity": "ERROR"
 }
]
}

```

### Warnings in NITRO Operations

Warnings can be captured by specifying the "warning" query parameter as "yes" when performing any NITRO operation. For example, to get warnings while connecting to the NetScaler appliance, the URL is as follows:

`http://<netscaler-ip-address>/nitro/v1/config/login?warning=yes`

If there are any warnings, the response is as follows:

#### HTTP Status Code

209 X-NITRO-WARNING

#### Response Header

Content-Type:application/vnd.com.citrix.netscaler.warning+json

#### Response Payload

```

{
 errorcode: <Code>
 message: "<Message>"
 severity: "WARNING"
}

```

# Java API

Jun 05, 2014

NetScaler NITRO APIs are categorized depending on the scope and purpose of the APIs into system APIs, feature configuration APIs, and feature statistics APIs. Additionally, you can import and export AppExpert applications. You can also troubleshoot NITRO operations.

Note: All NITRO operations are logged in the `/var/log/nitro.log` file on the appliance.

# Tutorials

Nov 05, 2013

These tutorials demonstrate the end-to-end usage of NITRO to achieve the following:

- [Create Your First NITRO Application](#)
- [Create a NetScaler Cluster](#)

# Create Your First NITRO Application

Sep 12, 2012

After completing this tutorial, you will understand and be able to perform the following tasks:

- Integrate NITRO with the IDE
- Log in to the appliance
- Create a load balancing virtual server (lbserver)
- Retrieve details of an lbserver
- Delete an lbserver
- Save the configurations on the appliance
- Log out of the appliance
- Debug the NITRO application

Before you begin, make sure that you have the latest NITRO SDK and that the client application satisfies the prerequisites for using the NITRO SDK.

For the executable code, see the <NITRO\_SDK\_HOME>/sample/MyFirstNitroApplication.java sample file.

1. Copy the libraries from <NITRO\_SDK\_HOME>/lib folder to the project classpath.
2. Create a new class and name it **MyFirstNitroApplication**.
3. Create an instance of `com.citrix.netscaler.nitro.service.nitro_service` class. This instance is used to perform all operations on the appliance:  

```
nitro_service ns_session = new nitro_service("10.102.29.170","HTTP");
```

This code establishes a connection with an appliance that has IP address 10.102.29.170 and uses the HTTP protocol. Replace 10.102.29.170 with the IP address of the NetScaler appliance that you have access to.
4. Use the `nitro_service` instance to log in to the appliance using your credentials:  

```
ns_session.login("admin","verysecret");
```

This code logs into the appliance, with user name as admin and password as verysecret. Replace the credentials with your login credentials.
5. Enable the load balancing feature:  

```
String[] features_to_be_enabled = {"lb"};
ns_session.enable_features(features_to_be_enabled);
```

This code first sets the features to be enabled in an array and then enables the LB feature.
6. Create an instance of the `com.citrix.netscaler.nitro.resource.config.lb.lbserver` class. You will use this instance to perform operations on the lbserver.  

```
lbserver new_lbserver_obj = new lbserver();
```
7. Use the `lbserver` instance to create a new lbserver:  

```
new_lbserver_obj.set_name("MyFirstLbVServer");
new_lbserver_obj.set_ipv46("10.102.29.88");
new_lbserver_obj.set_servicetype("HTTP");
new_lbserver_obj.set_port(88);
new_lbserver_obj.set_lbmethod("ROUNDROBIN");
lbserver.add(ns_session,new_lbserver_obj);
```

This code first sets the attributes (name, IP address, service type, port, and load balancing method) of the lbvserver locally and then adds it to the appliance by using the corresponding add() method.

8. Retrieve the details of the lbvserver you have created:

```
new_lbvserver_obj = lbvserver.get(ns_session,new_lbvserver_obj.get_name());
```

```
System.out.println("Name : " +new_lbvserver_obj.get_name() +"\n" +"Protocol : " +new_lbvserver_obj.get_servicetype());
```

This code first retrieves the details of the lbvserver as an object from the NetScaler, extracts the required attributes (name and service type) from the object, and displays the results.

9. Delete the lbvserver you created in the above steps:

```
lbvserver.delete(ns_session, new_lbvserver_obj.get_name());
```

10. Save the configurations:

```
ns_session.save_config();
```

11. Log out of the appliance:

```
ns_session.logout();
```

All NITRO exceptions are captured by the `com.citrix.netscaler.nitro.exception.nitro_exception` class. For a more detailed description, see [Exception Handling](#).

# Create a NetScaler Cluster

Nov 05, 2013

After completing this tutorial you will be able to create a two-node NetScaler cluster. To add more appliances to the cluster you must repeat the procedure that adds and joins the node to the cluster.

For the executable code, see the <NITRO\_SDK\_HOME>/sample/CreateCluster.java sample file.

1. Copy the libraries from <NITRO\_SDK\_HOME>/lib folder to the project classpath.
2. Create a new class and name it CreateCluster.
3. Log on to one of the appliances that you want to add to the cluster and create a cluster:

```
//Connect to the first appliance that you want to add to the cluster
```

```
nitro_service nonClipSession0 = new nitro_service(nsipAddress0,protocol);
nonClipSession0.login(uName,password);
```

```
//Create a cluster instance
```

```
clusterinstance newClusterInstance = new clusterinstance();
newClusterInstance.set_clid(1);
clusterinstance.add(nonClipSession0,newClusterInstance);
```

```
//Add the appliance to the cluster
```

```
clusternode ClusterNode0 = new clusternode();
ClusterNode0.set_nodeid(0);
ClusterNode0.set_ipaddress(nsipAddress0);
ClusterNode0.set_state("ACTIVE");
ClusterNode0.set_backplane("0/1/1");
clusternode.add(nonClipSession0,ClusterNode0);
```

```
//Add the cluster IP address
```

```
nsip newNSIPAddress = new nsip();
newNSIPAddress.set_ipaddress(clipAddress);
newNSIPAddress.set_netmask("255.255.255.255");
newNSIPAddress.set_type("CLIP");
nsip.add(nonClipSession0,newNSIPAddress);
```

```
//Enable the cluster instance
```

```
clusterinstance.enable(nonClipSession0, newClusterInstance);
```

```
//Save the configurations
```

```
nonClipSession0.save_config();
```

```
//Warm reboot the appliance
```

```
nonClipSession0.reboot(true);
```

The cluster is created and the first node is added to the cluster. This node becomes the initial configuration coordinator of the cluster.

4. Log on to the cluster IP address to add other appliances to the cluster:

```
//Connect to the cluster IP address
```

```
nitro_service clipSession = new nitro_service(clipAddress,protocol);
clipSession.login(uName,password);
```

```
//Add the node to the cluster
clusternode ClusterNode1 = new clusternode();
ClusterNode1.set_nodeid(1);
ClusterNode1.set_ipaddress(nsipAddress1);
ClusterNode1.set_state("ACTIVE");
ClusterNode1.set_backplane("1/1/1");
clusternode.add(clipSession,ClusterNode1);
```

```
//Save the configurations
clipSession.save_config();
```

5. Log on to the appliance that you added in the previous step and join it to the cluster:

```
//Connect to the node that you have just added to the cluster
nitro_service nonClipSession1 = new nitro_service(nsipAddress1,protocol);
nonClipSession1.login(uName,password);
```

```
//Join the node to the cluster
cluster newCluster = new cluster();
newCluster.set_clip(clipAddress);
newCluster.set_password(password);
cluster.join(nonClipSession1,newCluster);
```

```
//Save the configurations
nonClipSession1.save_config();
```

```
//Warm reboot the appliance
nonClipSession1.reboot(true);
The second node is now a part of the cluster.
```

6. Verify the details of the cluster by logging on to the cluster IP address

```
//Retrieving the cluster node details
Long id = new Long(1);
clusternode node= clusternode.get(clipSession, id);
System.out.println("Node ID: "+ node.get_nodeid() + " | Admin state: " + node.get_state() + " | Backplane interface: "+ node.get_backplane());
```

```
//Retrieving the cluster instance details
Long id1 = new Long(1);
clusterinstance instance= clusterinstance.get(clipSession, id1);
System.out.println("Cluster instance ID: "+ instance.get_clid() + " | Operational state: " +instance.get_operationalstate());
```

# System APIs

Mar 16, 2015

The first step towards using NITRO is to establish a session with the NetScaler appliance and then authenticate the session by using the NetScaler administrator's credentials.

You must create an object of the `com.citrix.netscaler.nitro.service.nitro_service` class by specifying the NetScaler IP (NSIP) address and the protocol to connect to the appliance (HTTP or HTTPS). You then use this object and log on to the appliance by specifying the user name and the password of the NetScaler administrator.

Note: You must have a user account on that appliance. The configuration operations that you perform are limited by the administrative roles assigned to your account.

The following sample code establishes a session with a NetScaler appliance with IP address 10.102.29.60 by using the HTTPS protocol:

```
//Specify the NetScaler appliance IP address and protocol
nitro_service ns_session = new nitro_service("10.102.29.60","https");
```

```
//Specify the login credentials
ns_session.login("admin","verysecret");
```

Note: When using HTTPS, you must make sure that the root CA is added to the truststore. By default, NITRO validates the SSL certificate and verifies the hostname. To disable this validation, use the following:

```
ns_session.set_certvalidation(false);
ns_session.set_hostnameverification(false);
```

Note: You can modify the timeout period by specifying a new timeout period (in seconds) in the login method. For example, to modify the timeout period to 60 minutes:

```
ns_session.login("admin","verysecret",3600);
```

Some points to note with regards to session timeout for NetScaler 10.5 and later versions:

- When restricted timeout param is enabled, NITRO, by default, uses the timeout value that is configured for the logged in user. You can customize this value but it must be limited to the value specified for the user. If no value is specified for the user, the default timeout value of 15 minutes is used.
- When restricted timeout param is not enabled, NITRO uses the default value of 30 minutes as session timeout.

You must use the `nitro_service` object in all further NITRO operations on the appliance. For example to save the configurations on the appliance, you must use the `nitro_service` object as follows:

```
ns_session.save_config();
```

The `nitro_service` class also provides APIs to perform other system-level operations such as enabling and disabling NetScaler features and modes, saving and clearing NetScaler configurations, setting the session timeout, setting the severity of the exceptions to be handled, setting the behavior of bulk operations, and disconnecting from the appliance.

# Feature Configuration APIs

Jun 03, 2014

NetScaler resources are organized into a set of packages or namespaces. Each package or namespace corresponds to a NetScaler feature. For example, all load-balancing related resources, such as load balancing virtual server, load balancing group, and load balancing monitor are available in `com.citrix.netscaler.nitro.resource.config.lb`.

Similarly, all application firewall related resources, such as application firewall policy and application firewall archive are available in `com.citrix.netscaler.nitro.resource.config.appfw`.

Each NetScaler resource is represented by a class. For example, the class that represents a load balancing virtual server is called `lbvserver` (in `com.citrix.netscaler.nitro.resource.config.lb`). The state of a resource is represented by properties of a class. You can set the value for these properties by using the `set_<propertyname>()` methods provided by the resource class. For example to set the IP address of a load balancing virtual server, the `lbvserver` class provides the `set_ipv46()` method. Similarly, you can get the value of these properties by using the `get_<propertyname>()` methods of the resource class.

Note: The setter and getter properties are always executed locally on the client. They do not involve any network interaction with the NITRO web service. All properties have basic simple types: integer, long, boolean, and string. A resource class provides APIs to perform the following operations:

[Create](#) | [Retrieve](#) | [Update](#) | [Delete](#) | [Enable/Disable](#) | [Unset](#) | [Bind/Unbind](#) | [Global bind](#) | [Bulk operations](#)

## Create

To create a new resource, instantiate the resource class, configure the resource by setting its properties locally, and then upload the new resource instance to the NetScaler appliance.

The following sample code creates a load balancing virtual server:

```
//Create an instance of the lbvserver class
lbvserver new_lbvserver_obj = new lbvserver();

//Set the properties of the resource locally
new_lbvserver_obj.set_name("MyFirstLbVServer");
new_lbvserver_obj.set_ipv46("10.102.29.88");
new_lbvserver_obj.set_port(88);
new_lbvserver_obj.set_servicetype("HTTP");
new_lbvserver_obj.set_lbmethod("ROUNDROBIN");

//Upload the resource to NetScaler
lbvserver.add(ns_session,new_lbvserver_obj);
```

## Retrieve

To retrieve the properties of a resource, you retrieve the resource object from the NetScaler appliance. Once the object is retrieved, you can extract the required properties of the resource locally, without further network traffic.

The following sample code retrieves the details of a load balancing virtual server:

```
//Retrieve the resource object from the NetScaler
new_lbvserver_obj = lbvserver.get(ns_session,"MyFirstLbVServer");
```

```
//Extract the properties of the resource from the object locally
```

```
System.out.println(new_lbserver_obj.get_name());
```

```
System.out.println(new_lbserver_obj.get_servicetype());
```

You can also retrieve resources by specifying a filter on the value of their properties by using the `com.citrix.netscaler.nitro.util.filtervalue` class.

For example, you can retrieve all the load balancing virtual servers that have their port set to 80 and servicetype to HTTP:

```
filtervalue[] filter = new filtervalue[2];
```

```
filter[0] = new filtervalue("port", "80");
```

```
filter[1] = new filtervalue("servicetype", "HTTP");
```

```
lbserver[] result = lbserver.get_filtered(ns_session, filter);
```

You can also retrieve all NetScaler resources of a certain type, such as all services in the NetScaler appliance, by calling the static `get()` method on the service class, without providing a second parameter, as follows:

```
service[] resources = service.get(ns_session);
```

### Update

To update the properties of a resource, instantiate the resource class, specify the name of the resource to be updated, configure the resource by updating its properties locally, and then upload the updated resource instance to the NetScaler appliance.

The following sample code updates the service type and load balancing method of a load balancing virtual server:

```
//Create an instance of the lbserver class
```

```
lbserver update_lb = new lbserver();
```

```
//Specify the name of the lbserver to be updated
```

```
update_lb.set_name("MyFirstLbVServer");
```

```
//Specify the updated service type and lb method
```

```
update_lb.set_servicetype("https");
```

```
update_lb.set_lbmethod("LEASTRESPONSETIME");
```

```
//Upload the resource to NetScaler
```

```
lbserver.update(ns_session, update_lb);
```

Note: Some properties in some NetScaler resources are not allowed to be modified after creation. The port number or the service type (protocol) of a load balancing virtual server or a service, are examples of such properties. Even though the update method appears to succeed, these properties retain their original values on the appliance.

### Delete

To delete an existing resource, invoke the `delete()` method on the resource class, by passing the name of the resource.

The following sample code deletes a load balancing virtual server with name "MyFirstLbVServer":

```
lbserver remove_lb = new lbserver();
```

```
remove_lb.set_name("MyFirstLbVServer");
```

```
lbserver.delete(ns_session, remove_lb);
```

### Enable/Disable

To enable a resource, invoke the `enable()` method.

The following sample code enables a load balancing virtual server named "lb\_vip":

```
lbvserver obj = new lbvserver();
obj.set_name = "lb_vip";
lbvserver.enable(ns_session, obj);
```

Note: To disable a resource, invoke the `disable()` method.

```
lbvserver.disable(ns_session,obj);
```

#### **Unset**

To unset the value that is set to a parameter, invoke the `unset()` method on the resource class, by passing the name of the resource and the parameters to be unset. If the parameter has a default value, the value is reset to that value.

The following sample code unsets the load balancing method and the comments of a load balancing virtual server named "lb\_123":

```
lbvserver lb1 = new lbvserver();
lb1.set_name("lb_123");
String args[] = {"comment", "lbmethod"};
lbvserver.unset(ns_session, lb1, args);
```

#### **Bind/Unbind**

NetScaler resources form relationships with each other through the process of binding. This is how services are associated with a load balancing virtual server (by binding them to it), or how various policies are bound to a load balancing virtual server. Each binding relationship is represented in NITRO by its own class.

To bind one NetScaler resource to another, you must instantiate the appropriate binding class (for example, to bind a service to a load balancing virtual server, you must instantiate the `lbvserver_service_binding` class) and add it to the NetScaler configuration (by using the static `add()` method on this class).

Binding classes have a property representing the name of each resource in the binding relationship. They can also have other properties related to that relationship (for example, the weight of the binding between a load balancing virtual server and a service).

The following sample code binds a service to a load balancing virtual server, by specifying a certain weight for the binding:

```
lbvserver_service_binding bindObj = new lbvserver_service_binding();
bindObj.set_name("MyFirstLbVServer");
bindObj.set_servicename("svc_prod");
bindObj.set_weight(20);
lbvserver_service_binding.add(ns_session,bindObj);
```

Note: To unbind a resource from another, invoke the `delete()` method from the resource binding class, by passing the name of the two resources.

The following code sample unbinds a service from a server:

```
lbvserver_service_binding bindObj = new lbvserver_service_binding();
bindObj.set_name("MyFirstLbVServer");
bindObj.set_servicename("svc_prod");
lbvserver_service_binding.delete(ns_session,bindObj);
```

#### **Global bind**

Some NetScaler resources can be bound globally to affect the whole system. For example, a compression policy can be bound to an load balancing virtual server, in which case the policy affects only the traffic on that load balancing virtual server. However, if bound globally, it can affect any traffic on the appliance, regardless of which virtual servers handle the traffic.

Some NITRO classes can be used to bind resources globally. These classes have names that follow the following pattern: <featurename>global\_<resourcetype>\_binding.

For example, the class `aaaglobal_preauthenticationpolicy_binding` is used to bind preauthentication policies globally.

The following sample code creates a preauthentication action and a preauthentication policy that uses that action, and then binds the policy globally at priority 200:

```
aaapreauthenticationaction preauth_act1;
aaapreauthenticationpolicy preauth_pol1;
aaaglobal_aaapreauthenticationpolicy_binding glob_binding;
preauth_act1 = new aaapreauthenticationaction();
preauth_act1.set_name("preauth_act1");
preauth_act1.set_preauthenticationaction("ALLOW");
aaapreauthenticationaction.add(ns_session,preauth_act1);

preauth_pol1 = new aaapreauthenticationpolicy();
preauth_pol1.set_name("preauth_pol1");
preauth_pol1.set_rule("CLIENT.APPLICATION.PROCESS(antivirus.exe) EXISTS");
preauth_pol1.set_reqaction("preauth_act1");
aaapreauthenticationpolicy.add(ns_session,preauth_pol1);

glob_binding = new aaaglobal_aaapreauthenticationpolicy_binding();
glob_binding.set_policy("preauth_pol1");
glob_binding.set_priority(200);
aaaglobal_aaapreauthenticationpolicy_binding.add(ns_session,glob_binding);
```

### Bulk operations

You can create, retrieve, update, and delete multiple resources simultaneously and thus minimize network traffic. For example, you can add multiple load balancing virtual servers in the same operation. To perform a bulk operation, you instantiate an array of the resource class, configure the properties of all the instances locally, and then upload all the instances to the NetScaler with one command.

To account for the failure of some operations within the bulk operation, NITRO allows you to configure one of the following behaviors:

- **Exit.** When the first error is encountered, the execution stops. The commands that were executed before the error are committed.
- **Rollback.** When the first error is encountered, the execution stops. The commands that were executed before the error are rolled back. Rollback is only supported for add and bind commands.
- **Continue.** All the commands in the list are executed even if some commands fail.

Note: You must configure the required behavior while establishing a connection with the appliance.

```
nitro_service ns_session = new nitro_service("10.102.29.60","http");
```

```
ns_session.set_onerror(OnerrorEnum.CONTINUE);
```

```
ns_session.login("admin","verysecret");
```

The following sample code creates two load balancing virtual servers:

```
//Create an array of lbvserver instances
```

```
lbvserver[] lbs = new lbvserver[2];
```

```
//Specify properties of the first lbvserver
```

```
lbs[0] = new lbvserver();
```

```
lbs[0].set_name("lbvserv1");
```

```
lbs[0].set_servicetype("http");
```

```
lbs[0].set_ipv46("10.70.136.5");
```

```
lbs[0].set_port(80);
```

```
//Specify properties of the second lbvserver
```

```
lbs[1] = new lbvserver();
```

```
lbs[1].set_name("lbvserv2");
```

```
lbs[1].set_servicetype("https");
```

```
lbs[1].set_ipv46("10.70.136.5");
```

```
lbs[1].set_port(443);
```

```
//Upload the properties of the two lbvservers to the NetScaler
```

```
lbvserver.add(ns_session,lbs);
```

# Cluster APIs

Jun 03, 2014

For managing clusters, you can add or remove a cluster instance or an individual node and perform a few other instance or node operations such as viewing instance or node properties. You can also configure the cluster IP address. Other cluster-management tasks include joining a NetScaler appliance to the cluster and configuring a linkset.

## Cluster Instance Operations

The `com.citrix.netscaler.nitro.resource.config.cluster.clusterinstance` class provides APIs to manage a cluster instance.

The following sample code creates a cluster instance with ID 1:

```
clusterinstance new_cl_inst_obj = new clusterinstance();
//Set the properties of the cluster instance locally
new_cl_inst_obj.set_clid(1);
new_cl_inst_obj.set_preemption("ENABLED");
```

```
//Upload the cluster instance
clusterinstance.add(ns_session,new_cl_inst_obj);
```

## Cluster Node Operations

The `com.citrix.netscaler.nitro.resource.config.cluster.clusternode` class provides APIs to manage cluster nodes.

The following sample code adds a cluster node with NSIP address 10.102.29.60:

```
clusternode new_cl_node_obj = new clusternode();
//Set the properties of the cluster node locally
new_cl_node_obj.set_nodeid(0);
new_cl_node_obj.set_ipaddress("10.102.29.60");
new_cl_node_obj.set_state("ACTIVE");
new_cl_node_obj.set_backplane("0/1/1");
```

```
//Upload the cluster node
clusternode.add(ns_session,new_cl_node_obj);
```

## Add a Cluster IP Address

The `com.citrix.netscaler.nitro.resource.config.ns.nsip` class provides the `add()` API to configure an IP address. To configure the IP address as a cluster IP address, you must specify the type as CLIP.

The following sample code configures a cluster IP address on NetScaler appliance with IP address 10.102.29.60:

```
nsip new_nsip_obj = new nsip();
//Set the properties locally
new_nsip_obj.set_ipaddress("10.102.29.61");
new_nsip_obj.set_netmask("255.255.255.255");
new_nsip_obj.set_type("CLIP");
```

```
//Upload the cluster node
nsip.add(ns_session,new_nsip_obj);
```

## Add a Spotted IP Address

The `com.citrix.netscaler.nitro.resource.config.ns.nsip` class provides the `add()` API to configure an IP address. To configure the IP address as spotted, you must specify the ID of the node that must own the IP address. This configuration must be done on the cluster IP address.

The following sample code configures a spotted SNIP address on a node with ID 1:

```
nsip new_nsip_obj = new nsip();
//Set the properties locally
new_nsip_obj.set_ipaddress("10.102.29.77");
new_nsip_obj.set_netmask("255.255.255.0");
new_nsip_obj.set_type("SNIP");
new_nsip_obj.set_ownernode(1);
```

```
//Upload the cluster node
```

```
nsip.add(ns_session,new_nsip_obj);
```

## Join NetScaler Appliance to Cluster

The `com.citrix.netscaler.nitro.resource.config.cluster.cluster` class provides the `join()` API to join a NetScaler appliance to the cluster. You must specify the cluster IP address and the `nsroot` password of the configuration coordinator.

The following sample joins a NetScaler appliance to a cluster:

```
cluster new_cl_obj = new cluster();
//Set the properties of the cluster locally
new_cl_obj.set_clip("10.102.29.61");
new_cl_obj.set_password("verysecret");
```

```
//Upload the cluster
```

```
cluster.add(ns_session,new_cl_obj);
```

## Linkset Operations

The `com.citrix.netscaler.nitro.resource.config.network.linkset` class provides the APIs to manage linksets.

To configure a linkset, do the following:

1. Add a linkset by invoking the `add()` method of the linkset class.
2. Bind the interfaces to the linkset using the `add()` method of the `linkset_interface_binding` class.

The following sample code creates a linkset LS/1 and bind interfaces 1/1/2 and 2/1/2 to it:

```
//Create the linkset
linkset new_linkset_obj = new linkset();
new_linkset_obj.set_id("LS/1");
linkset.add(ns_session,new_linkset_obj);
```

```
//Bind the interfaces to the linkset
```

```
linkset_interface_binding new_linkif_obj = new linkset_interface_binding();
new_linkif_obj.set_id("LS/1");
new_linkif_obj.set_ifnum("1/1/2 2/1/2");
```

```
linkset_interface_binding.add(ns_session,new_linkif_obj);
```

# Admin Partitions API

Nov 20, 2014

To create an admin partition, you must perform a set of operations on the default partition. To understand this procedure, let us consider a company that has two departments each of which has an application that requires the NetScaler functionality. The NetScaler admin wants to have a different partition for each department so that there is isolation of users and configurations. The NetScaler admin must do the following (the sample shows configurations only for a single admin partition):

Note: For detailed information and best practices, see [Admin Partitions](#).

1. Create a partition and allocate the required resources to that partition.

//Creating a new partition...

```
nspartition nspartitionObject = new nspartition();
nspartitionObject.set_partitionname("partition-dept1");
nspartitionObject.set_maxbandwidth(10240);
nspartitionObject.set_maxconn(1024);
nspartitionObject.set_maxmemlimit(10);
nspartitionObject.set_minbandwidth(1240);
base_response result = nspartition.add(nitroService, nspartitionObject);
```

2. Associate the appropriate users with the partition.

//Associating user1 to partition-dept1...

```
systemuser_nspartition_binding systemuser_nspartition_binding_object = new systemuser_nspartition_binding();
systemuser_nspartition_binding_object.set_partitionname("partition-dept1");
systemuser_nspartition_binding_object.set_username("user1");
base_response result = systemuser_nspartition_binding.add(nitroService, systemuser_nspartition_binding_object);
```

3. Associate an appropriate command policy to the admin partition user.

//Associating partition-admin to user1...

```
systemuser_systemcmdpolicy_binding systemuser_systemcmdpolicy_binding_object = new systemuser_systemcmdpolicy_binding();
systemuser_systemcmdpolicy_binding_object.set_username("user1");
systemuser_systemcmdpolicy_binding_object.set_policyname("partition-admin");
systemuser_systemcmdpolicy_binding_object.set_priority(1);
base_response result = systemuser_systemcmdpolicy_binding.add(nitroService,systemuser_systemcmdpolicy_binding_object);
```

4. Specify the VLANs or bridge groups to be associated with the partition. This step ensures network isolation of the traffic. Traffic received on the interfaces of the VLAN or bridge group is isolated from the traffic of other partitions.

//Specifying the VLAN to be associated with the partition...

```
nspartition_vlan_binding nspartition_vlan_binding_object = new nspartition_vlan_binding();
nspartition_vlan_binding_object.set_vlan(2);
nspartition_vlan_binding_object.set_partitionname("partition-dept1");
base_response result = nspartition_vlan_binding.add(nitroService, nspartition_vlan_binding_object);
```

5. Save the configurations

//Saving the configurations...

```
nitroService.save_config();
```

The admin partition is created.

6. Now, to configure this admin partition, you must logout of the default partition and logon again. You are automatically taken to the admin partition to which you were first bound and once there you can configure the NetScaler.

Note: If you want to configure another admin partition, perform the switch operation given in the next step before performing this step.

7. [Optional] If you are associated with multiple admin partitions, you can switch to the required partition.

//Switching to other partition named partition-dept2...

```
nspartition nspartitionObject = new nspartition();
```

```
nspartitionObject.set_partitionname("partition-dept2");
base_response result = nspartition.Switch(nitroService, nspartitionObject);
```

# Feature Statistics APIs

Jun 03, 2014

The NetScaler appliance collects statistics about the usage of its features and the corresponding resources. You can retrieve these statistics by using NITRO API. The statistics APIs are available in different packages from the configuration APIs.

The APIs to retrieve statistics of NetScaler features are available in packages that have the following pattern:  
`com.citrix.netscaler.nitro.resource.stat.<feature>`.

For example, APIs to retrieve statistics of the load balancing virtual server are available in the `com.citrix.netscaler.nitro.resource.stat.lb` package.

The following sample code retrieves the statistics of a load balancing virtual server and displays some of the statistics returned:

```
lbserver_stats stats = lbserver_stats.get(ns_session,"MyFirstLbVServer");
System.out.println(stats.get_curCntconnections());
System.out.println(stats.get_deferredregrate());
```

Note: Not all NetScaler features and resources have statistic objects associated with them.

# AppExpert Application APIs

Jun 03, 2014

To export an AppExpert application, you must instantiate the `com.citrix.netscaler.nitro.resource.config.app.application` class, configure the properties of the AppExpert locally, and then export the AppExpert application.

The following sample code exports an AppExpert application named "MyApp1":

```
application myapp = new application();
myapp.set_appname("MyApp1");
myapp.set_apptemplatefilename("myapp_template");
application.export(ns_session,myapp);
```

You can also import an AppExpert application. You must instantiate the `com.citrix.netscaler.nitro.resource.config.app.application` class, configure the properties of the AppExpert locally, and then import the AppExpert application.

The following sample code imports an AppExpert application named "MyApp1":

```
application myapp = new application();
myapp.set_appname("MyApp1");
myapp.set_apptemplatefilename("myapp_template");
application.Import(ns_session,myapp);
```

# Exception Handling

Jun 03, 2014

The status of a NITRO request is captured in the `com.citrix.netscaler.nitro.exception.nitro_exception` class. This class provides the following details of the exception:

- **Session ID.** The session in which the exception occurred.
- **Severity.** The severity of the exception: error or warning. By default, only errors are captured. To capture warnings, you must set the warning flag to true, while connecting to the appliance.
- **Error code.** The status of the NITRO request. An error code of 0 indicates that the NITRO request is successful. A non-zero error code indicates an error in processing the NITRO request.
- **Error message.** Provides a brief description of the exception.

For a list of error codes, see the `errorlisting.html` file available in the `<NITRO_SDK_HOME>/doc/api_reference` folder.

# .NET API

Jun 05, 2014

NetScaler NITRO APIs are categorized depending on the scope and purpose of the APIs into system APIs, feature configuration APIs, and feature statistics APIs. Additionally, you can import and export AppExpert applications. You can also troubleshoot NITRO operations.

Note: All NITRO operations are logged in the `/var/log/nitro.log` file on the appliance.

# Tutorials

Nov 05, 2013

These tutorials demonstrate the end-to-end usage of NITRO to achieve the following:

- [Create Your First NITRO Application](#)
- [Create a NetScaler Cluster](#)

# Create Your First NITRO Application

Sep 12, 2012

After completing this tutorial, you will understand and be able to perform the following tasks:

- Integrate NITRO with the IDE
- Log in to the appliance
- Create a load balancing virtual server (lbserver)
- Retrieve details of an lbserver
- Delete an lbserver
- Save the configurations on the appliance
- Log out of the appliance
- Debug the NITRO application

Before you begin, make sure that you have the latest NITRO SDK and that the client application satisfies the prerequisites for using the NITRO SDK.

For the executable code, see the <NITRO\_SDK\_HOME>/sample/MyFirstNitroApplication.cs sample file.

1. Copy the libraries from <NITRO\_SDK\_HOME>/lib folder to the project classpath.
2. Create a new class and name it **MyFirstNitroApplication**.
3. Create an instance of `com.citrix.netscaler.nitro.service.nitro_service` class. This instance is used to perform all operations on the appliance:  

```
nitro_service ns_session = new nitro_service("10.102.29.170", "http");
```

This code establishes a connection with an appliance that has IP address 10.102.29.170 and uses the HTTP protocol. Replace 10.102.29.170 with the IP address of the NetScaler appliance that you have access to.
4. Use the `nitro_service` instance to log in to the appliance using your credentials:  

```
ns_session.login("admin","verysecret");
```

This code logs into the appliance, with user name as admin and password as verysecret. Replace the credentials with your login credentials.
5. Enable the load balancing feature:  

```
String[] features_to_be_enabled = {"lb"};
ns_session.enable_features(features_to_be_enabled);
```

This code enables load balancing on the appliance.
6. Create an instance of the `com.citrix.netscaler.nitro.resource.config.lb.lbserver` class. You will use this instance to perform operations on the lbserver.  

```
lbserver new_lbserver_obj = new lbserver();
```
7. Use the `lbserver` instance to create a new lbserver:  

```
new_lbserver_obj.name = "MyFirstLbVServer";
new_lbserver_obj.ipv46 = "10.102.29.88";
new_lbserver_obj.servicetype = "HTTP";
new_lbserver_obj.port = 80;
new_lbserver_obj.lbmethod = "ROUNDROBIN";
lbserver.add(ns_session,new_lbserver_obj);
```

This code first sets the attributes (name, IP address, service type, port, and load balancing method) of the lbserver locally

and then adds it to the appliance by using the corresponding add() method.

8. Retrieve the details of the lbvserver you have created:

```
lbvserver new_lbvserver_obj1 = lbvserver.get(ns_session,new_lbvserver_obj.name);
```

```
System.Console.Out.WriteLine("Name : " +new_lbvserver_obj1.name +"\n" +"Protocol : " +new_lbvserver_obj1.servicetype);
```

This code first retrieves the details of the lbvserver as an object from the NetScaler, extracts the required attributes (name and service type) from the object, and displays the results.

9. Delete the lbvserver you created in the above steps:

```
lbvserver.delete(ns_session, new_lbvserver_obj.name);
```

10. Save the configurations:

```
ns_session.save_config();
```

11. Log out of the appliance:

```
ns_session.logout();
```

All NITRO exceptions are captured by the `com.citrix.netscaler.nitro.exception.nitro_exception` class. For a more detailed description, see [Exception Handling](#).

# Create a NetScaler Cluster

Nov 05, 2013

After completing this tutorial you will be able to create a two-node NetScaler cluster. To add more appliances to the cluster you must repeat the procedure that adds and joins the node to the cluster.

For the executable code, see the <NITRO\_SDK\_HOME>/sample/CreateCluster.cs sample file.

1. Copy the libraries from <NITRO\_SDK\_HOME>/lib folder to the project classpath.
2. Create a new class and name it CreateCluster.
3. Log on to one of the appliances that you want to add to the cluster and create a cluster:

```
//Connect to the first appliance that you want to add to the cluster
nitro_service nonClipSession0 = new nitro_service(nsipAddress0,protocol);
nonClipSession0.login(uName,password);
```

```
//Create a cluster instance
clusterinstance newClusterInstance = new clusterinstance();
newClusterInstance.clid = 1;
clusterinstance.add(nonClipSession0,newClusterInstance);
```

```
//Add the appliance to the cluster
clusternode ClusterNode0 = new clusternode();
ClusterNode0.nodeid = 0;
ClusterNode0.ipaddress = nsipAddress0;
ClusterNode0.state = "ACTIVE";
ClusterNode0.backplane = "0/1/1";
clusternode.add(nonClipSession0,ClusterNode0);
```

```
//Add the cluster IP address
nsip newNSIPAddress = new nsip();
newNSIPAddress.ipaddress = clipAddress;
newNSIPAddress.netmask = "255.255.255.255";
newNSIPAddress.type = "CLIP";
nsip.add(nonClipSession0,newNSIPAddress);
```

```
//Enable the cluster instance
clusterinstance.enable(nonClipSession0, newClusterInstance);
```

```
//Save the configurations
nonClipSession0.save_config();
```

```
//Warm reboot the appliance
nonClipSession0.reboot(true);
```

The cluster is created and the first node is added to the cluster. This node becomes the initial configuration coordinator of the cluster.

4. Log on to the cluster IP address to add other appliances to the cluster:

```
//Connect to the cluster IP address
nitro_service clipSession = new nitro_service(clipAddress,protocol);
```

```
clipSession.login(uName,password);
```

```
//Add the node to the cluster
```

```
clusternode ClusterNode1 = new clusternode();
```

```
ClusterNode1.nodeid = 1;
```

```
ClusterNode1.ipaddress = nsipAddress1;
```

```
ClusterNode1.state = "ACTIVE";
```

```
ClusterNode1.backplane = "1/1/1";
```

```
clusternode.add(clipSession,ClusterNode1);
```

```
//Save the configurations
```

```
clipSession.save_config();
```

5. Log on to the appliance that you added in the previous step and join it to the cluster:

```
//Connect to the node that you have just added to the cluster
```

```
nitro_service nonClipSession1 = new nitro_service(nsipAddress1,protocol);
```

```
nonClipSession1.login(uName,password);
```

```
//Join the node to the cluster
```

```
cluster newCluster = new cluster();
```

```
newCluster.clip = clipAddress;
```

```
newCluster.password = password;
```

```
cluster.join(nonClipSession1,newCluster);
```

```
//Save the configurations
```

```
nonClipSession1.save_config();
```

```
//Warm reboot the appliance
```

```
nonClipSession1.reboot(true);
```

The second node is now a part of the cluster.

6. Verify the details of the cluster by logging on to the cluster IP address

```
//Retrieving the cluster node details
```

```
uint id = 1;
```

```
clusternode node= clusternode.get(clipSession, id);
```

```
System.Console.Out.WriteLine("Node ID: " + node.nodeid + " | Admin state: " + node.state + " | Backplane interface: " + node.backplane);
```

```
//Retrieving the cluster instance details
```

```
uint id1 = 1;
```

```
clusterinstance instance= clusterinstance.get(clipSession, id1);
```

```
System.Console.Out.WriteLine("Cluster instance ID: "+ instance.clid + " | Operational state: " +instance.operationalstate);
```

# System APIs

Mar 16, 2015

The first step towards using NITRO is to establish a session with the NetScaler appliance and then authenticate the session by using the NetScaler administrator's credentials.

You must create an object of the `com.citrix.netscaler.nitro.service.nitro_service` class by specifying the NetScaler IP (NSIP) address and the protocol to connect to the appliance (HTTP or HTTPS). You then use this object and log on to the appliance by specifying the user name and the password of the NetScaler administrator.

Note: You must have a user account on that appliance. The configuration operations that you perform are limited by the administrative roles assigned to your account.

The following sample code establishes a session with a NetScaler appliance with IP address 10.102.29.60 by using the HTTPS protocol:

```
//Specify the NetScaler appliance IP address and protocol
nitro_service ns_session = new nitro_service("10.102.29.60","https");
```

```
//Specify the login credentials
ns_session.login("admin","verysecret");
```

Note: You can modify the timeout period by specifying a new timeout period (in seconds) in the login method. For example, to modify the timeout period to 60 minutes:

```
ns_session.login("admin","verysecret",3600);
```

Some points to note with regards to session timeout for NetScaler 10.5 and later versions:

- When restricted timeout param is enabled, NITRO, by default, uses the timeout value that is configured for the logged in user. You can customize this value but it must be limited to the value specified for the user. If no value is specified for the user, the default timeout value of 15 minutes is used.
- When restricted timeout param is not enabled, NITRO uses the default value of 30 minutes as session timeout.

You must use the `nitro_service` object in all further NITRO operations on the appliance. For example to save the configurations on the appliance, you must use the `nitro_service` object as follows:

```
ns_session.save_config();
```

The `nitro_service` class also provides APIs to perform other system-level operations such as enabling and disabling NetScaler features and modes, saving and clearing NetScaler configurations, setting the session timeout, setting the severity of the exceptions to be handled, setting the behavior of bulk operations, and disconnecting from the appliance.

# Feature Configuration APIs

Jun 03, 2014

NetScaler resources are organized into a set of packages or namespaces. Each package or namespace corresponds to a NetScaler feature. For example, all load-balancing related resources, such as load balancing virtual server, load balancing group, and load balancing monitor are available in `com.citrix.netscaler.nitro.resource.config.lb`.

Similarly, all application firewall related resources, such as application firewall policy and application firewall archive are available in `com.citrix.netscaler.nitro.resource.config.appfw`.

Each NetScaler resource is represented by a class. For example, the class that represents a load balancing virtual server is called `lbvserver` (in `com.citrix.netscaler.nitro.resource.config.lb`). The state of a resource is represented by properties of a class. You can get and set the properties of the class.

Note: The setter and getter properties are always executed locally on the client. They do not involve any network interaction with the NITRO web service. All properties have basic simple types: integer, long, boolean, and string. A resource class provides APIs to perform the following operations:

[Create](#) | [Retrieve](#) | [Update](#) | [Delete](#) | [Enable/Disable](#) | [Unset](#) | [Bind/Unbind](#) | [Global bind](#) | [Bulk operations](#)

## Create

To create a new resource, instantiate the resource class, configure the resource by setting its properties locally, and then upload the new resource instance to the NetScaler appliance.

The following sample code creates a load balancing virtual server:

```
//Create an instance of the lbvserver class
lbvserver new_lbvserver_obj = new lbvserver();

//Set the properties of the resource locally
new_lbvserver_obj.name = "MyFirstLbVServer";
new_lbvserver_obj.ipv46 = "10.102.29.88";
new_lbvserver_obj.port = 88;
new_lbvserver_obj.servicetype = "HTTP";
new_lbvserver_obj.lbmethod = "ROUNDROBIN";

//Upload the resource to NetScaler
lbvserver.add(ns_session,new_lbvserver_obj);
```

## Retrieve

To retrieve the properties of a resource, retrieve the resource object from the NetScaler appliance. Once the object is retrieved, you can extract the required properties of the resource locally, without incurring further network traffic.

The following sample code retrieves the details of a load balancing virtual server:

```
//Retrieve the resource object from the NetScaler
new_lbvserver_obj = lbvserver.get(ns_session,"MyFirstLbVServer");

//Extract the properties of the resource from the object locally
```

```
Console.WriteLine(new_lbserver_obj.name);
Console.WriteLine(new_lbserver_obj.servicetype);
```

You can also retrieve resources by specifying a filter on the value of their properties by using the `com.citrix.netscaler.nitro.util.filtervalue` class.

For example, you can retrieve all the load balancing virtual servers that have their port set to 80 and servicetype to HTTP:

```
filtervalue[] filter = new filtervalue[2];
filter[0] = new filtervalue("port","80");
filter[1] = new filtervalue("servicetype","HTTP");
lbserver[] result = lbserver.get_filtered(ns_session,filter);
```

You can also retrieve all NetScaler resources of a certain type, such as all services in the NetScaler appliance, by calling the static `get()` method on the service class, without providing a second parameter, as follows:

```
service[] resources = service.get(ns_session);
```

### Update

To update the properties of a resource, instantiate the resource class, specify the name of the resource to be updated, configure the resource by updating its properties locally, and then upload the updated resource instance to the NetScaler appliance.

The following sample code updates the service type and load balancing method of a load balancing virtual server:

```
//Create an instance of the lbserver class
lbserver update_lb = new lbserver();

//Specify the name of the lbserver to be updated
update_lb.name = "MyFirstLbVServer";

//Specify the updated service type and lb method
update_lb.servicetype = "https";
update_lb.lbmethod = "LEASTRESPONSETIME";

//Upload the resource to NetScaler
lbserver.update(ns_session, update_lb);
```

Note: Some properties in some NetScaler resources are not allowed to be modified after creation. The port number or the service type (protocol) of a load balancing virtual server or a service, are examples of such properties. Even though the update method appears to succeed, these properties retain their original values on the appliance.

### Delete

To delete an existing resource, invoke the static method `delete()` on the resource class, by passing the name of the resource.

The following sample code deletes a load balancing virtual server with name "MyFirstLbVServer":

```
lbserver remove_lb = new lbserver();
remove_lb.name("MyFirstLbVServer");
lbserver.delete(ns_session, remove_lb);
```

### Enable/Disable

To enable a resource, invoke the `enable()` method.

The following sample code enables a load balancing virtual server named "lb\_vip":

```
lbvserver obj = new lbvserver();
obj.name = "lb_vip";
lbvserver.enable(ns_session, obj);
```

Note: To disable a resource, invoke the `disable()` method.

```
lbvserver.disable(ns_session, obj);
```

### Unset

To unset the value that is set to a parameter, invoke the `unset()` method on the resource class, by passing the name of the resource and the parameters to be unset. If the parameter has a default value, the value is reset to that value.

The following sample code unsets the load balancing method and the comments of a load balancing virtual server named "lb\_123":

```
lbvserver obj = new lbvserver();
obj.name = "lb_123";
String[] args = { "lbmethod", "comment" };
lbvserver.unset(ns_session, obj, args);
```

### Bind/Unbind

NetScaler resources form relationships with each other through the process of binding. This is how services are associated with a load balancing virtual server (by binding them to it), or how various policies are bound to a load balancing virtual server. Each binding relationship is represented in NITRO by its own class.

To bind one NetScaler resource to another, you must instantiate the appropriate binding class (for example, to bind a service to a load balancing virtual server, you must instantiate the `lbvserver_service_binding` class) and add it to the NetScaler configuration (by using the static `add()` method on this class).

Binding classes have a property representing the name of each resource in the binding relationship. They can also have other properties related to that relationship (for example, the weight of the binding between a load balancing virtual server and a service).

The following sample code binds a service to a load balancing virtual server, by specifying a certain weight for the binding:

```
lbvserver_service_binding bindObj = new lbvserver_service_binding();
bindObj.name = "MyFirstLbVServer";
bindObj.servicename = "svc_prod";
bindObj.weight = 20;
lbvserver_service_binding.add(ns_session, bindObj);
```

Note: To unbind a resource from another, invoke the `delete()` method from the resource binding class, by passing the name of the two resources.

The following code sample unbinds a service from a server:

```
lbvserver_service_binding bindObj = new lbvserver_service_binding();
bindObj.name("MyFirstLbVServer");
bindObj.servicename("svc_prod");
lbvserver_service_binding.delete(ns_session, bindObj);
```

### Global bind

Some NetScaler resources can be bound globally to affect the whole system. For example, a compression policy can be

bound to an load balancing virtual server, in which case the policy affects only the traffic on that load balancing virtual server. However, if bound globally, it can affect any traffic on the appliance, regardless of which virtual servers handle the traffic.

Some NITRO classes can be used to bind resources globally. These classes have names that follow the following pattern: <featurename>global\_<resourcetype>\_binding.

For example, the class `aaaglobal_preauthenticationpolicy_binding` is used to bind preauthentication policies globally.

The following sample code creates a preauthentication action and a preauthentication policy that uses that action, and then binds the policy globally at priority 200:

```
aaapreauthenticationaction preauth_act1;
aaapreauthenticationpolicy preauth_pol1;
aaaglobal_aaapreauthenticationpolicy_binding glob_binding;
preauth_act1 = new aaapreauthenticationaction();
preauth_act1.name = "preauth_act1";
preauth_act1.preauthenticationaction = "ALLOW";
aaapreauthenticationaction.add(ns_session, preauth_act1);

preauth_pol1 = new aaapreauthenticationpolicy();
preauth_pol1.name = "preauth_pol1";
preauth_pol1.rule = "CLIENT.APPLICATION.PROCESS(antivirus.exe) EXISTS";
preauth_pol1.reqaction = "preauth_act1";
aaapreauthenticationpolicy.add(ns_session, preauth_pol1);

glob_binding = new aaaglobal_aaapreauthenticationpolicy_binding();
glob_binding.policy = "preauth_pol1";
glob_binding.priority = 200;
aaaglobal_aaapreauthenticationpolicy_binding.add(ns_session,glob_binding);
```

### Bulk operations

You can create, retrieve, update, and delete multiple resources simultaneously and thus minimize network traffic. For example, you can add multiple load balancing virtual servers in the same operation. To perform a bulk operation, you instantiate an array of the resource class, configure the properties of all the instances locally, and then upload all the instances to the NetScaler with one command.

To account for the failure of some operations within the bulk operation, NITRO allows you to configure one of the following behaviors:

- **Exit.** When the first error is encountered, the execution stops. The commands that were executed before the error are committed.
- **Rollback.** When the first error is encountered, the execution stops. The commands that were executed before the error are rolled back. Rollback is only supported for add and bind commands.
- **Continue.** All the commands in the list are executed even if some commands fail.

Note: You must configure the required behavior while establishing a connection with the appliance.

```
nitro_service ns_session = new nitro_service("10.102.29.60","http");
ns_session.onerror = OerrorEnum.CONTINUE;
ns_session.login("admin","verysecret");
```

The following sample code creates two load balancing virtual servers:

```
//Create an array of lbvserver instances
lbvserver[] lbs = new lbvserver[2];

//Specify details of first lbvserver
lbs[0] = new lbvserver();
lbs[0].name = "lbvserv1";
lbs[0].servicetype = "http";
lbs[0].ipv46 = "10.70.136.5";
lbs[0].port = 80;

//Specify details of second lbvserver
lbs[1] = new lbvserver();
lbs[1].name = "lbvserv2";
lbs[1].servicetype = "https";
lbs[1].ipv46 = "10.70.136.5";
lbs[1].port = 443;

//upload the details of the lbvservers to the NITRO server
lbvserver.add(ns_session,lbs);
```

# Cluster APIs

Nov 05, 2013

For managing clusters, you can add or remove a cluster instance or an individual node and perform a few other instance or node operations such as viewing instance or node properties. You can also configure the cluster IP address. Other cluster-management tasks include joining a NetScaler appliance to the cluster and configuring a linkset.

## Cluster Instance Operations

The `com.citrix.netscaler.nitro.resource.config.cluster.clusterinstance` class provides APIs to manage a cluster instance.

The following sample code creates a cluster instance with ID 1:

```
clusterinstance new_cl_inst_obj = new clusterinstance();
//Set the properties of the cluster instance locally
new_cl_inst_obj.clid = 1;
new_cl_inst_obj.preemption = "ENABLED";

//Upload the cluster instance
clusterinstance.add(ns_session,new_cl_inst_obj);
```

## Cluster Node Operations

The `com.citrix.netscaler.nitro.resource.config.cluster.clusternode` class provides APIs to manage cluster nodes.

The following sample code adds a cluster node with NSIP address 10.102.29.60:

```
clusternode new_cl_node_obj = new clusternode();
//Set the properties of the cluster node locally
new_cl_node_obj.nodeid = 0;
new_cl_node_obj.ipaddress = "10.102.29.60";
new_cl_node_obj.state = "ACTIVE";
new_cl_node_obj.backplane = "0/1/1";

//Upload the cluster node
clusternode.add(ns_session,new_cl_node_obj);
```

## Add a Cluster IP Address

The `com.citrix.netscaler.nitro.resource.config.ns.nsip` class provides the `add()` API to configure an IP address. To configure the IP address as a cluster IP address, you must specify the type as CLIP.

The following sample code configures a cluster IP address on NetScaler appliance with IP address 10.102.29.60:

```
nsip new_nsip_obj = new nsip();
//Set the properties locally
new_nsip_obj.ipaddress = "10.102.29.61";
new_nsip_obj.netmask = "255.255.255.255";
new_nsip_obj.type = "CLIP";

//Upload the cluster node
nsip.add(ns_session,new_nsip_obj);
```

## Add a Spotted IP Address

The `com.citrix.netscaler.nitro.resource.config.ns.nsip` class provides the `add()` API to configure an IP address. To configure the IP address as spotted, you must specify the ID of the node that must own the IP address. This configuration must be done on the cluster IP address.

The following sample code configures a spotted SNIP address on a node with ID 1:

```
nsip new_nsip_obj = new nsip();
//Set the properties locally
new_nsip_obj.ipaddress = "10.102.29.77";
new_nsip_obj.netmask = "255.255.255.0";
new_nsip_obj.type = "SNIP";
new_nsip_obj.ownernode = 1;
```

```
//Upload the cluster node
```

```
nsip.add(ns_session,new_nsip_obj);
```

## Join NetScaler Appliance to Cluster

The `com.citrix.netscaler.nitro.resource.config.cluster.cluster` class provides the `join()` API to join a NetScaler appliance to the cluster. You must specify the cluster IP address and the `nsroot` password of the configuration coordinator.

The following sample code joins a NetScaler appliance to a cluster:

```
cluster new_cl_obj = new cluster();
//Set the properties of the cluster locally
new_cl_obj.clip = "10.102.29.61";
new_cl_obj.password = "verysecret";
```

```
//Upload the cluster node
```

```
cluster.add(ns_session,new_cl_node_obj);
```

## Linkset Operations

The `com.citrix.netscaler.nitro.resource.config.network.linkset` class provides the APIs to manage linksets.

To configure a linkset, do the following:

1. Add a linkset by invoking the `add()` method of the linkset class.
2. Bind the interfaces to the linkset using the `add()` method of the `linkset_interface_binding` class.

The following sample code creates a linkset LS/1 and bind interfaces 1/1/2 and 2/1/2 to it:

```
//Create the linkset
linkset new_linkset_obj = new linkset();
new_linkset_obj.id = "LS/1";
linkset.add(ns_session,new_linkset_obj);
```

```
//Bind the interfaces to the linkset
```

```
linkset_interface_binding new_linkif_obj = new linkset_interface_binding();
new_linkif_obj.id = "LS/1";
new_linkif_obj.ifnum = "1/1/2 2/1/2";
```

```
linkset_interface_binding.add(ns_session,new_linkif_obj);
```

# Admin Partitions API

Nov 20, 2014

To create an admin partition, you must perform a set of operations on the default partition. To understand this procedure, let us consider a company that has two departments each of which has an application that requires the NetScaler functionality. The NetScaler admin wants to have a different partition for each department so that there is isolation of users and configurations. The NetScaler admin must do the following (the sample shows configurations only for a single admin partition):

Note: For detailed information and best practices, see [Admin Partitions](#).

1. Create a partition and allocate the required resources to that partition.

//Creating a new partition...

```
nspartition nspartitionObject = new nspartition();
nspartitionObject.partitionname = "partition-dept1";
nspartitionObject.maxbandwidth = 10240;
nspartitionObject.maxconn = 1024;
nspartitionObject.maxmemlimit = 10;
nspartitionObject.minbandwidth = 1240;
base_response result = nspartition.add(nitroService, nspartitionObject);
```

2. Associate the appropriate users with the partition.

//Associating user1 to partition-dept1...

```
systemuser_nspartition_binding systemuser_nspartition_binding_object = new systemuser_nspartition_binding();
systemuser_nspartition_binding_object.partitionname = "partition-dept1";
systemuser_nspartition_binding_object.username = "user1";
base_response result = systemuser_nspartition_binding.add(nitroService, systemuser_nspartition_binding_object);
```

3. Associate an appropriate command policy to the admin partition user.

//Associating partition-admin to user1...

```
systemuser_systemcmdpolicy_binding systemuser_systemcmdpolicy_binding_object = new systemuser_systemcmdpolicy_binding();
systemuser_systemcmdpolicy_binding_object.username = "user1";
systemuser_systemcmdpolicy_binding_object.policyname = "partition-admin";
systemuser_systemcmdpolicy_binding_object.priority = 1;
base_response result = systemuser_systemcmdpolicy_binding.add(nitroService, systemuser_systemcmdpolicy_binding_object);
```

4. Specify the VLANs or bridge groups to be associated with the partition. This step ensures network isolation of the traffic. Traffic received on the interfaces of the VLAN or bridge group is isolated from the traffic of other partitions.

//Specifying the VLAN to be associated with the partition...

```
nspartition_vlan_binding nspartition_vlan_binding_object = new nspartition_vlan_binding();
nspartition_vlan_binding_object.vlan = 2;
nspartition_vlan_binding_object.partitionname = "partition-dept1";
base_response result = nspartition_vlan_binding.add(nitroService, nspartition_vlan_binding_object);
```

5. Save the configurations

//Saving the configurations...

```
nitroService.save_config();
```

The admin partition is created.

6. Now, to configure this admin partition, you must logout of the default partition and logon again. You are automatically taken to the admin partition to which you were first bound and once there you can configure the NetScaler.

Note: If you want to configure another admin partition, perform the switch operation given in the next step before performing this step.

7. [Optional] If you are associated with multiple admin partitions, you can switch to the required partition.

//Switching to other partition named partition-dept2...

```
nspartition nspartitionObject = new nspartition();
```

```
nspartitionObject.partitionname = "partition-dept2";
base_response result = nspartition.Switch(nitroService, nspartitionObject);
```

# Feature Statistics APIs

Mar 14, 2012

The NetScaler appliance collects statistics about the usage of its features and the corresponding resources. You can retrieve these statistics by using NITRO API. The statistics APIs are available in different namespaces from the configuration APIs.

The APIs to retrieve statistics of NetScaler features are available in namespaces that have the following pattern: `com.citrix.netscaler.nitro.resource.stat.<feature>`.

For example, APIs to retrieve statistics of the load balancing virtual server are available in the `com.citrix.netscaler.nitro.resource.stat.lb` namespace.

The following sample code retrieves the statistics of a load balancing virtual server and displays some of the statistics returned:

```
lbserver_stats stats = lbserver_stats.get(ns_session,"MyFirstLbVServer");
Console.WriteLine(stats.curInConnections);
Console.WriteLine(stats.deferredRate);
```

Note: Not all NetScaler features and resources have statistic objects associated with them.

# AppExpert Application APIs

Mar 14, 2012

To export an AppExpert application, you must instantiate the `com.citrix.netscaler.nitro.resource.config.app.application` class, configure the properties of the AppExpert locally, and then export the AppExpert application.

The following sample code exports an AppExpert application named "MyApp1":

```
application myapp = new application();
myapp.appname = "MyApp1";
myapp.apptemplatefilename = "myapp_template";
application.export(ns_session,myapp);
```

You can also import an AppExpert application. You must instantiate the `com.citrix.netscaler.nitro.resource.config.app.application` class, configure the properties of the AppExpert locally, and then import the AppExpert application.

The following sample code imports an AppExpert application named "MyApp1":

```
application myapp = new application();
myapp.appname = "MyApp1";
myapp.apptemplatefilename = "myapp_template";
application.Import(ns_session,myapp);
```

# Exception Handling

Mar 14, 2012

The status of a NITRO request is captured in the `com.citrix.netscaler.nitro.exception.nitro_exception` class. This class provides the following details of the exception:

- **Session ID.** The session in which the exception occurred.
- **Severity.** The severity of the exception: error or warning. By default, only errors are captured. To capture warnings, you must set the warning flag to true, while connecting to the appliance.
- **Error code.** The status of the NITRO request. An error code of 0 indicates that the NITRO request is successful. A non-zero error code indicates an error in processing the NITRO request.
- **Error message.** Provides a brief description of the exception.

For a list of error codes, see the `errorlisting.html` file available in the `<NITRO_SDK_HOME>/doc/api_reference` folder.

# Python API

Jun 05, 2014

NetScaler NITRO APIs are categorized depending on the scope and purpose of the APIs into system APIs, feature configuration APIs, feature statistics APIs, and cluster APIs. Additionally, you can import and export AppExpert applications. You can also troubleshoot NITRO operations.

Note: All NITRO operations are logged in the `/var/log/nitro.log` file on the appliance.

# System APIs

Mar 16, 2015

The first step towards using NITRO is to establish a session with the NetScaler appliance and then authenticate the session by using the NetScaler administrator's credentials.

You must create an object of the `nssrc.com.citrix.netscaler.nitro.service.nitro_service` class by specifying the NetScaler IP (NSIP) address and the protocol to connect to the appliance (HTTP or HTTPS). You then use this object and log on to the appliance by specifying the user name and the password of the NetScaler administrator.

Note: You must have a user account on that appliance. The configuration operations that you perform are limited by the administrative roles assigned to your account.

The following sample code establishes a session with a NetScaler appliance with IP address 10.102.29.60 by using the HTTPS protocol:

```
//Specify the NetScaler appliance IP address and protocol
nitro_service ns_session = new nitro_service("10.102.29.60","https")
```

```
//Specify the login credentials
ns_session.login("admin","verysecret")
```

Note: When using HTTPS, you must make sure that the root CA is added to the truststore. By default, NITRO validates the SSL certificate and verifies the hostname. To disable this validation, use the following:

```
ns_session.certvalidation = false
ns_session.hostnameverification = false
```

Note: You can modify the timeout period by specifying a new timeout period (in seconds) in the login method. For example, to modify the timeout period to 60 minutes:

```
ns_session.login("admin","verysecret",3600)
```

Some points to note with regards to session timeout for NetScaler 10.5 and later versions:

- When restricted timeout param is enabled, NITRO, by default, uses the timeout value that is configured for the logged in user. You can customize this value but it must be limited to the value specified for the user. If no value is specified for the user, the default timeout value of 15 minutes is used.
- When restricted timeout param is not enabled, NITRO uses the default value of 30 minutes as session timeout.

You must use the `nitro_service` object in all further NITRO operations on the appliance. For example to save the configurations on the appliance, you must use the `nitro_service` object as follows:

```
ns_session.save_config()
```

The `nitro_service` class also provides APIs to perform other system-level operations such as enabling and disabling NetScaler features and modes, saving and clearing NetScaler configurations, setting the session timeout, setting the severity of the exceptions to be handled, setting the behavior of bulk operations, and disconnecting from the appliance.

# Feature Configuration APIs

Jun 16, 2014

NetScaler resources are organized into a set of packages or namespaces. Each package or namespace corresponds to a NetScaler feature. For example, all load-balancing related resources, such as load balancing virtual server, load balancing group, and load balancing monitor are available in `nsrc.com.citrix.netscaler.nitro.resource.config.lb`.

Similarly, all application firewall related resources, such as application firewall policy and application firewall archive are available in `nsrc.com.citrix.netscaler.nitro.resource.config.appfw`.

Each NetScaler resource is represented by a class. For example, the class that represents a load balancing virtual server is called `lbvserver` (in `nsrc.com.citrix.netscaler.nitro.resource.config.lb`). The state of a resource is represented by properties of a class. You can get and set the properties of the class.

Note: The setter and getter properties are always executed locally on the client. They do not involve any network interaction with the NITRO web service. All properties have basic simple types: integer, long, boolean, and string. A resource class provides APIs to perform the following operations:

[Create](#) | [Retrieve](#) | [Update](#) | [Delete](#) | [Enable/Disable](#) | [Unset](#) | [Bind/Unbind](#) | [Global bind](#) | [Bulk operations](#)

## Create

To create a new resource, instantiate the resource class, configure the resource by setting its properties locally, and then upload the new resource instance to the NetScaler appliance.

The following sample code creates a load balancing virtual server:

```
//Create an instance of the lbvserver class
lbvserver new_lbvserver_obj = new lbvserver()

//Set the properties of the resource locally
new_lbvserver_obj.name = "MyFirstLbVServer"
new_lbvserver_obj.ipv46 = "10.102.29.88"
new_lbvserver_obj.port = 88
new_lbvserver_obj.servicetype = "HTTP"
new_lbvserver_obj.lbmethod = "ROUNDROBIN"

//Upload the resource to NetScaler
lbvserver.add(ns_session, new_lbvserver_obj)
```

## Retrieve

To retrieve the properties of a resource, you retrieve the resource object from the NetScaler appliance. Once the object is retrieved, you can extract the required properties of the resource locally, without further network traffic.

The following sample code retrieves the details of a load balancing virtual server:

```
//Retrieve the resource object from the NetScaler
new_lbvserver_obj = lbvserver.get(ns_session, "MyFirstLbVServer")

//Extract the properties of the resource from the object locally
```

```
print(new_lbserver_obj.name)
print(new_lbserver_obj.servicetype)
```

You can also retrieve resources by specifying a filter on the value of their properties by using the `nsrc.com.citrix.netscaler.nitro.util.filtervalue` class.

For example, you can retrieve all the load balancing virtual servers that have their port set to 80 and servicetype to HTTP:

```
filtervalue[] filter = new filtervalue[2]
filter[0] = new filtervalue("port","80")
filter[1] = new filtervalue("servicetype","HTTP")
lbserver[] result = lbserver.filtered(ns_session, filter)
```

You can also retrieve all NetScaler resources of a certain type, such as all services in the NetScaler appliance, by calling the static `get()` method on the service class, without providing a second parameter, as follows:

```
service[] resources = service.get(ns_session)
```

### Update

To update the properties of a resource, instantiate the resource class, specify the name of the resource to be updated, configure the resource by updating its properties locally, and then upload the updated resource instance to the NetScaler appliance.

The following sample code updates the service type and load balancing method of a load balancing virtual server:

```
//Create an instance of the lbserver class
lbserver update_lb = new lbserver()

//Specify the name of the lbserver to be updated
update_lb.name = "MyFirstLbVServer"

//Specify the updated service type and lb method
update_lb.servicetype = "https"
update_lb.lbmethod = "LEASTRESPONSETIME"

//Upload the resource to NetScaler
lbserver.update(ns_session, update_lb)
```

Note: Some properties in some NetScaler resources are not allowed to be modified after creation. The port number or the service type (protocol) of a load balancing virtual server or a service, are examples of such properties. Even though the update method appears to succeed, these properties retain their original values on the appliance.

### Delete

To delete an existing resource, invoke the `delete()` method on the resource class, by passing the name of the resource.

The following sample code deletes a load balancing virtual server with name "MyFirstLbVServer":

```
lbserver remove_lb = new lbserver()
remove_lb.name = "MyFirstLbVServer"
lbserver.delete(ns_session, remove_lb)
```

### Enable/Disable

To enable a resource, invoke the `enable()` method.

The following sample code enables a load balancing virtual server named "lb\_vip":

```
lbvserver obj = new lbvserver()
obj.name = "lb_vip"
lbvserver.enable(ns_session, obj)
```

Note: To disable a resource, invoke the `disable()` method.

```
lbvserver.disable(ns_session, obj)
```

### Unset

To unset the value that is set to a parameter, invoke the `unset()` method on the resource class, by passing the name of the resource and the parameters to be unset. If the parameter has a default value, the value is reset to that value.

The following sample code unsets the load balancing method and the comments of a load balancing virtual server named "lb\_123":

```
lbvserver lb1 = new lbvserver()
lb1.name = "lb_123"
String args[] = {"comment", "lbmethod"}
lbvserver.unset(ns_session, lb1, args)
```

### Bind/Unbind

NetScaler resources form relationships with each other through the process of binding. This is how services are associated with a load balancing virtual server (by binding them to it), or how various policies are bound to a load balancing virtual server. Each binding relationship is represented in NITRO by its own class.

To bind one NetScaler resource to another, you must instantiate the appropriate binding class (for example, to bind a service to a load balancing virtual server, you must instantiate the `lbvserver_service_binding` class) and add it to the NetScaler configuration (by using the static `add()` method on this class).

Binding classes have a property representing the name of each resource in the binding relationship. They can also have other properties related to that relationship (for example, the weight of the binding between a load balancing virtual server and a service).

The following sample code binds a service to a load balancing virtual server, by specifying a certain weight for the binding:

```
lbvserver_service_binding bindObj = new lbvserver_service_binding()
bindObj.name = "MyFirstLbVServer"
bindObj.servicename = "svc_prod"
bindObj.weight = 20
lbvserver_service_binding.add(ns_session, bindObj)
```

Note: To unbind a resource from another, invoke the `delete()` method from the resource binding class, by passing the name of the two resources.

The following code sample unbinds a service from a server:

```
lbvserver_service_binding bindObj = new lbvserver_service_binding()
bindObj.name = "MyFirstLbVServer"
bindObj.servicename = "svc_prod"
lbvserver_service_binding.delete(ns_session, bindObj)
```

### Global bind

Some NetScaler resources can be bound globally to affect the whole system. For example, a compression policy can be

bound to a load balancing virtual server, in which case the policy affects only the traffic on that load balancing virtual server. However, if bound globally, it can affect any traffic on the appliance, regardless of which virtual servers handle the traffic.

Some NITRO classes can be used to bind resources globally. These classes have names that follow the following pattern: <featurename>global\_<resourcetype>\_binding.

For example, the class `aaaglobal_preauthenticationpolicy_binding` is used to bind preauthentication policies globally.

The following sample code creates a preauthentication action and a preauthentication policy that uses that action, and then binds the policy globally at priority 200:

```
aaapreauthenticationaction preauth_act1
aaapreauthenticationpolicy preauth_pol1
aaaglobal_aaapreauthenticationpolicy_binding glob_binding
preauth_act1 = new aaapreauthenticationaction()
preauth_act1.name = "preauth_act1"
preauth_act1.preauthenticationaction = "ALLOW"
aaapreauthenticationaction.add(ns_session, preauth_act1)

preauth_pol1 = new aaapreauthenticationpolicy()
preauth_pol1.name = "preauth_pol1"
preauth_pol1.rule = "CLIENT.APPLICATION.PROCESS(antivirus.exe) EXISTS"
preauth_pol1.reqaction = "preauth_act1"
aaapreauthenticationpolicy.add(ns_session, preauth_pol1)

glob_binding = new aaaglobal_aaapreauthenticationpolicy_binding()
glob_binding.policy = "preauth_pol1"
glob_binding.priority = 200
aaaglobal_aaapreauthenticationpolicy_binding.add(ns_session, glob_binding)
```

### Bulk operations

You can create, retrieve, update, and delete multiple resources simultaneously and thus minimize network traffic. For example, you can add multiple load balancing virtual servers in the same operation. To perform a bulk operation, you instantiate an array of the resource class, configure the properties of all the instances locally, and then upload all the instances to the NetScaler with one command.

To account for the failure of some operations within the bulk operation, NITRO allows you to configure one of the following behaviors:

- **Exit.** When the first error is encountered, the execution stops. The commands that were executed before the error are committed.
- **Rollback.** When the first error is encountered, the execution stops. The commands that were executed before the error are rolled back. Rollback is only supported for add and bind commands.
- **Continue.** All the commands in the list are executed even if some commands fail.

Note: You must configure the required behavior while establishing a connection with the appliance.

```
nitro_service ns_session = new nitro_service("10.102.29.60","http")
ns_session.onerror = OnerrorEnum.CONTINUE
ns_session.login("admin","verysecret")
```

The following sample code creates two load balancing virtual servers:

```
//Create an array of lbvserver instances
lbvserver[] lbs = new lbvserver[2]

//Specify properties of the first lbvserver
lbs[0] = new lbvserver()
lbs[0].name = "lbvserv1"
lbs[0].servicetype = "http"
lbs[0].ipv46 = "10.70.136.5"
lbs[0].port = 80

//Specify properties of the second lbvserver
lbs[1] = new lbvserver()
lbs[1].name = "lbvserv2"
lbs[1].servicetype = "https"
lbs[1].ipv46 = "10.70.136.5"
lbs[1].port = 443

//Upload the properties of the two lbvservers to the NetScaler
lbvserver.add(ns_session, lbs)
```

# Cluster APIs

Jun 16, 2014

For managing clusters, you can add or remove a cluster instance or an individual node and perform a few other instance or node operations such as viewing instance or node properties. You can also configure the cluster IP address. Other cluster-management tasks include joining a NetScaler appliance to the cluster and configuring a linkset.

## Cluster Instance Operations

The `nssrc.com.citrix.netscaler.nitro.resource.config.cluster.clusterinstance` class provides APIs to manage a cluster instance.

The following sample code creates a cluster instance with ID 1:

```
clusterinstance new_cl_inst_obj = new clusterinstance()
```

```
//Set the properties of the cluster instance locally
```

```
new_cl_inst_obj.clid = 1
```

```
new_cl_inst_obj.preemption = "ENABLED"
```

```
//Upload the cluster instance
```

```
clusterinstance.add(ns_session, new_cl_inst_obj)
```

## Cluster Node Operations

The `nssrc.com.citrix.netscaler.nitro.resource.config.cluster.clusternode` class provides APIs to manage cluster nodes.

The following sample code adds a cluster node with NSIP address 10.102.29.60:

```
clusternode new_cl_node_obj = new clusternode()
```

```
//Set the properties of the cluster node locally
```

```
new_cl_node_obj.nodeid = 0
```

```
new_cl_node_obj.ipaddress = "10.102.29.60"
```

```
new_cl_node_obj.state = "ACTIVE"
```

```
new_cl_node_obj.backplane = "0/1/1"
```

```
//Upload the cluster node
```

```
clusternode.add(ns_session, new_cl_node_obj)
```

## Add a Cluster IP Address

The `nssrc.com.citrix.netscaler.nitro.resource.config.ns.nsip` class provides the `add()` API to configure an IP address. To configure the IP address as a cluster IP address, you must specify the type as CLIP.

The following sample code configures a cluster IP address on NetScaler appliance with IP address 10.102.29.60:

```
nsip new_nsip_obj = new nsip()
```

```
//Set the properties locally
```

```
new_nsip_obj.ipaddress = "10.102.29.61"
```

```
new_nsip_obj.netmask = "255.255.255.255"
```

```
new_nsip_obj.type = "CLIP"
```

```
//Upload the cluster node
nsip.add(ns_session, new_nsip_obj)
```

### Add a Spotted IP Address

The `nssrc.com.citrix.netscaler.nitro.resource.config.ns.nsip` class provides the `add()` API to configure an IP address. To configure the IP address as spotted, you must specify the ID of the node that must own the IP address. This configuration must be done on the cluster IP address.

The following sample code configures a spotted SNIP address on a node with ID 1:

```
nsip new_nsip_obj = new nsip()

//Set the properties locally
new_nsip_obj.ipaddress = "10.102.29.77"
new_nsip_obj.netmask = "255.255.255.0"
new_nsip_obj.type = "SNIP"
new_nsip_obj.ownernode = 1
```

```
//Upload the cluster node
nsip.add(ns_session, new_nsip_obj)
```

### Join NetScaler Appliance to Cluster

The `nssrc.com.citrix.netscaler.nitro.resource.config.cluster.cluster` class provides the `join()` API to join a NetScaler appliance to the cluster. You must specify the cluster IP address and the `nsroot` password of the configuration coordinator.

The following sample joins a NetScaler appliance to a cluster:

```
cluster new_cl_obj = new cluster()

//Set the properties of the cluster locally
new_cl_obj.clip = "10.102.29.61"
new_cl_obj.password = "verysecret"
```

```
//Upload the cluster
cluster.add(ns_session, new_cl_obj)
```

### Linkset Operations

The `nssrc.com.citrix.netscaler.nitro.resource.config.network.linkset` class provides the APIs to manage linksets.

To configure a linkset, do the following:

1. Add a linkset by invoking the `add()` method of the linkset class.
2. Bind the interfaces to the linkset using the `add()` method of the `linkset_interface_binding` class.

The following sample code creates a linkset LS/1 and bind interfaces 1/1/2 and 2/1/2 to it:

```
//Create the linkset
linkset new_linkset_obj = new linkset()
new_linkset_obj.id = "LS/1"
linkset.add(ns_session, new_linkset_obj)
```

```
//Bind the interfaces to the linkset
linkset_interface_binding new_linkif_obj = new linkset_interface_binding()
new_linkif_obj.id = "LS/1"
new_linkif_obj.ifnum = "1/1/2 2/1/2"
linkset_interface_binding.add(ns_session, new_linkif_obj)
```

# Admin Partitions API

Nov 20, 2014

To create an admin partition, you must perform a set of operations on the default partition. To understand this procedure, let us consider a company that has two departments each of which has an application that requires the NetScaler functionality. The NetScaler admin wants to have a different partition for each department so that there is isolation of users and configurations. The NetScaler admin must do the following (the sample shows configurations only for a single admin partition):

Note: For detailed information and best practices, see [Admin Partitions](#).

1. Create a partition and allocate the required resources to that partition.

```
//Creating a new partition...
```

```
nspartition nspartitionObject = new nspartition()
nspartitionObject.partitionname = "partition-dept1"
nspartitionObject.maxbandwidth = 10240
nspartitionObject.maxconn = 1024
nspartitionObject.maxmemlimit = 10
nspartitionObject.minbandwidth = 1240
base_response result = nspartition.add(nitroService, nspartitionObject)
```

2. Associate the appropriate users with the partition.

```
//Associating user1 to partition-dept1...
```

```
systemuser_nspartition_binding systemuser_nspartition_binding_object = new systemuser_nspartition_binding()
systemuser_nspartition_binding_object.partitionname = "partition-dept1"
systemuser_nspartition_binding_object.username = "user1"
base_response result = systemuser_nspartition_binding.add(nitroService, systemuser_nspartition_binding_object)
```

3. Associate an appropriate command policy to the admin partition user.

```
//Associating partition-admin to user1...
```

```
systemuser_systemcmdpolicy_binding systemuser_systemcmdpolicy_binding_object = new systemuser_systemcmdpolicy_binding()
systemuser_systemcmdpolicy_binding_object.username = "user1"
systemuser_systemcmdpolicy_binding_object.policyname = "partition-admin"
systemuser_systemcmdpolicy_binding_object.priority = 1
base_response result = systemuser_systemcmdpolicy_binding.add(nitroService, systemuser_systemcmdpolicy_binding_object)
```

4. Specify the VLANs or bridgegroups to be associated with the partition. This step ensures network isolation of the traffic. Traffic received on the interfaces of the VLAN or bridgegroup is isolated from the traffic of other partitions.

```
//Specifying the VLAN to be associated with the partition...
```

```
nspartition_vlan_binding nspartition_vlan_binding_object = new nspartition_vlan_binding()
nspartition_vlan_binding_object.vlan = 2
nspartition_vlan_binding_object.partitionname = "partition-dept1"
base_response result = nspartition_vlan_binding.add(nitroService, nspartition_vlan_binding_object)
```

5. Save the configurations

```
//Saving the configurations...
```

```
nitroService.save_config()
```

The admin partition is created.

6. Now, to configure this admin partition, you must logout of the default partition and logon again. You are automatically taken to the admin partition to which you were first bound and once there you can configure the NetScaler.

Note: If you want to configure another admin partition, perform the switch operation given in the next step before performing this step.

7. [Optional] If you are associated with multiple admin partitions, you can switch to the required partition.

```
//Switching to other partition named partition-dept2...
```

```
nspartition nspartitionObject = new nspartition()
```

```
nspartitionObject.partitionname = "partition-dept2"
base_response result = nspartition.Switch(nitroService, nspartitionObject)
```

# Feature Statistics APIs

Jun 16, 2014

The NetScaler appliance collects statistics about the usage of its features and the corresponding resources. You can retrieve these statistics by using NITRO API. The statistics APIs are available in different packages from the configuration APIs.

The APIs to retrieve statistics of NetScaler features are available in packages that have the following pattern:  
nssrc.com.citrix.netscaler.nitro.resource.stat.<feature>.

For example, APIs to retrieve statistics of the load balancing virtual server are available in the  
nssrc.com.citrix.netscaler.nitro.resource.stat.lb package.

The following sample code retrieves the statistics of a load balancing virtual server and displays some of the statistics returned:

```
lbserver_stats stats = lbserver_stats.get(ns_session,"MyFirstLbVServer")
print(stats.curIntconnections)
print(stats.deferredreqrate)
```

Note: Not all NetScaler features and resources have statistic objects associated with them.

# AppExpert Application APIs

Jun 16, 2014

To export an AppExpert application, you must instantiate the `nssrc.com.citrix.netscaler.nitro.resource.config.app.application` class, configure the properties of the AppExpert locally, and then export the AppExpert application.

The following sample code exports an AppExpert application named "MyApp1":

```
application myapp = new application()
myapp.appname = "MyApp1"
myapp.apptemplatefilename = "myapp_template"
application.export(ns_session, myapp)
```

You can also import an AppExpert application. You must instantiate the `nssrc.com.citrix.netscaler.nitro.resource.config.app.application` class, configure the properties of the AppExpert locally, and then import the AppExpert application.

The following sample code imports an AppExpert application named "MyApp1":

```
application myapp = new application()
myapp.appname = "MyApp1"
myapp.apptemplatefilename = "myapp_template"
application.Import(ns_session, myapp)
```

# Exception Handling

Jun 16, 2014

The status of a NITRO request is captured in the `nssrc.com.citrix.netscaler.nitro.exception.nitro_exception` class. This class provides the following details of the exception:

- **Session ID.** The session in which the exception occurred.
- **Severity.** The severity of the exception: error or warning. By default, only errors are captured. To capture warnings, you must set the warning flag to true, while connecting to the appliance.
- **Error code.** The status of the NITRO request. An error code of 0 indicates that the NITRO request is successful. A non-zero error code indicates an error in processing the NITRO request.
- **Error message.** Provides a brief description of the exception.

For a list of error codes, see the `errorlisting.html` file available in the `<NITRO_SDK_HOME>/doc/api_reference` folder.

# NITRO Changes Across NetScaler Releases

Jul 04, 2014

NetScaler has introduced some changes in the NITRO API since the NetScaler 9.3 release. This could raise some compatibility issues for the following users:

- Users migrating from NetScaler 9.3 to 10.1
- Users migrating from NetScaler 9.3 to 10.5

Note: There are no changes introduced since the NetScaler 10.1 release. Therefore, you should not face any compatibility issues when migrating from NetScaler 10.1 to 10.5.

These NITRO changes from 9.3 to 10.1 or 10.5 are categorized as follows:

- [Resources Removed](#)
- [APIs Removed](#)
- [API Return Type Changed](#)
- [Attribute Type Changed](#)
- [Attributes Removed](#)
- [SDK Specific Changes](#)

Note: Unless otherwise specified, these changes are applicable to both REST and SDKs.

Resource	Replace with...	Comments
lbmonitor_lbmetricable_binding	lbmonitor_metric_binding	

Resource	API	Comments
vserver	GET	Perform the GET operation on specific virtual server types such as lb/cr/cs.
filterpolicy	POST with "action=unset"	This API is removed as unsetting the attributes('action') of a policy makes it invalid.
auditsyslogpolicy	POST with "action=unset"	This API is removed as unsetting the attributes('action') of a policy makes it invalid.
auditnslogpolicy	POST with "action=unset"	This API is removed as unsetting the attributes('action') of a policy makes it invalid.
authorizationpolicy	POST with "action=unset"	This API is removed as unsetting the attributes('action') of a policy makes it invalid.

Resource	API	Comments
snmpengineid	GET	Return type changed to an array.
nshostname	GET	Return type changed to an array.

Resource	Attribute	Comments
appfwpolicy_lbserver_binding	activepolicy	Data type changed from Boolean to Integer.
appfwpolicy_appfwglobal_binding	activepolicy	Data type changed from Boolean to Integer.
vlan	portbitmap	Data type changed from uint to ulong.
vlan	tagbitmap	Data type changed from uint to ulong.

Resource	Attribute	Replace with...	Comments
polycypatset_pattern_binding	indextype	- NA -	This attribute is moved to 'polycypatset' resource as this attribute is applicable at patset level.
system_stats	powersupply1failure	powersupply1status	Change is applicable from NetScaler 9.3 (65.8).
system_stats	powersupply2failure	powersupply2status	Change is applicable from NetScaler 9.3 (65.8).
server_servicegroup_binding	servicetype	svctype	
server_service_binding	servicetype	svctype	
crvserver	hits	- NA -	Hits are calculated per policy binding hence moved this parameter to binding resources.
crvserver	dstvsr	destinationvserver	
crvserver	destvserver	domain	

Resource	Attribute	Replace with...	Comments
crvserver	dnsvserver	dnsvservename	
appflowpolicylabel	type	policylabeltype	
sslcipher	ciphgrpals	ciphergroupname	This change is applicable for sslcipher_*_binding resources also.
csvserver_cspolicy_binding	targetvserver	targetlbserver	
csvserver_cspolicy_binding	targetvserver	targetlbserver	
rewriteaction	allow_unsafe_pi1, allow_unsafe_pi	bypassSafetyCheck	

Class	Method	Replace with...	Comments
Routerbgp	- NA -	- NA -	This class is removed as all router configurations are deprecated in 9.2.
dnsptrrec	get(dnsptrrec obj, nitro_service session)	get(nitro_service session, String reversedomain)	
dnsaddrec	get(dnsaddrec obj, nitro_service session)	get(nitro_service session, String hostname)	
dnsnsrec	get(dnsnsrec obj, nitro_service session)	get(nitro_service session, String domain)	
snmpengineid	unset(nitro_service session, String[] args)	unset(nitro_service session, snmpengineid resource, String[] args)	
arp	arp.get(nitro_service session, String ipaddress)	arp.get(nitro_service session, arp resource)	
nsip	get(nitro_service session, String ipaddress)	get(nitro_service client, nsip resource)	
nsip6	get(nitro_service session, String ipv6address)	get(nitro_service session, nsip6 resource)	
dnsmxrec	dnsmxrec.get(dnsmxrec obj, nitro_service session)	dnsmxrec[] get(nitro_service service, dnsmxrec_args args)	

# Unsupported NetScaler Operations

Nov 04, 2014

Some NetScaler operations that are available through the command line interface and through the configuration utility, are not available through NITRO APIs. The following list provides the NetScaler operations not supported by NITRO:

- install API
- diff API on nsconfig resource (supported from NetScaler 10.5 onwards)
- UI-internal APIs (update, unset, and get)
- show ns info
- Application firewall APIs:
  - importwsdl
  - importcustom
  - importxmlschema
  - importxmlerrorpage
  - importhtmlerrorpage
  - rmcustom
  - rmxmlschema
  - rmxmlerrorpage
  - rmhtmlerrorpage
- CLI-specific APIs:
  - ping/ping6
  - traceroute/traceroute6
  - start nstrace/stop nstrace/show nstrace
  - scp
  - configaudit
  - show defaults
  - show permission
  - batch
  - source

# Reference Material

Jul 05, 2017

Use the reference information in this section to get an in-depth understanding of the following NetScaler components:

[NetScaler SNMP OIDs](#) - Details of the SNMP OIDs that can be used to obtain information from a NetScaler appliance.

[NetScaler Syslog Messages](#) - Details of the Syslog messages given by the NetScaler appliance.

[NetScaler CLI Commands](#) - Details of the commands that can be used to configure the NetScaler appliance through the CLI. You can also view the details of each command in the NetScaler CLI, by entering the "man <ns-command-name>" command.

[NetScaler Advanced Policy Expressions](#) - Details of the expressions that can be used to define advanced policies.

[Quick Start Guides](#) - A reference to quick installation and configuration of your hardware appliance.
