1. Accept the user name and password supplied in the request and format them appropriately.
2. Connect to the database that contains all the valid user names and passwords.
3. Check the supplied credentials against your database.
4. Format the response as required by the HTTP callout.
5. Send the response to the NetScaler appliance.

Use Case: OWA-Based Spam Filtering

May 21, 2015

Spam filtering is the ability to dynamically block emails that are not from a known or trusted source or that have inappropriate content. Spam filtering requires an associated business logic that indicates that a particular kind of message is spam. When the NetScaler appliance processes Outlook Web Access (OWA) messages based on the HTTP protocol, HTTP callouts can be used to filter spam.

You can use HTTP callouts to extract any portion of the incoming message and check with an external callout server that has been configured with rules that are meant for determining whether a message is legitimate or spam. In case of spam email, for security reasons, the NetScaler appliance does not notify the sender that the email is marked as spam.

The following example conducts a very basic check for various listed keywords in the email subject. These checks can be more complex in a production environment.

To implement this configuration, you must perform the following tasks:

1. Enable the responder feature on the NetScaler appliance.
2. Create an HTTP callout on the NetScaler appliance and configure it with details about the external server and other required parameters.
3. Create a responder policy to analyze the response, and then bind the policy globally.
4. Create a callout agent on the remote server.

Enabling Responder

Updated: 2013-08-30

The responder feature must be enabled before it can be used on the NetScaler appliance.

To enable responder by using the configuration utility

1. Make sure that the responder license is installed.
2. In the configuration utility, expand AppExpert, and right-click Responder, and then click Enable Responder feature.

Creating an HTTP Callout on the NetScaler Appliance

Updated: 2013-08-30

Create an HTTP callout, HTTP-Callout-4, with the parameter settings shown in the following table. For more information about creating an HTTP callout, see "[Configuring an HTTP Callout](#)."

Table 1. Parameters and Values for HTTP-Callout-4

Parameter	Value
Name	HTTP-Callout-4
Server to receive callout request	
IP Address	10.103.56.51
Port	80
Request to send to the server	
Method	POST
Host Expression	ffffff
URL Stem Expression	"/cgi-bin/Callout/spam_filter.pl"
Headers	
Name	Request

Value-expression Parameter	Callout Request Value
Parameters	
Name	Subject
Value-expression	("\" + HTTP.REQ.BODY(1000).AFTER_STR("urn:schemas:html:subject=").BEFORE_STR("\n").TO_LOWER + "\")
Server Response	
Return Type	BOOL
Expression to extract data from the response	HTTP.RES.BODY(100).CONTAINS("\"Matched\"")

Creating a Responder Action

Updated: 2013-08-30

Create a responder action, Action-Responder-4. Create the action with the parameter settings shown in the following table.

Table 2. Parameters and Values for Action-Responder-4

Parameter	Value
Name	Action-Responder-4
Type	Respond with
Target	"\"HTTP/1.1 200 OK\n\nServer: Microsoft-IIS/6.0\n\nX-Powered-By: ASP.NET\n\nContent-Length: 0\n\nMS-WebStorage: 6.5.6944\n\nCache-Control: no-cache\n\n\n\""

To create a responder action by using the configuration utility

1. Navigate to AppExpert > Responder > Actions.
2. In the details pane, click Add.
3. In the Create Responder Action dialog box, in Name, type Action-Responder-4.
4. In Type, click Respond with.
5. In Target, type:
"\"HTTP/1.1 200 OK\n\nServer: Microsoft-IIS/6.0\n\nX-Powered-By: ASP.NET\n\nContent-Length: 0\n\nMS-WebStorage: 6.5.6944\n\nCache-Control: no-cache\n\n\n\""
6. Click Create, and then click Close.

Creating a Responder Policy to Invoke the HTTP Callout

Updated: 2013-08-30

Create a responder policy, Policy-Responder-4, that will check the request body and, if the body contains the word "subject," invoke the HTTP callout to verify the email. Create the policy with the parameter settings shown in the following table. While you can create a responder policy in the Policies subnode and then bind it globally by using the Responder Policy Manager, this demonstration uses the Responder Policy Manager to create the responder policy and bind it globally.

Table 3. Parameters and Values for Policy-Responder-4

Parameter	Value
Name	Policy-Responder-4
Action	Action-Responder-4
Undefined-Result-Action	-Global undefined-result action-
Expression	"HTTP.REQ.BODY(1000).CONTAINS("\"urn:schemas:html:subject\")" && SYS.HTTP_CALLOUT(HTTP-Callout-4)"

Parameter	Value
To create a responder	policy by using the configuration utility

1. Navigate to AppExpert > Responder.
2. In the details pane, under Policy Manager, click Responder policy manager.
3. In the Responder Policy Manger dialog box, click Override Global.
4. Click Insert Policy, and then, in the Policy Name column, click New Policy.
5. In the Create Responder Policy dialog box, do the following:
 1. In Name, type Policy-Responder-4.
 2. In Action, click Action-Responder-4.
 3. In Undefined-Result Action, click Global undefined-result action.
 4. In the Expression text box, type:
 "HTTP.REQ.BODY(1000).CONTAINS("urn:schemas:httpmail:subject") && SYS.HTTP_CALLOUT(HTTP-Callout-4)"
 5. Click Create, and then click Close.
6. Click Apply Changes, and then click Close.

Creating an HTTP Callout Agent on the Remote Server

You will now need to create an HTTP callout agent on the remote callout server. The HTTP callout agent receives callout requests from the NetScaler appliance and responds accordingly. The callout agent is a script that is different for each deployment and must be written with server specifications in mind, such as the type of database and the scripting language supported.

The following pseudo-code provides instructions for creating a callout agent that checks a list of words that are generally understood to indicate spam mails. The agent can be implemented in any programming language of your choice. The pseudo-code is to be used only as a guideline for developing the callout agent. You can build additional functionality into the program.

To identify spam email by using pseudo-code

1. Accept the email subject provided by the NetScaler appliance.
2. Connect to the database that contains all the terms against which the email subject is checked.
3. Check the words in the email subject against the spam word list.
4. Format the response as required by the HTTP callout.
5. Send the response to the NetScaler appliance.

Use Case: Dynamic Content Switching

May 21, 2015

This use case provides dynamic content switching by using an HTTP callout to get the name of the load balancing virtual server to which the request is forwarded.

1. Add a content switching virtual server.
> add cs vserver cs_vserver1 HTTP 10.102.29.196 80
2. Create an HTTP callout.
> add policy httpCallout http_callout1
3. Configure the HTTP callout to respond with the name of the load balancing virtual server from a request that contains the client IP address in the HTTP header "X-CLIENT-IP".
> set policy httpCallout http_callout1 -IPAddress 10.217.14.23 -port 80 -returnType TEXT -hostExpr "\"www.get-lbvip.com\"" -urlStemExpr "\"/index.html\"" -headers X-CLIENT-IP(CLIENT.IP.SRC) -res
4. Configure the content switching action to retrieve the callout response.
> add cs action cs_action1 -targetVserverExpr 'SYS.HTTP_CALLOUT(http_callout1)'
Note: You must bind a load balancing virtual server to the content switching virtual server to account for:
 - The non-availability of the load balancing virtual server that the callout resolves to.
 - A UNDEF condition that results from the execution of the callout.> bind cs vserver cs_vserver1 -lbvserver default_lbvip
5. Configure the content switching policy.
> add cs policy cs_policy1 -rule true -action cs_action1
6. Binding the content switching policy to the content switching virtual server.
> bind cs vserver cs_vserver1 -policyName cs_policy1 -priority 10

Pattern Sets and Data Sets

Jun 20, 2013

Policy expressions for string matching operations on a large set of string patterns tend to become long and complex. Resources consumed by the evaluation of such complex expressions are significant in terms of processing cycles, memory, and configuration size. You can create simpler, less resource-intensive expressions by using pattern matching.

Depending on the type of patterns that you want to match, you can use one of the following features to implement pattern matching:

- A pattern set is an array of indexed patterns used for string matching during default syntax policy evaluation. Example of a pattern set: `imagetypes {svg, bmp, png, gif, tiff, jpg}`.
- A data set is a specialized form of pattern set. It is an array of patterns of types number (integer), IPv4 address, or IPv6 address.

In many cases, you can use either pattern sets or data sets. However, in cases where you want specific matches for numerical data or IPv4 and IPv6 addresses, you must use data sets.

Note: Pattern sets and data sets can be used only in default syntax policies.

To use pattern sets or data sets, first create the pattern set or data set and bind patterns to it. Then, when you configure a policy for comparing a string in a packet, use an appropriate operator and pass the name of the pattern set or data set as an argument.

How String Matching works with Pattern Sets and Data Sets

Jul 11, 2013

A pattern set or data set contains a set of patterns, and each pattern is assigned a unique index. When a policy is applied to a packet, an expression identifies a string to be evaluated, and the operator compares the string to the patterns defined in the pattern set or data set until a match is found or all patterns have been compared. Then, depending on its function, the operator returns either a boolean value that indicates whether or not a matching pattern was found or the index of the pattern that matches the string.

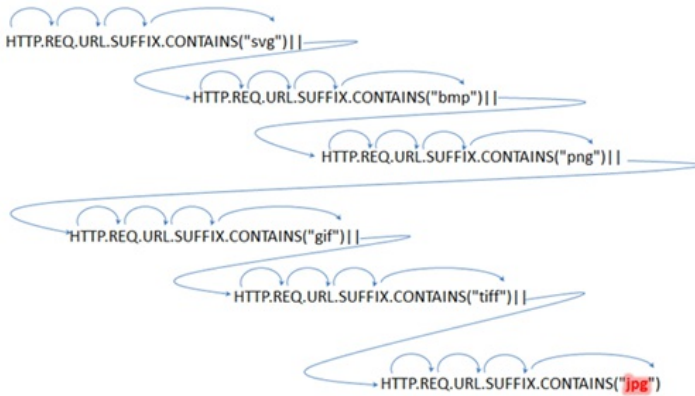

Note: This topic explains the working of a pattern set. Data sets work the same way. The only difference between pattern sets and data sets is the type of patterns defined in the set.

Consider the following use case to understand how patterns can be used for string matching.

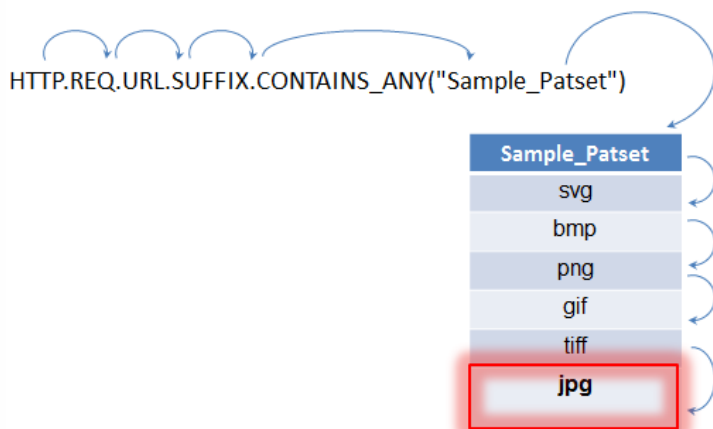

You want to determine whether the URL suffix (target text) contains any of the image file extensions. Without using pattern sets, you would have to define a complex expression, as follows:

```
HTTP.REQ.URL.SUFFIX.CONTAINS("svg") || HTTP.REQ.URL.SUFFIX.CONTAINS("bmp") || HTTP.REQ.URL.SUFFIX.CONTAINS("png") || HTTP.REQ.URL.SUFFIX.CONTAINS("gif") || HTTP.REQ.URL.SUFFIX.CONTAINS("tiff") || HTTP.REQ.URL.SUFFIX.CONTAINS("jpg")
```

If the URL has a suffix of "jpg," with the above compound expression, the NetScaler appliance has to iterate through the entire compound expression sequentially, from one sub expression to the next, to determine that the request refers to a jpg image. The following figure shows the steps in the process.

When a compound expression includes hundreds of sub expressions, the above process is resource intensive. A better alternative is an expression that invokes a pattern set, as shown in the following figure.

During policy evaluation as shown above, the operator (CONTAINS_ANY) compares the string identified in the request with the patterns defined in the pattern set until a match is found. With the Sample_Patset expression, the multiple iterations through six sub expressions are reduced to just one.

By eliminating the need to configure compound expressions that perform string matching with multiple OR operations, pattern sets or data sets simplify configuration and accelerate processing of requests and responses.

Configuring a Pattern Set

Oct 29, 2013

To configure a pattern set, you must specify the strings that are to serve as patterns. You can manually assign a unique index value to each of these patterns, or you can allow the index values to be assigned automatically.

Note: Pattern sets are case sensitive (unless you specify the expression to ignore case). Therefore, the string pattern "product1," for example, is not the same as the string pattern "Product1."

Points to remember about index values

- You cannot bind the same index value to more than one pattern.
- An automatically assigned index value is one number larger than the highest index value of the existing patterns within the pattern set. For example, if the highest index value of existing patterns in a pattern set is 104, the next automatically assigned index value will be 105.
- If you do not specify an index for the first pattern, index value 1 is automatically assigned to that pattern.
- Index values are not regenerated automatically if one or more patterns are deleted or modified. For example, if the set contains five patterns, with indexes from 1 through 5, and if the pattern with an index of 3 is deleted, the other index values in the pattern set are not automatically regenerated to produce values from 1 through 4.
- The maximum index value that can be assigned to a pattern is 4294967290. If that value is already assigned to a pattern in the set, you must manually assign index values to any newly added patterns. An unused index value that is lower than a currently used value cannot be assigned automatically.

To configure a pattern set by using the command line interface

At the command prompt, do the following:

1. Create a pattern set.
add policy patset <name>

Example:

```
> add policy patset samplepatset
```

2. Bind patterns to the pattern set.
bind policy patset <name> <string> [-index <positive_integer>]

Example:

```
> bind policy patset samplepatset product1 -index 1
```

Note: Repeat this step for all the patterns you want to bind to the pattern set.

3. Verify the configuration.
show policy patset <name>

To configure a pattern set by using the configuration utility

1. Navigate to AppExpert > Pattern Sets.
2. In the details pane, click Add to open the Create Pattern Set dialog box.
3. Specify a name for the pattern set in the Name text box.
4. Under Specify Pattern, type the first pattern and, optionally, specify values for the following parameters:
 - Treat back slash as escape character—Select this check box to specify that any backslash characters that you might include in the pattern are to be treated as escape characters.
 - Index—A user assigned index value, from 1 through 4294967290.

5. Verify that you have entered the correct characters, and then click Add.
6. Repeat steps 4 and 5 to add additional patterns, and then click Create.

Configuring a Data Set

Oct 11, 2017

To configure a data set, you must specify the strings that are to serve as patterns, and assign a type (number, IPv4 address, or IPv6 address) to each pattern. You can manually assign a unique index value to each of these patterns, or you can allow the index values to be assigned automatically. Dataset is not related to HTTP or any 7 layer protocol. It works only on text/string. There are different types of dataset such as num, ulong, ipv4, and ipv6. To use a dataset on IP, we have to convert the input into text/string.

Note: Datasets are case sensitive (unless you specify the expression to ignore case). Therefore, the string pattern "product1," for example, is not the same as the string pattern "Product1."

The rules applied for index values of data sets are the same as those applied for pattern sets. For information about index values, see "[Configuring a Pattern Set.](#)"

To configure a data set by using the command line interface

At the command prompt, do the following:

1. Create a data set.

```
add policy dataset <name> <type>
```

Example:

```
> add policy dataset sampledataset ipv4
```

2. Bind patterns to the data set.

```
bind policy dataset <name> <value> [-index <positive_integer>]
```

Example:

```
> bind policy dataset sampledataset 10.102.29.1 -index 1
```

Note: Repeat this step for all the patterns you want to bind to the data set.

3. add policy expression sampleexpression client.ip.src.typecast_text_t.equals_any("sampledataset")
4. Verify the configuration.

```
show policy dataset <name>
```

To configure a data set by using the configuration utility

Navigate to AppExpert > Data Sets, click Add and specify the relevant details.

Using Pattern Sets and Data Sets

Aug 30, 2013

Default syntax policy expressions that take pattern sets or data sets as an argument can be used to perform string matching operations.

The usage is as follows:

`<text>.<operator>("<name>")`

where,

- `<text>` is the expression that identifies a string in a packet. Example: `HTTP.REQ.HEADER("Host")`.
- `<operator>` is one of the operators described in the following table.

Table 1. Operators for pattern sets and data sets

Operator	Description
<code><text>.CONTAINS_ANY(<name>)</code>	Returns true if the target text contains one or more of the patterns defined in the specified pattern set or data set.
<code><text>.SUBSTR_ANY(<name>)</code>	Returns the first string that matches any pattern defined in the specified pattern set or data set.
<code><text>.BEFORE_STR_ANY(<name>)</code>	Returns the text that is present before the first occurrence of any of the patterns defined in the specified pattern set or data set.
<code><text>.AFTER_STR_ANY(<name>)</code>	Returns the text that is present after the first occurrence of any of the patterns defined in the specified pattern set or data set.
<code><text>.EQUALS_ANY (<name>)</code>	Returns true if the target text exactly matches any of the patterns defined in the specified pattern set or data set.
<code><text>.ENDSWITH_ANY(<name>)</code>	Returns true if the target text ends with any of the patterns that are defined in the specified pattern set or data set.
<code><text>.STARTSWITH_ANY(<name>)</code>	Returns true if the target text starts with any of the patterns that are defined in the specified pattern set or data set.
<code><text>.STARTSWITH_INDEX(<name>)</code>	Evaluates whether the target text starts with any of the patterns that are defined in the specified pattern set or data set. If a match is found, the index of the matching pattern is returned. Otherwise, 0 is returned.
<code><text>.ENDSWITH_INDEX(<name>)</code>	Evaluates whether the target text ends with any of the patterns that are defined in the specified pattern set or data set. If a match is found, the index of the matching pattern is returned. Otherwise, 0 is returned.
<code><text>.CONTAINS_INDEX(<name>)</code>	Evaluates whether the target text contains any of the patterns that are defined in the specified pattern set or data set. If a match is found, the index of the matching pattern is returned. Otherwise, 0 is returned.

Operator	Description
<text>=EQUALS_INDEX(<name>)	Evaluates whether the target text exactly matches any of the patterns that are defined in the specified pattern set or data set. If an exact match is found, the index of the pattern is returned. Otherwise, 0 is returned.

- <name> is the name of the pattern set or data set

For sample usage, see "[Sample Usage](#)."

Sample Usage

Jun 13, 2013

To understand the usage of pattern sets in expressions, consider the example of a pattern set named "imagetypes."

Table 1. Pattern set "imagetypes"

Patterns	Index value
svg	1
bmp	2
png	3
gif	4
tiff	5
jpg	6

Example 1: Determine whether the suffix of an HTTP request is one of the file extensions defined in the "imagetypes" pattern set.

- **Expression.** HTTP.REQ.URL.SUFFIX.EQUALS_ANY("imagetypes")
- **Sample URL.** http://www.example.com/homepageicon.jpg
- **Result.** TRUE

Example 2: Determine whether the suffix of an HTTP request is one of the file extensions defined in the "imagetypes" pattern set, and return the index of that pattern.

- **Expression.** HTTP.REQ.URL.SUFFIX.EQUALS_INDEX("imagetypes")
- **Sample URL.** http://www.example.com/mylogo.gif
- **Result.** 4 (The index value of the pattern "gif".)

Example 3: Use the index value of a pattern to determine whether the URL suffix is within a specified index-value range.

- **Expression.** HTTP.REQ.URL.SUFFIX.EQUALS_INDEX("imagetypes").GE(3) && HTTP.REQ.URL.SUFFIX.EQUALS_INDEX("imagetypes").LE(5)
- **Sample URL.** http://www.example.com/mylogo.gif
- **Result.** TRUE (The index value of gif file types is 4.)

Example 4: Implement one set of policies for file extensions bmp, jpg, and png, and a different set of policies for gif, tiff, and svg files.

An expression that returns the index of a matched pattern can be used to define traffic subsets for a web application. The

following two expressions could be used in content switching policies for a content switching virtual server:

- `HTTP.REQ.URL.SUFFIX.EQUALS_INDEX("imagetypes").LE(3)`
- `HTTP.REQ.URL.SUFFIX.EQUALS_INDEX("imagetypes").GE(4)`

Variables

Jun 02, 2015

Variables are named objects that store information in the form of tokens. These tokens are used within and across different transactions on the NetScaler Appliance for internal computation and policy processing.

The NetScaler appliance supports creation of variables of the following types:

- **Singleton variables.** Can have a single value of one of the following types: `ulong` and `text (max-size)`. The `ulong` type is an unsigned 64-bit integer, the `text` type is a sequence of bytes, and `max-size` is the maximum number of bytes in the sequence.
- **Map variables.** Maps hold values associated with keys: each key-value pair is called a map entry. The key for each entry is unique within the map. Maps are specified as follows:

```
map (key_type, value_type, max-values).
```

where,

- *key_type* is the data type of the key. It is of type `text (max-size)`.
- *value_type* is the data type of the values of the map. It can be of type `ulong` or `text (max-size)`.
- *max-values* is the maximum number of entries that the map can contain. It is of type `ulong`.

Values for these variables are set using assignments which must be invoked on policy actions.

Note: Variables are not yet supported in a high-availability setup or in a cluster.

Variables Scope

A map variable or a singleton variable can have a global scope. Alternatively, the scope of a singleton variable can be limited to a single transaction.

- **Global Scope Variable** - A variable with global scope (the default) has only one instance, and that instance has the same value(s) across all cores of a NetScaler appliance and across all nodes of a cluster or HA configuration. Global variable values exist until they are explicitly deleted, until they expire, or until a standalone appliance is restarted or all nodes of a cluster or HA configuration are restarted.
- **Transaction Scope Variable** - A variable with transaction scope has a separate instance, with its own value, for each transaction processed by the NetScaler appliance. When the transaction processing is complete, the transaction variable value is deleted.

Note: Transaction scope variables are available in NetScaler release 10.5.e or later.

Configuring and Using Variables

Mar 20, 2014

You must first create a variable and then assign a value or specify the operation that must be performed on the variable. After performing these operations, you can use the assignment as a policy action.

Note: Once configured, a variable's settings cannot be modified or reset. If the variable needs to be changed, the variable and all references to the variable (expressions and assignments) must be deleted. The variable can then be re-added with new settings, and the references (expressions and assignments) can be re-added.

To configure variables by using the command line interface

1. Create a variable.

```
add ns variable <name> -type <string> [-scope global] [-ifFull ( undef | lru )] [-ifValueTooBig ( undef | truncate )] [-ifNoValue ( undef | init )] [-init <string>] [-expires <positive_integer>] [-comment <string>]
```

Note: Refer to the man page "man add ns variable" for description of the command parameters.

Example 1: Create a ulong variable named "my_counter" and initialize it to 1.

```
add ns variable my_counter -type ulong -init 1
```

Example 2: Create a map named "user_privilege_map". The map will contain keys of maximum length 15 characters and text values of maximum length 10 characters, with a maximum of 10000 entries.

```
add ns variable user_privilege_map -type map(text(15),text(10),10000)
```

Note: If the map contains 10000 unexpired entries, assignments for new keys reuse one of the least recently used entries. By default, an expression trying to get a value for a non-existent key will initialize an empty text value.

2. Assign the value or specify the operation to be performed on the variable. This is done by creating an assignment.

```
add ns assignment <name> -variable <expression> [-set <expression> | -add <expression> | -sub <expression> | -append <expression> | -clear] [-comment <string>]
```

Note: A variable is referenced by using the variable selector (\$). Therefore, **\$variable1** is used to refer to text or ulong variables. Similarly, **\$variable2[key-expression]** is used to refer to map variables.

Example 1: Define an assignment named "inc_my_counter" that automatically adds 1 to the "my_counter" variable.

```
add ns assignment inc_my_counter -variable $my_counter -add 1
```

Example 2: Define an assignment named "set_user_privilege" that adds to the "user_privilege_map" variable an entry for the client's IP address with the value returned by the "get_user_privilege" HTTP callout.

```
add ns assignment set_user_privilege -variable $user_privilege_map[client.ip.src.typecast_text_t] -set sys.http.callout(get_user_privilege)
```

Note: If an entry for that key already exists, the value will be replaced. Otherwise a new entry for the key and value will be added. Based on the previous declaration for user_privilege_map, if the map already has 10000 entries, one of the least recently used entries will be reused for the new key and value.

3. Invoke the variable assignment in a policy.

There are two functions that can operate on map variables.

- **\$name.valueExists(key-expression)**. Returns true if there is a value in the map selected by the key-expression. Otherwise returns false. This function will update the expiration and LRU information if the map entry exists, but will not create a new map entry if the value does not exist.
- **\$name.valueCount**. Returns the number of values currently held by the variable. This is the number of entries in a map. For a singleton variable, this is 0 if the variable is uninitialized or 1 otherwise.

Example: Invoke the assignment named "set_user_privilege" with a compression policy.

```
> add cmp policy set_user_privilege_pol -rule $user_privilege_map.valueExists(client.ip.src.typecast_text_t).not -resAction set_user_privilege
```

To configure variables by using the configuration utility

1. Navigate to AppExpert > NS Variables, to create a variable.
2. Navigate to AppExpert > NS Assignments, to assign value(s) to the variable.
3. Navigate to the appropriate feature area where you want to configure the assignment as an action.

Use Case: Caching User Privileges

Aug 13, 2014

In this use case, user privileges ("GOLD", "SILVER", and so on) must be retrieved from an external web service.

To achieve this use case, perform the following operations:

1. Create an HTTP callout to fetch the user privileges from the external web service.
> add policy httpcallout get_user_privilege
> set policy httpcallout get_user_privilege -ipaddress 10.217.193.84 -port 80 -returntype text -httpmethod get -urlstemexpr ""/get_user_privilege"" -resultexpr 'http.res.body(5)'
2. Store the privileges in a variable.
> add ns variable user_privilege_map -type map(text(15),text(10),10000) -expires 1200
> add ns assignment set_user_privilege -variable \$user_privilege_map[client.ip.src] -set sys.http_callout(get_user_privilege)
3. Create a policy to check if there is already a cached entry for the client's IP address; if not, it calls the HTTP callout to set a map entry for the client.
> add cmp policy set_user_privilege_pol -rule \$user_privilege_map.valueExists(client.ip.src).not -resAction set_user_privilege
4. Create a policy that compresses if the cached privilege entry for the client is "GOLD".
> add cmp policy compress_if_gold_privilege_pol -rule '\$user_privilege_map[client.ip.src].eq("GOLD")' -resAction compress
5. Bind the compression policies globally.
> bind cmp global set_user_privilege_pol -priority 10 NEXT
> bind cmp global compress_if_gold_privilege_pol -priority 20 END

Use Case: Limiting the Number of Sessions

Aug 13, 2014

In this use case, the requirement is to limit the number of active backend sessions. In the deployment, each session login has login in the URL and each session logout has logout in the URL. On successful login, the backend sets a sessionid cookie with a unique 10 character value.

To achieve this use case, perform the following operations:

1. Create a map variable that can store each active session. The key of the map is the sessionid. The expiry time for the variable is set to 600 seconds (10 minutes).
> add ns variable session_map -type map(text(10),ulong,100) -expires 600
2. Create the following assignments for the map variable:
 - Create an entry for the sessionid and set that value to 1 (this value is not actually used).
> add ns assignment add_session -variable '\$session_map[http.req.cookie.value("sessionid")] -set 1
 - Deallocate the entry for a session ID, which implicitly decrements the value count for session_map.
> add ns assignment delete_session -variable '\$session_map[http.req.cookie.value("sessionid")] -clear
3. Create responder policies for the following:
 - To check if a map entry exists for that sessionid in the HTTP request. The add_session assignment is executed if the map entry does not exist.
> add responder policy add_session_pol '\$session_map.valueExists(http.req.cookie.value("sessionid"))' add_session
Note: The valueExists() function in the add_session_pol policy counts as a reference to the session's map entry, so each request resets the expiration timeout for its session. If no requests for a session are received after 10 minutes, the session's entry will be deallocated.
 - To check when the session is logged out. The delete_session assignment is executed.
> add responder policy delete_session_pol 'http.req.url.contains("logout")' delete_session
 - To check for login requests and if the number of active sessions exceed 100. If these conditions are satisfied, in order to limit the number of sessions, the user is redirected to a page that indicates that the server is busy.
> add responder action redirect_too_busy redirect "/too_busy.html"
> add responder policy check_login_pol 'http.req.url.contains("login") && \$session_map.valueCount > 100' redirect_too_busy
4. Bind the responder policies globally.
> bind responder global add_session_pol 10 next
> bind responder global delete_session_pol 20 next
> bind responder global check_login_pol 30

Policies and Expressions

May 26, 2015

The following topics provide the conceptual and reference information that you require for configuring advanced policies on the Citrix® NetScaler® appliance.

You can also download a list of all the expressions supported on the NetScaler appliance and the hierarchical order in which they can be invoked. The reference is in a zip file which you can download from:

- For NetScaler 10.5: <http://support.citrix.com/article/CTX141344>
- For NetScaler 10.1: <http://support.citrix.com/article/CTX137705>

Introduction to Policies and Expressions	Describes the purpose of expressions, policies, and actions, and how different NetScaler applications make use of them.
Configuring Advanced Policies	Describes the structure of advanced policies and how to configure them individually and as policy banks.
Configuring Advanced Expressions: Getting Started	Describes expression syntax and semantics, and briefly introduces how to configure expressions and policies.
Advanced Expressions: Evaluating Text	Describes expressions that you configure when you want to operate on text (for example, the body of an HTTP POST request or the contents of a user certificate).
Advanced Expressions: Working with Dates, Times, and Numbers	Describes expressions that you configure when you want to operate on any type of numeric data (for example, the length of a URL, a client's IP address, or the date and time that an HTTP request was sent).
Advanced Expressions: Parsing HTTP, TCP, and UDP Data	Describes expressions for parsing IP and IPv6 addresses, MAC addresses, and data that is specific to HTTP and TCP traffic.
Advanced Expressions: Parsing SSL Certificates	Describes how to configure expressions for SSL traffic and client certificates, for example, how to retrieve the expiration date of a certificate or the certificate issuer.
Advanced Expressions: IP and MAC Addresses, Throughput, VLAN IDs	Describes expressions that you can use to work with any other client- or server-related data not discussed in other chapters.
Typecasting Data	Describes expressions for transforming data of one type to another.
Regular Expressions	Describes how to pass regular expressions as arguments to operators in advanced

	expressions.
Configuring Classic Policies and Expressions	Provides details on how to configure the simpler policies and expressions known as classic policies and classic expressions.
Expressions Reference	A reference for classic and advanced expression arguments.
Summary Examples of Advanced Expressions and Policies	Examples of classic and advanced expressions and policies, in both quick reference and tutorial format, that you can customize for your own use.
Tutorial Examples of Advanced Policies for Rewrite	Examples of advanced policies for use in the Rewrite feature.
Tutorial Examples of Classic Policies	Examples of classic policies for NetScaler features such as application firewall and SSL.
Migration of Apache mod_rewrite Rules to Advanced Policies	Examples of functions that were written using the Apache HTTP Server mod_rewrite engine, with examples of these functions after translation into Rewrite and Responder policies on the NetScaler.

Introduction to Policies and Expressions

Jun 04, 2015

For many NetScaler features, policies control how a feature evaluates data, which ultimately determines what the feature does with the data. A policy uses a logical expression, also called a rule, to evaluate requests, responses, or other data, and applies one or more actions determined by the outcome of the evaluation. Alternatively, a policy can apply a profile, which defines a complex action.

Some NetScaler features use default syntax policies, which provide greater capabilities than do the older, classic, policies. If you migrated to a newer release of the NetScaler software and have configured classic policies for features that now use default syntax policies, you might have to manually migrate policies to the default syntax.

This document contains the following details:

- [Classic and Default Syntax Policies](#)
- [Classic and Default Syntax Expressions](#)
- [Converting Classic Expressions to the Newer Default Expression Syntax](#)
- [Before You Proceed](#)

Classic and Default Syntax Policies

May 25, 2015

Classic policies evaluate basic characteristics of traffic and other data. For example, classic policies can identify whether an HTTP request or response contains a particular type of header or URL.

Default syntax policies can perform the same type of evaluations as classic policies. In addition, default syntax policies enable you to analyze more data (for example, the body of an HTTP request) and to configure more operations in the policy rule (for example, transforming data in the body of a request into an HTTP header).

In addition to assigning a policy an action or profile, you bind the policy to a particular point in the processing associated with the NetScaler features. The bind point is one factor that determines when the policy will be evaluated.

This document includes the following details:

- [Benefits of Using Default Syntax Policies](#)
- [Basic Components of a Classic or Default Syntax Policy](#)
- [How Different NetScaler Features Use Policies](#)
- [About Actions and Profiles](#)
- [About Policy Bindings](#)
- [About Evaluation Order of Policies](#)
- [Order of Evaluation Based on Traffic Flow](#)

Benefits of Using Default Syntax Policies

Default syntax policies use a powerful expression language that is built on a class-object model, and they offer several options that enhance your ability to configure the behavior of various NetScaler features. With default syntax policies, you can do the following:

- Perform fine-grained analyses of network traffic from layers 2 through 7.
- Evaluate any part of the header or body of an HTTP or HTTPS request or response.
- Bind policies to the multiple bind points that the default syntax policy infrastructure supports at the default, override, and virtual server levels.
- Use goto expressions to transfer control to other policies and bind points, as determined by the result of expression evaluation.
- Use special tools such as pattern sets, policy labels, rate limit identifiers, and HTTP callouts, which enable you to configure policies effectively for complex use cases.

Additionally, the configuration utility extends robust graphical user interface support for default syntax policies and expressions and enables users who have limited knowledge of networking protocols to configure policies quickly and easily. The configuration utility also includes a policy evaluation feature for default syntax policies. You can use this feature to evaluate a default syntax policy and test its behavior before you commit it, thus reducing the risk of configuration errors.

Basic Components of a Classic or Default Syntax Policy

Updated: 2013-09-02

Following are a few characteristics of both classic and default syntax policies:

Name.

Each policy has a unique name.

Rule.

The rule is a logical expression that enables the NetScaler feature to evaluate a piece of traffic or another object. For example, a rule can enable the NetScaler to determine whether an HTTP request originated from a particular IP address, or whether a Cache-Control header in an HTTP request has the value “No-Cache.”

Default syntax policies can use all of the expressions that are available in a classic policy, with the exception of classic expressions for the SSL VPN client. In addition, default syntax policies enable you to configure more complex expressions.

Bindings.

To ensure that the NetScaler can invoke a policy when it is needed, you associate the policy, or bind it, to one or more bind points.

You can bind a policy globally or to a virtual server. For more information, see "[About Policy Bindings.](#)"

An associated action.

An action is a separate entity from a policy. Policy evaluation ultimately results in the NetScaler performing an action. For example, a policy in the integrated cache can identify HTTP requests for .gif or .jpeg files. An action that you associate with this policy determines that the responses to these types of requests are served from the cache.

For some features, you configure actions as part of a more complex set of instructions known as a profile. For more information, see "[Order of Evaluation Based on Traffic Flow.](#)"

How Different NetScaler Features Use Policies

Updated: 2013-09-30

The NetScaler supports a variety of features that rely on policies for operation. The following table summarizes how the NetScaler features use policies.

Table 1. NetScaler Feature, Policy Type, and Policy Usage

Feature Name	Policy Type	How You Use Policies in the Feature
System	Classic	<p>For the Authentication function, policies contain authentication schemes for different authentication methods.</p> <p>For example, you can configure LDAP and certificate-based authentication schemes.</p> <p>You also configure policies in the Auditing function.</p>
DNS	Default	To determine how to perform DNS resolution for requests.
SSL	Classic and Default	<p>To determine when to apply an encryption function and add certificate information to clear text.</p> <p>To provide end-to-end security, after a message is decrypted, the SSL feature re-encrypts clear text and uses SSL to communicate with Web servers.</p>

Feature Name	Policy Type	How You Use Policies in the Feature
Compression	Classic and Default	To determine what type of traffic is compressed.
Integrated Caching	Default	To determine whether HTTP responses are cacheable.
Responder	Default	To configure the behavior of the Responder function.
Protection Features	Classic	To configure the behavior of the Filter, SureConnect, and Priority Queuing functions.
Content Switching	Classic and Default	<p>To determine what server or group of servers is responsible for serving responses, based on characteristics of an incoming request.</p> <p>Request characteristics include device type, language, cookies, HTTP method, content type, and associated cache server.</p>
AAA - Traffic Management	<p>Classic</p> <p>Exceptions:</p> <ul style="list-style-type: none"> • Traffic policies support only default syntax policies • Authorization policies support both classic and default syntax policies. 	<p>To check for client-side security before users log in and establish a session.</p> <p>Traffic policies, which determine whether single sign-on (SSO) is required, use only the default syntax.</p> <p>Authorization policies authorize users and groups that access intranet resources through the appliance.</p>
Cache Redirection	Classic	To determine whether responses are served from a cache or from an origin server.
Rewrite	Default	<p>To identify HTTP data that you want to modify before serving. The policies provide rules for modifying the data.</p> <p>For example, you can modify HTTP data to redirect a request to a new home page, or a new server, or a selected server based on the address of the incoming request, or you can modify the data to mask server information in a response for security purposes.</p> <p>The URL Transformer function identifies URLs in HTTP transactions and text files for the purpose of evaluating whether a URL should be transformed.</p>

Application Firewall Name	Policy Type	How You Use Policies in the Feature
NetScaler Gateway, Clientless Access function	Default	To define rewrite rules for general Web access using the NetScaler Gateway.
NetScaler Gateway	Classic	To determine how the NetScaler Gateway performs authentication, authorization, auditing, and other functions.

About Actions and Profiles

Updated: 2013-09-30

Policies do not themselves take action on data. Policies provide read-only logic for evaluating traffic. To enable a feature to perform an operation based on a policy evaluation, you configure actions or profiles and associate them with policies.

Note: Actions and profiles are specific to particular features. For information about assigning actions and profiles to features, see the documentation for the individual features.

About Actions

Actions are steps that the NetScaler takes, depending on the evaluation of the expression in the policy. For example, if an expression in a policy matches a particular source IP address in a request, the action that is associated with this policy determines whether the connection is permitted.

The types of actions that the NetScaler can take are feature specific. For example, in Rewrite, actions can replace text in a request, change the destination URL for a request, and so on. In Integrated Caching, actions determine whether HTTP responses are served from the cache or an origin server.

In some NetScaler features actions are predefined, and in others they are configurable. In some cases, (for example, Rewrite), you configure the actions using the same types of expressions that you use to configure the associated policy rule.

About Profiles

Some NetScaler features enable you to associate profiles, or both actions and profiles, with a policy. A profile is a collection of settings that enable the feature to perform a complex function. For example, in the application firewall, a profile for XML data can perform multiple screening operations, such as examining the data for illegal XML syntax or evidence of SQL injection.

Use of Actions and Profiles in Particular Features

The following table summarizes the use of actions and profiles in different NetScaler features. The table is not exhaustive. For more information about specific uses of actions and profiles for a feature, see the documentation for the feature.

Table 2. Use of Actions and Profiles in Different NetScaler Features

Feature	Use of an Action	Use of a Profile
Application firewall	Synonymous with a profile	All application firewall features use profiles to define complex behaviors, including pattern-based learning. You add these profiles to policies.
NetScaler Gateway	The following features of the NetScaler Gateway use actions: <ul style="list-style-type: none"> ● Pre-Authentication. Uses Allow and Deny actions. You add these actions to a profile. ● Authorization. Uses Allow and Deny actions. You add these actions to a policy. ● TCP Compression. Uses various actions. You add these actions to a policy. 	The following features use a profile: <ul style="list-style-type: none"> ● Pre-Authentication ● Session ● Traffic ● Clientless Access After configuring the profiles, you add them to policies.
Rewrite	You configure URL rewrite actions and add them to a policy.	Not used.
Integrated Caching	You configure caching and invalidation actions within a policy	Not used.
AAA - Traffic Management	You select an authentication type, set an authorization action of ALLOW or DENY, or set auditing to SYSLOG or NSLOG.	You can configure session profiles with a default timeout and authorization action.
Protection Features	You configure actions within policies for the following functions: <ul style="list-style-type: none"> ● Filter ● Compression ● Responder ● SureConnect 	Not used.
SSL	You configure actions within SSL policies	Not used.
System	The action is implied. For the Authentication function, it is either Allow or Deny. For Auditing, it is Auditing On or Auditing Off.	Not used.

Feature	Use of an Action	Use of a Profile
	The action is implied. It is either Drop Packets or the location of a DNS server.	
SSL Offload	The action is implied. It is based on a policy that you associate with an SSL virtual server or a service.	Not used.
Compression	Determine the type of compression to apply to the data	Not used.
Content Switching	The action is implied. If a request matches the policy, the request is directed to the virtual server associated with the policy.	Not used.
Cache Redirection	The action is implied. If a request matches the policy, the request is directed to the origin server.	Not used.

About Policy Bindings

Updated: 2013-09-30

A policy is associated with, or bound to, an entity that enables the policy to be invoked. For example, you can bind a policy to request-time evaluation that applies to all virtual servers. A collection of policies that are bound to a particular bind point constitutes a policy bank.

Following is an overview of different types of bind points for a policy:

Request time global.

A policy can be available to all components in a feature at request time.

Response time global.

A policy can be available to all components in a feature at response time.

Request time, virtual server-specific.

A policy can be bound to request-time processing for a particular virtual server. For example, you can bind a request-time policy to a cache redirection virtual server to ensure that particular requests are forwarded to a load balancing virtual server for the cache, and other requests are sent to a load balancing virtual server for the origin.

Response time, virtual server-specific.

A policy can also be bound to response-time processing for a particular virtual server.

User-defined policy label.

For default syntax policies, you can configure custom groupings of policies (policy banks) by defining a policy label and collecting a set of related policies under the policy label.

Other bind points.

The availability of additional bind points depends on type of policy (classic or default syntax), and specifics of the relevant NetScaler feature. For example, classic policies that you configure for the NetScaler Gateway have user and group bind points.

For additional information about default syntax policy bindings, see "[Binding Policies That Use the Default Syntax](#)" and "[Configuring a Policy Bank for a Virtual Server](#)". For additional information about classic policy bindings, see "[Configuring a Classic Policy](#)".

About Evaluation Order of Policies

For classic policies, policy groups and policies within a group are evaluated in a particular order, depending on the following:

- The bind point for the policy, for example, whether the policy is bound to request-time processing for a virtual server or global response-time processing. For example, at request time, the NetScaler evaluates all request-time classic policies before evaluating any virtual server-specific policies.
- The priority level for the policy. For each point in the evaluation process, a priority level that is assigned to a policy determines the order of evaluation relative to other policies that share the same bind point. For example, when the NetScaler evaluates a bank of request-time, virtual server-specific policies, it starts with the policy that is assigned to the lowest priority value. In classic policies, priority levels must be unique across all bind points.

For default syntax policies, as with classic policies, the NetScaler selects a grouping, or bank, of policies at a particular point in overall processing. Following is the order of evaluation of the basic groupings, or banks, of default syntax policies:

1. Request-time global override
2. Request-time, virtual server-specific (one bind point per virtual server)
3. Request-time global default
4. Response-time global override
5. Response-time virtual server-specific
6. Response-time global default

However, within any of the preceding banks of policies, the order of evaluation is more flexible than in classic policies. Within a policy bank, you can point to the next policy to be evaluated regardless of the priority level, and you can invoke policy banks that belong to other bind points and user-defined policy banks.

Order of Evaluation Based on Traffic Flow

As traffic flows through the NetScaler and is processed by various features, each feature performs policy evaluation. Whenever a policy matches the traffic, the NetScaler stores the action and continues processing until the data is about to leave the NetScaler. At that point, the NetScaler typically applies all matching actions. Integrated Caching, which only applies a final Cache or NoCache action, is an exception.

Some policies affect the outcome of other policies. Following are examples:

- If a response is served from the integrated cache, some other NetScaler features do not process the response or the request that initiated it.
- If the Content Filtering feature prevents a response from being served, no subsequent features evaluate the response.

If the application firewall rejects an incoming request, no other features can process it.

Classic and Default Syntax Expressions

May 25, 2015

One of the most fundamental components of a policy is its rule. A policy rule is a logical expression that enables the policy to analyze traffic. Most of the policy's functionality is derived from its expression.

An expression matches characteristics of traffic or other data with one or more parameters and values. For example, an expression can enable the NetScaler to accomplish the following:

- Determine whether a request contains a certificate.
- Determine the IP address of a client that sent a TCP request.
- Identify the data that an HTTP request contains (for example, a popular spreadsheet or word processing application).
- Calculate the length of an HTTP request.

This document includes the following details:

- [About Classic Expressions](#)
- [About Default Syntax Expressions](#)

About Classic Expressions

Classic expressions enable you to evaluate basic characteristics of data. They have a structured syntax that performs string matching and other operations.

Following are a few simple examples of classic expressions:

- An HTTP response contains a particular type of Cache Control header.

```
res.http.header Cache-Control contains public
```

- An HTTP response contains image data.

```
res.http.header Content-Type contains image/
```

- An SSL request contains a certificate.

```
req.ssl.client.cert exists
```

About Default Syntax Expressions

Updated: 2013-09-02

Any feature that uses default syntax policies also uses default syntax expressions. For information about which features use default syntax policies, see the table "[NetScaler Feature, Policy Type, and Policy Usage](#)."

Default syntax expressions have a few other uses. In addition to configuring default syntax expressions in policy rules, you configure default syntax expressions in the following situations:

Integrated Caching:

You use default syntax expressions to configure a selector for a content group in the integrated cache.

Load Balancing:

You use default syntax expressions to configure token extraction for a load balancing virtual server that uses the TOKEN

method for load balancing.

Rewrite:

You use default syntax expressions to configure rewrite actions.

Rate-based policies:

You use default syntax expressions to configure limit selectors when configuring a policy to control the rate of traffic to various servers.

Following are a few simple examples of default syntax expressions:

- An HTTP request URL contains no more than 500 characters.

```
http.req.url.length <= 500
```

- An HTTP request contains a cookie that has fewer than 500 characters.

```
http.req.cookie.length < 500
```

- An HTTP request URL contains a particular text string.

```
http.req.url.contains(".html")
```

Converting Classic Expressions to the Newer Default Expression Syntax

Sep 15, 2016

You can convert a classic expression to the default expression syntax by using the nspepi conversion tool. You can also use the tool to convert all the classic expressions in the NetScaler configuration to the default syntax (with the exception of NetScaler entities that currently support only classic expressions).

The conversion tool does not convert policies configured for the following features, because the features currently support only classic policies:

- Authentication, Pre-authentication
- SSL
- Cache redirection
- VPN (session, traffic, and tunnel traffic)
- Content filtering (The responder feature not only provides you with functionality that is equivalent to that provided by the content filtering feature but also surpasses the content filtering feature in the use cases that it supports. Additionally, responder supports the more powerful default syntax for policy expressions.)

The following NetScaler features support both classic and default syntax expressions and, therefore, support the conversion of classic expressions to default syntax expressions:

- Application firewall policies
- Authorization policies
- Named expressions
- Compression policies
- Content switching policies
- User-defined, rule-based tokens/persistency (the `-rule` parameter value that is specified for a load balancing virtual server)

This document includes the following details:

- [About the Conversion Process](#)
- [Converting Expressions](#)
- [Converting a NetScaler Configuration File](#)
- [Conversion Warnings](#)

About the Conversion Process

Updated: 2013-09-02

When parsing a NetScaler configuration file, the conversion tool performs the following actions:

1. In commands that create classic named expressions, the conversion tool replaces the names of the classic expressions with default syntax expressions.
2. In commands that support only the classic syntax, if classic named expressions are used, the conversion tool replaces the names of the classic expressions with the actual classic expressions they represent. This action ensures that the names of expressions in classic-only features do not reference the default syntax expressions created from Step 1.
3. In commands associated with entities that support both the classic syntax and the default syntax, the conversion tool replaces all classic expressions in commands with default syntax expressions.

Example

Consider the following sample configuration commands:

```
add policy expression ne_c1 "METHOD == GET"
add policy expression ne_c2 "ne_c1 || URL == /*.htm "
add filter policy pol1 -rule "ne_c2" -reqAction YES
add cmp policy pol2 -rule "REQ.HTTP.HEADER Accept CONTAINS \'text/html\'" -resAction COMPRESS
add cmp policy pol3 -rule "ne_c1 || ne_c2" -resAction GZIP
```

In the commands that create the classic named expressions `ne_c1` and `ne_c2`, the tool replaces the names of the expressions with actual default syntax expressions. This action, which corresponds to Step 1 described earlier, results in the following commands:

```
add policy expression ne_c2 "HTTP.REQ.METHOD.EQ(\'GET\')"
add policy expression ne_c1 "HTTP.REQ.URL.SUFFIX.EQ(\'htm\')
```

The filter policy command supports only the classic syntax. Therefore, the conversion tool replaces the classic named expression `ne_c1` with the actual classic expression it represents. Note that the tool replaces `ne_c1` in the expression for `ne_c2`, and then replaces `ne_c2` in the filter policy with the classic expression. This action, which corresponds to Step 2 described earlier, results in the following command:

```
add filter policy pol1 -rule "METHOD == GET || URL == /*.htm" -reqAction YES
```

The compression feature supports both classic and default syntax expressions. Therefore, in the command that creates the compression policy `pol2`, the conversion tool replaces the expression with a default syntax expression. This action, which corresponds to Step 3 described earlier, results in the following command:

```
add cmp policy pol2 -rule "HTTP.REQ.HEADER(\'Accept\').AFTER_STR(\'text/html\').LENGTH.GT(0)" -resAction COMPRESS
```

The command that creates the compression policy `pol3` is unaffected by the conversion process because, after the conversion process is complete, `ne_c1` and `ne_c2` reference the default syntax expressions that result from Step 1.

Client security messages are not supported in the newer default policy format and, therefore, are lost. The `SYS.EVAL_CLASSIC_EXPR` function is replaced with a default policy expression. The following entities support the `SYS.EVAL_CLASSIC_EXPR` function:

- DNS policies
- Rate limit selectors
- Cache selectors
- Cache policies
- Content switching policies
- Rewrite policies
- URL transformation policies
- Responder policies
- Application firewall policies
- Authorization policies
- Compression policies
- CVPN access policies

After performing the conversion, the tool saves the changes in a new configuration file. The new configuration file is

created in the directory in which the input file exists. The name of the new configuration file is the same as the name of the input configuration file except for the string `new_` used as a prefix. Conversion warnings are reported in a warning line at the end of the screen output. Additionally, a warning file is created in the directory in which the input configuration file resides. For more information about the warning file and the types of warnings that are reported, see "[Conversion Warnings](#)."

Converting Expressions

Updated: 2013-09-02

You can use the `nspepi` tool to convert a single classic expression to the default syntax. The `nspepi` tool must be run from the shell prompt on the NetScaler appliance.

To convert a classic expression to the default syntax by using the command line interface

At the shell prompt, type:

```
nspepi -e "<classic expression>"
```

Example

```
root@NS# nspepi -e "REQ.HTTP.URL == /*.htm"  
"HTTP.REQ.URL.REGEX_MATCH(re#/(.*)\.htm#)"
```

Converting a NetScaler Configuration File

Updated: 2013-09-02

You can use the `nspepi` tool to convert all the classic expressions in a NetScaler configuration file to the default syntax (except for those commands that do not support the default syntax). The `nspepi` tool must be run from the shell prompt on the NetScaler appliance.

To convert all the classic expressions in a NetScaler configuration file to the default syntax by using the command line interface

At the shell prompt, type:

```
nspepi -f "<ns config file>" -v
```

Example

```
root@NS# nspepi -f ns.conf  
OUTPUT: New configuration file created: new_ns.conf  
OUTPUT: New warning file created: warn_ns.conf  
WARNINGS: Total number of warnings due to bind commands: 18  
WARNINGS: Line numbers which has bind command issues: 305, 306, 706, 707, 708, 709, 710, 711, 712, 713,  
714, 715, 767, 768, 774, 775, 776, 777  
root@NS#
```

Conversion Warnings

When classic expressions that are included in CLI commands are upgraded to the default syntax, the number of characters in the expression might exceed the 1499-character limit. The commands that include expressions longer than 1499 characters fail when the configuration is being applied. You must manually update these commands.

In addition, multiple classic policies can be bound to a given bind point with priority 0 or with equal priority, but the default syntax policy infrastructure does not support a priority value of 0 or policies with the same priority at a given bind point. These commands fail when the configuration is being applied. The commands must be updated manually with the correct priority values.

The line numbers of lines that threw a warning during conversion are listed at the end of the output in a warning line. In addition, a warning file is created in the same directory as the one in which the old and new configuration files reside. The name of the warning file is the same as the name of the input configuration file except that the string warn_ is added as a prefix.

Before You Proceed

May 25, 2015

Before configuring expressions and policies, be sure you understand the relevant NetScaler feature and the structure of your data, as follows:

- Read the documentation on the relevant feature.
- Look at the data stream for the type of data that you want to configure.

You may want to run a trace on the type of traffic or content that you want to configure. This will give you an idea of the parameters and values, and operations on these parameters and values, that you need to specify in an expression.

Note: The NetScaler supports either classic or default syntax policies within a feature. You cannot have both types in the same feature. Over the past few releases, some NetScaler features have migrated from using classic policies and expressions to default syntax policies and expressions. If a feature of interest to you has changed to the default syntax format, you may have to manually migrate the older information. Following are guidelines for deciding if you need to migrate your policies:

- If you configured classic policies in a version of the Integrated Caching feature prior to release 9.0 and then upgrade to version 9.0 or later, there is no impact. All legacy policies are migrated to the default syntax policy format.
- For other features, you need to manually migrate classic policies and expressions to the default syntax if the feature has migrated to the default syntax.

Configuring Default Syntax Policies

Sep 30, 2013

You can create default syntax policies for various NetScaler features, including DNS, Rewrite, Responder, and Integrated Caching, and the clientless access function in the NetScaler Gateway. Policies control the behavior of these features.

When you create a policy, you assign it a name, a rule (an expression), feature-specific attributes, and an action that is taken when data matches the policy. After creating the policy, you determine when it is invoked by binding it globally or to either request-time or response-time processing for a virtual server.

Policies that share the same bind point are known as a *policy bank*. For example, all policies that are bound to a virtual server constitute the policy bank for the virtual server. When binding the policy, you assign it a priority level to specify when it is invoked relative to other policies in the bank. In addition to assigning a priority level, you can configure an arbitrary evaluation order for policies in a bank by specifying Goto expressions.

In addition to policy banks that are associated with a built-in bind point or a virtual server, you can configure *policy labels*. A policy label is a policy bank that is identified by an arbitrary name. You invoke a policy label, and the policies in it, from a global or virtual-server-specific policy bank. A policy label or a virtual-server policy bank can be invoked from multiple policy banks.

For some features, you can use the policy manager to configure and bind policies.

Rules for Names in Identifiers Used in Policies

Mar 20, 2012

The names of identifiers in the named expression, HTTP callout, pattern set, and rate limiting features must begin with an ASCII alphabet or an underscore (_). The remaining characters can be ASCII alphanumeric characters or underscores (_).

The names of these identifiers must not begin with the following reserved words:

- The words ALT, TRUE, or FALSE or the Q or S one-character identifier.
- The special-syntax indicator RE (for regular expressions) or XP (for XPath expressions).
- Expression prefixes, which currently are the following:
 - CLIENT
 - EXTEND
 - HTTP
 - SERVER
 - SYS
 - TARGET
 - TEXT
 - URL
 - MYSQL
 - MSSQL

Additionally, the names of these identifiers cannot be the same as the names of enumeration constants used in the policy infrastructure. For example, the name of an identifier cannot be IGNORECASE, YEAR, or LATIN2_CZECH_CS (a MySQL character set).

Note: The NetScaler appliance performs a case-insensitive comparison of identifiers with these words and enumeration constants. For example, names of the identifiers cannot begin with TRUE, True, or true.

Creating or Modifying a Policy

Nov 14, 2013

All policies have some common elements. Creating a policy consists, at minimum, of naming the policy and configuring a rule. The policy configuration tools for the various features have areas of overlap, but also differences. For the details of configuring a policy for a particular feature, including associating an action with the policy, see the documentation for the feature.

To create a policy, begin by determining the purpose of the policy. For example, you may want to define a policy that identifies HTTP requests for image files, or client requests that contain an SSL certificate. In addition to knowing the type of information that you want the policy to work with, you need to know the format of the data that the policy is analyzing.

Next, determine whether the policy is globally applicable, or if it pertains to a particular virtual server. Also consider the effect that the order in which your policies are evaluated (which will be determined by how you bind the policies) will have on the policy that you are about to configure.

To create a policy by using the command line interface

At the command prompt, type the following commands to create a policy and verify the configuration:

- add responder | dns | cs | rewrite | cache policy <policyName> -rule <expression> [<feature-specific information>]
- show rewrite policy <name>

Example 1:

```
add rewrite policy "pol_remove-ae" true "act_remove-ae"
```

```
Done
```

```
> show rewrite policy pol_remove-ae
```

```
  Name: pol_remove-ae
```

```
  Rule: true
```

```
  RewriteAction: act_remove-ae
```

```
  UndefAction: Use Global
```

```
  Hits: 0
```

```
  Undef Hits: 0
```

```
  Bound to: GLOBAL RES_OVERRIDE
```

```
  Priority: 90
```

```
  GotoPriorityExpression: END
```

```
Done
```

```
>
```

Example 2:

```
add cache policy BranchReportsCachePolicy -rule q{http.req.url.query.value("actionoverride").contains("branchReport s")} -action cache
```

```
Done
```

```
show cache policy BranchReportsCachePolicy
```

```
  Name: BranchReportsCachePolicy
```

```
  Rule: http.req.url.query.value("actionoverride").contains("branchReports")
```

```
  CacheAction: CACHE
```

```
  Stored in group: DEFAULT
```

```
  UndefAction: Use Global
```

```
  Hits: 0
```

```
  Undef Hits: 0
```

```
Done
```

Note: At the command line, quote marks within a policy rule (the expression) must be escaped or delimited with the q delimiter. For more information, see ["Configuring Default Syntax Expressions in a Policy."](#)

To create or modify a policy by using the configuration utility

1. In the navigation pane, expand the name of the feature for which you want to configure a policy, and then click Policies. For example, you can select Content Switching, Integrated Caching, DNS, Rewrite, or Responder.
2. In the details pane, click Add, or select an existing policy and click Open. A policy configuration dialog box appears.
3. Specify values for the following parameters. (An asterisk indicates a required parameter. For a term in parentheses, see the corresponding parameter in "Parameters for creating or modifying a policy.")
4. Click Create, and then click Close.
5. Click Save. A policy is added.

Note: After you create a policy, you can view the policy's details by clicking the policy entry in the configuration pane. Details that are highlighted and underlined are links to the corresponding entity (for example, a named expression).

Policy Configuration Examples

Sep 02, 2013

These examples show how policies and their associated actions are entered at the command line interface. In the configuration utility, the expressions would appear in the Expression window of the feature-configuration dialog box for the integrated caching or rewrite feature.

Following is an example of creating a caching policy. Note that actions for caching policies are built in, so you do not need to configure them separately from the policy.

```
add cache policy BranchReportsCachePolicy -rule q{http.req.url.query.value("actionoverride").contains("branchReports")} -action cache
```

Following is an example of a Rewrite policy and action:

```
add rewrite action myAction1 INSERT_HTTP_HEADER "myHeader" "valueForMyHeader"  
add rewrite policy myPolicy1 "http.req.url.contains(\"myURLstring\")" myAction1
```

Note: At the command line, quote marks within a policy rule (the expression) must be escaped or delimited with the q delimiter. For more information, see "[Configuring Default Syntax Expressions in a Policy.](#)"

Binding Policies That Use the Default Syntax

Sep 30, 2013

After defining a policy, you indicate when the policy is to be invoked by binding the policy to a bind point and specifying a priority level. You can bind a policy to only one bind point. A bind point can be global, that is, it can apply to all virtual servers that you have configured. Or, a bind point can be specific to a particular virtual server, which can be either a load balancing or a content switching virtual server. Not all bind points are available for all features.

The order in which policies are evaluated determines the order in which they are applied, and features typically evaluate the various policy banks in a particular order. Sometimes, however, other features can affect the order of evaluation. Within a policy bank, the order of evaluation depends on the values of parameters configured in the policies. Most features apply all of the actions associated with policies whose evaluation results in a match with the data that is being processed. The integrated caching feature is an exception.

Feature-Specific Differences in Policy Bindings

You can bind policies to built-in, global bind points (or banks), to virtual servers, or to policy labels.

However, the NetScaler features differ in terms of the types of bindings that are available. The following table summarizes how you use policy bindings in various NetScaler features that use policies.

Table 1. Feature-Specific Bindings for Policies

Feature Name	Virtual Servers Configured in the Feature	Policies Configured in the Feature	Bind Points Configured for the Policies	Use of Policies in the Feature
DNS	none	DNS policies	Global	To determine how to perform DNS resolution for requests.
Content Switching Note: This feature can support either or classic policies or policies that use the default syntax, but not both.	Content Switching (CS)	Content Switching policies	<ul style="list-style-type: none">• Content switching or cache redirection virtual server• Policy label	To determine what server or group of servers is responsible for serving responses, based on characteristics of an incoming request. Request characteristics include device type, language, cookies, HTTP method, content type, and associated cache server.
Integrated Caching	none	Caching policies	<ul style="list-style-type: none">• Global override• Global default	To determine whether HTTP responses can be stored in, and served from, the NetScaler appliance's integrated cache.

Feature Name	Virtual Servers Configured in the Feature	Policies Configured in the Feature	Bind Points Configured for the Policies	Use of Policies in the Feature
			<ul style="list-style-type: none"> • Policy label • Load balancing, content switching, or SSL offload virtual server 	
Responder	none	Responder policies	<ul style="list-style-type: none"> • Global override • Global default • Policy label • Load balancing, content switching, or SSL offload virtual server 	To configure the behavior of the Responder function.
Rewrite	none	Rewrite policies	<ul style="list-style-type: none"> • Global override • Global default • Policy label • Load balancing, content switching, or SSL offload virtual server 	<p>To identify HTTP data that you want to modify before serving. The policies provide rules for modifying the data.</p> <p>For example, you can modify HTTP data to redirect a request to a selected server based on the address of the incoming request, or to mask server information in a response for security purposes.</p>
URL Transform function in the Rewrite feature	none	Transformation policies	<ul style="list-style-type: none"> • Global override • Global default 	To identify URLs in HTTP transactions and text files for the purpose of evaluating whether a URL should be altered.

Feature Name	Virtual Servers Configured in the VPN server Feature	Policies Configured in the Feature	Policy Bind Points Configured for the Policies	Use of Policies in the Feature
NetScaler Gateway (clientless VPN functions only)		Clientless Access policies	<ul style="list-style-type: none"> • VPN Global • VPN server 	To determine how the NetScaler Gateway performs authentication, authorization, auditing, and other functions, and to define rewrite rules for general Web access using the NetScaler Gateway.

Bind Points and Order of Evaluation

For a policy to take effect, you must ensure that the policy is invoked at some point during processing. To do so, you associate the policy with a bind point. The collection of policies that is bound to a bind point is known as a policy bank.

Following are the bind points that the NetScaler evaluates, listed in the typical order of evaluation within a policy bank

1. **Request-time override.** When a request flows through a feature, the NetScaler first evaluates request-time override policies for the feature.
2. **Request-time Load Balancing virtual server.** If policy evaluation cannot be completed after all the request-time override policies have been evaluated, the NetScaler processes request-time policies for load balancing virtual servers.
3. **Request-time Content Switching virtual server.** If policy evaluation cannot be completed after all the request-time policies for load balancing virtual servers have been evaluated, the NetScaler processes request-time policies for content switching virtual servers.
4. **Request-time default.** If policy evaluation cannot be completed after all request-time, virtual server-specific policies have been evaluated, the NetScaler processes request-time default policies.
5. **Response-time override.** At response time, the NetScaler starts with policies that are bound to the response-time override bind point.
6. **Response-time Load Balancing virtual server.** If policy evaluation cannot be completed after all response-time override policies have been evaluated, the NetScaler process the response-time policies for load balancing virtual servers.
7. **Response-time Content Switching virtual server.** If policy evaluation cannot be completed after all policies have been evaluated for load balancing virtual servers, the NetScaler process the response-time policies for content switching virtual servers.
8. **Response-time default.** If policy evaluation cannot be completed after all response-time, virtual-server-specific policies have been evaluated, the NetScaler processes response-time default policies.

Policy Evaluation across Features

In addition to attending to evaluation of policies within a feature, if you have bound policies to a content switching virtual server, note that these policies are evaluated before other policies. Binding a policy to a content switching vserver produces a different result in NetScaler versions 9.0.x and later than in 8.x versions. In NetScaler 9.0 and later versions, evaluation occurs as follows:

- Content switching policies are evaluated before other policies. If a content switching policy evaluates to TRUE, the target load balancing vserver is selected.
- If all content switching policies evaluate to FALSE, the default load balancing vserver under the content switching VIP is selected.

After a target load balancing vserver is selected by the content switching process, policies are evaluated in the following

order:

1. Policies that are bound to the global override bind point.
2. Policies that are bound to the default load balancing vserver.
3. Policies that are bound to the target content switching vserver.
4. Policies that are bound to the global default bind point.

To be sure that the policies are evaluated in the intended order, follow these guidelines:

- Make sure that the default load balancing vserver is not directly reachable from the outside; for example, the vserver IP address can be 0.0.0.0.
- To prevent exposing internal data on the load balancing default vserver, configure a policy to respond with a “503 Service Unavailable” status and bind it to the default load balancing vserver.

Entries in a Policy Bank

Each entry in a policy bank has, at minimum, a policy and a priority level. You can also configure entries that change the priority-based evaluation order, and you can configure entries that invoke external policy banks.

The following table summarizes each entry in a policy bank.

Table 2. Format of Each Entry in a Policy Bank

Policy Name	Priority	Goto Expression	Invocation Type	Policy Bank to Be Invoked
The policy name, or a “dummy” policy named NOPOLICY. The NOPOLICY entry controls evaluation flow without processing a rule.	An integer.	Optional. Identifies the next policy in the bank to evaluate, or ends any further evaluation	Optional. Indicates that an external policy bank will be invoked. This field restricts the choices to a global policy label or a virtual server.	Optional. Used with Invocation Type. This is the label for a policy bank or a virtual server name. The NetScaler returns to the current bank after processing the external bank.

If the policy evaluates to TRUE, the NetScaler stores the action that is associated with the policy. If the policy evaluates to FALSE, the NetScaler evaluates the next policy. If the policy is neither TRUE nor FALSE, the NetScaler uses the associated Undef (undefined) action.

Evaluation Order within a Policy Bank

Within a policy bank, the evaluation order depends on the following items:

A priority.

The most minimal amount of information about evaluation order is a numeric priority level. The lower the number, the higher the priority.

A Goto expression.

If supplied, the Goto expression indicates the next policy to be evaluated, typically within the same policy bank.. Goto expressions can only proceed forward in a bank. To prevent looping, a policy bank configuration is not valid if a Goto statement points backwards in the bank.

Invocation of other policy banks.

Any entry can invoke an external policy bank. The NetScaler provides a built-in entity named NOPOLICY that does not have a rule. You can add a NOPOLICY entry in a policy bank when you want to invoke another policy bank, but do not want to process any other rules prior to the invocation. You can have multiple NOPOLICY entries in multiple policy banks.

Values for a Goto expression are as follows:

NEXT.

This keyword selects the policy with the next higher priority level in the current policy bank.

An integer.

If you supply an integer, it must match the priority level of another policy in the current policy bank.

END.

This keyword stops evaluation after processing the current policy, and no additional policies in this bank are processed.

Blank.

If the Goto expression is empty, it is the same as specifying END.

A numeric expression.

This is a default syntax expression that resolves to a priority number for another policy in the current bank.

USE_INVOCATION_RESULT.

This phrase can be used only if you are invoking an external policy bank. Entering this phrase causes the NetScaler to perform one of the following actions:

- If the final Goto in the invoked policy bank has a value of END or is empty, the invocation result is END, and evaluation stops.
- If the final Goto expression in the invoked policy bank is anything other than END, the NetScaler performs a NEXT.

The following table illustrates a policy bank that uses Goto statements and policy bank invocations.

Table 3. Example of a Policy Bank That Uses Gotos and External Bank Invocations

Policy Name	Priority	Goto	Invocation	Policy Bank to Be Invoked
ClientCertificatePolicy (rule: does the request contain a client certificate?)	100	300	None	None
SubnetPolicy (rule: is the client from a private subnet?)	200	NEXT	None	None
NOPOLICY	300	USE INVOCATION RESULT	Request vserver	My_Request_VServer

NO POLICY Policy Name	350 Priority	USE Goto INVOCATION RESULT	Policy Invocation Label	My Policy Label Policy Bank to Be Invoked
WorkingHoursPolicy (rule: is it working hours?)	400	END	None	None

How Policy Evaluation Ends

Evaluation of a policy bank ends when one of the following takes place:

- A policy evaluates to TRUE and its Goto statement value is END.
No further policies or policy banks in this feature are evaluated.
- An external policy bank is invoked, its evaluation returns an END, and the Goto statement uses a value of USE_INVOCATION_RESULT or END.
Evaluation continues with the next policy bank for this feature. For example, if the current bank is the request-time override bank, the NetScaler next evaluates request-time policy banks for the virtual servers.
- The NetScaler has walked through all the policy banks in this feature, but has not encountered an END.
If this is the last entry to be evaluated in this policy bank, the NetScaler proceeds to the next feature.

How Features Use Actions after Policy Evaluation

After evaluating all relevant policies for a particular data point (for example, an HTTP request), the NetScaler stores all the actions that are associated with any policy that matched the data.

For most features, all the actions from matching policies are applied to a traffic packet as it leaves the NetScaler. The Integrated Caching feature only applies one action: CACHE or NOCACHE. This action is associated with the policy with the lowest priority value in the “highest priority” policy bank (for example, request-time override policies are applied before virtual server-specific policies).

Binding a Policy Globally

Nov 14, 2013

The following binding procedures are typical. However, refer to the documentation for the feature of interest to you for complete instructions.

To bind an Integrated Caching policy globally by using the command line interface

At the command prompt, type the following commands to bind an Integrated Caching policy and verify the configuration:

- bind cache global <policy> -priority <positiveInteger> [-type REQ_OVERRIDE | REQ_DEFAULT | RES_OVERRIDE | RES_DEFAULT]
- show cache global

Example

```
bind cache global _nonPostReq -priority 100 -type req_default
```

```
Done
```

```
> show cache global
```

```
1) Global bindpoint: REQ_DEFAULT
```

```
Number of bound policies: 2
```

```
2) Global bindpoint: RES_DEFAULT
```

```
Number of bound policies: 1
```

```
Done
```

The type argument is optional to maintain backward compatibility. If you omit the type, the policy is bound to REQ_DEFAULT or RES_DEFAULT, depending on whether the policy rule is a response-time or a request-time expression.

To bind a Rewrite policy globally by using the command line interface

At the command prompt, type the following commands to bind a Rewrite policy and verify the configuration:

- bind rewrite global <policyName> <priority> [-type REQ_OVERRIDE | REQ_DEFAULT | RES_OVERRIDE | RES_DEFAULT]
- show rewrite global

Example

```
bind rewrite global pol_remove-pdf 100
```

```
Done
```

```
> show rewrite global
```

```
1) Global bindpoint: REQ_DEFAULT
```

```
Number of bound policies: 1
```

```
2) Global bindpoint: REQ_OVERRIDE
```

```
Number of bound policies: 1
```

```
Done
```

The type argument is optional for globally bound policies, to maintain backward compatibility. If you omit the type, the policy is bound to REQ_DEFAULT or RES_DEFAULT, depending on whether the policy rule is a response-time or a request-time expression.

To bind a compression policy globally by using the command line interface

At the command prompt, type the following commands to bind a compression policy and verify the configuration:

- bind cmp global <policyName> -priority <positiveInteger> [-type REQ_OVERRIDE | REQ_DEFAULT | RES_OVERRIDE | RES_DEFAULT]
- show cmp global

Example

```
> bind cmp global cmp_pol_1 -priority 100
Done
> show cmp policy cmp_pol_1
  Name: cmp_pol_1
  Rule: HTTP.REQ.URL.SUFFIX.EQ("BMP")
  Response Action: COMPRESS
  Hits: 0

  Policy is bound to following entities
  1) GLOBAL REQ_DEFAULT
  Priority: 100
  GotoPriorityExpression: END
Done
>
```

To bind a Responder policy globally by using the command line interface

At the command prompt, type the following commands to bind a Responder policy and verify the configuration:

- bind responder global <policyName> <priority> [-type OVERRIDE | DEFAULT]
- show responder global

Example

```
bind responder global pol404Error1 200
Done
> show responder global
1) Global bindpoint: REQ_DEFAULT
   Number of bound policies: 1

Done
```

To bind a DNS policy globally by using the command line interface

At the command prompt, type the following commands to bind a DNS policy and verify the configuration:

- bind dns global <policyName> <priority>
- show dns global

Example

```
> bind dns global pol_ddos_drop1 150
Done
> show dns global
Policy name : pol_ddos_drop
Priority : 100
```

```
Goto expression : END
Policy name : pol_ddos_drop1
Priority : 150
Done
>
```

To bind an Integrated Caching, Responder, Rewrite, or Compression policy globally by using the configuration utility

1. In the navigation pane, click the name of the feature for which you want to bind the policy.
2. In the details pane, click <Feature Name> policy manager.
3. In the Policy Manager dialog box, select the bind point to which you want to bind the policy (for example, for Integrated Caching, Rewrite, or Compression, you could select Request and Default Global). The Responder does not differentiate between request-time and response-time policies.
4. Click Insert Policy and, from the Policy Name pop-up menu, select the policy name. A priority is assigned automatically to the policy, but you can click the cell in the Priority column and drag it anywhere within the dialog box if you want the policy to be evaluated after other policies in this bank. The priority is automatically reset. Note that priority values within a policy bank must be unique.
5. Click Apply Changes.
6. Click Close. A message in the status bar indicates that the policy is bound successfully.

To bind a DNS policy globally by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.
3. In the global bindings dialog box, click Insert Policy, and select the policy that you want to bind globally.
4. Click in the Priority field and enter the priority level.
5. Click OK. A message in the status bar indicates that the policy is bound successfully.

Binding a Policy to a Virtual Server

Nov 14, 2013

A globally bound policy applies to all load balancing and content switching virtual servers.

Note that when binding a policy to a virtual server, you must identify it as a request-time or a response-time policy.

To bind a policy to a load balancing or content switching virtual server by using the command line interface

At the command prompt, type the following commands to bind a policy to a load balancing or content switching virtual server and verify the configuration:

- bind lb|cs vserver <virtualServerName> -policyName <policyName> -priority <positiveInteger> -type REQUEST | RESPONSE
- show lb vserver <name>

Example

```
> bind lb vserver lbvip -policyName ns_cmp_msapp -priority 50
Done
> show lb vserver lbvip
  lbvip (8.7.6.6:80) - HTTP    Type: ADDRESS
  State: DOWN
  Last state change was at Wed Jul 15 05:54:24 2009 (+226 ms)
  Time since last state change: 28 days, 01:57:26.350
  Effective State: DOWN
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Port Rewrite : DISABLED
  No. of Bound Services : 0 (Total)    0 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE
  Vserver IP and Port insertion: OFF
  Push: DISABLED  Push VServer:
  Push Multi Clients: NO
  Push Label Rule: none
```

1) **Policy : ns_cmp_msapp Priority:50**

2) Policy : cf-pol Priority:1 Inherited

Done

To bind a policy to an SSL offload virtual server by using the command line interface

At the command prompt, type the following commands to bind a policy to an SSL offload virtual server and verify the configuration:

```
bind ssl vserver <vServerName>@ -policyName <policyName> -priority <positiveInteger>
```

To bind a policy to a virtual server by using the configuration utility

1. In the navigation pane, expand Traffic Management > Load Balancing, Traffic Management > Content Switching, Traffic Management > SSL Offload, Security > AAA- Application Traffic, or NetScaler Gateway, and then click Virtual Servers.
2. In the details pane, double-click the virtual server to which you want to bind the policy, and then click Open.
3. On the Policies tab, click the icon for the type of policy that you want to bind (the choices are feature-specific), and then click the name of the policy. Note that for some features, you can bind both classic policies and policies that use the default syntax to the virtual server.
4. If you are binding a policy to a Content Switching virtual server, in the Target field select a load balancing virtual server to which traffic that matches the policy is sent.
5. Click OK. A message in the status bar indicates that the policy is bound successfully.

Displaying Policy Bindings

Oct 29, 2013

You can display policy bindings to verify that they are correct.

To display policy bindings by using the command line interface

At the command prompt, type the following commands to display policy bindings and verify the configuration:
show rewrite policy <name>

Example

```
> show rewrite policy pol_remove-pdf
```

```
  Name: pol_remove-pdf
```

```
  Rule: http.req.url.contains(".pdf")
```

```
  RewriteAction: act_remove-ae
```

```
  UndefAction: Use Global
```

```
  Hits: 0
```

```
  Undef Hits: 0
```

```
  Bound to: GLOBAL REQ_DEFAULT
```

```
  Priority: 100
```

```
  GotoPriorityExpression: END
```

```
Done
```

```
>
```

To display global policy bindings for Integrated Caching, Rewrite, or Responder by using the configuration utility

1. In the navigation pane, expand the feature that contains the policy that you want to view, and then click Policies.
2. In the details pane, click the policy. Bound policies have a check mark next to them.
3. At the bottom of the page, under Details, next to Bound to, view the entity to which the policy is bound.

To display global policy bindings for DNS or Clientless Access in the NetScaler Gateway by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.

To display global policy bindings for Content Switching by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. In detailed pane, select policy.
3. In the details pane, click Show Bindings.

Unbinding a Policy

Nov 14, 2013

If you want to re-assign a policy or delete it, you must first remove its binding.

To unbind an integrated caching, rewrite, or compression default syntax policy globally by using the command line interface

At the command prompt, type the following commands to unbind an integrated caching, rewrite, or compression default syntax policy globally and verify the configuration:

- unbind cache | rewrite | cmp global <policyName> [-type req_override | req_default | res_override | res_default] [-priority <positiveInteger>]
- show cache | rewrite | cmp global

Example

```
> unbind cache global_nonPostReq
```

```
Done
```

```
> show cache global
```

```
1) Global bindpoint: REQ_DEFAULT  
   Number of bound policies: 1
```

```
2) Global bindpoint: RES_DEFAULT  
   Number of bound policies: 1
```

```
Done
```

The priority is required only for the “dummy” policy named NOPOLICY.

To unbind a responder policy globally by using the command line interface

At the command prompt, type the following commands to unbind a responder policy globally and verify the configuration:

- unbind responder global <policyName> [-type override | default] [-priority <positiveInteger>]
- show responder global

Example

```
> unbind responder global pol404Error
```

```
Done
```

```
> show responder global
```

```
1) Global bindpoint: REQ_DEFAULT  
   Number of bound policies: 1
```

```
Done
```

The priority is required only for the “dummy” policy named NOPOLICY.

To unbind a DNS policy globally by using the command line interface

At the command prompt, type the following commands to unbind a DNS policy globally and verify the configuration:

- unbind responder global <policyName>
- unbind responder global

Example

```
unbind dns global dfgdfg
Done
show dns global
Policy name : dfgdfggfghg
  Priority : 100
  Goto expression : END
Done
```

To unbind a default syntax policy from a virtual server by using the command line interface

At the command prompt, type the following commands to unbind a default syntax policy from a virtual server and verify the configuration:

- unbind cs vserver <name> -policyName <policyName> [-priority <positiveInteger>] [-type REQUEST | RESPONSE]
- show lb vserver <name>

Example

```
unbind cs vserver vs-cont-switch -policyName pol1
Done
> show cs vserver vs-cont-switch
vs-cont-switch (10.102.29.10:80) - HTTP Type: CONTENT
State: UP
Last state change was at Wed Aug 19 08:56:55 2009 (+18 ms)
Time since last state change: 0 days, 02:47:55.750
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Port Rewrite : DISABLED
State Update: DISABLED
Default: Content Precedence: RULE
Vserver IP and Port insertion: OFF
Case Sensitivity: ON
Push: DISABLED Push VServer:
Push Label Rule: none
Done
```

The priority is required only for the “dummy” policy named NOPOLICY.

To unbind an integrated caching, responder, rewrite, or compression default syntax policy globally by using the configuration utility

1. In the navigation pane, click the feature with the policy that you want to unbind (for example, Integrated Caching).
2. In the details pane, click <Feature Name> policy manager.
3. In the Policy Manager dialog box, select the bind point with the policy that you want to unbind, for example, Default Global.
4. Click the policy name that you want to unbind, and then click Unbind Policy.
5. Click Apply Changes.
6. Click Close. A message in the status bar indicates that the policy is unbound successfully.

To unbind a DNS policy globally by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.
3. In the Global Bindings dialog box, select policy and click unbind policy.
4. Click OK. A message in the status bar indicates that the policy is unbinded successfully.

To unbind a default syntax policy from a load balancing or content switching virtual server by using the configuration utility

1. Navigate to Traffic Management, and expand Load Balancing or Content Switching, and then click Virtual Servers.
2. In the details pane, double-click the virtual server from which you want to unbind the policy.
3. On the Policies tab, in the Active column, clear the check box next to the policy that you want to unbind.
4. Click OK. A message in the status bar indicates that the policy is unbinded successfully.

Creating Policy Labels

May 25, 2015

In addition to the built-in bind points where you set up policy banks, you can also configure user-defined policy labels and associate policies with them.

Within a policy label, you bind policies and specify the order of evaluation of each policy relative to others in the bank of policies for the policy label. The NetScaler also permits you to define an arbitrary evaluation order as follows:

- You can use “goto” expressions to point to the next entry in the bank to be evaluated after the current one.
- You can use an entry in a policy bank to invoke another bank.

This document includes the following details:

- [Creating Policy Labels](#)
- [Binding a Policy to a Policy Label](#)

Creating Policy Labels

Updated: 2013-11-14

Each feature determines the type of policy that you can bind to a policy label, the type of load balancing virtual server that you can bind the label to, and the type of content switching virtual server from which the label can be invoked. For example, a TCP policy label can only be bound to a TCP load balancing virtual server. You cannot bind HTTP policies to a policy label of this type. And you can invoke a TCP policy label only from a TCP content switching virtual server.

After configuring a new policy label, you can invoke it from one or more banks for the built-in bind points.

To create a caching policy label by using the command line interface

At the command prompt, type the following commands to create a Caching policy label and verify the configuration:

- `add cache policylabel <labelName> -evaluates req|res`
- `show cache policylabel<labelName>`

Example

```
> add cache policylabel lbl-cache-pol -evaluates req
Done
```

```
> show cache policylabel lbl-cache-pol
Label Name: lbl-cache-pol
Evaluates: REQ
Number of bound policies: 0
Number of times invoked: 0
Done
>
```

To create a Content Switching policy label by using the command line interface

At the command prompt, type the following commands to create a Content Switching policy label and verify the configuration:

- `add cs policylabel <labelName> http|tcp|rtsp|ssl`

- show cs policylabel <labelName>

Example

```
> add cs policylabel lbl-cs-pol http
Done
> show cs policylabel lbl-cs-pol
  Label Name: lbl-cs-pol
  Label Type: HTTP
  Number of bound policies: 0
  Number of times invoked: 0
Done
```

To create a Rewrite policy label by using the command line interface

At the command prompt, type the following commands to create a Rewrite policy label and verify the configuration:

- add rewrite policylabel <labelName> http_req | http_res | url | text | clientless_vpn_req | clientless_vpn_res
- show rewrite policylabel <labelName>

Example

```
> add rewrite policylabel lbl-rewrt-pol http_req
Done

> show rewrite policylabel lbl-rewrt-pol
  Label Name: lbl-rewrt-pol
  Transform Name: http_req
  Number of bound policies: 0
  Number of times invoked: 0
Done
```

To create a Responder policy label by using the command line interface

At the command prompt, type the following commands to create a Responder policy label and verify the configuration:

- add responder policylabel <labelName>
- show responder policylabel <labelName>

Example

```
> add responder policylabel lbl-respndr-pol
Done

> show responder policylabel lbl-respndr-pol
  Label Name: lbl-respndr-pol
  Number of bound policies: 0
  Number of times invoked: 0
Done
```

Note: Invoke this policy label from a policy bank. For more information, see "[Binding a Policy to a Policy Label](#)."

To create a policy label by using the configuration utility

1. In the navigation pane, expand the feature for which you want to create a policy label, and then click Policy Labels. The choices are Integrated Caching, Rewrite, Content Switching, or Responder.
2. In the details pane, click Add.
3. In the Name box, enter a unique name for this policy label.
4. Enter feature-specific information for the policy label. For example, for Integrated Caching, in the Evaluates drop-down menu, you would select REQ if you want this policy label to contain request-time policies, or select RES if you want this policy label to contain response-time policies. For Rewrite, you would select a Transform name.
5. Click Create.
6. Configure one of the built-in policy banks to invoke this policy label. For more information, see "[Binding a Policy to a Policy Label](#)." A message in the status bar indicates that the policy label is created successfully.

Binding a Policy to a Policy Label

As with policy banks that are bound to the built-in bind points, each entry in a policy label is a policy that is bound to the policy label. As with policies that are bound globally or to a vserver, each policy that is bound to the policy label can also invoke a policy bank or a policy label that is evaluated after the current entry has been processed. The following table summarizes the entries in a policy label.

Name

The name of a policy, or, to invoke another policy bank without evaluating a policy, the “dummy” policy name NOPOLICY. You can specify NOPOLICY more than once in a policy bank, but you can specify a named policy only once.

Priority

An integer. This setting can work with the Goto expression.

Goto Expression

Determines the next policy to evaluate in this bank. You can provide one of the following values:

NEXT:

Go to the policy with the next higher priority.

END:

Stop evaluation.

USE_INVOCATION_RESULT:

Applicable if this entry invokes another policy bank. If the final Goto in the invoked bank has a value of END, evaluation stops. If the final Goto is anything other than END, the current policy bank performs a NEXT.

Positive number:

The priority number of the next policy to be evaluated.

Numeric expression:

An expression that produces the priority number of the next policy to be evaluated.

The Goto can only proceed forward in a policy bank.

If you omit the Goto expression, it is the same as specifying END.

Invocation Type

Designates a policy bank type. The value can be one of the following:

Request Vserver:

Invokes request-time policies that are associated with a virtual server.

Response Vserver:

Invokes response-time policies that are associated with a virtual server.

Policy label:

Invokes another policy bank, as identified by the policy label for the bank.

Invocation Name

The name of a virtual server or a policy label, depending on the value that you specified for the Invocation Type.

Configuring a Policy Label or Virtual Server Policy Bank

May 25, 2015

After you have created policies, and created policy banks by binding the policies, you can perform additional configuration of policies within a label or policy bank. For example, before you configure invocation of an external policy bank, you might want to wait until you have configured that policy bank.

This document includes the following details:

- [Configuring a Policy Label](#)
- [Configuring a Policy Bank for a Virtual Server](#)

Configuring a Policy Label

Updated: 2013-11-14

A policy label consists of a set of policies and invocations of other policy labels and virtual server-specific policy banks. An Invoke parameter enables you to invoke a policy label or a virtual server-specific policy bank from any other policy bank. A special-purpose NoPolicy entry enables you to invoke an external bank without processing an expression (a rule). The NoPolicy entry is a "dummy" policy that does not contain a rule.

For configuring policy labels from the NetScaler command line, note the following elaborations of the command syntax:

- gotoPriorityExpression is configured as described in "[Entries in a Policy Bank](#)."
- The type argument is required. This is unlike binding a conventional policy, where this argument is optional.
- You can invoke the bank of policies that are bound to a virtual server by using the same method as you use for invoking a policy label.

To configure a policy label by using the command line interface

At the command prompt, type the following commands to configure a policy label and verify the configuration:

- `bind cache | rewrite | responder policylabel <policylabelName> -policyName <policyName> -priority <priority> [-gotoPriorityExpression <gotopriorityExpression>] [-invoke reqvserver | resvserver | policylabel <policyLabelName> | <vserverName>]`
- `show cache | rewrite | responder policylabel <policylabelName>`

Example

```
bind cache policylabel _reqBuiltinDefaults -policyName _nonGetReq -priority 100
```

```
Done
```

```
show cache policylabel _reqBuiltinDefaults
```

```
Label Name: _reqBuiltinDefaults
```

```
Evaluates: REQ
```

```
Number of bound policies: 3
```

```
Number of times invoked: 0
```

```
1) Policy Name: _nonGetReq
```

```
Priority: 100
```

```
GotoPriorityExpression: END
```

```
2) Policy Name: _advancedConditionalReq
```

```
Priority: 200
```

```
GotoPriorityExpression: END
```

```
3) Policy Name: _personalizedReq
```

```
Priority: 300
```

```
GotoPriorityExpression: END
```

```
Done
```

To invoke a policy label from a Rewrite policy bank with a NOPOLICY entry by using the command line interface

At the command prompt, type the following commands to invoke a policy label from a Rewrite policy bank with a NOPOLICY entry and verify the configuration:

- `bind rewrite global <policyName> <priority> <gotopriorityExpression> -type REQ_OVERRIDE | REQ_DEFAULT | RES_OVERRIDE | RES_DEFAULT -invoke reqvserver | resvserver | policylabel <policyLabelName> | <vserverName>`
- `show rewrite global`

Example

```
> bind rewrite global NOPOLICY 100 -type REQ_DEFAULT -invoke policylabel lbl-rewrt-pol
```

```

Done
> show rewrite global
1) Global bindpoint: REQ_DEFAULT
   Number of bound policies: 1

2) Global bindpoint: REQ_OVERRIDE
   Number of bound policies: 1
Done

```

To invoke a policy label from an Integrated Caching policy bank by using the command line interface

At the command prompt, type the following commands to invoke a policy label from an Integrated Caching policy bank and verify the configuration:

- bind cache global NOPOLICY -priority <priority> -gotoPriorityExpression <gotopriorityExpression> -type REQ_OVERRIDE | REQ_DEFAULT | RES_OVERRIDE | RES_DEFAULT -invoke reqvserver | resvserver | policylabel <policyLabelName> | <vserverName>
- show cache global

Example

```

bind cache global NOPOLICY -priority 100 -gotoPriorityExpression END -type REQ_DEFAULT -invoke policylabel lbl-cache-pol
Done
> show cache global
1) Global bindpoint: REQ_DEFAULT
   Number of bound policies: 2

2) Global bindpoint: RES_DEFAULT
   Number of bound policies: 1

Done

```

To invoke a policy label from a Responder policy bank by using the command line interface

At the command prompt, type the following commands to invoke a policy label from a Responder policy bank and verify the configuration:

- bind responder global NOPOLICY <priority> <gotopriorityExpression> -type OVERRIDE | DEFAULT -invoke vserver | policylabel <policyLabelName> | <vserverName>
- show responder global

Example

```

> bind responder global NOPOLICY 100 NEXT -type DEFAULT -invoke policylabel lbl-respndr-pol
Done
> show responder global
1) Global bindpoint: REQ_DEFAULT
   Number of bound policies: 2

Done

```

To configure a policy label by using the configuration utility

1. In the navigation pane, expand the feature for which you want to configure a policy label, and then click Policy Labels. The choices are Integrated Caching, Rewrite, or Responder.
2. In the details pane, double-click the label that you want to configure.
3. If you are adding a new policy to this policy label, click Insert Policy, and in the Policy Name field, select New Policy. For more information about adding a policy, see "[Creating or Modifying a Policy](#)." Note that if you are invoking a policy bank, and do not want a rule to be evaluated prior to the invocation, click Insert Policy, and in the Policy Name field select NOPOLICY.
4. For each entry in this policy label, configure the following:

Policy Name:

This is already determined by the Policy Name, new policy, or NOPOLICY entry that you inserted in this bank.

Priority:

A numeric value that determines either an absolute order of evaluation within the bank, or is used in conjunction with a Goto expression.

Expression:

The policy rule. Policy expressions are described in detail in the following chapters. For an introduction, see "[Configuring Default Syntax Expressions: Getting Started](#)."

Action:

The action to be taken if this policy evaluates to TRUE.

Goto Expression:

Optional. Used to augment the Priority level to determine the next policy or policy bank to evaluate. For more information on possible values for a Goto expression, see the table "Entries in a Policy Bank."

Invoke:

Optional. Invokes another policy bank.

5. Click Ok. A message in the status bar indicates that the policy label is configured successfully.

Configuring a Policy Bank for a Virtual Server

Updated: 2013-09-02

You can configure a bank of policies for a virtual server. The policy bank can contain individual policies, and each entry in the policy bank can optionally invoke a policy label or a bank of policies that you configured for another virtual server. If you invoke a policy label or policy bank, you can do so without triggering an expression (a rule) by selecting a NOPOLICY "dummy" entry instead of a policy name.

To add policies to a virtual server policy bank by using the command line interface

At the command prompt, type the following commands to add policies to a virtual server policy bank and verify the configuration:

- `bind lb | cs vserver <virtualServerName> <serviceType> [-policyName <policyName>] [-priority <positiveInteger>] [-gotoPriorityExpression <expression>] [-type REQUEST | RESPONSE]`
- `show lb | cs vserver <virtualServerName>`

Example

```
add lb vserver vs-cont-sw TCP
Done
show lb vserver vs-cont-sw
vs-cont-sw (0.0.0.0:0) - TCP   Type: ADDRESS
State: DOWN
Last state change was at Wed Aug 19 10:04:02 2009 (+279 ms)
Time since last state change: 0 days, 00:02:14.420
Effective State: DOWN
Client Idle Timeout: 9000 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
No. of Bound Services : 0 (Total)    0 (Active)
Configured Method: LEASTCONNECTION
Mode: IP
Persistence: NONE
Connection Failover: DISABLED
Done
```

To invoke a policy label from a virtual server policy bank with a NOPOLICY entry by using the command line interface

At the command prompt, type the following commands to invoke a policy label from a virtual server policy bank with a NOPOLICY entry and verify the configuration:

- `bind lb | cs vserver <virtualServerName> -policyName NOPOLICY_REWRITE|NOPOLICY_CACHE|NOPOLICY_RESPONDER -priority <integer> -type REQUEST | RESPONSE -gotoPriorityExpression <gotopriorityExpression> -invoke reqVserver|resVserver|policyLabel <vserverName> |<labelName>`
- `show lb vserver`

Example

```
> bind lb vserver vs-cont-sw -policyname NOPOLICY-REWRITE -priority 200 -type REQUEST -gotoPriorityExpression NEXT -invoke policyLabel lbl-rewrt-pol
Done
```

To configure a virtual server policy bank by using the configuration utility

1. In the left navigation pane, expand Traffic Management > Load Balancing, Traffic Management > Content Switching, Traffic Management > SSL Offload, Security > AAA - Application Traffic, or NetScaler Gateway, as appropriate, and then click Virtual Servers.
2. In the details pane, select the virtual server that you want to configure, and then click Open.
3. In the Configure Virtual Server dialog box click the Policies tab.

4. To create a new policy in this bank, click the icon for the type of policy or policy label that you want to add to the virtual server's bank of policies, click Insert Policy. Note that if you want to invoke a policy label without evaluating a policy rule, select the NOPOLICY "dummy" policy.
5. To configure an existing entry in this policy bank, enter the following:

Priority:

A numeric value that determines either an absolute order of evaluation within the bank or is used in conjunction with a Goto expression.

Expression:

The policy rule. Policy expressions are described in detail in the following chapters. For an introduction, see "[Configuring Default Syntax Expressions: Getting Started](#)."

Action: on:

The action to be taken if this policy evaluates to TRUE.

Goto Expression:

Optional. Determines the next policy or policy bank to evaluate. For more information on possible values for a Goto expression, see "[Entries in a Policy Bank](#)."

Invoke:

Optional. To invoke another policy bank, select the name of the policy label or virtual server policy bank that you want to invoke.

6. When you are done, click OK. A message in the status bar indicates that the policy is configured successfully.

Invoking or Removing a Policy Label or Virtual Server Policy Bank

Nov 14, 2013

Unlike a policy, which can only be bound once, you can use a policy label or a virtual server's policy bank any number of times by invoking it. Invocation can be performed from two places:

- From the binding for a named policy in a policy bank.
- From the binding for a NOPOLICY "dummy" entry in a policy bank.

Typically, the policy label must be of the same type as the policy from which it is invoked. For example, you would invoke a responder policy label from a responder policy.

Note: When binding or unbinding a global NOPOLICY entry in a policy bank at the command line, you specify a priority to distinguish one NOPOLICY entry from another.

To invoke a rewrite or integrated caching policy label by using the command line interface

At the command prompt, type the one of the following commands to invoke a rewrite or integrated caching policy label and verify the configuration:

- **bind cache global** <policy> -priority <positive_integer> [-**gotoPriorityExpression** <expression>] -**type REQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT** -**invoke reqvserver|resvserver|policylabel** <label_name>
- **bind rewrite global**<policy> -priority <positive_integer> [-**gotoPriorityExpression** <expression>] -**type REQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT** -**invoke reqvserver|resvserver|policylabel** <label_name>
- **show cache global|show rewrite global**

Example

```
> bind cache global _nonPostReq2 -priority 100 -type req_override -invoke  
policylabel lbl-cache-pol
```

```
Done
```

```
> show cache global
```

```
1) Global bindpoint: REQ_DEFAULT  
   Number of bound policies: 2
```

```
2) Global bindpoint: RES_DEFAULT  
   Number of bound policies: 1
```

```
3) Global bindpoint: REQ_OVERRIDE  
   Number of bound policies: 1
```

```
Done
```

To invoke a responder policy label by using the command line interface

At the command prompt, type the following commands to invoke a responder policy label and verify the configuration:

- **bind responder global** <policy_Name> <priority_as_positive_integer> [<gotoPriorityExpression>] -**type REQ_OVERRIDE|REQ_DEFAULT|OVERRIDE|DEFAULT** -**invoke vserver|policylabel** <label_name>
- **show responder global**

Example

```
> bind responder global pol404Error1 300 -invoke policylabel lbl-respndr-pol
Done
> show responder global
1) Global bindpoint: REQ_DEFAULT
   Number of bound policies: 2

Done
>
```

To invoke a Virtual Server Policy Bank by using the command line interface

At the command prompt, type the following commands to invoke a Virtual Server Policy Bank and verify the configuration:

- **bind lb vserver** <vserver_name> **-policyName** <policy_Name> **-priority** <positive_integer> [**-gotoPriorityExpression** <expression>] **-type REQUEST|RESPONSE -invoke reqvserver|resvserver|policylabel** <policy_Label_Name>
- **bind lb vserver** <vserver_name>

Example

```
> bind lb vserver lbvip -policyName ns_cmp_msapp -priority 100
Done

> show lb vserver lbvip
  lbvip (8.7.6.6:80) - HTTP    Type: ADDRESS
  State: DOWN
  Last state change was at Wed Jul 15 05:54:24 2009 (+166 ms)
  Time since last state change: 28 days, 06:37:49.250
  Effective State: DOWN
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Port Rewrite : DISABLED
  No. of Bound Services : 0 (Total)    0 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE
  Vserver IP and Port insertion: OFF
  Push: DISABLED Push VServer:
  Push Multi Clients: NO
  Push Label Rule: none

1)  CSPolicy: pol-cont-sw CSVserver: vs-cont-sw Priority: 100 Hits: 0

1)  Policy : pol-ssl Priority:0
2)  Policy : ns_cmp_msapp Priority:100
3)  Policy : cf-pol Priority:1    Inherited
Done
>
```

To remove a rewrite or integrated caching policy label by using the command line interface

At the command prompt, type one of the following commands to remove a rewrite or integrated caching policy label and verify the configuration:

- unbind rewrite global <policyName> -priority <positiveInteger> -type **REQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT**
- unbind cache global <policyName> -priority <positiveInteger> -type **REQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT**
- show rewrite global|show cache global

Example

```
> unbind rewrite global NOPOLICY -priority 100 -type REQ_OVERRIDE
Done
> show rewrite global
1) Global bindpoint: REQ_DEFAULT
   Number of bound policies: 1

Done
```

To remove a responder policy label by using the command line interface

At the command prompt, type the following commands to remove a responder policy label and verify the configuration:

- unbind responder global <policyName> -priority <positiveInteger> -type **VERRIDE|DEFAULT**
- **show responder global**

Example

```
> unbind responder global NOPOLICY -priority 100 -type REQ_DEFAULT
Done
> show responder global
1) Global bindpoint: REQ_DEFAULT
   Number of bound policies: 1

Done
```

To remove a Virtual Server policy label by using the command line interface

At the command prompt, type one of the following commands to remove a Virtual Server policy label and verify the configuration:

- unbind lb vserver <virtualServerName> -policyName **NOPOLICY-REWRITE|NOPOLICY-RESPONDER|NOPOLICY-CACHE -type REQUEST|RESPONSE -priority <positiveInteger>**
- unbind cs vserver <virtualServerName> -policyName **NOPOLICY-REWRITE|NOPOLICY-RESPONDER|NOPOLICY-CACHE -type REQUEST|RESPONSE -priority <positiveInteger>**
- show lb vserver|show cs vserver

Example

```
> unbind lb vserver lbvip -policyName ns_cmp_msapp -priority 200
Done
> show lb vserver lbvip
  lbvip (8.7.6.6:80) - HTTP    Type: ADDRESS
  State: DOWN
```

Last state change was at Wed Jul 15 05:54:24 2009 (+161 ms)
Time since last state change: 28 days, 06:47:54.600
Effective State: DOWN
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Port Rewrite : DISABLED
No. of Bound Services : 0 (Total) 0 (Active)
Configured Method: LEASTCONNECTION
Mode: IP
Persistence: NONE
Vserver IP and Port insertion: OFF
Push: DISABLED Push VServer:
Push Multi Clients: NO
Push Label Rule: none

1) CSPolicy: pol-cont-sw CSVserver: vs-cont-sw Priority: 100 Hits: 0

1) Policy : pol-ssl Priority:0

2) Policy : cf-pol Priority:1 Inherited

Done

To invoke a policy label or virtual server policy bank by using the configuration utility

1. Bind a policy, as described in "[Binding a Policy Globally](#)", "[Binding a Policy to a Virtual Server](#)", or "[Binding a Policy to a Policy Label](#)." Alternatively, you can enter a NOPOLICY “dummy” entry instead of a policy name. You do this if you do not want to evaluate a policy before evaluating the policy bank.
2. In the Invoke field, select the name of the policy label or virtual server policy bank that you want to evaluate if traffic matches the bound policy. A message in the status bar indicates that the policy label or virtual server policy bank is invoked successfully.

To remove a policy label invocation by using the configuration utility

1. Open the policy and clear the Invoke field. Unbinding the policy also removes the invocation of the label. A message in the status bar indicates that the policy label is removed successfully.

Configuring and Binding Policies with the Policy Manager

Sep 02, 2013

Some applications provide a specialized Policy Manager in the NetScaler configuration utility to simplify configuring policy banks. It also lets you find and delete policies and actions that are not being used.

The Policy Manager is currently available for the Rewrite, Integrated Caching, Responder, and Compression features.

The following are keyboard equivalents for the procedures in this section:

- For editing a cell in the Policy Manager, you can tab to the cell and click F2 or press the SPACE bar on the keyboard.
- To select an entry in a drop-down menu, you can tab to the entry, press the space bar to view the drop-down menu, use the UP and DOWN ARROW keys to navigate to the entry that you want, and press the space bar again to select the entry.
- To cancel a selection in a drop-down menu, press the Escape key.
- To insert a policy, tab to the row above the insertion point and press Control + Insert, or click Insert Policy.
- To remove a policy, tab to the row that contains the policy and press Delete.

Note: Note that when you delete the policy, the NetScaler searches the Goto Expression values of other policies in the bank. If any of these Goto Expression values match the priority level of the deleted policy, they are removed.

To configure policy bindings by using the Policy Manager

1. In the navigation pane, click the feature for which you want to configure policies. The choices are Responder, Integrated Caching, Rewrite or Compression.
2. In the details pane, click Policy Manager.
3. If you are configuring classic policy bindings for compression, in the Compression Policy Manager dialog box, click **Switch to Classic Syntax**. The dialog box switches to the classic syntax view and displays the Switch to Default Syntax button. At any time before you complete configuring policy bindings, if you want to configure bindings for policies that use the default syntax, click the Switch to Default Syntax button.
4. For features other than Responder, to specify the bind point, click Request or Response, and then click one of the request-time or response-time bind points. The options are Override Global, LB Virtual Server, CS Virtual Server, Default Global, or Policy Label. If you are configuring the Responder, the Request and Response flow types are not available.
5. To bind a policy to this bind point, click Insert Policy, and select a previously configured policy, a NOPOLICY label, or the New policy option. Depending on the option that you select, you have the following choices:
 - **New policy:** Create the policy as described in "[Creating or Modifying a Policy](#)," and then configure the priority level, GoTo expression, and policy invocation as described in the table, "[Format of Each Entry in a Policy Bank](#)."
 - **Existing policy, NOPOLICY, or NOPOLICY<feature name>:** Configure the priority level, GoTo expression, and policy invocation as described in the table, "[Format of Each Entry in a Policy Bank](#)." The **NOPOLICY** or **NOPOLICY<feature name>** options are available only for policies that use default syntax expressions.
6. Repeat the preceding steps to add entries to this policy bank.
7. To modify the priority level for an entry, you can do any of the following:
 - Double-click the Priority field for an entry and edit the value.
 - Click and drag a policy to another row in the table.
 - Click Regenerate Priorities.

In all three cases, priority levels of all other policies are modified as needed to accommodate the new value. Goto Expressions with integer values are also updated automatically. For example, if you change a priority value of 10 to 100,

all policies with a Goto Expression value of 10 are updated to the value 100.

8. To change the policy, action, or policy bank invocation for an row in the table, click the down arrow to the right of the entry and do one of the following:
 - To change the policy, select another policy name or select New Policy and follow the steps in "[Creating or Modifying a Policy.](#)"
 - To change the Goto Expression, select Next, End, USE_INVOCATION_RESULT, or select more and enter an expression whose result returns the priority level of another entry in this policy bank.
 - To modify an invocation, select an existing policy bank, or click New Policy Label and follow the steps in "[Binding a Policy to a Policy Label.](#)"
9. To unbind a policy or a policy label invocation from this bank, click any field in the row that contains the policy or policy label, and then click Unbind Policy.
10. When you are done, click Apply Changes. A message in the status bar indicates that the policy is bound successfully.

To remove unused policies by using the Policy Manager

1. In the navigation pane, click the feature for which you want to configure the policy bank. The choices are Responder, Integrated Caching, or Rewrite.
2. In the details pane, click <Feature Name> policy manager.
3. In the <Feature Name> Policy Manager dialog box, click Cleanup Configuration.
4. In the Cleanup Configuration dialog box, select the items that you want to delete, and then click Remove.
5. In the Remove dialog box, click Yes.
6. Click Close. A message in the status bar indicates that the policy is removed successfully.

Configuring Default Syntax Expressions: Getting Started

May 25, 2015

Default syntax policies evaluate data on the basis of information that you supply in default syntax expressions. A default syntax expression analyzes data elements (for example, HTTP headers, source IP addresses, the NetScaler system time, and POST body data). In addition to configuring a default syntax expression in a policy, in some NetScaler features you configure default syntax expressions outside of the context of a policy.

To create a default syntax expression, you select a prefix that identifies a piece of data that you want to analyze, and then you specify an operation to perform on the data. For example, an operation can match a piece of data with a text string that you specify, or it can transform a text string into an HTTP header. Other operations match a returned string with a set of strings or a string pattern. You configure compound expressions by specifying Boolean and arithmetic operators, and by using parentheses to control the order of evaluation.

Default syntax expressions can also contain classic expressions. You can assign a name to a frequently used expression to avoid having to build the expression repeatedly.

Policies and a few other entities include rules that the NetScaler uses to evaluate a packet in the traffic flowing through it, to extract data from the NetScaler system itself, to send a request (a “callout”) to an external application, or to analyze another piece of data. A rule takes the form of a logical expression that is compared against traffic and ultimately returns values of TRUE or FALSE.

The elements of the rule can themselves return TRUE or FALSE, string, or numeric values.

Before configuring a default syntax expression, you need to understand the characteristics of the data that the policy or other entity is to evaluate. For example, when working with the Integrated Caching feature, a policy determines what data can be stored in the cache. With Integrated Caching, you need to know the URLs, headers, and other data in the HTTP requests and responses that the NetScaler receives. With this knowledge, you can configure policies that match the actual data and enable the NetScaler to manage caching for HTTP traffic. This information helps you determine the type of expression that you need to configure in the policy.

Basic Elements of a Default Syntax Expression

May 25, 2015

A default syntax expression consists of, at a minimum, a prefix (or a single element used in place of a prefix). Most expressions also specify an operation to be performed on the data that the prefix identifies. You format an expression of up to 1,499 characters as follows:

```
<prefix>.<operation> [<compound-operator> <prefix>.<operation>. . .]
```

where

<prefix>

is an anchor point for starting an expression.

The prefix is a period-delimited key that identifies a unit of data. For example, the following prefix examines HTTP requests for the presence of a header named Content-Type:

```
http.req.header("Content-Type")
```

Prefixes can also be used on their own to return the value of the object that the prefix identifies.

<operation>

identifies an evaluation that is to be performed on the data identified by the prefix.

For example, consider the following expression:

```
http.req.header("Content-Type").eq("text/html")
```

In this expression, the following is the operator component:

```
eq("text/html")
```

This operator causes the NetScaler to evaluate any HTTP requests that contain a Content-Type header, and in particular, to determine if the value of this header is equal to the string "text/html." For more information, see "[Operations](#)."

<compound-operator>

is a Boolean or arithmetic operator that forms a compound expression from multiple prefix or prefix.operation elements.

For example, consider the following expression:

```
http.req.header("Content-Type").eq("text/html") && http.req.url.contains(".html")
```

Prefixes

Updated: 2013-09-30

An expression prefix represents a discrete piece of data. For example, an expression prefix can represent an HTTP URL, an HTTP Cookie header, or a string in the body of an HTTP POST request. An expression prefix can identify and return a wide

variety of data types, including the following:

- A client IP address in a TCP/IP packet
- NetScaler system time
- An external callout over HTTP
- A TCP or UDP record type

In most cases, an expression prefix begins with one of the following keywords:

CLIENT:

Identifies a characteristic of the client that is either sending a request or receiving a response, as in the following examples:

- The prefix `client.ip.dst` designates the destination IP address in the request or response.
- The prefix `client.ip.src` designates the source IP address.

HTTP:

Identifies an element in an HTTP request or a response, as in the following examples:

- The prefix `http.req.body(integer)` designates the body of the HTTP request as a multiline text object, up to the character position designated in integer.
- The prefix `http.req.header("header_name")` designates an HTTP header, as specified in `header_name`.
- The prefix `http.req.url` designates an HTTP URL in URL-encoded format.

SERVER:

Identifies an element in the server that is either processing a request or sending a response.

SYS:

Identifies a characteristic of the NetScaler that is processing the traffic.

Note: Note that DNS policies support only SYS, CLIENT, and SERVER objects.

In addition, in the NetScaler Gateway, the Clientless VPN function can use the following types of prefixes:

TEXT:

Identifies any text element in a request or a response.

TARGET:

Identifies the target of a connection.

URL:

Identifies an element in the URL portion of an HTTP request or response.

As a general rule of thumb, any expression prefix can be a self-contained expression. For example, the following prefix is a complete expression that returns the contents of the HTTP header specified in the string argument (enclosed in quotation marks):

```
http.res.header("myheader")
```

Or you can combine prefixes with simple operations to determine TRUE and FALSE values. For example, the following returns a value of TRUE or FALSE:

```
http.res.header("myheader").exists
```

You can also use complex operations on individual prefixes and multiple prefixes within an expression, as in the following example:

```
http.req.url.length + http.req.cookie.length <= 500
```

Which expression prefixes you can specify depends on the NetScaler feature. The following table describes the expression prefixes that are of interest on a per-feature basis

Table 1. Permitted Types of Expression Prefixes in Various NetScaler Features

Feature	Types of Expression Prefix Used in the Feature
DNS	SYS, CLIENT, SERVER
Responder in Protection Features	HTTP, SYS, CLIENT
Content Switching	HTTP, SYS, CLIENT
Rewrite	HTTP, SYS, CLIENT, SERVER, URL, TEXT, TARGET, VPN
Integrated Caching	HTTP, SYS, CLIENT, SERVER
NetScaler Gateway, Clientless Access	HTTP, SYS, CLIENT, SERVER, URL, TEXT, TARGET, VPN

Note: For details on the permitted expression prefixes in a feature, see the documentation for that feature.

Single-Element Expressions

The simplest type of default syntax expression contains a single element. This element can be one of the following:

- **true.** A default syntax expression can consist simply of the value true. This type of expression always returns a value of TRUE. It is useful for chaining policy actions and triggering Goto expressions.
- **false.** A default syntax expression can consist simply of the value false. This type of expression always returns a value of FALSE.
- A prefix for a compound expression. For example, the prefix HTTP.REQ.HOSTNAME is a complete expression that returns a host name and HTTP.REQ.URL is a complete expression that returns a URL. The prefix could also be used in conjunction with operations and additional prefixes to form a compound expression.

Operations

In most expressions, you also specify an operation on the data that the prefix identifies. For example, suppose that you specify the following prefix:

`http.req.url`

This prefix extracts URLs in HTTP requests. This expression prefix does not require any operators to be used in an expression. However, when you configure an expression that processes HTTP request URLs, you can specify operations that analyze particular characteristics of the URL. Following are a few possibilities:

- Search for a particular host name in the URL.
- Search for a particular path in the URL.
- Evaluate the length of the URL.
- Search for a string in the URL that indicates a time stamp and convert it to GMT.

The following is an example of a prefix that identifies an HTTP header named Server and an operation that searches for the string IIS in the header value:

```
http.res.header("Server").contains("IIS")
```

Following is an example of a prefix that identifies host names and an operation that searches for the string "www.mycompany.com" as the value of the name:

```
http.req.hostname.eq("www.mycompany.com")
```

Basic Operations on Expression Prefixes

The following table describes a few of the basic operations that can be performed on expression prefixes.

Table 2. Basic Operations for Expressions

Operation	Determines Whether or Not
CONTAINS(<string>)	The object matches <string>. Following is an example: http.req.header("Cache-Control").contains("no-cache")
EXISTS	A particular item is present in an object. Following is an example: http.res.header("MyHdr").exists
EQ(<text>)	A particular non-numeric value is present in an object. Following is an example: http.req.method.eq(post)
EQ(<integer>)	A particular numeric value is present in an object. Following is an example: client.ip.dst.eq(10.100.10.100)
LT(<integer>)	An object's value is less than a particular value. Following is an example: http.req.content_length.lt(5000)
GT(<integer>)	An object's value is greater than a particular value. Following is an example: http.req.content_length.gt(5)

The following table summarizes a few of the available types of operations.

Table 3. Basic Types of Operations

Operation Type	Description
Text operations	<p>Match individual strings and sets of strings with any portion of a target. The target can be an entire string, the start of a string, or any portion of text in between the start and the end of the string.</p> <p>For example, you can extract the string "XYZ" from "XYZSomeText". Or, you can compare an HTTP header value with an array of different strings.</p> <p>You can also transform text into another type of data. Following are examples:</p> <ul style="list-style-type: none">• Transform a string into an integer value• Create a list from the query strings in a URL• Transform a string into a time value
Numeric operations	Numeric operations include applying arithmetic operators, evaluating content length, the number of items in a list, dates, times, and IP addresses.

Compound Default Syntax Expressions

May 25, 2015

You can configure a default syntax expression that contains Boolean or arithmetic operators and multiple atomic operations. The following compound expression contains a boolean AND:

```
http.req.hostname.eq("mycompany.com") && http.req.method.eq(post)
```

The following expression adds the value of two targets, and compares the result to a third value:

```
http.req.url.length + http.req.cookie.length <= 500
```

A compound expression can contain any number of logical and arithmetic operators. The following expression evaluates the length of an HTTP request on the basis of its URL and cookie, evaluates text in the header, and performs a Boolean AND on these two results:

```
http.req.url.length + http.req.cookie.length <= 500 && http.req.header.contains("some text")
```

You can use parentheses to control the order of evaluation in a compound expression.

This document includes the following details:

- [Booleans in Compound Expressions](#)
- [Parentheses in Compound Expressions](#)
- [Compound Operations for Strings](#)
- [Compound Operations for Numbers](#)

Booleans in Compound Expressions

You configure compound expressions with the following operators:

&&.

This operator is a logical AND. For the expression to evaluate to TRUE, all components that are joined by the And must evaluate to TRUE. Following is an example:

```
http.req.url.hostname.eq("myHost") && http.req.header("myHeader").exists
```

||.

This operator is a logical OR. If any component of the expression that is joined by the OR evaluates to TRUE, the entire expression is TRUE.

!.

Performs a logical NOT on the expression.

In some cases, the NetScaler configuration utility offers AND, NOT, and OR operators in the Add Expression dialog box. However, these are of limited use. Citrix recommends that you use the operators &&, ||, and ! to configure compound expressions that use Boolean logic.

Parentheses in Compound Expressions

You can use parentheses to control the order of evaluation of an expression. The following is an example:

```
http.req.url.contains("myCompany.com") || (http.req.url.hostname.eq("myHost") && http.req.header("myHeader").exists)
```

The following is another example:

```
(http.req.header("Content-Type").exists && http.req.header("Content-Type").eq("text/html")) || (http.req.header("Transfer-Encoding").exists || http.req.header("Content-Length").exists)
```

Compound Operations for Strings

The following table describes operators that you can use to configure compound operations on string data.

Table 1. String-Based Operations for Compound Default Syntax Expressions

All string operations	
Operations that produce a string value	
str + str	Concatenates the value of the expression on the left of the operator with the value on the right. Following is an example: http.req.hostname + http.req.url.protocol
str + num	Concatenates the value of the expression on the left of the operator with a numeric value on the right. Following is an example: http.req.hostname + http.req.url.content_length
num + str	Concatenates the numeric value of the expression on the left side of the operator with a string value on the right. Following is an example: http.req.url.content_length + http.req.url.hostname
str + ip	Concatenates the string value of the expression on the left side of the operator with an IP address value on the right. Following is an example: http.req.hostname + 10.00.000.00
ip + str	Concatenates the IP address value of the expression on the left of the operator with a string value on the right. Following is an example: client.ip.dst + http.req.url.hostname
str1 ALT str2	Uses the string1 or string2 value that is derived from the expression on either side of the operator, as long as neither of these expressions is a compound expressions. Following is an example: http.req.hostname alt client.ip.src
Operations on strings that produce a result of TRUE or FALSE	

All string operations	
str == str	Evaluates whether the strings on either side of the operator are the same. Following is an example: <code>http.req.header("myheader") == http.res.header("myheader")</code>
str <= str	Evaluates whether the string on the left side of the operator is the same as the string on the right, or precedes it alphabetically.
str >= str	Evaluates whether the string on the left side of the operator is the same as the string on the right, or follows it alphabetically.
str < str	Evaluates whether the string on the left side of the operator precedes the string on the right alphabetically.
str > str	Evaluates whether the string on the left side of the operator follows the string on the right alphabetically.
str != str	Evaluates whether the strings on either side of the operator are different.
Logical operations on strings	
bool && bool	This operator is a logical AND. When evaluating the components of the compound expression, all components that are joined by the AND must evaluate to TRUE. Following is an example: <code>http.req.method.eq(GET) && http.req.url.query.contains("viewReport && my_pagelabel")</code>
bool bool	This operator is a logical OR. When evaluating the components of the compound expression, if any component of the expression that is joined by the OR evaluates to TRUE, the entire expression is TRUE. Following is an example: <code>http.req.url.contains(".js") http.res.header("Content-Type").contains("javascript")</code>
!bool	Performs a logical NOT on the expression.

Compound Operations for Numbers

Updated: 2013-09-02

You can configure compound numeric expressions. For example, the following expression returns a numeric value that is the sum of an HTTP header length and a URL length:

`http.req.header.length + http.req.url.length`

The following tables describes operators that you can use to configure compound expressions for numeric data.

Table 2. Arithmetic Operations on Numbers

Operator	Description
<code>num + num</code>	Add the value of the expression on the left of the operator to the value of the expression on the right. Following is an example: <code>http.req.content_length + http.req.url.length</code>
<code>num - num</code>	Subtract the value of the expression on the right of the operator from the value of the expression on the left.
<code>num * num</code>	Multiply the value of the expression on the left of the operator with the value of the expression on the right. Following is an example: <code>client.interface.rxthroughput * 9</code>
<code>num / num</code>	Divide the value of the expression on the left of the operator by the value of the expression on the right.
<code>num % num</code>	Calculate the modulo, or the numeric remainder on a division of the value of the expression on the left of the operator by the value of the expression on the right. For example, the values "15 mod 4" equals 3, and "12 mod 4" equals 0.
<code>~number</code>	Returns a number after applying a bitwise logical negation of the number. The following example assumes that <code>numeric.expression</code> returns 12 (binary 1100): <code>~numeric.expression.</code> The result of applying the <code>~</code> operator is -11 (a binary 1110011, 32 bits total with all ones to the left). Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.
<code>number ^ number</code>	Compares two bit patterns of equal length and performs an XOR operation on each pair of corresponding bits in each number argument, returning 1 if the bits are different, and 0 if they are the same. Returns a number after applying a bitwise XOR to the integer argument and the current number value. If the values in the bitwise comparison are the same, the returned value is a 0. The following example assumes that <code>numeric.expression1</code> returns 12 (binary 1100) and <code>numeric.expression2</code> returns 10 (binary 1010): <code>numeric.expression1 ^ numeric.expression2</code>

Operator	Description
	<p>The result of applying the ^ operator to the entire expression is 6 (binary 0110).</p> <p>Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.</p>
number number	<p>Returns a number after applying a bitwise OR to the number values. If either value in the bitwise comparison is a 1, the returned value is a 1. The following example assumes that numeric.expression1 returns 12 (binary 1100) and numeric.expression2 returns 10 (binary 1010):</p> <pre>numeric.expression1 numeric.expression2</pre> <p>The result of applying the operator to the entire expression is 14 (binary 1110).</p> <p>Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.</p>
number & number	<p>Compares two bit patterns of equal length and performs a bitwise AND operation on each pair of corresponding bits, returning 1 if both of the bits contains a value of 1, and 0 if either bits are 0.</p> <p>The following example assumes that numeric.expression1 returns 12 (binary 1100) and numeric.expression2 returns 10 (binary 1010):</p> <pre>numeric.expression1 & numeric.expression2</pre> <p>The whole expression evaluates to 8 (binary 1000).</p> <p>Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.</p>
num << num	<p>Returns a number after a bitwise left shift of the number value by the right-side number argument number of bits.</p> <p>Note that the number of bits shifted is integer modulo 32. The following example assumes that numeric.expression1 returns 12 (binary 1100) and numeric.expression2 returns 3:</p> <pre>numeric.expression1 << numeric.expression2</pre> <p>The result of applying the LSHIFT operator is 96 (a binary 1100000).</p> <p>Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.</p>
num >> num	<p>Returns a number after a bitwise right shift of the number value by the integer argument number of bits.</p> <p>Note that the number of bits shifted is integer modulo 32. The following example assumes that numeric.expression1 returns 12 (binary 1100) and numeric.expression2 returns 3:</p> <pre>numeric.expression1 >> numeric.expression2</pre> <p>The result of applying the RSHIFT operator is 1 (a binary 0001).</p>

Operator	Description
	Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.

Table 3. Numeric Operators That Produce a Result of TRUE or FALSE

Operator	Description
num == num	Determine if the value of the expression on the left of the operator is equal to the value of the expression on the right.
num != num	Determine if the value of the expression on the left of the operator is not equal to the value of the expression on the right.
num > num	Determine if the value of the expression on the left of the operator is greater than the value of the expression on the right.
num < num	Determine if the value of the expression on the left of the operator is less than the value of the expression on the right.
num >= num	Determine if the value of the expression on the left of the operator is greater than or equal to the value of the expression on the right.
num <= num	Determine if the value of the expression on the left of the operator is less than or equal to the value of the expression on the right.

Functions for Data Types in the Policy Infrastructure

The NetScaler policy infrastructure supports the following numeric data types:

- Integer (32 bits)
- Unsigned long (64 bits)
- Double (64 bits)

Simple expressions can return all of these data types. Therefore, you can create compound expressions that use arithmetic operators and logical operators to evaluate or return values of these data types. Additionally, you can use all of these values in policy expressions. Literal constants of type unsigned long can be specified by appending the string ul to the number. Literal constants of type double contain a period (.), an exponent, or both.

Arithmetic Operators, Logical Operators, and Type Promotion

In compound expressions, the following standard arithmetic and logical operators can be used for the double and unsigned long data types:

- +, -, *, and /

- %, ~, ^, &, |, <<, and >> (do not apply to double)
- ==, !=, >, <, >=, and <=

All of these operators have the same meaning as in the C programming language.

In all cases of mixed operations between operands of type integer, unsigned long, and double, type promotion is performed so that the operation can be performed on operands of the same type. A type of lower precedence is automatically promoted to the type of the operand with the highest precedence involved in the operation. The order of precedence (higher to lower) is as follows:

- Double
- Unsigned long
- Integer

Therefore, an operation that returns a numeric result returns a result of the highest type involved in the operation.

For example, if the operands are of type integer and unsigned long, the integer operand is automatically converted to type unsigned long. This type conversion is performed even in simple expressions in which the type of data identified by the expression prefix does not match the type of data that is passed as the argument to the function. To illustrate such an example, in the operation `HTTP.REQ.CONTENT_LENGTH.DIV(3ul)`, the integer returned by the prefix `HTTP.REQ.CONTENT_LENGTH` is automatically converted to unsigned long (the type of the data passed as the argument to the `DIV()` function), and an unsigned long division is performed. Similarly, the argument can be promoted in an expression. For example, `HTTP.REQ.HEADER("myHeader").TYPECAST_DOUBLE_AT.DIV(5)` promotes the integer 5 to type double and performs double-precision division.

The following table describes the arithmetic and Boolean functions that can be used with the integer, unsigned long, and double data types. For information about expressions for casting data of one type to data of another type, see "[Typecasting Data](#)."

Specifying the Character Set in Expressions

Jul 11, 2013

The policy infrastructure on the Citrix® NetScaler® appliance supports the ASCII and UTF-8 character sets. The default character set is ASCII. If the traffic for which you are configuring an expression consists of only ASCII characters, you need not specify the character set in the expression. However, you must specify the character set in every simple expression that is meant for UTF-8 traffic. To specify the UTF-8 character set in a simple expression, you must include the `SET_CHAR_SET(<charset>)` function, with `<charset>` specified as `UTF_8`, as shown in the following examples:

```
HTTP.REQ.BODY(10).SET_CHAR_SET(UTF_8).CONTAINS("ß")
```

```
HTTP.RES.BODY(100).SET_CHAR_SET(UTF_8).BEFORE_STR("Bücher").AFTER_STR("Wörterbuch")
```

In an expression, the `SET_CHAR_SET()` function must be introduced at the point in the expression after which data processing must be carried out in the specified character set. For example, in the expression `HTTP.REQ.BODY(1000).AFTER_REGEX(re/following example/).BEFORE_REGEX(re/In the preceding example/).CONTAINS_ANY("Greek_alphabet")`, if the strings stored in the pattern set "Greek_alphabet" are in UTF-8, you must include the `SET_CHAR_SET(UTF_8)` function immediately before the `CONTAINS_ANY("<string>")` function, as follows:

```
HTTP.REQ.BODY(1000).AFTER_REGEX(re/following example/).BEFORE_REGEX(re/In the preceding example/).SET_CHAR_SET(UTF_8).CONTAINS_ANY("Greek_alphabet")
```

The `SET_CHAR_SET()` function sets the character set for all further processing (that is, for all subsequent functions) in the expression unless it is overridden later in the expression by another `SET_CHAR_SET()` function that changes the character set. Therefore, if all the functions in a given simple expression are intended for UTF-8, you can include the `SET_CHAR_SET(UTF_8)` function immediately after functions that identify text (for example, the `HEADER("<name>")` or `BODY(<int>)` functions). In the second example that follows the first paragraph above, if the ASCII arguments passed to the `AFTER_REGEX()` and `BEFORE_REGEX()` functions are changed to UTF-8 strings, you can include the `SET_CHAR_SET(UTF_8)` function immediately after the `BODY(1000)` function, as follows:

```
HTTP.REQ.BODY(1000).SET_CHAR_SET(UTF_8).AFTER_REGEX(re/Bücher/).BEFORE_REGEX(re/Wörterbuch/).CONTAINS_ANY("Greek_alphabet")
```

The UTF-8 character set is a superset of the ASCII character set, so expressions configured for the ASCII character set continue to work as expected if you change the character set to UTF-8.

Compound Expressions with Different Character Sets

In a compound expression, if one subset of expressions is configured to work with data in the ASCII character set and the rest of the expressions are configured to work with data in the UTF-8 character set, the character set specified for each individual expression is considered when the expressions are evaluated individually. However, when processing the compound expression, just before processing the operators, the appliance promotes the character set of the returned ASCII values to UTF-8. For example, in the following compound expression, the first simple expression evaluates data in the ASCII character set while the second simple expression evaluates data in the UTF-8 character set:

```
HTTP.REQ.HEADER("MyHeader") == HTTP.REQ.BODY(10).SET_CHAR_SET(UTF_8)
```

However, when processing the compound expression, just before evaluating the "is equal to" Boolean operator, the NetScaler appliance promotes the character set of the value returned by `HTTP.REQ.HEADER("MyHeader")` to UTF-8.

The first simple expression in the following example evaluates data in the ASCII character set. However, when the NetScaler appliance processes the compound expression, just before concatenating the results of the two simple expressions, the appliance promotes the character set of the value returned by `HTTP.REQ.BODY(10)` to UTF-8.

```
HTTP.REQ.BODY(10) + HTTP.REQ.HEADER("MyHeader").SET_CHAR_SET(UTF_8)
```

Consequently, the compound expression returns data in the UTF-8 character set.

Specifying the Character Set Based on the Character Set of Traffic

You can set the character set to UTF-8 on the basis of traffic characteristics. If you are not sure whether the character set of the traffic being evaluated is UTF-8, you can configure a compound expression in which the first expression checks for UTF-8 traffic and subsequent expressions set the character set to UTF-8. Following is an example of a compound expression that first checks the value of "charset" in the request's Content-Type header for "UTF-8" before checking whether the first 1000 bytes in the request contain the UTF-8 string `Bücher`:

```
HTTP.REQ.HEADER("Content-Type").SET_TEXT_MODE(IGNORECASE).TYPECAST_NVLIST_T('=', ';', '').VALUE("charset").EQ("UTF-8") &&  
HTTP.REQ.BODY(1000).SET_CHAR_SET(UTF_8).CONTAINS("Bücher")
```

If you are sure that the character set of the traffic being evaluated is UTF-8, the second expression in the example is sufficient.

Character and String Literals in Expressions

During expression evaluation, even if the current character set is ASCII, character literals and string literals, which are enclosed in single quotation marks (') and quotation marks (""), respectively, are considered to be literals in the UTF-8 character set. In a given expression, if a function is operating on character or string literals in the ASCII character set and you include a non-ASCII character in the literal, an error is returned.

Values in Hexadecimal and Octal Formats

When configuring an expression, you can enter values in octal and hexadecimal formats. However, each hexadecimal or octal byte is considered a UTF-8 byte. Invalid UTF-8 bytes result in errors regardless of whether the value is entered manually or pasted from the clipboard. For example, "\xce\x20" is an invalid UTF-8 character because "c8" cannot be followed by "20" (each byte in a multi-byte UTF-8 string must have the high bit set). Another example of an invalid UTF-8 character is "\xce \xa9," since the hexadecimal characters are separated by a white-space character.

Functions That Return UTF-8 Strings

Only the <text>.XPATH and <text>.XPATH_JSON functions always return UTF-8 strings. The following MySQL routines determine at runtime which character set to return, depending on the data in the protocol:

- MYSQL_CLIENT_T.USER
- MYSQL_CLIENT_T.DATABASE
- MYSQL_REQ_QUERY_T.COMMAND
- MYSQL_REQ_QUERY_T.TEXT
- MYSQL_REQ_QUERY_T.TEXT(<unsigned int>)
- MYSQL_RES_ERROR_T.SQLSTATE
- MYSQL_RES_ERROR_T.MESSAGE
- MYSQL_RES_FIELD_T.CATALOG
- MYSQL_RES_FIELD_T.DB
- MYSQL_RES_FIELD_T.TABLE
- MYSQL_RES_FIELD_T.ORIGINAL_TABLE
- MYSQL_RES_FIELD_T.NAME
- MYSQL_RES_FIELD_T.ORIGINAL_NAME
- MYSQL_RES_OK_T.MESSAGE
- MYSQL_RES_ROW_T.TEXT_ELEM(<unsigned int>)

Terminal Connection Settings for UTF-8

When you set up a connection to the NetScaler appliance by using a terminal connection (by using PuTTY, for example), you must set the character set for transmission of data to UTF-8.

Classic Expressions in Default Syntax Expressions

Mar 20, 2012

Classic expressions describe basic characteristics of traffic. In some cases, you may want to use a classic expression in a default syntax expression. You can do so with the default syntax expression configuration tool. This can be helpful when manually migrating the older classic expressions to the default syntax.

Note that when you upgrade the NetScaler to version 9.0 or higher, Integrated Caching policies are automatically upgraded to default syntax policies, and the expressions in these policies are upgraded to the default syntax.

The following is the syntax for all default syntax expressions that use a classic expression:

```
SYS.EVAL_CLASSIC_EXPR("expression")
```

Following are examples of the SYS.EVAL_CLASSIC_EXPR("expression") expression:

```
sys.eval_classic_expr("req.ssl.client.cipher.bits > 1000")
sys.eval_classic_expr("url contains abc")
sys.eval_classic_expr("req.ip.sourceip == 10.102.1.61 -netmask 255.255.255.255")
sys.eval_classic_expr("time >= *:30:00GMT")
sys.eval_classic_expr("e1 || e2")
sys.eval_classic_expr("req.http.urlLen > 50")
sys.eval_classic_expr("dayofweek == wedGMT")
```

Configuring Default Syntax Expressions in a Policy

Sep 02, 2013

You can configure a default syntax expression of up to 1,499 characters in a policy. The user interface for default syntax expressions depends to some extent on the feature for which you are configuring the expression, and on whether you are configuring an expression for a policy or for another use.

When configuring expressions on the command line, you delimit the expression by using quotation marks (“.” or ‘.’). Within an expression, you escape additional quotation marks by using a back-slash (\). For example, the following are standard methods for escaping quotation marks in an expression:

```
"\"abc\""
```

```
\"abc\"
```

You must also use a backslash to escape question marks and other backslashes on the command line. For example, the expression `http.req.url.contains("\\?")` requires a backslash so that the question mark is parsed. Note that the backslash character will not appear on the command line after you type the question mark. On the other hand, if you escape a backslash (for example, in the expression `'http.req.url.contains("\\\\http\\")'`), the escape characters are echoed on the command line.

To make an entry more readable, you can escape the quotation marks for an entire expression. At the start of the expression you enter the escape sequence “q” plus one of the following special characters: `{<|~$^+=&%@`?``.

You enter only the special character at the end of the expression, as follows:

```
q@http.req.url.contains("sometext") && http.req.cookie.exists@
```

```
q~http.req.url.contains("sometext") && http.req.cookie.exists~
```

Note that an expression that uses the `{` delimiter is closed with `}`.

For some features (for example, Integrated Caching and Responder), the policy configuration dialog box provides a secondary dialog box for configuring expressions. This dialog enables you to choose from drop-down lists that show the available choices at each point during expression configuration. You cannot use arithmetic operators when using these configuration dialogs, but most other default syntax expression features are available. To use arithmetic operators, write your expressions in free-form format.

To configure a default syntax rule by using the command line interface

At the command prompt, type the following commands to configure a default syntax rule and verify the configuration:

1. `add cache|dns|rewrite|cs policy policyName -rule expression featureSpecificParameters -action`
2. `show cache|dns|rewrite|cs policy policyName`

Following is an example of configuring a caching policy:

Example

```
> add cache policy pol-cache -rule http.req.content_length.le(5) -action INVALID
Done
```

```
> show cache policy pol-cache
```

Name: pol-cache
Rule: http.req.content_length.le(5)
CacheAction: INVALID
Invalidate groups: DEFAULT
UndefAction: Use Global
Hits: 0
Undef Hits: 0

Done

To configure a default syntax policy expression by using the configuration utility

1. In the navigation pane, click the name of the feature where you want to configure a policy, for example, you can select Integrated Caching, Responder, DNS, Rewrite, or Content Switching, and then click Policies.
2. Click Add.
3. For most features, click in the Expression field. For Content Switching, click Configure.
4. Click the Prefix icon (the house) and select the first expression prefix from the drop-down list. For example, in Responder, the options are HTTP, SYS, and CLIENT. The next set of applicable options appear in a drop-down list.
5. Double-click the next option to select it, and then type a period (.). Again, a set of applicable options appears in another drop-down list.
6. Continue selecting options until an entry field (signalled by parentheses) appears. When you see an entry field, enter an appropriate value in the parentheses. For example, if you select GT(int) (greater-than, integer format), you specify an integer in the parentheses. Text strings are delimited by quotation marks. Following is an example:
`HTTP.REQ.BODY(1000).BETWEEN("this","that")`
7. To insert an operator between two parts of a compound expression, click the Operators icon (the sigma), and select the operator type. Following is an example of a configured expression with a Boolean OR (signalled by double vertical bars, ||):
`HTTP.REQ.URL.EQ("www.mycompany.com")||HTTP.REQ.BODY(1000).BETWEEN("this","that")`
8. To insert a named expression, click the down arrow next to the Add icon (the plus sign) and select a named expression.
9. To configure an expression using drop-down menus, and to insert built-in expressions, click the Add icon (the plus sign). The Add Expression dialog box works in a similar way to the main dialog box, but it provides drop-down lists for selecting options, and it provides text fields for data entry instead of parentheses. This dialog box also provides a Frequently Used Expressions drop-down list that inserts commonly used expressions. When you are done adding the expression, click OK.
10. When finished, click Create. A message in the status bar indicates that the policy expression is configured successfully.

To test a default syntax expression by using the configuration utility

1. In the navigation pane, click the name of the feature for which you want to configure a policy (for example, you can select Integrated Caching, Responder, DNS, Rewrite, or Content Switching), and then click Policies.
2. Select a policy and click Open.
3. To test the expression, click the Evaluate icon (the check mark).
4. In the expression evaluator dialog box, select the Flow Type that matches the expression.
5. In the HTTP Request Data or HTTP Response Data field, paste the HTTP request or response that you want to parse with the expression, and click Evaluate. Note that you must supply a complete HTTP request or response, and the header and body should be separated by blank line. Some programs that trap HTTP headers do not also trap the response. If you are copying and pasting only the header, insert a blank line at the end of the header to form a complete HTTP request or response.

6. Click Close to close this dialog box.

Configuring Named Default Syntax Expressions

Oct 29, 2013

Instead of retyping the same expression multiple times in multiple policies, you can configure a named expression and refer to the name any time you want to use the expression in a policy. For example, you could create the following named expressions:

ThisExpression:

```
http.req.body(100).contains("this")
```

ThatExpression:

```
http.req.body(100).contains("that")
```

You can then use these named expressions in a policy expression. For example, the following is a legal expression based on the preceding examples:

```
ThisExpression || ThatExpression
```

You can use the name of a default syntax expression as the prefix to a function. The named expression can be either a simple expression or a compound expression. The function must be one that can operate on the type of data that is returned by the named expression.

Example 1: Simple Named Expression as a Prefix

The following simple named expression, which identifies a text string, can be used as a prefix to the AFTER_STR("<string>")function, which works with text data:

```
HTTP.REQ.BODY(1000)
```

If the name of the expression is top1KB, you can use top1KB.AFTER_STR("username") instead of HTTP.REQ.BODY(1000).AFTER_STR("username").

Example 2: Compound Named Expression as a Prefix

You can create a compound named expression called basic_header_value to concatenate the user name in a request, a colon (:), and the user's password, as follows:

```
add policy expression basic_header_value "HTTP.REQ.USER.NAME + \":\" + HTTP.REQ.USER.PASSWD"
```

You can then use the name of the expression in a rewrite action, as shown in the following example:

```
add rewrite action insert_b64encoded_authorization insert_http_header authorization "Basic " +  
basic_header_value.b64encode' -bypassSafetyCheck YES
```

In the example, in the expression that is used to construct the value of the custom header, the B64 encoding algorithm is applied to the string returned by the compound named expression.

You can also use a named expression (either by itself or as a prefix to a function) to create the text expression for the replacement target in a rewrite.

To configure a named default syntax expression by using the command line interface

At the command prompt, type the following commands to configure a named expression and verify the configuration:

- add policy expression <name><value>

- show policy expression <name>

Example

```
> add policy expression myExp "http.req.body(100).contains(\"the other\")"
```

Done

```
> show policy expression myExp
```

```
1) Name: myExp Expr: "http.req.body(100).contains(\"the other\")" Hits: 0 Type : ADVANCED
```

Done

The expression can be up to 1,499 characters.

To configure a named expression by using the configuration utility

1. In the navigation pane, expand AppExpert, and then click Expressions.
2. Click Advanced Expressions.
3. Click Add.
4. Enter a name and a description for the expression.
5. Configure the expression by using the process described in "[To configure a default syntax policy expression by using the configuration utility](#)." A message in the status bar indicates that the policy expression is configured successfully.

Configuring Default Syntax Expressions Outside the Context of a Policy

Oct 29, 2013

A number of functions, including the following, can require a default syntax expression that is not part of a policy:

Integrated Caching selectors:

You define multiple non-compound expressions (selectlets) in the definition of the selector. Each selectlet is in an implicit logical AND relationship with the others.

Load Balancing:

You configure an expression for the TOKEN method of load balancing for a load balancing virtual server.

Rewrite actions:

Expressions define the location of the rewrite action and the type of rewriting to be performed, depending on the type of rewrite action that you are configuring. For example, a DELETE action only uses a target expression. A REPLACE action uses a target expression and an expression to configure the replacement text.

Rate-based policies:

You use default syntax expressions to configure Limit Selectors. You can use these selectors when configuring policies to throttle the rate of traffic to various servers. You define up to five non-compound expressions (selectlets) in the definition of the selector. Each selectlet is in an implicit logical AND with the others.

To configure a default syntax expression outside a policy by using the command line interface (cache selector example)

At the command prompt, type the following commands to configure a default syntax expression outside a policy and verify the configuration:

- add cache selector <selectorName> <rule>
- show cache selector <selectorName>

Example

```
> add cache selector mainpageSelector "http.req.cookie.value("\ABC_def")"
"http.req.url.query.value("\_ghi")"selector "mainpageSelector" added
Done
> show cache selector mainpageSelector
  Name: mainpageSelector
  Expressions:
    1) http.req.cookie.value("ABC_def")
    2) http.req.url.query.value("_ghi")
Done
```

Following is an equivalent command that uses the more readable q delimiter, as described in "[Configuring Default Syntax Expressions in a Policy](#)":

```
> add cache selector mainpageSelector2 q~http.req.cookie.value("ABC_def")~
q~http.req.url.query.value("_ghi")~selector "mainpageSelector2" added
Done
> show cache selector mainpageSelector2
  Name: mainpageSelector2
  Expressions:
```

```
1) http.req.cookie.value("ABC_def")
```

```
2) http.req.url.query.value("_ghi")
```

Done

Default Syntax Expressions: Evaluating Text

Sep 02, 2013

You can configure a policy with a default syntax expression that evaluates text in a request or response. Default syntax text expressions can range from simple expressions that perform string matching in HTTP headers to complex expressions that encode and decode text. You can configure text expressions to be case sensitive or case insensitive and to use or ignore spaces. You can also configure complex text expressions by combining text expressions with Boolean operators

You can use expression prefixes and operators for evaluating HTTP requests, HTTP responses, and VPN and Clientless VPN data. However, text expression prefixes are not restricted to evaluating these elements of your traffic. For information about additional default syntax text expression prefixes and operators, see the following topics:

- [Pattern Sets](#)
- [Regular Expressions](#)
- [Typecasting Data](#)
- [Default Syntax Expressions: Parsing HTTP, TCP, and UDP Data](#)
- [Default Syntax Expressions: Parsing SSL Certificates](#)
- [Expressions for SSL Certificate Dates](#)

About Text Expressions

Sep 02, 2013

You can configure various expressions for working with text that flows through the NetScaler appliance. Following are some examples of how you can parse text by using a default syntax expression:

- Determine that a particular HTTP header exists.
For example, you may want to identify HTTP requests that contains a particular Accept-Language header for the purpose of directing the request to a particular server.
- Determine that a particular HTTP URL contains a particular string.
For example, you may want to block requests for particular URLs. Note that the string can occur at the beginning, middle, or end of another string.
- Identify a POST request that is directed to a particular application.
For example, you may want to identify all POST requests that are directed to a database application for the purpose of refreshing cached application data.

Note that there are specialized tools for viewing the data stream for HTTP requests and responses. For example, from the following URL, you can download a Firefox Web browser plug-in that displays HTTP request and response headers:

["https://addons.mozilla.org/en-US/firefox/addon/3829"](https://addons.mozilla.org/en-US/firefox/addon/3829)

The following plug-in displays headers, query strings, POST data, and other information:

["https://addons.mozilla.org/en-US/firefox/addon/6647"](https://addons.mozilla.org/en-US/firefox/addon/6647)

After you download these plug-ins, they are accessible from the Firefox Tools menu.

About Operations on Text

A text-based expression consists of at least one prefix to identify an element of data and usually (although not always) an operation on that prefix. Text-based operations can apply to any part of a request or a response. Basic operations on text include various types of string matches.

For example, the following expression compares a header value with a string:

```
http.req.header("myHeader").contains("some-text")
```

Following expressions are examples of matching a file type in a request:

```
http.req.url.suffix.contains("jpeg")
```

```
http.req.url.suffix.eq("jpeg")
```

In the preceding examples, the contains operator permits a partial match and the eq operator looks for an exact match.

Other operations are available to format the string before evaluating it. For example, you can use text operations to strip out quotes and white spaces, to convert the string to all lowercase, or to concatenate strings.

Note: Complex operations are available to perform matching based on patterns or to convert one type of text format to another type.

For more information, see the following topics:

- ["Pattern Sets and Data Sets."](#)
- ["Regular Expressions."](#)
- ["Typecasting Data."](#)

Compounding and Precedence in Text Expressions

You can apply various operators to combine text prefixes or expressions. For example, the following expression concatenates the returned values of each prefix:

```
http.req.hostname + http.req.url
```

Following is an example of a compound text expression that uses a logical AND. Both components of this expression must be TRUE for a request to match the expression:

```
http.req.method.eq(post) && http.req.body(1024).startswith("destination=")
```

Note: For more information on operators for compounding, see ["Compound Default Syntax Expressions."](#)

Categories of Text Expressions

The primary categories of text expressions that you can configure are:

- Information in HTTP headers, HTTP URLs, and the POST body in HTTP requests.
For more information, see ["Expression Prefixes for Text in HTTP Requests and Responses."](#)
- Information regarding a VPN or a clientless VPN.
For more information, see ["Expression Prefixes for VPNs and Clientless VPNs."](#)
- TCP payload information.
For more information about TCP payload expressions, see ["Default Syntax Expressions: Parsing HTTP, TCP, and UDP Data."](#)
- Text in a Secure Sockets Layer (SSL) certificate.
For information about text expressions for SSL and SSL certificate data, see ["Default Syntax Expressions: Parsing SSL Certificates"](#) and ["Expressions for SSL Certificate Dates."](#)

Note: Parsing a document body, such as the body of a POST request, can affect performance. You may want to test the performance impact of policies that evaluate a document body.

Guidelines for Text Expressions

From a performance standpoint, it typically is best to use protocol-aware functions in an expression. For example, the following expression makes use of a protocol-aware function:

```
HTTP.REQ.URL.QUERY
```

The previous expression performs better than the following equivalent expression, which is based on string parsing:

```
HTTP.REQ.URL.AFTER_STR("?")
```

In the first case, the expression looks specifically at the URL query. In the second case, the expression scans the data for the first occurrence of a question mark.

There is also a performance benefit from structured parsing of text, as in the following expression:

```
HTTP.REQ.HEADER("Example").TYPECAST_LIST_T(',').GET(1)
```

(For more information on typecasting, see "[Typecasting Data](#).") The typecasting expression, which collects comma-delimited data and structures it into a list, typically would perform better than the following unstructured equivalent:

```
HTTP.REQ.HEADER("Example").AFTER_STR(",").BEFORE_STR(",")
```

Finally, unstructured text expressions typically have better performance than regular expressions. For example, the following is an unstructured text expression:

```
HTTP.REQ.HEADER("Example").AFTER_STR("more")
```

The previous expression would generally provide better performance than the following equivalent, which uses a regular expression:

```
HTTP.REQ.HEADER("Example").AFTER_REGEX(re/more/)
```

For more information on regular expressions, see "[Regular Expressions](#)."

Expression Prefixes for Text in HTTP Requests and Responses

Oct 07, 2016

An HTTP request or response typically contains text, such as in the form of headers, header values, URLs, and POST body text. You can configure expressions to operate on one or more of these text-based items in an HTTP request or response.

The following table describes the expression prefixes that you can configure to extract text from different parts of an HTTP request or response.

Table 1. HTTP Expression Prefixes That Return Text

Prefix	Description
HTTP.REQ.BODY(<integer>)	<u>Example:</u> HTTP.REQ.BODY(100) It will return first 100 characters of HTTP Request body. If the length of body is less than 100 then whole body will result as output.
HTTP.REQ.HOSTNAME	<u>Example:</u> HTTP.REQ.HOSTNAME.EQ("abc.com") The above example returns true if hostname is abc.com. It returns HTTP Host Name object from this request. If the target hostname is present in the first line of the request then that is selected. Otherwise the value in the last occurrence of the HOST header is selected. The format of output is abc.foo.com:8080. For more information on typecasting, see " Typecasting Data ."
HTTP.REQ.HOSTNAME.DOMAIN	<u>Example:</u> HTTP.REQ.URL.HOSTNAME.DOMAIN.EQ("foobar.com") The above example returns true if domain name is foobar.com. It returns Domain name part of the hostname. If the hostname is www.foobar.com or www.foobar.com:8080 , then domain is foobar.com.
HTTP.REQ.HOSTNAME.SERVER	<u>Example:</u> HTTP.REQ.URL.HOSTNAME.SERVER.EQ(" www.foobar.com ") The above example returns true if server name is www.foobar.com . It returns Domain name part of the hostname. If the hostname is www.foobar.com or www.foobar.com:8080 , then domain is www.foobar.com .
HTTP.REQ.METHOD	<u>Example:</u> HTTP.REQ.HOSTNAME.SERVER(" www.foobar.com ") The above example returns true if domain name is www.foobar.com . Correct one is HTTP.REQ.HOSTNAME.SERVER. It returns Domain name part of the hostname.
HTTP.REQ.URL	<u>Example:</u> HTTP.REQ.URL.EQ(" http://www.google.com ") The above example returns true if domain name is http://www.google.com . It returns the HTTP URL object from request.
HTTP.REQ.URL.HOSTNAME	<u>Example:</u> HTTP.REQ.URL.HOSTNAME.EQ("abc.foo.com:8080") The above example returns true if hostname in URL is abc.foo.com:8080. It returns HTTP Host Name present in the URL. For more information on typecasting, see " Typecasting Data ."
HTTP.REQ.URL.HOSTNAME.DOMAIN	<u>Example:</u> HTTP.REQ.URL.HOSTNAME.DOMAIN.EQ("foobar.com")

	The above example returns true if domain name is foobar.com. It returns Domain name part of the hostname. If the hostname is www.foobar.com or www.foobar.com:8080 , then domain is foobar.com.
HTTP.REQ.URL.HOSTNAME.SERVER	<u>Example:</u> The above example returns true if server name is www.foobar.com . It returns Domain name part of the hostname. If the hostname is www.foobar.com or www.foobar.com:8080 , then domain is www.foobar.com .
HTTP.REQ.URL.HOSTNAME.PORT	<u>Example:</u> HTTP.REQ.URL.HOSTNAME.PORT.EQ(80) The above example returns true if port is 80. It returns number on the port part of the hostname.
HTTP.REQ.URL.PATH	<u>Example:</u> HTTP.REQ.URL.PATH.GET(1) If the URL is http://www.foo.com/a/b/c/bar.html?a=1 then operation will select /a/b/c/bar.html, then the above example will result in "a". It returns / separated List on the path component of the URL.
HTTP.REQ.URL.PATH_AND_QUERY	<u>Example:</u> HTTP.REQ.URL.PATH_AND_QUERY If the URL is http://www.foo.com/a/b/c/bar.html?a=1 then it will return /a/b/c/bar.html?a=1. It returns the portion of the URL following the hostname
HTTP.REQ.URL.PROTOCOL	<u>Example:</u> HTTP.REQ.URL.PROTOCOL If the URL is http://www.foo.com/a/b/c/bar.html?a=1 then operation will result in HTTP. It results in the protocol present in the URL.
HTTP.REQ.URL.QUERY	<u>Example:</u> HTTP.REQ.URL.QUERY If the URL is http://www.foo.com?abc=1&def=2 will result in abc=1&def=2. It results as Name-Value List (with delimiters = and &) on the query component of the URL.
HTTP.REQ.URL.QUERY.VALUE	<u>Example:</u> -NA- It returns the value component of the specified name-value component in the list.
HTTP.REQ.URL.SUFFIX	<u>Example:</u> HTTP.REQ.URL.SUFFIX If the path is /a/b/c.html then this operation will result html. It returns filename suffice of the URL.
HTTP.REQ.USER	<u>Example:</u> HTTP.REQ.USER.GROUPS('grp1:grp2') The above example will return list on the Group which is separated by given delimiter I.e. ":" It returns the AAA User associated with the current HTTP transaction.
HTTP.REQ.USER.EXTERNAL_GROUPS	<u>Example:</u> HTTP.REQ.USER.EXTERNAL_GROUPS The above example will list external groups which are separated by ":". IT returns list of external groups which is separated by ":".
HTTP.REQ.USER.EXTERNAL_GROUPS.IGNORE_EMPTY_ELEMENTS	<u>Example:</u> HTTP.REQ.USER.EXTERNAL_GROUPS.IGNORE_EMPTY_ELEMENTS.COUNT If AAA User associated with the current HTTP transaction is part of some external groups : 123,,24,,15 then HTTP.REQ.USER.EXTERNAL_GROUPS.

	IGNORE_EMPTY_ELEMENTS.COUNT gives 4, whereas HTTPREQ.USER.EXTERNAL_GROUPS.COUNT gives 5. It ignores empty elements in the list.
HTTPREQ.USER.EXTERNAL_GROUPS(sep)	<u>Example:</u> HTTPREQ.USER.EXTERNAL_GROUPS(":") The above example will list external groups which are separated by ":" It returns list of external groups which is separated by given delimiter.
HTTPREQ.USER.GROUPS	<u>Example:</u> HTTPREQ.USER.GROUPS The above example will list groups which are separated by ",". IT returns list of groups which is separated by ",".
HTTPREQ.USER.GROUPS.IGNORE_EMPTY_ELEMENTS	<u>Example:</u> HTTPREQ.USER.GROUPS.IGNORE_EMPTY_ELEMENTS.COUNT If AAA User associated with the current HTTP transaction is part of some groups : 123,,24, ,15 then HTTPREQ.USER.GROUPS.IGNORE_EMPTY_ELEMENTS.COUNT gives 4, whereas HTTPREQ.USER.GROUPS.COUNT gives 5. It ignores empty elements in the list.
HTTPREQ.USER.GROUPS(sep)	<u>Example:</u> HTTPREQ.USER.GROUPS(":") The above example will list groups which are separated by ":" IT returns list of groups which is separated by given delimiter.
HTTPREQ.USER.INTERNAL_GROUPS	<u>Example:</u> HTTPREQ.USER.INTERNAL_GROUPS The above example will list internal groups which are separated by ",". IT returns list of internal groups which is separated by ",".
HTTPREQ.USER.INTERNAL_GROUPS.IGNORE_EMPTY_ELEMENTS	<u>Example:</u> HTTPREQ.USER.INTERNAL_GROUPS.IGNORE_EMPTY_ELEMENTS.COUNT If AAA User associated with the current HTTP transaction is part of some internal groups : 123,,24, ,15 then HTTPREQ.USER.INTERNAL_GROUPS.IGNORE_EMPTY_ELEMENTS.COUNT gives 4, whereas HTTPREQ.USER.INTERNAL_GROUPS.COUNT gives 5. It ignores empty elements in the list.
HTTPREQ.USER.INTERNAL_GROUPS(sep)	<u>Example:</u> HTTPREQ.USER.INTERNAL_GROUPS(":") The above example will list internal groups which are separated by ":" IT returns list of internal groups which is separated by given delimiter.
HTTPREQ.USER.IS_MEMBER_OF(group_name)	<u>Example:</u> HTTPREQ.USER.IS_MEMBER_OF(grp1) The above example returns true is the current AAA user is member of group grp1. It returns TRUE if the user is a member of the group group_name.
HTTPREQ.USER.NAME	<u>Example:</u> HTTPREQ.USER.NAME The above example will return name of the user. It returns the name of user. This is the name used by user for login unless it is overridden by name from external authentication server.
HTTPREQ.USER.PASSWD	<u>Example:</u> HTTPREQ.USER.PASSWD The above example will return password of the user. It returns the password of user.

HTTP.REQ.VERSION	<p><u>Example:</u> HTTP.REQ.VERSION</p> <p>The above example returns HTTP version information.</p>
HTTP.RES.BODY(<integer>)	<p><u>Example:</u> HTTP.RES.BODY(100)</p> <p>It will return first 100 characters of HTTP Response body. If the length of body is less than 100 then whole body will result as output.</p>
HTTP.RES.STATUS_MSG	<p><u>Example:</u> HTTP.RES.STATUS_MSG</p> <p>The above example results status message of response. It can be "Done", some error etc.</p>
HTTP.RES.VERSION	<p><u>Example:</u> HTTP.RES.VERSION</p> <p>The above example returns HTTP version information.</p>
HTTP.REQ.URL.HOSTNAME.EQ(<hostname>)	<p><u>Example:</u> HTTP.REQ.URL.HOSTNAME.EQ("abc.foo.com:8080")</p> <p>The above example returns true if hostname in URL is abc.foo.com:8080. It returns HTTP Host Name present in the URL.</p>
HTTP.REQ.IS_NTLM_OR_NEGOTIATE	<p><u>Example:</u> HTTP.REQ.IS_NTLM_OR_NEGOTIATE</p> <p>The above example returns TRUE if request is part of NTLM or NEGOTIATE connection.</p>
HTTP.REQ.URL.PATH.IGNORE_EMPTY_ELEMENTS	<p><u>Example:</u> HTTP.REQ.URL.PATH.IGNORE_EMPTY_ELEMENTS.COUNT</p> <p>If request URL has path (/123//24//15) elements as : 123,,24,,15 then HTTP.REQ.URL.PATH.IGNORE_EMPTY_ELEMENTS.COUNT gives 4, whereas HTTP.REQ.URL.PATHS.COUNT gives 5. It ignores empty elements in the list.</p>
HTTP.REQ.URL.QUERY.IGNORE_EMPTY_ELEMENTS	<p><u>Example:</u> HTTP.REQ.URL.QUERY.IGNORE_EMPTY_ELEMENTS.COUNT</p> <p>If request URL has path as : abc=1&&def=2&g=3&h=6 then HTTP.REQ.URL.QUERY.IGNORE_EMPTY_ELEMENTS.COUNT gives 4, whereas HTTP.REQ.URL.QUERY.COUNT gives 5. It ignores empty elements in the list.</p>

Expression Prefixes for VPNs and Clientless VPNs

Aug 30, 2013

The default syntax expression engine provides prefixes that are specific to parsing VPN or Clientless VPN data. This data includes the following:

- Host names, domains, and URLs in VPN traffic.
- Protocols in the VPN traffic.
- Queries in the VPN traffic.

These text elements are often URLs and components of URLs. In addition to applying the text-based operations on these elements, you can parse these elements by using operations that are specific to parsing URLs. For more information, see "[Expressions for Extracting Segments of URLs.](#)"

The following table describes the expression prefixes for this type of data.

Table 1. VPN and Clientless VPN Expression Prefixes That Return Text

VPN and Clientless VPN Expression	Description
VPN.BASEURL.CVPN_DECODE	Extracts the original URL from a clientless VPN URL.
VPN.BASEURL.CVPN_ENCODE	Converts a URL to clientless VPN format.
VPN.BASEURL.HOSTNAME	Extracts the HTTP host name from the host name in the URL. This prefix cannot be used in bidirectional policies.
VPN.BASEURL.HOSTNAME.DOMAIN	Extracts the domain name from the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, this prefix extracts mycompany.com. This prefix returns incorrect results if the host name is an IP address. For information on expressions for IP addresses, see " Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs. " All text operations after this prefix are case insensitive.
VPN.BASEURL.HOSTNAME.EQ (<hostname>)	Returns a Boolean TRUE if the host name matches <hostname>. The comparison is case insensitive. For example, if the host name is www.mycompany.com, the following returns TRUE: vpn.baseurl.hostname.eq("www.mycompany.com") If the text mode is URLENCODED, the host name is decoded before comparison. For more information, see " Operations for HTTP, HTML, and XML Encoding and "Safe" Characters. "
VPN.BASEURL.HOSTNAME.SERVER	Evaluates the server portion of the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the server is www.mycompany.com. All text operations after this prefix are case insensitive.
VPN.BASEURL.PATH	Extracts a slash- (/) separated list from the path component of the URL. For example, this prefix extracts /a/b/c/myPage.html from the following URL: http://www.mycompany.com/a/b/c/myPage.html?a=1 The following expression selects just the "a":

VPN and Clientless VPN Expression	Description
	<p><code>http.req.url.path.get(1)</code></p> <p>For more information on the GET operation, see "Expressions for Extracting Segments of URLs."</p>
VPN.BASEURL.PATH.IGNORE_EMPTY_ELEMENTS	<p>This prefix ignores the elements in a list. For example, the following comma-separated list has an empty element after "a=10":</p> <pre>a=10,,b=11, ,c=89</pre> <p>The element following b=11 contains a space, and by default, is not considered an empty element.</p> <p>Consider the following HTTP header:</p> <pre>Cust_Header : 123,,24, ,15</pre> <p>The following expression returns a count of 4 when evaluating this header:</p> <pre>http.req.header("Cust_Header").typecase_list_t(',').ignore_empty_elements.count</pre> <p>The following expression returns a count of 5 when evaluating this header:</p> <pre>http.req.header("Cust_Header").typecase_list_t(',').count</pre>
VPN.BASEURL.PATH_AND_QUERY	<p>Evaluates the text in the URL that follows the host name.</p> <p>For example, if the URL is <code>http://www.mycompany.com/a/b/c/mypage.html?a=1</code>, this prefix evaluates <code>/a/b/c/mypage.html?a=1</code>.</p>
VPN.BASEURL.PROTOCOL	<p>Evaluates the protocol in the URL.</p> <p>Do not use this prefix in bidirectional policies.</p>
VPN.BASEURL.QUERY	<p>Extracts a name-value list, using the "=" and "&" delimiters from the query string in a URL.</p>
VPN.BASEURL.QUERY.IGNORE_EMPTY_ELEMENTS	<p>This method ignores the empty elements in a name-value list. For example, in the following name-value list, there is an empty element following "a=10":</p> <pre>a=10;;b=11; ;c=89</pre> <p>The element following b=11 contains a space and is not considered an empty element.</p> <p>Consider the following HTTP header:</p> <pre>Cust_Header : a=1;;b=2; ;c=3</pre> <p>The following expression produces a count of 4 after evaluating this header:</p> <pre>http.req.header("Cust_Header").typecast_nvlist_t(';',').ignore_empty_elements.count</pre> <p>The following expression produces a count of 5 after evaluating the header:</p> <pre>http.req.header("Cust_Header").typecast_nvlist_t(';',').</pre>
VPN.BASEURL.SUFFIX	<p>Evaluates the file name suffix in a URL.</p> <p>For example, if the path is <code>/a/b/c/my.page.html</code>, this operation selects "html."</p>
VPN.CLIENTLESS_BASEURL	<p>Evaluates the clientless VPN base URL.</p>
VPN.CLIENTLESS_BASEURL.CVPN_DECODE	<p>Extracts the original URL from the clientless VPN formatted URL.</p>

VPN and Clientless VPN Expression	Description
VPN.CLIENTLESS_BASEURL.CVPN_ENCODE	Converts a URL to the clientless VPN format.
VPN.CLIENTLESS_BASEURL.HOSTNAME	Evaluates the host name in the URL. Do not use this prefix in bidirectional policies.
VPN.CLIENTLESS_BASEURL.HOSTNAME.DOMAIN	Evaluates the domain name part of the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the domain is mycompany.com. This operation returns incorrect results if the host name is an IP address. For information on expressions for IP addresses, see " Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs. " All text operations after this prefix are case insensitive.
VPN.CLIENTLESS_BASEURL.HOSTNAME.EQ(<hostname>)	Returns a Boolean TRUE if the host name matches <hostname>. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the following is true: vpn.clientless_baseurl.hostname.eq("www.mycompany.com") The comparison is case insensitive. If the textmode is URLENCODED, the host name is decoded before comparison. For more information, see " Operations for HTTP, HTML, and XML Encoding and "Safe" Characters. "
VPN.CLIENTLESS_BASEURL.HOSTNAME.SERVER	Evaluates the server part of a host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the server is www.mycompany.com. All text operations after this prefix are case insensitive.
VPN.CLIENTLESS_BASEURL.PATH	Evaluates a slash- (/) separated list in the URL path. For example, this prefix selects /a/b/c/mypage.html from the following URL: http://www.mycompany.com/a/b/c/mypage.html?a=1 The following expression selects "a" from the preceding URL: http.req.url.path.get(1) For more information on the GET operation, see " Expressions for Extracting Segments of URLs. "
VPN.CLIENTLESS_BASEURL.PATH.IGNORE_EMPTY_ELEMENTS	Ignores empty elements in a list. For example, if the list delimiter is a comma (,) the following list has an empty element following "a=10": a=10,b=11, ,c=89 The element following b=11 contains a space and is not considered an empty element. Consider the following HTTP header: Cust_Header: 123,,24, ,15 The following expression returns a value of 4 after evaluating this header: http.req.header("Cust_Header").typecast_list_t(',').ignore_empty_elements.count

VPN and Clientless VPN Expression	Description
	<p>The following expression returns a value of 5 after evaluating this header:</p> <pre>http.req.header("Cust_Header").typecast_list_t(',')</pre>
VPN.CLIENTLESS_BASEURL.PATH_AND_QUERY	<p>Evaluates the text following the host name in a URL.</p> <p>For example, this prefix selects /a/b/c/mypage.html?a=1 from the following URL:</p> <pre>http://www.mycompany.com/a/b/c/mypage.html?a=1</pre>
VPN.CLIENTLESS_BASEURL.PROTOCOL	<p>Evaluates the protocol in the URL.</p> <p>Do not use this prefix in bidirectional policies.</p>
VPN.CLIENTLESS_BASEURL.QUERY	<p>Extracts a name-value list that uses the delimiters "=" and "&" from a URL query string.</p>
VPN.CLIENTLESS_BASEURL.QUERY.IGNORE_EMPTY_ELEMENTS	<p>Ignores empty elements in a name-value list. For example, the following list contains an empty element after "a=10":</p> <pre>a=10;;b=11;c=89</pre> <p>The element following b=11 contains a space and is not considered an empty element.</p> <p>As another example, consider the following http header:</p> <pre>Cust_Header : a=1;;b=2; ;c=3</pre> <p>The following expression returns a value of 4 after evaluating the preceding header:</p> <pre>http.req.header("Cust_Header").typecast_nvlist_t(';',').ignore_empty_elements.count</pre> <p>The following expression returns a value of 5 after evaluating the preceding header:</p> <pre>http.req.header("Cust_Header").typecast_nvlist_t(';',')</pre>
VPN.CLIENTLESS_BASEURL.SUFFIX	<p>Evaluates the file suffix in a URL. For example, if the URL path is /a/b/c/mypage.html then this operation selects html.</p>
VPN.CLIENTLESS_HOSTURL	<p>Selects the clientless VPN host URL.</p>
VPN.CLIENTLESS_HOSTURL.CVPN_DECODE	<p>Selects the original URL from the clientless VPN formatted URL.</p>
VPN.CLIENTLESS_HOSTURL.CVPN_ENCODE	<p>Converts a URL to clientless VPN format.</p>
VPN.CLIENTLESS_HOSTURL.HOSTNAME	<p>Extracts the host name in the URL.</p> <p>Do not use this prefix in bidirectional policies.</p>
VPN.CLIENTLESS_HOSTURL.HOSTNAME.DOMAIN	<p>Extracts the domain name from the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the domain is mycompany.com.</p> <p>This operation returns incorrect results if the host name contains an IP address. For information on expressions for IP addresses, see "Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs."</p> <p>All text operations after this prefix are case insensitive.</p>

VPN.CLIENTLESS_HOSTURL.HOSTNAME.EQ(<hostname> VPN and Clientless-VPN Expression	Description
	<p>Results in Boolean TRUE if the host name matches the <hostname> argument. The comparison is case insensitive.</p> <p>For example, if the host name is www.mycompany.com or www.mycompany.com, the following expression returns TRUE:</p> <pre>vpn.clientless_hosturl.hostname.eq("www.mycompany.com")</pre> <p>If the text mode is URLENCODED, the host name is decoded before comparison. For more information, see "Operations for HTTP, HTML, and XML Encoding and "Safe" Characters."</p>
VPN.CLIENTLESS_HOSTURL.HOSTNAME.SERVER	<p>Evaluates the server part of the host name.</p> <p>For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the server is www.mycompany.com.</p> <p>The comparison is case insensitive, and all text operations after this method are case insensitive.</p>
VPN.CLIENTLESS_HOSTURL.PATH	<p>Evaluates a slash- (/) separated list on the path component of the URL.</p> <p>For example, consider the following URL:</p> <pre>http://www.mycompany.com/a/b/c/mypage.html?a=1</pre> <p>This prefix selects /a/b/c/mypage.html from the preceding URL.</p>
VPN.CLIENTLESS_HOSTURL.PATH.IGNORE_EMPTY_ELEMENTS	<p>This method ignores the empty elements in a list. For example, if the delimiter in a list is ",", the following list contains an empty element after the entry "a=10":</p> <pre>a=10,b=11, ,c=89</pre> <p>The element following b=11 contains a space and is not considered an empty element.</p> <p>Consider the following header:</p> <pre>Cust_Header: 123,,24, ,15</pre> <p>The following expression returns a value of 4 for this header:</p> <pre>http.req.header("Cust_Header").typecast_list_t(';').ignore_empty_elements.count</pre> <p>The following expression returns a value of 5 for the same header:</p> <pre>http.req.header("Cust_Header").typecast_list_t(';').</pre>
VPN.CLIENTLESS_HOSTURL.PATH_AND_QUERY	<p>Evaluates the portion of the URL that follows the host name.</p> <p>For example, consider the following URL:</p> <pre>http://www.mycompany.com/a/b/c/mypage.html?a=1</pre> <p>This prefix returns /a/b/c/mypage.html?a=1 from the preceding URL.</p>
VPN.CLIENTLESS_HOSTURL.PROTOCOL	<p>Evaluates the protocol in the URL.</p> <p>Do not use this prefix in bidirectional policies.</p>
VPN.CLIENTLESS_HOSTURL.QUERY	<p>Extracts a name-value list, using the "=" and "&" delimiters from a URL query string.</p>
VPN.CLIENTLESS_HOSTURL.QUERY.IGNORE_EMPTY_ELEMENTS	<p>Ignores empty elements in a name-value list. For example, the following list uses a semicolon (;) delimiter. This list contains an empty element after "a=10":</p>

VPN and Clientless VPN Expression	Description
	<p data-bbox="746 159 906 188">a=10;b=11;c=89</p> <p data-bbox="746 208 1485 264">In the preceding example, the element following b=11 is not considered an empty element.</p> <p data-bbox="746 288 1026 315">Consider the following header:</p> <p data-bbox="746 340 1007 367">Cust_Header: a=1;;b=2; ;c=3</p> <p data-bbox="746 392 1414 418">The following expression returns a value of 4 after evaluating this header:</p> <p data-bbox="746 443 1506 470"><code>http.req.header("Cust_Header").typecast_nvlist_t('=',';').ignore_empty_elements.count</code></p> <p data-bbox="746 495 1465 521">The following expression returns a value of 5 after evaluating the same header:</p> <p data-bbox="746 546 1230 573"><code>http.req.header("Cust_Header").typecast_nvlist_t('=',';')</code></p>
VPN.CLIENTLESS_HOSTURL.SUFFIX	<p data-bbox="746 622 1062 649">Extracts a file name suffix in a URL.</p> <p data-bbox="746 674 1390 701">For example, if the path is /a/b/c/my.page.html, this prefix selects html.</p>
VPN.HOST.DOMAIN	<p data-bbox="746 745 1490 835">Extracts the domain name part of the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the domain is mycompany.com.</p> <p data-bbox="746 860 1469 949">This prefix returns incorrect results if the host name contains an IP address. For information on expressions for IP addresses, see "Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs."</p> <p data-bbox="746 974 1206 1001">All text operations after this prefix case insensitive.</p>
VPN.HOST.EQ(<hostname>)	<p data-bbox="746 1070 1458 1126">Returns a Boolean TRUE value if the host name matches the <hostname>. The comparison is case insensitive.</p> <p data-bbox="746 1151 1270 1209">For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the following returns TRUE:</p> <p data-bbox="746 1234 1078 1261"><code>vpn.host.eq("www.mycompany.com")</code></p> <p data-bbox="746 1285 1474 1375">If the text mode is URLENCODED the host name is decoded before comparison. For more information, see "Operations for HTTP, HTML, and XML Encoding and "Safe" Characters."</p>
VPN.HOST.SERVER	<p data-bbox="746 1417 1477 1507">Extracts the server name part of the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the server is www.mycompany.com.</p> <p data-bbox="746 1532 1238 1559">All text operations after this prefix are case insensitive.</p>

Basic Operations on Text

Aug 30, 2013

Basic operations on text include operations for string matching, calculating the length of a string, and controlling case sensitivity. You can include white space in a string that is passed as an argument to an expression, but the string cannot exceed 255 characters.

String Comparison Functions

The following table lists basic string matching operations in which the functions return a Boolean TRUE or FALSE.

Table 1. String Comparison Functions

Function	Description
<code><text>.CONTAINS(<string>)</code>	Returns a Boolean TRUE value if the target contains <code><string></code> . Following is an example: <code>http.req.url.contains(".jpeg")</code>
<code><text>.EQ(<string>)</code>	Returns a Boolean TRUE value if the target is an exact match with <code><string></code> . For example, the following expression returns a Boolean TRUE for a URL with a host name of "myhostabc": <code>http.req.url.hostname.eq("myhostabc")</code>
<code><text>.STARTSWITH(<string>)</code>	Returns a Boolean TRUE value if the target begins with <code><string></code> . For example, the following expression returns a Boolean TRUE for a URL with a host name of "myhostabc": <code>http.req.url.hostname.startswith("myhost")</code>
<code><text>.ENDSWITH(<string>)</code>	Returns a Boolean TRUE value if the target ends with <code><string></code> . For example, the following expression returns a Boolean TRUE for a URL with a host name of "myhostabc": <code>http.req.url.hostname.endswith("abc")</code>
<code><text>.NE(<string>)</code>	Returns a Boolean TRUE value if the prefix is not equal to the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with <code>SET_TEXT_MODE(IGNORECASE)</code> or <code>SET_TEXT_MODE(NOIGNORECASE)</code> , and

Function	Description
<text>.GT(<string>)	<p>Returns a Boolean TRUE value if the prefix is alphabetically greater than the string argument.</p> <p>If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with SET_TEXT_MODE(IGNORECASE) or SET_TEXT_MODE(NOIGNORECASE), and with both ASCII and UTF-8 character sets.</p>
<text>.GE(<string>)	<p>Returns a Boolean TRUE value if the prefix is alphabetically greater than or equal to the string argument.</p> <p>If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with SET_TEXT_MODE(IGNORECASE) or SET_TEXT_MODE(NOIGNORECASE), and with both ASCII and UTF-8 character sets.</p>
<text>.LT(<string>)	<p>Returns a Boolean TRUE value if the prefix is alphabetically lesser than the string argument.</p> <p>If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with SET_TEXT_MODE(IGNORECASE) or SET_TEXT_MODE(NOIGNORECASE), and with both ASCII and UTF-8 character sets.</p>
<text>.LE(<string>)	<p>Returns a Boolean TRUE value if the prefix is alphabetically lesser than or equal to the string argument.</p> <p>If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with SET_TEXT_MODE(IGNORECASE) or SET_TEXT_MODE(NOIGNORECASE), and with both ASCII and UTF-8 character sets.</p>

Calculating the Length of a String

The <text>.LENGTH operation returns a numeric value that is equal to the number of characters (not bytes) in a string:

```
<text>.LENGTH
```

For example, you may want to identify request URLs that exceed a particular length. Following is an expression that implements this example:

```
HTTP.REQ.URL.LENGTH < 500
```

After taking a count of the characters or elements in a string, you can apply numeric operations to them. For more information, see "[Default Syntax Expressions: Working with Dates, Times, and Numbers.](#)"

Considering, Ignoring, and Changing Text Case

The following functions operate on the case (upper-case or lower-case) of the characters in the string.

Table 2. Functions for Considering, Ignoring, and Changing Text Case

Function	Description
<code><text>.SET_TEXT_MODE(IGNORECASE NOIGNORECASE)</code>	This function turns case sensitivity on or off for all text operations.
<code><text>.TO_LOWER</code>	Converts the target to lowercase for a text block of up to 2 kilobyte (KB). Returns UNDEF if the target exceeds 2 KB. For example, the string "ABCd:" is converted to "abcd:".
<code><text>.TO_UPPER</code>	Converts the target to uppercase. Returns UNDEF if the target exceeds 2 KB. For example, the string "abcD:" is converted to "ABCD:".

Stripping Specific Characters from a String

You can use the `STRIP_CHARS(<string>)` function to remove specific characters from the text that is returned by a default syntax expression prefix (the input string). All instances of the characters that you specify in the argument are stripped from the input string. You can use any text method on the resulting string, including the methods used for matching the string with a pattern set.

For example, in the expression `CLIENT.UDP.DNS.DOMAIN.STRIP_CHARS("._-")`, the `STRIP_CHARS(<string>)` function strips all periods (.), hyphens (-), and underscores (_) from the domain name returned by the prefix `CLIENT.UDP.DNS.DOMAIN`. If the domain name that is returned is "a.dom_ai_n-name", the function returns the string "adomainname".

In the following example, the resulting string is compared with a pattern set called "listofdomains":

```
CLIENT.UDP.DNS.DOMAIN.STRIP_CHARS("._-").CONTAINS_ANY("listofdomains")
```

Note: You cannot perform a rewrite on the string that is returned by the `STRIP_CHARS(<string>)` function. The following functions strip matching characters from the beginning and end of a given string input.

Table 3. Functions for Stripping Characters From the Beginning or End of a String

Function	Description
<code><text>.STRIP_START_CHARS(s)</code>	Strips matching characters from the beginning of the input string until the first non-matching character is found and returns the remainder of the string. You must specify the characters that you want to strip as a single string within quotation marks.

Function	Description
	<p>For example, if the name of a header is <code>TestLang</code> and <code>://_en_us:</code> is its value, <code>HTTP.RES.HEADER("TestLang").STRIP_START_CHARS(":/_")</code> strips the specified characters from the beginning of the value of the header until the first non-matching character <code>e</code> is found and returns <code>en_us:</code> as a string.</p>
<code><text>.STRIP_END_CHARS(s)</code>	<p>Strips matching characters from the end of the input string to the first non-matching character is found and returns the remainder of the string. You must specify the characters that you want to strip as a single string within quotation marks.</p> <p>For example, if the name of a header is <code>TestLang</code> and <code>://_en_us:</code> is its value, <code>HTTP.RES.HEADER("TestLang").STRIP_END_CHARS(":/_")</code> strips the specified characters from the end of the value of the header until the first non-matching character <code>s</code> is found and returns <code>://_en_us</code> as a string.</p>

Appending a String to Another String

You can use the `APPEND()` function to append the string representation of the argument to the string representation of the value returned by the preceding function. The preceding function can be one that returns a number, unsigned long, double, time value, IPv4 address, or IPv6 address. The argument can be a text string, number, unsigned long, double, time value, IPv4 address, or IPv6 address. The resulting string value is the same string value that is obtained by using the `+` operator.

Complex Operations on Text

May 25, 2015

In addition to performing simple string matching, you can configure expressions that examine more complex aspects of text, including examining the length of a string and looking within a text block for patterns rather than specific strings.

Be aware of the following for any text-based operation:

- For any operation that takes a string argument, the string cannot exceed 255 characters.
- You can include white space when you specify a string in an expression.

This document includes the following details:

- [Operations on the Length of a String](#)
- [Operations on a Portion of a String](#)
- [Operations for Comparing the Alphanumeric Order of Two Strings](#)
- [Extracting an Integer from a String of Bytes That Represent Text](#)
- [Converting Text to a Hash Value](#)
- [Encoding and Decoding Text by Applying the Base64 Encoding Algorithm](#)
- [Refining the Search in a Rewrite Action by Using the EXTEND Function](#)
- [Converting Text to Hexadecimal Format](#)
- [Encrypting and Decrypting Text](#)

Operations on the Length of a String

The following operations extract strings on the basis of a character count.

Table 1. String Operations Based on a Character Count

Character Count Operation	Description
<code><text>.TRUNCATE(<count>)</code>	Returns a string after truncating the end of the target by the number of characters in <code><count></code> . If the entire string is shorter than <code><count></code> , nothing is returned.
<code><text>.TRUNCATE(<character>, <count>)</code>	Returns a string after truncating the text after <code><character></code> by the number of characters specified in <code><count></code> .
<code><text>.PREFIX(<character>, <count>)</code>	Selects the longest prefix in the target that has at most <code><count></code> occurrences of <code><character></code> .
	<code><text>.SUFFIX(<character>, <count>)</code> Selects the longest suffix in the target that has at most <code><count></code> occurrences of <code><character></code> . For example, consider the following response body: JLEwx

Character Count Operation	Description
	The following expression returns a value of "JLEwx": <code>http.res.body(100).suffix('L',1)</code>
	The following expression returns "LLEwx": <code>http.res.body(100).suffix('L',2)</code>
<code><text>.SUBSTR(<starting_offset>,<length>)</code>	Select a string with <length> number of characters from the target object. Begin extracting the string after the <starting_offset>. If the number of characters after the offset are fewer than the value of the <length> argument, select all the remaining characters.
<code><text>.SKIP(<character>,<count>)</code>	Select a string from the target after skipping over the longest prefix that has at most <count> occurrences of <character>.

Operations on a Portion of a String

You can extract a subset of a larger string by using one of the operations in the following table.

Table 2. Basic Operations on a Portion of a String

Basic Text Operation	Description
<code><text>.BEFORE_STR(<string>)</code>	Returns the text that precedes the first occurrence of <string>. If there is no match for <string>, the expression returns a text object of 0 length. Following is an example: <code>http.res.body(1024).after_str("start_string").before_str("end_string").contains("https")</code>
<code><text>.AFTER_STR(<string>)</code>	Returns the text that follows the first occurrence of <string>. If there is no match for <string>, the expression returns a text object of 0 length. Following is an example: <code>http.res.body(1024).after_str("start_string").before_str("end_string").contains("https")</code>
<code><text>.BETWEEN(<starting string>,<ending string>)</code>	Returns a Boolean TRUE value if the length of the text object is greater than or equal to the sum <starting string>, <ending string> argument lengths, and if a prefix of the target matches <starting string>, and if the suffix of the target matches <ending string>.
<code><text>.PREFIX(<prefix length>)</code>	Returns the starting string from a target block of text that contains the number of characters in the <prefix length> argument.

Basic Text Operation	Description
<text>.SUFFIX(<suffix length>)	Returns the ending string from a target block of text that contains the number of characters in the <suffix length> argument. If the <suffix length> argument exceeds the number characters in the target, the entire string is selected.
<text>.SUBSTR(<string>)	Select the first block of text in the target that matches the <string>.
<text>.SKIP(<prefix length>)	Selects the text in the target after skipping over a <prefix length> number of characters. If the entire target has fewer characters than <prefix length>, the entire target is skipped.
<text>.STRIP_END_WS	Selects the text after removing white space from the end of the target.
<text>.STRIP_START_WS	Selects the text after removing white space from the beginning of the target.
<text>.UNQUOTE(<character>)	Selects the <character>, removes white space that immediately precedes and follows the <character>, and if the remaining text is quoted by <character>, this prefix also removes the quotes. For example, the operation UNQUOTE("") changes the following text: "abc xyz def " To the following: abc xyz def

Operations for Comparing the Alphanumeric Order of Two Strings

The COMPARE operation examines the first nonmatching character of two different strings. This operation is based on lexicographic order, which is the method used when ordering terms in dictionaries.

This operation returns the arithmetic difference between the ASCII values of the first nonmatching characters in the compared strings. The following differences are examples:

- The difference between “abc” and “abd” is -1 (based on the third pair-wise character comparison).
- The difference between “@” and “abc” is -33.
- The difference between “1” and “abc” is -47.

Following is the syntax for the COMPARE operation.

```
<text>.COMPARE(<string>)
```

Extracting an Integer from a String of Bytes That Represent Text

You can use the following functions to treat a string of bytes that represent text as a sequence of bytes, extract 8, 16, or 32 bits from the sequence, and then convert the extracted bits to an integer.

Table 3. Operations for Extracting an Integer from a String of Bytes That Represent Text

Function	Description
<text>.GET_SIGNED8(<n>)	Treats the string of bytes represented by text as a sequence of 8-bit signed integers and returns the integer at byte offset n. If the offset makes all or part of the value outside of the current text, an UNDEF condition is raised.
<text>.GET_UNSIGNED8(<n>)	Treats the string of bytes represented by text as a sequence of 8-bit unsigned integers and returns the integer at byte offset n. If the offset makes all or part of the value outside of the current text, an UNDEF condition is raised.
<text>.GET_SIGNED16(<n>, <endianness>)	<p>Treats the text string returned by the prefix as a string of bytes, extracts 16 bits starting at byte offset n, and converts the extracted bit sequence to a 16-bit signed integer. If the offset makes all or part of the value outside of the current text, an UNDEF condition is raised.</p> <p>The first parameter n is the byte offset from the current position in the text string. Providing a byte offset enables the function to handle items that are not aligned on the boundaries that are required by indexes. The second parameter, endianness, takes a mnemonic value of LITTLE_ENDIAN or BIG_ENDIAN.</p> <p>Note: In NetScaler 9.2, the parameter n was an index into an array of 16-bit items. In NetScaler 9.3, the parameter is a byte offset. Therefore, if you used this function in NetScaler 9.2, after you upgrade to NetScaler 9.3, you must change n to 2*n to obtain the same results as you did earlier. For example, if the value of n before the upgrade was 4, you must change the value of n to 8. The parameter endianness also no longer takes the values that it did in NetScaler 9.2, which were 0 and 1. Instead, endianness accepts the mnemonic values mentioned earlier.</p> <p>Example</p> <p>HTTP.REQ.BODY(100).GET_SIGNED16(8, BIG_ENDIAN)</p>
<text>.GET_UNSIGNED16(<n>, <endianness>)	<p>Treats the text string returned by the prefix as a string of bytes, extracts 16 bits starting at byte offset n, and converts the extracted bit sequence to a 16-bit unsigned integer. If the offset makes all or part of the value outside of the current text, an UNDEF condition is raised.</p> <p>The first parameter n is the byte offset from the current position in the text string. Providing a byte offset enables the function to handle items that are not aligned on the boundaries that are required by indexes. The second parameter, endianness, takes a mnemonic value of LITTLE_ENDIAN or BIG_ENDIAN.</p>

Function	Description
	<p>Note: In NetScaler 9.2, the parameter <i>n</i> was an index into an array of 16-bit items. In NetScaler 9.3, the parameter is a byte offset. Therefore, if you used this function in NetScaler 9.2, after you upgrade to NetScaler 9.3, you must change <i>n</i> to $2*n$ to obtain the same results as you did earlier. For example, if the value of <i>n</i> before the upgrade was 4, you must change the value of <i>n</i> to 8. The parameter <i>endianness</i> also no longer takes the values that it did in NetScaler 9.2, which were 0 and 1. Instead, <i>endianness</i> accepts the mnemonic values mentioned earlier.</p> <p>Example</p> <pre>HTTP.REQ.BODY(100).GET_UNSIGNED16(8, LITTLE_ENDIAN)</pre>
<pre><text>.GET_SIGNED32(<n>, <endianness>)</pre>	<p>Treats the text string returned by the prefix as a string of bytes, extracts 32 bits starting at byte offset <i>n</i>, and converts the extracted bit sequence to a 32-bit signed integer. If the offset makes all or part of the value outside of the current text, an UNDEF condition is raised.</p> <p>The first parameter <i>n</i> is the byte offset from the current position in the text string. Providing a byte offset enables the function to handle items that are not aligned on the boundaries that are required by indexes. The second parameter, <i>endianness</i>, takes a mnemonic value of LITTLE_ENDIAN or BIG_ENDIAN.</p> <p>Note: In NetScaler 9.2, the parameter <i>n</i> was an index into an array of 32-bit items. In NetScaler 9.3, the parameter is a byte offset. Therefore, if you used this function in NetScaler 9.2, after you upgrade to NetScaler 9.3, you must change <i>n</i> to $4*n$ to obtain the same results as you did earlier. For example, if the value of <i>n</i> before the upgrade was 4, you must change the value of <i>n</i> to 16. The parameter <i>endianness</i> also no longer takes the values that it did in NetScaler 9.2, which were 0 and 1. Instead, <i>endianness</i> accepts the mnemonic values mentioned earlier.</p> <p>Example</p> <pre>HTTP.REQ.BODY(1000).GET_SIGNED32(12, BIG_ENDIAN)</pre>
<pre><text>.GET_UNSIGNED32(<n>, <endianness>)</pre>	<p>Treats the text string returned by the prefix as a string of bytes, extracts 32 bits starting at byte offset <i>n</i>, and returns the extracted bit sequence as part of a 64-bit unsigned long integer. If the offset makes all or part of the value outside of the current text, an UNDEF condition is raised.</p> <p>The first parameter <i>n</i> is the byte offset from the current position in the text string. Providing a byte offset enables the function to handle items that are not aligned on the boundaries that are required by indexes. The second parameter, <i>endianness</i>, takes a mnemonic value of LITTLE_ENDIAN or BIG_ENDIAN.</p> <p>Example</p> <pre>HTTP.REQ.BODY(1000).GET_UNSIGNED32(30, LITTLE_ENDIAN)</pre>

Converting Text to a Hash Value

You can convert a text string to a hash value by using the HASH function. This function returns a 31-bit positive integer as a result of the operation. Following is the format of the expression:

<text>.HASH

This function ignores case and white spaces. For example, after the operation, the two strings Ab c and a bc would produce the same hash value.

Encoding and Decoding Text by Applying the Base64 Encoding Algorithm

The following two functions encode and decode a text string by applying the Base64 encoding algorithm

Table 4. Functions for Encoding and Decoding a Text String by Using Base64 Encoding

Function	Description
text.B64ENCODE	Encodes the text string (designated by text) by applying the Base64 encoding algorithm.
text.B64DECODE	Decodes the Base64-encoded string (designated by text) by applying the Base64 decoding algorithm. The operation raises an UNDEF if text is not in B64-encoded format.

Refining the Search in a Rewrite Action by Using the EXTEND Function

The EXTEND function is used in rewrite actions that specify patterns or pattern sets and target the bodies of HTTP packets. When a pattern match is found, the EXTEND function extends the scope of the search by a predefined number of bytes on both sides of the matching string. A regular expression can then be used to perform a rewrite on matches in this extended region. Rewrite actions that are configured with the EXTEND function perform rewrites faster than rewrite actions that evaluate entire HTTP bodies using only regular expressions.

The format of the EXTEND function is EXTEND(m,n), where m and n are the number of bytes by which the scope of the search is extended before and after the matching pattern, respectively. When a match is found, the new search scope comprises m bytes that immediately precede the matching string, the string itself, and the n bytes that follow the string. A regular expression can then be used to perform a rewrite on a portion of this new string.

The EXTEND function can be used only if the rewrite action in which it is used fulfills the following requirements:

- The search is performed by using patterns or patterns sets (not regular expressions)
- The rewrite action evaluates only the bodies of HTTP packets.

Additionally, the EXTEND function can be used only with the following types of rewrite actions:

- replace_all
- insert_after_all
- delete_all
- insert_before_all

For example, you might want to delete all instances of "http://exampleurl.com/" and "http://exampleurl.au/" in the first 1000 bytes of the body. To do this, you can configure a rewrite action to search for all instances of the string exampleurl, extend the scope of the search on both sides of the string when a match is found, and then use a regular expression to

perform the rewrite in the extended region. The following example extends the scope of the search by 20 bytes to the left and 50 bytes to the right of the matching string:

```
add rewrite action delurl_example delete_all 'HTTP.REQ.BODY(1000)' -pattern exampleurl -refineSearch
'extend(20,50).regex_select(re#http://exampleurl.(com|au)#)'
```

Converting Text to Hexadecimal Format

The following function converts text to hexadecimal format and extracts the resulting string:

```
<text>.BLOB_TO_HEX(<string>)
```

For example, this function converts the byte string “abc” to “61:62:63”.

Encrypting and Decrypting Text

Updated: 2013-09-02

In default syntax expressions, you can use the ENCRYPT and DECRYPT functions to encrypt and decrypt text. Data encrypted by the ENCRYPT function on a given NetScaler appliance or high availability (HA) pair is intended for decryption by the DECRYPT function on the same NetScaler appliance or HA pair. The appliance supports the RC4, DES3, AES128, AES192, and AES256 encryption methods. The key value that is required for encryption is not user-specifiable. When an encryption method is set, the appliance automatically generates a random key value that is appropriate for the specified method. The default method is AES256 encryption, which is the most secure encryption method and the one that Citrix recommends.

You do not need to configure encryption unless you want to change the encryption method or you want the appliance to generate a new key value for the current encryption method.

Note: You can also encrypt and decrypt XML payloads. For information about the functions for encrypting and decrypting XML payloads, see "[Encrypting and Decrypting XML Payloads](#)."

Configuring Encryption

Updated: 2013-09-02

During startup, the appliance runs the `set ns encryptionParams` command with, by default, the AES256 encryption method, and uses a randomly generated key value that is appropriate for AES256 encryption. The appliance also encrypts the key value and saves the command, with the encrypted key value, to the NetScaler configuration file. Consequently, the AES256 encryption method is enabled for the ENCRYPT and DECRYPT functions by default. The key value that is saved in the configuration file persists across reboots even though the appliance runs the command each time you restart it.

You can run the `set ns encryptionParams` command manually, or use the configuration utility, if you want to change the encryption method or if you want the appliance to generate a new key value for the current encryption method. To use the CLI to change the encryption method, set only the `method` parameter, as shown in "**Example 1: Changing the Encryption Method**." If you want the appliance to generate a new key value for the current encryption method, set the `method` parameter to the current encryption method and the `keyValue` parameter to an empty string (""), as shown in "**Example 2: Generating a New Key Value for the Current Encryption Method**." After you generate a new key value, you must save the configuration. If you do not save the configuration, the appliance uses the newly generated key value only until the next restart, after which it reverts to the key value in the saved configuration.

To configure encryption by using the configuration utility

1. Navigate to System > Settings.
2. In the Settings area, click Change Encryption parameters.
3. In the Change Encryption Parameters dialog box, do one of the following:
 - To change the encryption method, in the Method list, select the encryption method that you want.
 - To generate a new key value for the current encryption method, click Generate a new key for the selected method.
4. Click OK.

Using the ENCRYPT and DECRYPT Functions

You can use the ENCRYPT and DECRYPT functions with any expression prefix that returns text. For example, you can use the ENCRYPT and DECRYPT functions in rewrite policies for cookie encryption. In the following example, the rewrite actions encrypt a cookie named MyCookie, which is set by a back-end service, and decrypt the same cookie when it is returned by a client:

```
add rewrite action my-cookie-encrypt-action replace "HTTP.RES.SET_COOKIE.COOKIE(\"MyCookie\").VALUE(0)"  
"HTTP.RES.SET_COOKIE.COOKIE(\"MyCookie\").VALUE(0).ENCRYPT" -bypassSafetyCheck YES
```

```
add rewrite action my-cookie-decrypt-action replace "HTTP.REQ.COOKIE.VALUE(\"MyCookie\")"  
"HTTP.REQ.COOKIE.VALUE(\"MyCookie\").DECRYPT" -bypassSafetyCheck YES
```

After you configure policies for encryption and decryption, save the configuration to bring the policies into effect.

Default Syntax Expressions: Working with Dates, Times, and Numbers

Sep 02, 2013

Most numeric data that the NetScaler appliance processes consists of dates and times. In addition to working with dates and times, the appliance processes other numeric data, such as the lengths of HTTP requests and responses. To process this data, you can configure default syntax expressions that process numbers.

A numeric expression consists of an expression prefix that returns a number and sometimes, but not always, an operator that can perform an operation on the number. Examples of expression prefixes that return numbers are `SYS.TIME.DAY`, `HTTP.REQ.CONTENT_LENGTH`, and `HTTP.RES.BODY.LENGTH`. Numeric operators can work with any prefix expression that returns data in numeric format. The `GT(<int>)` operator, for example, can be used with any prefix expression, such as `HTTP.REQ.CONTENT_LENGTH`, that returns an integer. Numeric expression prefixes and operators are also covered in "[Compound Operations for Numbers](#)" and "[Default Syntax Expressions: Parsing HTTP, TCP, and UDP Data](#)."

Format of Dates and Times in an Expression

Nov 14, 2013

When configuring a default syntax expression in a policy that works with dates and times (for example, the NetScaler system time or a date in an SSL certificate), you specify a time format as follows:

```
GMT|LOCAL [<yyyy>] [<month>] [<d>] [<h>] [<m>] [<s>]
```

Where:

- <yyyy> is a four-digit year after GMT or LOCAL.
- <month> is a three-character abbreviation for the month, for example, Jan, Dec.
- <d> is a day of the week or an integer for the date.

You cannot specify the day as Monday, Tuesday, and so on. You specify either an integer for a specific day of the month, or you specify a date as the first, second, third weekday of the month, and so on. Following are examples of specifying a day of the week:

- Sun_1 is the first Sunday of the month.
- Sun_3 is the third Sunday of the month.
- Wed_3 is the third Wednesday of the month.
- 30 is an example of an exact date in a month.
- <h> is the hour, for example, 10h.
- <s> is the number of seconds, for example, 30s.

The following example expression is true if the date is between 2008 Jan and 2009 Jan, based on GMT.

```
http.req.date.between(GMT 2008 Jan, GMT 2009 Jan)
```

The following example expression is true for March and all months that follow March in the calendar year, based on GMT:

```
sys.time.ge(GMT 2008 Mar)
```

When you specify a date and time, note that the format is case sensitive and must preserve the exact number of blank spaces between entries.

Note: In an expression that requires two time values, both must use GMT or both must use LOCAL. You cannot mix the two in an expression.

Note: Unlike when you use the SYS.TIME prefix in a default syntax expression, if you specify SYS.TIME in a rewrite action, the NetScaler returns a string in conventional date format (for example, Sun, 06 Nov 1994 08:49:37 GMT). For example, the following rewrite action replaces the http.res.date header with the NetScaler system time in a conventional date format:
add rewrite action sync_date replace http.res.date sys.time

Expressions for the NetScaler System Time

Mar 20, 2012

The `SYS.TIME` expression prefix extracts the NetScaler system time. You can configure expressions that establish whether a particular event occurred at a particular time or within a particular time range according to the NetScaler system time.

The following table describes the expressions that you can create by using the `SYS.TIME` prefix.

Table 1. Expressions That Return NetScaler System Dates and Times

NetScaler Time Operation	Description
<code>SYS.TIME.BETWEEN(<time1>, <time2>)</code>	<p>Returns a Boolean TRUE if the returned value is later than <time1> and earlier than <time2>.</p> <p>You format the <time1>, <time2> arguments as follows:</p> <ul style="list-style-type: none"> • They must both be GMT or both LOCAL. • <time2> must be later than <time1>. <p>For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following:</p> <ul style="list-style-type: none"> • <code>sys.time.between(GMT 2004, GMT 2006)</code> • <code>sys.time.between(GMT 2004 Jan, GMT 2006 Nov)</code> • <code>sys.time.between(GMT 2004 Jan, GMT 2006)</code> • <code>sys.time.between(GMT 2005 May Sun_1, GMT 2005 May Sun_3)</code> • <code>sys.time.between(GMT 2005 May 1, GMT May 2005 1)</code> • <code>sys.time.between(LOCAL 2005 May 1, LOCAL May 2005 1)</code>
<code>SYS.TIME.DAY</code>	Returns the current day of the month as a number from 1 through 31.
<code>SYS.TIME.EQ(<time>)</code>	<p>Returns a Boolean TRUE if the current time is equal to the <time> argument.</p> <p>For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):</p> <ul style="list-style-type: none"> • <code>sys.time.eq(GMT 2005)</code> (TRUE in this example.) • <code>sys.time.eq(GMT 2005 Dec)</code> (FALSE in this example.) • <code>sys.time.eq(LOCAL 2005 May)</code> (Evaluates to TRUE or FALSE in this example, depending on the current time zone.) • <code>sys.time.eq(GMT 10h)</code> (TRUE in this example.) • <code>sys.time.eq(GMT 10h 30s)</code> (TRUE in this example.) • <code>sys.time.eq(GMT May 10h)</code> (TRUE in this example.) • <code>sys.time.eq(GMT Sun)</code> (TRUE in this example.) • <code>sys.time.eq(GMT May Sun_1)</code> (TRUE in this example.)

NetScaler Time Operation	Description
SYS.TIME.NE(<time>)	Returns a Boolean TRUE if the current time is not equal to the <time> argument.
SYS.TIME.GE(<time>)	<p>Returns a Boolean TRUE if the current time is later than or equal to <time>.</p> <p>For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):</p> <ul style="list-style-type: none"> • sys.time.ge(GMT 2004) (TRUE in this example.) • sys.time.ge(GMT 2005 Jan) (TRUE in this example.) • sys.time.ge(LOCAL 2005 May) (TRUE or FALSE in this example, depending on the current time zone.) • sys.time.ge(GMT 8h) (TRUE in this example.) • sys.time.ge(GMT 30m) (FALSE in this example.) • sys.time.ge(GMT May 10h) (TRUE in this example.) • sys.time.ge(GMT May 10h 0m) (TRUE in this example.) • sys.time.ge(GMT Sun) (TRUE in this example.) • sys.time.ge(GMT May Sun_1) (TRUE in this example.)
SYS.TIME.GT(<time>)	<p>Returns a Boolean TRUE if the time value is later than the <time> argument.</p> <p>For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):</p> <ul style="list-style-type: none"> • sys.time.gt(GMT 2004) (TRUE in this example.) • sys.time.gt(GMT 2005 Jan) (TRUE in this example.) • sys.time.gt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • sys.time.gt(GMT 8h) (TRUE in this example.) • sys.time.gt(GMT 30m) (FALSE in this example.) • sys.time.gt(GMT May 10h) (FALSE in this example.) • sys.time.gt(GMT May 10h 0m) (TRUE in this example.) • sys.time.gt(GMT Sun) (FALSE in this example.) • sys.time.gt(GMT May Sun_1) (FALSE in this example.)
SYS.TIME.HOURS	Returns the current hour as an integer from 0 to 23.
SYS.TIME.LE(<time>)	<p>Returns a Boolean TRUE if the current time value precedes or is equal to the <time> argument.</p> <p>For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):</p>

NetScaler Time Operation	Description
	<ul style="list-style-type: none"> • sys.time.le(GMT 2006) (TRUE in this example.) • sys.time.le(GMT 2005 Dec) (TRUE in this example.) • sys.time.le(LOCAL 2005 May) (TRUE or FALSE depending on the current time zone.) • sys.time.le(GMT 8h) (FALSE in this example.) • sys.time.le(GMT 30m) (TRUE in this example.) • sys.time.le(GMT May 10h) (TRUE in this example.) • sys.time.le(GMT Jun 11h) (TRUE in this example.) • sys.time.le(GMT Wed) (TRUE in this example.) • sys.time.le(GMT May Sun_1) (TRUE in this example.)
SYS.TIME.LT(<time>)	<p>Returns a Boolean TRUE if the current time value precedes the <time> argument.</p> <p>For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):</p> <ul style="list-style-type: none"> • sys.time.lt(GMT 2006) (TRUE in this example.) • sys.time.lt.time.lt(GMT 2005 Dec) (TRUE in this example.) • sys.time.lt(LOCAL 2005 May) (TRUE or FALSE depending on the current time zone.) • sys.time.lt(GMT 8h) (FALSE in this example.) • sys.time.lt(GMT 30m) (TRUE in this example.) • sys.time.lt(GMT May 10h) (FALSE in this example.) • sys.time.lt(GMT Jun 11h) (TRUE in this example.) • sys.time.lt(GMT Wed) (TRUE in this example.) • sys.time.lt(GMT May Sun_1) (FALSE in this example.)
SYS.TIME.MINUTES	Returns the current minute as an integer from 0 to 59.
SYS.TIME.MONTH	Extracts the current month and returns an integer from 1 (January) to 12 (December).
SYS.TIME.RELATIVE_BOOT	<p>Calculates the number of seconds to the closest previous or scheduled reboot, and returns an integer.</p> <p>If the closest boot time is in the past, the integer is negative. If it is in the future, the integer is positive.</p>
SYS.TIME.RELATIVE_NOW	<p>Calculates the number of seconds between the current NetScaler system time and the specified time, and returns an integer showing the difference.</p> <p>If the designated time is in the past, the integer is negative; if it is in the future, the integer is positive.</p>
SYS.TIME.SECONDS	Extracts the seconds from the current NetScaler system time, and returns that value

NetScaler Time Operation	Description
SYS.TIME.WEEKDAY	Returns the current weekday as a value from 0 (Sunday) to 6 (Saturday).
SYS.TIME.WITHIN (<time1>, <time2>)	<p>If you omit an element of time in <time1>, for example, the day or hour, it is assumed to have the lowest value in its range. If you omit an element in <time2>, it is assumed to have the highest value of its range.</p> <p>The ranges for the elements of time are as follows: month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds 0-59. If you specify the year, you must do so in both <time1> and <time2>.</p> <p>For example, if the time is GMT 2005 May 10 10h 15m 30s, and it is the second Tuesday of the month, you can specify the following (evaluation results are shown in parentheses):</p> <ul style="list-style-type: none"> • sys.time.within(GMT 2004, GMT 2006) (TRUE in this example.) • sys.time.within(GMT 2004 Jan, GMT 2006 Mar) (FALSE, May is not in the range of January to March.) • sys.time.within(GMT Feb, GMT) (TRUE, May is in the range of February to December.) • sys.time.within(GMT Sun_1, GMT Sun_3) (TRUE, the second Tuesday is between the first Sunday and the third Sunday.) • sys.time.within(GMT 2005 May 1 10h, GMT May 2005 1 17h) (TRUE in this example.) • sys.time.within(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone.)
SYS.TIME.YEAR	Extracts the year from the current system time and returns that value as a four-digit integer.

Expressions for SSL Certificate Dates

May 11, 2012

You can determine the validity period for SSL certificates by configuring an expression that contains the following prefix:

CLIENT.SSL.CLIENT_CERT

The following example expression matches a particular time for expiration with the information in the certificate:

client.ssl.client_cert.valid_not_after.eq(GMT 2009)

The following table describes time-based operations on SSL certificates. To obtain the expression you want, replace *certificate* in the expression in the first column with the prefix expression, "CLIENT.SSL.CLIENT_CERT".

Table 1. Operations on Certificate (client.ssl.client_cert) Dates and Times

SSL Certificate Operation	Description
<certificate>.VALID_NOT_AFTER	Returns the last day before certificate expiration. The return format is the number of seconds since GMT January 1, 1970 (0 hours, 0 minutes, 0 seconds).
<certificate>.VALID_NOT_AFTER.BETWEEN(<time1>, <time2>)	<p>Returns a Boolean TRUE value if the certificate validity is between the <time1> and <time2> arguments. Both <time1> and <time2> must be fully specified. Following are examples:</p> <p>GMT 1995 Jan is fully specified.</p> <p>GMT Jan is not fully specified</p> <p>GMT 1995 20 is not fully specified.</p> <p>GMT Jan Mon_2 is not fully specified.</p> <p>The <time1> and <time2> arguments must be both GMT or both LOCAL, and <time2> must be greater than <time1>.</p> <p>For example, if it is GMT 2005 May 1 10h 15m 30s, and the first Sunday of the month, you can specify the following (evaluation results are in parentheses).</p> <ul style="list-style-type: none"> • ...between(GMT 2004, GMT 2006) (TRUE) • ...between(GMT 2004 Jan, GMT 2006 Nov) (TRUE) • ...between(GMT 2004 Jan, GMT 2006) (TRUE) • ...between(GMT 2005 May Sun_1, GMT 2005 May Sun_3) (TRUE) • ...between(GMT 2005 May 1, GMT May 2005 1) (TRUE) • ...between(LOCAL 2005 May 1, LOCAL May 2005 1)

SSL Certificate Operation	Description (TRUE or FALSE, depending on the NetScaler system time zone.)
<certificate>.VALID_NOT_AFTER.DAY	Extracts the last day of the month that the certificate is valid, and returns a number from 1 through 31, as appropriate for the date.
<certificate>.VALID_NOT_AFTER.EQ(<time>)	<p>Returns a Boolean TRUE if the time is equal to the <time> argument.</p> <p>For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results for this example are in parentheses):</p> <ul style="list-style-type: none"> • ..eq(GMT 2005) (TRUE) • ..eq(GMT 2005 Dec) (FALSE) • ..eq(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone) • ..eq(GMT 10h) (TRUE) • ..eq(GMT 10h 30s) (TRUE) • ..eq(GMT May 10h) (TRUE) • ..eq(GMT Sun) (TRUE) • ..eq(GMT May Sun_1) (TRUE)
<certificate>.VALID_NOT_AFTER.GE(<time>)	<p>Returns a Boolean TRUE if the time value is greater than or equal to the argument <time>.</p> <p>For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):</p> <ul style="list-style-type: none"> • ..ge(GMT 2004) (TRUE) • ..ge(GMT 2005 Jan) (TRUE) • ..ge(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • ..ge(GMT 8h) (TRUE) • ..ge(GMT 30m) (FALSE) • ..ge(GMT May 10h) (TRUE) • ..ge(GMT May 10h 0m) (TRUE) • ..ge(GMT Sun) (TRUE) • ..ge(GMT May Sun_1) (TRUE)
<certificate>.VALID_NOT_AFTER.GT(<time>)	Returns a Boolean TRUE if the time value is greater than the argument <time>.

SSL Certificate Operation	Description
	<p>For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):</p> <ul style="list-style-type: none"> • ..gt(GMT 2004) (TRUE) • ..gt(GMT 2005 Jan) (TRUE) • ..gt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • ..gt(GMT 8h) (TRUE) • ..gt(GMT 30m) (FALSE) • ..gt(GMT May 10h) (FALSE) • ..gt(GMT Sun) (FALSE) • ..gt(GMT May Sun_1) (FALSE)
<certificate>.VALID_NOT_AFTER.HOURS	Extracts the last hour that the certificate is valid and returns that value as an integer from 0 to 23.
<certificate>.VALID_NOT_AFTER.LE(<time>)	<p>Returns a Boolean TRUE if the time precedes or is equal to the <time> argument.</p> <p>For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):</p> <ul style="list-style-type: none"> • ..le(GMT 2006) (TRUE) • ..le(GMT 2005 Dec) (TRUE) • ..le(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • ..le(GMT 8h) (FALSE) • ..le(GMT 30m) (TRUE) • ..le(GMT May 10h) (TRUE) • ..le(GMT Jun 11h) (TRUE) • ..le(GMT Wed) (TRUE) • ..le(GMT May Sun_1) (TRUE)
<certificate>.VALID_NOT_AFTER.LT(<time>)	<p>Returns a Boolean TRUE if the time precedes the <time> argument.</p> <p>For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following:</p> <ul style="list-style-type: none"> • ..lt(GMT 2006) (TRUE) • ..lt(GMT 2005 Dec) (TRUE) • ..lt(LOCAL 2005 May) (TRUE or FALSE, depending on

SSL Certificate Operation	Description
	<p>the current time zone.)</p> <ul style="list-style-type: none"> • ...It(GMT 8h) (FALSE) • ...It(GMT 30m) (TRUE) • ...It(GMT May 10h) (FALSE) • ...It(GMT Jun 11h) (TRUE) • ...It(GMT Wed) (TRUE) • ...It(GMT May Sun_1) (FALSE)
<certificate>.VALID_NOT_AFTER.MINUTES	Extracts the last minute that the certificate is valid and returns that value as an integer from 0 to 59.
<certificate>.VALID_NOT_AFTER.MONTH	Extracts the last month that the certificate is valid and returns that value as an integer from 1 (January) to 12 (December).
<certificate>.VALID_NOT_AFTER.RELATIVE_BOOT	Calculates the number of seconds to the closest previous or scheduled reboot and returns an integer. If the closest boot time is in the past, the integer is negative. If it is in the future, the integer is positive.
<certificate>.VALID_NOT_AFTER.RELATIVE_NOW	Calculates the number of seconds between the current system time and the specified time and returns an integer. If the time is in the past, the integer is negative; if it is in the future, the integer is positive.
<certificate>.VALID_NOT_AFTER.SECONDS	Extracts the last second that the certificate is valid and returns that value as an integer from 0 to 59.
<certificate>.VALID_NOT_AFTER.WEEKDAY	Extracts the last weekday that the certificate is valid. Returns a number between 0 (Sunday) and 6 (Saturday) to give the weekday in the time value.
<certificate>.VALID_NOT_AFTER.WITHIN(<time1>, <time2>)	<p>Returns a Boolean TRUE if the time lies within all the ranges defined by the elements in <time1> and <time2>.</p> <p>If you omit an element of time from <time1>, it is assumed to have the lowest value in its range. If you omit an element from <time2>, it is assumed to have the highest value of its range. If you specify a year in <time1>, you must specify it in <time2>.</p> <p>The ranges for elements of time are as follows: month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds</p>

SSL Certificate Operation	Description
	<p>0-59. For the result to be TRUE, each element in the time must exist in the corresponding range that you specify in <time1>, <time2>.</p> <p>For example, if time is GMT 2005 May 10 10h 15m 30s, and it is the second Tuesday of the month, you can specify the following (evaluation results are in parentheses):</p> <ul style="list-style-type: none"> • . . .within(GMT 2004, GMT 2006) (TRUE) • . . .within(GMT 2004 Jan, GMT 2006 Mar) (FALSE, May is not in the range of January to March.) • . . .within(GMT Feb, GMT) (TRUE, May is in the range for February to December) • . . .within(GMT Sun_1, GMT Sun_3) (TRUE, the second Tuesday lies within the range of the first Sunday through the third Sunday) • . . .within(GMT 2005 May 1 10h, GMT May 2005 1 17h) (TRUE) • . . .within(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone)
<certificate>.VALID_NOT_AFTER.YEAR	Extracts the last year that the certificate is valid and returns a four-digit integer.
<certificate>.VALID_NOT_BEFORE	<p>Returns the date that the client certificate becomes valid.</p> <p>The return format is the number of seconds since GMT January 1, 1970 (0 hours, 0 minutes, 0 seconds).</p>
<certificate>.VALID_NOT_BEFORE.BETWEEN(<time1>, <time2>)	<p>Returns a Boolean TRUE if the time value is between the two time arguments. Both <time1> and <time2> arguments must be fully specified.</p> <p>Following are examples:</p> <ul style="list-style-type: none"> • GMT 1995 Jan is fully specified. • GMT Jan is not fully specified. • GMT 1995 20 is not fully specified. • GMT Jan Mon_2 is not fully specified. <p>The time arguments must be both GMT or both LOCAL, and <time2> must be greater than <time1>.</p> <p>For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):</p>

SSL Certificate Operation	Description
	<ul style="list-style-type: none"> • ...between(GMT 2004, GMT 2006) (TRUE) • ...between(GMT 2004 Jan, GMT 2006 Nov) (TRUE) • ...between(GMT 2004 Jan, GMT 2006) (TRUE) • ...between(GMT 2005 May Sun_1, GMT 2005 May Sun_3) (TRUE) • ...between(GMT 2005 May 1, GMT May 2005 1) (TRUE) • ...between(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone.)
<certificate>.VALID_NOT_BEFORE.DAY	Extracts the last day of the month that the certificate is valid and returns that value as a number from 1 through 31 representing that day.
<certificate>.VALID_NOT_BEFORE.EQ(<time>)	<p>Returns a Boolean TRUE if the time is equal to the <time> argument.</p> <p>For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):</p> <ul style="list-style-type: none"> • ...eq(GMT 2005) (TRUE) • ...eq(GMT 2005 Dec) (FALSE) • ...eq(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • ...eq(GMT 10h) (TRUE) • ...eq(GMT 10h 30s) (TRUE) • ...eq(GMT May 10h) (TRUE) • ...eq(GMT Sun) (TRUE) • ...eq(GMT May Sun_1) (TRUE)
<certificate>.VALID_NOT_BEFORE.GE(<time>)	<p>Returns a Boolean TRUE if the time is greater than (after) or equal to the <time> argument.</p> <p>For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results are in parentheses):</p> <ul style="list-style-type: none"> • ...ge(GMT 2004) (TRUE) • ...ge(GMT 2005 Jan) (TRUE) • ...ge(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • ...ge(GMT 8h) (TRUE) • ...ge(GMT 30m) (FALSE)

SSL Certificate Operation	Description
	<ul style="list-style-type: none"> • ..ge(GMT May 10h) (TRUE) • ..ge(GMT May 10h 0m) (TRUE) • ..ge(GMT Sun) (TRUE) • ..ge(GMT May Sun_1) (TRUE)
<certificate>.VALID_NOT_BEFORE.GT(<time>)	<p>Returns a Boolean TRUE if the time occurs after the <time> argument.</p> <p>For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results are in parentheses):</p> <ul style="list-style-type: none"> • ..gt(GMT 2004) (TRUE) • ..gt(GMT 2005 Jan) (TRUE) • ..gt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • ..gt(GMT 8h) (TRUE) • ..gt(GMT 30m) (FALSE) • ..gt(GMT May 10h) (FALSE) • ..gt(GMT May 10h 0m) (TRUE) • ..gt(GMT Sun) (FALSE) • ..gt(GMT May Sun_1) (FALSE)
<certificate>.VALID_NOT_BEFORE.HOURS	<p>Extracts the last hour that the certificate is valid and returns that value as an integer from 0 to 23.</p>
<certificate>.VALID_NOT_BEFORE.LE(<time>)	<p>Returns a Boolean TRUE if the time precedes or is equal to the <time> argument.</p> <p>For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):</p> <ul style="list-style-type: none"> • ..le(GMT 2006) (TRUE) • ..le(GMT 2005 Dec) (TRUE) • ..le(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • ..le(GMT 8h) (FALSE) • ..le(GMT 30m) (TRUE) • ..le(GMT May 10h) (TRUE) • ..le(GMT Jun 11h) (TRUE) • ..le(GMT Wed) (TRUE) • ..le(GMT May Sun_1) (TRUE)

SSL Certificate Operation <certificate>.VALID_NOT_BEFORE.LT(<time>)	Description Returns a Boolean TRUE if the time precedes the <time> argument.
	<p>For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):</p> <ul style="list-style-type: none"> • ..lt(GMT 2006) (TRUE) • ..lt(GMT 2005 Dec) (TRUE) • ..lt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.) • ..lt(GMT 8h) (FALSE) • ..lt(GMT 30m) (TRUE) • ..lt(GMT May 10h) (FALSE) • ..lt(GMT Jun 11h) (TRUE) • ..lt(GMT Wed) (TRUE) • ..lt(GMT May Sun_1) (FALSE)
<certificate>.VALID_NOT_BEFORE.MINUTES	Extracts the last minute that the certificate is valid. Returns the current minute as an integer from 0 to 59.
<certificate>.VALID_NOT_BEFORE.MONTH	Extracts the last month that the certificate is valid. Returns the current month as an integer from 1 (January) to 12 (December).
<certificate>.VALID_NOT_BEFORE.RELATIVE_BOOT	Calculates the number of seconds to the closest previous or scheduled NetScaler reboot and returns an integer. If the closest boot time is in the past, the integer is negative; if it is in the future, the integer is positive.
<certificate>.VALID_NOT_BEFORE.RELATIVE_NOW	Returns the number of seconds between the current NetScaler system time and the specified time as an integer. If the designated time is in the past, the integer is negative. If it is in the future, the integer is positive.
<certificate>.VALID_NOT_BEFORE.SECONDS	Extracts the last second that the certificate is valid. Returns the current second as an integer from 0 to 59.
<certificate>.VALID_NOT_BEFORE.WEEKDAY	Extracts the last weekday that the certificate is valid. Returns the weekday as a number between 0 (Sunday) and 6 (Saturday).
<certificate>.VALID_NOT_BEFORE.WITHIN(<time1>,	Returns a Boolean TRUE if each element of time exists

<p><time2>). SSL Certificate Operation</p>	<p>within the range defined in the <time1>, <time2> arguments. Description</p> <p>If you omit an element of time from <time1>, it is assumed to have the lowest value in its range. If you omit an element of time from <time2>, it is assumed to have the highest value in its range. If you specify a year in <time1>, it must be specified in <time2>. The ranges for elements of time are as follows: month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds 0-59.</p> <p>For example, if the time is GMT 2005 May 10 10h 15m 30s, and it is the second Tuesday of the month, you can specify the following (evaluation results are in parentheses):</p> <ul style="list-style-type: none"> • . . .within(GMT 2004, GMT 2006) (TRUE) • . . .within(GMT 2004 Jan, GMT 2006 Mar) (FALSE, May is not in the range of January to March.) • . . .within(GMT Feb, GMT) (TRUE, May is in the range of February to December.) • . . .within(GMT Sun_1, GMT Sun_3) (TRUE, the second Tuesday is between the first Sunday and the third Sunday.) • . . .within(GMT 2005 May 1 10h, GMT May 2005 1 17h) (TRUE) • . . .within(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone)
<p><certificate>.VALID_NOT_BEFORE.YEAR</p>	<p>Extracts the last year that the certificate is valid. Returns the current year as a four-digit integer.</p>

Expressions for HTTP Request and Response Dates

Sep 02, 2013

The following expression prefixes return the contents of the HTTP Date header as text or as a date object. These values can be evaluated as follows:

- As a number. The numeric value of an HTTP Date header is returned in the form of the number of seconds since Jan 1 1970.
For example, the expression `http.req.date.mod(86400)` returns the number of seconds since the beginning of the day. These values can be evaluated using the same operations as other non-date-related numeric data. For more information, see "[Expression Prefixes for Numeric Data Other Than Date and Time.](#)"
- As an HTTP header. Date headers can be evaluated using the same operations as other HTTP headers. For more information, see "[Default Syntax Expressions: Parsing HTTP, TCP, and UDP Data.](#)"
- As text. Date headers can be evaluated using the same operations as other strings.

For more information, see "[Default Syntax Expressions: Evaluating Text.](#)"

Table 1. Prefixes That Evaluate HTTP Date Headers

Prefix	Description
HTTP.REQ.DATE	Returns the contents of the HTTP Date header as text or as a date object. The date formats recognized are: RFC822. Sun, 06 Jan 1980 08:49:37 GMT RFC850. Sunday, 06-Jan-80 09:49:37 GMT ASCTIME. Sun Jan 6 08:49:37 1980
HTTP.RES.DATE	Returns the contents of the HTTP Date header as text or as a date object. The date formats recognized are: RFC822. Sun, 06 Jan 1980 8:49:37 GMT RFC850. Sunday, 06-Jan-80 9:49:37 GMT ASCTIME. Sun Jan 6 08:49:37 1980

Generating the Day of the Week, as a String, in Short and Long Formats

Mar 20, 2012

The functions, `WEEKDAY_STRING_SHORT` and `WEEKDAY_STRING`, generate the day of the week, as a string, in short and long formats, respectively. The strings that are returned are always in English. The prefix used with these functions must return the day of the week in integer format and the acceptable range for the value returned by the prefix is 0-6. Therefore, you can use any prefix that returns an integer in the acceptable range. An `UNDEF` condition is raised if the returned value is not in this range or if memory allocation fails.

Following are the descriptions of the functions:

Table 1. Functions That Generate the Day of the Week, as a String, in Short and Long Formats

Function	Description
<code><prefix>.WEEKDAY_STRING_SHORT</code>	Returns the day of the week in short format. The short form is always 3 characters long with an initial capital and the remaining characters in lower case. For example, <code>SYS.TIME.WEEKDAY.WEEKDAY_STRING_SHORT</code> returns Sun if the value returned by the <code>WEEKDAY</code> function is 0 and Sat if the value returned by the prefix is 6.
<code><prefix>.WEEKDAY_STRING</code>	Returns the day of the week in long format. The long form always has an initial capital, with the remaining characters in lower case. For example, <code>SYS.TIME.WEEKDAY.WEEKDAY_STRING</code> returns Sunday if the value returned by the <code>WEEKDAY</code> function is 0 and Saturday if the value returned by the prefix is 6.

Expression Prefixes for Numeric Data Other Than Date and Time

Sep 02, 2013

In addition to configuring expressions that operate on time, you can configure expressions for the following types of numeric data:

- The length of HTTP requests, the number of HTTP headers in a request, and so on.
For more information, see "[Expressions for Numeric HTTP Payload Data Other Than Dates.](#)"
- IP and MAC addresses.
For more information, see "[Expressions for IP Addresses and IP Subnets.](#)"
- Client and server data in regard to interface IDs and transaction throughput rate.
For more information, see "[Expressions for Numeric Client and Server Data.](#)"
- Numeric data in client certificates other than dates.
For information on these prefixes, including the number of days until certificate expiration and the encryption key size, see "[Prefixes for Numeric Data in SSL Certificates.](#)"

Converting Numbers to Text

Sep 02, 2013

The following functions produce binary strings from a number returned by an expression prefix. These functions are particularly useful in the TCP rewrite feature as replacement strings for binary data. For more information about the TCP rewrite feature, see "[Rewrite](#)."

All the functions return a value of type text. The endianness that some of the functions accept as a parameter is either LITTLE_ENDIAN or BIG_ENDIAN.

Table 1. Functions That Produce a Binary String From a Number

Function	Description
<number>.SIGNED8_STRING	<p>Produces an 8-bit signed binary string representing the number. If the value is out of range, an undef condition is raised.</p> <p>Example</p> <p>HTTP.REQ.BODY(100).GET_SIGNED8(16).SUB(3).SIGNED8_STRING</p>
<number>.UNSIGNED8_STRING	<p>Produces an 8-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised.</p> <p>Example</p> <p>HTTP.REQ.BODY(100).GET_UNSIGNED8(31).ADD(3).UNSIGNED8_STRING</p>
<number>.SIGNED16_STRING(<endianness>)	<p>Produces a 16-bit signed binary string representing the number. If the value is out of range, an undef condition is raised.</p> <p>Example</p> <p>HTTP.REQ.BODY(100).SKIP(12).GET_SIGNED16(0, BIG_ENDIAN).SUB(4).SIGNED16_STRING(BIG_ENDIAN)</p>
<number>.UNSIGNED16_STRING(<endianness>)	<p>Produces a 16-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised.</p> <p>Example</p> <p>HTTP.REQ.BODY(100).GET_UNSIGNED16(47, LITTLE_ENDIAN).ADD(7).UNSIGNED16_STRING(LITTLE_ENDIAN)</p>
<number>.SIGNED32_STRING(<endianness>)	<p>Produces a 32-bit signed binary string representing the number.</p> <p>Example</p> <p>HTTP.REQ.BODY(100).AFTER_STR("delim").GET_SIGNED32(0, BIG_ENDIAN).SUB(1).SIGNED32_STRING(BIG_ENDIAN)</p>
<unsigned_long_number>.UNSIGNED8_STRING	<p>Produces an 8-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised.</p> <p>Example</p> <p>HTTP.REQ.BODY(100).GET_UNSIGNED8(24).TYPECAST_UNSIGNED_LONG_AT.ADD(12).UNSIGNED8_STRING</p>
<unsigned_long_number>.UNSIGNED16_STRING(<endianness>)	<p>Produces a 16-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised.</p> <p>Example</p> <p>HTTP.REQ.BODY(100).GET_UNSIGNED16(23, LITTLE_ENDIAN).TYPECAST_UNSIGNED_LONG_AT.ADD(10).UNSIGNED16_STRING(LITTLE_ENDIAN)</p>
<unsigned_long_number>.UNSIGNED32_STRING(<endianness>)	<p>Produces a 32-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised.</p> <p>Example</p> <p>HTTP.REQ.BODY(100).AFTER_STR("delim2").GET_UNSIGNED32(0, BIG_ENDIAN).ADD(2).UNSIGNED32_STRING(BIG_ENDIAN)</p>

Virtual Server Based Expressions

Apr 17, 2012

The `SYS.VSERVER("<vserver-name>")` expression prefix enables you to identify a virtual server. You can use the following functions with this prefix to retrieve information related to the specified virtual server:

- **THROUGHPUT.** Returns the throughput of the virtual server in Mbps (Megabits per second). The value returned is an unsigned long number.
Usage: `SYS.VSERVER("vserver").THROUGHPUT`
- **CONNECTIONS.** Returns the number of connections being managed by the virtual server. The value returned is an unsigned long number.
Usage: `SYS.VSERVER("vserver").CONNECTIONS`
- **STATE.** Returns the state of the virtual server. The value returned is `UP`, `DOWN`, or `OUT_OF_SERVICE`. One of these values can therefore be passed as an argument to the `EQ()` operator to perform a comparison that results in a Boolean `TRUE` or `FALSE`.
Usage: `SYS.VSERVER("vserver").STATE`
- **HEALTH.** Returns the percentage of services in an `UP` state for the specified virtual server. The value returned is an integer.
Usage: `SYS.VSERVER("vserver").HEALTH`
- **RESPTIME.** Returns the response time as an integer representing the number of microseconds. Response time is the average TTFB (Time To First Byte) from all the services bound to the virtual server.
Usage: `SYS.VSERVER("vserver").RESPTIME`
- **SURGECOUNT.** Returns the number of requests in the surge queue of the virtual server. The value returned is an integer.
Usage: `SYS.VSERVER("vserver").SURGECOUNT`

Example 1

The following rewrite policy aborts rewrite processing if the number of connections at the load balancing virtual server `LBvserver` exceeds 10000:

```
add rewrite policy norewrite_pol sys.vserver("LBvserver").connections.gt(10000) norewrite
```

Example 2

The following rewrite action inserts a custom header, `TP`, whose value is the throughput at the virtual server `LBvserver`:

```
add rewrite action tp_header insert_http_header TP SYS.VSERVER("LBvserver").THROUGHPUT
```

Example 3

The following audit log message action writes the average TTFB of the services bound to a virtual server, to the `newslog` log file:

```
add audit messageaction log_vserver_resptime_act INFORMATIONAL "\"NS Response Time to Servers:\" + sys.vserver(\"ssl\b\").resptime + \" millisec\"\" -logtoNewslog YES -bypassSafetyCheck YES
```

Default Syntax Expressions: Parsing HTTP, TCP, and UDP Data

Sep 02, 2013

You can configure default syntax expressions to evaluate and process the payload in HTTP requests and responses. The payload associated with an HTTP connection includes the various HTTP headers (both standard and custom headers), the body, and other connection information such as the URL. Additionally, you can evaluate and process the payload in a TCP or UDP packet. For HTTP connections, for example, you can check whether a particular HTTP header is present or if the URL includes a particular query parameter.

You can configure expressions to transform the URL encoding and apply HTML or XML “safe” coding for subsequent evaluation. You can also use XPATH and JSON prefixes to evaluate data in XML and JSON files, respectively.

You can also use text-based and numeric default syntax expressions to evaluate HTTP request and response data. For more information, see "[Default Syntax Expressions: Evaluating Text](#)" and "[Default Syntax Expressions: Working with Dates, Times, and Numbers](#)."

About Evaluating HTTP and TCP Payload

Sep 02, 2013

The payload of an HTTP request or response consists of HTTP protocol information such as headers, a URL, body content, and version and status information. When you configure a default syntax expression to evaluate HTTP payload, you use a default syntax expression prefix and, if necessary, an operator.

For example, you use the following expression, which includes the `http.req.header("<header_name>")` prefix and the `exists` operator, if you want to determine whether an HTTP connection includes a custom header named "myHeader":

```
http.req.header("myHeader").exists
```

You can also combine multiple default syntax expressions with Boolean and arithmetic operators. For example, the following compound expression could be useful with various NetScaler features, such as Integrated Caching, Rewrite, and Responder. This expression first uses the `&&` Boolean operator to determine whether an HTTP connection includes the Content-Type header with a value of "text/html." If that operation returns a value of FALSE, the expression determines whether the HTTP connection includes a "Transfer-Encoding" or "Content-Length" header.

```
(http.req.header("Content-Type").exists && http.req.header("Content-Type").eq("text/html")) || (http.req.header("Transfer-Encoding").exists) || (http.req.header("Content-Length").exists)
```

The payload of a TCP or UDP packet is the data portion of the packet. You can configure default syntax expressions to examine features of a TCP or UDP packet, including the following:

- Source and destination domains
- Source and destination ports
- The text in the payload
- Record types

The following expression prefixes extract text from the body of the payload:

- `HTTP.REQ.BODY(integer)`. Returns the body of an HTTP request as a multiline text object, up to the character position designated in the integer argument. If there are fewer characters in the body than is specified in the argument, the entire body is returned.
- `HTTP.RES.BODY(integer)`. Returns a portion of the HTTP response body. The length of the returned text is equal to the number in the integer argument. If there are fewer characters in the body than is specified in integer, the entire body is returned.
- `CLIENT.TCP.PAYLOAD(integer)`. Returns TCP payload data as a string, starting with the first character in the payload and continuing for the number of characters in the integer argument.

Following is an example that evaluates to TRUE if a response body of 1024 bytes contains the string "https", and this string occurs after the string "start string" and before the string "end string":

```
http.res.body(1024).after_str("start_string").before_str("end_string").contains("https")
```

Note: You can apply any text operation to the payload body. For information on operations that you can apply to text, see "[Default Syntax Expressions: Evaluating Text.](#)"

Expressions for Identifying the Protocol in an Incoming IP Packet

May 21, 2015

The following table lists the expressions that you can use to identify the protocol in an incoming packet.

Expression	Description
CLIENT.IP.PROTOCOL	Identifies the protocol in IPv4 packets sent by clients.
CLIENT.IPV6.PROTOCOL	Identifies the protocol in IPv6 packets sent by clients.
SERVER.IP.PROTOCOL	Identifies the protocol in IPv4 packets sent by servers.
SERVER.IPV6.PROTOCOL	Identifies the protocol in IPv6 packets sent by servers.

Arguments to the PROTOCOL function

You can pass the Internet Assigned Numbers Authority (IANA) protocol number to the PROTOCOL function. For example, if you want to determine whether the protocol in an incoming packet is TCP, you can use `CLIENT.IP.PROTOCOL.EQ(6)`, where 6 is the IANA-assigned protocol number for TCP. For some protocols, you can pass an enumeration value instead of the protocol number. For example, instead of `CLIENT.IP.PROTOCOL.EQ(6)`, you can use `CLIENT.IP.PROTOCOL.EQ(TCP)`. The following table lists the protocols for which you can use enumeration values, and the corresponding enumeration values for use with the PROTOCOL function.

Protocol	Enumeration value
Transmission Control Protocol (TCP)	TCP
User Datagram Protocol (UDP)	UDP
Internet Control Message Protocol (ICMP)	ICMP
IP Authentication Header (AH), for providing authentication services in IPv4 and IPv6	AH
Encapsulating Security Payload (ESP) protocol	ESP
General Routing Encapsulation (GRE)	GRE
IP-within-IP Encapsulation Protocol	IPIP

Protocol	Enumeration value
Internet Control Message Protocol for IPv6 (ICMPv6)	ICMPv6
Fragment Header for IPv6	FRAGMENT

Use Case Scenarios

The protocol expressions can be used in both request-based and response-based policies. You can use the expressions in various NetScaler features, such as load balancing, WAN optimization, content switching, rewrite, and listen policies. You can use the expressions with functions such as EQ() and NE(), to identify the protocol in a policy and perform an action.

Following are some use cases for the expressions:

- In Branch Repeater load balancing configurations, you can use the expressions in a listen policy for the wildcard virtual server. For example, you can configure the wildcard virtual server with the listen policy CLIENT.IP.PROTOCOL.EQ(TCP) so that the virtual server processes only TCP traffic and simply bridges all non-TCP traffic. Even though you can use an Access Control List instead of the listen policy, the listen policy provides better control over what traffic is processed.
- For content switching virtual servers of type ANY, you can configure content switching policies that switch requests on the basis of the protocol in incoming packets. For example, you can configure content switching policies to direct all TCP traffic to one load balancing virtual server and all non-TCP traffic to another load balancing virtual server.
- You can use the client-based expressions to configure persistence based on the protocol. For example, you can use CLIENT.IP.PROTOCOL to configure persistence on the basis of the protocols in incoming IPv4 packets.

Expressions for HTTP and Cache-Control Headers

Sep 02, 2013

One common method of evaluating HTTP traffic is to examine the headers in a request or a response. A header can perform a number of functions, including the following:

- Provide cookies that contain data about the sender.
- Identify the type of data that is being transmitted.
- Identify the route that the data has traveled (the Via header).

Note: Note that if an operation is used to evaluate both header and text data, the header-based operation always overrides the text-based operation. For example, the AFTER_STR operation, when applied to a header, overrides text-based AFTER_STR operations for all instances of the current header type.

Prefixes for HTTP Headers

The following table describes expression prefixes that extract HTTP headers.

Table 1. Prefixes That Extract HTTP Headers

HTTP Header Prefix	Description
HTTP.REQ.HEADER("<header_name>")	Returns the contents of the HTTP header specified by the <header_name> argument. The header name cannot exceed 32 characters. Note that this prefix returns the value from the Host header by default. To use this value as a host name you need to typecast it as follows: <code>http.req.header("host").typecast_http_hostname_t</code> For more information on typecasting, see " Typecasting Data ."
HTTP.REQ.FULL_HEADER	Returns the contents of the complete set of HTTP header fields including the request line (for example, "GET /brochures/index.html HTTP/1.1") and the terminating \n\n\n sequence.
HTTP.REQ.DATE	Returns the contents of the HTTP Date header. The following date formats are recognized: RFC822. Sun, 06 Jan 1980 8:49:37 GMT RFC850. Sunday, 06-Jan-80 9:49:37 GMT ASCII TIME. Sun Jan 6 08:49:37 1980 To evaluate a Date header as a date object, see " Default Syntax Expressions: Working with Dates, Times, and Numbers ."
HTTP.REQ.COOKIE	(Name/Value List) Returns the contents of the HTTP Cookie header.
HTTP.REQ.TXID	Returns the HTTP transaction ID. The value is a function of an internal

HTTP Header Prefix	Description
HTTP.RES.HEADER("<header_name>")	Returns the contents of the HTTP header specified by the <header_name> argument. The header name cannot exceed 32 characters.
HTTP.RES.FULL_HEADER	Returns the contents of the complete set of HTTP header fields including the status line (for example, "HTTP/1.1 200 OK") and the terminating \r\n\r\n sequence.
HTTP.RES.SET_COOKIE or HTTP.RES.SET_COOKIE2	Returns the HTTP Set-Cookie header object in a response.
HTTP.RES.SET_COOKIE("<name>") or HTTP.RES.SET_COOKIE2("<name>")	Returns the cookie of the specified name if it is present. If it is not present, returns a text object of length 0. Returns UNDEF if more than 15 Set-Cookie headers are present and the specified cookie was not found in these headers.
HTTP.RES.SET_COOKIE("<name>").DOMAIN or HTTP.RES.SET_COOKIE2("<name>").DOMAIN	Returns the value of the first Domain field in the cookie. For example, if the cookie is Set-Cookie : Customer = "ABC"; DOMAIN=".abc.com"; DOMAIN=.xyz.com, the following expression returns .abc.com: <code>http.res.set_cookie.cookie("customer").domain</code> A string of zero length is returned if the Domain field or its value is absent.
HTTP.RES.SET_COOKIE.EXISTS("<name>") or HTTP.RES.SET_COOKIE2.EXISTS("<name>")	Returns a Boolean TRUE if a Cookie with the name specified in the <name> argument exists in the Set-Cookie header. This prefix returns UNDEF if more than 15 Set-Cookie headers are present and the named cookie is not in the first 15 headers.
HTTP.RES.SET_COOKIE.COOKIE("<name>").EXPIRES or HTTP.RES.SET_COOKIE2.COOKIE("<name>").EXPIRES	Returns the Expires field of the cookie. This is a date string that can be evaluated as a number, as a time object, or as text. If multiple Expires fields are present, the first one is returned. If the Expires field is absent, a text object of length zero is returned. To evaluate the returned value as a time object, see "Default Syntax Expressions: Working with Dates, Times, and Numbers."
HTTP.RES.SET_COOKIE.COOKIE("<name>").PATH PATH.GET(n) or HTTP.RES.SET_COOKIE2.COOKIE("<name>").PATH PATH.GET(n)	Returns the value of Path field of the cookie as a slash- ("/") separated list. Multiple instances of a slash are treated as single slash. If multiple Path fields are present, the value of the first instance is returned. For example, the following is a cookie with two path fields: Set-Cookie : Customer = "ABC"; PATH="/a/b/c"; PATH= "/x/y/z"

HTTP Header Prefix	Description
	<p>The following expression returns /a//b/c from this cookie:</p> <pre>http.res.set_cookie.cookie("Customer").path</pre> <p>The following expression returns b:</p> <pre>http.res.set_cookie.cookie("Customer").path.get(2)</pre> <p>Quotes are stripped from the returned value. A string of zero length is returned if the Path field or its value is absent.</p>
<pre>HTTP.RES.SET_COOKIE.COOKIE("<name>").PATH.IGNORE_EMPTY_ELEMENTS</pre> <p>or</p> <pre>HTTP.RES.SET_COOKIE2.COOKIE("<name>").PATH.IGNORE_EMPTY_ELEMENTS</pre>	<p>Ignores the empty elements in the list. For example, in the list a=10,b=11, ,c=89, the element delimiter in the list is , and the list has an empty element following a=10. The element following b=11 is not considered an empty element.</p> <p>As another example, in the following expression, if a request contains Cust_Header : 123,,24, ,15 the following expression returns a value of 4:</p> <pre>http.req.header("Cust_Header").typecast_list_t(',').ignore_empty_elements.count</pre> <p>The following expression returns a value of 5:</p> <pre>http.req.header("Cust_Header").typecast_list_t(',').count</pre>
<pre>HTTP.RES.SET_COOKIE.COOKIE("<name>").PORT</pre> <p>or</p> <pre>HTTP.RES.SET_COOKIE2.COOKIE("<name>").PORT</pre>	<p>Returns the value of Port field of the cookie. Operate as a comma-separated list.</p> <p>For example, the following expression returns 80. 2580 from Set-Cookie : Customer = "ABC"; PATH="/a/b/c"; PORT= "80, 2580":</p> <pre>http.res.set_cookie.cookie("ABC").port</pre> <p>A string of zero length is returned if the Port field or value is absent.</p>
<pre>HTTP.RES.SET_COOKIE.COOKIE("<name>").PORT.IGNORE_EMPTY_ELEMENTS</pre> <p>or</p> <pre>HTTP.RES.SET_COOKIE2.COOKIE("<name>").PORT.IGNORE_EMPTY_ELEMENTS</pre>	<p>Ignores the empty elements in the list. For example, in the list a=10,b=11, ,c=89, the element delimiter in the list is , and the list has an empty element following a=10. The element following b=11 is not considered an empty element.</p> <p>As another example, in the following expression, if a request contains Cust_Header : 123,,24, ,15 the following expression returns a value of 4:</p> <pre>http.req.header("Cust_Header").typecast_list_t(',').ignore_empty_elements.count</pre> <p>The following expression returns a value of 5:</p> <pre>http.req.header("Cust_Header").typecast_list_t(',').count</pre>
<pre>HTTP.RES.SET_COOKIE.COOKIE("<name>").VERSION</pre> <p>or</p> <pre>HTTP.RES.SET_COOKIE2.COOKIE("<name>").VERSION</pre>	<p>Returns the value of the first Version field in the cookie as a decimal integer.</p> <p>For example, the following expression returns 1 from the cookie Set-Cookie : Customer = "ABC"; VERSION = "1"; VERSION = "0"</p> <pre>http.res.set_cookie.cookie("CUSTOMER").version</pre> <p>A zero is returned if the Version field or its value is absent or if the value is not</p>

HTTP Header Prefix	Description
<p>HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>)</p> <p>or</p> <p>HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>)</p>	<p>Returns the nth instance (0-based) of the cookie with the specified name. If the cookie is absent, returns a text object of length 0.</p> <p>Returns UNDEF if more than 15 Set-Cookie headers are present and the cookie is not found.</p>
<p>HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).DOMAIN</p> <p>or</p> <p>HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).DOMAIN</p>	<p>Returns the value of the Domain field of the first cookie with the specified name. For example, the following expression returns a value of abc.com from the cookie Set-Cookie : Customer = "ABC"; DOMAIN=".abc.com"; DOMAIN=xyz.com</p> <p><code>http.res.set_cookie.cookie("CUSTOMER").domain</code></p> <p>A string of zero length is returned if the Domain field or its value is absent.</p>
<p>HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).EXPIRES</p> <p>or</p> <p>HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).EXPIRES</p>	<p>Returns the nth instance (0-based) of the Expires field of the cookie with the specified name as a date string. The value can be operated upon as a time object that supports a number of date formats. If the Expires attribute is absent a string of length zero is returned.</p>
<p>HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).PATH PATH.GET(i)</p> <p>or</p> <p>HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).PATH PATH.GET(i)</p>	<p>Returns the value of the Path field of the nth cookie, as a '/' separated list. Multiple /s are treated as a single /.</p> <p>For example, the following expression returns /a//b/c from the cookie Set-Cookie : Customer = "ABC"; PATH="/a//b/c"; PATH= "/x/y/z"</p> <p><code>http.res.set_cookie.cookie("CUSTOMER").path</code></p> <p>The following returns b:</p> <p><code>http.res.set_cookie.cookie("CUSTOMER").path.get(2)</code></p> <p>A string of zero length is returned if the Path field or its value is absent.</p>
<p>HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).PATH.IGNORE_EMPTY_ELEMENTS</p> <p>or</p> <p>HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).PATH.IGNORE_EMPTY_ELEMENTS</p>	<p>Ignores the empty elements in the list. For example, in the list a=10,b=11, ,c=89, the element delimiter in the list is , and the list has an empty element following a=10. The element following b=11 is not considered an empty element.</p> <p>As another example, in the following expression, if a request contains Cust_Header : 123,,24, ,15 the following expression returns a value of 4:</p> <p><code>http.req.header("Cust_Header").typecast_list_t(',').ignore_empty_elements.count</code></p> <p>The following expression returns a value of 5:</p> <p><code>http.req.header("Cust_Header").typecast_list_t(',').count</code></p>

HTTP Header Prefix	Description
HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).PORT or HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).PORT	Returns the value or values of the Port field of the named cookie as a ',' separated list. For example, the following expression returns 80, 2580 from the cookie Set-Cookie : Customer = "ABC"; PATH="/a/b/c"; PORT= "80, 2580" http.res.set_cookie.cookie("ABC").port A string of zero length is returned if the Port field or its value is absent.
HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).PORT.IGNORE_EMPTY_ELEMENTS or HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).PORT.IGNORE_EMPTY_ELEMENTS	Ignores the empty elements in the list. For example, in the list a=10,b=11, ,c=89, the element delimiter in the list is , and the list has an empty element following a=10. The element following b=11 is not considered an empty element. As another example, in the following expression, if a request contains Cust_Header : 123,,24, ,15 the following expression returns a value of 4: http.req.header("Cust_Header").typecast_list_t(',').ignore_empty_elements.count The following expression returns a value of 5: http.req.header("Cust_Header").typecast_list_t(',').count
HTTP.RES.SET_COOKIE.COOKIE("<name>", <integer>).VERSION or HTTP.RES.SET_COOKIE2.COOKIE("<name>", <integer>).VERSION	Returns the value of Version field of the <i>n</i> th cookie as a decimal integer. A string of zero length is returned if the Port field or its value is absent.
HTTP.RES.TXID	Returns the HTTP transaction ID. The value is a function of an internal transaction number, system boot time and system MAC address.

Operations for HTTP Headers

The following table describes operations that you can specify with the prefixes for HTTP headers.

Table 2. Operations That Evaluate HTTP Headers

HTTP Header Operation	Description
http header .EXISTS	Returns a Boolean TRUE if an instance of the specified header type exists. Following is an example: http.req.header("Cache-Control").exists
http header.CONTAINS" http header . CONTAINS("<string>")	Returns a Boolean TRUE if the <string> argument appears in any instance of the header value. Note: This operation overrides any text-based Contains operations on all instances of the current header type. Following is an example of request with two headers:

	<pre>HTTP/1.1 200 OK\r\n MyHeader: abc\r\n Content-Length: 200\r\n MyHeader: def\r\n \r\n</pre> <p>The following returns a Boolean TRUE:</p> <pre>http.res.header("MyHeader").contains("de")</pre> <p>The following returns FALSE. Note that the NetScaler does not concatenate the different values.</p> <pre>http.res.header("MyHeader").contains("bcd")</pre>
<pre>http header .COUNT</pre>	<p>Returns the number of headers in a request or response, to a maximum of 15 headers of the same type. The result is undefined if there are more than 15 instances of the header.</p> <p>Following is sample data in a request:</p> <pre>HTTP/1.1 200 OK\r\n MyHeader: abc\r\n Content-Length: 200\r\n MyHeader: def\r\n \r\n</pre> <p>When evaluating the preceding request, the following returns a count of 2:</p> <pre>http.res.header("MyHeader").count</pre>
<pre>http header.AFTER_STR("<string>")</pre>	<p>Extracts the text that follows the first occurrence of the <string> argument. The headers are evaluated from the last instance to the first.</p> <p>Following is an example of a request:</p> <pre>HTTP/1.1 200 OK\r\n MyHeader: 111abc\r\n Content-Length: 200\r\n MyHeader: 111def\r\n \r\n</pre> <p>The following extracts the string "def" from the last instance of MyHeader. This is value "111def."</p> <pre>http.res.header("MyHeader").after_str("111")</pre> <p>The following extracts the string "c" from the first instance of MyHeader. This is the value "abc111."</p>

	<pre>http.res.header("MyHeader").after_str("1ab")</pre>
<pre>http header.BEFORE_STR(" <string>")</pre>	<p>Extracts the text that appears prior to the first occurrence of the input <string> argument. The headers are evaluated from the last instance to the first.</p> <p>Following is an example of a request that contains headers:</p> <pre>HTTP/1.1 200 OK\r\n MyHeader: abc111\r\n Content-Length: 200\r\n MyHeader: def111\r\n \r\n</pre> <p>The following extracts the string "def" from the last instance of MyHeader. This is the value "def111."</p> <pre>http.res.header("MyHeader").before_str("111")</pre> <p>The following extracts the string "a" from the first instance of MyHeader. This is the value "abc111."</p> <pre>http.res.header("MyHeader").before_str("bc1")</pre>
<pre>http header.INSTANCE(<instance number>)</pre>	<p>An HTTP header can occur multiple times in a request or a response. This operation returns the header that occurs <instance number> of places before the final instance. For example, instance(0) selects the last instance of the current type, instance(1) selects the next-to-last instance, and so on. This prefix cannot be used in bidirectional policies.</p> <p>The <instance number> argument cannot exceed 14. Following is an example of a request with two headers:</p> <pre>HTTP/1.1 200 OK\r\n MyHeader: abc\r\n Content-Length: 200\r\n MyHeader: def\r\n \r\n</pre> <p>The following returns a text object that refers to "MyHeader: abc\r\n":</p> <pre>http.res.header("MyHeader").instance(1)</pre>
<pre>http header.SUBSTR(" <string>")</pre>	<p>Extracts the text that matches the <string> argument. The headers are evaluated from the last instance to the first. Following is an example of a request with two headers that contain the string "111":</p> <pre>HTTP/1.1 200 OK\r\n MyHeader: abc111\r\n</pre>

	<pre>Content-Length: 200\r\n MyHeader: 111def\r\n \r\n The following returns "111" from the last instance of MyHeader. This is the header with the value "111def." http.res.header("MyHeader").substr("111")</pre>
<pre>http header.VALUE(<instance number>)</pre>	<p>An HTTP header can occur multiple times in a request or a response. VALUE(0) selects the value in the last instance, VALUE(1) selects the value in the next-to-last instance, and so on. The <instance number> argument cannot exceed 14.</p> <p>Following is an example of a request with two headers:</p> <pre>HTTP/1.1 200 OK\r\n MyHeader: abc\r\n Content-Length: 200\r\n MyHeader: def\r\n \r\n The following returns "abc\r\n": http.res.header("MyHeader").value(1)</pre>

Prefixes for Cache-Control Headers

The following prefixes apply specifically to Cache-Control headers.

Table 3. Prefixes That Extract Cache-Control Headers

HTTP Header Prefix	Description
HTTP.REQ.CACHE_CONTROL	Returns a Cache-Control header in an HTTP request.
HTTP.RES.CACHE_CONTROL	Returns a Cache-Control header in an HTTP response.

Operations for Cache-Control Headers

You can apply any of the operations for HTTP headers to Cache-Control headers. For more information, see "[Operations for HTTP Headers](#)."

In addition, the following operations identify specific types of Cache-Control headers. See RFC 2616 for information about these header types.

Table 4. Operations That Evaluate Cache-Control Headers

HTTP Header Operation	Description
Cache-Control header.NAME(<integer>)	<p>Returns as a text value the name of the Cache-Control header that corresponds to the nth component in a name-value list, as specified by <integer>.</p> <p>The index of the name-value component is 0-based. If the <integer> that is specified by the integer argument is greater than the number of components in the list, a zero-length text object is returned.</p> <p>Following is an example:</p> <pre>http.req.cache_control.name(3).contains("some_text")</pre>
Cache-Control header.IS_INVALID	<p>Returns a Boolean TRUE if the Cache-Control header is not present in the request or response.</p> <p>Following is an example:</p> <pre>http.req.cache_control.is_invalid</pre>
Cache-Control header.IS_PRIVATE	<p>Returns a Boolean TRUE if the Cache-Control header has the value Private.</p> <p>Following is an example:</p> <pre>http.req.cache_control.is_private</pre>
Cache-Control header.IS_PUBLIC	<p>Returns a Boolean TRUE if the Cache-Control header has the value Private.</p> <p>Following is an example:</p> <pre>http.req.cache_control.is_public</pre>
Cache-Control header.IS_NO_STORE	<p>Returns a Boolean TRUE if the Cache-Control header has the value No-Store.</p> <p>Following is an example:</p> <pre>http.req.cache_control.is_no_store</pre>
Cache-Control header.IS_NO_CACHE	<p>Returns a Boolean TRUE if the Cache-Control header has the value No-Cache.</p> <p>Following is an example:</p> <pre>http.req.cache_control.is_no_cache</pre>
Cache-Control header.IS_MAX_AGE	<p>Returns a Boolean TRUE if the Cache-Control header has the value Max-Age.</p> <p>Following is an example:</p> <pre>http.req.cache_control.is_max_age</pre>

Cache-Control HTTP Header Operation header.IS_MIN_FRESH	Description
	Returns a Boolean TRUE if the Cache-Control header has the value Min-Fresh. Following is an example: <code>http.req.cache_control.is_min_fresh</code>
Cache-Control header.IS_MAX_STALE	Returns a Boolean TRUE if the Cache-Control header has the value Max-Stale. Following is an example: <code>http.req.cache_control.is_max_stale</code>
Cache-Control header.IS_MUST_REVALIDATE	Returns a Boolean TRUE if the Cache-Control header has the value Must-Revalidate. Following is an example: <code>http.req.cache_control.is_must_revalidate</code>
Cache-Control header.IS_NO_TRANSFORM	Returns a Boolean TRUE if the Cache-Control header has the value No-Transform. Following is an example: <code>http.req.cache_control.is_no_transform</code>
Cache-Control header.IS_ONLY_IF_CACHED	Returns a Boolean TRUE if the Cache-Control header has the value Only-If-Cached. Following is an example: <code>http.req.cache_control.is_only_if_cached</code>
Cache-Control header.IS_PROXY_REVALIDATE	Returns a Boolean TRUE if the Cache-Control header has the value Proxy-Revalidate. Following is an example: <code>http.req.cache_control.is_proxy_revalidate</code>
Cache-Control header.IS_S_MAXAGE	Returns a Boolean TRUE if the Cache-Control header has the value S-Maxage. Following is an example: <code>http.req.cache_control.is_s_maxage</code>
Cache-Control header.IS_UNKNOWN	Returns a Boolean TRUE if the Cache-Control header is of an unknown type. Following is an example: <code>http.req.cache_control.is_unknown</code>
Cache-Control header.MAX_AGE	Returns the value of the Cache-Control header Max-Age. If this header is absent or invalid, 0 is returned. Following is an example:

HTTP Header Operation	Description
Cache-Control header.MAX_STALE	<p>http.req.cache_control.max_age.le(3)</p> <p>Returns the value of the Cache-Control header Max-Stale. If this header is absent or invalid, 0 is returned.</p> <p>Following is an example:</p> <p>http.req.cache_control.max_stale.le(3)</p>
Cache-Control header.MIN_FRESH	<p>Returns the value of the Cache-Control header Min-Fresh. If this header is absent or invalid, 0 is returned.</p> <p>Following is an example:</p> <p>http.req.cache_control.min_fresh.le(3)</p>
Cache-Control header.S_MAXAGE	<p>Returns the value of the Cache-Control header S-Maxage. If this header is absent or invalid, 0 is returned.</p> <p>Following is an example:</p> <p>http.req.cache_control.s_maxage.eq(2)</p>

Expressions for Extracting Segments of URLs

Sep 02, 2013

You can extract URLs and portions of URLs, such as the host name, or a segment of the URL path. For example, the following expression identifies HTTP requests for image files by extracting image file suffixes from the URL:

```
http.req.url.suffix.eq("jpeg") || http.req.url.suffix.eq("gif")
```

Most expressions for URLs operate on text and are described in "[Expression Prefixes for Text in HTTP Requests and Responses](#)." This section discusses the GET operation. The GET operation extracts text when used with the following prefixes:

- HTTP.REQ.URL.PATH
- VPN.BASEURL.PATH
- VPN.CLIENTLESS_BASEURL.PATH

The following table describes prefixes for HTTP URLs.

Table 1. Prefixes That Extract URLs

URL Prefix	Description
HTTP.REQ.URL.PATH.GET(<n>)	Returns a slash- ("/") separated list from the URL path. For example, consider the following URL: <code>http://www.mycompany.com/dir1/dir2/dir3/index.html?a=1</code> The following expression returns dir1 from this URL: <code>http.req.url.path.get(1)</code> The following expression returns dir2: <code>http.req.url.path.get(2)</code>
HTTP.REQ.URL.PATH.GET_REVERSE(<n>)	Returns a slash- ("/") separated list from the URL path, starting from the end of the path. For example, consider the following URL: <code>http://www.mycompany.com/dir1/dir2/dir3/index.html?a=1</code> The following expression returns index.html from this URL: <code>http.req.url.path.get_reverse(0)</code> The following expression returns dir3: <code>http.req.url.path.get_reverse(1)</code>

Expressions for HTTP Status Codes and Numeric HTTP Payload Data Other Than Dates

Mar 20, 2012

The following table describes prefixes for numeric values in HTTP data other than dates.

Table 1. Prefixes That Evaluate HTTP Request or Response Length

Prefix	Description
HTTP.REQ.CONTENT_LENGTH	Returns the length of an HTTP request as a number. Following is an example: <code>http.req.content_length < 500</code>
HTTP.RES.CONTENT_LENGTH	Returns the length of the HTTP response as a number. Following is an example: <code>http.res.content_length <= 1000</code>
HTTP.RES.STATUS	Returns the response status code
HTTP.RES.IS_REDIRECT	Returns a Boolean TRUE if the response code is associated with a redirect. Following are the redirect response codes: <ul style="list-style-type: none"> • 300 (Multiple Choices) • 301 (Moved Permanently) • 302 (Found) • 303 (See Other) • 305 (Use Proxy) • 307 (Temporary Redirect) <p>Note: Status code 304 is not considered a redirect HTTP response status code. Status code 306 is unused.</p> <p>In the following example, the rewrite action replaces <code>http</code> in the Location header of an HTTP response with <code>https</code> if the response is associated with an HTTP redirect.</p> <pre>add rewrite action redloc replace 'http.res.header("Location").before_regex(re#://#)' ""https" add rewrite policy pol1 HTTP.RES.IS_REDIRECT red_location bind rewrite global pol1 100</pre>

SIP Expressions

Sep 23, 2014

Introduction

The NetScaler default expressions language contains a number of expressions that operate on Session Initiation Protocol (SIP) connections. These expressions are intended to be used in policies for any supported protocol that operates on a request/response basis. These expressions can be used in content switching, rate limiting, responder, and rewrite policies.

Certain limitations apply to SIP expressions used with responder policies. Only the DROP, NOOP or RESPONDWITH actions are allowed on a SIP load balancing virtual server. Responder policies can be bound to a load balancing virtual server, an override global bind point, a default global bind point, or a sip_udp policy label.

The header format used by the SIP protocol is similar to that used by the HTTP protocol, so many of the new expressions look and function much like their HTTP analogs. Each SIP header consists of a line that includes the SIP method, the URL, and the version, followed by a series of name-value pairs that look like HTTP headers.

Following is a sample SIP header that is referred to in the expressions tables beneath it:

```
INVITE sip:16@www.sip.com:5060;transport=udp SIP/2.0
Record-Route: <sip:200.200.100.22;lr=on>
Via: SIP/2.0/UDP 200.200.100.22;branch=z9hG4bK444b.c8e103d1.0;rport=5060;
received=10.102.84.18
Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;
received=10.102.84.160
From: "12" <sip:12@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185
To: "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185
Call-ID: 00127f54-ec850017-0e46f5b9-5ec149c2@10.102.84.180
Max-Forwards: 69CSeq: 101 INVITE
User-Agent: Cisco-CP7940G/8.0
Contact: <sip:12@10.102.84.180:5060;transport=udp>
Expires: 180
Accept: application/sdp
Allow: ACK,BYE,CANCEL,INVITE,NOTIFY,OPTIONS,REFER,REGISTER,UPDATE
Supported: replaces,join,norefersub
Content-Length: 277
Content-Type: application/sdp
Content-Disposition: session;handling=optiona
```

SIP Reference Tables

The following tables contain lists of expressions that operate on SIP headers. The first table contains expressions that apply to request headers. Most response-based expressions are nearly the same as the corresponding request-based expressions. To create a response expression from the corresponding request expression, you change the first two sections of the expression from SIP.REQ to SIP.RES, and make other obvious adjustments. The second table contains those response expressions that are unique to responses and have no request equivalents. You can use any element in the following tables as a complete expression on its own, or you can use various operators to combine these expression elements with others to form more complex expressions.

Table 1. SIP Request Expressions

Expression	Description
SIP.REQ.METHOD	Operates on the method of the SIP request. The supported SIP request methods are ACK, BYE, CANCEL, INFO, INVITE, MESSAGE, NOTIFY, OPTIONS, PRACK, PUBLISH, REFER, REGISTER, SUBSCRIBE, and UPDATE. This expression is a derivative of the text class, so all operations that are applicable to text are applicable to this

Expression	Description
SIP.REQ.URL	Operates on the SIP request URL. This expression is a derivative of the text class, so all operations that are applicable to text are applicable to this method. For example, for a SIP request of INVITE sip:16@10.102.84.181:5060;transport=udp SIP/2.0, this expression returns sip:16@10.102.84.181:5060;transport=udp.
SIP.REQ.URL.PROTOCOL	Returns the URL protocol. For example, for a SIP URL of sip:16@www.sip.com:5060;transport=udp, this expression returns sip.
SIP.REQ.URL.HOSTNAME	Returns the hostname portion of the SIP URL. For example, for a SIP URL of sip:16@www.sip.com:5060;transport=udp, this expression returns www.sip.com:5060.
SIP.REQ.URL.HOSTNAME.PORT	Returns the port portion of the SIP URL hostname. If no port is specified, this expression returns the default SIP port, 5060. For example, for a SIP hostname of www.sip.com:5060, this expression returns 5060.
SIP.REQ.URL.HOSTNAME.DOMAIN	Returns the domain name portion of the SIP URL hostname. If the host is an IP address, then this expression returns an incorrect result. For example, for a SIP hostname of www.sip.com:5060, this expression returns sip.com. For a SIP hostname of 192.168.43.15:5060, this expression returns an error.
SIP.REQ.URL.HOSTNAME.SERVER	Returns the server portion of the host. For example, for a SIP hostname of www.sip.com:5060, this expression returns www.
SIP.REQ.URL.USERNAME	Returns the username that precedes the @ character. For example, for a SIP URL of sip:16@www.sip.com:5060;transport=udp, this expression returns 16.
SIP.REQ.VERSION	Returns the SIP version number in the request. For example, for a SIP request of INVITE sip:16@10.102.84.181:5060;transport=udp SIP/2.0, this expression returns SIP/2.0.
SIP.REQ.VERSION.MAJOR	Returns the major version number (the number to the left of the period). For example, for a SIP version number of SIP/2.0, this expression returns 2.
SIP.REQ.VERSION.MINOR	Returns the minor version number (the number to the right of the period). For example, for a SIP version number of SIP/2.0, this expression returns 0.
SIP.REQ.CONTENT_LENGTH	Returns the contents of the Content-Length header. This expression is a derivative of the sip_header_t class, so all operations that are available for SIP headers can be used. For example, for a SIP Content-Length header of Content-Length: 277, this expression returns 277.
SIP.REQ.TO	Returns the contents of the To header. For example, for a SIP To header of To: "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185.

Expression	Description
SIP.REQ.TO.ADDRESS	Returns the SIP URI, which is found in the sip_url object. All operations that are available for SIP URIs can be used. For example, for a SIP To header of To: "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns sip:16@sip_example.com.
SIP.REQ.TO.DISPLAY_NAME	Returns the display name portion of the To header. For example, for a SIP To header of To: "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 16.
SIP.REQ.TO.TAG	Returns the "tag" value from the "tag" name value pair in the TO header. For example, for a SIP To header of To: "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 00127f54ec85a6d90cc14f45-53cc0185.
SIP.REQ.FROM	Returns the contents of the From header. For example, for a SIP From header of From: "12" <sip:12@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns sip:12@sip_example.com.
SIP.REQ.FROM.ADDRESS	Returns the SIP URI, which is found in the sip_url object. All operations that are available for SIP URIs can be used. For example, for a SIP From header of From: "12" <sip:12@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns sip:12@sip_example.com.
SIP.REQ.FROM.DISPLAY_NAME	Returns the display name portion of the To header. For example, for a SIP From header of From: "12" <sip:12@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 12.
SIP.REQ.FROM.TAG	Returns the "tag" value from the "tag" name/value pair in the TO header. For example, for a SIP From header of From: "12" <sip:12@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 00127f54ec85a6d90cc14f45-53cc0185.
SIP.REQ.VIA	Returns the complete Via header. If there are multiple Via headers in the request, returns the last Via header. For example, for the two Via headers in the sample SIP header, this expression returns Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160.
SIP.REQ.VIA.SENTBY_ADDRESS	Returns the address that sent the request. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 10.102.84.180.
SIP.REQ.VIA.SENTBY_PORT	Returns the port that sent the request. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 5060.

SIP.REQ.VIA.RPORT Expression	Description
	Returns the value from the rport name/value pair. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 5060.
SIP.REQ.VIA.BRANCH	Returns the value from the branch name/value pair. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns z9hG4bK03e76d0b.
SIP.REQ.VIA.RECEIVED	Returns the value from the received name/value pair. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 10.102.84.160.
SIP.REQ.CALLID	Returns the contents of the Callid header. This expression is a derivative of the sip_header_t class, so all operations that are available for SIP headers can be used. For example, for a SIP Callid header of Call-ID: 00127f54-ec850017-0e46f5b9-5ec149c2@10.102.84.180, this expression returns 00127f54-ec850017-0e46f5b9-5ec149c2@10.102.84.180.
SIP.REQ.CSEQ	Returns the CSEQ number from the CSEQ, as an integer. For example, for a SIP CSEQ header of CSeq: 101 INVITE, this expression returns 101.
SIP.REQ.HEADER("<header_name>")	Returns the specified SIP header. For <header_name>, substitute the name of the header that you want. For example, to return the SIP From header, you would type SIP.REQ.HEADER("From").
SIP.REQ.HEADER("<header_name>").INSTANCE(<line_number>)	Returns the specified instance of the specified SIP header. Multiple instances of the same SIP header can occur. Where you want a specific instance of such a SIP header (for example, a specific Via header), you can specify that header by typing a number as the <line_number>. Header instances are matched from last (0) to first. In other words, SIP.REQ.HEADER("Via").INSTANCE(0) returns the last instance of the Via header, while SIP.REQ.HEADER("Via").INSTANCE(1) returns the last instance but one of the Via header, and so on. For example, if used on the example SIP header, SIP.REQ.HEADER("Via").INSTANCE(1) returns Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060.
SIP.REQ.HEADER("<header_name>").VALUE(<line_number>)	Returns the contents of the specified instance of the specified SIP header. The usage is nearly the same as the previous expression. For example, if used on the SIP header example in the preceding table entry, SIP.REQ.HEADER("Via").VALUE(1) returns SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060.
SIP.REQ.HEADER("<header_name>").COUNT	Returns the number of instances of a particular header as an integer. For example, if used on the SIP header example above, SIP.REQ.HEADER("Via").COUNT returns 2.
SIP.REQ.HEADER("<header_name>").EXISTS	Returns a boolean value of true or false, depending upon whether the specified header exists or not. For example, if used on the SIP header example above,

Expression	Description
SIP.REQ.HEADER("<header_name>").LIST	<p>Returns the comma-separated parameter list in the specified header. For example, if used on the SIP header example above, SIP.REQ.HEADER("Allow").LIST returns ACK,BYE,CANCEL,INVITE,NOTIFY,OPTIONS,REFER,REGISTER,UPDATE.</p> <p>You can append the string .GET(<list_item_number>) to select a specific list item. For example, to get the first item (ACK) from the above list, you would type SIP.REQ.HEADER("Allow").LIST.GET(0). To extract the second item (BYE), you would type SIP.REQ.HEADER("Allow").LIST.GET(1).</p> <p>Note: If the specified header contains a list of name/value pairs, the entire name/value pair is returned.</p>
SIP.REQ.HEADER("<header_name>").TYPECAST_SIP_HEADER_T("<in_header_name>")	<p>Typecasts <header_name> to <in_header_name>. Any text can be typecasted to the sip_header_t class, after which all header-based operations can be used. After you perform this operation, you can apply all operations that can be used with <in_header_name>.</p> <p>For example, the expression SIP.REQ.CONTENT_LENGTH.TYPECAST_SIP_HEADER_T typecasts all instances of the Content-Length header. After you perform this operation, you can apply all header operations to all instances of the specified header.</p>
SIP.REQ.HEADER("<header_name>").CONTAINS("<string>").	<p>Returns boolean true if the specified text string is present in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</p>
SIP.REQ.HEADER("<header_name>").EQUALS_ANY(<patset>)	<p>Returns boolean true if any pattern associated with <patset> matches any content in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</p>
SIP.REQ.HEADER("<header_name>").CONTAINS_ANY(<patset>)	<p>Returns Boolean true if any pattern associated with <patset> matches any content in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</p>
SIP.REQ.HEADER("<header_name>").CONTAINS_INDEX(<patset>)	<p>Returns the index of the matching pattern associated with <patset> if that pattern matches any content in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</p>
SIP.REQ.HEADER("<header_name>").EQUALS_INDEX(<patset>)	<p>Returns the index of the matching pattern associated with <patset> if that pattern matches any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</p>
SIP.REQ.HEADER("<header_name>").SUBSTR("<string>")	<p>If the specified string is present in any instance of the specified header, this expression returns that string. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160", SIP.REQ.HEADER("Via").SUBSTR("rport=5060") returns "rport=5060". SIP.REQ.HEADER("Via").SUBSTR("rport=5061") returns an empty string.</p>

Expression SIP.REQ.HEADER(" <header_name>").AFTER_STR("<string>")	Description If the specified string is present in any instance of the specified header, this expression returns the string immediately after that string. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER("Via").AFTER_STR("rport=") returns 5060.
SIP.REQ.HEADER(" <header_name>").REGEX_MATCH(<regex>)	Returns boolean true if the specified regular expression (<i>regex</i>) matches any instance of the specified header. You must specify the regular expression in the following format: re<delimiter>regular expression<same delimiter> The regular expression cannot be larger than 1499 characters in length. It must conform to the PCRE regular expression library. See http://www.pcre.org/pcre.txt for documentation on PCRE regular expression syntax. The <code>pcrepattern</code> man page also has useful information on specifying patterns by using PCRE regular expressions. The regular expression syntax supported in this expression has some differences from PCRE. Back references are not allowed. You should avoid recursive regular expressions; although some work, many do not. The dot (.) metacharacter matches newlines. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.
SIP.REQ.HEADER(" <header_name>").REGEX_SELECT(<regex>)	If the specified regex matches any text in any instance of the specified header, this expression returns the text. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER("Via").REGEX_SELECT("received=[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}") returns received=10.102.84.160.
SIP.REQ.HEADER(" <header_name>").AFTER_REGEX(<regex>)	If the specified regex matches any text in any instance of the specified header, this expression returns the string immediately after that text. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER("Via").AFTER_REGEX("received=") returns 10.102.84.160.
SIP.REQ.HEADER(" <header_name>").BEFORE_REGEX(<regex>)	If the specified regex matches any text in any instance of the specified header, this expression returns the string immediately before that text. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER("Via").BEFORE_REGEX("[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}") returns received=.
SIP.REQ.FULL_HEADER	Returns the entire SIP header, including the terminating CR/LF.
SIP.REQ.IS_VALID	Returns boolean true if the request format is valid.
SIP.REQ.BODY(<length>)	Returns the request body, up to the specified length. If the specified length is greater than the length of the request body, this expression returns the entire request body.

Expression	Description
SIP.RES.LB_VSERVER	Returns the name of the load balancing virtual server (<i>LB vserver</i>) that is serving the current request.
SIP.RES.CS_VSERVER	Returns the name of the content switching virtual server (<i>CS vserver</i>) that is serving the current request.

Table 2. SIP Response Expressions

Expression	Description
SIP.RES.STATUS	Returns the SIP response status code. For example, if the first line of the response is SIP/2.0 100 Trying, this expression returns 100.
SIP.RES.STATUS_MSG	Returns the SIP response status message. For example, if the first line of the response is SIP/2.0 100 Trying, this expression returns Trying.
SIP.RES.IS_REDIRECT	Returns boolean true if the response code is a redirect.
SIP.RES.METHOD	Returns the response method extracted from the request method string in the CSeq header.

Operations for HTTP, HTML, and XML Encoding and “Safe” Characters

Nov 27, 2014

The following operations work with the encoding of HTML data in a request or response and XML data in a POST body.

Table 1. Operations That Evaluate HTML and XML Encoding

HTML or XML Operation	Description
<text>.HTML_XML_SAFE	<p>Transforms special characters into XML safe format, as in the following examples:</p> <ul style="list-style-type: none"> • A left-pointing angle bracket (<) is converted to &lt; • A right-pointing angle bracket (>) is converted to &gt; • An ampersand (&) is converted to &amp; <p>This operation safeguards against cross-site scripting attacks. Maximum length of the transformed text is 2048 bytes. This is a read-only operation.</p> <p>After applying the transformation, additional operators that you specify in the expression are applied to the selected text. Following is an example:</p> <p><code>http.req.url.query.html_xml_safe.contains("myQueryString")</code></p>
<text>.HTTP_HEADER_SAFE	<p>Converts all new line ('\n') characters in the input text to '%0A' to enable the input to be used safely in HTTP headers.</p> <p>This operation safeguards against response-splitting attacks.</p> <p>The maximum length of the transformed text is 2048 bytes. This is a read-only operation.</p>
<text>.HTTP_URL_SAFE	<p>Converts unsafe URL characters to '%xx' values, where "xx" is a hex-based representation of the input character. For example, the ampersand (&) is represented as %26 in URL-safe encoding. The maximum length of the transformed text is 2048 bytes. This is a read-only operation.</p> <p>Following are URL safe characters. All others are unsafe:</p> <ul style="list-style-type: none"> • Alpha-numeric characters: a-z, A-Z, 0-9 • Asterix: "*" • Ampersand: "&" • At-sign: "@" • Colon: ":" • Comma: "," • Dollar: "\$" • Dot: "." • Equals: "=" • Exclamation mark: "!" • Hyphen: "-" • Open and close parentheses: "(", ")" • Percent: "%" • Plus: "+" • Semicolon: ";"

HTML or XML Operation	Description
	<ul style="list-style-type: none"> • Single quote: "'" • Slash: "/" • Question mark: "?" • Tilde: "~" • Underscore: "_"
<text>.MARK_SAFE	Marks the text as safe without applying any type of data transformation.
<text>.SET_TEXT_MODE(URLENCODED NOURLENCODED)	<p>Transforms all %HH encoding in the byte stream. This operation works with characters (not bytes). By default, a single byte represents a character in ASCII encoding. However, if you specify URLENCODED mode, three bytes can represent a character.</p> <p>In the following example, a PREFIX(3) operation selects the first 3 characters in a target.</p> <pre>http.req.url.hostname.prefix(3)</pre> <p>In the following example, the NetScaler can select up to 9 bytes from the target:</p> <pre>http.req.url.hostname.set_text_mode(urlencoded).prefix(3)</pre>
<text>.SET_TEXT_MODE(PLUS_AS_SPACE NO_PLUS_AS_SPACE)	Specifies how to treat the plus character (+). The PLUS_AS_SPACE option replaces a plus character with white space. For example, the text "hello+world" becomes "hello world." The NO_PLUS_AS_SPACE option leaves plus characters as they are.
<text>.SET_TEXT_MODE(BACKSLASH_ENCODED NO_BACKSLASH_ENCODED)	<p>Specifies whether or not backslash decoding is performed on the text object represented by <text>.</p> <p>If BACKSLASH_ENCODED is specified, the SET_TEXT_MODE operator performs the following operations on the text object:</p> <ul style="list-style-type: none"> • All occurrences of "\XXX" will be replaced with the character "Y" (where XXX represents a number in the octal system and Y represents the ASCII equivalent of XXX). The valid range of octal values for this type of encoding is 0 to 377. For example, the encoded text "http\72/" and "http\072/" will both be decoded to "http:/", where the colon (:) is the ASCII equivalent of the octal value "72". • All occurrences of "\xHH" will be replaced with the character "Y" (HH represents a number in the hexadecimal system and Y denotes the ASCII equivalent of HH. For example, the encoded text "http\x3a/" will be decoded to "http:/", where the colon (:) is the ASCII equivalent of the hexadecimal value "3a". • All occurrences of "\uWWXX" will be replaced with the character sequence "YZ" (Where WW and XX represent two distinct hexadecimal values and Y and Z represent their ASCII equivalents of WW and XX respectively. For example, the encoded text "http%u3a2f/" and "http%u003a/" will both be decoded to "http:/", where "3a" and "2f" are two hexadecimal values and the colon (:) and forward slash ("/") represent their ASCII equivalents respectively. • All occurrences of "\b", "\n", "\t", "\f", and "\r" are

HTML or XML Operation	Description
	<p>replaced with the corresponding ASCII characters.</p> <p>If NO_BACKSLASH_ENCODED is specified, backslash decoding is not performed on the text object.</p>
<p><text>.SET_TEXT_MODE(BAD_ENCODE_RAISE_UNDEF NO_BAD_ENCODE_RAISE_UNDEF)</p>	<p>Performs the associated undefined action if either the URLENCODED or the BACKSLASH_ENCODED mode is set and bad encoding corresponding to the specified encoding mode is encountered in the text object represented by <text>.</p> <p>If NO_BAD_ENCODE_RAISE_UNDEF is specified, the associated undefined action will not be performed when bad encoding is encountered in the text object represented by <text>.</p>

Expressions for TCP, UDP, and VLAN Data

Sep 02, 2013

TCP and UDP data take the form of a string or a number. For expression prefixes that return string values for TCP and UDP data, you can apply any text-based operations. For more information, see "[Default Syntax Expressions: Evaluating Text.](#)"

For expression prefixes that return numeric value, such as a source port, you can apply an arithmetic operation. For more information, see "[Basic Operations on Expression Prefixes](#)" and "[Compound Operations for Numbers.](#)"

The following table describes prefixes that extract TCP and UDP data.

Table 1. Prefixes That Extract TCP and UDP Data

GET Operation	Description
CLIENT.TCP.PAYLOAD(<integer>)	Returns TCP payload data as a string, starting with the first character in the payload and continuing for the number of characters in the <integer> argument. You can apply any text-based operation to this prefix.
CLIENT.TCP.SRCPORT	Returns the ID of the current packet's source port as a number.
CLIENT.TCP.DSTPORT	Returns the ID of the current packet's destination port as a number.
CLIENT.TCP.OPTIONS	Returns the TCP options set by the client. Examples of TCP options are Maximum Segment Size (MSS), Window Scale, Selective Acknowledgements (SACK), and Time Stamp Option. The COUNT, TYPE(<type>), and TYPE_NAME(<m>) operators can be used with this prefix. For the TCP options set by the server, see the SERVER.TCP.OPTIONS prefix.
CLIENT.TCP.OPTIONS.COUNT	Returns the number of TCP options that the client has set.
CLIENT.TCP.OPTIONS.TYPE(<type>)	Returns the value of the TCP option whose type (or <i>option kind</i>) is specified as the argument. The value is returned as a string of bytes in big endian format (or <i>network byte order</i>). Parameters: type - Type value
CLIENT.TCP.OPTIONS.TYPE_NAME(<m>)	Returns the value of the TCP option whose enumeration constant is specified as the argument. The enumeration constants that you can

GET Operation	Description
	<p>pass as the argument are REPEATER, TIMESTAMP, SACK_PERMITTED, WINDOW, and MAXSEG. To specify the TCP option kind instead of these enumeration constants, use CLIENT.TCP.OPTIONS.TYPE(<type>). For other TCP options, you must use CLIENT.TCP.OPTIONS.TYPE(<type>).</p> <p>Parameters:</p> <p>m - TCP option enumeration constant</p>
CLIENT.TCP.REPEATER_OPTION.EXISTS	Returns a Boolean TRUE if Repeater TCP options exist.
CLIENT.TCP.REPEATER_OPTION.IP	Returns the branch repeater's IPv4 address from the Repeater TCP options.
CLIENT.TCP.REPEATER_OPTION.MAC	Returns the branch repeater's MAC address from the Repeater TCP options.
CLIENT.UDP.DNS.DOMAIN	Returns the DNS domain name.
CLIENT.UDP.DNS.DOMAIN.EQ("<hostname>")	<p>Returns a Boolean TRUE if the domain name matches the <hostname> argument. The comparison is case insensitive.</p> <p>Following is an example:</p> <pre>client.udp.dns.domain.eq("www.mycompany.com")</pre>
CLIENT.UDP.DNS.IS_AAAAREC	Returns a Boolean TRUE if the record type is AAAA. These types of records indicate an IPv6 address in forward lookups.
CLIENT.UDP.DNS.IS_ANYREC	Returns a Boolean TRUE if it is of any record type.
CLIENT.UDP.DNS.IS_AREC	Returns a Boolean TRUE if the record is type A. Type A records provide the host address.
CLIENT.UDP.DNS.IS_CNAMEREC	Returns a Boolean TRUE if the record is of type CNAME. In systems that use multiple names to identify a resource, there is one canonical name and a number of aliases. The CNAME provides the canonical name.
CLIENT.UDP.DNS.IS_MXREC	Returns a Boolean TRUE if the record is of type MX (mail exchanger). This DNS record describes a priority and a host name. The MX records for the same domain name specify the email servers in the domain and

GET Operation	Description
CLIENT.UDP.DNS.IS_NSREC	Returns a Boolean TRUE if the record is of type NS. This is a name server record that includes a host name with an associated A record. This enables locating the domain name that is associated with the NS record.
CLIENT.UDP.DNS.IS_PTRREC	Returns a Boolean TRUE if the record is of type PTR. This is a domain name pointer and is often used to associate a domain name with an IPv4 address.
CLIENT.UDP.DNS.IS_SOAREC	Returns a Boolean TRUE if the record is of type SOA. This is a start of authority record.
CLIENT.UDP.DNS.IS_SRVREC	Returns a Boolean TRUE if the record is of type SRV. This is a more general version of the MX record.
CLIENT.UDP.DSTPORT	Returns the numeric ID of the current packet's UDP destination port.
CLIENT.UDP.SRCPORT	Returns the numeric ID of the current packet's UDP source port.
CLIENT.UDP.RADIUS	Returns RADIUS data for the current packet.
CLIENT.UDP.RADIUS.ATTR_TYPE(<type>)	Returns the value for the attribute type specified as the argument.
CLIENT.UDP.RADIUS.USERNAME	Returns the RADIUS user name.
CLIENT.TCP.MSS	Returns the maximum segment size (MSS) for the current connection as a number.
CLIENT.VLAN.ID	Returns the numeric ID of the VLAN through which the current packet entered the NetScaler.
SERVER.TCP.DSTPORT	Returns the numeric ID of the current packet's destination port.
SERVER.TCP.SRCPORT	Returns the numeric ID of the current packet's source port.
SERVER.TCP.OPTIONS	Returns the TCP options set by the server. Examples of TCP options are Maximum Segment Size (MSS), Window Scale, Selective Acknowledgements (SACK), and Time Stamp Option. The COUNT, TYPE(<type>), and TYPE_NAME(<m>) operators can be used with this

GET Operation	Description
SERVER.TCP.OPTIONS.COUNT	Returns the number of TCP options that the server has set.
SERVER.TCP.OPTIONS.TYPE(<type>)	<p>Returns the value of the TCP option whose type (or <i>option kind</i>) is specified as the argument. The value is returned as a string of bytes in big endian format (or <i>network byte order</i>).</p> <p>Parameters:</p> <p>type - Type value</p>
SERVER.TCP.OPTIONS.TYPE_NAME(<m>)	<p>Returns the value of the TCP option whose enumeration constant is specified as the argument. The enumeration constants that you can pass as the argument are REPEATER, TIMESTAMP, SACK_PERMITTED, WINDOW, and MAXSEG. To specify the TCP option kind instead of these enumeration constants, use CLIENT.TCP.OPTIONS.TYPE(<type>). For other TCP options, you must use CLIENT.TCP.OPTIONS.TYPE(<type>).</p> <p>Parameters:</p> <p>m - TCP option enumeration constant</p>
SERVER.VLAN	Operates on the VLAN through which the current packet entered the NetScaler.
SERVER.VLAN.ID	Returns the numeric ID of the VLAN through which the current packet entered the NetScaler.

Expressions for Evaluating a DNS Message and Identifying Its Carrier Protocol

Aug 30, 2013

You can evaluate DNS requests and responses by using expressions that begin with DNS.REQ and DNS.RES, respectively. You can also identify the transport layer protocol that is being used to send the DNS messages.

The following functions return the contents of a DNS query.

Table 1. Functions that return the contents of a DNS query

Function	Description
DNS.REQ.QUESTION.DOMAIN	Return the domain name (the value of the QNAME field) in the question section of the DNS query. The domain name is returned as a text string, which can be passed to EQ(), NE(), and any other functions that work with text.
DNS.REQ.QUESTION.TYPE	<p>Return the query type (the value of the QTYPE field) in the DNS query. The field indicates the type of resource record (for example, A, NS, or CNAME) for which the name server is being queried. The returned value can be compared to one of the following values by using the EQ() and NE() functions:</p> <ul style="list-style-type: none">• A• AAAA• NS• SRV• PTR• CNAME• SOA• MX• ANY <p>Note: You can use only the EQ() and NE() functions with the TYPE function.</p> <p>Example:</p> <p>DNS.REQ.QUESTION.TYPE.EQ(MX)</p>

The following functions return the contents of a DNS response.

Table 2. Functions that return the contents of a DNS response

Function	Description
DNS.RES.HEADER.RCODE	Return the response code (the value of the RCODE field) in the header section of the DNS response. You can use only the EQ() and NE() functions with the RCODE

Function	Description
	<p>function. Following are the possible values:</p> <ul style="list-style-type: none"> • NOERROR • FORMERR • SERVFAIL • NXDOMAIN • NOTIMP • REFUSED
DNS.RES.QUESTION.DOMAIN	Return the domain name (the value of the QNAME field) in the question section of the DNS response. The domain name is returned as a text string, which can be passed to EQ(), NE(), and any other functions that work with text.
DNS.RES.QUESTION.TYPE	<p>Return the query type (the value of the QTYPE field) in the question section of the DNS response. The field indicates the type of resource record (for example, A, NS, or CNAME) that is contained in the response. The returned value can be compared to one of the following values by using the EQ() and NE() functions:</p> <ul style="list-style-type: none"> • A • AAAA • NS • SRV • PTR • CNAME • SOA • MX • ANY <p>You can use only the EQ() and NE() functions with the TYPE function.</p> <p>Example:</p> <p>DNS.RES.QUESTION.TYPE.EQ(SOA)</p>

The following functions return the transport layer protocol name.

Table 3. Functions that return the transport layer protocol name

Function	Description
DNS.REQ.TRANSPORT	<p>Return the name of the transport layer protocol that was used to send the DNS query. Possible values returned are TCP and UDP. You can use only the EQ() and NE() functions with the TRANSPORT function.</p> <p>Example:</p> <p>DNS.REQ.TRANSPORT.EQ(TCP)</p>
DNS.RES.TRANSPORT	Return the name of the transport layer protocol that was used for the DNS response.

Function	Possible values returned are TCP and UDP. You can use only the EQ() and NE() functions with the TRANSPORT function.
	Example: DNS.RES.TRANSPORT.EQ(TCP)

XPath and HTML, XML, or JSON Expressions

Mar 20, 2012

The default syntax expression engine supports expressions for evaluating and retrieving data from HTML, XML, and JavaScript Object Notation (JSON) files. This enables you to find specific nodes in an HTML, XML, or JSON document, determine if a node exists in the file, locate nodes in XML contexts (for example, nodes that have specific parents or a specific attribute with a given value), and return the contents of such nodes. Additionally, you can use XPath expressions in rewrite expressions.

The default syntax expression implementation for XPath comprises a default syntax expression prefix (such as “HTTP.REQ.BODY”) that designates HTML or XML text, and the XPATH operator that takes the XPath expression as its argument.

HTML files are a largely free-form collection of tags and text elements. You can use the XPATH_HTML operator, which takes an XPath expression as its argument, to process HTML files. JSON files are either a collection of name/value pairs or an ordered list of values. You can use the XPATH_JSON operator, which takes an XPath expression as its argument, to process JSON files.

Table 1. XPath and JSON Expression Prefixes That Return Text

XPath Prefix	Description
<text>.XPATH(xpathex)	<p>Operate on an XML file and return a Boolean value.</p> <p>For example, the following expression returns a Boolean TRUE if a node called “creator” exists under the node “Book” within the first 1000 bytes of the XML file.</p> <p>HTTP.REQ.BODY(1000).XPATH(xp%boolean(/Book/creator)%)</p> <p>Parameters:</p> <p>xpathex - XPath Boolean expression</p>
<text>.XPATH(xpathex)	<p>Operate on an XML file and return a value of data type “double.”</p> <p>For example, the following expression converts the string “36” (a price value) to a value of data type “double” if the string is in the first 1000 bytes of the XML file:</p> <p>HTTP.REQ.BODY(1000).XPATH(xp%number(/Book/price)%)</p> <p>Parameters:</p> <p>xpathex - XPath numeric expression</p>
<text>.XPATH(xpathex)	<p>Operate on an XML file and return a node-set or a string. Node-sets are converted to corresponding strings by using the standard XPath string conversion routine.</p> <p>For example, the following expression selects all the nodes that are enclosed by “/Book/creator” (a node-set) in the first 1000 bytes of the body:</p> <p>HTTP.REQ.BODY(1000).XPATH(xp%/Book/creator%)</p> <p>Parameters:</p>

XPath Prefix	Description
<text>.XPATH_HTML(xpathex)	<p>Operate on an HTML file and return a text value.</p> <p>For example, the following expression operates on an HTML file and returns the text enclosed in <title></title> tags if the title HTML element is found in the first 1000 bytes:</p> <pre>HTTP.REQ.BODY(1000).XPATH_HTML(xp%/html/head/title%)</pre> <p>Parameters:</p> <p>xpathex - XPath text expression</p>
<text>.XPATH_HTML_WITH_MARKUP(xpathex)	<p>Operate on an HTML file and return a string that contains the entire selected portion of the document, including markup such as including the enclosing element tags.</p> <p>The following expression operates on the HTML file and selects all content within the <title> tag, including markup.</p> <pre>HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%/html/head/title%)</pre> <p>The portion of the HTML body that is selected by the expression is marked for further processing.</p> <p>Parameters:</p> <p>xpathex - XPath expression</p>
<text>.XPATH_JSON(xpathex)	<p>Operate on a JSON file and return a Boolean value.</p> <p>For example, consider the following JSON file:</p> <pre>{ "Book":{ "creator":{ "person":{ "name":<name> } }, "title":<title> } }</pre> <p>The following expression operates on the JSON file and returns a Boolean TRUE if the JSON file contains a node named “creator,” whose parent node is “Book,” in the first 1000 bytes:</p> <pre>HTTP.REQ.BODY(1000).XPATH_JSON(xp%boolean(/Book/creator%))</pre> <p>Parameters:</p> <p>xpathex - XPath Boolean expression</p>
<text>.XPATH_JSON(xpathex)	<p>Operate on a JSON file and return a value of data type “double.”</p> <p>For example, consider the following JSON file:</p> <pre>{ "Book":{ "creator":{ "person":{ "name":<name> } }, "title":<title>, "price":36 } }</pre>

XPath Prefix	Description
	<p>The following expression operates on the JSON file and converts the string “36” to a value of data type “double” if the string is present in the first 1000 bytes of the JSON file.</p> <p>HTTP.REQ.BODY(1000).XPATCH_JSON(xp%number(/Book/price)%)</p> <p>Parameters:</p> <p>xpathex - XPath numeric expression</p>
<text>.XPATCH_JSON(xpathex)	<p>Operate on a JSON file and return a node-set or a string. Node-sets are converted to corresponding strings by using the standard XPath string conversion routine.</p> <p>For example, consider the following JSON file:</p> <pre>{ "Book":{ "creator":{ "person":{ "name":'<name>' } }, "title":'<title>' } }</pre> <p>The following expression selects all the nodes that are enclosed by “/Book” (a node-set) in the first 1000 bytes of the body of the JSON file and returns the corresponding string value, which is “<name><title>”:</p> <p>HTTP.REQ.BODY(1000).XPATCH_JSON(xp%/Book%)</p> <p>Parameters:</p> <p>xpathex - XPath expression</p>
<text>.XPATCH_JSON_WITH_MARKUP(xpathex)	<p>Operate on an XML file and return a string that contains the entire portion of the document for the result node, including markup such as including the enclosing element tags.</p> <p>For example, consider the following JSON file:</p> <pre>{ "Book":{ "creator":{ "person":{ "name":'<name>' } }, "title":'<title>' } }</pre> <p>The following expression operates on the JSON file and selects all the nodes that are enclosed by “/Book/creator” in the first 1000 bytes of the body, which is “creator:{ person:{ name:'<name>' } }.”</p> <p>HTTP.REQ.BODY(1000).XPATCH_JSON_WITH_MARKUP(xp%/Book/creator%)</p> <p>The portion of the JSON body that is selected by the expression is marked for further processing.</p> <p>Parameters:</p> <p>xpathex - XPath expression</p>
<text>.XPATCH_WITH_MARKUP(xpathex)	<p>Operate on an XML file and return a string that contains the entire portion of the document for the result node, including markup such as including the enclosing element tags.</p> <p>For example, the following expression operates on an XML file and selects all the nodes enclosed by “/Book/creator” in the first 1000 bytes of the body.</p>

XPath Prefix	HTTP.REQ.BODY(1000).XPATH_WITH_MARKUP(xp%/Book/creator%) Description
	<p>The portion of the JSON body that is selected by the expression is marked for further processing.</p> <p>Parameters:</p> <p>xpathex - XPath expression</p>

Encrypting and Decrypting XML Payloads

Sep 02, 2013

You can use the XML_ENCRYPT() and XML_DECRYPT() functions in default syntax expressions to encrypt and decrypt, respectively, XML data. These functions conform to the W3C XML Encryption standard defined at "<http://www.w3.org/TR/2001/PR-xmldsig-core-20010820/>." XML_ENCRYPT() and XML_DECRYPT() support a subset of the XML Encryption specification. In the subset, data encryption uses a bulk cipher method (RC4, DES3, AES128, AES192, or AES256), and an RSA public key is used to encrypt the bulk cipher key.

Note: If you want to encrypt and decrypt text in a payload, you must use the ENCRYPT and DECRYPT functions. For more information about these functions, see "[Encrypting and Decrypting Text](#)."

The XML_ENCRYPT() and XML_DECRYPT() functions are not dependent on the encryption/decryption service that is used by the ENCRYPT and DECRYPT commands for text. The cipher method is specified explicitly as an argument to the XML_ENCRYPT() function. The XML_DECRYPT() function obtains the information about the specified cipher method from the <xenc:EncryptedData> element. Following are synopses of the XML encryption and decryption functions:

- **XML_ENCRYPT(<certKeyName>, <method> [, <flags>])**. Returns an <xenc:EncryptedData> element that contains the encrypted input text and the encryption key, which is itself encrypted by using RSA.
- **XML_DECRYPT(<certKeyName>)**. Returns the decrypted text from the input <xenc:EncryptedData> element, which includes the cipher method and the RSA-encrypted key.

Note: The <xenc:EncryptedData> element is defined in the W3C XML Encryption specification.

Following are descriptions of the arguments:

certKeyName

Selects an X.509 certificate with an RSA public key for XML_ENCRYPT() or an RSA private key for XML_DECRYPT(). The certificate key must have been previously created by an add ssl certKey command.

method

Specifies which cipher method to use for encrypting the XML data. Possible values: RC4, DES3, AES128, AES192, AES256.

flags

A bitmask specifying the following optional key information (<ds:KeyInfo>) to be included in the <xenc:EncryptedData> element that is generated by XML_ENCRYPT():

- **1** - Include a KeyName element with the certKeyName. The element is <ds:KeyName>.
- **2** - Include a KeyValue element with the RSA public key from the certificate. The element is <ds:KeyValue>.
- **4** - Include an X509IssuerSerial element with the certificate serial number and issuer DN. The element is <ds:X509IssuerSerial>.
- **8** - Include an X509SubjectName element with the certificate subject DN. The element is <ds:X509SubjectName>.
- **16** - Include an X509Certificate element with the entire certificate. The element is <ds:X509Certificate>.

Using the XML_ENCRYPT() and XML_DECRYPT() Functions in Expressions

The XML encryption feature uses SSL certificate-key pairs to provide X.509 certificates (with RSA public keys) for key encryption and RSA private keys for key decryption. Therefore, before you use the XML_ENCRYPT() function in an expression, you must create an SSL certificate-key pair. The following command creates an SSL certificate-key pair, my-

certkey, with the X.509 certificate, my-cert.pem, and the private key file, my-key.pem.

```
add ssl certKey my-certkey -cert my-cert.pem -key my-key.pem -passcrypt kxPeMRyNitY=
```

The following CLI commands create rewrite actions and policies for encrypting and decrypting XML content.

```
add rewrite action my-xml-encrypt-action replace "HTTP.RES.BODY(10000).XPATH_WITH_MARKUP(xp%/%)"  
"HTTP.RES.BODY(10000).XPATH_WITH_MARKUP(xp%/%).XML_ENCRYPT("my-certkey", AES256, 31)" -  
bypassSafetyCheck YES
```

```
add rewrite action my-xml-decrypt-action replace  
"HTTP.REQ.BODY(10000).XPATH_WITH_MARKUP(xp%/xenc:EncryptedData%)"  
"HTTP.REQ.BODY(10000).XPATH_WITH_MARKUP(xp%/xenc:EncryptedData%).XML_DECRYPT("my-certkey")" -  
bypassSafetyCheck YES
```

```
add rewrite policy my-xml-encrypt-policy "HTTP.REQ.URL.CONTAINS("xml-encrypt")" my-xml-encrypt-action
```

```
add rewrite policy my-xml-decrypt-policy "HTTP.REQ.BODY(10000).XPATH(xp%boolean(//xenc:EncryptedData%)" my-xml-  
decrypt-action
```

```
bind rewrite global my-xml-encrypt-policy 30
```

```
bind rewrite global my-xml-decrypt-policy 30
```

In the above example, the rewrite action my-xml-encrypt-action encrypts the entire XML document (XPATH_WITH_MARKUP(xp%/%) in the request by using the AES-256 bulk encryption method and the RSA public key from my-certkey to encrypt the bulk encryption key. The action replaces the document with an <xenc:EncryptedData> element containing the encrypted data and an encrypted key. The flags represented by 31 include all of the optional <ds:KeyInfo> elements.

The action my-xml-decrypt-action decrypts the first <xenc:EncryptedData> element in the response (XPATH_WITH_MARKUP(xp%/xenc:EncryptedData%). This requires the prior addition of the xenc XML namespace by use of the following CLI command:

```
add ns xmlnsnamespace xenc http://www.w3.org/2001/04/xmlenc#
```

The my-xml-decrypt-action action uses the RSA private key in my-certkey to decrypt the encrypted key and then uses the bulk encryption method specified in the element to decrypt the encrypted contents. Finally, the action replaces the encrypted data element with the decrypted content.

The rewrite policy my-xml-encrypt-policy applies my-xml-encrypt-action to requests for URLs containing xml-encrypt. The action encrypts the entire response from a service configured on the NetScaler appliance.

The rewrite policy my-xml-decrypt-policy applies my-xml-decrypt-action to requests that contain an <xenc:EncryptedData> element ((XPATH(xp%/xenc:EncryptedData%) returns a non-empty string). The action decrypts the encrypted data in requests that are bound for a service configured on the NetScaler appliance.

Default Syntax Expressions: Parsing SSL Certificates

Oct 22, 2015

You can use default syntax expressions to evaluate X.509 Secure Sockets Layer (SSL) client certificates. A client certificate is an electronic document that can be used to authenticate a user's identity. A client certificate contains (at a minimum) version information, a serial number, a signature algorithm ID, an issuer name, a validity period, a subject (user) name, a public key, and signatures.

You can examine both SSL connections and data in client certificates. For example, you may want to send SSL requests that use low-strength ciphers to a particular load balancing virtual server farm. The following command is an example of a Content Switching policy that parses the cipher strength in a request and matches cipher strengths that are less than or equal to 40:

```
add cs policy p1 -rule "client.ssl.cipher_bits.le(40)"
```

As another example, you can configure a policy that determines whether a request contains a client certificate:

```
add cs policy p2 -rule "client.ssl.client_cert EXISTS"
```

Or, you might want to configure a policy that examines particular information in a client certificate. For example, the following policy verifies that the certificate has one or more days before expiration:

```
add cs policy p2 -rule "client.ssl.client_cert exists && client.ssl.client_cert.days_to_expire.ge(1)"
```

Note: For information on parsing dates and times in a certificate, see ["Format of Dates and Times in an Expression"](#) and ["Expressions for SSL Certificate Dates."](#)

This document includes the following details:

- [Prefixes for Text-Based SSL and Certificate Data](#)
- [Prefixes for Numeric Data in SSL Certificates](#)
- [Expressions for SSL Certificates](#)

Prefixes for Text-Based SSL and Certificate Data

The following table describes expression prefixes that identify text-based items in SSL transactions and client certificates.

Table 1. Prefixes That Return Text or Boolean Values for SSL and Client Certificate Data

Prefix	Description
CLIENT.SSL.CLIENT_CERT	Returns the SSL client certificate in the current SSL transaction.
CLIENT.SSL.CLIENT_CERT.TO_PEM	Returns the SSL client certificate in binary format.
CLIENT.SSL.CIPHER_EXPORTABLE	Returns a Boolean TRUE if the SSL cryptographic cipher is exportable.
CLIENT.SSL.CIPHER_NAME	Returns the name of the SSL Cipher if invoked from an SSL connection, and a NULL string if invoked from a non-SSL connection.
CLIENT.SSL.IS_SSL	Returns a Boolean TRUE if the current connection is SSL-based.

Prefixes for Numeric Data in SSL Certificates

Updated: 2013-09-02

The following table describes prefixes that evaluate numeric data other than dates in SSL certificates. These prefixes can be used with the operations that are described in ["Basic Operations on Expression Prefixes"](#) and ["Compound Operations for Numbers."](#)

Table 2. Prefixes That Evaluate Numeric Data Other Than Dates in SSL Certificates

Prefix	Description
CLIENT.SSL.CLIENT_CERT.DAYS_TO_EXPIRE	Returns the number of days that the certificate is valid, or returns -1 for expired certificates.
CLIENT.SSL.CLIENT_CERT.PK_SIZE	Returns the size of the public key used in the certificate.
CLIENT.SSL.CLIENT_CERT.VERSION	Returns the version number of the certificate. If the connection is not SSL-based, returns zero (0).
CLIENT.SSL.CIPHER_BITS	Returns the number of bits in the cryptographic key. Returns 0 if the connection is not SSL-based.
CLIENT.SSL.VERSION	Returns a number that represents the SSL protocol version, as follows: <ul style="list-style-type: none">• 0. The transaction is not SSL-based.• 0x002. The transaction is SSLv2.• 0x300. The transaction is SSLv3.• 0x301. The transaction is TLSv1.• 0x302. The transaction is TLSv1.1.• 0x303. The transaction is TLSv1.2.

Note: For expressions related to expiration dates in a certificate, see ["Expressions for SSL Certificate Dates."](#)

Expressions for SSL Certificates

You can parse SSL certificates by configuring expressions that use the following prefix:

CLIENT.SSL.CLIENT_CERT

This section discusses the expressions that you can configure for certificates, with the exception of expressions that examine certificate expiration. Time-based operations are described in "Default Syntax Expressions: Working with Dates, Times, and Numbers."

The following table describes operations that you can specify for the CLIENT.SSL.CLIENT_CERT prefix.

Table 3. Operations That Can Be Specified with the CLIENT.SSL.CLIENT_CERT Prefix

SSL Certificate Operation	Description
<certificate>.EXISTS	Returns a Boolean TRUE if the client has an SSL certificate.
<certificate>.ISSUER	Returns the Distinguished Name (DN) of the Issuer in the certificate as a name-value list. An equals sign ("=") is the delimiter for the name and the value, and the slash ("/") is the delimiter that separates the name-value pairs. Following is an example of the returned DN: /C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@mycompany.c
<certificate>.ISSUER.IGNORE_EMPTY_ELEMENTS	Returns the Issuer and ignores the empty elements in a name-value list. For example, consider the following: Cert-Issuer: /c=in/st=kar/l=l=bangalore //o=mycompany/ou=sales/ /emailAddress=myuserid@mycompany.com The following Rewrite action returns a count of 6 based on the preceding Issuer definition: sh rewrite action insert_ssl_header Name: insert_ssl Operation: insert_http_header Target:Cert-Issuer Value:CLIENT.SSL.CLIENT_CERT.ISSUER.COUNT However, if you change the value to the following, the returned count is 9: CLIENT.SSL.CLIENT_CERT.ISSUER.IGNORE_EMPTY_ELEMENTS.COUNT
<certificate>.AUTH_KEYID	Returns a string that contains the Authority Key Identifier extension of the X.509 V3 certificate.
<certificate>.AUTH_KEYID.CERT_SERIALNUMBER	Returns the SerialNumber field of the Authority Key Identifier as a blob.
<certificate>.AUTH_KEYID.EXISTS	Returns a Boolean TRUE if the certificate contains an Authority Key Identifier extension.
<certificate>.AUTH_KEYID.ISSUER_NAME	Returns the Issuer Distinguished Name in the certificate as a name-value list. An equals sign ("=") is the delimiter for the name and the value, and the slash ("/") is the delimiter that separates the name-value pairs. Following is an example: /C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@mycompany.c
<certificate>.AUTH_KEYID.ISSUER_NAME.IGNORE_EMPTY_ELEMENTS	Returns the Issuer Distinguished Name in the certificate as a name-value list and ignores the empty elements in the list For example, the following name-value list has an empty element following "a=10": a=10;;b=11;;c=89 The element following b=11 is not considered an empty element.
<certificate>.AUTH_KEYID.KEYID	Returns the keyIdentifier field of the Authority Key Identifier as a blob.
<certificate>.CERT_POLICY	Returns a string that contains the client certificate policy. Note that this represents a sequence of certificate policies.
<certificate>.KEY_USAGE(string)	Returns a Boolean value to indicate whether the specified key usage extension bit value in the X.509 certificate is set. The string argument specifies which bit is checked. Following are valid arguments: <ul style="list-style-type: none"> • DIGITAL_SIGNATURE. Returns TRUE if the digital signature bit is set; otherwise, it returns FALSE. • NONREPUDIATION. Returns TRUE if the nonrepudiation bit is set; otherwise, it returns FALSE. • KEYENCIPHERMENT. Returns TRUE if the key encipherment bit is set; otherwise, it returns FALSE. • DATAENCIPHERMENT. Returns TRUE if the data encipherment bit is set; otherwise, it returns FALSE. • KEYAGREEMENT. Returns TRUE if the key agreement bit is set; otherwise, it returns FALSE. • KEYCERTSIGN. Returns TRUE if the key cert sign bit is set; otherwise, it returns FALSE. • CRLSIGN. Returns TRUE if the CRL bit is set; otherwise, it returns FALSE. • ENCIPHERONLY. Returns TRUE if the encipher only bit is set; otherwise, it returns FALSE. • DECIPHERONLY. Returns TRUE if the decipher only bit is set; otherwise, it returns FALSE.

SSL Certificate Operation <certificate>.PK_ALGORITHM	Description Returns the name of the public key algorithm used by the certificate.
<certificate>.PK_SIZE	Returns the size of the public key used in the certificate.
<certificate>.SERIALNUMBER	Returns the serial number of the client certificate. If this is a non-SSL transaction or there is an error in the certificate, this operation returns an empty string.
<certificate>.SIGNATURE_ALGORITHM	Returns the name of the cryptographic algorithm used by the CA to sign this certificate.
<certificate>.SUBJECT	Returns the Distinguished Name of the Subject as a name-value. An equals sign ("=") separates names and values and a slash ("/") delimits name-value pairs. Following is an example: /C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@mycompany.c
<certificate>.SUBJECT.IGNORE_EMPTY_ELEMENTS	Returns the Subject as a name-value list, but ignores the empty elements in the list. For example, consider the following: Cert-Issuer: /c=in/st=kar/l=bangalore //o=mycompany/ou=sales/ /emailAddress=myuserid@mycompany.com The following Rewrite action returns a count of 6 based on the preceding Issuer definition: sh rewrite action insert_ssl_header Name: insert_ssl Operation: insert_http_header Target:Cert-Issuer Value:CLIENT.SSL.CLIENT_CERT.ISSUER.COUNT However, if you change the value to the following, the returned count is 9: CLIENT.SSL.CLIENT_CERT.ISSUER.IGNORE_EMPTY_ELEMENTS.COUNT
<certificate>.SUBJECT_KEYID	Returns the Subject KeyID of the client certificate. If there is no Subject KeyID, this operation returns a zero-length te object.

Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs

May 26, 2015

You can use default syntax expression prefixes that return IPv4 and IPv6 addresses, MAC addresses, IP subnets, useful client and server data such as the throughput rates at the interface ports (Rx, Tx, and RxTx), and the IDs of the VLANs through which packets are received. You can then use various operators to evaluate the data that is returned by these expression prefixes.

This document includes the following details:

- [Expressions for IP Addresses and IP Subnets](#)
- [Expressions for MAC Addresses](#)
- [Expressions for Numeric Client and Server Data](#)

Expressions for IP Addresses and IP Subnets

Updated: 2013-09-02

You can use default syntax expressions to evaluate addresses and subnets that are in Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) format. Expression prefixes for IPv6 addresses and subnets include IPv6 in the prefix. Expression prefixes for IPv4 addresses and subnets include IP in the prefix. Following is an example of an expression that identifies whether a request has originated from a particular IPv4 subnet.

```
client.ip.src.in_subnet(147.1.0.0/16)
```

Following are two examples of Rewrite policies that examine the subnet from which the packet is received and perform a rewrite action on the Host header. With these two policies configured, the rewrite action that is performed depends on the subnet in the request. These two policies evaluate IP addresses that are in the IPv4 address format.

```
add rewrite action URL1-rewrite-action replace "http.req.header("Host")" "\"www.mycompany1.com\""  
add rewrite policy URL1-rewrite-policy "http.req.header("Host").contains("\"www.test1.com\")" && client.ip.src.in_subnet(147.1.0.0/16)" URL1-rewrite-action  
add rewrite action URL2-rewrite-action replace "http.req.header("Host")" "\"www.mycompany2.com\""  
add rewrite policy URL2-rewrite-policy "http.req.header("Host").contains("\"www.test2.com\")" && client.ip.src.in_subnet(10.202.0.0/16)" URL2-rewrite-action
```

Note: The preceding examples are commands that you type at the NetScaler command-line interface (CLI) and, therefore, each quotation mark must be preceded by a backslash (\). For more information, see "[Configuring Default Syntax Expressions in a Policy](#)."

Prefixes for IPV4 Addresses and IP Subnets

Updated: 2013-09-02

The following table describes prefixes that return IPv4 addresses and subnets, and segments of IPv4 addresses. You can use numeric operators and operators that are specific to IPv4 addresses with these prefixes. For more information about numeric operations, see "[Basic Operations on Expression Prefixes](#)" and "[Compound Operations for Numbers](#)."

Table 1. Prefixes That Evaluate IP and MAC Addresses

Prefix	Description
CLIENT.IP.SRC	Returns the source IP of the current packet as an IP address or as a number.
CLIENT.IP.DST	Returns the destination IP of the current packet as an IP address or as a number.
SERVER.IP.SRC	Returns the source IP of the current packet as an IP address or as a number.
SERVER.IP.DST	Returns the destination IP of the current packet as an IP address or as a number.

Operations for IPV4 Addresses

The following table describes the operators that can be used with prefixes that return an IPv4 address.

Table 2. Operations on IPV4 Addresses

Prefix	Description
<ip address>.EQ(<address>)	Returns a Boolean TRUE if the IP address value is same as the <address> argument. The following example checks whether the client's destination IP address is equal to 10.100.10.100: client.ip.dst.eq(10.100.10.100)
<ip address>.GET1 . .GET4	Returns a portion of an IP address as a numeric value. For example, if the IP address value is 10.100.200.1, the following is returned: client.ip.src.get1 Returns 10 client.ip.src.get2 returns 100 client.ip.src.get3 returns 200
<ip address>.IN_SUBNET(<subnet>)	Returns a Boolean TRUE if the <subnet> argument matches the subnet of the IP address value. For example, the following determines whether the client's destination IP address subnet is 10.100.10.100/18: client.ip.dst.eq(10.100.10.100/18)
<ip address>.SUBNET(<n>)	Returns the IP address after applying the subnet mask specified as the argument. The subnet mask can take values between 0 and 32. For example: CLIENT.IP.SRC.SUBNET(24) returns 192.168.1.0 if the IP address represented by the prefix is 192.168.1.[0-255].
<ip address>.IS_IPV6	Returns a Boolean TRUE if this is an Internet Protocol version 6 (IPv6) host for the client or server. Following is an example: client.ip.src.is_ipv6
<ip address>.MATCHES(<hostname>)	Returns a Boolean TRUE if the IP address for the host specified in <hostname> matches the current IP address. The <hostname> cannot exceed 255 characters.
<ip address>.MATCHES_LOCATION(<location>)	Returns a Boolean TRUE if the location of the IP address matches the <location> argument. The Location string can take the following form: qual1.qual2.qual3.qual4.qual5.qual6, for example: NorthAmerica.CA.* Following is an example: client.ip.src.matches_location("\Europe.GB.17.London.*.*")

About IPv6 Expressions

The IPv6 address format allows more flexibility than the older IPv4 format. IPv6 addresses are in the hexadecimal format (RFC 2373). In the following examples, Example 1 is an IPv6 address, Example 2 is a URL that includes the IPv6 address, and Example 3 includes the IPv6 address and a port number.

Example 1:

9901:0ab1:22a2:88a3:3333:4a4b:5555:6666

Example 2:

http://[9901:0ab1:22a2:88a3:3333:4a4b:5555:6666]/

Example 3:

[https://\[9901:0ab1:22a2:88a3:3333:4a4b:5555:6666\]:8080/](https://[9901:0ab1:22a2:88a3:3333:4a4b:5555:6666]:8080/)

In Example 3, the brackets separate the IP address from the port number (8080).

Note that you can only use the '+' operator to combine IPv6 expressions with other expressions. The output is a concatenation of the string values that are returned from the individual expressions. You cannot use any other arithmetic operator with an IPv6 expression. The following syntax is an example:

`client.ipv6.src + server.ip.dst`

For example, if the client source IPv6 address is ABCD:1234::ABCD, and the server destination IPv4 address is 10.100.10.100, the preceding expression returns "ABCD:1234::ABCD10.100.10.100".

Note that when the NetScaler appliance receives an IPv6 packet, it assigns a temporary IPv4 address from an unused IPv4 address range and changes the source address of the packet to this temporary address. At response time, the outgoing packet's source address is replaced with the original IPv6 address.

Note: You can combine an IPv6 expression with any other expression except an expression that produces a Boolean result.

Expression Prefixes for IPv6 Addresses

The IPv6 addresses that are returned by the expression prefixes in the following table can be treated as text data. For example, the prefix `client.ipv6.dst` returns the destination IPv6 address as a string that can be evaluated as text.

The following table describes expression prefixes that return an IPv6 address.

Table 3. IPv6 Expression Prefixes That Return Text

Prefix	Description
CLIENT.IPV6	Operates on the IPv6 address in with the current packet.
CLIENT.IPV6.DST	Returns the IPv6 address in the destination field of the IP header.
CLIENT.IPV6.SRC	Returns the IPv6 address in the source field of the IP header. Following are examples: <code>client.ipv6.src.in_subnet(2007::2008/64)</code> <code>client.ipv6.src.get1.le(2008)</code>
SERVER.IPV6	Operates on the IPv6 address in with the current packet.
SERVER.IPV6.DST	Returns the IPv6 address in the destination field of the IP header.
SERVER.IPV6.SRC	Returns the IPv6 address in the source field of the IP header. Following are examples: <code>server.ipv6.src.in_subnet(2007::2008/64)</code> <code>server.ipv6.src.get1.le(2008)</code>

Operations for IPv6 Prefixes

The following table describes the operators that can be used with prefixes that return an IPv6 address:

Table 4. Operations That Evaluate IPv6 Addresses

IPv6 Operation	Description
<code><ipv6>.EQ(<IPv6_address>)</code>	Returns a Boolean TRUE if the IP address value is same as the <code><IPv6_address></code> argument. Following is an example:

IPv6 Operation	Description
	client.ipv6.dst.eq(ABCD:1234::ABCD)
<ipv6>.GET1. .GET8	<p>Returns a segment of an IPv6 address as a number.</p> <p>The following example expressions retrieve segments from the ipv6 address 1000:1001:CD10:0000:0000:89AB:4567:CDEF:</p> <ul style="list-style-type: none"> • client.ipv6.dst.get5 extracts 0000, which is the fifth set of bits in the address. • client.ipv6.dst.get6 extracts 89AB. • client.ipv6.dst.get7 extracts 4567. <p>You can perform numeric operations on these segments. Note that you cannot perform numeric operations when you retrieve an entire IPv6 address. This is because expressions that return an entire IPv6 address, such as CLIENT.IPV6.SRC, return the address in text format.</p>
<ipv6>.IN_SUBNET(<subnet>)	<p>Returns a Boolean TRUE if the IPv6 address value is in the subnet specified by the <subnet> argument.</p> <p>Following is an example:</p> <p>client.ipv6.dst.eq(1000:1001:CD10:0000:0000:89AB:4567:CDEF/60)</p>
<ipv6>.IS_IPV4	Returns a Boolean TRUE if this is an IPv4 client, and returns a Boolean FALSE if it is not.
<ipv6>.SUBNET(<n>)	<p>Returns the IPv6 address after applying the subnet mask specified as the argument. The subnet mask can take values between 0 and 128.</p> <p>For example:</p> <p>CLIENT.IPV6.SRC.SUBNET(24)</p>

Expressions for MAC Addresses

A MAC address consists of colon-delimited hexadecimal values in the format `##:##:##:##:##:##`, where each “#” represents either a number from 0 through 9 or a letter from A through F. Default syntax expression prefixes and operators are available for evaluating source and destination MAC addresses.

Prefixes for MAC Addresses

The following table describes prefixes that return MAC addresses.

Table 5. Prefixes That Evaluate MAC Addresses

Prefix	Description
client.ether.dstmac	Returns the MAC address in the destination field of the Ethernet header.
client.ether.srcmac	Returns the MAC address in the source field of the Ethernet header.

Operations for MAC Addresses

The following table describes the operators that can be used with prefixes that return a MAC address.

Table 6. Operations on MAC Addresses

Prefix	Description
<mac address>.EQ(<address>)	Returns a Boolean TRUE if the MAC address value is same as the <address> argument.

Prefix <mac address>.GET1 . . .GET4	Description Returns a numeric value extracted from the segment of the MAC address that is specified in the GET operation.
	For example, if the MAC address is 12:34:56:78:9a:bc, the following returns 34: client.ether.dstmac.get2

Expressions for Numeric Client and Server Data

The following table describes prefixes for working with numeric client and server data, including throughput, port numbers, and VLAN IDs.

Table 7. Prefixes That Evaluate Numeric Client and Server Data

Prefix	Description
client.interface.rxthroughput	Returns an integer representing the raw received traffic throughput in kilobytes per second (KBps) for the previous seven seconds.
client.interface.txthroughput	Returns an integer representing the raw transmitted traffic throughput in KBps for the previous seven seconds.
client.interface.rxtxthroughput	Returns an integer representing the raw received and transmitted traffic throughput in KBps for the previous seven seconds.
server.interface.rxthroughput	Returns an integer representing the raw received traffic throughput in KBps for the previous seven seconds.
server.interface.txthroughput	Returns an integer representing the raw transmitted traffic throughput in KBps for the previous seven seconds.
server.interface.rxtxthroughput	Returns an integer representing the raw received and transmitted traffic throughput in KBps for the previous seven seconds.
server.vlan.id	Returns a numeric ID of the VLAN through which the current packet entered the NetScaler.
client.vlan.id	Returns a numeric ID for the VLAN through which the current packet entered the NetScaler.

Default Syntax Expressions: Stream Analytics Functions

May 21, 2015

Stream Analytics expressions begin with the `ANALYTICS.STREAM(<identifier_name>)` prefix. The following list describes the functions that can be used with this prefix.

COLLECT_STATS

Collect statistical data from the requests that are evaluated against the policy and create a record for each request.

REQUESTS

Return the number of requests that exist for the specified record grouping. The value returned is of type unsigned long.

BANDWIDTH

Return the bandwidth statistic for the specified record grouping. The value returned is of type unsigned long.

RESPTIME

Return the response time statistic for the specified record grouping. The value returned is of type unsigned long.

CONNECTIONS

Return the number of concurrent connections that exist for the specified record grouping. The value returned is of type unsigned long.

IS_TOP(n)

Return a Boolean TRUE if the statistical value for the specified record grouping is one among the top n groups. Otherwise, return a Boolean FALSE.

CHECK_LIMIT

Return a Boolean TRUE if the statistic for the specified record grouping has hit the preconfigured limit. Otherwise, return a Boolean FALSE.

Default Syntax Expressions: DataStream

May 25, 2015

The policy infrastructure on the Citrix NetScaler appliance includes expressions that you can use to evaluate and process database server traffic when the appliance is deployed between a farm of application servers and their associated database servers.

This document includes the following details:

- [Expressions for the MySQL Protocol](#)
- [Expressions for Evaluating Microsoft SQL Server Connections](#)

Expressions for the MySQL Protocol

The following expressions evaluate traffic associated with MySQL database servers. You can use the request-based expressions (expressions that begin with `MYSQL.CLIENT` and `MYSQL.REQ`) in policies to make request switching decisions at the content switching virtual server bind point and the response-based expressions (expressions that begin with `MYSQL.RES`) to evaluate server responses to user-configured health monitors.

- **MYSQL.CLIENT.** Operates on the client properties of a MySQL connection.
- **MYSQL.CLIENT.CAPABILITIES.** Returns the set of flags that the client has set in the capabilities field of the handshake initialization packet during authentication. Examples of the flags that are set are `CLIENT_FOUND_ROWS`, `CLIENT_COMPRESS`, and `CLIENT_SSL`.
- **MYSQL.CLIENT.CHAR_SET.** Returns the enumeration constant assigned to the character set that the client uses. The `EQ(<m>)` and `NE(<m>)` operators, which return Boolean values to indicate the result of a comparison, are used with this prefix. Following are the character set enumeration constants:
 - `LATIN2_CZECH_CS`
 - `DEC8_SWEDISH_CI`
 - `CP850_GENERAL_CI`
 - `GREEK_GENERAL_CI`
 - `LATIN1_GERMAN1_CI`
 - `HP8_ENGLISH_CI`
 - `KOI8R_GENERAL_CI`
 - `LATIN1_SWEDISH_CI`
 - `LATIN2_GENERAL_CI`
 - `SWE7_SWEDISH_CI`
 - `ASCII_GENERAL_CI`
 - `CP1251_BULGARIAN_CI`
 - `LATIN1_DANISH_CI`
 - `HEBREW_GENERAL_CI`
 - `LATIN7_ESTONIAN_CS`
 - `LATIN2_HUNGARIAN_CI`
 - `KOI8U_GENERAL_CI`
 - `CP1251_UKRAINIAN_CI`
 - `CP1250_GENERAL_CI`
 - `LATIN2_CROATIAN_CI`
 - `CP1257_LITHUANIAN_CI`
 - `LATIN5_TURKISH_CI`

- LATIN1_GERMAN2_CI
- ARMSII8_GENERAL_CI
- UTF8_GENERAL_CI
- CP1250_CZECH_CS
- CP866_GENERAL_CI
- KEYBCS2_GENERAL_CI
- MACCE_GENERAL_CI
- MACROMAN_GENERAL_CI
- CP852_GENERAL_CI
- LATIN7_GENERAL_CI
- LATIN7_GENERAL_CS
- MACCE_BIN
- CP1250_CROATIAN_CI
- LATIN1_BIN
- LATIN1_GENERAL_CI
- LATIN1_GENERAL_CS
- CP1251_BIN
- CP1251_GENERAL_CI
- CP1251_GENERAL_CS
- MACROMAN_BIN
- CP1256_GENERAL_CI
- CP1257_BIN
- CP1257_GENERAL_CI
- ARMSII8_BIN
- ASCII_BIN
- CP1250_BIN
- CP1256_BIN
- CP866_BIN
- DEC8_BIN
- GREEK_BIN
- HEBREW_BIN
- HP8_BIN
- KEYBCS2_BIN
- KOI8R_BIN
- KOI8U_BIN
- LATIN2_BIN
- LATIN5_BIN
- LATIN7_BIN
- CP850_BIN
- CP852_BIN
- SWE7_BIN
- UTF8_BIN
- GEOSTD8_GENERAL_CI
- GEOSTD8_BIN
- LATIN1_SPANISH_CI
- UTF8_UNICODE_CI

- UTF8_ICELANDIC_CI
- UTF8_LATVIAN_CI
- UTF8_ROMANIAN_CI
- UTF8_SLOVENIAN_CI
- UTF8_POLISH_CI
- UTF8_ESTONIAN_CI
- UTF8_SPANISH_CI
- UTF8_SWEDISH_CI
- UTF8_TURKISH_CI
- UTF8_CZECH_CI
- UTF8_DANISH_CI
- UTF8_LITHUANIAN_CI
- UTF8_SLOVAK_CI
- UTF8_SPANISH2_CI
- UTF8_ROMAN_CI
- UTF8_PERSIAN_CI
- UTF8_ESPERANTO_CI
- UTF8_HUNGARIAN_CI
- INVALID_CHARSET
- **MYSQL.CLIENT.DATABASE.** Returns the name of the database specified in the authentication packet that the client sends to the database server. This is the `databasename` attribute.
- **MYSQL.CLIENT.USER.** Returns the user name (in the authentication packet) with which the client is attempting to connect to the database. This is the `user` attribute.
- **MYSQL.REQ.** Operates on a MySQL request.
- **MYSQL.REQ.COMMAND.** Identifies the enumeration constant assigned to the type of command in the request. The `EQ(<m>)` and `NE(<m>)` operators, which return Boolean values to indicate the result of a comparison, are used with this prefix. Following are the enumeration constant values:
 - SLEEP
 - QUIT
 - INIT_DB
 - QUERY
 - FIELD_LIST
 - CREATE_DB
 - DROP_DB
 - REFRESH
 - SHUTDOWN
 - STATISTICS
 - PROCESS_INFO
 - CONNECT
 - PROCESS_KILL
 - DEBUG
 - PING
 - TIME
 - DELAYED_INSERT
 - CHANGE_USER
 - BINLOG_DUMP

- TABLE_DUMP
- CONNECT_OUT
- REGISTER_SLAVE
- STMT_PREPARE
- STMT_EXECUTE
- STMT_SEND_LONG_DATA
- STMT_CLOSE
- STMT_RESET
- SET_OPTION
- STMT_FETCH
- **MYSQL.REQ.QUERY.** Identifies the query in the MySQL request.
- **MYSQL.REQ.QUERY.COMMAND.** Returns the first keyword in the MySQL query.
- **MYSQL.REQ.QUERY.SIZE.** Returns the size of the request query in integer format. The SIZE method is similar to the CONTENT_LENGTH method that returns the length of an HTTP request or response.
- **MYSQL.REQ.QUERY.TEXT.** Returns a string covering the entire query.
- **MYSQL.REQ.QUERY.TEXT(<n>).** Returns the first n bytes of the MySQL query as a string. This is similar to HTTP.BODY(<n>).

Parameters:

n - Number of bytes to be returned

- **MYSQL.RES.** Operates on a MySQL response.
- **MYSQL.RES.ATLEAST_ROWS_COUNT(<i>).** Checks whether the response has at least i number of rows and returns a Boolean TRUE or FALSE to indicate the result.

Parameters:

i - Number of rows

- **MYSQL.RES.ERROR.** Identifies the MySQL error object. The error object includes the error number and the error message.
- **MYSQL.RES.ERROR.MESSAGE.** Returns the error message that is retrieved from the server's error response.
- **MYSQL.RES.ERROR.NUM.** Returns the error number that is retrieved from the server's error response.
- **MYSQL.RES.ERROR.SQLSTATE.** Returns the value of the SQLSTATE field in the server's error response. The MySQL server translates error number values to SQLSTATE values.
- **MYSQL.RES.FIELD(<i>).** Identifies the packet that corresponds to the ith individual field in the server's response. Each field packet describes the properties of the associated column. The packet count (i) begins at 0.

Parameters:

i - Packet number

- **MYSQL.RES.FIELD(<i>).CATALOG.** Returns the catalog property of the field packet.
- **MYSQL.RES.FIELD(<i>).CHAR_SET.** Returns the character set of the column. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix.
- **MYSQL.RES.FIELD(<i>).DATATYPE.** Returns an enumeration constant that represents the data type of the column. This is the type (also called enum_field_type) attribute of the column. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix. The possible values for the various data types are:
 - DECIMAL

- TINY
- SHORT
- LONG
- FLOAT
- DOUBLE
- NULL
- TIMESTAMP
- LONGLONG
- INT24
- DATE
- TIME
- DATETIME
- YEAR
- NEWDATE
- VARCHAR (new in MySQL 5.0)
- BIT (new in MySQL 5.0)
- NEWDECIMAL (new in MySQL 5.0)
- ENUM
- SET
- TINY_BLOB
- MEDIUM_BLOB
- LONG_BLOB
- BLOB
- VAR_STRING
- STRING
- GEOMETRY
- **MYSQL.RES.FIELD(<i>).DB**. Returns the database identifier (db) attribute of the field packet.
- **MYSQL.RES.FIELD(<i>).DECIMALS**. Returns the number of positions after the decimal point if the type is DECIMAL or NUMERIC. This is the decimals attribute of the field packet.
- **MYSQL.RES.FIELD(<i>).FLAGS**. Returns the flags property of the field packet. Following are the possible hexadecimal flag values:
 - 0001: NOT_NULL_FLAG
 - 0002: PRI_KEY_FLAG
 - 0004: UNIQUE_KEY_FLAG
 - 0008: MULTIPLE_KEY_FLAG
 - 0010: BLOB_FLAG
 - 0020: UNSIGNED_FLAG
 - 0040: ZEROFILL_FLAG
 - 0080: BINARY_FLAG
 - 0100: ENUM_FLAG
 - 0200: AUTO_INCREMENT_FLAG
 - 0400: TIMESTAMP_FLAG
 - 0800: SET_FLAG
- **MYSQL.RES.FIELD(<i>).LENGTH**. Returns the length of the column. This is the value of the length attribute of the field packet. The value that is returned might be larger than the actual value. For example, an instance of a VARCHAR(2) column might return a value of 2 even when it contains only one character.

- **MYSQL.RES.FIELD(<i>).NAME.** Returns the column identifier (the name after the AS clause, if any). This is the name attribute of the field packet.
- **MYSQL.RES.FIELD(<i>).ORIGINAL_NAME.** Returns the original column identifier (before the AS clause, if any). This is the org_name attribute of the field packet.
- **MYSQL.RES.FIELD(<i>).ORIGINAL_TABLE.** Returns the original table identifier of the column (before the AS clause, if any). This is the org_table attribute of the field packet.
- **MYSQL.RES.FIELD(<i>).TABLE.** Returns the table identifier of the column (after the AS clause, if any). This is the table attribute of the field packet.
- **MYSQL.RES.FIELDS_COUNT.** Returns the number of field packets in the response (the field_count attribute of the OK packet).
- **MYSQL.RES.OK.** Identifies the OK packet sent by the database server.
- **MYSQL.RES.OK.AFFECTED_ROWS.** Returns the number of rows affected by an INSERT, UPDATE, or DELETE query. This is the value of the affected_rows attribute of the OK packet.
- **MYSQL.RES.OK.INSERT_ID.** Identifies the unique_id attribute of the OK packet. If an auto-increment identity is not generated by the current MySQL statement or query, the value of unique_id, and hence the value returned by the expression, is 0.
- **MYSQL.RES.OK.MESSAGE.** Returns the message property of the OK packet.
- **MYSQL.RES.OK.STATUS.** Identifies the bit string in the server_status attribute of the OK packet. Clients can use the server status to check whether the current command is a part of a running transaction. The bits in the server_status bit string correspond to the following fields (in the given order):
 - IN TRANSACTION
 - AUTO_COMMIT
 - MORE RESULTS
 - MULTI QUERY
 - BAD INDEX USED
 - NO INDEX USED
 - CURSOR EXISTS
 - LAST ROW SEEN
 - DATABASE DROPPED
 - NO BACKSLASH ESCAPES
- **MYSQL.RES.OK.WARNING_COUNT.** Returns the warning_count attribute of the OK packet.
- **MYSQL.RES.ROW(<i>).** Identifies the packet that corresponds to the i^{th} individual row in the database server's response.

Parameters:

i - Row number

- **MYSQL.RES.ROW(<i>).DOUBLE_ELEM(<j>).** Checks whether the j^{th} column of the i^{th} row of the table is NULL. Following C conventions, both indexes i and j start from 0. Therefore, row i and column j are actually the $(i+1)^{\text{th}}$ row and the $(j+1)^{\text{th}}$ column, respectively.

Parameters:

i - Row number

j - Column number

- **MYSQL.RES.ROW(<i>).IS_NULL_ELEM(j).** Checks whether the j^{th} column of the i^{th} row of the table is NULL. Following C conventions, both indexes i and j start from 0. Therefore, row i and column j are actually the $(i+1)^{\text{th}}$ row and the $(j+1)^{\text{th}}$

column, respectively.

Parameters:

i - Row number

j - Column number

- **MYSQL.RES.ROW(<i>).NUM_ELEM(<j>)**. Returns an integer value from the j^{th} column of the i^{th} row of the table. Following C conventions, both indexes i and j start from 0. Therefore, row i and column j are actually the $(i+1)^{\text{th}}$ row and the $(j+1)^{\text{th}}$ column, respectively.

Parameters:

i - Row number

j - Column number

- **MYSQL.RES.ROW(<i>).TEXT_ELEM(j)**. Returns a string from the j^{th} column of the i^{th} row of the table. Following C conventions, both indexes i and j start from 0. Therefore, row i and column j are actually the $(i+1)^{\text{th}}$ row and the $(j+1)^{\text{th}}$ column, respectively.

Parameters:

i - Row number

j - Column number

- **MYSQL.RES.TYPE**. Returns an enumeration constant for the response type. Its values can be ERROR, OK, and RESULT_SET. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix.

Expressions for Evaluating Microsoft SQL Server Connections

The following expressions evaluate traffic associated with Microsoft SQL Server database servers. You can use the request-based expressions (expressions that begin with MSSQL.CLIENT and MSSQL.REQ) in policies to make request switching decisions at the content switching virtual server bind point and the response-based expressions (expressions that begin with MSSQL.RES) to evaluate server responses to user-configured health monitors.

Table 1. Expressions for Evaluating Microsoft SQL Server Connections

Expression	Description
MSSQL.CLIENT.CAPABILITIES	Returns the OptionFlags1, OptionFlags2, OptionFlags3, and TypeFlags fields of the LOGIN7 authentication packet, in that order, as a 4-byte integer. Each field is 1 byte long and specifies a set of client capabilities.
MSSQL.CLIENT.DATABASE	Returns the name of the client database. The value returned is of type text.
MSSQL.CLIENT.USER	Returns the user name with which the client authenticated. The value returned is of type text.

Expression	Description
MSSQL.REQ.COMMAND	<p>Returns an enumeration constant that identifies the type of command in the request sent to a Microsoft SQL Server database server. The value returned is of type text.</p> <p>Examples of the values of the enumeration constant are QUERY, RESPONSE, RPC, and ATTENTION.</p> <p>The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this expression.</p>
MSSQL.REQ.QUERY.COMMAND	Returns the first keyword in the SQL query. The value returned is of type text.
MSSQL.REQ.QUERY.SIZE	Returns the size of the SQL query in the request. The value returned is a number.
MSSQL.REQ.QUERY.TEXT	Returns the entire SQL query as a string. The value returned is of type text.
MSSQL.REQ.QUERY.TEXT(<n>)	<p>Returns the first n bytes of the SQL query. The value returned is of type text.</p> <p>Parameters:</p> <p>n - Number of bytes</p>
MSSQL.REQ.RPC.NAME	Returns the name of the procedure that is being called in a remote procedure call (RPC) request. The name is returned as a string.
MSSQL.REQ.RPC.IS_PROCID	Returns a Boolean value that indicates whether the remote procedure call (RPC) request contains a procedure ID or an RPC name. A return value of TRUE indicates that the request contains a procedure ID and a return value of FALSE indicates that the request contains an RPC name.
MSSQL.REQ.RPC.PROCID	Returns the procedure ID of the remote procedure call (RPC) request as an integer.
MSSQL.REQ.RPC.BODY Note: Not available for releases before 10.1.	Returns the body of the SQL request as a string in the form of parameters represented as "a=b" clauses separated by commas, where "a" is the RPC parameter name and "b" is its value.
MSSQL.REQ.RPC.BODY(n) Note: Not available for releases before 10.1.	Returns part of the body of the SQL request as a string in the form of parameters represented as "a=b" clauses separated by commas, where

Expression	Description
	<p>"a" is the RPC parameter name and "b" is its value. Parameters are returned from only the first "n" bytes of the request, skipping the SQL header. Only complete name-value pairs are returned.</p>
MSSQL.RES.ATLEAST_ROWS_COUNT(i)	<p>Checks whether the response has at least i number of rows. The value returned is a Boolean TRUE or FALSE value.</p> <p>Parameters:</p> <p>i - Number of rows</p>
MSSQL.RES.DONE.ROWCOUNT	<p>Returns a count of the number of rows affected by an INSERT, UPDATE, or DELETE query. The value returned is of type unsigned long.</p>
MSSQL.RES.DONE.STATUS	<p>Returns the status field from the DONE token sent by a Microsoft SQL Server database server. The value returned is a number.</p>
MSSQL.RES.ERROR.MESSAGE	<p>Returns the error message from the ERROR token sent by a Microsoft SQL Server database server. This is the value of the MsgText field in the ERROR token. The value returned is of type text.</p>
MSSQL.RES.ERROR.NUM	<p>Returns the error number from the ERROR token sent by a Microsoft SQL Server database server. This is the value of the Number field in the ERROR token. The value returned is a number.</p>
MSSQL.RES.ERROR.STATE	<p>Returns the error state from the ERROR token sent by a Microsoft SQL Server database server. This is the value of the State field in the ERROR token. The value returned is a number.</p>
MSSQL.RES.FIELD(<i>).DATATYPE	<p>Returns the data type of the ith field in the server response. The EQ(<m>) and NE(<m>) functions, which return Boolean values to indicate the result of a comparison, are used with this prefix.</p> <p>For example, the following expression returns a Boolean TRUE if the DATATYPE function returns a value of datetime for the third field in the response:</p> <p>MSSQL.RES.FIELD(<2>).DATATYPE.EQ(datetime)</p> <p>Parameters:</p> <p>i - Row number</p>
MSSQL.RES.FIELD(<i>).LENGTH	<p>Returns the maximum possible length of the ith field in the server</p>

Expression	Description
	<p>response. The value returned is a number.</p> <p>Parameters:</p> <p>i - Row number</p>
MSSQL.RES.FIELD(<i>).NAME	<p>Returns the name of the i^{th} field in the server response. The value returned is of type text.</p> <p>Parameters:</p> <p>i - Row number</p>
MSSQL.RES.ROW(<i>).DOUBLE_ELEM(<j>)	<p>Returns a value of type double from the j^{th} column of the i^{th} row of the table. If the value is not a double value, an UNDEF condition is raised. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the $(i + 1)^{\text{th}}$ row and the $(j + 1)^{\text{th}}$ column, respectively.</p> <p>Parameters:</p> <p>i - Row number</p> <p>j - Column number</p>
MSSQL.RES.ROW(<i>).NUM_ELEM(j)	<p>Returns an integer value from the j^{th} column of i^{th} row of the table. If the value is not an integer value, an UNDEF condition is raised. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the $(i + 1)^{\text{th}}$ row and the $(j + 1)^{\text{th}}$ column, respectively.</p> <p>Parameters:</p> <p>i - Row number</p> <p>j - Column number</p>
MSSQL.RES.ROW(<i>).IS_NULL_ELEM(j)	<p>Checks whether the j^{th} column of the i^{th} row of the table is NULL and returns a Boolean TRUE or FALSE to indicate the result. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the $(i + 1)^{\text{th}}$ row and the $(j + 1)^{\text{th}}$ column, respectively.</p> <p>Parameters:</p> <p>i - Row number</p> <p>j - Column number</p>

<p>MSSQL.RES.ROW(<i>).TEXT_ELEM(j) Expression</p>	<p>Description</p> <p>Returns a text string from the jth column of ith row of the table. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the (i + 1)th row and the (j + 1)th column, respectively.</p> <p>Parameters:</p> <p>i - Row number</p> <p>j - Column number</p>
<p>MSSQL.RES.TYPE</p>	<p>Returns an enumeration constant that identifies the response type. Following are the possible return values:</p> <ul style="list-style-type: none"> • ERROR • OK • RESULT_SET <p>The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this expression.</p>

Typecasting Data

May 14, 2012

You can extract data of one type (for example, text or an integer) from requests and responses and transform it to data of another type. For example, you can extract a string and transform the string to time format. You can also extract a string from an HTTP request body and treat it like an HTTP header or extract a value from one type of request header and insert it in a response header of a different type.

After typecasting the data, you can apply any operation that is appropriate for the new data type. For example, if you typecast text to an HTTP header, you can apply any operation that is applicable to HTTP headers to the returned value.

The following table describes various typecasting operations.

Table 1. Typecasting Functions

Function	Description
<p><code><text>.TYPECAST_LIST_T(<separator>)</code></p>	<p>Treats the text in an HTTP request or response body as a list whose elements are delimited by the character in the <code><separator></code> argument. Index values in the list that is created start with zero (0).</p> <p>Text mode settings have no effect on the separator. For example, even if you set the text mode to IGNORECASE, and the separator is the letter “p,” an uppercase “P” is not treated as a separator.</p> <p>The following example creates a Rewrite action that constructs a list from an HTTP request body and extracts the fourth item in the list:</p> <pre>add rewrite action myreplace_action REPLACE 'http.req.body(100)' 'http.req.body(100).typecast_list_t('?').get(4)' set rewrite policy myreplace_policy -action myreplace_action</pre> <p>This policy returns the string “fourth item” from the following request:</p> <pre>GET?first item?second item?third item?fourth item?</pre> <p>The following example extracts the fourth-from-last item from the list.</p> <pre>add rewrite action myreplace_action1 REPLACE 'http.req.body(100)' 'http.req.body(100).typecast_list_t('?').get_reverse(4)' set rewrite policy myreplace_policy1 -action myreplace_action1</pre> <p>This policy returns the string “first item” from the following request:</p> <pre>GET?first item?second item?third item?fourth item.</pre>
<p><code><text>.TYPECAST_NVLIST_T(<separator>, <delimiter>)</code></p> <p>or</p> <p><code>text.TYPECAST_NVLIST_T(<separator>, <delimiter>, <quote>)</code></p>	<p>Treats the text as a name-value list. The <code><separator></code> argument identifies the character and separates the name and the value. The <code><delimiter></code> argument identifies the character that separates each name-value pair. The <code><quote></code> character is required when typecasting text into a name-value list that supports quoted strings. Any delimiters that appear within the quoted string are ignored.</p> <p>The text mode has no effect on the delimiters. For example, if the current text mode is IGNORECASE and you specify “p” as the delimiter, an uppercase “P” is not treated as a delimiter.</p> <p>For example, the following policy counts the number of name-value pairs and inserts</p>

Function	Description
	<p>the result in a header named name-value-count:</p> <pre>add rewrite action mycount_action insert_http_header name-value-count 'http.req.header("Cookie").typecast_nvlist_t(=',;').count'</pre> <pre>set rewrite policy mycount_policy -action mycount_action</pre> <p>This policy can extract a count of arguments in Cookie headers and insert the count in a name-value-count header.</p> <pre>Cookie: name=name1 ; rank=rank1</pre>
<text>.TYPECAST_TIME_T	<p>Treats the designated text as a date string. The following formats are supported:</p> <ul style="list-style-type: none"> • RFC822: Sun, 06 Nov 1994 08:49:37 GMT • RFC850: Sunday, 06-Nov-94 08:49:37 GMT • ASCII TIME: Sun Nov 6 08:49:37 1994 • HTTP Set-Cookie Expiry date: Sun, 06-Nov-1994 08:49:37 GMT <p>For example, the following policy converts the string to a time value and then extracts the day. This policy matches all requests that have a day value lesser than or equal to 10.</p> <pre>Add rewrite policy mytime_policy "http.req.body(100) .typecast_time_t.day.le(10)" mytime_action</pre> <pre>bind rewrite global mytime_policy 100</pre>
<numeric string>.TYPECAST_IP_ADDRESS_T	<p>Treats a numeric string as an IP address.</p> <p>For example, the following policy matches HTTP requests that contains Cookie headers with a value of: 12.34.56.78\r\n.</p> <pre>set rewrite policy ip_check_policy -rule 'http.req.cookie .value("ip").typecast_ip_address_t.eq(12.34.56.78)'</pre> <pre>bind rewrite global ip_check_policy 200 -type req_default</pre>
<numeric string>.TYPECAST_IPV6_ADDRESS_T	<p>Treats a string as an IPv6 address in the following format:</p> <pre>0000:0000:CD00:0000:0000:00AB:0000:CDEF</pre>
<text>.TYPECAST_HTTP_URL_T	<p>Treats the designated text as the URL in the first line of an HTTP request header. The supported format is [<protocol>://<hostname>]<path>?<query>, and the text mode is set to URLENCODED by default.</p> <p>For example, the following policy replaces a URL-encoded part of a string in an HTTP header named Test.</p> <pre>add rewrite action replace_header_string replace 'http.req.header("Test").typecast_http_url_t.path .before_str("123").after_str("ABC") "'string''</pre> <pre>add rewrite policy rewrite_test_header_policy true replace_header_string bind rewrite global rewrite_test_header_policy 1 END -type res_override</pre> <p>Consider the following header:</p>

Function	Description
	<p>Test: ABC%12123\r\n</p> <p>This policy would replace the preceding header with the value ABC%string123\r\n.</p>
<text>.TYPECAST_HTTP_HOSTNAME_T	Provides operations for parsing an HTTP host name as it appears in HTTP data. The format for a host name is abc.def.com:8080.
<text>.TYPECAST_HTTP_METHOD_T	<p>Converts text to an HTTP method.</p> <p>For example, the following policy matches any HTTP request that contains a Host header with a value equal to POST:</p> <pre>Add rewrite policy method_policy "http.req.header("Host") .typecast_http_method_t.eq(POST)" act1</pre>
<text>.TYPECAST_DNS_DOMAIN_T	Enables the designated text to be parsed like a DNS domain name in the format ab.def.com.
<text>.TYPECAST_HTTP_HEADER_T("<name>")	<p>Converts the designated text to a multi-line HTTP header that you specify in a <name> argument.</p> <p>For example, the following expression converts "MyHeader" to "InHeader":</p> <pre>http.req.header("MyHeader").typcast_http_header_t("InHeader")</pre> <p>Typically, text operations that you specify in this type of expression apply to only the last line of this header, with some exceptions. For example, the CONTAINS operation operates on values in all the lines in instances of this header type.</p>
<text>.TYPECAST_COOKIE_T	<p>Treats the designated text as an HTTP cookie as it appears in a Set-Cookie or Set-Cookie2 header. You can apply name-value list operations as well as text operations to the designated text. For example, you can designate equals (=) as the name-value delimiter and the semicolon (;) as the list element delimiter.</p> <p>If you apply name-value list operations, the list is parsed as if IGNORE_EMPTY_ELEMENTS were in effect.</p> <p>Each cookie begins with a cookie-name=cookie-value pair, optionally followed by attribute-value pairs that are separated by a semicolon, as follows:</p> <pre>cookie1=value1;version=n.n;value;domain=value;path=value</pre> <p>If the same attribute appears more than once in a cookie, the value for the first instance of the attribute is returned.</p>
<number>.TYPECAST_DOUBLE_AT	Transforms the number to a value of data type double.
<number>.TYPECAST_IP_ADDRESS_AT	Converts the number to an IP address.
<number>.TYPECAST_TIME_AT	Converts the number to time format.
<number>.TYPECAST_TIME_AT.BETWEEN(<time1>, <time2>)	Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> is between the lower and upper time value arguments <time1> and <time2>.

Function	Description
	<p>The following are prerequisites for this function:</p> <ul style="list-style-type: none"> • Both the lower and upper time arguments must be fully specified. For example, GMT 1995 Jan is fully specified. But GMT Jan, GMT 1995 20 and GMT Jan Mon_2 are not fully specified. • Both arguments must be either GMT or Local. • The day of the week must not be present in either argument. However, the day of the month can be specified as the first, second, third, or fourth weekday of the month (example Wed_3 is the third Wednesday of the month). • The upper time argument, <time2>, must be bigger than the lower time argument, <time1>. <p>The following examples assume that the current time value is GMT 2005 May 1 10h 15m 30s and that the day is the first Sunday of the month of May in 2005. The result of the evaluation is given after each example.</p> <p>BETWEEN(GMT 2004, GMT 2006): TRUE BETWEEN(GMT 2004 Jan, GMT 2006 Nov): TRUE BETWEEN(GMT 2004 Jan, GMT 2006): TRUE BETWEEN(GMT 2005 May Sun_1, GMT 2005 May Sun_3): TRUE BETWEEN(GMT 2005 May 1, GMT May 2005 1): TRUE BETWEEN(LOCAL 2005 May 1, LOCAL May 2005 1): The result depends on the NetScaler system's timezone.</p> <p>Parameters:</p> <p><time1> - Lower time value <time2> - Upper time value</p>
<number>.TYPECAST_TIME_AT.DAY	<p>Extracts the day of the month from the current system time and returns the value as a number that corresponds to the day of the month. The returned value ranges from 1 to 31.</p>
<number>.TYPECAST_TIME_AT.EQ(<t>)	<p>Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> is equal to the time value argument <t>.</p> <p>The following examples assume that the current time value is GMT 2005 May 1 10h 15m 30s and that the day is the 1st Sunday of the month of May in 2005. The result of the evaluation is given after each example.</p> <p>EQ(GMT 2005): TRUE EQ(GMT 2005 Dec): FALSE EQ(Local 2005 May): TRUE or FALSE, depending on the time zone. EQ(GMT 10h): TRUE EQ(GMT 10h 30s): TRUE EQ(GMT May 10h): TRUE EQ(GMT Sun): TRUE EQ(GMT May Sun_1): TRUE</p> <p>Parameters:</p> <p><t> - Time</p>
<number>.TYPECAST_TIME_AT.GE(<t>)	<p>Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> is greater than or equal to the time value argument <t>.</p> <p>The following examples assume that the current time value is GMT 2005 May 1 10h 15m 30s and that the day is the 1st Sunday of the month of May in 2005. The result of</p>

Function	Description
	<p>The evaluation is given after each example.</p> <p>GE(GMT 2004): TRUE GE(GMT 2005 Jan): TRUE GE(Local 2005 May): TRUE or FALSE, depending on the time zone. GE(GMT 8h): TRUE GE(GMT 30m): FALSE GE(GMT May 10h): TRUE GE(GMT May 10h 0m): TRUE GE(GMT Sun): TRUE GE(GMT May Sun_1): TRUE</p> <p>Parameters:</p> <p><t> - Time</p>
<number>.TYPECAST_TIME_AT.GT(<t>)	<p>Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> is greater than the time value argument <t>.</p> <p>The following examples assume that the current time value is GMT 2005 May 1 10h 15m 30s and that the day is the 1st Sunday of the month of May in 2005. The result of the evaluation is given after each example.</p> <p>GT(GMT 2004): TRUE GT(GMT 2005 Jan): TRUE GT(Local 2005 May): TRUE or FALSE, depending on the time zone. GT(GMT 8h): TRUE GT(GMT 30m): FALSE GT(GMT May 10h): FALSE GT(GMT May 10h 0m): TRUE GT(GMT Sun): FALSE GT(GMT May Sun_1): FALSE</p> <p>Parameters:</p> <p><t> - Time</p>
<number>.TYPECAST_TIME_AT.HOURS	<p>Extracts the hour from the current system time and returns the corresponding value as an integer that can range from 0 to 23.</p>
<number>.TYPECAST_TIME_AT.LE(<t>)	<p>Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> is lesser than or equal to the time value argument <t>.</p> <p>The following examples assume that the current time value is GMT 2005 May 1 10h 15m 30s and that the day is the 1st Sunday of the month of May in 2005. The result of the evaluation is given after each example.</p> <p>LE(GMT 2006): TRUE LE(GMT 2005 Dec): TRUE LE(Local 2005 May): TRUE or FALSE, depending on the time zone. LE(GMT 8h): FALSE LE(GMT 30m): TRUE LE(GMT May 10h): TRUE LE(GMT Jun 11h): TRUE LE(GMT Wed): TRUE LE(GMT May Sun_1): TRUE</p> <p>Parameters:</p>

Function	<t> - Time Description
<number>.TYPECAST_TIME_AT.LT(<t>)	<p>Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> is lesser than the time value argument <t>.</p> <p>The following examples assume that the current time value is GMT 2005 May 1 10h 15m 30s and that the day is the 1st Sunday of the month of May in 2005. The result of the evaluation is given after each example.</p> <p>LT(GMT 2006): TRUE LT(GMT 2005 Dec): TRUE LT(Local 2005 May): TRUE or FALSE, depending on the time zone. LT(GMT 8h): FALSE LT(GMT 30m): TRUE LT(GMT May 10h): FALSE LT(GMT Jun 11h): TRUE LT(GMT Wed): TRUE LT(GMT May Sun_1): FALSE</p> <p>Parameters: <t> - Time</p>
<number>.TYPECAST_TIME_AT.MINUTES	Extracts the minute from the current system time and returns the value as an integer that can range from 0 to 59.
<number>.TYPECAST_TIME_AT.MONTH	Extracts the month from the current system time and returns the value as an integer that can range from 1 (January) to 12 (December).
<number>.TYPECAST_TIME_AT.RELATIVE_BOOT	Calculates the number of seconds that have elapsed after the most recent reboot or the number of seconds to the next scheduled reboot, depending on which is closer to the current time, and returns an integer. If the closest boot time is in the past, the integer is negative. If the closest boot time is in the future (scheduled reboot time), the integer is positive.
<number>.TYPECAST_TIME_AT.RELATIVE_NOW	Calculates the number of seconds between the current system time and the specified time, and returns the value as an integer. If the designated time is in the past, the integer is negative. If it is in the future, the integer is positive.
<number>.TYPECAST_TIME_AT.SECONDS	Extracts the seconds from the current system time and returns the value as an integer that can range from 0 to 59.
<number>.TYPECAST_TIME_AT.WEEKDAY	Returns an integer that corresponds to the day of the week; 0 for Sunday and 6 for Saturday.
<number>.TYPECAST_TIME_AT.WITHIN(<time1>, <time2>)	<p>Returns a Boolean value (TRUE or FALSE) that indicates whether the time value designated by <number> lies within all the ranges defined by lower and upper time value arguments <time1> and <time2>.</p> <p>If an element of time such as the day or the hour is left unspecified in the lower argument, <time1>, then it is assumed to have the lowest value possible for its range.</p> <p>If an element is left unspecified in the upper argument, <time2>, then it is assumed to have the highest value possible for its range.</p>

Function	Description
	<p>If the year is specified in one of the arguments, then it must be specified in the other argument as well.</p> <p>Following are the ranges for different elements of time:</p> <ul style="list-style-type: none"> • month: 1-12 • day: 1-31 • weekday: 0-6 • hour: 0-23 • minutes: 0-59 • seconds: 0-59. <p>Each element of time in the lower time value argument defines a range in combination with the corresponding element in the upper time value argument. For the result to be TRUE, each element of time in the time value designated by <number> must lie in the corresponding range specified by the lower and upper arguments.</p> <p>The following examples assume that the current time value is GMT 2005 May 10 10h 15m 30s and that the day is the second Tuesday of the month. The result of the evaluation is given after each example.</p> <p>WITHIN(GMT 2004, GMT 2006): TRUE WITHIN(GMT 2004 Jan, GMT 2006 Mar): FALSE (May doesn't fall in the Jan-Mar range.) WITHIN(GMT Feb, GMT): TRUE (May falls in the Feb-Dec range.) WITHIN(GMT Sun_1, GMT Sun_3): TRUE (2nd Tuesday lies within 1st Sunday and the 3rd Sunday.)</p> <p>WITHIN(GMT 2005 May 1 10h, GMT May 2005 1 17h): TRUE WITHIN(LOCAL 2005 May 1, LOCAL May 2005 1): The result depends on the NetScaler system's timezone.</p> <p>Parameters:</p> <p><time1> - Lower time value <time2> - Upper time value</p>
<number>.TYPECAST_TIME_AT.YEAR	<p>Extracts the year from the current system time and returns the value as a four-digit integer.</p>
<prefix>.TYPECAST_NUM_T(<type>)	<p>Casts numeric string data to a signed 32-bit number. The argument <type> can be one of the following:</p> <ul style="list-style-type: none"> • DECIMAL. Treat the string as a decimal number and cast to a signed 32-bit number. • HEX. Treat the string as a hexadecimal number and cast to a signed 32-bit number. • DECIMAL_PREFIX. Consider the part of the string up to the first occurrence of a character that is not a valid decimal character and cast to a signed 32-bit number. • HEX_PREFIX. Consider the part of the string up to the first occurrence of a character that is not a valid hexadecimal character and cast to a signed 32-bit number. <p>For example, the following policy extracts a numeric portion of a query string, adds 4 to the number, and inserts an HTTP header named Company with the resulting decimal value.</p> <pre>add rewrite action myadd_action insert_http_header Company "http.req.url.query.typecast_num_t(decimal).add(4)"</pre>

Function	Description
	<pre>add rewrite policy myadd_policy true myadd_action bind rewrite global myadd_policy 300 END -type RES_DEFAULT</pre> <p>For example, this policy would extract “4444” from the following URL stub:</p> <pre>/test/file.html?4444</pre> <p>The action that is associated with the policy would insert the following HTTP response header:</p> <pre>Company: 4448\r\n</pre>
<prefix>.TYPECAST_NUM_AT	Casts a number of any data type to a number of data type integer.
<prefix>.TYPECAST_DOUBLE_AT	Casts a number of any data type to a number of data type double.
<prefix>.TYPECAST_UNSIGNED_LONG_AT	Casts a number of any data type to a number of data type unsigned long.
<prefix>.TYPECAST_NUM_T(<type>,<default>)	Casts string data to a signed 32-bit number. If the typecasting operation raises an undefined (UNDEF) condition, the function returns the value specified for default. The type argument takes the values specified for TYPECAST_NUM_T(<type>).
<prefix>.TYPECAST_UNSIGNED_LONG_T(<type>)	<p>Casts string data to data of type unsigned long. The argument can be one of the following:</p> <ul style="list-style-type: none"> • DECIMAL. Treat the string as a decimal number and cast to unsigned long. • HEX. Treat the string as a hexadecimal number and cast to unsigned long. • DECIMAL_PREFIX. Consider the part of the string up to the first occurrence of a character that is not a valid decimal character and cast to unsigned long. • HEX_PREFIX. Consider the part of the string up to the first occurrence of a character that is not a valid hexadecimal character and cast to unsigned long.
<prefix>.TYPECAST_UNSIGNED_LONG_T(<type>,<default>)	Casts string data to data of type unsigned long. If the typecasting operation raises an undefined (UNDEF) condition, the function returns the value specified for default. The type argument takes the values specified for TYPECAST_UNSIGNED_LONG_T(<type>).

Regular Expressions

Sep 02, 2013

When you want to perform string matching operations that are more complex than the operations that you perform with the CONTAINS("<string>") or EQ("<string>") operators, you use regular expressions. The policy infrastructure on the Citrix® NetScaler® appliance includes operators to which you can pass regular expressions as arguments for text matching. The names of the operators that work with regular expressions include the string REGEX. The regular expressions that you pass as arguments must conform to the regular expression syntax that is described in "<http://www.pcre.org/pcre.txt>." You can learn more about regular expressions at "<http://www.regular-expressions.info/quickstart.html>" and at "<http://www.silverstones.com/thebat/Regex.html>."

The target text for an operator that works with regular expressions can be either text or the value of an HTTP header. Following is the format of a default syntax expression that uses a regular expression operator to operate on text:

```
<text>.<regex_operator>(re<delimiter><regex_pattern><delimiter>)
```

The string <text> represents the default syntax expression prefix that identifies a text string in a packet (for example, HTTP.REQ.URL). The string <regex_operator> represents the regular expression operator. The regular expression always begins with the string re. A pair of matching delimiters, represented by <delimiter>, enclose the string <regex_pattern>, which represents the regular expression.

The following example expression checks whether the URL in an HTTP packet contains the string *.jpeg (where all the files with suffix "jpeg" is listed) and returns a Boolean TRUE or FALSE to indicate the result. The regular expression is enclosed within a pair of slash marks (/), which act as delimiters.

```
http.req.url.regex_match(re/*.jpeg/)
```

Regular expression operators can be combined to define or refine the scope of a search. For example, <text>.AFTER_REGEX(re/regex_pattern1/).BEFORE_REGEX(re/regex_pattern2/) specifies that the target for string matching is the text between the patterns regex_pattern1 and regex_pattern2. You can use a text operator on the scope that is defined by the regular expression operators. For example, you can use the CONTAINS("<string>") operator to check whether the defined scope contains the string abc:

```
<text>.AFTER_REGEX(re/regex_pattern1/).BEFORE_REGEX(re/regex_pattern2/).CONTAINS("abc")
```

Note: The process of evaluating a regular expression inherently takes more time than that for an operator such as CONTAINS("<string>") or EQ("<string>"), which work with simple string arguments. You should use regular expressions only if your requirement is beyond the scope of other operators.

Basic Characteristics of Regular Expressions

Jul 10, 2013

Following are notable characteristics of regular expressions as defined on the NetScaler appliance:

- A regular expression always begins with the string “re” followed by a pair of delimiting characters (called delimiters) that enclose the regular expression that you want to use.

For example, `re#<regex_pattern>#` uses the number sign (#) as a delimiter.

- A regular expression cannot exceed 1499 characters.
- Digit matching can be done by using the string `\d` (a backslash followed by d).
- White space can be represented by using `\s` (a backslash followed by s).
- A regular expression can contain white spaces.

Following are the differences between the NetScaler syntax and the PCRE syntax:

- The NetScaler does not allow back references in regular expressions.
- You should not use recursive regular expressions.
- The dot meta-character also matches the newline character.
- Unicode is not supported.
- The operation `SET_TEXT_MODE(IGNORECASE)` overrides the `(?)` internal option in the regular expression.

Operations for Regular Expressions

Jul 10, 2013

The following table describes the operators that work with regular expressions. The operation performed by a regular expression operator in a given default syntax expression depends on whether the expression prefix identifies text or HTTP headers. Operations that evaluate headers override any text-based operations for all instances of the specified header type. When you use an operator, replace <text> with the default syntax expression prefix that you want to configure for identifying text.

Table 1. Default Syntax Expression Operators That Work with Regular Expressions

Regular Expression Operation	Description
<text>.BEFORE_REGEX(<regular expression>)	<p>Selects the text that precedes the string that matches the <regular expression> argument. If the regular expression does not match any data in the target, the expression returns a text object of length 0.</p> <p>The following expression selects the string "text" from "text/plain".</p> <pre>http.res.header("content-type").before_regex(re##/##)</pre>
<text>.AFTER_REGEX(<regular expression>)	<p>Selects the text that follows the string that matches the <regular expression> argument. If the regular expression does not match any text in the target, the expression returns a text object of length 0.</p> <p>The following expression extracts "Example" from "myExample":</p> <pre>http.req.header("etag").after_regex(re/my/)</pre>
<text>.REGEX_SELECT(<regular expression>)	<p>Selects a string that matches the <regular expression> argument. If the regular expression does not match the target, a text object of length 0 is returned.</p> <p>The following example extracts the string "NS-CACHE-9.0: 90" from a Via header:</p> <pre>http.req.header("via").regex_select(re!NS-CACHE-\d\\.d:\\s*d{1,3}!)</pre>
<text>.REGEX_MATCH(<regular expression>)	<p>Returns TRUE if the target matches a <regular expression> argument of up to 1499 characters.</p> <p>The regular expression must be of the following format:</p> <pre>re<delimiter>regular expression< delimiter></pre> <p>Both delimiters must be the same. Additionally, the regular expression must conform to the Perl-compatible (PCRE) regular expression library syntax. For more information, go to http://www.pcre.org/pcre.txt. In particular, see the pcrepattern man page. However, note the following:</p>

Regular Expression Operation	Description
	<ul style="list-style-type: none"> • Back-references are not allowed. • Recursive regular expressions are not recommended. • The dot metacharacter also matches the newline character. • The Unicode character set is not supported. • SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression. <p>The following are examples:</p> <pre>http.req.hostname.regex_match(re/[[:alpha:]]+(abc){2,3}/) http.req.url.set_text_mode(urlencoded).regex_match(re#(a*b+c*)#)</pre> <p>The following example matches ab and aB:</p> <pre>http.req.url.regex_match(re/a(?i)b/)</pre> <p>The following example matches ab, aB, Ab and AB:</p> <pre>http.req.url.set_text_mode(ignorecase).regex_match(re/ab/)</pre> <p>The following example performs a case-insensitive, multiline match in which the dot meta-character also matches a newline character:</p> <pre>http.req.body.regex_match(re/(?ixm) (^ab (.*) cd\$) /)</pre>

Configuring Classic Policies and Expressions

May 25, 2015

Some NetScaler features use classic policies and classic expressions. As with default syntax policies, classic policies can be either global or specific to a virtual server. However, to a certain extent, the configuration method and bind points for classic policies are different from those of default syntax policies. As with default syntax expressions, you can configure named expressions and use a named expression in multiple classic policies.

The following table summarizes NetScaler features that can be configured by using classic policies.

Table 1. Policy Type and Bind Points for Policies in Features That Use Classic Policies

Feature	Virtual Servers	Supported Policies	Policy Bind Points	How You Use the Policies
System features, Authentication	None	Authentication policies	Global	For the Authentication feature, policies contain authentication schemes for different authentication methods. For example, you can configure LDAP and certificate-based authentication schemes.
SSL	None	SSL policies	<ul style="list-style-type: none"> Global Load Balancing virtual server 	<p>To determine when to apply an encryption function and add certificate information to clear text.</p> <p>To provide end-to-end security. After a message is decrypted, the SSL feature re-encrypts clear text and uses SSL to communicate with back-end Web servers.</p>
Content Switching (Can use either classic or default syntax policies, but not both)	Content Switching virtual server	Content Switching policies	<ul style="list-style-type: none"> Content Switching virtual server Cache Redirection virtual server 	<p>To determine what server or group of servers is responsible for serving responses, based on characteristics of an incoming request.</p> <p>Request characteristics include device type, language, cookies, HTTP method, content type and associated cache server.</p>
Compression	None	HTTP Compression policies	<ul style="list-style-type: none"> Global Content Switching virtual server Load Balancing virtual server 	To determine what type of HTTP traffic is compressed.

Feature	Virtual Servers	Supported Policies	Policy Bind Points	How You Use the Policies
Protection features, Filter	None	Content Filtering policies	<ul style="list-style-type: none"> • SSL Offload virtual server • Service 	To configure the behavior of the filter function.
Protection features, SureConnect	None	SureConnect policies	<ul style="list-style-type: none"> • Load Balancing virtual server • SSL Offload virtual server • Service 	To configure the behavior of the SureConnect function.
Protection features, Priority Queuing	None	Priority Queuing policies	<ul style="list-style-type: none"> • Load Balancing virtual server • SSL Offload virtual server 	To configure the behavior of the Priority Queuing function.
HTML Injection	None	HTML Injection Policies	<ul style="list-style-type: none"> • Global • Load Balancing virtual server • Content Switching virtual server • SSL Offload virtual server 	To enable the NetScaler to insert text or scripts into an HTTP response that it serves to a client.

Configuring a Classic Policy

Oct 29, 2013

You can configure classic policies and classic expressions by using either the configuration utility or the command-line interface. A policy rule cannot exceed 1,499 characters. When configuring the policy rule, you can use named classic expressions. For more information about named expressions, see "[Creating Named Classic Expressions](#)." After configuring the policy, you bind it either globally or to a virtual server.

Note that there are small variations in the policy configuration methods for various NetScaler features.

Note: You can embed a classic expression in a default syntax expression by using the syntax `SYS.EVAL_CLASSIC_EXPR(classic_expression)`, specifying the `classic_expression` as the argument.

To create a classic policy by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add cmp policy <name> -rule <expression> -action <action>`
- `show cmp policy [<policyName>]`

Example

The following commands first create a compression action and then create a compression policy that applies the action:

```
> add cmp action cmp-act-compress compress
Done
> show cmp action cmp-act-compress
1) Name: cmp-act-compress Compression Type: compress
Done
> add cmp pol cmp-pol-compress -rule ExpCheckIp -resAction cmp-act-compress
Done
> show cmp pol cmp-pol-compress
1) Name: cmp-pol-compress Rule: ExpCheckIp
   Response action: cmp-act-compress Hits: 0
Done
>
```

To create a policy with classic expressions by using the configuration utility

1. In the navigation pane, expand the feature for which you want to configure a policy and, depending on the feature, do the following:
 - For Content Switching, Cache Redirection, and the application firewall, click Policies.
 - For SSL, click Policies, and then in the details pane, click the Policies tab.
 - For System Authentication, click Authentication, and then in the details pane, click the Policies tab.
 - For Filter, SureConnect, and Priority Queuing, expand Protection Features, select the desired function, and then in the details pane, click the Policies tab.
 - For the NetScaler Gateway, expand NetScaler Gateway, expand Policies, select the desired function, and then in the details pane, click the Policies tab.
2. For most features, click the Add button.
3. In the Create <feature name> Policy dialog box, in the Name* text box, enter a name for the policy.

Note: Note: You must begin a policy name with a letter or underscore. A policy name can consist of 1 to 31 characters, including letters, numbers, hyphen (-), period (.), pound sign (#), space (), and underscore (_).

4. For most features, you associate an action or a profile. For example, you may be required to select an action, or, in the case of an NetScaler Gateway or application firewall policy, you select a profile to associate with the policy. A profile is a set of configuration options that operate as a set of actions that are applied when the data being analyzed matches the policy rule.
5. Create an expression that describes the type of data that you want this policy to match.

Depending on the type of policy you want to create, you can choose a predefined expression, or you can create a new expression. For instructions on how to create an expression for most types of classic policies, see "[Configuring a Classic Expression](#)."

Named expressions are predefined expressions that you can reference by name in a policy rule. For more information about named expressions, see "[Creating Named Classic Expressions](#)." For a list of all the default named expressions and a definition of each, see "[Expressions Reference](#)."

6. Click Create to create your new policy.
7. Click Close to return to the Policies screen for the type of policy you were creating.

Configuring a Classic Expression

Oct 29, 2013

Classic expressions consist of the following expression elements, listed in hierarchical order:

- **Flow Type.** Specifies whether the connection is incoming or outgoing. The flow type is REQ for incoming connections and RES for outgoing connections.
- **Protocol.** Specifies the protocol, the choices for which are HTTP, SSL, TCP, and IP.
- **Qualifier.** The protocol attribute, which depends on the selected protocol.
- **Operator.** The type of test you want to perform on the connection data. Your choice of operator depends upon the connection information you are testing. If the connection information you are testing is text, you use text operators. If it is a number, you use standard numeric operators.
- **Value.** The string or number against which the connection data element—defined by the flow type, protocol, and qualifier—is tested. The value can be either a literal or an expression. The literal or expression must match the data type of the connection data element.

In a policy, classic expressions can be combined to create more complex expressions using Boolean and comparative operators.

Expression elements are parsed from left to right. The leftmost element is either REQ or RES and designates a request or a response, respectively. Successive terms define a specific connection type and a specific attribute for that connection type. Each term is separated from any preceding or following term by a period. Arguments appear in parentheses and follow the expression element to which they are passed.

The following classic expression fragment returns the client source IP for an incoming connection.

```
REQ.IP.SOURCEIP
```

The example identifies an IP address in a request. The expression element SOURCEIP designates the source IP address. This expression fragment may not be useful by itself. You can use an additional expression element, an operator, to determine whether the returned value meets specific criteria. The following expression tests whether the client IP is in the subnet 200.0.0.0/8 and returns a Boolean TRUE or FALSE:

```
REQ.IP.SOURCEIP == 200.0.0.0 -netmask 255.0.0.0
```

To create a classic policy expression by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- set appfw policy <name> -rule <expression> -action <action>
- show appfw policy <name>

Example

```
> set appfw policy GenericApplicationSSL_ 'HTTP.REQ.METHOD.EQ("get")' APPFW_DROP
Done
> show appfw policy GenericApplicationSSL_
  Name: GenericApplicationSSL_  Rule: HTTP.REQ.METHOD.EQ("get")
  Profile: APPFW_DROP  Hits: 0
  Undef Hits: 0
  Policy is bound to following entities
```

1) REQ VSERVER app_u_GenericApplicationSSLPortalPages PRIORITY : 100

Done

To add an expression for a classic policy by using the configuration utility

This procedure documents the Add Expression dialog box. Depending on the feature for which you are configuring a policy, the route by which you arrive at this dialog box may be different.

1. Perform steps 1-4 in "[To create a policy with classic expressions by using the configuration utility.](#)"
2. In the Add Expression dialog box, in Expression Type, click the type of expression you want to create.
3. Under Flow Type, click the down arrow and choose a flow type.

The flow type is typically REQ or RES. The REQ option specifies that the policy applies to all incoming connections or requests. The RES option applies the policy to all outgoing connections or responses.

For Application Firewall policies, you should leave the expression type set to General Expression, and the flow type set to REQ. The Application Firewall treats each request and response as a single paired entity, so all Application Firewall policies begin with REQ.

4. Under Protocol, click the down arrow and choose the protocol you want for your policy expression. Your choices are:
 - HTTP. Evaluates HTTP requests that are sent to a Web server. For classic expressions, HTTP includes HTTPS requests.
 - SSL. Evaluates SSL data associated with the current connection.
 - TCP. Evaluates the TCP data associated with the current connection.
 - IP. Evaluates the IP addresses associated with the current connection.
5. Under Qualifier, click the down arrow and choose a qualifier for your policy.

The qualifier defines the type of data to be evaluated. The list of qualifiers that appears depends on which protocol you selected in step 4.

The following list describes the qualifier choices for the HTTP protocol. For a complete list of protocols and qualifiers, see "[Classic Expressions.](#)"

The following choices appear for the HTTP protocol:

- METHOD. Filters HTTP requests that use a particular HTTP method.
 - URL. Filters HTTP requests for a specific Web page.
 - URLQUERY. Filters HTTP requests that contain a particular query string.
 - VERSION. Filters HTTP requests on the basis of the specified HTTP protocol version.
 - HEADER. Filters on the basis of a particular HTTP header.
 - URLLLEN. Filters on the basis of the length of the URL.
 - URLQUERY. Filters on the basis of the query portion of the URL.
 - URLQUERYLEN. Filters on the basis of the length of the query portion of the URL only.
6. Under Operator, click the down arrow and choose the operator for your policy expression. For a complete list of choices see the "Operators" table in "[Classic Expressions.](#)" Some common operators are:

Operator	Description
==	Matches the specified value exactly or is exactly equal to the specified value.
!=	Does not match the specified value.

Operator	Description
>	Is greater than the specified value.
<	Is less than the specified value.
>=	Is greater than or equal to the specified value.
<=	Is less than or equal to the specified value.
CONTAINS	Contains the specified value.
CONTENTS	Returns the contents of the designated header, URL, or URL query.
EXISTS	The specified header or query exists.
NOTCONTAINS	Does not contain the specified value.
NOTEXISTS	The specified header or query does not exist.

7. If a Value text box appears, type a string or numeric value, as appropriate. For example, chose REQ as the Flow Type, HTTP as the Protocol, and HEADER as the qualifier, and then type the value of the header string in the Value field and the header type for which you want to match the string in the Header Name text box.
8. Click OK.
9. To create a compound expression, click Add. Note that the type of compounding that is done depends on the following choices in the Create Policy dialog box:
 - **Match Any Expression.** The expressions are in a logical OR relationship.
 - **Match All Expressions.** The expressions are in a logical AND relationship.
 - **Tabular Expressions.** Click the AND, OR, and parentheses buttons to control evaluation.
 - **Advanced Free-Form.** Enter the expressions components directly into the Expression field, and click the AND, OR, and parentheses buttons to control evaluation.

Binding a Classic Policy

Oct 29, 2013

Depending on the policy type, you can bind a classic policy either globally or to a virtual server. Policy bind points are described in the table, "[Policy Type and Bind Points for Policies in Features That Use Classic Policies.](#)"

Note: You can bind a classic policy to multiple bind points.

To bind a classic policy globally by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- bind cmp global <policyName> [-priority <positive_integer>]
- show cmp global

Example

```
> bind cmp global cmp-pol-compress -priority 2
Done
> show cmp global
1) Policy Name: cmp-pol-compress Priority: 2
2) Policy Name: ns_nocmp_xml_ie Priority: 8700
3) Policy Name: ns_nocmp_mozilla_47 Priority: 8800
4) Policy Name: ns_cmp_mscss Priority: 8900
5) Policy Name: ns_cmp_msapp Priority: 9000
6) Policy Name: ns_cmp_content_type Priority: 10000
Done
>
```

To bind a classic policy to a virtual server by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- bind lb vserver <name> [<targetVserver>] [-policyName <string>] [-priority <positive_integer>]
- show lb vserver<name>

Example

```
> bind lb vserver lbtemp -policyName cmp-pol-compress -priority 1
Done
> show lb vserver lbtemp
lbtemp (10.102.29.101:80) - HTTP Type: ADDRESS
State: UP
Last state change was at Tue Oct 27 06:40:38 2009 (+557 ms)
Time since last state change: 0 days, 02:00:40.330
Effective State: UP
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Port Rewrite : DISABLED
No. of Bound Services : 1 (Total) 1 (Active)
```

Configured Method: LEASTCONNECTION

Current Method: Round Robin, Reason: Bound service's state changed to UP

Group: vserver-grp

Mode: IP

Persistence: COOKIEINSERT (version 0) Persistence Backup: SOURCEIP Persistence Mask: 255.255.255.255

Persistence Timeout: 2 min Backup Persistence Timeout: 2 min

Vserver IP and Port insertion: OFF

Push: DISABLED Push VServer:

Push Multi Clients: NO

Push Label Rule: none

1) http-one (10.102.29.252: 80) - HTTP State: UP Weight: 1

Persistence Cookie Value : NSC_wtfsdfs-hsq=ffffff096e03ed45525d5f4f58455e445a4a423660

1) **Policy : cmp-pol-compress Priority:1**

Done

>

To bind a classic policy globally by using the configuration utility

Note: This procedure documents the Global Bindings dialog box. Depending on the feature for which you want to globally bind a policy, the route by which you arrive at this dialog box may be different.

1. In the navigation pane, expand the feature for which you want to globally bind a classic policy, and then locate the policy that you want to bind globally.

Note: You cannot globally bind policies for Content Switching, Cache Redirection, SureConnect, Priority Queuing, or NetScaler Gateway Authorization.

2. In the details pane, click Global Bindings.
3. In the Bind/Unbind <feature name> Policy(s) to Global dialog box, click Insert Policy.
4. In the Policy Name column, click the name of an existing policy that you want to globally bind, or click New Policy to open the Create <feature name> Policy dialog box.
5. After you have selected the policy or created a new policy, in the Priority column, type the priority value.

The lower the number, the sooner this policy is applied relative to other policies. For example, a policy assigned a priority of 10 is applied before a policy with a priority of 100. You can use the same priority for different policies. All features that use classic policies implement only the first policy that a connection matches, so policy priority is important for getting the results you intend.

As a best practice, leave room to add policies by setting priorities with intervals of 50 (or 100) between each policy.

6. Click OK.

To bind a classic policy to a virtual server by using the configuration utility

1. In the navigation pane, expand the feature that contains the virtual server to which you want to bind a classic policy (for example, if you want to bind a classic policy to a content switching virtual server, expand Traffic Management > Content Switching), and then click Virtual Servers.
2. In the details pane, select the virtual server, and then click Open.
3. In the Configure <Feature> Virtual Server dialog box, on the Policies tab, click the feature icon for the type policy that you want, and then click Insert Policy.
4. In the Policy Name column, click the name of an existing policy that you want to bind to a virtual server, or click A to open the Create <feature name> Policy dialog box.
5. After you have selected the policy or created a new policy, in the Priority column, set the priority.

If you are binding a policy to a content switching virtual server, in the Target column, select a load balancing virtual server to which traffic that matches the policy should be sent.

6. Click OK.

Viewing Classic Policies

Oct 29, 2013

You can view classic policies by using either the configuration utility or the command line. You can view details such as the policy's name, expression, and bindings.

To view a classic policy and its binding information by using the command line interface

At the command prompt, type the following commands to view a classic policy and its binding information:

```
show <featureName> policy [policyName]
```

Example

```
> show appfw policy GenericApplicationSSL_  
  Name: GenericApplicationSSL_  Rule: ns_only_get_adv  
  Profile: GenericApplicationSSL_Prof1  Hits: 0  
  Undef Hits: 0  
  Policy is bound to following entities  
  1) REQ VSERVER app_u_GenericApplicationSSLPortalPages  PRIORITY : 100  
Done
```

Note: If you omit the policy name, all policies are listed without the binding details.

To view classic policies and policy bindings by using the configuration utility

1. In the navigation pane, expand the feature whose policies you want to view, (for example, if you want to view application firewall policies, expand Application Firewall), and then click Policies.
2. In the details pane, do one or more of the following:
 - To view details for a specific policy, click the policy. Details appear in the Details area of the configuration pane.
 - To view bindings for a specific policy, click the policy, and then click Show Bindings.
 - To view global bindings, click the policy, and then click Global Bindings. Note that you cannot bind a Content Switching, Cache Redirection, SureConnect, Priority Queuing, or NetScaler Gateway Authorization policy globally.

Creating Named Classic Expressions

Sep 30, 2013

A named classic expression is a classic expression that can be referenced through an assigned name. Often, you need to configure classic expressions that are large or complex and form a part of a larger compound expression. You might also configure classic expressions that you need to use frequently and in multiple compound expressions or classic policies. In these scenarios, you can create the classic expression you want, save it with a name of your choice, and then reference the expression from compound expressions or policies through its name. This saves configuration time and improves the readability of complex compound expressions. Additionally, any modifications to a named classic expression need to be made only once.

Some named expressions are built-in, and a subset of these are read-only. Built-in named expressions are divided into four categories: General, Anti-Virus, Personal Firewall, and Internet Security. General named expressions have a wide variety of uses. For example, from the General category, you can use the expressions `ns_true` and `ns_false` to specify a value of TRUE or FALSE, respectively, to be returned for all traffic. You can also identify data of a particular type (for example, HTM, DOC, or GIF files), determine whether caching headers are present, or determine whether the round trip time for packets between a client and the NetScaler is high (over 80 milliseconds).

Anti-Virus, Personal Firewall, and Internet Security named expressions test clients for the presence of a particular program and version and are used primarily in NetScaler Gateway policies.

For descriptions of the built-in named expressions, see "[Classic Expressions](#)."

Note: You cannot modify or delete built-in named expressions.

To create a named classic expression by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add expression <name> <value> [-comment <string>] [-clientSecurityMessage <string>]`
- `show expression [<name> | -type CLASSIC]`

Example

```
> add expression classic_ne "REQ.HTTP.URL CONTAINS www.example1.com" -comment "Checking the URL for www.example1.com"
Done
> show expression classic_ne
1) Name: classic_ne Expr: REQ.HTTP.URL CONTAINS www.example1.com Hits: 0 Type : CLASSIC
   Comment: "Checking the URL for www.example1.com"
Done
>
```

To create a named classic expression by using the configuration utility

1. In the navigation pane, expand AppExpert, expand Expressions, and then click Classic Expressions.
2. In the details pane, click Add.

Note: Some of the built-in expressions in the Expressions list are read-only.

3. In the Create Policy Expression dialog box, specify values for the following parameters:

- Expression Name*—name
- Client Security Message—clientSecurityMessage
- Comments—comment

* A required parameter

4. To create the expression, do one of the following:

- You can choose inputs to this expression from the Named Expressions drop-down list.
 - You can create a new expression, as described in "[To add an expression for a classic policy by using the configuration utility.](#)"
5. When you are done, click Close. Verify that your new expression was created by scrolling to the bottom of the Classic Expressions list to view it.

Expressions Reference-Default Syntax Expressions

May 26, 2015

The following table is a listing of default syntax expression prefixes, with cross-references to descriptions of these prefixes and the operators that you can specify for them. Note that some prefixes can work with multiple types of operators. For example, a cookie can be parsed by using operators for text or operators for HTTP headers.

You can use any element in the following tables as a complete expression on its own, or you can use various operators to combine these expression elements with others to form more complex expressions.

Note: The Description column in the following table contains cross-references to additional information about prefix usage and applicable operators for the prefix.

Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
CLIENT.ETHER	"Prefixes for MAC Addresses." "Operations for MAC Addresses."
CLIENT.ETHER.[DSTMAC SRCMAC]	"Prefixes for MAC Addresses." "Operations for MAC Addresses."
CLIENT.INTERFACE	Designates an expression that refers to the ID of the network interface through which the current packet entered the Application Switch. See the other CLIENT.INTERFACE prefix descriptions in this table.
CLIENT.INTERFACE.ID	Extracts the ID of the network interface that received the current packet of data. See the other CLIENT.INTERFACE prefix descriptions in this table.
CLIENT.INTERFACE.ID.EQ("id")	Returns Boolean TRUE if the interface's ID matches the ID that is passed as the argument. For example: CLIENT.INTERFACE.ID.EQ("1/1") See "Booleans in Compound Expressions."
CLIENT.INTERFACE.[RXTHROUGHPUT RXTXTHROUGHPUT	"Expressions for Numeric Client and Server

TXTHROUGHPUT] Expression Prefix	Data" Links to Relevant Information, with Applicable Notes and Operator Descriptions
CLIENT.IP	Operates on the IP protocol data associated with the current packet. See the other CLIENT.IP prefixes in this table.
CLIENT.IP.DST	"Prefixes for IPV4 Addresses and IP Subnets." "Operations for IPV4 Addresses." "Compound Operations for Numbers."
CLIENT.IP.SRC	"Prefixes for IPV4 Addresses and IP Subnets." "Operations for IPV4 Addresses." "Compound Operations for Numbers."
CLIENT.IPV6	Operates on IPv6 protocol data. See the other CLIENT.IPV6 prefixes in this table.
CLIENT.IPV6.DST	"Expression Prefixes for IPv6 Addresses." "Operations for IPV6 Prefixes."
CLIENT.IPV6.SRC	"Expression Prefixes for IPv6 Addresses." "Operations for IPV6 Prefixes."
CLIENT.SSL	Operates on the SSL protocol data for the current packet. See the other CLIENT.SSL prefixes in this table.
CLIENT.SSL.CIPHER_BITS	"Prefixes for Numeric Data in SSL Certificates." "Compound Operations for Numbers."
CLIENT.SSL.CIPHER_EXPORTABLE	"Prefixes for Text-Based SSL and Certificate Data." "Booleans in Compound Expressions."

Expression Prefix CLIENT.SSL.CLIENT_CERT	Links to Relevant Information, with Applicable Notes and Operator Descriptions "Expressions for SSL Certificate Dates."
CLIENT.SSL.IS_SSL	"Prefixes for Text-Based SSL and Certificate Data." "Booleans in Compound Expressions."
CLIENT.SSL.VERSION	"Prefixes for Numeric Data in SSL Certificates." "Compound Operations for Numbers."
CLIENT.TCP	Operates on TCP protocol data. See the other CLIENT.TCP prefixes in this table.
CLIENT.TCP.[DSTPORT MSS SRCPORT]	"Expressions for TCP, UDP, and VLAN Data." "Compound Operations for Numbers."
CLIENT.TCP.PAYLOAD(integer)	"Expressions for TCP, UDP, and VLAN Data." "Default Syntax Expressions: Evaluating Text."
CLIENT.UDP	Operates on the UDP protocol data associated with the current packet. See the other CLIENT.UDP prefixes in this table.
CLIENT.UDP.DNS.DOMAIN	"Expressions for TCP, UDP, and VLAN Data." "Default Syntax Expressions: Evaluating Text."
CLIENT.UDP.DNS.DOMAIN.EQ("hostname")	"Expressions for TCP, UDP, and VLAN Data." "Booleans in Compound Expressions."
CLIENT.UDP.DNS. [IS_AAAAREC IS_ANYREC IS_AREC IS_CNAMEREC IS_MXREC IS_NSREC IS_PTRREC IS_SOAREC IS_SRVREC]	"Expressions for TCP, UDP, and VLAN Data." "Booleans in Compound Expressions."

CLIENT.UDP.ID[STPORT SRCPORT] Expression Prefix	"Expressions for TCP, UDP, and VLAN Data." Links to Relevant Information, with Applicable Notes and Operator Descriptions "Compound Operations for Numbers."
CLIENT.VLAN	Operates on the VLAN through which the current packet entered the NetScaler. See the other CLIENT.VLAN prefixes in this table.
CLIENT.VLAN.ID	"Expressions for TCP, UDP, and VLAN Data." "Compound Operations for Numbers."
HTTP.REQ	Operates on HTTP requests. See the other HTTP.REQ prefixes in this table.
HTTP.REQ.BODY(integer)	"Expression Prefixes for Text in HTTP Requests and Responses." "Basic Operations on Text."
HTTP.REQ.CACHE_CONTROL	"Prefixes for Cache-Control Headers." "Operations for Cache-Control Headers."
HTTP.REQ.CONTENT_LENGTH	"Expressions for Numeric HTTP Payload Data Other Than Dates." "Compound Operations for Numbers."
HTTP.REQ.COOKIE	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.REQ.DATE	"Format of Dates and Times in an Expression." "Expressions for HTTP Request and Response Dates." "Default Syntax Expressions: Evaluating Text." "Compound Operations for Numbers."

Expression Prefix	Operations for HTTP Headers Links to Relevant Information, with Applicable Notes and Operator Descriptions
HTTP.REQ.HEADER("header_name")	Expression Prefixes for Text in HTTP Requests and Responses.
	"Prefixes for HTTP Headers." "Operations for HTTP Headers."
HTTP.REQ.FULL_HEADER("header_name")	"Prefixes for HTTP Headers." "Operations for HTTP Headers."
HTTP.REQ.HOSTNAME	"Expression Prefixes for Text in HTTP Requests and Responses."
HTTP.REQ.HOSTNAME.[DOMAIN Server]	"Expression Prefixes for Text in HTTP Requests and Responses." "Basic Operations on Text."
HTTP.REQ.HOSTNAME.EQ("hostname")	"Expression Prefixes for Text in HTTP Requests and Responses." "Booleans in Compound Expressions." "Basic Operations on Expression Prefixes".
HTTP.REQ.HOSTNAME.PORT	"Expression Prefixes for Text in HTTP Requests and Responses." "Compound Operations for Numbers."
HTTP.REQ.IS_VALID	Returns TRUE if the HTTP request is properly formed. See "Booleans in Compound Expressions."
HTTP.REQ.METHOD	"Expression Prefixes for Text in HTTP Requests and Responses." "Basic Operations on Text." "Complex Operations on Text."
HTTP.REQ.TRACKING	Returns the HTTP body tracking mechanism.

Expression Prefix	See the descriptions of other HTTP.REQ.TRACKING prefixes in this table. Applicable Notes and Operator
HTTP.REQ.TRACKING.EQ("tracking_mechanism")	Descriptions Returns TRUE or FALSE. See " Booleans in Compound Expressions. "
HTTP.REQ.URL	Obtains the HTTP URL object from the request and sets the text mode to URLENCODED by default. See " Expression Prefixes for Text in HTTP Requests and Responses. "
HTTP.REQ.URL.[CVPN_ENCODE HOSTNAME HOSTNAME.DOMAIN SERVER PATH PATH_AND_QUERY PROTOCOL QUERY SUFFIX VERSION]	" Expression Prefixes for Text in HTTP Requests and Responses. " " Basic Operations on Text. " " Complex Operations on Text. "
HTTP.REQ.URL.HOSTNAME.EQ("hostname")	" Expression Prefixes for Text in HTTP Requests and Responses. " " Booleans in Compound Expressions. "
HTTP.REQ.URL.HOSTNAME.PORT	" Expression Prefixes for Text in HTTP Requests and Responses. " " Compound Operations for Numbers. "
HTTP.REQ.URL.PATH.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. See the table " HTTP Expression Prefixes that Return Text. "
HTTP.REQ.URL.QUERY.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. See the table " HTTP Expression Prefixes that Return Text. "
HTTP.REQ.USER.IS_MEMBER_OF	" HTTP Expression Prefixes that Return Text. "
HTTP.REQ.USER.NAME	" HTTP Expression Prefixes that Return Text. "
HTTP.REQ.VERSION	" Expression Prefixes for Text in HTTP Requests and Responses. "
HTTP.REQ.VERSION.[MAJOR MINOR]	Operates on the major or minor HTTP

Expression Prefix	version string. See "Expression Prefixes for Links to Relevant Information, with Applicable Notes and Operator Descriptions"
HTTP.RES	Operates on HTTP responses.
HTTP.RES.BODY(integer)	"Expression Prefixes for Text in HTTP Requests and Responses." "Basic Operations on Text." "Complex Operations on Text."
HTTP.RES.CACHE_CONTROL	"Prefixes for Cache-Control Headers." "Operations for Cache-Control Headers."
HTTP.RES.CONTENT_LENGTH	"Expression Prefixes for Text in HTTP Requests and Responses." "Operations for HTTP Headers." "Compound Operations for Numbers."
HTTP.RES.DATE	"Format of Dates and Times in an Expression." "Expressions for HTTP Request and Response Dates." "Expression Prefixes for Text in HTTP Requests and Responses." "Compound Operations for Numbers." "Operations for HTTP Headers."
HTTP.RES.HEADER("header_name")	"Expression Prefixes for Text in HTTP Requests and Responses." "Prefixes for HTTP Headers." "Operations for HTTP Headers."
HTTP.REQ.FULL_HEADER("header_name")	"Prefixes for HTTP Headers." "Operations for HTTP Headers."

Expression Prefix HTTP.REQ.TXID	Links to Relevant Information, with Applicable Notes and Operator Descriptions "Prefixes for HTTP Headers." "Operations for HTTP Headers."
HTTP.RES.IS_VALID	Returns TRUE if the HTTP response is properly formed. See "Booleans in Compound Expressions."
HTTP.RES.SET_COOKIE	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE.COOKIE("name")	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE.COOKIE.[DOMAIN PATH PORT]	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE.COOKIE.EXPIRES	Obtains the Expires field of the cookie as a date string. The value of the Expires attribute can be operated upon as a time object. If multiple Expires fields are present, this expression operates on the first one. If the Expires attribute is absent, a string of length zero is returned. Also see: "Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text." "Compound Operations for Numbers."

Expression Prefix HTTP.RES.SET_COOKIE.COOKIE.PATH.IGNORE_EMPTY_ELEMENTS	Links to Relevant Information, with Applicable Notes and Operator Descriptions Ignores spaces in the data. For an example, see the table "Expression Prefixes for Text in HTTP Requests and Responses."
HTTP.RES.SET_COOKIE.COOKIE.PORT.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table "HTTP Expression Prefixes that Return Text."
HTTP.RES.SET_COOKIE.COOKIE.VERSION	"Prefixes for HTTP Headers." "Compound Operations for Numbers."
HTTP.RES.SET_COOKIE.COOKIE("name",integer)[.PORT PATH DOMAIN VERSION EXPIRES]	"Prefixes for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE.COOKIE.EXPIRES	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text." "Compound Operations for Numbers."
HTTP.RES.SET_COOKIE.EXISTS("name")	"Prefixes for HTTP Headers." "Booleans in Compound Expressions."
HTTP.RES.SET_COOKIE2	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE2.COOKIE("name")	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE2.COOKIE.[DOMAIN PATH PORT]	"Prefixes for HTTP Headers."

Expression Prefix	"Operations for HTTP Headers" Links to Relevant Information, with Applicable Notes and Operator Descriptions Default Syntax Expressions: Evaluating Text.
HTTP.RES.SET_COOKIE2.COOKIE.EXPIRES	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text." "Compound Operations for Numbers."
HTTP.RES.SET_COOKIE2.COOKIE.PATH.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table HTTP Expression Prefixes that Return Text.
HTTP.RES.SET_COOKIE2.COOKIE.PORT.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table "HTTP Expression Prefixes that Return Text." See also "Default Syntax Expressions: Evaluating Text" and "Compound Operations for Numbers."
HTTP.RES.SET_COOKIE2.COOKIE("name",integer)[.PORT PATH DOMAIN VERSION EXPIRES]	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE2.COOKIE.DOMAIN	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."
HTTP.RES.SET_COOKIE2.COOKIE.EXPIRES	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Default Syntax Expressions: Evaluating Text."

Expression Prefix HTTP.RES.SET_COOKIE2.COOKIE.VERSION	"Compound Operations for Numbers" Links to Relevant Information, with Applicable Notes and Operator Descriptions "Prefixes for HTTP Headers." "Operations for HTTP Headers."
	"Default Syntax Expressions: Evaluating Text." "Compound Operations for Numbers."
HTTP.RES.SET_COOKIE2.EXISTS("name")	"Prefixes for HTTP Headers." "Operations for HTTP Headers." "Booleans in Compound Expressions."
HTTP.RES.STATUS	"Expression Prefixes for Text in HTTP Requests and Responses." "Compound Operations for Numbers."
HTTP.RES.STATUS_MSG	"Expression Prefixes for Text in HTTP Requests and Responses."
HTTP.RES.TRACKING	Returns the HTTP body tracking mechanism. See the descriptions of other HTTP.REQ.TRACKING prefixes in this table.
HTTP.RES.TRACKING.EQ("tracking_method")	Returns TRUE or FALSE. See "Booleans in Compound Expressions."
HTTP.RES.TXID	"Prefixes for HTTP Headers." "Operations for HTTP Headers."
HTTP.RES.VERSION	"Expression Prefixes for Text in HTTP Requests and Responses."
HTTP.RES.VERSION.[MAJOR MINOR]	Operates on the major or minor HTTP version string. See "Expression Prefixes for Text in HTTP Requests and Responses" and "Compound Operations for Numbers."

SERVER Expression Prefix	Links to Relevant Information, with Applicable Notes and Operator Descriptions
SERVER.ETHER	Designates an expression that refers to the server. This is the starting point for access into parameters such as Ether and SSL. See the other SERVER prefixes in this table.
SERVER.ETHER.DSTMAC	<p>"Prefixes for MAC Addresses."</p> <p>"Prefixes for MAC Addresses."</p>
SERVER.INTERFACE	Designates an expression that refers to the ID of the network interface that received the current packet of data. See the other SERVER.INTERFACE prefixes in this table.
SERVER.INTERFACE.ID.EQ("id")	<p>Returns Boolean TRUE if the interface's ID matches the ID that is passed as the argument. For example:</p> <p>SERVER.INTERFACE.ID.EQ("LA/1")</p> <p>See "Booleans in Compound Expressions."</p>
SERVER.INTERFACE.[RXTHROUGHPUT RXTXTHROUGHPUT TXTHROUGHPUT]	<p>"Expressions for Numeric Client and Server Data."</p> <p>"Compound Operations for Numbers."</p>
SERVER.IP	Operates on the IP protocol data associated with the current packet. See the other SERVER.IP prefixes in this table.
SERVER.IP.[DST SRC]	<p>"Prefixes for IPV4 Addresses and IP Subnets."</p> <p>"Operations for IPV4 Addresses."</p> <p>"Compound Operations for Numbers."</p>
SERVER.IPV6	Operates on IPv6 protocol data. See the other SERVER.IPV6 prefixes in this table.

SERVER.IPV6.DST Expression Prefix	"Expression Prefixes for IPv6 Addresses." Links to Relevant Information, with Applicable Notes and Operator Descriptions Operations for IPv6 Prefixes.
SERVER.IPV6.SRC	"Expression Prefixes for IPv6 Addresses." "Operations for IPV6 Prefixes."
SERVER.TCP	Operates on TCP protocol data. See the other CLIENT.TCP prefixes in this table.
SERVER.TCP.[DSTPORT MSS SRCPORT]	"Expressions for TCP, UDP, and VLAN Data." "Compound Operations for Numbers."
SERVER.VLAN	Operates on the VLAN through which the current packet entered the NetScaler. See the other SERVER.VLAN prefixes in this table.
SERVER.VLAN.ID	"Expressions for TCP, UDP, and VLAN Data." "Compound Operations for Numbers."
SYS	Designates an expression that refers to the NetScaler itself, not to the client or server. See the other SYS prefixes in this table.
SYS.EVAL_CLASSIC_EXPR(classic_expression)	"Classic Expressions in Default Syntax Expressions." "Booleans in Compound Expressions."
SYS.HTTP_CALLOUT(http_callout)	"HTTP Callouts."
SYS.CHECK_LIMIT	"Rate Limiting."
SYS.TIME	"Expressions for the NetScaler System Time." "Compound Operations for Numbers."
SYS.TIME.[BETWEEN(time1, time2) EQ(time) GE(time) GT(time) LE(time) LT(time) WITHIN(time1, time2)]	"Expressions for the NetScaler System Time." "Booleans in Compound Expressions."

<p>Expression Prefix</p> <p>SYS.TIME.[DAY HOURS MINUTES MONTH RELATIVE_BOOT RELATIVE_NOW SECONDS WEEKDAY YEAR]</p>	<p>"Compound Operations for Numbers" Links to Relevant Information, with Applicable Notes and Operator Descriptions Expressions for the NetScaler System Time."</p> <p>"Compound Operations for Numbers."</p>
<p>SYS.RANDOM</p>	<p>Returns a random number between 0 and 1, inclusive of 0 but exclusive of 1.</p>
<p>VPN.BASEURL.[CVPN_DECODE CVPN_ENCODE HOSTNAME HOSTNAME.DOMAIN HOSTNAME.SERVER PATH PATH_AND_QUERY PROTOCOL QUERY SUFFIX]</p>	<p>"Expression Prefixes for VPNs and Clientless VPNs."</p>
<p>VPN.BASEURL.HOSTNAME.EQ("hostname")</p>	<p>"Expression Prefixes for VPNs and Clientless VPNs."</p> <p>"Booleans in Compound Expressions."</p>
<p>VPN.BASEURL.HOSTNAME.PORT</p>	<p>"Expression Prefixes for VPNs and Clientless VPNs."</p> <p>"Compound Operations for Numbers."</p>
<p>VPN.BASEURL.PATH.IGNORE_EMPTY_ELEMENTS</p>	<p>Ignores spaces in the data. For an example, see the table "HTTP Expression Prefixes that Return Text."</p>
<p>VPN.BASEURL.QUERY.IGNORE_EMPTY_ELEMENTS</p>	<p>Ignores spaces in the data. For an example, see the table "HTTP Expression Prefixes that Return Text."</p>
<p>VPN.CLIENTLESS_BASEURL</p>	<p>"Expression Prefixes for VPNs and Clientless VPNs."</p>
<p>VPN.CLIENTLESS_BASEURL.[CVPN_DECODE CVPN_ENCODE HOSTNAME HOSTNAME.DOMAIN HOSTNAME.SERVER PATH PATH_AND_QUERY PROTOCOL QUERY SUFFIX]</p>	<p>"Expression Prefixes for VPNs and Clientless VPNs."</p>
<p>VPN.CLIENTLESS_BASEURL.HOSTNAME.EQ("hostname")</p>	<p>"Expression Prefixes for VPNs and Clientless VPNs."</p> <p>"Booleans in Compound Expressions."</p>
<p>VPN.CLIENTLESS_BASEURL.HOSTNAME.PORT</p>	<p>"Expression Prefixes for VPNs and Clientless</p>

Expression Prefix	VPNs Links to Relevant Information, with Applicable Notes and Operator Descriptions
VPN.CLIENTLESS_BASEURL.PATH.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table " HTTP Expression Prefixes that Return Text. "
VPN.CLIENTLESS_BASEURL.QUERY.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table " HTTP Expression Prefixes that Return Text. "
VPN.CLIENTLESS_HOSTURL	" Expression Prefixes for VPNs and Clientless VPNs. "
VPN.CLIENTLESS_HOSTURL.[CVPN_DECODE CVPN_ENCODE HOSTNAME HOSTNAME.DOMAIN HOSTNAME.SERVER PATH PATH_AND_QUERY PROTOCOL QUERY SUFFIX]	" Expression Prefixes for VPNs and Clientless VPNs. "
VPN.CLIENTLESS_HOSTURL.HOSTNAME.EQ("hostname")	"Expression Prefixes for VPNs and Clientless VPNs." "Booleans in Compound Expressions.
VPN.CLIENTLESS_HOSTURL.HOSTNAME.PORT	"Expression Prefixes for VPNs and Clientless VPNs." "Compound Operations for Numbers."
VPN.CLIENTLESS_HOSTURL.PATH.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table " HTTP Expression Prefixes that Return Text. "
VPN.CLIENTLESS_HOSTURL.QUERY.IGNORE_EMPTY_ELEMENTS	Ignores spaces in the data. For an example, see the table " HTTP Expression Prefixes that Return Text. "
VPN.HOST	" Expression Prefixes for VPNs and Clientless VPNs. "
VPN.HOST.[DOMAIN Server]	" Expression Prefixes for VPNs and Clientless VPNs. "

<p>VPN.HOST.EQ("hostname") Expression Prefix</p>	<p>"Expression Prefixes for VPNs and Clientless VPNs." Links to Relevant Information, with Applicable Notes and Operator Descriptions Booleans in Compound Expressions.</p>
<p>VPN.HOST.PORT</p>	<p>"Expression Prefixes for VPNs and Clientless VPNs."</p> <p>"Default Syntax Expressions: Evaluating Text."</p> <p>"Compound Operations for Numbers."</p>

Expressions Reference-Classic Expressions

May 25, 2015

The subtopics listed in the table of contents on the left side of your screen contain tables listing the NetScaler classic expressions.

In the table of operators, the result type of each operator is shown at the beginning of the description. In the other tables, the level of each expression is shown at the beginning of the description. For named expressions, each expression is shown as a whole.

This document includes the following details:

- [Operators](#)
- [General Expressions](#)
- [Client Security Expressions](#)
- [Network-Based Expressions](#)
- [Date/Time Expressions](#)
- [File System Expressions](#)
- [Built-In Named Expressions \(General\)](#)
- [Built-In Named Expressions \(Anti-Virus\)](#)
- [Built-In Named Expressions \(Personal Firewall\)](#)
- [Built-In Named Expressions \(Client Security\)](#)

Operators

Expression Element	Definition
==	Boolean. Returns TRUE if the current expression equals the argument. For text operations, the items being compared must exactly match one another. For numeric operations, the items must evaluate to the same number.
!=	Boolean. Returns TRUE if the current expression does not equal the argument. For text operations, the items being compared must not exactly match one another. For numeric operations, the items must not evaluate to the same number.
CONTAINS	Boolean. Returns TRUE if the current expression contains the string that is designated in the argument.
NOTCONTAINS	Boolean. Returns TRUE if the current expression does not contain the string that is designated in the

Expression Element	Definition
CONTENTS	Text. Returns the contents of the current expression.
EXISTS	Boolean. Returns TRUE if the item designated by the current expression exists.
NOTEXISTS	Boolean. Returns TRUE if the item designated by the current expression does not exist.
>	Boolean. Returns TRUE if the current expression evaluates to a number that is greater than the argument.
<	Boolean. Returns TRUE if the current expression evaluates to a number that is less than the argument.
>=	Boolean. Returns TRUE if the current expression evaluates to a number that is greater than or equal to the argument.
<=	Boolean. Returns TRUE if the current expression evaluates to a number that is less than or equal to the argument.

General Expressions

Expression Element	Definition
REQ	Flow Type. Operates on incoming (or request) packets.
REQ.HTTP	Protocol Operates on HTTP requests.

REQ.HTTP.METHOD Expression Element	Qualifier Definition
	Designates the HTTP method.
REQ.HTTP.URL	Qualifier Designates the URL.
REQ.HTTP.URLTOKENS	Qualifier Designates the URL token.
REQ.HTTP.VERSION	Qualifier Designates the HTTP version.
REQ.HTTP.HEADER	Qualifier Designates the HTTP header.
REQ.HTTP.URLLEN	Qualifier Designates the number of characters in the URL.
REQ.HTTP.URLQUERY	Qualifier Designates the query portion of the URL.
REQ.HTTP.URLQUERYLEN	Qualifier Designates the length of the query portion of the URL.
REQ.SSL	Protocol Operates on SSL requests.
REQ.SSL.CLIENT.CERT	Qualifier Designates the entire client certificate.
REQ.SSL.CLIENT.CERT.SUBJECT	Qualifier Designates the client certificate subject.
REQ.SSL.CLIENT.CERT.ISSUER	Qualifier

Expression Element	Definition
REQ.SSL.CLIENT.CERT.SIGALGO	Qualifier Designates the validation algorithm used by the client certificate.
REQ.SSL.CLIENT.CERT.VERSION	Qualifier Designates the client certificate version.
REQ.SSL.CLIENT.CERT.VALIDFROM	Qualifier Designates the date before which the client certificate is not valid.
REQ.SSL.CLIENT.CERT.VALIDTO	Qualifier Designates the date after which the client certificate is not valid.
REQ.SSL.CLIENT.CERT.SERIALNUMBER	Qualifier Designates the serial number of the client certificate.
REQ.SSL.CLIENT.CIPHER.TYPE	Qualifier Designates the encryption protocol used by the client.
REQ.SSL.CLIENT.CIPHER.BITS	Qualifier Designates the number of bits used by the client's SSL key.
REQ.SSL.CLIENT.SSL.VERSION	Qualifier Designates the SSL version that the client is using.
REQ.TCP	Protocol Operates on incoming TCP packets.
REQ.TCP.SOURCEPORT	Qualifier Designates the source port of the incoming packet.
REQ.TCP.DESTPORT	Qualifier Designates the destination port of the incoming packet.

Expression Element	Definition
REQ	Protocol Operates on incoming IP packets.
REQ.IP.SOURCEIP	Qualifier Designates the source IP of the incoming packet.
REQ.IP.DESTIP	Qualifier Designates the destination IP of the incoming packet.
RES	Flow Type Operates on outgoing (or response) packets.
RES.HTTP	Protocol Operates on HTTP responses.
RES.HTTP.VERSION	Qualifier Designates the HTTP version.
RES.HTTP.HEADER	Qualifier Designates the HTTP header.
RES.HTTP.STATUSCODE	Qualifier Designates the status code of the HTTP response.
RES.TCP	Protocol Operates on incoming TCP packets.
RES.TCP.SOURCEPORT	Qualifier Designates the source port of the outgoing packet.
RES.TCP.DESTPORT	Qualifier Designates the destination port of the outgoing packet.
RES.IP	Protocol

Expression Element	Definition
	Operates on outgoing IP packets.
RES.IP.SOURCEIP	<p>Qualifier</p> <p>Designates the source IP of the outgoing packet. This can be in IPv4 or IPv6 format. For example:</p> <p>add expr exp3 "sourceip == 10.102.32.123 -netmask 255.255.255.0 && destip == 2001::23/120".</p>
RES.IP.DESTIP	<p>Qualifier</p> <p>Designates the destination IP of the outgoing packet.</p>

Client Security Expressions

Updated: 2013-10-21

The expressions to configure client settings on the Access Gateway with the following software:

- Antivirus
- Personal firewall
- Antispam
- Internet Security

For example usage, see <http://support.citrix.com/article/CTX112599>.

Actual Expression	Definition
CLIENT.APPLICATION.AV(<NAME>.VERSION == <VERSION>)	Checks whether the client is running the designated anti-virus program and version.
CLIENT.APPLICATION.AV(<NAME>.VERSION != <VERSION>)	Checks whether the client is not running the designated anti-virus program and version.
CLIENT.APPLICATION.PF(<NAME>.VERSION == <VERSION>)	Checks whether the client is running the designated personal firewall program and version.
CLIENT.APPLICATION.PF(<NAME>.VERSION != <VERSION>)	Checks whether the client is not running the designated personal firewall program and version.
CLIENT.APPLICATION.IS(<NAME>.VERSION == <VERSION>)	Checks whether the client is running the designated internet security program and version.

Actual Expression CLIENT.APPLICATION.IS(<NAME>.VERSION != <VERSION>)	Definition Checks whether the client is not running the designated internet security program and version.
CLIENT.APPLICATION.AS(<NAME>.VERSION == <VERSION>)	Checks whether the client is running the designated anti-spam program and version.
CLIENT.APPLICATION.AS(<NAME>.VERSION != <VERSION>)	Checks whether the client is not running the designated anti-spam program and version.

Network-Based Expressions

Expression	Definition
REQ	Flow Type. Operates on incoming, or request, packets.
REQ.VLANID	Qualifier. Operates on the virtual LAN (VLAN) ID.
REQ.INTERFACE.ID	Qualifier. Operates on the ID of the designated NetScaler interface.
REQ.INTERFACE.RXTHROUGHPUT	Qualifier. Operates on the raw received packet throughput of the designated NetScaler interface.
REQ.INTERFACE.TXTHROUGHPUT	Qualifier. Operates on the raw transmitted packet throughput of the designated NetScaler interface.
REQ.INTERFACE.RXTXTHROUGHPUT	Qualifier. Operates on the raw received and transmitted packet throughput of the designated NetScaler interface.
REQ.ETHER.SOURCEMAC	Qualifier. Operates on the source MAC address.

Expression	Definition
REQ.ETHER.DESTMAC	Qualifier. Operates on the destination MAC address.
RES	Flow Type. Operates on outgoing (or response) packets.
RES.VLANID	Qualifier. Operates on the virtual LAN (VLAN) ID.
RES.INTERFACE.ID	Qualifier. Operates on the ID of the designated NetScaler interface.
RES.INTERFACE.RXTHROUGHPUT	Qualifier. Operates on the raw received packet throughput of the designated NetScaler interface.
RES.INTERFACE.TXTHROUGHPUT	Qualifier. Operates on the raw transmitted packet throughput of the designated NetScaler interface.
RES.INTERFACE.RXTXTHROUGHPUT	Qualifier. Operates on the raw received and transmitted packet throughput of the designated NetScaler interface.
RES.ETHER.SOURCEMAC	Qualifier. Operates on the source MAC address.
RES.ETHER.DESTMAC	Qualifier. Operates on the destination MAC address.

Date/Time Expressions

Expression	Definition
TIME	Qualifier.

Expression	Definition
DATE	Operates on the date and time of day, GMT. Qualifier. Operates on the date, GMT.
DAYOFWEEK	Operates on the specified day in the week, GMT.

File System Expressions

Updated: 2013-09-30

You can specify file system expressions in authorization policies for users and groups who access file sharing through the NetScaler Gateway file transfer utility (the VPN portal). These expressions work with the NetScaler Gateway file transfer authorization feature to control user access to file servers, folders, and files. For example, you can use these expressions in authorization policies to control access based on file type and size.

Expression	Definition
FS.COMMAND	Qualifier. Operates on a file system command. The user can issue multiple commands on a file transfer portal. (For example, ls to list files or mkdir to create a directory). This expression returns the current action that the user is taking. Possible values: Neighbor, login, ls, get, put, rename, mkdir, rmdir, del, logout, any. Following is an example: Add authorization policy pol1 "fs.command eq login && (fs.user eq administrator fs.serverip eq 10.102.88.221 –netmask 255.255.255.252)" allow
FS.USER	Returns the user who is logged on to the file system.
FS.SERVER	Returns the host name of the target server. In the following example, the string win2k3-88-22 is the server name: fs.server eq win2k3-88-221
FS.SERVERIP	Returns the IP address of the target server.
FS.SERVICE	Returns a shared root directory on the file server. If a particular folder is exposed as shared, a user can directly log on to the specified first level folder. This first level folder is called a service. For example, in the path \\hostname\SERVICEX\ETC, SERVICEX is the service. As another example, if a user accesses the file \\hostname\service1\dir1\file1.doc, FS.SERVICE

Expression	will return service1. Definition Following is an example:
	fs.service notcontains New
FS.DOMAIN	Returns the domain name of the target server.
FS.PATH	Returns the complete path of the file being accessed. For example, if a user accesses the file \\hostname\service1\dir1\file1.doc, FS.PATH will return \service\dir1\file1.doc. Following is an example: fs.path notcontains SSL
FS.FILE	Returns the name of the file being accessed. For example, if a user accesses the file \\hostname\service1\dir1\file1.doc, FS.FILE will return file1.doc.
FS.DIR	Returns the directory being accessed. For example, if a user accesses the file \\hostname\service1\dir1\file1.doc, FS.DIR will return \service\dir1.
FS.FILE.ACCESTIME	Returns the time at which the file was last accessed. This is one of several options that provide you with granular control over actions that the user performs. (See the following entries in this table.)
FS.FILE.CREATETIME	Returns the time at which the file was created.
FS.FILE.MODIFYTIME	Returns the time at which the file was edited.
FS.FILE.WRITETIME	Returns the time of the most recent change in the status of the file.
FS.FILE.SIZE	Returns the file size.
FS.DIR.ACCESTIME	Returns the time at which the directory was last accessed.
FS.DIR.CREATETIME	Returns the time at which the directory was created.
FS.DIR.MODIFYTIME	Returns the time at which the directory was last modified.
FS.DIR.WRITETIME	Returns the time at which the directory status last changed.

Note: File system expressions do not support regular expressions.

Built-In Named Expressions (General)

Expression	Definition
ns_all_apps_ncomp	Tests for connections with destination ports between 0 and 65535. In other words, tests for all applications.
ns_cachecontrol_nocache	Tests for connections with an HTTP Cache-Control header that contains the value “no-cache”.
ns_cachecontrol_nostore	Tests for connections with an HTTP Cache-Control header that contains the value “no-store”.
ns_cmpclient	Tests the client to determine if it accepts compressed content.
ns_content_type	Tests for connections with an HTTP Content-Type header that contains “text”.
ns_css	Tests for connections with an HTTP Content-Type header that contains “text/css”.
ns_ext_asp	Tests for HTTP connections to any URL that contains the string .asp—in other words, any connection to an active server page (ASP).
ns_ext_cfm	Tests for HTTP connections to any URL that contains the string .cfm
ns_ext_cgi	Tests for HTTP connections to any URL that contains the string .cgi—in other words, any connection to a common gateway interface (CGI) script.
ns_ext_ex	Tests for HTTP connections to any URL that contains the string .ex
ns_ext_exe	Tests for HTTP connections to any URL that contains the string .exe—in other words, any connection to a executable file.
ns_ext_htx	Tests for HTTP connections to any URL that contains the string .htx
ns_ext_not_gif	Tests for HTTP connections to any URL that does not contain the string .gif—in other words, any connection to a URL that is not a GIF image.
ns_ext_not_jpeg	Tests for HTTP connections to any URL that does not contain the string .jpeg—in other words, any connection to a URL that is not a JPEG image.

Expression	Definition
ns_ext_shtml	Tests for HTTP connections to any URL that contains the string .shtml—in other words, any connection to a server-parsed HTML page.
ns_false	Always returns a value of FALSE.
ns_farclient	<p>Client is in a different geographical region from the NetScaler, as determined by the geographical region in the client's IP address. The following regions are predefined:</p> <p>192.0.0.0 – 193.255.255.255: Multi-regional</p> <p>194.0.0.0 – 195.255.255.255: European Union</p> <p>196.0.0.0 – 197.255.255.255: Other1</p> <p>198.0.0.0 – 199.255.255.255: North America</p> <p>200.0.0.0 – 201.255.255.255: Central and South America</p> <p>202.0.0.0 – 203.255.255.255: Pacific Rim</p> <p>204.0.0.0 – 205.255.255.255: Other2</p> <p>206.0.0.0 – 207.255.255.255: Other3</p>
ns_header_cookie	Tests for HTTP connections that contain a Cookie header
ns_header_pragma	Tests for HTTP connections that contain a Pragma: no-cache header.
ns_mozilla_47	Tests for HTTP connections whose User-Agent header contains the string Mozilla/4.7—in other words, any connection from a client using the Mozilla 4.7 Web browser.
ns_msexcel	Tests for HTTP connections whose Content-Type header contains the string application/vnd.ms-excel—in other words, any connection transmitting a Microsoft Excel spreadsheet.
ns_msie	Tests for HTTP connections whose User-Agent header contains the string MSIE—in other words, any connection from a client using any version of the Internet Explorer Web browser.
ns_msppt	Tests for HTTP connections whose Content-Type header contains the string application/vnd.ms-powerpoint—in other words, any connection transmitting a Microsoft PowerPoint file.
ns_msword	Tests for HTTP connections whose Content-Type header contains the string

Expression	Definition
	application/vnd.msword—in other words, any connection transmitting a Microsoft Word file.
ns_non_get	Tests for HTTP connections that use any HTTP method except for GET.
ns_slowclient	Returns TRUE if the average round trip time between the client and the NetScaler is more than 80 milliseconds.
ns_true	Returns TRUE for all traffic.
ns_url_path_bin	Tests the URL path to see if it points to the /bin/ directory.
ns_url_path_cgibin	Tests the URL path to see if it points to the CGI-BIN directory.
ns_url_path_exec	Tests the URL path to see if it points to the /exec/ directory.
ns_url_tokens	Tests for the presence of URL tokens.
ns_xmldata	Tests for the presence of XML data.

Built-In Named Expressions (Anti-Virus)

Expression	Definition
McAfee Virus Scan 11	Tests to determine whether the client is running the latest version of McAfee VirusScan.
McAfee Antivirus	Tests to determine whether the client is running any version of McAfee Antivirus.
Symantec AntiVirus 10 (with Updated Definition File)	Tests to determine whether the client is running the most current version of Symantec AntiVirus.
Symantec AntiVirus 6.0	Tests to determine whether the client is running Symantec AntiVirus 6.0.
Symantec AntiVirus 7.5	Tests to determine whether the client is running Symantec AntiVirus 7.5.

Expression	Definition
OfficeScan 7.3	Tests to determine whether the client is running Trend Microsystems' OfficeScan, version 7.3.
TrendMicro AntiVirus 11.25	Tests to determine whether the client is running Trend Microsystems' AntiVirus, version 11.25.
Sophos Antivirus 4	Tests to determine whether the client is running Sophos Antivirus, version 4.
Sophos Antivirus 5	Tests to determine whether the client is running Sophos Antivirus, version 5.
Sophos Antivirus 6	Tests to determine whether the client is running Sophos Antivirus, version 6.

Built-In Named Expressions (Personal Firewall)

Expression	Definition
TrendMicro OfficeScan 7.3	Tests to determine whether the client is running Trend Microsystems' OfficeScan, version 7.3.
Sygate Personal Firewall 5.6	Tests to determine whether the client is running the Sygate Personal Firewall, version 5.6.
ZoneAlarm Personal Firewall 6.5	Tests to determine whether the client is running the ZoneAlarm Personal Firewall, version 6.5.

Built-In Named Expressions (Client Security)

Expression	Definition
Norton Internet Security	Tests to determine whether the client is running any version of Norton Internet Security.

Summary Examples of Default Syntax Expressions and Policies

Jul 10, 2013

The following table provides examples of default syntax expressions that you can use as the basis for your own default syntax expressions.

Table 1. Examples of Default Syntax Expressions

Expression Type	Sample Expressions
Look at the method used in the HTTP request.	<pre>http.req.method.eq(post)</pre> <pre>http.req.method.eq(get)</pre>
Check the Cache-Control or Pragma header value in an HTTP request (req) or response (res).	<pre>http.req.header("Cache-Control").contains("no-store")</pre> <pre>http.req.header("Cache-Control").contains("no-cache")</pre> <pre>http.req.header("Pragma").contains("no-cache")</pre> <pre>http.res.header("Cache-Control").contains("private")</pre> <pre>http.res.header("Cache-Control").contains("public")</pre> <pre>http.res.header("Cache-Control").contains("must-revalidate")</pre> <pre>http.res.header("Cache-Control").contains("proxy-revalidate")</pre> <pre>http.res.header("Cache-Control").contains("max-age")</pre>
Check for the presence of a header in a request (req) or response (res).	<pre>http.req.header("myHeader").exists</pre> <pre>http.res.header("myHeader").exists</pre>
Look for a particular file type in an HTTP request based on the file extension.	<pre>http.req.url.contains(".html")</pre> <pre>http.req.url.contains(".cgi")</pre> <pre>http.req.url.contains(".asp")</pre>

Expression Type	Sample Expressions
	<pre>http.req.url.contains(".exe") http.req.url.contains(".cfm") http.req.url.contains(".ex") http.req.url.contains(".shtml") http.req.url.contains(".htx") http.req.url.contains("/cgi-bin/") http.req.url.contains("/exec/") http.req.url.contains("/bin/")</pre>
<p>Look for anything that is other than a particular file type in an HTTP request.</p>	<pre>http.req.url.contains(".gif").not http.req.url.contains(".jpeg").not</pre>
<p>Check the type of file that is being sent in an HTTP response based on the Content-Type header.</p>	<pre>http.res.header("Content-Type").contains("text") http.res.header("Content-Type").contains("application/msword") http.res.header("Content-Type").contains("vnd.ms-excel") http.res.header("Content-Type").contains("application/vnd.ms-powerpoint") http.res.header("Content-Type").contains("text/css") http.res.header("Content-Type").contains("text/xml") http.res.header("Content-Type").contains("image")</pre>
<p>Check whether this response contains an expiration header.</p>	<pre>http.res.header("Expires").exists</pre>
<p>Check for a Set-Cookie header in a response.</p>	<pre>http.res.header("Set-Cookie").exists</pre>
<p>Check the agent that sent the response.</p>	<pre>http.res.header("User-Agent").contains("Mozilla/4.7") http.res.header("User-Agent").contains("MSIE")</pre>
<p>Check if the first 1024 bytes of the body of a request starts with</p>	<pre>http.req.body(1024).contains("some text")</pre>

the string "some text".
Expression Type

Sample Expressions

The following table shows examples of policy configurations and bindings for commonly used functions.

Table 2. Examples of Default Syntax Expressions and Policies

Purpose	Example
Use the rewrite feature to replace occurrences of http:// with https:// in the body of an HTTP response.	<pre>add rewrite action httpRewriteAction replace_all http.res.body(50000) "\"https://\"" -pattern http:// add rewrite policy demo_rep34312 "http.res.body(50000).contains(\"http://\")" httpRewriteAction</pre>
Replace all occurrences of "abcd" with "1234" in the first 1000 bytes of the HTTP body.	<pre>add rewrite action abcdTo1234Action replace_all "http.req.body(1000)" "\"1234\"" -pattern abcd add rewrite policy abcdTo1234Policy "http.req.body(1000).contains(\"abcd\")" abcdTo1234Action bind rewrite global abcdTo1234Policy 100 END -type REQ_OVERRIDE</pre>
Downgrade the HTTP version to 1.0 to prevent the server from chunking HTTP responses.	<pre>add rewrite action downgradeTo1.0Action replace http.req.version.minor "\"0\"" add rewrite policy downgradeTo1.0Policy "http.req.version.minor.eq(1)" downgradeTo1.0Action bind lb vserver myLBVserver -policyName downgradeTo1.0Policy -priority 100 - gotoPriorityExpression NEXT -type REQUEST</pre>
Remove references to the HTTP or HTTPS protocol in all responses, so that if the user's connection is HTTP, the link is opened by using HTTP, and if the user's connection is HTTPS, the link is opened by using HTTPS.	<pre>add rewrite action remove_http_https replace_all "http.res.body(1000000).set_text_mode(ignorecase)" "\"/\"" -pattern "re~https?:// HTTPS?://~" add rewrite policy remove_http_https true remove_http_https bind lb vserver test_vsvr -policyName remove_http_https -priority 20 -gotoPriorityExpression NEXT -type RESPONSE</pre>

<p>Purpose</p> <p>Rewrite instances of http:// to https:// in all URLs.</p> <p>This policy uses the responder functionality.</p>	<p>Example</p> <pre>add responder action httpToHttpsAction redirect "https://^" + http.req.hostname + http.req.url" - bypassSafetyCheck YES add responder policy httpToHttpsPolicy "!CLIENT.SSL.IS_SSL" httpToHttpsAction bind responder global httpToHttpsPolicy 1 END -type OVERRIDE</pre>
<p>Modify a URL to redirect from URL A to URL B. In this example, "file5.html" is appended to the path.</p> <p>This policy uses the responder functionality.</p>	<pre>add responder action appendFile5Action redirect "http://^" + http.req.hostname + http.req.url + "/file5.html/" -bypassSafetyCheck YES add responder policy appendFile5Policy "http.req.url.eq("/testsite/")" appendFile5Action bind responder global appendFile5Policy 1 END -type OVERRIDE</pre>
<p>Redirect an external URL to an internal URL.</p>	<pre>add rewrite action act_external_to_internal REPLACE 'http.req.hostname.server' "www.my.host.com" add rewrite policy pol_external_to_internal 'http.req.hostname.server.eq("www.external.host.com")' act_external_to_internal bind rewrite global pol_external_to_internal 100 END - type REQ_OVERRIDE</pre>
<p>Redirect requests to www.example.com that have a query string to www.Webn.example.com. The value n is derived from a server parameter in the query string, for example, server=5.</p>	<pre>add rewrite action act_redirect_query REPLACE q#http.req.header("Host").before_str(".example.com")' "Web" + http.req.url.query.value("server")# add rewrite policy pol_redirect_query q#http.req.header("Host").eq("www.example.com") && http.req.url.contains("?")' act_redirect_query#</pre>
<p>Limit the number of requests per second from a URL.</p>	<pre>add ns limitSelector ip_limit_selector http.req.url "client.ip.src" add ns limitIdentifier ip_limit_identifier -threshold 4 - timeSlice 3600 -mode request_rate -limitType smooth - selectorName ip_limit_selector add responder action my_Web_site_redirect_action redirect "http://www.mycompany.com/"</pre>

<p>Purpose</p>	<p>Example</p> <pre>add responder policy ip_limit_responder_policy "http.req.url.contains(\"myasp.asp\") && sys.check_limit(\"ip_limit_identifier\")" my_Web_site_redirect_action bind responder global ip_limit_responder_policy 100 END -type default</pre>
<p>Check the client IP address but pass the request without modifying the request.</p>	<pre>add rewrite policy check_client_ip_policy 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS HTTP.REQ.HEADER("client-ip").EXISTS' NOREWRITE bind rewrite global check_client_ip_policy 100 END</pre>
<p>Remove old headers from a request and insert an NS-Client header.</p>	<pre>add rewrite action del_x_forwarded_for delete_http_header x-forwarded-for add rewrite action del_client_ip delete_http_header client-ip add rewrite policy check_x_forwarded_for_policy 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS' del_x_forwarded_for add rewrite policy check_client_ip_policy 'HTTP.REQ.HEADER("client-ip").EXISTS' del_client_ip add rewrite action insert_ns_client_header insert_http_header NS-Client 'CLIENT.IP.SRC' add rewrite policy insert_ns_client_policy 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS HTTP.REQ.HEADER("client-ip").EXISTS' insert_ns_client_header bind rewrite global check_x_forwarded_for_policy 100 200 bind rewrite global check_client_ip_policy 200 300 bind rewrite global insert_ns_client_policy 300 END</pre>
<p>Remove old headers from a request, insert an NS-Client header, and then modify the “insert header” action so that the value of the inserted header contains the client IP values from the old headers and the NetScaler appliance's connection IP</p>	<pre>add rewrite action del_x_forwarded_for delete_http_header x-forwarded-for add rewrite action del_client_ip delete_http_header client-ip</pre>

<p>address. Purpose</p> <p>Note that this example repeats the previous example, with the exception of the final set rewrite action.</p>	<p>Example</p> <pre> add rewrite policy check_x_forwarded_for_policy 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS' del_x_forwarded_for add rewrite policy check_client_ip_policy 'HTTP.REQ.HEADER("client-ip").EXISTS' del_client_ip add rewrite action insert_ns_client_header insert_http_header NS-Client 'CLIENT.IP.SRC' add rewrite policy insert_ns_client_policy 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS HTTP.REQ.HEADER("client-ip").EXISTS' insert_ns_client_header bind rewrite global check_x_forwarded_for_policy 100 200 bind rewrite global check_client_ip_policy 200 300 bind rewrite global insert_ns_client_policy 300 END set rewrite action insert_ns_client_header - stringBuilderExpr 'HTTP.REQ.HEADER("x-forwarded- for").VALUE(0) + " " + HTTP.REQ.HEADER("client- ip").VALUE(0) + " " + CLIENT.IP.SRC' - bypassSafetyCheck YES </pre>
--	--

Tutorial Examples of Default Syntax Policies for Rewrite

May 26, 2015

With the rewrite feature, you can modify any part of an HTTP header, and, for responses, you can modify the HTTP body. You can use this feature to accomplish a number of useful tasks, such as removing unnecessary HTTP headers, masking internal URLs, redirecting Web pages, and redirecting queries or keywords.

In the following examples, you first create a rewrite action and a rewrite policy. Then you bind the policy globally.

This document includes the following details:

- [Redirecting an External URL to an Internal URL](#)
- [Redirecting a Query](#)
- [Rewriting HTTP to HTTPS](#)
- [Removing Unwanted Headers](#)
- [Reducing Web Server Redirects](#)
- [Masking the Server Header](#)

Redirecting an External URL to an Internal URL

Updated: 2013-10-29

This example describes how to create a rewrite action and rewrite policy that redirects an external URL to an internal URL. You create an action, called `act_external_to_internal`, that performs the rewrite. Then you create a policy called `pol_external_to_internal`.

To redirect an external URL to an internal URL by using the command line interface

- To create the rewrite action, at the command prompt, type:

```
add rewrite action act_external_to_internal REPLACE 'http.req.hostname.server' ""host_name_of_internal_Web_server"
```

- To create the rewrite policy, at the NetScaler command prompt, type:

```
add rewrite policy pol_external_to_internal 'http.req.hostname.server.eq("host_name_of_external_Web_server")'  
act_external_to_internal
```

- Bind the policy globally.

To redirect an external URL to an internal URL by using the configuration utility

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, click Add.
3. In the Create Rewrite Action dialog box, enter the name `act_external_to_internal`.
4. To replace the HTTP server host name with the internal server name, choose Replace from the Type list box.
5. In the Header Name field, type Host.
6. In the String expression for replacement text field, type the internal host name of your Web server.
7. Click Create and then click Close.

8. In the navigation pane, click Policies.
9. In the details pane, click Add.
10. In the Name field, type `pol_external_to_internal`. This policy will detect connections to the Web server.
11. In the Action drop-down menu, choose the action `act_external_to_internal`.
12. In the Expression editor, construct the following expression:

```
HTTP.REQ.HOSTNAME.SERVER.EQ("www.example.com")
```

13. Bind your new policy globally.

Redirecting a Query

This example describes how to create a rewrite action and rewrite policy that redirects a query to the proper URL. The example assumes that the request contains a Host header set to **www.example.com** and a GET method with the **string** `/query.cgi?server=5`. The redirect extracts the domain name from the host header and the number from the query string, and redirects the user's query to the server **Web5.example.com**, where the rest of the user's query is processed.

Note: Although the following commands appears on multiple lines, you should enter them on a single line without line breaks.

To redirect a query to the appropriate URL using the command line

- To create a rewrite action named `act_redirect_query` that replaces the HTTP server host name with the internal server name, type:

```
add rewrite action act_redirect_query REPLACE q#http.req.header("Host").before_str(".example.com") "'Web' + http.req.url.query.value("server")#
```

- To create a rewrite policy named `pol_redirect_query`, type the following commands at the NetScaler command prompt. This policy detects connections, to the Web server, that contain a query string. Do not apply this policy to connections that do not contain a query string:

```
add rewrite policy pol_redirect_query q#http.req.header("Host").eq("www.example.com") && http.req.url.contains("?")' act_redirect_query#
```

- Bind your new policy globally.

Because this rewrite policy is highly specific and should be run before any other rewrite policies, it is advisable to assign it a high priority. If you assign it a priority of 1, it will be evaluated first.

Rewriting HTTP to HTTPS

Updated: 2014-09-17

This example describes how to rewrite Web server responses to find all URLs that begin with the string "http" and replace that string with "https." You can use this to avoid having to update Web pages after moving a server from HTTP to HTTPS.

To redirect HTTP URLs to HTTPS by using the command line interface

- To create a rewrite action named `act_replace_http_with_https` that replaces all instances of the string "http" with the string "https," enter the following command:

```
add rewrite action act_replace_http_with_https replace_all 'http.res.body(100)' "'https'" -pattern http
```

- To create a rewrite policy named `pol_replace_http_with_https` that detects connections to the Web server, enter the following command:
`add rewrite policy pol_replace_http_with_https TRUE act_replace_http_with_https NOREWRITE`
- Bind your new policy globally.

To troubleshoot this rewrite operation, see "[Case Study: Rewrite Policy for Converting HTTP Links to HTTPS not Working.](#)"

Removing Unwanted Headers

Updated: 2013-09-02

This example explains how to use a Rewrite policy to remove unwanted headers. Specifically, the example shows how to remove the following headers:

- **Accept Encoding header.** Removing the Accept Encoding header from HTTP responses prevents compression of the response.
- **Content Location header.** Removing the Content Location header from HTTP responses prevents your server from providing a hacker with information that might allow a security breach.

To delete headers from HTTP responses, you create a rewrite action and a rewrite policy, and you bind the policy globally.

To create the appropriate Rewrite action by using the command line interface

At the command prompt, type one of the following commands to either remove the Accept Encoding header and prevent response compression or remove the Content Location header:

- `add rewrite action "act_remove-ae" delete_http_header "Accept-Encoding"`
- `add rewrite action "act_remove-cl" delete_http_header "Content-Location"`

To create the appropriate Rewrite policy by using the command line interface

At the command prompt, type one of the following commands to remove either the Accept Encoding header or the Content Location header:

- `add rewrite policy "pol_remove-ae" true "act_remove-ae"`
- `add rewrite policy "pol_remove-cl" true "act_remove-cl"`

To bind the policy globally by using the command line interface

At the command prompt, type one of the following commands, as appropriate, to globally bind the policy that you have created:

- `bind rewrite global pol_remove_ae 100`
- `bind rewrite global pol_remove_cl 200`

Reducing Web Server Redirects

This example explains how to use a Rewrite policy to modify connections to your home page and other URLs that end with a forward slash (/) to the default index page for your server, preventing redirects and reducing load on your server.

To modify directory-level HTTP requests to include the default home page by using

the command line

- To create a Rewrite action named action-default-homepage that modifies URLs that end in a forward slash to include the default home page index.html, type:

```
add rewrite action "action-default-homepage" replace q#http.req.url.path "/" "/index.html"#
```

- To create a Rewrite policy named policy-default-homepage that detects connections to your home page and applies your new action, type:

```
add rewrite policy "policy-default-homepage" q#http.req.url.path.EQ("/") "action-default-homepage"#
```

- Globally bind your new policy to put it into effect.

Masking the Server Header

This example explains how to use a Rewrite policy to mask the information in the Server header in HTTP responses from your Web server. That header contains information that hackers can use to compromise your Web site. While masking the header will not prevent a skilled hacker from finding out information about your server, it will make hacking your Web server more difficult and encourage hackers to choose less well protected targets.

To mask the Server header in responses from the command line

1. To create a Rewrite action named act_mask-server that replaces the contents of the Server header with an uninformative string, type:

```
add rewrite action "act_mask-server" replace "http.RES.HEADER(\"Server\")" "\"Web Server 1.0\""
```

2. To create a Rewrite policy named pol_mask-server that detects all connections, type:

```
add rewrite policy "pol_mask-server" true "act_mask-server"
```

3. Globally bind your new policy to put it into effect.

Tutorial Examples of Classic Policies

May 26, 2015

The following examples describe useful examples of classic policy configuration for certain NetScaler features, such as NetScaler Gateway, application firewall, and SSL.

This document includes the following details:

- [NetScaler Gateway Policy to Check for a Valid Client Certificate](#)
- [Application Firewall Policy to Protect a Shopping Cart Application](#)
- [Application Firewall Policy to Protect Scripted Web Pages](#)
- [DNS Policy to Drop Packets from Specific IPs](#)
- [SSL Policy to Require Valid Client Certificates](#)

NetScaler Gateway Policy to Check for a Valid Client Certificate

Updated: 2014-09-25

The following policies enable the NetScaler to ensure that a client presents a valid certificate before establishing a connection to a company's SSL VPN.

To check for a valid client certificate by using the command line interface

- Add an action to perform client certificate authentication.

```
add ssl action act1 -clientAuth DOCLIENTAUTH
```

- Create an SSL policy to evaluate the client requests.

```
add ssl policy pol1 -rule "REQ.HTTP.METHOD == GET" -action act1
```

- Add a rewrite action to insert the certificate issuer details into the HTTP header of the requests being sent to web server.

```
add rewrite action act2 insert_http_header "CertDN" CLIENT.SSL.CLIENT_CERT.SUBJECT
```

- Create a rewrite policy to insert the certificate issuer details, if the client certificate exists.

```
add rewrite policy pol2 "CLIENT.SSL.CLIENT_CERT.EXISTS" act2
```

Bind these new policies to the NetScaler VIP to put them into effect.

Application Firewall Policy to Protect a Shopping Cart Application

Updated: 2013-09-02

Shopping cart applications handle sensitive customer information, for example, credit card numbers and expiration dates, and they access back-end database servers. Many shopping cart applications also use legacy CGI scripts, which can contain security flaws that were unknown at the time they were written, but are now known to hackers and identity thieves.

A shopping cart application is particularly vulnerable to the following attacks:

- **Cookie tampering.** If a shopping cart application uses cookies, and does not perform the appropriate checks on the

cookies that users return to the application, an attacker could modify a cookie and gain access to the shopping cart application under another user's credentials. Once logged on as that user, the attacker could obtain sensitive private information about the legitimate user or place orders using the legitimate user's account.

- **SQL injection.** A shopping cart application normally accesses a back-end database server. Unless the application performs the appropriate safety checks on the data users return in the form fields of its Web forms before it passes that information on to the SQL database, an attacker can use a Web form to inject unauthorized SQL commands into the database server. Attackers normally use this type of attack to obtain sensitive private information from the database or modify information in the database.

The following configuration will protect a shopping cart application against these and other attacks.

To protect a shopping cart application by using the configuration utility

1. Navigate to Security > Application Firewall > Profiles, and then click Add.
2. In the Create Application Firewall Profile dialog box, in the Profile Name field, enter shopping_cart.
3. In the Profile Type drop-down list, select Web Application.
4. In the Configure Select Advanced defaults.
5. Click Create and then click Close.
6. In the details view, double-click the new profile.
7. In the Configure Web Application Profile dialog box, configure your new profile as described below:
 1. Click the Checks tab, double-click the Start URL check, and in the Modify Start URL Check dialog box, click the General tab and disable blocking, and enable learning, logging, statistics, and URL closure. Click OK and then click Close.

Note that if you are using the command line, you configure these settings by typing the following at the prompt, and pressing ENTER:

```
set appfw profile shopping_cart -startURLAction LEARN LOG STATS -startURLClosure ON
```

2. For the Cookie Consistency check and Form Field Consistency checks, disable blocking, and enable learning, logging, statistics, using a similar method to the Modify Start URL Check configuration.

If you are using the command line, you configure these settings by typing the following commands:

```
set appfw profile shopping_cart -cookieConsistencyAction LEARN LOG STATS
```

```
set appfw profile shopping_cart -fieldConsistencyAction LEARN LOG STATS
```

3. For the SQL Injection check, disable blocking, and enable learning, logging, statistics, and transformation of special characters in the Modify SQL Injection Check dialog box, General tab, Check Actions section.

If you are using the command line, you configure these settings by typing the following at the prompt, and pressing ENTER:

```
set appfw profile shopping_cart -SQLInjectionAction LEARN LOG STATS -SQLInjectionTransformSpecialChars ON
```

4. For the Credit Card check, disable blocking; enable logging, statistics, and masking of credit card numbers; and enable protection for those credit cards you accept as forms of payment.

- If you are using the configuration utility, you configure blocking, logging, statistics, and masking (or x-out) in the Modify Credit Card Check dialog box, General tab, Check Actions section. You configure protection for specific credit cards in the Settings tab of the same dialog box.

- If you are using the command line, you configure these settings by typing the following at the prompt, and pressing ENTER:
set appfw profile shopping_cart -creditCardAction LOG STATS -creditCardXOut ON -creditCard <name> [<name>...]

For <name> you substitute the name of the credit card you want to protect. For Visa, you substitute VISA. For Master Card, you substitute MasterCard. For American Express, you substitute Amex. For Discover, you substitute Discover. For Diners Club, you substitute DinersClub. For JCB, you substitute JCB.

8. Create a policy named shopping_cart that detects connections to your shopping cart application and applies the shopping_cart profile to those connections.

To detect connections to the shopping cart, you examine the URL of incoming connections. If you host your shopping cart application on a separate host (a wise measure for security and other reasons), you can simply look for the presence of that host in the URL. If you host your shopping cart in a directory on a host that handles other traffic, as well, you must determine that the connection is going to the appropriate directory and/or HTML page.

The process for detecting either of these is the same; you create a policy based on the following expression, and substitute the proper host or URL for <string>.

REQ.HTTP.HEADER URL CONTAINS <string>

- If you are using the configuration utility, you navigate to the application firewall Policies page, click the Add... button to add a new policy, and follow the policy creation process described in “To create a policy with classic expressions using the configuration utility” beginning on page 201 and following.
- If you are using the command line, you type the following command at the prompt and press Enter:
add appfw policy shopping_cart "REQ.HTTP.HEADER URL CONTAINS <string>" shopping_cart

9. Globally bind your new policy to put it into effect.

Because you want to ensure that this policy will match all connections to the shopping cart, and not be preempted by another more general policy, you should assign a high priority to it. If you assign one (1) as the priority, no other policy can preempt this one.

Application Firewall Policy to Protect Scripted Web Pages

Updated: 2013-11-14

Web pages with embedded scripts, especially legacy JavaScripts, often violate the “same origin rule,” which does not allow scripts to access or modify content on any server but the server where they are located. This security vulnerability is called cross-site scripting. The application firewall Cross-Site Scripting rule normally filters out requests that contain cross-site scripting.

Unfortunately, this can cause Web pages with older JavaScripts to stop functioning, even when your system administrator has checked those scripts and knows that they are safe. The example below explains how to configure the application firewall to allow cross-site scripting in Web pages from trusted sources without disabling this important filter for the rest of your Web sites.

To protect Web pages with cross-site scripting by using the command line interface

- At the command line, to create an advanced profile, type:

add appfw profile pr_xssokay -defaults advanced

- To configure the profile, type:

```
set appfw profile pr_xssokay -startURLAction NONE -startURLClosure OFF -cookieConsistencyAction LEARN LOG  
STATS -fieldConsistencyAction LEARN LOG STATS -crossSiteScriptingAction LEARN LOG STAT$"
```

- Create a policy that detects connections to your scripted Web pages and applies the pr_xssokay profile, type:

```
add appfw policy pol_xssokay "REQ.HTTP.HEADER URL CONTAINS ^\,p\|?$ || REQ.HTTP.HEADER URL CONTAINS ^\,js$"
pr_xssokay
```

- Globally bind the policy.

To protect Web pages with cross-site scripting by using the configuration utility

1. Navigate to Security > Application Firewall > Profiles.
2. In the details view, click Add.
3. In the Create Application Firewall Profile dialog box, create a Web Application profile with advanced defaults and name it pr_xssokay. Click Create and then click Close.
4. In the details view, click the profile, click Open, and in the Configure Web Application Profile dialog box, configure the pr_xssokay profile as shown below.

Start URL Check: Clear all actions.

- Cookie Consistency Check: Disable blocking.
- Form Field Consistency Check: Disable blocking.
- Cross-Site Scripting Check: Disable blocking.

This should prevent blocking of legitimate requests involving Web pages with cross-site scripting that you know are nonetheless safe.

5. Click Policies, and then click Add.
6. In the Create Application Firewall Policy dialog box, create a policy that detects connections to your scripted Web pages and applies the pr_xssokay profile:

- Policy name: pol_xssokay
- Associated profile: pr_xssokay

Policy expression: "REQ.HTTP.HEADER URL CONTAINS ^\,p\|?\$ || REQ.HTTP.HEADER URL CONTAINS ^\,js\$"

7. Globally bind your new policy to put it into effect.

DNS Policy to Drop Packets from Specific IPs

Updated: 2013-09-02

The following example describes how to create a DNS action and DNS policy that detects connections from unwanted IPs or networks, such as those used in a DDOS attack, and drops all packets from those locations. The example shows networks within the IANA reserved IP block 192.168.0.0/16. A hostile network will normally be on publicly routable IPs.

To drop packets from specific IPs by using the command line interface

- To create a DNS policy named pol_ddos_drop that detects connections from hostile networks and drops those packets,

type:

```
add dns policy pol_ddos_drop 'client.ip.src.in_subnet(192.168.253.128/25) || client.ip.src.in_subnet(192.168.254.32/27)' -drop YES'
```

For the example networks in the 192.168.0.0/16 range, you substitute the IP and netmask in ###.###.###.###/## format of each network you want to block. You can include as many networks as you want, separating each CLIENT.IP.SRC.IN_SUBNET(###.###.###.###/##) command with the OR operator.

- Globally bind your new policy to put it into effect.

SSL Policy to Require Valid Client Certificates

Updated: 2013-09-02

The following example shows an SSL policy that checks the user's client certificate validity before initiating an SSL connection with a client.

To block connections from users with expired client certificates

- Log on to the command line interface.
If you are using the GUI, navigate to the SSL Policies page, then in the Data area, click the Actions tab.
- Create an SSL action named act_current_client_cert that requires that users have a current client certificate to establish an SSL connection with the NetScaler.

```
add ssl action act_current_client_cert-clientAuth DOCLIENTAUTH -clientCert ENABLED -certHeader "clientCertificateHeader" -clientCertNotBefore ENABLED -certNotBeforeHeader "Mon, 01 Jan 2007 00:00:00 GMT"
```

- Create an SSL policy named pol_current_client_cert that detects connections to the Web server that contain a query string.

```
add ssl policy pol_current_client_cert 'REQ.SSL.CLIENT.CERT.VALIDFROM >= "Mon, 01 Jan 2007 00:00:00 GMT"' act_block_ssl
```

- Bind your new policy globally.

Because this SSL policy should apply to any user's SSL connection unless a more specific SSL policy applies, you may want to assign it a low priority. If you assign it a priority of one thousand (1000), that should ensure that other SSL policies are evaluated first, meaning that this policy will apply only to connections that do not match more specific policy criteria.

Migration of Apache mod_rewrite Rules to the Default Syntax

May 26, 2015

The Apache HTTP Server provides an engine known as mod_rewrite for rewriting HTTP request URLs. If you migrate the mod_rewrite rules from Apache to the NetScaler, you boost back-end server performance. In addition, because the NetScaler typically load balances multiple (sometimes thousands of) Web servers, after migrating the rules to the NetScaler you will have a single point of control for these rules.

Following are examples of mod_rewrite functions, and translations of these functions into Rewrite and Responder policies on the NetScaler.

This document includes the following details:

- [Converting URL Variations into Canonical URLs](#)
- [Converting Host Name Variations to Canonical Host Names](#)
- [Moving a Document Root](#)
- [Moving Home Directories to a New Web Server](#)
- [Working with Structured Home Directories](#)
- [Redirecting Invalid URLs to Other Web Servers](#)
- [Rewriting a URL Based on Time](#)
- [Redirecting to a New File Name \(Invisible to the User\)](#)
- [Redirecting to New File Name \(User-Visible URL\)](#)
- [Accommodating Browser Dependent Content](#)
- [Blocking Access by Robots](#)
- [Blocking Access to Inline Images](#)
- [Creating Extensionless Links](#)
- [Redirecting a Working URI to a New Format](#)
- [Ensuring That a Secure Server Is Used for Selected Pages](#)

Converting URL Variations into Canonical URLs

On some Web servers you can have multiple URLs for a resource. Although the canonical URLs should be used and distributed, other URLs can exist as shortcuts or internal URLs. You can make sure that users see the canonical URL regardless of the URL used to make an initial request.

In the following examples, the URL /-user is converted to /u/user.

Apache mod_rewrite solution for converting a URL

```
RewriteRule ^/~([^/]+)/?(.*) /u/$1$2[R]
```

NetScaler solution for converting a URL

```
add responder action act1 redirect "'/u/'+HTTP.REQ.URL.AFTER_STR('/~') -bypassSafetyCheck yes
add responder policy pol1 'HTTP.REQ.URL.STARTSWITH('/~') && HTTP.REQ.URL.LENGTH.GT(2)' act1
bind responder global pol1 100
```

Converting Host Name Variations to Canonical Host Names

You can enforce the use of a particular host name for reaching a site. For example, you can enforce the use of www.example.com instead of example.com.

Apache mod_rewrite solution for enforcing a particular host name for sites running on a port other than 80

```
RewriteCond %{HTTP_HOST} !^www.example.com
RewriteCond %{HTTP_HOST} !^$
RewriteCond %{SERVER_PORT} !^80$
RewriteRule ^/(.*) http://www.example.com:%{SERVER_PORT}/$1 [L,R]
```

Apache mod_rewrite solution for enforcing a particular host name for sites running on port 80

```
RewriteCond %{HTTP_HOST} !^www.example.com
RewriteCond %{HTTP_HOST} !^$
RewriteRule ^/(.*) http://www.example.com/$1 [L,R]
```

NetScaler solution for enforcing a particular host name for sites running on a port other than 80

```
add responder action act1 redirect "'http://www.example.com:'+CLIENT.TCP.DSTPORT+HTTP.REQ.URL' -bypassSafetyCheck yes
add responder policy pol1 '!HTTP.REQ.HOSTNAME.CONTAINS('www.example.com')&&!HTTP.REQ.HOSTNAME.EQ('')&&!HTTP.REQ.HOSTNAME.PORT.EQ(80)&&HTTP.REQ.HOSTNAME.CONT
bind responder global pol1 100 END
```

NetScaler solution for enforcing a particular host name for sites running on port 80

```
add responder action act1 redirect "'http://www.example.com'+HTTP.REQ.URL' -bypassSafetyCheck yes
add responder policy pol1 '!HTTP.REQ.HOSTNAME.CONTAINS('www.example.com')&&!HTTP.REQ.HOSTNAME.EQ('')&&HTTP.REQ.HOSTNAME.PORT.EQ(80)&&HTTP.REQ.HOSTNAME.CONT
bind responder global pol1 100 END
```

Moving a Document Root

Usually the document root of a Web server is based on the URL "/". However, the document root can be any directory. You can redirect traffic to the document root if it changes from the top-level "/" directory to another directory.

In the following examples, you change the document root from / to /e/www. The first two examples simply replace one string with another. The third example is more universal because, along with replacing the root directory, it preserves the rest of the URL (the path and query string), for example, redirecting /example/file.html to /e/www/example/file.html.

Apache mod_rewrite solution for moving the document root

```
RewriteEngine on
```

```
RewriteRule ^/$ /e/www/ [R]
```

NetScaler solution for moving the document root

```
add responder action act1 redirect ""/e/www/" -bypassSafetyCheck yes
```

```
add responder policy pol1 'HTTP.REQ.URL.EQ("/")' act1
```

```
bind responder global pol1 100
```

NetScaler solution for moving the document root and appending path information to the request

```
add responder action act1 redirect ""/e/www"+HTTP.REQ.URL' -bypassSafetyCheck yes
```

```
add responder policy pol1 'HTTP.REQ.URL.STARTSWITH("/e/www/")' act1
```

```
bind responder global pol1 100 END
```

Moving Home Directories to a New Web Server

You may want to redirect requests that are sent to home directories on a Web server to a different Web server. For example, if a new Web server is replacing an old one over time, as you migrate home directories to the new location you need to redirect requests for the migrated home directories to the new Web server.

In the following examples, the host name for the new Web server is newserver.

Apache mod_rewrite solution for redirecting to another Web server

```
RewriteRule ^/(+) http://newserver/$1 [R,L]
```

NetScaler solution for redirecting to another Web server (method 1)

```
add responder action act1 redirect ""http://newserver"+HTTP.REQ.URL' -bypassSafetyCheck yes
```

```
add responder policy pol1 'HTTP.REQ.URL.REGEX_MATCH(re#/(+)#)' act1
```

```
bind responder global pol1 100 END
```

NetScaler solution for redirecting to another Web server (method 2)

```
add responder action act1 redirect ""http://newserver"+HTTP.REQ.URL' -bypassSafetyCheck yes
```

```
add responder policy pol1 'HTTP.REQ.URL.LENGTH.GT(1)' act1
```

```
bind responder global pol1 100 END
```

Working with Structured Home Directories

Typically, a site with thousands of users has a structured home directory layout. For example, each home directory may reside under a subdirectory that is named using the first character of the user name. For example, the home directory for jsmith (/~jsmith/anypath) might be /home/j/smith/.www/anypath, and the home directory for rvalveti (/~rvalveti/anypath) might be /home/r/rvalveti/.www/anypath.

The following examples redirect requests to the home directory.

Apache mod_rewrite solution for structured home directories

```
RewriteRule ^/~([a-z])[a-z0-9]+(.*) /home/$2/$1/.www$3
```

NetScaler solution for structured home directories

NetScaler solution for structured home directories

```
add rewrite action act1 replace 'HTTP.REQ.URL' ""/home/" + HTTP.REQ.URL.AFTER_STR("~").PREFIX(1)+" "+ HTTP.REQ.URL.AFTER_STR("~").BEFORE_STR("~")+ ".www" + HTTP.REQ.URL.SKIP(
```

```
add rewrite policy pol1 'HTTP.REQ.URL.PATH.STARTSWITH("/~")' act1
```

```
bind rewrite global pol1 100
```

Redirecting Invalid URLs to Other Web Servers

If a URL is not valid, it should be redirected to another Web server. For example, you should redirect to another Web server if a file that is named in a URL does not exist on the server that is named in the URL.

On Apache, you can perform this check using mod_rewrite. On the NetScaler, an HTTP callout can check for a file on a server by running a script on the server. In the following NetScaler examples, a script named file_check.cgi processes the URL and uses this information to check for the presence of the target file on the server. The script returns TRUE or FALSE, and the NetScaler uses the value that the script returns to validate the policy.

In addition to performing the redirection, the NetScaler can add custom headers or, as in the second NetScaler example, it can add text in the response body.

Apache mod_rewrite solution for redirection if a URL is wrong

```
RewriteCond /your/docroot%{REQUEST_FILENAME} !f
```

```
RewriteRule ^/(+) http://webserverB.com/$1 [R]
```

NetScaler solution for redirection if a URL is wrong (method 1)

```
add HTTPCallout Call
```

```
set policy httpCallout Call -IPAddress 10.102.59.101 -port 80 -hostExpr ""10.102.59.101" -returnType BOOL -ResultExpr 'HTTP.RES.BODY(100).CONTAINS("True")' -urlStemExpr ""/cgi-bin/file_check.cg
```

```
add responder action act1 redirect ""http://webserverB.com"+HTTP.REQ.URL' -bypassSafetyCheck yes
```

```
add responder policy pol1 'HTTP.REQ.HEADER("Name").EXISTS && !SYS.HTTP_CALLOUT(call)' act1
```

```
bind responder global pol1 100
```

NetScaler solution for redirection if a URL is wrong (method 2)

```

add HTTPCallout Call
set policy httpCallout Call -IPAddress 10.102.59.101 -port 80 -hostExpr ""10.102.59.101"" -returnType BOOL -ResultExpr 'HTTP.RES.BODY(100).CONTAINS("True")' -urlStemExpr ""/cgi-bin/file_check.cg
add responder action act1 respondwith ""HTTP/1.1 302 Moved Temporarily\r\nLocation: http://webserverB.com"+HTTP.REQ.URL+"\r\n\r\nHTTPCallout Used"" -bypassSafetyCheck yes
add responder policy pol1 'HTTP.REQ.HEADER("Name").EXISTS && !SYS.HTTP_CALLOUT(call)' act1
bind responder global pol1 100

```

Rewriting a URL Based on Time

You can rewrite a URL based on the time. The following examples change a request for example.html to example.day.html or example.night.html, depending on the time of day.

Apache mod_rewrite solution for rewriting a URL based on the time

```

RewriteCond %{TIME_HOUR}%{TIME_MIN} >0700
RewriteCond %{TIME_HOUR}%{TIME_MIN} <1900
RewriteRule ^example\.html$ example.day.html [L]
RewriteRule ^example\.html$ example.night.html

```

NetScaler solution for rewriting a URL based on the time

```

add rewrite action act1 insert_before 'HTTP.REQ.URL.PATH.SUFFIX('\',0)' ""day.""
add rewrite action act2 insert_before 'HTTP.REQ.URL.PATH.SUFFIX('\',0)' ""night.""
add rewrite policy pol1 'SYS.TIME.WITHIN(LOCAL 07h 00m,LOCAL 18h 59m)' act1
add rewrite policy pol2 'true' act2
bind rewrite global pol1 101
bind rewrite global pol2 102

```

Redirecting to a New File Name (Invisible to the User)

If you rename a Web page, you can continue to support the old URL for backward compatibility while preventing users from recognizing that the page was renamed.

In the first two of the following examples, the base directory is /~quux/. The third example accommodates any base directory and the presence of query strings in the URL.

Apache mod_rewrite solution for managing a file name change in a fixed location

```

RewriteEngine on
RewriteBase /~quux/
RewriteRule ^foo\.html$ bar.html

```

NetScaler solution for managing a file name change in a fixed location

```

add rewrite action act1 replace 'HTTP.REQ.URL.AFTER_STR("/~quux/").SUBSTR("foo.html)" "bar.html"
add rewrite policy pol1 'HTTP.REQ.URL.ENDSWITH("/~quux/foo.html)" act1
bind rewrite global pol1 100

```

NetScaler solution for managing a file name change regardless of the base directory or query strings in the URL

```

add rewrite action act1 replace 'HTTP.REQ.URL.PATH.SUFFIX('\',0)' ""bar.html""
Add rewrite policy pol1 'HTTP.REQ.URL.PATH.CONTAINS("foo.html)" act1
Bind rewrite global pol1 100

```

Redirecting to New File Name (User-Visible URL)

If you rename a Web page, you may want to continue to support the old URL for backward compatibility and allow users to see that the page was renamed by changing the URL that is displayed in the browser.

In the first two of the following examples, redirection occurs when the base directory is /~quux/. The third example accommodates any base directory and the presence of query strings in the URL.

Apache mod_rewrite solution for changing the file name and the URL displayed in the browser

```

RewriteEngine on
RewriteBase /~quux/
RewriteRule ^old\.html$ new.html [R]

```

NetScaler solution for changing the file name and the URL displayed in the browser

```

add responder action act1 redirect 'HTTP.REQ.URL.BEFORE_STR("foo.html")+new.html" -bypassSafetyCheck yes
add responder policy pol1 'HTTP.REQ.URL.ENDSWITH("/~quux/old.html)" act1
bind responder global pol1 100

```

NetScaler solution for changing the file name and the URL displayed in the browser regardless of the base directory or query strings in the URL

```

add responder action act1 redirect 'HTTP.REQ.URL.PATH.BEFORE_STR("old.html")+new.html"+HTTP.REQ.URL.AFTER_STR("old.html)" -bypassSafetyCheck yes
add responder policy pol1 'HTTP.REQ.URL.PATH.CONTAINS("old.html)" act1
bind responder global pol1 100

```

Accommodating Browser Dependent Content

To accommodate browser-specific limitations—at least for important top-level pages—it is sometimes necessary to set restrictions on the browser type and version. For example, you might want to set a maximum version for the latest Netscape variants, a minimum version for Lynx browsers, and an average feature version for all others.

The following examples act on the HTTP header "User-Agent", such that if this header begins with "Mozilla/3", the page MyPage.html is rewritten to MyPage.NS.html. If the browser is "Lynx" or "Mozilla" version 1 or 2, the URL becomes MyPage.20.html. All other browsers receive page MyPage.32.html.

Apache mod_rewrite solution for browser-specific settings

```
RewriteCond %{HTTP_USER_AGENT} ^Mozilla/3.*
RewriteRule ^MyPage\.html$ MyPage.NS.html [L]
RewriteCond %{HTTP_USER_AGENT} ^Lynx/.* [OR]
RewriteCond %{HTTP_USER_AGENT} ^Mozilla/[12].*
RewriteRule ^MyPage\.html$ MyPage.20.html [L]
RewriteRule ^MyPage\.html$ MyPage.32.html [L]
NetScaler solution for browser-specific settings
add patset pat1
bind patset pat1 Mozilla/1
bind Patset pat1 Mozilla/2
bind patset pat1 Lynx
bind Patset pat1 Mozilla/3
add rewrite action act1 insert_before 'HTTP.REQ.URL.SUFFIX' ""NS.""
add rewrite action act2 insert_before 'HTTP.REQ.URL.SUFFIX' ""20.""
add rewrite action act3 insert_before 'HTTP.REQ.URL.SUFFIX' ""32.""
add rewrite policy pol1 'HTTP.REQ.HEADER("User-Agent").STARTSWITH_INDEX("pat1").EQ(4)' act1
add rewrite policy pol2 'HTTP.REQ.HEADER("User-Agent").STARTSWITH_INDEX("pat1").BETWEEN(1,3)' act2
add rewrite policy pol3 'HTTP.REQ.HEADER("User-Agent").STARTSWITH_ANY("pat1")' act3
bind rewrite global pol1 101 END
bind rewrite global pol2 102 END
bind rewrite global pol3 103 END
Blocking Access by Robots
```

You can block a robot from retrieving pages from a specific directory or a set of directories to ease up the traffic to and from these directories. You can restrict access based on the specific location or you can block requests based on information in User-Agent HTTP headers.

In the following examples, the Web location to be blocked is `/~quux/foo/arc/`, the IP addresses to be blocked are 123.45.67.8 and 123.45.67.9, and the robot's name is NameOfBadRobot.

Apache mod_rewrite solution for blocking a path and a User-Agent header

```
RewriteCond %{HTTP_USER_AGENT} ^NameOfBadRobot.*
RewriteCond %{REMOTE_ADDR} ^123\.45\.67\.[8-9]$
RewriteRule ^/~quux/foo/arc/.+ - [F]
```

NetScaler solution for blocking a path and a User-Agent header

```
add responder action act1 respondwith ""HTTP/1.1 403 Forbidden\r\n\r\n""
add responder policy pol1 'HTTP.REQ.HEADER("User-Agent").STARTSWITH("NameOfBadRobot")&&CLIENT.IP.SRC.EQ(123.45.67.8)&&CLIENT.IP.SRC.EQ(123.45.67.9) && HTTP.REQ.URL.STAF
bind responder global pol1 100
Blocking Access to Inline Images
```

If you find people frequently going to your server to copy inline graphics for their own use (and generating unnecessary traffic), you may want to restrict the browser's ability to send an HTTP Referer header.

In the following example, the graphics are located in `http://www.quux-corp.de/~quux/`.

Apache mod_rewrite solution for blocking access to an inline image

```
RewriteCond %{HTTP_REFERER} !^$
RewriteCond %{HTTP_REFERER} !^http://www.quux-corp.de/~quux/.*$
RewriteRule .*\.gif$ - [F]
```

NetScaler solution for blocking access to an inline image

```
add patset pat1
bind patset pat1 .gif
bind patset pat1 .jpeg
add responder action act1 respondwith ""HTTP/1.1 403 Forbidden\r\n\r\n""
add responder policy pol1 '!HTTP.REQ.HEADER("Referer").EQ("") && !HTTP.REQ.HEADER("Referer").STARTSWITH("http://www.quux-corp.de/~quux/")&&HTTP.REQ.URL.ENDSWITH_ANY("pat1")'
bind responder global pol1 100
Creating Extensionless Links
```

To prevent users from knowing application or script details on the server side, you can hide file extensions from users. To do this, you may want to support extensionless links. You can achieve this behavior by using rewrite rules to add an extension to all requests, or to selectively add extensions to requests.

The first two of the following examples show adding an extension to all request URLs. In the last example, one of two file extensions is added. Note that in the last example, the `mod_rewrite` module can easily find the file extension because this module resides on the Web server. In contrast, the NetScaler must invoke an HTTP callout to check the extension of the requested file on the Web server. Based on the callout response, the NetScaler adds the `.html` or `.php` extension to the request URL.

Note: In the second NetScaler example, an HTTP callout is used to query a script named `file_check.cgi` hosted on the server. This script checks whether the argument that is provided in the callout is a valid file name.

Apache mod_rewrite solution for adding a .php extension to all requests

```
RewriteRule ^/?([a-z]+)$ $1.php [L]
```

NetScaler policy for adding a .php extension to all requests

```
add rewrite action act1 insert_after 'HTTP.REQ.URL' ".php"
add rewrite policy pol1 'HTTP.REQ.URL.PATH.REGEX_MATCH(re#^/([a-z]+)$#)' act1
bind rewrite global pol1 100
```

Apache mod_rewrite solution for adding either .html or .php extensions to requests

```
RewriteCond %{REQUEST_FILENAME}.php -f
RewriteRule ^?([a-zA-Z0-9]+)$ $1.php [L]
RewriteCond %{REQUEST_FILENAME}.html -f
RewriteRule ^?([a-zA-Z0-9]+)$ $1.html [L]
```

NetScaler policy for adding either .html or .php extensions to requests

```
add HTTPCallout Call_html
add HTTPCallout Call_php
set policy httpCallout Call_html -IPAddress 10.102.59.101 -port 80 -hostExpr "10.102.59.101" -returnType BOOL -ResultExpr 'HTTP.RES.BODY(100).CONTAINS("True")' -urlStemExpr "/cgi-bin/file_ch
set policy httpCallout Call_php -IPAddress 10.102.59.101 -port 80 -hostExpr "10.102.59.101" -returnType BOOL -ResultExpr 'HTTP.RES.BODY(100).CONTAINS("True")' -urlStemExpr "/cgi-bin/file_che
add patset pat1
bind patset pat1 .html
bind patset pat1 .php
bind patset pat1 .asp
bind patset pat1 .cgi
add rewrite action act1 insert_after 'HTTP.REQ.URL.PATH' ".html"
add rewrite action act2 insert_after "HTTP.REQ.URL.PATH" ".php"
add rewrite policy pol1 'HTTP.REQ.URL.CONTAINS_ANY("pat1") && SYS.HTTP_CALLOUT(Call_html)' act1
add rewrite policy pol2 'HTTP.REQ.URL.CONTAINS_ANY("pat1") && SYS.HTTP_CALLOUT(Call_php)' act2
bind rewrite global pol1 100 END
bind rewrite global pol2 101 END
```

Redirecting a Working URI to a New Format

Suppose that you have a set of working URLs that resemble the following:

```
/index.php?id=nnnn
```

To change these URLs to /nnnn and make sure that search engines update their indexes to the new URI format, you need to do the following:

- Redirect the old URLs to the new ones so that search engines update their indexes.
- Rewrite the new URI back to the old one so that the index.php script runs correctly.

To accomplish this, you can insert marker code into the query string (making sure that the marker code is not seen by visitors), and then removing the marker code for the index.php script.

The following examples redirect from an old link to a new format only if a marker is not present in the query string. The link that uses the new format is re-written back to the old format, and a marker is added to the query string.

Apache mod_rewrite solution

```
RewriteCond %{QUERY_STRING} !marker
RewriteCond %{QUERY_STRING} id=([a-zA-Z0-9_+])
RewriteRule ^?index\.php$%1? [R,L]
RewriteRule ^?([a-zA-Z0-9_+])$ index.php?marker&id=$1 [L]
```

NetScaler solution

```
add responder action act_redirect redirect 'HTTP.REQ.URL.PATH.BEFORE_STR("index.php")+HTTP.REQ.URL.QUERY.VALUE("id") -bypassSafetyCheck yes
add responder policy pol_redirect 'HTTP.REQ.URL.QUERY.CONTAINS("marker")&& HTTP.REQ.URL.QUERY.VALUE("id").REGEX_MATCH(re-[a-zA-Z0-9_+]) && HTTP.REQ.URL.PATH.CONTAIN
bind responder global pol_redirect 100 END
add rewrite action act1 replace 'HTTP.REQ.URL.PATH.SUFFIX("\0")' "index.phpmarker&id="+HTTP.REQ.URL.PATH.SUFFIX("\0") -bypassSafetyCheck yes
add rewrite policy pol1 'HTTP.REQ.URL.QUERY.CONTAINS("marker")' act1
bind rewrite global pol1 100 END
```

Ensuring That a Secure Server Is Used for Selected Pages

To make sure that only secure servers are used for selected Web pages, you can use the following Apache mod_rewrite code or NetScaler Responder policies.

Apache mod_rewrite solution

```
RewriteCond %{SERVER_PORT} !=443$
RewriteRule ^?(page1|page2|page3|page4|page5)$ https://www.example.com/%1 [R,L]
```

NetScaler solution using regular expressions

```
add responder action res_redirect redirect "https://www.example.com"+HTTP.REQ.URL' -bypassSafetyCheck yes
add responder policy pol_redirect 'CLIENT.TCP.DSTPORT.EQ(443)&&HTTP.REQ.URL.REGEX_MATCH(re/page[1-5])' res_redirect
bind responder global pol_redirect 100 END
```

NetScaler solution using pattern sets

```
add patset pat1
bind patset pat1 page1
bind patset pat1 page2
bind patset pat1 page3
bind patset pat1 page4
bind patset pat1 page5
```

```
add responder action res_redirect redirect "https://www.example.com"+HTTP.REQ.URL' -bypassSafetyCheck yes
add responder policy pol_redirect 'CLIENT.TCP.DSTPORT.EQ(443)&&HTTP.REQ.URL.CONTAINS_ANY("pat1")' res_redirect
bind responder global pol_redirect 100 END
```

Rate Limiting

Aug 12, 2014

The rate limiting feature enables you to define the maximum load for a given network entity or virtual entity on the Citrix NetScaler appliance. The feature enables you to configure the appliance to monitor the rate of traffic associated with the entity and take preventive action, in real time, based on the traffic rate. This feature is particularly useful when the network is under attack from a hostile client that is sending the appliance a flood of requests. You can mitigate the risks that affect the availability of resources to clients, and you can improve the reliability of the network and the resources that the appliance manages.

You can monitor and control the rate of traffic that is associated with virtual and user-defined entities, including virtual servers, URLs, domains, and combinations of URLs and domains. You can throttle the rate of traffic if it is too high, base information caching on the traffic rate, and redirect traffic to a given load balancing virtual server if the traffic rate exceeds a predefined limit. You can apply rate-based monitoring to HTTP, TCP, and DNS requests.

To monitor the rate of traffic for a given scenario, you configure a *rate limit identifier*. A rate limit identifier specifies numeric thresholds such as the maximum number of requests or connections (of a particular type) that are permitted in a specified time period called a *time slice*.

Optionally, you can configure filters, known as *stream selectors*, and associate them with rate limit identifiers when you configure the identifiers. After you configure the optional stream selector and the limit identifier, you must invoke the limit identifier from a default syntax policy. You can invoke identifiers from any feature in which the identifier may be useful, including rewrite, responder, DNS, and integrated caching.

You can globally enable and disable SNMP traps for rate limit identifiers. Each trap contains cumulative data for the rate limit identifier's configured data collection interval (time slice), unless you specified multiple traps to be generated per time slice. For more information about configuring SNMP traps and managers, see "[SNMP](#)."

Configuring a Stream Selector

Jul 30, 2014

A traffic stream selector is an optional filter for identifying an entity for which you want to throttle access. The selector is applied to a request or a response and selects data points (keys) that can be analyzed by a rate stream identifier. These data points can be based on almost any characteristic of the traffic, including IP addresses, subnets, domain names, TCP or UDP identifiers, and particular strings or extensions in URLs.

A stream selector consists of individual default syntax expressions called selectlets. Each selectlet is a non-compound default syntax expression. A traffic stream selector can contain up to five non-compound expressions called selectlets. Each selectlet is considered to be in an AND relationship with the other expressions. Following are some examples of selectlets:

```
http.req.url
http.res.body(1000>after_str(\"car_model\").before_str(\"made_in\"))
\"client.ip.src.subnet(24)\"
```

The order in which you specify parameters is significant. For example, if you configure an IP address and a domain (in that order) in one selector, and then specify the domain and the IP address (in the reverse order) in another selector, the NetScaler considers these values to be unique. This can lead to the same transaction being counted twice. Also, if multiple policies invoke the same selector, the NetScaler, again, can count the same transaction more than once.

Note: If you modify an expression in a stream selector, you may get an error if any policy that invokes it is bound to a new policy label or bind point. For example, suppose that you create a stream selector named myStreamSelector1, invoke it from myLimitID1, and invoke the identifier from a DNS policy named dnsRateLimit1. If you change the expression in myStreamSelector1, you might receive an error when binding dnsRateLimit1 to a new bind point. The workaround is to modify these expressions before creating the policies that invoke them.

To configure a traffic stream selector by using the command line interface

At the command prompt, type:

```
add stream selector <name> <rule> ...
```

Example

```
> add stream selector myStreamSel HTTP.REQ.URL CLIENT.IP.SRC
```

To configure a stream selector by using the configuration utility

Navigate to AppExpert > Rate Limiting > Selectors, click Add and specify the relevant details.

Configuring a Traffic Rate Limit Identifier

Oct 16, 2017

A rate limit identifier returns a Boolean TRUE if the amount of traffic exceeds a numeric limit within a particular time interval. The rate limit identifier definition can optionally include a stream selector. When you include a limit identifier in the compound default syntax expression in a policy rule, if you do not specify a stream selector, the limit identifier is applied to all the requests or responses that are identified by the compound expression.

Note: The maximum length for storing string results of selectors (for example, HTTP.REQ.URL) is 60 characters. If the string (for example, URL) is 1000 characters long, of which 50 characters are enough to uniquely identify a string, use an expression to extract only the required 50 characters.

To configure a traffic limit identifier from the command line interface

At the command prompt, type:

```
add ns limitIdentifier <limitIdentifier> -threshold <positive_integer> -timeSlice <positive_integer> -mode <mode> -limitType ( BURSTY | SMOOTH ) -selectorName <string>
-maxBandwidth <positive_integer> -trapsInTimeSlice <positive_integer>
```

Argument description

limitIdentifier. Name for a rate limit identifier. Must begin with an ASCII letter or underscore (_) character, and must consist only of ASCII alphanumeric or underscore characters. Reserved words must not be used. This is a mandatory argument. Maximum Length: 31

threshold. A maximum number of requests that are allowed in the given timeslice when requests (mode is set as REQUEST_RATE) are tracked per timeslice. When connections (mode is set as CONNECTION) are tracked, it is the total number of connections that would be let through. Default value: 1 Minimum value: 1 Maximum Value: 4294967295

timeSlice. Time interval, in milliseconds, specified in multiples of 10, during which requests are tracked to check if they cross the threshold. This argument is needed only when the mode is set to REQUEST_RATE. Default value: 1000 Minimum value: 10 Maximum Value: 4294967295

mode. Defines the type of traffic to be tracked. * REQUEST_RATE - Tracks requests/timeslice. * CONNECTION - Tracks active transactions.

limitType. Smooth or bursty request type.

selectorName. Name of the rate limit selector. If this argument is NULL, rate limiting will be applied on all traffic received by the virtual server or the NetScaler (depending on whether the limit identifier is bound to a virtual server or globally) without any **filtering**. **Maximum Length: 31**

maxBandwidth. Maximum bandwidth permitted, in kbps. Minimum value: 0 Maximum value: 4294967287

Example

Configuring traffic rate limit identifier in BURSTY mode:

```
> add ns limitIdentifier 100_request_limit -threshold 100 -timeSlice 1000 -mode REQUEST_RATE -limitType BURSTY -selectorName limit_100_requests_selector -trapsInTimeSlice 30
```

Configuring traffic rate limit identifier in SMOOTH mode:

```
> add ns limitIdentifier limit_req -mode request_rate -limitType smooth -timeslice 1000 -Threshold 2000 -trapsInTimeSlice 200
```

To configure a traffic limit identifier by using the configuration utility

Navigate to AppExpert > Rate Limiting > Limit Identifiers, click Add and specify the relevant details.

Configuring and Binding a Traffic Rate Policy

Aug 30, 2013

You implement rate-based application behavior by configuring a policy in an appropriate NetScaler feature. The feature must support default syntax policies. The policy expression must contain the following expression prefix to enable the feature to analyze the traffic rate:

```
sys.check_limit(<limit_identifier>)
```

Where `limit_identifier` is the name of a limit identifier.

The policy expression must be a compound expression that contains at least two components:

- An expression that identifies traffic to which the rate limit identifier is applied. For example:
`http.req.url.contains("my_aspx.aspx")`.
- An expression that identifies a rate limit identifier, for example, `sys.check_limit("my_limit_identifier")`. This must be the last expression in the policy expression.

To configure a rate-based policy by using the command line interface

At the command prompt, type the following command to configure a rate-based policy and verify the configuration:

```
add cache | dns | rewrite | responder policy <policy_name> -rule expression && sys.check_limit("<LimitIdentifierName>") [<feature-specific information>]
```

Following is a complete example of a rate-based policy rule. Note that this example assumes that you have configured the responder action, `send_direct_url`, that is associated with the policy. Note that the `sys.check_limit` parameter must be the last element of the policy expression:

```
add responder policy responder_threshold_policy "http.req.url.contains(\"myindex.html\") && sys.check_limit(\"my_limit_identifier\")" send_direct_url
```

For information about binding a policy globally or to a virtual server, see "[Binding Default Syntax Policies](#)."

To configure a rate-based policy by using the configuration utility

1. In the navigation pane, expand the feature in which you want to configure a policy (for example, Integrated Caching, Rewrite, or Responder), and then click Policies.
2. In the details pane, click Add. In Name, enter a unique name for the policy.
3. Under Expression, enter the policy rule, and make sure that you include the `sys.check_limit` parameter as the final component of the expression. For example:

```
http.req.url.contains("my_aspx.aspx") && sys.check_limit("my_limit_identifier")
```

4. Enter feature-specific information about the policy.

For example, you may be required to associate the policy with an action or a profile. For more information, see the feature-specific documentation.

5. Click Create, and then click Close.
6. Click Save.

Viewing the Traffic Rate

Aug 30, 2013

If traffic through one or more virtual servers matches a rate-based policy, you can view the rate of this traffic. The rate statistics are maintained in the limit identifier that you named in the rule for the rate-based policy. If more than one policy uses the same limit identifier, you can view the traffic rate as defined by hits to all of the policies that use the particular limit identifier.

To view the traffic rate by using the command line interface

At the command prompt, type the following command to view the traffic rate:

```
show ns limitSessions <limitIdentifier>
```

Example

```
sh limitSession myLimitSession
```

To view the traffic rate by using the configuration utility

1. Navigate to AppExpert > Rate Limiting > Limit Identifiers.
2. Select a limit identifier whose traffic rate you want to view.
3. Click the Show Sessions button. If traffic through one or more virtual servers has matched a rate limiting policy that uses this limit identifier (and the hits are within the configured time slice for this identifier), the Session Details dialog box appears. Otherwise, you receive a “No session exists” message.

Testing a Rate-Based Policy

Oct 29, 2013

To test a rate-based policy, you can send traffic to any virtual server to which a rate-based policy is bound.

Task overview: Testing a rate-based policy

1. Configure a stream selector (optional) and a rate limit identifier (required). For example:

```
add stream selector sel_subnet Q.URL "CLIENT.IP.SRC.SUBNET(24)"
add ns limitIdentifier k_subnet -Threshold 4 -timeSlice 3600 -mode REQUEST_RATE -limitype smooth -selectorName sel_subnet -trapsInTimeSlice 8
```

2. Configure the action that you want to associate with the policy that uses the rate limit identifier. For example:

```
add responder action resp_redirect redirect "\"http://response_site.com/\""
```

3. Configure a policy that uses the `sys.check_limit` expression prefix to call the rate limit identifier. For example, the policy can apply a rate limit identifier to all requests arriving from a particular subnet, as follows:

```
add responder policy resp_subnet "SYS.CHECK_LIMIT(\"k_subnet\")" resp_redirect
```

4. Bind the policy globally or to a virtual server. For example:

```
bind responder global resp_subnet 6 END -type DEFAULT
```

5. In a browser address bar, send a test HTTP query to a virtual server. For example:

```
http://<IP of a vserver>/testsite/test.txt
```

6. At the NetScaler command prompt, type:

```
show ns limitSessions <limitIdentifier>
```

Example

```
> sh limitSession k_subnet
```

```
1) Time Remaining: 98 secs Hits: 2 Action Taken: 0
```

```
Total Hash: 1718618 Hash String: /test.txt
```

```
IPs gathered:
```

```
1) 10.217.253.0
```

```
Active Transactions: 0
```

```
Done
```

```
>
```

7. Repeat the query and check the limit identifier statistics again to verify that the statistics are being updated correctly.

Examples of Rate-Based Policies

Apr 18, 2013

The following table shows examples of rate-based policies.

Table 1. Examples of Rate-Based Policies

Purpose	Example
Limit the number of requests per second from a URL	<pre>add stream selector ipStreamSelector http.req.url "client.ip.src" add ns limitIdentifier ipLimitIdentifier -threshold 4 -timeSlice 1000 -mode request_rate -limitType smooth -selectorName ipStreamSelector add responder action myWebSiteRedirectAction redirect "http://www.mycompany.com/" add responder policy ipLimitResponderPolicy "http.req.url.contains(\"myasp.asp\") && sys.check_limit(\"ipLimitIdentifier\")" myWebSiteRedirectAction bind responder global ipLimitResponderPolicy 100 END -type default</pre>
Cache a response if the request URL rate exceeds 5 per 20000 milliseconds	<pre>add stream selector cacheStreamSelector http.req.url add ns limitIdentifier cacheRateLimitIdentifier -threshold 5 -timeSlice 2000 -selectorName cacheStreamSelector add cache policy cacheRateLimitPolicy -rule "http.req.method.eq(get) && sys.check_limit(\"cacheRateLimitIdentifier\")" -action cache bind cache global cacheRateLimitPolicy -priority 10</pre>
Drop a connection on the basis of cookies received in requests from www.yourcompany.com if the requests exceed the rate limit	<pre>add stream selector reqCookieStreamSelector "http.req.cookie .value(\"mycookie\") \"client.ip.src.subnet(24)\" add ns limitIdentifier myLimitIdentifier -Threshold 2 -timeSlice 3000 -selectorName reqCookieStreamSelector add responder action sendRedirectUrl redirect "http://www.mycompany.com\" + http.req.url' -bypassSafetyCheck YES add responder policy rateLimitCookiePolicy "http.req.url.contains(\"www.yourcompany.com\") && sys.check_limit(\"myLimitIdentifier\")" sendRedirectUrl</pre>
Drop a DNS packet if the requests from a particular client IP address and DNS domain exceed the rate limit	<pre>add stream selector dropDNSStreamSelector client.udp.dns.domain client.ip.src add ns limitIdentifier dropDNSRateIdentifier -timeslice 20000 -mode request_rate -selectorName dropDNSStreamSelector -maxBandwidth 1 -trapsintimeslice 20</pre>

Purpose	<pre>add dns policy dnsDropOnClientRatePolicy "sys.check_limit (dropDNSRateIdentifier)" -drop yes</pre>
<p>Limit the number of HTTP requests that arrive from the same subnet (with a subnet mask of 32) and that have the same destination IP address.</p>	<pre>add stream selector ipv6_sel "CLIENT.IPv6.src.subnet(32)" CLIENT.IPv6.dst Q.URL add ns limitIdentifier ipv6_id -imeSlice 20000 -selectorName ipv6_sel add lb vserver ipv6_vip HTTP 3ffe::209 80 -persistenceType NONE -cltTimeout 180 add responder action redirect_page redirect ""http://redirectpage.com/"" add responder policy ipv6_resp_pol "SYS.CHECK_LIMIT(\"ipv6_id\")" redirect_page bind responder global ipv6_resp_pol 5 END -type DEFAULT</pre>

Sample Use Cases for Rate-Based Policies

Dec 10, 2013

The following scenarios describe two uses of rate-based policies in global server load balancing (GSLB):

- The first scenario describes the use of a rate-based policy that sends traffic to a new data center if the rate of DNS requests exceed 1000 per second.
- In the second scenario, if more than five DNS requests arrive for a local DNS (LDNS) client within a particular period, the additional requests are dropped.

Redirecting Traffic on the Basis of Traffic Rate

In this scenario, you configure a proximity-based load balancing method, and a rate-limiting policy that identifies DNS requests for a particular region. In the rate-limiting policy, you specify a threshold of 1000 DNS requests per second. A DNS policy applies the rate limiting policy to DNS requests for the region "Europe.GB.17.London.UK-East.ISP-UK." In the DNS policy, DNS requests that exceed the rate limiting threshold, starting with request 1001 and continuing to the end of the one-second interval, are to be forwarded to the IP addresses that are associated with the region "North America.US.TX.Dallas.US-East.ISP-US."

The following configuration demonstrates this scenario:

```
add stream selector DNSSelector1 client.udp.dns.domain
add ns limitIdentifier DNSLimitIdentifier1 -threshold 5 -timeSlice 1000 -selectorName DNSSelector1
add dns policy DNSLimitPolicy1 "client.ip.src.matches_location(\"Europe.GB.17.London.*\") &&
sys.check_limit(\"DNSLimitIdentifier1\")" -preferredLocation "North America.US.TX.Dallas.*.*"
bind dns global DNSLimitPolicy1 5
```

Dropping DNS Requests on the Basis of Traffic Rate

In the following example of global server load balancing, you configure a rate limiting policy that permits a maximum of five DNS requests in a particular interval, per domain, to be directed to an LDNS client for resolution. Any requests that exceed this rate are dropped. This type of policy can help protect the NetScaler from resource exploitation. For example, in this scenario, if the time to live (TTL) for a connection is five seconds, this policy prevents the LDNS from requerying a domain. Instead, it uses data that is cached on the NetScaler.

```
add stream selector LDNSSelector1 client.udp.dns.domain client.ip.src
add ns limitIdentifier LDNSLimitIdentifier1 -threshold 5 -timeSlice 1000 -selectorName LDNSSelector1
add dns policy LDNSPolicy1 "client.udp.dns.domain.contains(\".\") && sys.check_limit(\"LDNSLimitIdentifier1\")" -drop YES
bind dns global LDNSPolicy1 6
show gslb vserver gvip

Rate Limiting for Traffic Domains

Jun 19, 2014

You can configure rate limiting for traffic domains. The following expression in the NetScaler expressions language for identifies traffic associated with traffic domains.

- `client.traffic_domain.id`

You can configure rate limiting for traffic associated with a particular traffic domain, a set of traffic domains, or all traffic domains.

For configuring rate limiting for traffic domains, you perform the following steps on a NetScaler appliance by using the configuration utility or the NetScaler command line:

1. Configure a stream selector that uses the `client.traffic_domain.id` expression for identifying the traffic, associated with traffic domains, to be rate limited.
2. Configure a rate limit identifier that specifies parameters such as maximum threshold for traffic to be rate limited. You also associate a stream selector to the rate limiter in this step.
3. Configure an action that you want to associate with the policy that uses the rate limit identifier.
4. Configure a policy that uses the `sys.check_limit` expression prefix to call the rate limit identifier, and associate the action with this policy.
5. Bind the policy globally.

Consider an example in which two traffic domains, with IDs 10 and 20, are configured on NetScaler ADC NS1. On traffic domain 10, LB1-TD-1 is configured to load balance servers S1 and S2; LB2-TD1 is configured to load balance servers S3 and S4.

On traffic domain 20, LB1-TD-2 is configured to load balance servers S5 and S6; LB2-TD2 is configured to load balance servers S7 and S8.

The following table lists some examples of rate limiting policies for traffic domains in the example setup.

Purpose	CLI commands
Limit the number of requests to 10 per second for each of the traffic domains.	<pre>add stream selector tdratelimit-1 CLIENT.TRAFFIC_DOMAIN.ID add ns limitIdentifier limitidf-1 -threshold 10 -selectorName tdratelimit-1 -trapsInTimeSlice 0 add responder policy ratelimit-pol "sys.check_limit(\"limitidf-1\")" DROP bind responder global ratelimit-pol 1</pre>
Limit the number of requests to 5 per client per second for each of the traffic domains.	<pre>add stream selector tdandclientip CLIENT.IP.SRC,CLIENT.TRAFFIC_DOMAIN.ID add ns limitIdentifier td_limitidf -threshold 5 -selectorName tdandclientip -trapsInTimeSlice 5 add responder policy tdratelimit-pol "sys.check_limit(\"td_limitidf\")" DROP bind responder global tdratelimit-pol 2</pre>
Limit the number of requests sent for a particular traffic domain (for example traffic domain 10) to 30 requests every 3 seconds.	<pre>add stream selector tdratelimit CLIENT.TRAFFIC_DOMAIN.ID add ns limitIdentifier td10_limitidf -threshold 30 -timeSlice 3000 -selectorName tdratelimit -trapsInTimeSlice 5 add responder policy td10ratelimit "client.traffic_domain.id==10 && sys.check_limit(\"td10_limitidf\")" DROP bind responder global td10ratelimit 3</pre>

<p>Purpose</p> <p>Limit the number of connections to 5 per client per second for a particular traffic domain (for example traffic domain 20).</p>	<p>CLI commands</p> <pre>add stream selector tdandclientip CLIENT.IP.SRC CLIENT.TRAFFIC_DOMAIN.ID add ns limitIdentifier td20_limitidf -threshold 5 -mode CONNECTION -selectorName tdandclientip -trapsInTimeSlice 5 add responder policy td20_ratelimit "client.traffic_domain.id==20 && sys.check_limit(\"td20_limitidf\")" DROP bind responder global td20_ratelimit 4</pre>
--	--

Responder

Mar 20, 2012

Today's complex Web configurations often require different responses to HTTP requests that appear, on the surface, to be similar. When users request a Web site's home page, you may want to provide a different home page depending on where each user is located, which browser the user is using, or which language(s) the browser accepts and the order of preference. You might want to break the connection immediately if the request is coming from an IP range that has been generating DDoS attacks or initiating hacking attempts.

With the Responder feature, responses can be based on who sends the request, where it is sent from, and other criteria with security and system management implications. The feature is simple and quick to use. By avoiding the invocation of more complex features, it reduces CPU cycles and time spent in handling requests that do not require complex processing.

For handling sensitive data such as financial information, if you want to ensure that the client uses a secure connection to browse a site, you can redirect the request to secure connection by using `https://` instead of `http://`.

To use the Responder feature, do the following:

- Enable the Responder feature on the NetScaler.
- Configure responder actions. The action can be to generate a custom response, redirect a request to a different Web page, or reset a connection.
- Configure responder policies. The policy determines the requests (traffic) on which an action has to be taken.
- Bind each policy to a bind point put it into effect. A bind point refers to an entity at which NetScaler examines the traffic to see if it matches a policy. For example, a bind point can be a load balancing virtual server.

You can specify a default action for requests that do not match any policy, and you can bypass the safety check for actions that would otherwise generate error messages.

The Rewrite feature of NetScaler helps in rewriting some information in the requests or responses handled by NetScaler. The following section shows some differences between the two features.

Comparison between Rewrite and Responder options

The main difference between the rewrite feature and the responder feature is as follows:

Responder cannot be used for response or server-based expressions. Responder can be used only for the following scenarios depending on client parameters:

- Redirecting a http request to new Web sites or Web pages
- Responding with some custom response
- Dropping or resetting a connection at request level

In case of a responder policy, the NetScaler examines the request from the client, takes action according to the applicable policies, sends the response to the client, and closes the connection with the client.

In case of a rewrite policy, the NetScaler examines the request from the client or response from the server, takes action according to the applicable policies, and forwards the traffic to the client or the server.

In general, it is recommended to use responder if you want the NetScaler to reset or drop a connection based on a client or request-based parameter. Use responder to redirect traffic, or respond with custom messages. Use rewrite for manipulating data on HTTP requests and responses.

Enabling the Responder Feature

Oct 29, 2013

To use the Responder feature, you must first enable it.

To enable the responder feature by using the command line interface

At the command prompt, type the following commands to enable the responder feature and verify the configuration:

- enable ns feature<feature>
- show ns feature

Example

```
enable ns feature Responder
```

```
Done
```

```
> show ns feature
```

	Feature	Acronym	Status
	-----	-----	-----
1)	Web Logging	WL	ON
2)	Surge Protection	SP	ON
.			
.			
.			
22)	Responder	RESPONDER	ON
23)	HTML Injection	HTMLInjection	ON
24)	NetScaler Push	push	OFF

```
Done
```

```
>
```

To enable the responder feature by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change advanced features.
3. In the Configure Advanced Features dialog box, select the Responder check box, and then click OK.
4. In the Enable/Disable Feature(s)? dialog box, click YES. A message appears in the status bar, stating that the feature has been enabled.

Configuring a Responder Action

Oct 23, 2017

After enabling the responder feature, you must configure one or more actions for handling requests. The responder supports the following types of actions:

Respond with

Sends the response defined by the Target expression without forwarding the request to a web server. (The NetScaler appliance substitutes for and acts as a web server.) Use this type of action to manually define a simple HTML-based response. Normally the text for a Respond with action consists of a web server error code and brief HTML page.

Respond with SQL OK

Sends the designated SQL OK response defined by the Target expression. Use this type of action to send an SQL OK response to an SQL query.

Respond with SQL Error

Sends the designated SQL Error response defined by the Target expression. Use this type of action to send an SQL Error response to an SQL query.

Respond with HTML page

Sends the designated HTML page as the response. You can choose from a drop-down list of HTML pages that were previously uploaded, or upload a new HTML page. Use this type of action to send an imported HTML page as the response.

Redirect

Redirects the request to a different web page or web server. A Redirect action can redirect requests originally sent to a "dummy" web site that exists in DNS, but for which there is no actual web server, to an actual web site. It can also redirect search requests to an appropriate URL. Normally, the redirection target for a Redirect action consists of a complete URL.

To configure a responder action by using the command line interface

Displays the current settings for the specified responder action. If no action name is provided, displays a list of all responder actions currently configured on the NetScaler appliance, with abbreviated settings.

At the command prompt, type the following commands to configure a responder action and verify the configuration:

- add responder action <name> <type> <target> [-bypassSafetyCheck (YES | NO)]
- show responder action

Arguments

Name. Name of the responder action. Maximum Length: 127

type. Type of responder action. It can be: (respondwith).

target. An expression specifying what to respond with

htmlpage. Option specifying to respondwith htmlpage

bypassSafetyCheck. The safety check to allow unsafe expressions. NOTE: This attribute is deprecated.

hits. The number of times the action has been taken.

referenceCount. The number of references to the action.

undefHits. The number of times the action resulted in UNDEF.

comment. Any type of information about this responder action.

builtin. Flag to determine whether responder action is built-in or not

Example

To create a responder action that displays a "Not Found" error page for URLs that do not exist:

```
add responder action act404Error respondWith "'HTTP/1.1 404 Not Found\r\n\r\n'+ 'HTTP:REQURL.HTTP_URL_SAFE' + 'does not exist on the web
```

```
server:"
Done
> show responder action
```

```
1) Name: act404Error
Operation: respondwith
Target: "HTTP/1.1 404 Not Found
```

```
" + "HTTP.REQ.URL.HTTP_URL_SAFE" + "does not exist on the web server."
BypassSafetyCheck : NO
Hits: 0
Undef Hits: 0
Action Reference Count: 0
Done
```

To create a responder action that displays a “Not Found” error page for URLs that do not exist:

```
add responder action act404Error respondWith "HTTP/1.1 404 Not Found\r\n\r\n" + "HTTP.REQ.URL.HTTP_URL_SAFE" + "does not exist on the web
server."
Done
> show responder action
```

```
1) Name: act404Error
Operation: respondwith
Target: "HTTP/1.1 404 Not Found
```

```
" + "HTTP.REQ.URL.HTTP_URL_SAFE" + "does not exist on the web server."
BypassSafetyCheck : NO
Hits: 0
Undef Hits: 0
Action Reference Count: 0
Done
```

To modify an existing responder action by using the command line interface

At the command prompt, type the following command to modify an existing responder action and verify the configuration:

- set responder action <name> -target <string> [-bypassSafetyCheck (YES | NO)]
- show responder action

Example

```
set responder action act404Error -target "HTTP/1.1 404 Not Found\r\n\r\n" + "HTTP.REQ.URL.HTTP_URL_SAFE" + "does not exist on the web server."
Done
> show responder action
```

```
1) Name: act404Error
Operation: respondwith
Target: "HTTP/1.1 404 Not Found
```

```
" + "HTTP.REQ.URL.HTTP_URL_SAFE" + "does not exist on the web server."
BypassSafetyCheck : NO
Hits: 0
Undef Hits: 0
Action Reference Count: 0
Done
```

To remove a responder action by using the command line interface

At the command prompt, type the following command to remove a responder action and verify the configuration:

- rm responder action <name>
- show responder action

Example

```
rm responder action act404Error
Done
```

```
> show responder action
Done
```

To configure a responder action by using the configuration utility

1. Navigate to AppExpert > Responder > Actions.
2. In the details pane, do one of the following:
 - To create a new action, click Add.
 - To modify an existing action, select the action, and then click Open.
3. Click Create or OK, depending on whether you are creating a new action or modifying an existing action.
4. Click Close. A message appears in the status bar, stating that the feature has been enabled.
5. To delete a responder action, select the action, and then click Remove. A message appears in the status bar, stating that the feature has been disabled.

To add an expression by using the Add Expression dialog box

1. In the Create Responder Action or Configure Responder Action dialog box, click Add.
2. In the Add Expression dialog box, in the first list box choose the first term for your expression.

HTTP

The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.

SYS

The protected web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

CLIENT

The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

ANALYTICS

The analytics data associated with the request. Choose this if you want to examine request metadata.

SIP

A SIP request. Choose this if you want to examine some aspect of a SIP request.

When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.

3. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.
4. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

Configuring the Global HTTP Action

You can configure the global HTTP action to invoke a responder action when an HTTP request times out. To configure this feature, you must first create the responder action that you want to invoke. Then, you configure the global HTTP timeout action to respond to a timeout with that responder action.

To configure the global HTTP action by using the command line interface

At the command prompt, type the following command:

- `set ns httpProfile -reqTimeoutAction <responder action name>`
- `save ns config`

For <responder action name>, substitute the name of the responder action.

Configuring a Responder Policy

Oct 29, 2013

After you configure a responder action, you must next configure a responder policy to select the requests to which the NetScaler appliance should respond. A responder policy is based on a rule, which consists of one or more expressions. The rule is associated with an action, which is performed if a request matches the rule.

Note: For creating and managing responder policies, the configuration utility provides assistance that is not available at the NetScaler command prompt.

To configure a responder policy by using the command line interface

At the command prompt, type the following command to add a new responder policy and verify the configuration:

- add responder policy <name> <expression> <action> [<undefaction>]-appFlowaction<actionName>
- show responder policy <name>

Example

```
> add responder policy policyThree "CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)" RESET
Done
> show responder policy policyThree
```

```
Name: policyThree
Rule: CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)
Responder Action: RESET
UndefAction: Use Global
Hits: 0
Undef Hits: 0
```

Done

To modify an existing responder policy by using the command line interface

At the command prompt, type the following command to modify an existing responder policy and verify the configuration:

- set responder policy <name> [-rule <expression>] [-action <string>] [-undefAction <string>]
- show responder policy <name>

To remove a responder policy by using the command line interface

At the command prompt, type the following command to remove a responder policy and verify the configuration:

- rm responder policy <name>
- show responder policy

Example

```
>rm responder policy pol404Error
Done
```

```
> show responder policy
Done
```

To configure a responder policy by using the configuration utility

1. Navigate to AppExpert > Responder > Policies.
2. In the details pane, do one of the following:
 - To create a new policy, click Add.
 - To modify an existing policy, select the policy, and then click Open.
3. Click Create or OK, depending on whether you are creating a new policy or modifying an existing policy.
4. Click Close. A message appears in the status bar, stating that the feature has been configured.

Binding a Responder Policy

Oct 29, 2013

To put a policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the NetScaler, or to a specific virtual server, so that the policy applies only to requests whose destination IP address is the VIP of that virtual server.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

In the NetScaler operating system, policy priorities work in reverse order—the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is performed first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000. The responder feature implements only the first policy that a request matches, not any additional policies that it might also match, so policy priority is important for getting the results you intend.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you globally bind it. You can then add additional policies at any time without having to reassign the priority of an existing policy.

For additional information about binding policies on the NetScaler, see "[Policies and Expressions](#)."

Note: Responder policies cannot be bound to TCP-based virtual servers.

To globally bind a responder policy by using the command line interface

At the command prompt, type the following command to globally bind a responder policy and verify the configuration:

- bind responder global <policyName> <priority> [<gotoPriorityExpression [-type <type>] [-invoke (<labelType> <labelName>)]
- show responder global

Example

```
> bind responder global poliError 100
```

```
Done
```

```
> show responder global
```

```
1) Global bindpoint: REQ_DEFAULT
```

```
Number of bound policies: 1
```

```
Done
```

To bind responder policy to a specific virtual server by using the command line interface

At the command prompt, type the following command to bind responder policy to a specific virtual server and verify the configuration:

```
bind lb vserver <name> -policyname <policy_name> -priority <priority>
```

Example

```
> bind lb vserver vs-loadbal -policyName policyTwo -priority 100
```

```
Done
```

```
> show lb vserver
```

1) vs-loadbal (10.102.29.20:80) - HTTP Type: ADDRESS
State: OUT OF SERVICE
Last state change was at Wed Aug 19 09:05:47 2009 (+211 ms)
Time since last state change: 2 days, 00:58:03.260
Effective State: DOWN
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Port Rewrite : DISABLED
No. of Bound Services : 0 (Total) 0 (Active)
Configured Method: LEASTCONNECTION
Mode: IP
Persistence: NONE
Vserver IP and Port insertion: OFF
Push: DISABLED Push VServer:
Push Multi Clients: NO
Push Label Rule: none

2) vs-cont-sw (0.0.0.0:0) - TCP Type: ADDRESS
State: DOWN
Last state change was at Wed Aug 19 10:03:46 2009 (+213 ms)
Time since last state change: 2 days, 00:00:04.260
Effective State: DOWN
Client Idle Timeout: 9000 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
No. of Bound Services : 0 (Total) 0 (Active)
Configured Method: LEASTCONNECTION
Mode: IP
Persistence: NONE
Connection Failover: DISABLED

Done

To globally bind a responder policy by using the configuration utility

1. Navigate to AppExpert > Responder > Policies.
2. On the Responder Policies page, select a responder policy, and then click Policy Manager.
3. In the Responder Policy Manager dialog box Bind Points menu, select Default Global.
4. Click Insert Policy to insert a new row and display a drop-down list of all unbound responder policies.
5. Click one of the policies on the list. That policy is inserted into the list of globally bound responder policies.
6. Click Apply Changes.
7. Click Close. A message appears in the status bar, stating that the configuration has been successfully completed.

To bind a responder policy to a specific virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. On the Load Balancing Virtual Servers page, select the virtual server to which you want to bind the responder policy, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab, which displays a list of all policies configured on your NetScaler appliance.
4. Select the check box next to the name of the policy you want to bind to this virtual server.

5. Click OK. A message appears in the status bar, stating that the configuration has been successfully completed.

Setting the Default Action for a Responder Policy

Oct 25, 2016

The NetScaler appliance generates an undefined event (UNDEF event) when a request does not match a responder policy, and then carries out the default action assigned to undefined events. By default, that action is to forward the request to the next feature without changing it. This default behavior is normally what you want; it ensures that requests that do not require special handling by a specific responder action are sent to your Web servers and clients receive access to the content that they requested.

If the Web site(s) your NetScaler appliance protects receive a significant number of invalid or malicious requests, however, you may want to change the default action to either reset the client connection or drop the request. In this type of configuration, you would write one or more responder policies that would match any legitimate requests, and simply redirect those requests to their original destinations. Your NetScaler appliance would then block any other requests as specified by the default action you configured.

You can assign any one of the following actions to an undefined event:

NOOP

The NOOP action aborts responder processing but does not alter the packet flow. This means that the appliance continues to process requests that do not match any responder policy, and eventually forwards them to the requested URL unless another feature intervenes and blocks or redirects the request. This action is appropriate for normal requests to your Web servers and is the default setting.

RESET

If the undefined action is set to RESET, the appliance resets the client connection, informing the client that it must re-establish its session with the Web server. This action is appropriate for repeat requests for Web pages that do not exist, or for connections that might be attempts to hack or probe your protected Web site(s).

DROP

If the undefined action is set to DROP, the appliance silently drops the request without responding to the client in any way. This action is appropriate for requests that appear to be part of a DDoS attack or other sustained attack on your servers.

Note: UNDEF events are triggered only for client requests. No UNDEF events are triggered for responses.
To set the undefined action by using the command line interface

At the command prompt, type the following command to set the undefined action and verify the configuration:

- set responder param -undefAction (RESET | DROP | NOOP)
- show responder param

Example

```
>set responder param -undefAction RESET
Done
> show responder param
  Action Name: RESET
Done
>
```

To set the undefined action by using the configuration utility

1. Navigate to AppExpert > Responder, and then under Settings, click the Change Responder Settings link.
2. In the Set Responder Params dialog box, under Global Undefined-Result Action, select NOOP, RESET, or DROP.
3. Click OK. A message appears in the status bar, stating that the Responder Parameters have been configured.

Responder Action and Policy Examples

Nov 07, 2016

Responder actions and policies are powerful and complex, but you can get started with relatively simple applications. For typical examples, see "[Example: Blocking Access from Specified IPs](#)" and "[Example: Redirecting a Client to a new URL](#)."

Example: Blocking Access from Specified IPs

The following procedures block access to your protected Web site(s) by clients originating from the CIDR 222.222.0.0/16. The responder sends an error message stating that the client is not authorized to access the URL requested.

To block access by using the command line interface

At the command prompt, type the following commands to block access:

- add responder action act_unauthorized respondwith "HTTP/1.1 403 Forbidden\r\n\r\n" + "Client: " + CLIENT.IP.SRC + " is not authorized to access URL:" + "HTTP.REQ.URL.HTTP_URL_SAFE"
- add responder policy pol_un "CLIENT.IP.SRC.IN_SUBNET (222.222.0.0/16)" act_unauthorized
- bind responder global pol_un 10

To block access by using the configuration utility

1. In the navigation pane, expand Responder, and then click Actions.
2. In the details pane, click Add.
3. In the Create Responder Action dialog box, do the following:
 1. In the Name text box, type act_unauthorized.
 2. Under Type, select Respond with.
 3. In the Target text area, type the following string: "HTTP/1.1 200 OK\r\n\r\n" + "Client: " + CLIENT.IP.SRC + " is not authorized to access URL:" + HTTP.REQ.URL.HTTP_URL_SAFE
 4. Click Create, and then click Close.

The responder action you configured, named act_unauthorized, now appears in the Responder Actions page.

4. In the navigation pane, click Policies.
5. In the details pane, click Add.
6. In the Create Responder Policy dialog box, do the following:
 1. In the Name text box, type pol_unauthorized.
 2. Under Action, select act_unauthorized.
 3. In the Expression window, type the following rule: CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)
 4. Click Create, then click Close.

The responder policy you configured, named pol_unauthorized, now appears in the Responder Policies page.

7. Globally bind your new policy, pol_unauthorized, as described in "[Binding a Responder Policy](#)."

Example: Redirecting a Client to a new URL

The following procedures redirect clients who access your protected Web site(s) from within the CIDR 222.222.0.0/16 to a specified URL.

To redirect clients by using the command line interface

At the command prompt, type the following commands to redirect clients and verify the configuration:

- add responder action act_redirect redirect "http://www.example.com/404.html"
- show responder action act_redirect

- add responder policy pol_redirect "CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)" act_redirect
- show responder policy pol_redirect
- bind responder global pol_redirect 10

Example

```
> add responder action act_redirect redirect "" http ://www.example.com/404.html ""  
> add responder policy pol_redirect "CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)" act_redirect
```

To redirect clients by using the configuration utility

1. Navigate to AppExpert > Responder > Actions.
2. In the details pane, click Add.
3. In the Create Responder Action dialog box, do the following:
 1. In the Name text box, type act_redirect.
 2. Under Type, select Redirect.
 3. In the Target text area, type the following string: "http://www.example.com/404.html"
 4. Click Create, then click Close.The responder action you configured, named act_redirect, now appears in the Responder Actions page.
4. In the navigation pane, click Policies.
5. In the details pane, click Add.
6. In the Create Responder Policy dialog box, do the following:
 1. In the Name text box, type pol_redirect.
 2. Under Action, select act_redirect.
 3. In the Expression window, type the following rule: CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)
 4. Click Create, then click Close.The responder policy you configured, named pol_redirect, now appears in the Responder Policies page.
7. Globally bind your new policy, pol_redirect, as described in "[Binding a Responder Policy](#)."

Diameter Support for Responder

Apr 09, 2014

The Responder feature now supports the Diameter protocol. You can configure Responder to respond to Diameter requests as it does HTTP and TCP requests. For example, you could configure Responder to respond to requests from a specific Diameter origin with a redirect to a web page enhanced for mobile devices. A number of NetScaler expressions have been added that support examination of the Diameter header and the attribute-value pairs (AVPs). These expressions support lookup of specific AVPs by index, ID or name, examine the information in each AVP, and send an appropriate response.

To configure Responder to respond to a Diameter request

To configure the Responder feature to send a response to a diameter request, at the command prompt, type the following commands:

- `add responder action <actname> RESPONDWITH "DIAMETER.NEW_REDIRECT(\"aaa://host.example.com\")"`
For <actname>, substitute a name for your new action. The name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For `aaa://host.example.com`, substitute the URL of the diameter host to which you want to redirect connections.
- `add responder policy <polname> "diameter.req.avp(264).value.eq(\"host1.example.net\")" <actname>`
For <polname>, substitute a name for your new policy. As with <actname>, the name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For `host1.example.net`, substitute the name of the originating host of the requests that you want to redirect. For <actname>, substitute the name of the action that you just created.
- `bind lb vserver <vservname> -policyName <polname> -priority <priority> -type REQUEST`
For <vservname>, substitute the name of the load balancing virtual server to which you want to bind the policy. For <polname>, substitute the name of the policy you just created. For <priority>, substitute a priority for the policy.

Example

To create a Responder action and policy to respond to Diameter requests that originate from "host1.example.net" with a redirect to "host.example.com", you could add the following action and policy, and bind the policy as shown.

```
> add responder action act_resp-dm-redirect RESPONDWITH "DIAMETER.NEW_REDIRECT(\"aaa://host.example.com\")"  
> add responder pol_resp-dm-redirect "diameter.req.avp(264).value.eq(\"host1.example.net\")" act_resp-dm-redirect  
> bind lb vserver vs1 -policyName pol_resp-dm-redirect -priority 10 -type REQUEST
```

Done

RADIUS Support for Responder

Oct 16, 2014

The NetScaler expressions language contains expressions that can extract information from and manipulate RADIUS requests. These expressions enable you to use the Responder feature to respond to RADIUS requests. Your responder policies and actions can use any expression that is appropriate or relevant to a RADIUS request. The available expressions enable you to identify the RADIUS message type, extract any attribute-value pair (AVP) from the connection, and send different responses on the basis of that information. You can also create policy labels that invoke all responder policies for RADIUS connections.

You can use RADIUS expressions to construct simple responses that do not require communication with the RADIUS server to which the request was sent. When a responder policy matches a connection, the NetScaler ADC constructs and sends the appropriate RADIUS response without contacting the RADIUS authentication server. For example, if the source IP address of a RADIUS request is from a subnet that is specified in the responder policy, the NetScaler ADC can reply to that request with an access-reject message, or can simply drop the request.

You can also create policy labels to route specific types of RADIUS requests through a series of policies that are appropriate to those requests.

Note: The current RADIUS expressions do not work with RADIUS IPv6 attributes.

The NetScaler documentation for expressions that support RADIUS assumes familiarity with the basic structure and purpose of RADIUS communications. If you need more information about RADIUS, see your RADIUS server documentation or search online for an introduction to the RADIUS protocol.

Configuring Responder Policies for RADIUS

The following procedure uses the NetScaler command line to configure a responder action and policy, and bind the policy to a RADIUS-specific global bind point.

To configure a Responder action and policy, and bind the policy

At the command prompt, type the following commands:

- add responder action <actName> <actType>
- add responder policy <polName> <rule> <actName>
- bind responder policy <polName> <priority> <nextExpr> -type <bindPoint> where <bindPoint> represents one of the RADIUS-specific global bind points.

RADIUS Expressions for Responder

In a responder configuration, you can use the following NetScaler expressions to refer to various portions of a RADIUS request.

Identifying the Type of Connection

RADIUS.IS_CLIENT

Returns TRUE if the connection is a RADIUS client (request) message.

RADIUS.IS_SERVER

Returns TRUE if the connection is a RADIUS server (response) message.

Request Expressions

RADIUS.REQ.CODE

Returns the number that corresponds to the RADIUS request type. A derivative of the num_at class. For example, a RADIUS access request would return 1 (one). A RADIUS accounting request would return 4.

RADIUS.REQ.LENGTH

Returns the length of the RADIUS request, including the header. A derivative of the num_at class.

RADIUS.REQ.IDENTIFIER

Returns the RADIUS request identifier, a number assigned to each request that allows the request to be matched to the corresponding response. A derivative of the num_at class.

RADIUS.REQ.AVP(<AVP Code No>).VALUE

Returns the value of first occurrence of this AVP as a string of type text_t.

RADIUS.REQ.AVP(<AVP code no>).INSTANCE(instance number)

Returns the specified instance of the AVP as a string of type RAVP_t. A specific RADIUS AVP can occur multiple times in a RADIUS message. INSTANCE (0) returns the first instance, INSTANCE (1) returns second instance, and so on, up to sixteen instances.

RADIUS.REQ.AVP(<AVP code no>).VALUE(instance number)

Returns the value of specified instance of the AVP as a string of type text_t.

RADIUS.REQ.AVP(<AVP code no>).COUNT

Returns the number of instances of a specific AVP in a RADIUS connection, as an integer.

RADIUS.REQ.AVP(<AVP code no>).EXISTS

Returns TRUE if the specified type of AVP exists in the message, or FALSE if it does not.

Response Expressions

RADIUS response expressions are identical to RADIUS request expressions, except that RES replaces REQ.

Typecasts of AVP Values

The ADC supports expressions to typecast RADIUS AVP values to the text, integer, unsigned integer, long, unsigned long, ipv4 address, ipv6 address, ipv6 prefix and time data types. The syntax is the same as for other NetScaler typecast expressions.

Example

The ADC supports expressions to typecast RADIUS AVP values to the text, integer, unsigned integer, long, unsigned long, ipv4 address, ipv6 address, ipv6 prefix and time data types. The syntax is the same as for other NetScaler typecast expressions.

`RADIUS.REQ.AVP(8).VALUE(0).typecast_ip_address_at`

AVP Type Expressions

The NetScaler ADC supports expressions to extract RADIUS AVP values by using the assigned integer codes described in RFC2865 and RFC2866. You can also use text aliases to accomplish the same task. Some examples follow.

RADIUS.REQ.AVP (1).VALUE or RADIUS.REQ.USERNAME.value

Extracts the RADIUS user-name value.

RADIUS.REQ.AVP (4). VALUE or RADIUS.REQ. ACCT_SESSION_ID.value

Extracts the Acct-Session-ID AVP (code 44) from the message.

RADIUS.REQ.AVP (26). VALUE or RADIUS.REQ.VENDOR_SPECIFIC.VALUE

Extracts the vendor-specific value.

The values of most commonly-used RADIUS AVPs can be extracted in the same manner.

RADIUS Bind Points

Four global bind points are available for policies that contain RADIUS expressions.

RADIUS_REQ_OVERRIDE

Priority/override request policy queue.

RADIUS_REQ_DEFAULT

Standard request policy queue.

RADIUS_RES_OVERRIDE

Priority/override response policy queue.

RADIUS_RES_DEFAULT

Standard response policy queue.

RADIUS Responder-Specific Expressions

RADIUS_RESPONDWITH

Respond with the specified RADIUS response. The response is created with NetScaler expressions, both RADIUS expressions and any others that are applicable.

RADIUS.NEW_ANSWER

Sends a new RADIUS answer to the user.

RADIUS.NEW_ACCESSREJECT

Rejects the RADIUS request.

RADIUS.NEW_AVP

Adds the specified new AVP to the response.

Use Cases

Following are use cases for RADIUS with responder.

Blocking RADIUS Requests from a Specific Network

To configure the responder feature to block authentication requests from a specific network, begin by creating a responder action that rejects requests. Use the action in a policy that selects requests from the networks that you want to block.

Bind the responder policy to a RADIUS-specific global bind point, specifying:

- The priority
- END as the nextExpr value, to ensure that policy evaluation stops when this policy is matched
- RADIUS_REQ_OVERRIDE as the queue to which you assign the policy, so that it is evaluated before policies assigned to the default queue

To configure Responder to block logons from a specific network

- add responder action <actName> <actType>
- add responder policy <polName> <rule> <actName>

- bind responder global <polName> <priority> <nextExpr> -type <bindPoint>

Example

```
add responder action rspActRadiusReject respondwith radius.new_accessreject
add responder policy rspPolRadiusReject client.ip.src.in_subnet(10.224.85.0/24) rspActRadiusReject
bind responder global rspPolRadiusReject 1 END -type RADIUS_REQ_OVERRIDE
```

Troubleshooting

Jul 22, 2013

If the responder feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

Resources for Troubleshooting

Updated: 2013-07-22

For best results, use the following resources to troubleshoot an integrated cache issue on a NetScaler appliance:

- The ns.conf file
- The relevant trace files from the client and the NetScaler appliance

In addition to the above resources, the following tools expedite troubleshooting:

- The iehttpheaders or a similar utility
- The Wireshark application customized for the NetScaler trace files

Troubleshooting Responder Issues

Updated: 2013-07-29

- **Issue**

The Responder feature is configured, but the responder action is not working.

Resolution

- Verify that the feature is enabled.
- Check the hit counters of any of the policies to see if the counters are getting incremented.
- Verify that the policies and actions are configured correctly.
- Verify that the actions and policies are bound appropriately.
- Record the packet traces on the client and the NetScaler appliance, and analyze them to get some pointer to the issue.
- Record the iehttpheaders packet traces on the client and verify the HTTP requests and responses to get some pointer to the issue.

- **Issue**

You need to create a maintenance page.

Resolution

1. Configure the services and virtual Server.
2. Configure a backup virtual server with a service bound to it. This ensures that the status of the Web site is always displayed as UP.
3. Configure the primary virtual server to use the backup virtual server as a backup.
4. Create a responder action with an appropriate target. Following is an example for your reference:
add responder action sorry_page respondwith q{"HTTP/1.0 200 OK" + "\n\n" + "<html><body>Sorry, this page is not available</body></html>" + "\n"} .
5. Create a responder policy and bind the action to it.
6. Bind the responder policy to the backup virtual Server.

Rewrite

Aug 30, 2013

Rewrite refers to the rewriting of some information in the requests or responses handled by the NetScaler appliance. Rewriting can help in providing access to the requested content without exposing unnecessary details about the Web site's actual configuration. A few situations in which the rewrite feature is useful are described below:

- To improve security, the NetScaler can rewrite all the http:// links to https:// in the response body.
- In the SSL offload deployment, the insecure links in the response have to be converted into secure links. Using the rewrite option, you can rewrite all the http:// links to https:// for making sure that the outgoing responses from NetScaler to the client have the secured links.
- If a Web site has to show an error page, you can show a custom error page instead of the default 404 Error page. For example, if you show the home page or site map of the Web site instead of an error page, the visitor remains on the site instead of moving away from the Web site.
- If you want to launch a new Web site, but use the old URL, you can use the Rewrite option.
- When a topic in a site has a complicated URL, you can rewrite it with a simple, easy-to-remember URL (also referred to as 'cool URL').
- You can append the default page name to the URL of a Web site. For example, if the default page of a company's Web site is 'http://www.abc.com/index.php', when the user types 'abc.com' in the address bar of the browser, you can rewrite the URL to 'abc.com/index.php'.

When you enable the rewrite feature, NetScaler can modify the headers and body of HTTP requests and responses.

To rewrite HTTP requests and responses, you can use protocol-aware NetScaler policy expressions in the rewrite policies you configure. The virtual servers that manage the HTTP requests and responses must be of type HTTP or SSL. In HTTP traffic, you can take the following actions:

- Modify the URL of a request
- Add, modify or delete headers
- Add, replace, or delete any specific string within the body or headers.

To rewrite TCP payloads, consider the payload as a raw stream of bytes. Each of the virtual servers that managing the TCP connections must be of type TCP or SSL_TCP. The term TCP rewrite is used to refer to the rewrite of TCP payloads that are not HTTP data. In TCP traffic, you can add, modify, or delete any part of the TCP payload.

For examples to use the rewrite feature, see "[Rewrite Action and Policy Examples](#)."

Comparison between Rewrite and Responder options

The main difference between the rewrite feature and the responder feature is as follows:

Responder cannot be used for response or server-based expressions. Responder can be used only for the following scenarios depending on client parameters:

- Redirecting a http request to new Web sites or Web pages
- Responding with some custom response
- Dropping or resetting a connection at request level

In case of a responder policy, the NetScaler examines the request from the client, takes action according to the applicable policies, sends the response to the client, and closes the connection with the client.

In case of a rewrite policy, the NetScaler examines the request from the client or response from the server, takes action according to the applicable policies, and forwards the traffic to the client or the server.

In general, it is recommended to use responder if you want the NetScaler to reset or drop a connection based on a client or request-based parameter. Use responder to redirect traffic, or respond with custom messages. Use rewrite for manipulating data on HTTP requests and responses.

How Rewrite Works

Aug 30, 2013

A rewrite policy consists of a rule and action. The rule determines the traffic on which rewrite is applied and the action determines the action to be taken by the NetScaler. You can define multiple rewrite policies. For each policy, specify the bind point and priority.

A bind point refers to a point in the traffic flow at which the NetScaler examines the traffic to verify whether any rewrite policy can be applied to it. You can bind a policy to a specific load balancing or content switching virtual server, or make the policy global if you want the policy to be applied to the entire traffic handled by the NetScaler. These policies are referred to as global policies.

In addition to the user-defined policies, the NetScaler has some default policies. You cannot modify or delete a default policy.

For evaluating the policies, NetScaler follows the order mentioned below:

- Global policies
- Policies bound to specific virtual servers
- Default policies

Note: NetScaler can apply a rewrite policy only when it is bound to a point.

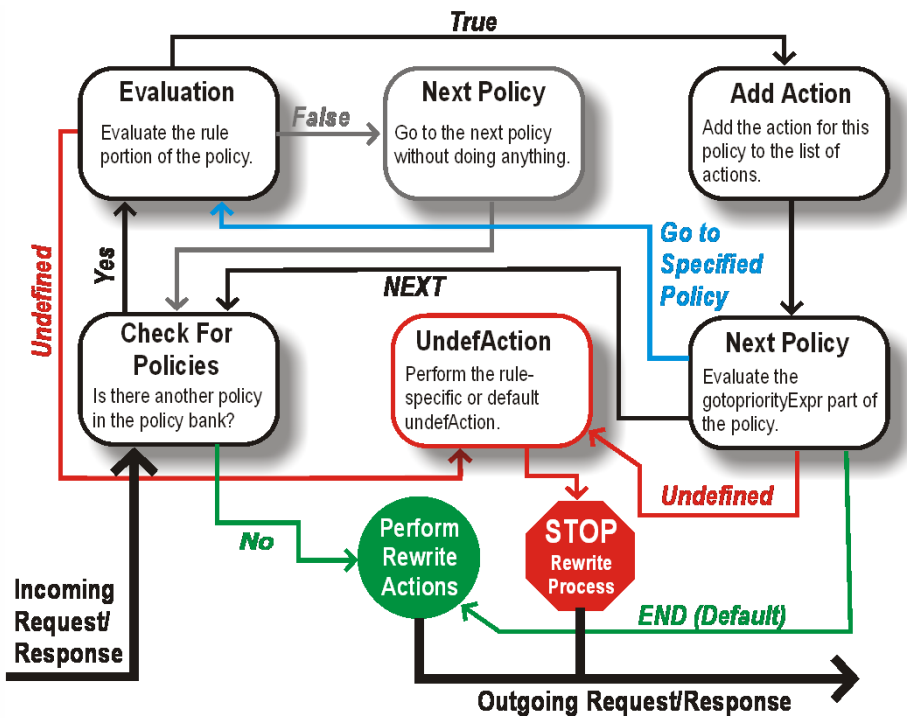

NetScaler implements the rewrite feature in the following steps:

- The NetScaler appliance checks for global policies and then checks for policies at individual bind points.
- If multiple policies are bound to a bind point, the NetScaler evaluates the policies in the order of their priority. The policy with the highest priority is evaluated first. After evaluating each policy, if the policy is evaluated to TRUE (the traffic matches the rule), it adds the action associated with the policy to a list of actions to be performed. A match occurs when the characteristics specified in the policy rule match the characteristics of the request or response being evaluated.
- For any policy, in addition to the action, you can specify the policy that should be evaluated after the current policy is evaluated. This policy is referred to as the 'Go to Expression'. For any policy, if a Go to Expression (gotoPriorityExpr) is specified, the NetScaler evaluates the Go to Expression policy; it ignores policy with the next highest priority. You can specify the priority of the policy to indicate the Go to Expression policy; you cannot use the name of the policy. If you want the NetScaler to stop evaluating other policies after evaluating a particular policy, you can set the Go to Expression to 'END'.
- After all the policies are evaluated or when a policy has the Go to Expression set as END, the NetScaler starts performing the actions according to the list of actions.

For more information about configuring rewrite policies, see "[Configuring a Rewrite Policy](#)" and about binding rewrite policies, see "[Binding a Rewrite Policy](#)."

The following figure illustrates how NetScaler processes a request or response when the rewrite feature is used.

Figure 1. The Rewrite Process

Policy Evaluation

The policy with the highest priority is evaluated first. NetScaler does not stop the evaluation of rewrite policies when it finds a match; it evaluates all the rewrite policies configured on the NetScaler.

- If a policy evaluates to TRUE, the NetScaler follows the procedure below:
 - If the policy has the Go to Expression set to END, the NetScaler stops evaluating all the other policies and starts performing the rewrite.
 - The gotoPriorityExpression can be set to 'NEXT', 'END', some integer or 'INVOCATION_LIST'. The value determines the policy with the next priority. The following table shows the action taken by NetScaler for each value of the expression.

Value of the expression	Action
NEXT	Policy with the next priority gets evaluated.
END	Evaluation of policies stops.
<an integer>	Policy with specified priority gets evaluated.
INVOCATION_LIST	Goto NEXT or END is applied based on the result of the invocation list.

- If a policy evaluates to FALSE, the NetScaler continues the evaluation in the order of priority.
- If a policy evaluates to UNDEFINED (cannot be evaluated on the received traffic due to an error), the NetScaler performs the action assigned to the UNDEFINED condition (referred to as undefAction) and stops further evaluation of policies.

The NetScaler starts the actual rewriting only after the evaluation is complete. It refers to the list of actions identified by

policies that are evaluated to TRUE, and starts the rewriting. After implementing all the actions in the list, the NetScaler forwards the traffic as required.

Note: Ensure that the policies do not specify conflicting or overlapping actions on the same part of the HTTP header or body, or TCP payload. When such a conflict occurs, the NetScaler encounters an undefined situation and aborts the rewrite.

Rewrite Actions

On the NetScaler appliance, specify the actions to be taken such as adding, replacing, or deleting text within the body, or adding, modifying or deleting headers, or any changes in the TCP payload as rewrite actions. For more information about rewrite actions, see "[Configuring a Rewrite Action](#)."

The following table describes the steps the NetScaler can take when a policy evaluates to TRUE.

Action	Result
Insert	The rewrite action specified for the policy is carried out.
NOREWRITE	The request or response is not rewritten. NetScaler forwards the traffic without rewriting any part of the message.
RESET	The connection is aborted at the TCP level.
DROP	The message is dropped.

Note: For any policy, you can configure the undefaction (action to be taken when the policy evaluates to UNDEFINED) as NOREWRITE, RESET, or DROP.

To use the Rewrite feature, take the following steps:

- Enable the feature on the NetScaler.
- Define rewrite actions.
- Define rewrite policies.
- Bind the policies to a bind point to bring a policy into effect.

Enabling the Rewrite Feature

Aug 30, 2013

Enable the rewrite feature on the NetScaler appliance if you want to rewrite the HTTP or TCP requests or responses. If the feature is enabled, NetScaler takes rewrite action according to the specified policies. For more information, see "[How Rewrite Works](#)."

To enable the rewrite feature by using the command line interface

At the command prompt, type the following commands to enable the rewrite feature and verify the configuration:

- enable ns feature REWRITE
- show ns feature

Example

```
> enable ns feature REWRITE
```

```
Done
```

```
> show ns feature
```

	Feature	Acronym	Status
	-----	-----	-----
1)	Web Logging	WL	OFF
2)	Surge Protection	SP	ON
.			
.			
.			
19)	Rewrite	REWRITE	ON
.			
.			
24)	NetScaler Push	push	OFF

```
Done
```

To enable the rewrite feature by using the configuration utility

1. In the navigation pane, click System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure basic features.
3. In the Configure Basic Features dialog box, select the Rewrite check box, and then click OK.
4. In the Enable/Disable Feature(s) dialog box, click Yes. A message appears in the status bar, stating that the selected feature was enabled.

Configuring a Rewrite Action

Nov 24, 2014

After enabling the rewrite feature, you need to configure one or more actions unless a built-in rewrite action is sufficient. All of the built-in actions have names beginning with the string `ns_cvpn`, followed by a string of letters and underscore characters. Built-in actions perform useful and complex tasks such as decoding parts of a clientless VPN request or response or modifying JavaScript or XML data. The built-in actions can be viewed, enabled, and disabled, but cannot be modified or deleted.

Target expressions in actions for TCP rewrite must begin with one of the following expression prefixes:

- **CLIENT.TCP.PAYLOAD.** For rewriting TCP payloads in client requests. For example, `CLIENT.TCP.PAYLOAD(10000).AFTER_STR("string1")`.
- **SERVER.TCP.PAYLOAD.** For rewriting TCP payloads in server responses. For example, `SERVER.TCP.PAYLOAD(1000).B64DECODE.BETWEEN("string1","string2")`.

You can use all types of existing string manipulation functions with these prefixes to identify the strings that you want to rewrite. To configure a rewrite action, you assign it a name, specify an action type, and add one or more arguments specifying additional data. The following table describes the action types and the arguments you use with them.

Note: Action types that can be used only for HTTP rewrite are identified in the **Rewrite Action Type** column.

Table 1. Rewrite Action Types and Their Arguments

Rewrite Action Type	Argument 1	Argument 2
INSERT_HTTP_HEADER: Inserts the HTTP header you specify into the HTTP request or response. This is the default choice. This action type can be used only with HTTP requests and responses.	The HTTP header you want to insert. For example, if you want to insert the client IP from which a request is sent, type <code>Client-IP</code> .	A string expression that describes the contents of the header you want to insert. For example, if you want to insert the Client IP from which a request is sent, type <code>CLIENT.IPSRC</code> .
INSERT_BEFORE: Inserts a new string before the designated string.	A string expression that describes the string before which you want to insert a new string. For example, if you want to find the hostname <code>www.example.com</code> and insert a string before the <code>example.com</code> portion, type the following: <code>HTTPREQ.HOSTNAME.BEFORE_STR("example.com")</code>	A string expression that describes the new string you want to insert. For example, if you want to insert the new string <code>en.</code> before the string <code>example</code> in the hostname, type <code>en</code> followed by a period.
INSERT_AFTER: Inserts a new string after the designated string.	A string expression that describes the string after which you want to insert a	A string expression that describes the new string

Rewrite Action Type	new string. Argument 1	Argument 2 you want to insert.
	<p>For example, if you want to find the hostname www.example.com, and insert a string after the www. portion, type the following:</p> <pre>HTTP.REQ.HOSTNAME.AFTER_STR ("www.")</pre>	<p>For example, if you want to insert the new string en. after the string www. in the hostname, type en followed by a period.</p>
<p>REPLACE: Replaces the designated string with a different string.</p>	<p>A string expression that describes the string you want to replace with a new string.</p> <p>For example, if you want to replace the entire hostname in the Host header, type HTTP.REQ.HOSTNAME.SERVER.</p>	<p>A string expression that describes the new string you want to insert.</p> <p>For example, if you want to replace the current host header with the string web01.example.net, type web01.example.net.</p>
<p>DELETE: Deletes the designated string.</p>	<p>A string expression that describes the string you want to delete.</p> <p>For example, if you want to find and delete the string .en in the hostname of HTTP response headers, type the following:</p> <pre>HTTP.RES.HEADER("Host").SUBSTR("en.")</pre>	
<p>DELETE_HTTP_HEADER: Deletes the designated HTTP header, including all header contents. This action type can be used only with HTTP requests and responses.</p>	<p>The name of the HTTP header you want to delete.</p> <p>For example, if you want to delete the cache-control header from HTTP responses, type HTTP.RES.HEADER("Cache-Control").</p>	
<p>CORRUPT_HTTP_HEADER: Replaces the name of the given HTTP header with a corrupted name so that it will not be recognized by the receiver. This action type can be used only with HTTP requests and responses.</p>	<p>The name of the HTTP header that you want to corrupt. If the specified header occurs more than once in a request, all the occurrences are corrupted.</p> <p>For example, if you want to corrupt the Host header in an HTTP request, you can use the following rewrite action command:</p> <pre>add rewrite action corrupt_header_act</pre>	

Rewrite Action Type	CORRUPT_HTTP_HEADER Host. Argument 1	Argument 2
<p>REPLACE_HTTP_RES: Replace the http response with the value specified in the target field. This action type can be used only with HTTP requests and responses.</p>	<p>A string expression that describes the string you want to replace the HTTP response with.</p> <p>For example, type HTTP 200 OK You are not authorized to view this page to replace the entire HTTP response with this warning.</p>	
<p>REPLACE_ALL: Will replace all occurrences of a pattern in the target text reference with the value specified in the string builder expression.</p>	<p>The part of either the HTTP request or response where you want to carry out the replacement.</p>	<p>A string expression that describes the new string you want to insert.</p>
<p>DELETE_ALL: Delete every occurrence of the pattern specified in the target text reference.</p>	<p>The part of either the HTTP request or response where you want the deletion to occur.</p>	<p>A string pattern after which the deletion should occur.</p>
<p>INSERT_AFTER_ALL: Inserts the value specified by string builder expression after each occurrence of a specified pattern in the target text reference.</p>	<p>The part of either the HTTP request or response where you want the insertion to occur.</p>	<p>A string expression that describes the new string you want to insert.</p>
<p>INSERT_BEFORE_ALL: Inserts the value you specify before each occurrence of the pattern you specify.</p>	<p>The part of either the HTTP request or response that you want to delete.</p>	<p>A string expression that describes the new string you want to insert.</p>
<p>CLIENTLESS_VPN_ENCODE: Encodes the URL you specify in clientless VPN format.</p>	<p>The URL you want to encode.</p>	
<p>CLIENTLESS_VPN_ENCODE_ALL: Encodes all of the URLs you specify in clientless VPN format.</p>	<p>A pattern that matches the URLs you want to encode.</p>	
<p>CLIENTLESS_VPN_DECODE: Decodes the URL you specify from clientless VPN format and returns it as unencoded text.</p>	<p>The URL you want to decode.</p>	
<p>CLIENTLESS_VPN_DECODE_ALL: Decodes all of the URLs you specify from clientless VPN format and returns them as unencoded text.</p>	<p>A pattern that matches all of the URLs you want to decode.</p>	

To create a new rewrite action by using the command line interface

At the command prompt, type the following commands to create a new rewrite action and verify the configuration:

- add rewrite action <name> <type> <target> [<stringBuilderExpr>][(-pattern <expression> | -patset <string>)] [-bypassSafetyCheck (YES | NO)]
- show rewrite action <name>

Example 1: Inserting an HTTP Header With the Client IP

```
> add rewrite action insertact INSERT_HTTP_HEADER "client-IP" CLIENT.IP.SRC
Done
```

```
> show rewrite action insertact
```

```
Name: insertact
Operation: insert_http_header Target:Client-IP
Value:CLIENT.IP.SRC
BypassSafetyCheck : NO
Hits: 0
Undef Hits: 0
Action Reference Count: 0
```

```
Done
```

Example 2: Replacing Strings in a TCP Payload (TCP Rewrite)

```
> add rewrite action client_tcp_payload_replace_all REPLACE_ALL
'client.tcp.payload(1000)' "new-string" -search text("old-string")
```

```
Done
```

```
> show rewrite action client_tcp_payload_replace_all
```

```
Name: client_tcp_payload_replace_all
Operation: replace_all
Target:client.tcp.payload(1000)
Value:"new-string"
Search: text("old-string")
BypassSafetyCheck : NO
Hits: 0
Undef Hits: 0
Action Reference Count: 0
```

```
Done
```

>
To modify an existing rewrite action by using the command line interface

At the command prompt, type the following commands to modify an existing rewrite action and verify the configuration:

- set rewrite action <name> [-target <string>] [-stringBuilderExpr <string>][(-pattern <expression> | -patset <string>)] [-bypassSafetyCheck (YES | NO)]
- show rewrite action <name>

Example

```
> set rewrite action insertact -target "Client-IP"
```

```
Done
```

```
> show rewrite action insertact
```

```
Name: insertact  
Operation: insert_http_header Target:Client-IP  
Value:CLIENT.IP.SRC  
BypassSafetyCheck : NO  
Hits: 0  
Undef Hits: 0  
Action Reference Count: 0
```

Done

To remove a rewrite action by using the command line interface

At the command prompt, type the following commands to remove a rewrite action :

```
rm rewrite action <name>
```

Example

```
> rm rewrite action insertact
```

Done

To configure a rewrite action by using the configuration utility

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, do one of the following:
 - To create a new action, click Add.
 - To modify an existing action, select the action, and then click Open.
3. Click Create or OK. A message appears in the status bar, stating that the Action has been configured successfully.
4. Repeat steps 2 through 4 to create or modify as many rewrite actions as you wish.
5. Click Close.

To add an expression by using the Add Expression dialog box

1. In the Create Rewrite Action or Configure Rewrite Action dialog box, under the text area for the type argument you want to enter, click Add.
2. In the Add Expression dialog box, in the first list box choose the first term for your expression.

HTTP

The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.

SYS

The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

CLIENT

The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.

3. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.
4. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

For more information about the PI expressions language and creating expressions for responder policies, see "[Policies and Expressions](#)."

If you want to test the effect of a rewrite action when used on sample HTTP data, you can use the Rewrite Expression Evaluator.

Note: The Rewrite Expression Evaluator is only available in the configuration utility. There is no NetScaler command line version.

To evaluate a rewrite action by using the Rewrite Action Evaluator dialog box

1. In the Rewrite Actions details pane, select the rewrite action that you want to evaluate, and then click Evaluate.
2. In the Rewrite Expression Evaluator dialog box, specify values for the following parameters. (An asterisk indicates a required parameter.)
 - Rewrite Action*—If the rewrite action you want to evaluate is not already selected, select it from the drop-down list. After you select a Rewrite action, the Details section displays the details of the selected Rewrite action.
 - New*—Select New to open the Create Rewrite Action dialog box and create a new rewrite action.
 - Modify*—Select Modify to open the Configure Rewrite Action dialog box and modify the selected rewrite action.
 - Flow Type*—Specifies whether to test the selected rewrite action with HTTP Request data or HTTP Response data. The default is Request. If you want to test with Response data, select Response.
 - HTTP Request/Response Data*—Provides a space for you to provide the HTTP data that the Rewrite Action Evaluator will use for testing. You can paste the data directly into the window, or click Sample to insert some sample HTTP headers.
 - Show end-of-line—Specifies whether to show UNIX-style end-of-line characters (\n) at the end of each line of sample HTTP data.
 - Sample—Inserts sample HTTP data into the HTTP Request/Response Data window. You can choose either GET or POST data.
 - Browse—Opens a local browse window so that you can choose a file containing sample HTTP data from a local or network location.
 - Clear—Clears the current sample HTTP data from the HTTP Request/Response Data window.
3. Click Evaluate. The Rewrite Action Evaluator evaluates the effect of the Rewrite action on the sample data that you chose, and displays the results as modified by the selected Rewrite action in the Results window. Additions and deletions are highlighted as indicated in the legend in the lower left-hand corner of the dialog box.
4. Continue evaluating Rewrite actions until you have determined that all of your actions have the effect that you wanted.
 - You can modify the selected rewrite action and test the modified version by clicking Modify to open the Configure Rewrite Action dialog box, making and saving your changes, and then clicking Evaluate again.
 - You can evaluate a different rewrite action using the same request or response data by selecting it from the Rewrite Action drop-down list, and then clicking Evaluate again.
5. Click Close to close the Rewrite Expression Evaluator and return to the Rewrite Actions pane.

To delete a rewrite action, select the rewrite action you want to delete, then click Remove and, when prompted, confirm your choice by clicking OK.

Configuring a Rewrite Policy

Aug 30, 2013

After you create any needed rewrite action(s), you must create at least one rewrite policy to select the requests that you want the NetScaler appliance to rewrite.

A rewrite policy consists of a rule, which itself consists of one or more expressions, and an associated action that is performed if a request or response matches the rule. Policy rules for evaluating HTTP requests and responses can be based on almost any part of a request or response.

Even though you cannot use TCP rewrite actions to rewrite data other than the TCP payload, you can base the policy rules for TCP rewrite policies on the information in the transport layer and the layers below the transport layer.

If a configured rule matches a request or response, the corresponding policy is triggered and the action associated with it is carried out.

Note: You can use either the command line interface or the configuration utility to create and configure rewrite policies. Users who are not thoroughly familiar with the command line interface and the NetScaler Policy expression language will usually find using the configuration utility much easier.

To add a new rewrite policy by using the command line interface

At the command prompt, type the following commands to add a new rewrite policy and verify the configuration:

- add rewrite policy <name> <expression> <action> [<undefaction>]
- show rewrite policy <name>

Example 1: Rewriting HTTP Content

```
> add rewrite policy policyNew "HTTP.RES.IS_VALID" insertact NOREWRITE
Done
> show rewrite policy policyNew
  Name: policyNew
  Rule: HTTP.RES.IS_VALID
  RewriteAction: insertact
  UndefAction: NOREWRITE
  Hits: 0
  Undef Hits: 0
```

Done

Example 2: Rewriting a TCP Payload (TCP Rewrite)

```
> add rewrite policy client_tcp_payload_policy CLIENT.IP.SRC.EQ(172.168.12.232) client_tcp_payload_replace_all
Done
> show rewrite policy client_tcp_payload_policy
  Name: client_tcp_payload_policy
  Rule: CLIENT.IP.SRC.EQ(172.168.12.232)
  RewriteAction: client_tcp_payload_replace_all
  UndefAction: Use Global
  LogAction: Use Global
  Hits: 0
```

Undef Hits: 0

Done

>
To modify an existing rewrite policy by using the command line interface

At the command prompt, type the following commands to modify an existing rewrite policy and verify the configuration:

- set rewrite policy <name> -rule <expression> -action <action> [<undefaction>]
- show rewrite policy <name>

Example

```
> set rewrite policy policyNew -rule "HTTP.RES.IS_VALID" -action insertaction
```

Done

```
> show rewrite policy policyNew
```

```
Name: policyNew  
Rule: HTTP.RES.IS_VALID  
RewriteAction: insertaction  
UndefAction: NOREWRITE  
Hits: 0  
Undef Hits: 0
```

Done

To remove a rewrite policy by using the command line interface

At the command prompt, type the following command to remove a rewrite policy:

```
rm rewrite policy <name>
```

Example

```
> rm rewrite policy policyNew
```

Done

To configure a rewrite policy by using the configuration utility

1. Navigate to AppExpert > Rewrite > Policies.
2. In the details pane, do one of the following:
 - To create a new policy, click Add.
 - To modify an existing policy, select the policy, and then click Open.
3. Click Create or OK. A message appears in the status bar, stating that the Policy has been configured successfully.
4. Repeat steps 2 through 4 to create or modify as many rewrite actions as you wish.
5. Click Close. To delete a rewrite policy, select the rewrite policy you want to delete, then click Remove and, when prompted, confirm your choice by clicking OK.

Binding a Rewrite Policy

Oct 29, 2013

After creating a rewrite policy, you must bind it to put it into effect. You can bind your policy to Global if you want to apply it to all traffic that passes through your NetScaler, or you can bind your policy to a specific virtual server or bind point to direct only that virtual server or bind point's incoming traffic to that policy. If an incoming request matches a rewrite policy, the action associated with that policy is carried out.

Rewrite policies for evaluating HTTP requests and responses can be bound to virtual servers of type HTTP or SSL, or they can be bound to the REQ_OVERRIDE, REQ_DEFAULT, RES_OVERRIDE, and RES_DEFAULT bind points. Rewrite policies for TCP rewrite can be bound only to virtual servers of type TCP or SSL_TCP, or to the OTHERTCP_REQ_OVERRIDE, OTHERTCP_REQ_DEFAULT, OTHERTCP_RES_OVERRIDE, and OTHERTCP_RES_DEFAULT bind points.

Note: The term OTHERTCP is used in the context of the NetScaler appliance to refer to all TCP or SSL_TCP requests and responses that you want to treat as a raw stream of bytes regardless of the protocols that the TCP packets encapsulate.

When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

In the NetScaler operating system, policy priorities work in reverse order - the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is applied first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000.

Unlike most other features in the NetScaler operating system, the rewrite feature continues to evaluate and implement policies after a request matches a policy. However, the effect of a particular action policy on a request or response will often be different depending on whether it is performed before or after another action. Priority is important to get the results you intended.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you bind it. If you do this, you can add additional policies at any time without having to reassign the priority of an existing policy.

When binding a rewrite policy, you also have the option of assigning a goto expression (gotoPriorityExpression) to the policy. A goto expression can be any positive integer that matches the priority assigned to a different policy that has a higher priority than the policy that contains the goto expression. If you assign a goto expression to a policy, and a request or response matches the policy, the NetScaler will immediately go to the policy whose priority matches the goto expression. It will skip over any policies with priority numbers that are lower than that of the current policy, but higher than the priority number of the goto expression, and not evaluate those policies.

For more information about binding policies on the NetScaler, see "[Binding a Rewrite Policy](#)."

To globally bind a rewrite policy by using the command line interface

At the command prompt, type the following commands to globally bind a rewrite policy and verify the configuration:

- bind rewrite global <policyName> <priority> [<gotoPriorityExpression>] [-type <type>] [-invoke (<labelType> <labelName>)]
- show rewrite global

Example

```
>bind rewrite global policyNew 10
Done
```

```
> show rewrite global
1) Global bindpoint: RES_DEFAULT
   Number of bound policies: 1

2) Global bindpoint: REQ_OVERRIDE
   Number of bound policies: 1
```

Done

To bind rewrite policy to a specific virtual server by using the command line interface

At the command prompt, type the following commands to bind rewrite policy to a specific virtual server and verify the configuration:

- bind lb vserver <name>@ (<serviceName>@ [-weight <positive_integer>]) | <serviceGroupName>@ | (-policyName <string>@ [-priority <positive_integer>] [-gotoPriorityExpression <expression>] [-type (REQUEST | RESPONSE)] [-invoke (<labelType> <labelName>)])
- show lb vserver <name>

Example

```
> bind lb vserver lbvip -policyName ns_cmp_msapp -priority 50
Done
```

```
>
```

```
> show lb vserver lbvip
  lbvip (8.7.6.6:80) - HTTP      Type: ADDRESS
  State: DOWN
  Last state change was at Wed Jul 15 05:54:24 2009 (+226 ms)
  Time since last state change: 28 days, 01:57:26.350
  Effective State: DOWN
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Port Rewrite : DISABLED
  No. of Bound Services : 0 (Total)    0 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE
  Vserver IP and Port insertion: OFF
  Push: DISABLED  Push VServer:
  Push Multi Clients: NO
  Push Label Rule: none
```

- 1) Policy : ns_cmp_msapp Priority:50
- 2) Policy : cf-pol Priority:1 Inherited

Done

To bind a rewrite policy to a bind point by using the configuration utility

1. Navigate to AppExpert > Rewrite > Policies.
2. In the details pane, select the rewrite policy you want to globally bind, and then click Policy Manager.
3. In the Rewrite Policy Manager dialog box, in the Bind Points menu, do one of the following:
 1. If you want to configure bindings for HTTP rewrite policies, click HTTP, and then click either Request or Response, depending on whether you want to configure request-based rewrite policies or response-based rewrite policies.
 2. If you want to configure bindings for TCP rewrite policies, click TCP, and then click either Client or Server, depending on whether you want to configure client-side TCP rewrite policies or server-side TCP rewrite policies.
4. Click the bind point to which you want to bind the rewrite policy. The Rewrite Policy Manager dialog box displays all the rewrite policies that are bound to the selected bind point.
5. Click Insert Policy to insert a new row and display a drop-down list with all available, unbound rewrite policies.
6. Click the policy you want to bind to the bind point. The policy is inserted into the list of rewrite policies bound to the bind point.
7. In the Priority column, you can change the priority to any positive integer. For more information about this parameter, see priority in "Parameters for binding a rewrite policy."
8. If you want to skip over policies and go directly to a specific policy in the event that the current policy is matched, change the value in the Goto Expression column to equal the priority of the next policy to be applied.. For more information about this parameter, see gotoPriorityExpression in "Parameters for binding a rewrite policy."
9. To modify a policy, click the policy, and then click Modify Policy.
10. To unbind a policy, click the policy, and then click Unbind Policy.
11. To modify an action, in the Action column, click the action you want to modify, and then click Modify Action.
12. To modify an invoke label, in the Invoke column, click the invoke label you want to modify, and then click Modify Invoke Label.
13. To regenerate the priorities of all the policies that are bound to the bind point you are currently configuring, click Regenerate Priorities. The policies retain their existing priorities relative to the other policies, but the priorities are renumbered in multiples of ten.
14. Click Apply Changes.
15. Click Close. A message appears in the status bar, stating that the Policy has been configured successfully.

To bind a rewrite policy to a specific virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane list of virtual servers, select the virtual server to which you want to bind the rewrite policy, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab. All policies configured on your NetScaler appear on the list.
4. Select the check box next to the name of the policy you want to bind to this virtual server.
5. Click OK. A message appears in the status bar, stating that the Policy has been configured successfully.

Configuring Rewrite Policy Labels

Aug 30, 2013

If you want to build a more complex policy structure than is supported by single policies, you can create policy labels and then bind them as you would policies. A policy label is a user-defined point to which policies are bound. When a policy label is invoked, all the policies bound to it are evaluated in the order of the priority you configured. A policy label can include one or multiple policies, each of which can be assigned its own result. A match on one policy in the policy label can result in proceeding to the next policy, invoking a different policy label or appropriate resource, or an immediate end to policy evaluation and return of control to the policy that invoked the policy label.

A rewrite policy label consists of a name, a transform name that describes the type of policy included in the policy label, and a list of policies bound to the policy label. Each policy that is bound to the policy label contains all of the elements described in "[Configuring a Rewrite Policy](#)."

Note: You can use either the command line interface or the configuration utility to create and configure rewrite policy labels. Users who are not thoroughly familiar with the command line interface and the NetScaler Policy Infrastructure (PI) language will usually find using the configuration utility much easier.

To configure a rewrite policy label by using the command line interface

To add a new rewrite policy label, at the command prompt, type the following command:

```
add rewrite policylabel <labelName> <transform>
```

For example, to add a rewrite policy label named `polLabelHTTPResponses` to group all policies that work on HTTP responses, you would type the following:

```
add rewrite policylabel polLabelHTTPResponses http_res
```

To modify an existing rewrite policy label, at the NetScaler command prompt, type the following command:

```
set rewrite policy <name> <transform>
```

Note: The `set rewrite policy` command takes the same options as the `add rewrite policy` command.

To remove a rewrite policy label, at the NetScaler command prompt, type the following command:

```
rm rewrite policy<name>
```

For example, to remove a rewrite policy label named `polLabelHTTPResponses`, you would type the following:

```
rm rewrite policy polLabelHTTPResponses
```

To configure a rewrite policy label by using the configuration utility

1. Navigate to AppExpert > Rewrite > Policy Labels.
2. In the details pane, do one of the following:
 - To create a new policy label, click Add.
 - To modify an existing policy label, select the policy, and then click Open.
3. Add or remove policies from the list that is bound to the policy label.
 - To add a policy to the list, click Insert Policy, and choose a policy from the drop-down list. You can create a new policy and add it to the list by choosing New Policy in the list, and following the instructions in "[Configuring a Rewrite Policy](#)."

- To remove a policy from the list, select that policy, and then click Unbind Policy.

4. Modify the priority of each policy by editing the number in the Priority column.

You can also automatically renumber policies by clicking Regenerate Priorities.

5. Click Create or OK, and then click Close.

To remove a policy label, select it, and then click Remove. To rename a policy label, select it and then click Rename. Edit the name of the policy, and then click OK to save your changes.

Configuring the Default Rewrite Action

Aug 30, 2013

An undefined event is triggered when the NetScaler cannot evaluate a policy, usually because it detects a logical or other error in the policy or an error condition on the NetScaler. When the rewrite policy evaluation results in an error, the specified undefined action is carried out. Undefined actions configured at the rewrite policy level are carried out before a globally configured undefined action.

The NetScaler supports following three types of undefined actions:

undefAction NOREWRITE

Aborts rewrite processing, but does not alter the packet flow. This means that the NetScaler continues to process requests and responses that do not match any rewrite policy, and eventually forwards them to the requested URL unless another feature intervenes and blocks or redirects the request. This action is appropriate for normal requests to your Web servers, and is the default setting.

undefAction RESET

Resets the client connection. This means that the NetScaler tells the client that it must re-establish its session with the Web server. This action is appropriate for repeat requests for Web pages that do not exist, or for connections that might be attempts to hack or probe your protected Web site(s).

undefAction DROP

Silently drops the request without responding to the client in any way. This means that the NetScaler simply discards the connection without responding to the client. This action is appropriate for requests that appear to be part of a DDoS attack or another sustained attack on your servers.

Note: Undefined events can be triggered for both request and response flow specific policies.

To configure the default action by using the command line interface

At the command prompt, type the following commands to configure the default action and verify the configuration:

- set rewrite param -undefAction (NOREWRITE | RESET | DROP)
- show rewrite param

Example

```
> set rewrite param -undefAction NOREWRITE
```

```
Done
```

```
> show rewrite param
```

```
  Action Name: NOREWRITE
```

```
Done
```

To configure the default action by using the configuration utility

1. Navigate to AppExpert > Rewrite.
2. In the details pane, under Rewrite Overview, click the Change Rewrite Settings link. The Set Rewrite Params dialog box appears.
3. Under Global Undefined-Result Action, select an option as follows:
 - NoRewrite—NOREWRITE
 - Reset—RESET
 - Drop—DROP

4. Click OK. The global undefined action is set to the value you chose.

Bypassing the Safety Check

Oct 29, 2013

When you create a rewrite action, the NetScaler verifies that the expression you used to create the action is safe. Expressions created by the NetScaler from run-time data, such as URLs contained in HTTP requests, can cause unexpected errors. The NetScaler reports expressions that cause such errors as unsafe expressions.

In some cases, the expressions may be safe. For example, the NetScaler cannot validate an expression that contains a URL that does not resolve, even if the URL does not resolve because the Web server is temporarily unavailable. You can manually bypass the Safety Check to allow these expressions.

To bypass the safety check by using the command line interface

At the command prompt, type the following commands to bypass the safety check and verify the configuration:

- set rewrite action <name> -bypassSafetyCheck YES
- show rewrite action <name>

Example

```
> set rewrite action insertact -bypassSafetyCheck YES
```

```
Done
```

```

To bypass safety check by using the configuration utility

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, select the rewrite action to be exempted from the safety check, and then click Open.
3. In the Configure Rewrite Action dialog box, select the Bypass Safety Check check box.
4. Click OK.

Rewrite Action and Policy Examples

Mar 20, 2012

The examples in this section demonstrate how to configure rewrite to perform various useful tasks. The examples occur in the server room of Example Manufacturing Inc., a mid-sized manufacturing company that uses its Web site to manage a considerable portion of its sales, deliveries, and customer support.

Example Manufacturing has two domains: example.com for its Web site and email to customers, and example.net for its intranet. Customers use the Example Web site to place orders, request quotes, research products, and contact customer service and technical support.

As an important part of Example's revenue stream, the Web site must respond quickly and keep customer data confidential. Example therefore has several Web servers and uses Citrix NetScaler appliances to balance the Web site load and manage traffic to and from its Web servers.

The Example system administrators use the rewrite features to perform the following tasks:

Example 1: Delete old X-Forwarded-For and Client-IP Headers.

Example Inc. removes old X-Forwarded-For and Client-IP HTTP headers from incoming requests.

Example 2: Adding a Local Client-IP Header.

Example Inc. adds a new, local Client-IP header to incoming requests.

Example 3: Tagging Secure and Insecure Connections.

Example Inc. tags incoming requests with a header that indicates whether the connection is a secure connection.

Example 4: Mask the HTTP Server Type.

Example Inc. modifies the HTTP Server: header so that unauthorized users and malicious code cannot use that header to determine the HTTP server software it uses.

Example 5: Redirect an External URL to an Internal URL.

Example Inc. hides information about the actual names of its Web servers and the configuration of its server room from users, to make URLs on its Web site shorter and easier to remember, and to improve security on its site.

Example 6: Migrating Apache Rewrite Module Rules.

Example Inc. moved its Apache rewrite rules to a NetScaler appliance, translating the Apache PERL-based script syntax to the NetScaler rewrite rule syntax.

Example 7: Marketing Keyword Redirection.

The marketing department at Example Inc. sets up simplified URLs for certain predefined keyword searches on the company's Web site.

Example 8: Redirect Queries to the Queried Server.

Example Inc. redirects certain query requests to the appropriate server.

Example 9: Home Page Redirection.

Example Inc. recently acquired a smaller competitor, and it now redirects requests for the acquired company's home page to a page on its own Web site.

Each of these tasks requires that the system administrators create rewrite actions and policies and bind them to a valid bind point on the NetScaler.

Example 1: Delete Old X-Forwarded-For and Client-IP Headers

Aug 30, 2013

Example Inc. wants to remove old X-Forwarded-For and Client-IP HTTP headers from incoming requests, so that the only X-Forwarded-For headers that appear are the ones added by the local server. This configuration can be done through the NetScaler command line or the configuration utility. The Example Inc. system administrator is an old-school networking engineer and prefers to use a CLI where possible, but wants to be sure he understands the configuration utility interface so that he can show new system administrators on the team how to use it.

The examples below demonstrate how to perform each configuration with both the CLI and the configuration utility. The procedures are abbreviated on the assumption that users will already know the basics of creating rewrite actions, creating rewrite policies, and binding policies.

- For more detailed information about creating rewrite actions, see [Configuring a Rewrite Action](#).
- For more detailed information about creating rewrite policies, see [Configuring a Rewrite Policy](#).
- For more detailed information about binding rewrite policies, see [Binding a Rewrite Policy](#).

To delete old X-Forwarded and Client-IP headers from a request by using the command line interface

At the command prompt, type the following commands in the order shown:

```
add rewrite action act_del_xfor delete_http_header x-forwarded-for
add rewrite action act_del_cip delete_http_header client-ip
add rewrite policy pol_check_xfor 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS' act_del_xfor
add rewrite policy pol_check_cip 'HTTP.REQ.HEADER("client-ip").EXISTS' act_del_cip
bind rewrite global pol_check_xfor 100 200
bind rewrite global pol_check_cip 200 300
```

To delete old X-Forwarded and Client-IP headers from a request by using the configuration utility

In the Create Rewrite Action dialog box, create two rewrite actions with the following descriptions.

Name	Type	Argument(s)
act_del_xfor	delete_http_header	x-forwarded-for
act_del_cip	delete_http_header	client-ip

In the Create Rewrite Policy dialog box, create two rewrite policies with the following descriptions.

Name	Expression	Action
pol_check_xfor	'HTTP.REQ.HEADER("x-forwarded-for").EXISTS'	act_del_xfor
pol_check_cip	'HTTP.REQ.HEADER("client-ip").EXISTS'	act_del_cip

Bind both policies to global, assigning the priorities and goto expression values shown below.

Name	Priority	Goto Expression
pol_check_xfor	100	200
pol_check_cip	200	300

All old X-Forwarded-For and Client-IP HTTP headers are now deleted from incoming requests.

Example 2: Adding a Local Client-IP Header

Aug 30, 2013

Example Inc. wants to add a local Client-IP HTTP header to incoming requests. This example contains two slightly different versions of the same basic task.

To add a local Client-IP header by using the command line interface

At the command prompt, type the following commands in the order shown:

```
add rewrite action act_ins_client insert_http_header NS-Client 'CLIENT.IP.SRC'  
add rewrite policy pol_ins_client 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS || HTTP.REQ.HEADER("client-ip").EXISTS' act_ins_client  
bind rewrite global pol_ins_client 300 END
```

To add a local Client-IP header by using the configuration utility

In the Create Rewrite Action dialog box, create a rewrite action with the following description.

Name	Type	Argument(s)
act_ins_client	insert_http_header	NS-Client 'CLIENT.IP.SRC'

In the Create Rewrite Policy dialog box, create a rewrite policy with the following description.

Name	Expression	Action
pol_ins_client	'HTTP.REQ.HEADER("x-forwarded-for").EXISTS HTTP.REQ.HEADER("client-ip").EXISTS'	act_ins_client

Bind both policies to global, assigning the priorities and goto expression values shown below.

Name	Priority	GoTo
pol_ins_client	100	Next

A local Client-IP HTTP header is now added to incoming requests. You can also modify the configuration above to append all IPs from X-Forwarded-For headers to the new Client-IP header, as shown below.

Example 3: Tagging Secure and Insecure Connections

Mar 20, 2012

Example Inc. wants to tag incoming requests with a header that indicates whether or not the connection is a secure connection. This helps the server keep track of secure connections after the NetScaler has decrypted the connections.

To implement this configuration, you would begin by creating rewrite actions with the values shown in the following tables. These actions label connections to port 80 as insecure connections, and connections to port 443 as secure connections.

Action Name	Type of Rewrite Action	Header Name	Value
Action-Rewrite-SSL_YES	INSERT_HTTP_HEADER	SSL	YES

Action Name	Type of Rewrite Action	Header Name	Value
Action-Rewrite-SSL_NO	INSERT_HTTP_HEADER	SSL	NO

You would then create a rewrite policy with the values shown in the following tables. These policies check incoming requests to determine which requests are directed to port 80 and which are directed to port 443. The policies then add the correct SSL header.

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-SSL_YES	Action-Rewrite-SSL_YES	NOREWRITE	CLIENT.TCP.DSTPORT.EQ(443)
Policy-Rewrite-SSL_NO	Action-Rewrite-SSL_NO	NOREWRITE	CLIENT.TCP.DSTPORT.EQ(80)

Finally, you would bind the rewrite policies to NetScaler, assigning the first policy a priority of 200, and the second a priority of 300, and setting the goto expression of both policies to END.

Each incoming connection to port 80 now has an SSL:NO HTTP header added to it and each incoming connection to port 443 has an SSL:YES HTTP header added to it.

Example 4: Mask the HTTP Server Type

Mar 20, 2012

Example Inc. wants to modify the HTTP Server: header so that unauthorized users and malicious code cannot use the header to identify the software that the HTTP server uses.

To modify the HTTP Server: header, you would create a rewrite action and a rewrite policy with the values in the following tables.

Action Name	Type of Rewrite Action	Expression to choose target reference	String expression for replacement text
Action-Rewrite-Server_Mask	REPLACE	HTTP.RES.HEADER("Server")	"Web Server 1.0"

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-Server_Mask	Action-Rewrite-Server_Mask	NOREWRITE	HTTP.RES.IS_VALID

You would then globally bind the rewrite policy, assigning a priority of 100 and setting the Goto Priority Expression of the policy to END.

The HTTP Server: header is now modified to read "Web Server 1.0," masking the actual HTTP server software used by the Example Inc. Web site.

Example 5: Redirect an External URL to an Internal URL

Mar 20, 2012

Example Inc. wants to hide its actual server room configuration from users to improve security on its Web servers.

To do this, you would create a rewrite action with the values as shown in the following tables. For request headers, the action in the table modifies `www.example.com` to `web.hq.example.net`. For response headers, the action does the opposite, translating `web.hq.example.net` to `www.example.com`.

Action Name	Type of Rewrite Action	Expression to choose target reference	String expression for replacement text
Action-Rewrite-Request_Server_Replace	REPLACE	HTTP.REQ.HOSTNAME.SERVER	"Web.hq.example.net"
Action-Rewrite-Response_Server_Replace	REPLACE	HTTP.RES.HEADER("Server")	"www.example.com"

Next, you would create rewrite policies using the values shown in the following tables. The first policy checks incoming requests to see if they are valid, and if they are, it performs the Action-Rewrite-Request_Server_Replace action. The second policy checks responses to see if they originate at the server `web.hq.example.net`. If they do, it performs the Action-Rewrite-Response_Server_Replace action.

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-Request_Server_Replace	Action-Rewrite-Request_Server_Replace	NOREWRITE	HTTP.REQ.HOSTNAME.SERVER.EQ("www.example.com")
Policy-Rewrite-Response_Server_Replace	Action-Rewrite-Response_Server_Replace	NOREWRITE	HTTP.RES.HEADER("Server").EQ("web.hq.example.net")

Finally, you would bind the rewrite policies, assigning each a priority of 500 because they are in different policy banks and therefore will not conflict. You should set the `goto` expression to `NEXT` for both bindings.

All instances of `www.example.com` in the request headers are now changed to `web.hq.example.net`, and all instances of `web.hq.example.net` in response headers are now changed to `www.example.com`.

Example 6: Migrating Apache Rewrite Module Rules

Mar 20, 2012

Example Inc., is currently using the Apache rewrite module to process search requests sent to its Web servers and redirect those requests to the appropriate server on the basis of information in the request URL. Example Inc. wants to simplify its setup by migrating these rules onto the NetScaler platform.

Several Apache rewrite rules that Example currently uses are shown below. These rules redirect search requests to a special results page if they do not have a SiteID string or if they have a SiteID string equal to zero (0), or to the standard results page if these conditions do not apply.

The following are the current Apache rewrite rules:

- RewriteCond %{REQUEST_FILENAME} ^/search\$ [NC]
- RewriteCond %{QUERY_STRING} !SiteId= [OR]
- RewriteCond %{QUERY_STRING} SiteId=0
- RewriteCond %{QUERY_STRING} CallName=DisplayResults [NC]
- RewriteRule ^.*\$ /results2.html [P,L]
- RewriteCond %{REQUEST_FILENAME} ^/search\$ [NC]
- RewriteCond %{QUERY_STRING} CallName=DisplayResults [NC]
- RewriteRule ^.*\$ /results.html [P,L]

To implement these Apache rewrite rules on the NetScaler, you would create rewrite actions with the values in the following tables.

Action Name	Type of Rewrite Action	Expression to choose target reference	String expression for replacement text
Action-Rewrite-Display_Results_NulSiteID	REPLACE	HTTP.REQ.URL	"/results2.html"
Action-Rewrite-Display_Results	REPLACE	HTTP.REQ.URL	"/results2.html"

You would then create rewrite policies with the values as shown in the tables below.

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-Display_Results_NulSiteID	Action-Rewrite-Display_Results_NulSiteID	NOREWRITE	HTTP.REQ.URL.PATH.SET_TEXT_MODE(IGNORECASE).EQ("/search") && (!HTTP.REQ.URL.QUERY.CONTAINS("SiteId=") HTTP.REQ.URL.QUERY.CONTAINS("SiteId=0")) HTTP.REQ.URL.QUERY.SET_TEXT_MODE(IGNORECASE).CONTAINS("CallName=DisplayResults")
Policy-Rewrite-Display_Results	Action-Rewrite-Display_Results	NOREWRITE	HTTP.REQ.URL.PATH.SET_TEXT_MODE(IGNORECASE).EQ("/search") HTTP.REQ.URL.QUERY.SET_TEXT_MODE(IGNORECASE).CONTAINS("CallName=DisplayResults")

Finally, you would bind the rewrite policies, assigning the first a priority of 600 and the second a priority of 700, and then set the goto expression to NEXT for both bindings.

The NetScaler now handles these search requests exactly as the Web server did before the Apache rewrite module rules were migrated.

Example 7: Marketing Keyword Redirection

Mar 20, 2012

The marketing department at Example Inc. wants to set up simplified URLs for certain predefined keyword searches on the company's Web site. For these keywords, it wants to redefine the URL as shown below.

- External URL: `http://www.example.com/<marketingkeyword>`
- Internal URL: `http://www.example.com/go/kwsearch.asp?keyword=<marketingkeyword>`

To set up redirection for marketing keywords, you would create a rewrite action with the values in the following table.

Action Name	Type of Rewrite Action	Expression to choose target location	String expression for replacement text
Action-Rewrite-Modify_URL	INSERT_BEFORE	HTTP.REQ.URL.PATH.GET(1)	""go/kwsearch.aspkeyword=""

You would then create a rewrite policy with the values in the following table.

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-Modify_URL	Action-Rewrite-Modify_URL	NOREWRITE	HTTP.REQ.HOSTNAME.SERVER.EQ("www.example.com")

Finally, you would bind the rewrite policy, assigning it a priority of 800. Unlike the previous rewrite policies, this policy should be the last to be applied to a request that matches its criteria. For this reason, NetScaler administrator sets its Goto Priority Expression to END.

Any request using a marketing keyword is redirected to the keyword search CGI page, whereupon a search is performed and all remaining policies are skipped.

Example 8: Redirect Queries to the Queried Server

Mar 20, 2012

Example Inc. wants to redirect query requests to the appropriate server, as shown here.

- Request: GET /query.cgi?server=5HOST: www.example.com
- Redirect URL: http://web-5.example.com/

To implement this redirection, you would first create a rewrite action with the values in the following table.

Action Name	Type of Rewrite Action	Expression to choose target reference	String expression for replacement text
Action-Rewrite-Replace_Hostheader	REPLACE	HTTP.REQ.HEADER("Host").BEFORE_STR(".example.com")	"server-" + HTTP.REQ.URL.QUERY.VALUE("web")

You would then create a rewrite policy with the values in the following table.

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-Replace_Hostheader	Action-Rewrite-Replace_Hostheader	NOREWRITE	HTTP.REQ.HEADER("Host").EQ("www.example.com")

Finally, you would bind the rewrite policy, assigning it a priority of 900. Because this policy should be the last policy applied to a request that matches its criteria, you set the goto expression to END.

Incoming requests to any URL that begins with http://www.example.com/query.cgi?server= are redirected to the server number in the query.

Example 9: Home Page Redirection

Mar 20, 2012

New Company, Inc. recently acquired a smaller competitor, Purchased Company, and wants to redirect the home page for Purchased Company to a new page on its own Web site, as shown here.

- Old URL: <http://www.purchasedcompany.com/>*
- New URL: <http://www.newcompany.com/products/page.htm>

To redirect requests to the Purchased Company home page, you would create rewrite actions with the values in the following table.

Action Name	Type of Rewrite Action	Expression to choose target reference	String expression for replacement text
Action-Rewrite-Replace_URLr	REPLACE	HTTP.REQ.URLPATH_AND_QUERY	"/products/page.htm"
Action-Rewrite-Replace_Host	REPLACE	HTTP.REQ.HOSTNAME	"www.newcompany.com"

You would then create rewrite policies with the values in the following table.

Policy Name	Action Name	Undefined Action	Expression
Policy-Rewrite-Replace-None	Action-Rewrite-Replace-None	NOREWRITE	!HTTP.REQ.HOSTNAME.SERVER.EQ("www.purchasedcompany.com")
Policy-Rewrite-Replace-Host	Action-Rewrite-Replace_Host	NOREWRITE	HTTP.REQ.HOSTNAME.SERVER.EQ("www.purchasedcompany.com")
Policy-Rewrite-Replace-URL	Action-Rewrite-Replace_URL	NOREWRITE	HTTP.REQ.IS_VALID

Finally, you would bind the rewrite policies globally, assigning the first a priority of 100, the second a priority of 200, and the third a priority of 300. These policies should be the last policies applied to a request that matches the criteria. For this reason, set the goto expression to END for the first and third policies, and to 300 for the second policy. This ensures that all remaining requests are processed correctly.

Requests to the acquired company's old Web site are now redirected to the correct page on the New Company home page.

URL Transformation

Mar 21, 2012

The URL transformation feature provides a method for modifying all URLs in designated requests from an external version seen by outside users to an internal URL seen only by your Web servers and IT staff. You can redirect user requests seamlessly, without exposing your network structure to users. You can also modify complex internal URLs that users may find difficult to remember into simpler, more easily remembered external URLs.

Note: Before you can use the URL transformation feature, you must enable the Rewrite feature. To enable the Rewrite feature, see [Enabling the Rewrite Feature](#).

To begin configuring URL transformation, you create profiles, each describing a specific transformation. Within each profile, you create one or more actions that describe the transformation in detail. Next, you create policies, each of which identifies a type of HTTP request to transform, and you associate each policy with an appropriate profile. Finally, you globally bind each policy to put it into effect.

Configuring URL Transformation Profiles

Oct 29, 2013

A profile describes a specific URL transformation as a series of actions. The profile functions primarily as a container for the actions, determining the order in which the actions are performed. Most transformations transform an external hostname and optional path into a different, internal hostname and path. Most useful transformations are simple and require only a single action, but you can use multiple actions to perform complex transformations.

You cannot create actions and then add them to a profile. You must create the profile first, and then add actions to it. In the CLI, creating an action and configuring the action are separate steps. Creating a profile and configuring the profile are separate steps in both the CLI and the configuration utility.

To create a URL transformation profile by using the NetScaler command line

At the NetScaler command prompt, type the following commands, in the order shown, to create a URL transformation profile and verify the configuration. You can then repeat the second and third commands to configure additional actions:

- add transform profile <profileName> -type URL [-onlyTransformAbsURLinBody (ON | OFF)] [-comment <comment>]
- add transform action <name> <profileName> <priority>
- set transform action <name> [-priority <priority>] [-reqUrlFrom <expression>] [-reqUrlInto <expression>] [-resUrlFrom <expression>] [-resUrlInto <expression>] [-cookieDomainFrom <expression>] [-cookieDomainInto <expression>] [-state (ENABLED | DISABLED)] [-comment "<string>"]
- show transform profile <name>

Example

```
> add transform profile shoppingcart -type URL
Done
> add transform action actshopping shoppingcart 1000
Done
> set transform action actshopping -priority 1000 -reqUrlFrom 'shopping.example.com' -reqUrlInto 'www.example.net/shopping' -resUrlFrom 'www.example.net/shopping' -resUrlInto 'shopping.example.com'
Done
> show transform profile shoppingcart
Name: shoppingcart
Type: URL    onlyTransformAbsURLinBody: OFF
Comment:
Actions:
```

```
1) Priority 1000 Name: actshopping ENABLED
```

Done

To modify an existing URL transformation profile or action by using the NetScaler command line

At the NetScaler command prompt, type the following commands to modify an existing URL transformation profile or action and verify the configuration:

Note: Use a set transform profile or set transform action command, respectively. The set transform profile command takes the same arguments as does the add transform profile command, and set transform action is the same command that was used for initial configuration.

- set transform action <name> [-priority <priority>] [-reqUrlFrom <expression>] [-reqUrlInto <expression>] [-resUrlFrom <expression>] [-resUrlInto <expression>] [-cookieDomainInto <expression>] [-state (ENABLED | DISABLED)] [-comment "<string>"]
- show transform profile <name>

Example

```
> set transform action actshopping -priority 1000 -reqUrlFrom 'searching.example.net' -reqUrlInto 'www.example.net/searching' -resUrlFrom 'www.example.net/searching' -resUrlInto 'searching.example.com'
Done
> show transform profile shoppingcart
Name: shoppingcart
Type: URL    onlyTransformAbsURLinBody: OFF
Comment:
Actions:
```

```
1) Priority 1000 Name: actshopping ENABLED
```

Done

To remove a URL transformation profile and actions by using the NetScaler command line

First remove all actions associated with that profile by typing the following command once for each action:

- rm transform action <name> After you have removed all actions associated with a profile, remove the profile as shown below.
- rm transform profile <name>

To create a URL transformation profile by using the configuration utility

1. In the navigation pane, expand Rewrite, expand URL Transformation, and then click Profiles.
2. In the details pane, click Add.
3. In the Create URL Transformation Profile dialog box, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring URL transformation profiles" as follows (asterisk indicates a required parameter):
 - Name*—name
 - Comment—comment
 - Only transform absolute URLs in response body—onlyTransformAbsURLinBody
4. Click Create, and then click Close. A message appears in the status bar, stating that the Profile has been configured successfully.

To configure a URL transformation profile and actions by using the configuration utility

1. In the navigation pane, expand Rewrite, expand URL Transformation, and then click Profiles.
2. In the details pane, select the profile you want to configure, and then click Open.
3. In the Configure URL Transformation Profile dialog box, do one of the following.

- To create a new action, click Add.
 - To modify an existing action, select the action, and then click Open.
4. Fill in the Create URL Transformation Action or Modify URL Transformation Action dialog box by typing or selecting values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring URL transformation profiles" as follows (asterisk indicates a required parameter):
 - Action Name*—name
 - Comments—comment
 - Priority*—priority
 - Request URL from—reqUrlFrom
 - Request URL into—reqUrlInto
 - Response URL from—resUrlFrom
 - Response URL into—resUrlInto
 - Cookie Domain from—cookieDomainFrom
 - Cookie Domain into—cookieDomainInto
 - Enabled—state
 5. Save your changes.
 - If you are creating a new action, click Create, and then Close.
 - If you are modifying an existing action, click OK.A message appears in the status bar, stating that the Profile has been configured successfully.
 6. Repeat step 3 through step 5 to create or modify any additional actions.
 7. To delete an action, select the action, and then click Remove. When prompted, click OK to confirm the deletion.
 8. Click OK to save your changes and close the Modify URL Transformation Profile dialog box.
 9. To delete a profile, in the details pane select the profile, and then click Remove. When prompted, click OK to confirm the deletion.

Configuring URL Transformation Policies

Oct 29, 2013

After you create a URL transformation profile, you next create a URL transformation policy to select the requests and responses that the NetScaler should transform by using the profile. URL transformation considers each request and the response to it as a single unit, so URL transformation policies are evaluated only when a request is received. If a policy matches, the NetScaler transforms both the request and the response.

Note: The URL transformation and rewrite features cannot both operate on the same HTTP header during request processing. Because of this, if you want to apply a URL transformation to a request, you must make sure that none of the HTTP headers it will modify are manipulated by any rewrite action.

To configure a URL transformation policy by using the NetScaler command line

You must create a new policy. On the command line, an existing policy can only be removed. At the NetScaler command prompt, type the following commands to configure a URL transformation policy and verify the configuration:

- add transform policy <name> <rule> <profileName>
- show transform policy <name>

Example

```
> add transform policy polsearch HTTP.REQ.URL.SUFFIX.EQ("Searching") prosearching
```

Done

```
> show transform policy polsearch
```

```
1) Name: polsearch
   Rule: HTTP.REQ.URL.SUFFIX.EQ("Searching")
   Profile: prosearching
   Priority: 0
   Hits: 0
```

Done

To remove a URL transformation policy by using the NetScaler command line

At the NetScaler command prompt, type the following command to remove a URL transformation policy:

```
rm transform policy <name>
```

Example

```
> rm transform policy polsearch
```

Done

To configure a URL transformation policy by using the configuration utility

1. In the navigation pane, expand Rewrite, expand URL Transformation, and then click Policies.
2. In the details pane, do one of the following:
 - To create a new policy, click Add.
 - To modify an existing policy, select the policy, and then click Open.
3. In the Create URL Transformation Policy or Configure URL Transformation Policy dialog box, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring URL transformation policies" as follows (asterisk indicates a required parameter):
 - Name*—name (Cannot be changed for a previously configured policy.)
 - Profile*—profileName
 - Expression—rule

If you want help with creating an expression for a new policy, you can either hold down the Control key and press the space bar while your cursor is in the Expression text box. To create the expression, you can type it directly as described below, or you can use the Add Expression dialog box as described in [To add an expression by using the Add Expression dialog box](#).

1. Click Prefix, and choose the prefix for your expression.

Your choices are:

- HTTP—The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
 - SYS—The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
 - CLIENT—The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
 - SERVER—The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.
 - URL—The URL of the request. Choose this if you want to examine some aspect of the URL to which the request was sent.
 - TEXT—Any text string in the request. Choose this if you want to examine a text string in the request.
 - TARGET—The target of the request. Choose this if you want to examine some aspect of the request target.
- After you choose a prefix, the NetScaler displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom. The choices depend on which prefix you chose.

2. Select your next term.

If you chose HTTP as your prefix, your choices are REQ, which specifies HTTP requests, and RES, which specifies HTTP responses. If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

When you are certain which choice you want, double-click it to insert it into the Expression window.

3. Type a period, and then continue selecting terms from the list boxes that appear to the right of the previous list box.

You type the appropriate text strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

4. Click Create or OK, depending on whether you are creating a new policy or modifying an existing policy.
5. Click Close. A message appears in the status bar, stating that the Policy has been configured successfully.

To add an expression by using the Add Expression dialog box

1. In the Create Responder Action or Configure Responder Action dialog box, click Add.
2. In the Add Expression dialog box, in the first list box choose the first term for your expression.

HTTP

The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.

SYS

The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

CLIENT

The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

SERVER

The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

URL

The URL of the request. Choose this if you want to examine some aspect of the URL to which the request was sent.

TEXT

Any text string in the request. Choose this if you want to examine a text string in the request.

TARGET

The target of the request. Choose this if you want to examine some aspect of the request target.

When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.

3. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.
4. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

Globally Binding URL Transformation Policies

Oct 29, 2013

After you have configured your URL transformation policies, you bind them to Global or a bind point to put them into effect. After binding, any a request or response that matches a URL transformation policy is transformed by the profile associated with that policy.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the NetScaler OS, policy priorities work in reverse order - the higher the number, the lower the priority.

Because the URL transformation feature implements only the first policy that a request matches, not any additional policies that it might also match, policy priority is important for achieving the results that you intend. If you give your first policy a low priority (such as 1000), you tell the NetScaler to perform it only if other policies with a higher priority do not match a request. If you give your first policy a high priority (such as 1), you tell the NetScaler to perform it first, and skip any other policies that might also match. You can leave yourself plenty of room to add other policies in any order, without having to reassign priorities, by setting priorities with intervals of 50 or 100 between each policy when you globally bind your policies.

Note: URL transformation policies cannot be bound to TCP-based virtual servers.

To bind a URL transformation policy by using the NetScaler command line

At the NetScaler command prompt, type the following commands to globally bind a URL transformation policy and verify the configuration:

- bind transform global <policyName> <priority>
- show transform global

Example

```
> bind transform global polisearching 100
```

```
Done
```

```
> show transform global
```

- ```
1) Policy Name: polisearching
Priority: 100
```

```
Done
```

To bind a URL transformation policy by using the configuration utility

1. In the navigation pane, expand Rewrite, then expand URL Transformation, and then click Policies.
2. In the details pane, click Policy Manager.
3. In the Transform Policy Manager dialog box, choose the bind point to which you want to bind the policy. The choices are:
  - **Override Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance, and are applied before any other policies.
  - **LB Virtual Server.** Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.

- **CS Virtual Server.** Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.
  - **Default Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance.
  - **Policy Label.** Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.
4. Select Insert Policy to insert a new row and display a drop-down list with all available, unbound URL transformation policies.
  5. Select the policy you want to bind, or select New Policy to create a new policy. The policy that you selected or created is inserted into the list of globally bound URL transformation policies.
  6. Make any additional adjustments to the binding.
    - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
    - To modify the policy expression, double click that field to open the Configure Transform Policy dialog box, where you can edit the policy expression.
    - To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
    - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression
  7. Repeat steps 3 through 6 to add any additional URL transformation policies you want to globally bind.
  8. Click OK to save your changes. A message appears in the status bar, stating that the Policy has been configured successfully.

# RADIUS Support for the Rewrite Feature

Oct 27, 2015

The NetScaler expressions language includes expressions that can extract information from and manipulate RADIUS messages in requests and responses. These expressions enable you to use the rewrite feature to modify portions of a RADIUS message before sending it to its destination. Your rewrite policies and actions can use any expression that is appropriate or relevant to a RADIUS message. The available expressions enable you to identify the RADIUS message type, extract any attribute-value pair (AVP) from the connection, and modify RADIUS AVPs. You can also create policy labels for RADIUS connections.

You can use the new RADIUS expressions in Rewrite rules for a number of purposes. For example, you could:

- Remove the domain\ portion of the RADIUS user-name AVP to simplify single sign-on (SSO).
- Insert a vendor-specific AVP, such as the MSISDN field used in telephone company operations to contain subscriber information.

You can also create policy labels to route specific types of RADIUS requests through a series of policies that are appropriate to those requests.

Note: RADIUS for Rewrite has the following limitations:

- The NetScaler ADC does not re-sign rewritten RADIUS requests or responses. If the RADIUS authentication server requires signed RADIUS messages, authentication will fail.
- The currently available RADIUS expressions do not work with RADIUS IPv6 attributes.

The NetScaler documentation for expressions that support RADIUS assumes familiarity with the basic structure and purpose of RADIUS communications. If you need more information about RADIUS, see your RADIUS server documentation or search online for an introduction to the RADIUS protocol.

## Configuring Rewrite Policies for RADIUS

The following procedure uses the NetScaler command line to configure a rewrite action and policy and bind the policy to a rewrite-specific global bind point.

### To configure a Rewrite action and policy, and bind the policy

At the command prompt, type the following commands:

- add rewrite action <actName> <actType>
- add rewrite policy <polName> <rule> <actName>
- bind rewrite policy <polName> <priority> <nextExp> -type <bindPoint>  
where <bindPoint> represents one of the rewrite-specific global bind points.

## RADIUS Expressions for Rewrite

In a rewrite configuration, you can use the following NetScaler expressions to refer to various portions of a RADIUS request or response.

### Identifying the Type of Connection

#### **RADIUS.IS\_CLIENT**

Returns TRUE if the connection is a RADIUS client (request) message.

#### **RADIUS.IS\_SERVER**

Returns TRUE if the connection is a RADIUS server (response) message.

### Request Expressions

#### **RADIUS.REQ.CODE**

Returns the number that corresponds to the RADIUS request type. A derivative of the num\_at class. For example, a RADIUS access request would return 1 (one). A RADIUS accounting request would return 4.

#### **RADIUS.REQ.LENGTH**

Returns the length of the RADIUS request, including the header. A derivative of the num\_at class.

#### **RADIUS.REQ.IDENTIFIER**

Returns the RADIUS request identifier, a number assigned to each request that allows the request to be matched to the corresponding response. A derivative of the num\_at class.

#### **RADIUS.REQ.AVP(<AVP Code No>).VALUE**

Returns the value of first occurrence of this AVP as a string of type text\_t.

#### **RADIUS.REQ.AVP(<AVP code no>).INSTANCE(instance number)**

Returns the specified instance of the AVP as a string of type RAVP\_t. A specific RADIUS AVP can occur multiple times in a RADIUS message. INSTANCE (0) returns the first instance, INSTANCE (1) returns second instance, and so on, up to sixteen instances.

#### **RADIUS.REQ.AVP(<AVP code no>).VALUE(instance number)**

Returns the value of specified instance of the AVP as a string of type text\_t.

#### **RADIUS.REQ.AVP(<AVP code no>).COUNT**

Returns the number of instances of a specific AVP in a RADIUS connection, as an integer.

#### **RADIUS.REQ.AVP(<AVP code no>).EXISTS**

Returns TRUE if the specified type of AVP exists in the message, or FALSE if it does not.

### Response Expressions

RADIUS response expressions are identical to RADIUS request expressions, except that RES replaces REQ.

### Typecasts of AVP Values

The ADC supports expressions to typecast RADIUS AVP values to the text, integer, unsigned integer, long, unsigned long, ipv4 address, ipv6 address, ipv6 prefix and time data types. The syntax is the same as for other NetScaler typecast expressions.

#### Example

The ADC supports expressions to typecast RADIUS AVP values to the text, integer, unsigned integer, long, unsigned long, ipv4 address, ipv6 address, ipv6 prefix and time data types. The syntax is the same as for other NetScaler typecast expressions.

`RADIUS.REQ.AVP(8).VALUE(0).typecast_ip_address_at`

#### AVP Type Expressions

The NetScaler ADC supports expressions to extract RADIUS AVP values by using the assigned integer codes described in RFC2865 and RFC2866. You can also use text aliases to accomplish the same task. Some examples follow.

#### **RADIUS.REQ.AVP (1).VALUE or RADIUS.REQ.USERNAME.value**

Extracts the RADIUS user-name value.

#### **RADIUS.REQ.AVP (4). VALUE or RADIUS.REQ. ACCT\_SESSION\_ID.value**

Extracts the Acct-Session-ID AVP (code 44) from the message.

#### **RADIUS.REQ.AVP (26). VALUE or RADIUS.REQ.VENDOR\_SPECIFIC.VALUE**

Extracts the vendor-specific value.

The values of most commonly-used RADIUS AVPs can be extracted in the same manner.

#### RADIUS Bind Points

Four global bind points are available for policies that contain RADIUS expressions.

#### **RADIUS\_REQ\_OVERRIDE**

Priority/override request policy queue.

#### **RADIUS\_REQ\_DEFAULT**

Standard request policy queue.

#### **RADIUS\_RES\_OVERRIDE**

Priority/override response policy queue.

#### **RADIUS\_RES\_DEFAULT**

Standard response policy queue.

#### RADIUS Rewrite-Specific Expressions

#### **RADIUS.NEW\_AVP**

Returns the specified RADIUS AVP as a string.

#### **RADIUS.NEW\_AVP\_INTEGER32**

Returns the specified RADIUS AVP as an integer.

#### **RADIUS.NEW\_AVP\_UNSIGNED32**

Returns the specified RADIUS AVP as an unsigned integer.

#### **RADIUS.NEW\_VENDOR\_SPEC\_AVP(<ID>, <definition>)**

Adds the specified extended vendor specific AVPs to the connection. For <ID>, substitute a long number. For <definition>, substitute a string that contains the data for the AVP.

#### **RADIUS.REQ.AVP\_START**

Returns the location between the end of the RADIUS header and the start of the AVPs. Used in rewrite actions.

#### Example:

```
add rewrite action insert1 insert_after radius.req.avp_start radius.new_avp(33, "NEW AVP")
```

#### **RADIUS.REQ.AVP\_END**

Returns the location at the end of radius message (or in other words end of all AVPs) in radius message. Used when performing rewrite actions.

#### Example:

```
add rewrite action insert2 insert_before radius.req.avp_end "radius.new_avp(33, \"NEW AVP\")"
```

#### **RADIUS.REQ.AVP\_LIST**

Returns the location at the start of the AVPs in a RADIUS message, and the length of the RADIUS message, excluding the header. In other words, returns all AVPs in a RADIUS message. Used to perform Rewrite actions.

#### Example:

```
add rewrite action insert3 insert_before_all radius.req.avp_list "radius.new_avp(33, \"NEW AVP\")" -search "avp(33)"
```

#### Valid Rewrite-Action Types for RADIUS

The Rewrite action types that can be used with RADIUS expressions are:

- INSERT\_AFTER
- INSERT\_BEFORE
- INSERT\_AFTER\_ALL
- INSERT\_BEFORE\_ALL

- DELETE
- DELETE\_ALL
- REPLACE
- REPLACE\_ALL

All INSERT\_ actions can be used to insert a RADIUS AVP into a RADIUS connection.

#### Use Cases

Following are use cases for RADIUS with rewrite.

#### Rewriting the User-Name AVP

To configure the rewrite feature to remove the Domain\ string from the RADIUS user-name AVP, begin by creating a rewrite REPLACE action as shown in the example below. Use the action in a Rewrite policy that selects all RADIUS requests. Bind the policy to a global bind point. When you do so, set the priority the appropriate level to allow any block or reject policies to take effect first, but ensure that all requests that are not blocked or rejected are rewritten. Set the Goto Expression (gotoPriorityExpr) to NEXT to continue policy evaluation, and attach the policy to the RADIUS\_REQ\_DEFAULT queue.

#### Example:

```
add rewrite action rwActRadiusDomainDel replace radius.req.user_name "radius.new_avp(0, "radius.req.user_name.value.AFTER_STR(\)")/
add rewrite policy rwPolRadiusDomainDel true rwActRadiusDomainDel bind rewrite global rwPolRadiusDomainDel 100 NEXT -type RADIUS_REQ_DEFAULT
```

#### Inserting a Vendor-Specific AVP

To configure Rewrite action to insert a Vendor-Specific AVP containing the contents of the MSISDN field, begin by creating a rewrite INSERT action that inserts the MSISDN field into the request. Use the action in a Rewrite policy that selects all RADIUS requests. bind the policy to global, setting the priority to an appropriate level and the other parameters as shown in the following example.

#### Example:

```
add rewrite action rwActRadiusInsMSISDN insert_after radius.req.avp_start RADIUS.NEW_VENDOR_SPEC_AVP(<VENDOR ID>, "RADIUS.NEW_AVP(<Attribute Code>, <MSISDN>)")
add rewrite policy rwPolRadiusInsMSISDN true rwActRadiusInsMSISDN
bind rewrite global rwPolRadiusInsMSISDN 100 NEXT -type RADIUS_REQ_DEFAULT
```

# Diameter Support for Rewrite

Apr 09, 2014

The Rewrite feature now supports the Diameter protocol. You can configure Rewrite to modify Diameter requests and response as you would HTTP or TCP requests and responses, allowing you to use Rewrite to manage the flow of Diameter requests and make necessary modifications. For example, if the "Origin-Host" value in a Diameter request is inappropriate, you can use Rewrite to replace it with a value that is acceptable to the Diameter server.

To configure Rewrite to modify a Diameter request

To configure the Rewrite feature to replace the Origin-Host in a diameter request with a different value, at the command prompt, type the following commands:

- add rewrite action <actname> replace "DIAMETER.REQ.AVP(264,\"netscaler.example.net\")"  
For <actname>, substitute a name for your new action. The name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (\_) symbols. For `netscaler.example.net`, substitute the Host-Origin that you want to use instead of the original Host-Name.
- add rewrite policy <polname> "diameter.req.avp(264).value.eq(\"host.example.com\")" <actname>  
For <polname>, substitute a name for your new policy. As with <actname>, the name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (\_) symbols. For `host.example.com`, substitute the name of the Host-Origin that you want to change. For <actname>, substitute the name of the action that you just created.
- bind lb vserver <vservname> -policyName <polname> -priority <priority> -type REQUEST  
For <vservname>, substitute the name of the load balancing virtual server to which you want to bind the policy. For <polname>, substitute the name of the policy you just created. For <priority>, substitute a priority for the policy.

## Example

To create a Rewrite action and policy to modify all Diameter Host-Origins of "host.example.com" to "netscaler.example.net", you could add the following action and policy, and bind the policy as shown.

```
> add rewrite action rw_act_replace_avp replace "diameter.req.avp(264)" "diameter.new.avp(264,\"netscaler.example.net\")"
> add rewrite policy rw_diam_pol "diameter.req.avp(264).value.eq(\"client.realm2.net\")" rw_act_replace_avp
> bind lb vserver vs1 -policyName rw_diam_pol -priority 10 -type REQUEST
```

Done

# String Maps

Apr 20, 2015

You can use string maps to perform pattern matching in all NetScaler features that use the default policy syntax. A string map is a NetScaler entity that consists of key-value pairs. The keys and values are strings in either ASCII or UTF-8 format. String comparison uses two new functions, `MAP_STRING(<string_map_name>)` and `IS_STRINGMAP_KEY(<string_map_name>)`.

A policy configuration that uses string maps performs better than one that does string matching through policy expressions, and you need fewer policies to perform string matching with a large number of key-value pairs. String maps are also intuitive, simple to configure, and result in a smaller configuration.

## How String Maps Work

String maps are similar in structure to pattern sets (a pattern set defines a mapping of index values to strings; a string map defines a mapping of strings to strings) and the configuration commands for string maps (commands such as `add`, `bind`, `unbind`, `remove`, and `show`) are syntactically similar to configuration commands for pattern sets. Also, as with index values in a pattern set, each key in a string map must be unique across the map. The following table illustrates a string map called `url_string_map`, which contains URLs as keys and values.

**Table 1. String Map "url\_string\_map"**

| Key         | Value                                    |
|-------------|------------------------------------------|
| /url_1.html | http://www.redirect_url_1.com/url_1.html |
| /url_2.html | http://www.redirect_url_2.com/url_2.html |
| /url_3.html | http://www.redirect_url_1.com/url_1.html |

The following table describes the two functions that have been introduced to enable string matching with keys in a string map. String matching is always performed with the keys. Additionally, the following functions perform a comparison between the keys in the string map and the complete string that is returned by the expression prefix. The examples in the descriptions refer to the preceding example.

**Table 2. String Map Functions**

| Function                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;TEXT&gt;.MAP_STRING(&lt;string_map_name&gt;)</code> | <p>Checks whether the value returned by the expression prefix <code>TEXT</code> matches any of the keys in the string map, and returns the value that corresponds to the key. If no key in the string map matches the value returned by the expression prefix, the function returns a null string. The <code>IGNORECASE</code> and <code>NOIGNORECASE</code> functions can be used for case-insensitive and case-sensitive comparison, respectively.</p> <p><b>Example 1:</b> <code>HTTP.REQ.URL.MAP_STRING("url_string_map")</code> checks whether the string returned by <code>HTTP.REQ.URL</code> is a key in the string map <code>url_string_map</code>. If the value of <code>HTTP.REQ.URL</code> is <code>/url_1.html</code>, the function returns <code>http://www.redirect_url_1.com/url_1.html</code>.</p> <p><b>Example 2:</b></p> <p><code>HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).MAP_STRING("url_string_map")</code> checks whether the string returned by <code>HTTP.REQ.URL</code> is a key in the string map <code>url_string_map</code>. The comparison does not consider case. If the string returned by <code>HTTP.REQ.URL</code> is <code>/URL_1.html</code>, the function returns <code>http://www.redirect_url_1.com/url_1.html</code>.</p> <p><b>Parameters:</b></p> |

| Function                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;TEXT&gt;.IS_STRINGMAP_KEY(&lt;string_map_name&gt;)</code> | <p>Returns TRUE if the string returned by the expression prefix TEXT is a key in the string map. The IGNORECASE and NOIGNORECASE functions can be used for case-insensitive and case-sensitive string matching, respectively.</p> <p><b>Example 1:</b></p> <p>HTTP.REQ.URL.IS_STRINGMAP_KEY("url_string_map") returns TRUE if the value of HTTP.REQ.URL is one of the keys in url_string_map.</p> <p><b>Example 2:</b> HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_string_map") returns TRUE if the value of HTTP.REQ.URL is one of the keys in url_string_map. In this case, key lookup does not consider case. Therefore, the function returns TRUE even if the value of HTTP.REQ.URL is /URL_3.html.</p> <p><b>Parameters:</b></p> <p>string_map_name - The string map.</p> |

## Configuring a String Map

You first create a string map and then bind key-value pairs to it. You can create a string map from the command line interface (CLI) or the configuration utility.

### To configure a string map by using the command line interface

At the command prompt, do the following:

1. Create a string map.  
`add policy stringmap <name> -comment <string>`
2. Bind a key-value pair to the string map.  
`bind policy stringmap <name> <key> <value>`

Example:

```
> bind policy stringmap url_string_map1 "/url_1.html" "http://www.redirect_url_1.com/url_1.html"
```

### To configure a string map by using the configuration utility

Create a string map and bind the key-value pair to the created entity.

Navigate to **AppExpert > String Maps**, click **Add** and specify the relevant details.

### Example: Responder Policy With a Redirect Action

The following use case involves a responder policy with a redirect action. In the example below, the first four commands create the string map url\_string\_map and bind the three key-value pairs used in the earlier example. After creating the map and binding the key-value pairs, you create a responder action (act\_url\_redirects) that redirects the client to the corresponding URL in the string map or to www.default.com. You also configure a responder policy (pol\_url\_redirects) that checks whether requested URLs match any of the keys in url\_string\_map and then performs the configured action. Finally, you bind the responder policy to the content switching virtual server that receives the client requests that are to be evaluated.

```
add stringmap url_string_map

bind stringmap url_string_map /url_1.html http://www.redirect_url_1.com/url_1.html

bind stringmap url_string_map /url_2.html http://www.redirect_url_2.com/url_2.html
```

```
bind stringmap url_string_map /url_3.html http://www.redirect_url_1.com/url_1.html
add responder action act_url_redirects redirect 'HTTP.REQ.URL.MAP_STRING("url_string_map") ALT "www.default.com" -bypassSafetyCheck yes
add responder policy pol_url_redirects TRUE act_url_redirects
bind cs vserver csw_redirect -policyname pol_url_redirects -priority 1 -type request
```

# Traffic Management

Nov 09, 2016

The following topics cover configuration and installation information for NetScaler traffic management features.

|                              |                                                                                                                                                                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cache Redirection            | Analyzes incoming requests and forwards the requests for already cached data to cache servers. Dynamic HTTP requests and non-cacheable requests are forwarded to the origin servers. Cache redirection is a policy-based feature.                               |
| Content Switching            | Analyzes client requests and redirects the requests to specific servers on the basis of geographical area, authorization credentials, and device from which the request was initiated.                                                                          |
| DataStream                   | Ensures optimal distribution of traffic from the application and web servers to the database servers. Enables you to segment traffic according to information in the SQL query and on the basis of database names, user names, character sets, and packet size. |
| Domain Name System           | Provides authoritative domain name server (ADNS server) functionality for a domain. The NetScaler appliance functions as a DNS end resolver and forwarder, and also helps in name resolution when fully qualified domain names are not configured.              |
| Firewall Load Balancing      | Distributes the traffic across multiple firewalls, providing fault tolerance, increased throughput, and high availability.                                                                                                                                      |
| Global Server Load Balancing | Enables disaster recovery and ensures continuous availability of applications by protecting against points of failure in a wide area network (WAN).                                                                                                             |
| Link Load Balancing          | Load balances outbound traffic across multiple Internet connections to transmit packets seamlessly over the best possible link.                                                                                                                                 |
| Load Balancing               | Distributes user requests for web pages and other protected applications across multiple servers to prevent server overloading and failure. Load balancing also provides fault tolerance.                                                                       |
| SSL Offload and Acceleration | Offloads SSL processing from a server to the NetScaler appliance to accelerate SSL transactions.                                                                                                                                                                |

# Cache Redirection

Mar 30, 2012

In a typical deployment, different clients ask web servers for the same content repeatedly. To relieve the origin web server of processing each request, a NetScaler® appliance with cache redirection enabled can serve this content from a cache server instead of from the origin server.

The NetScaler analyzes incoming requests, sends requests for cacheable data to cache servers, and sends non-cacheable requests and dynamic HTTP requests to origin servers.

Cache redirection is a policy-based feature. By default, requests that match a policy are sent to the origin server, and all other requests are sent to a cache server. For testing or maintenance, you might want to skip policy evaluation and direct all requests to the cache or to the origin server.

You can combine content switching with cache redirection to cache selective content and serve content from specific cache servers for specific types of requested content.

A NetScaler configured for cache redirection can be deployed at the edge of a network, in front of the origin server, or anywhere along the network backbone. In an edge deployment, commonly used by Internet Service Providers (ISPs), cable companies, content delivery distribution networks, and enterprise networks, the NetScaler resides directly in front of the clients. In a server-side deployment, the NetScaler is closer to the origin servers.

Cache redirection is used most commonly with the HTTP service type, but it also supports the secure HTTPS protocol.

# Cache Redirection Policies

Mar 30, 2012

A cache redirection virtual server applies cache redirection policies to each incoming request. By default, if a request matches one of the configured policies, it is considered non-cacheable, and the NetScaler appliance sends it to the origin server. Other requests are sent to a cache server. This behavior can be reversed, so that requests that match configured cache redirection policies are sent to cache servers.

The NetScaler provides a set of policies for cache redirection. If these built-in policies are not adequate for your deployment, you can configure user-defined cache redirection policies.

Note: Once you have determined which built-in cache redirection policies to use, or have created user-defined policies, proceed with configuring cache redirection. To use this feature, you must configure at least one cache redirection virtual server, and, for normal operation, you must bind at least one cache redirection policy to that virtual server.

# Built-in Cache Redirection Policies

May 14, 2015

The NetScaler appliance provides built-in cache redirection policies that handle typical cache requests. These policies are based on HTTP methods, the URL or URL tokens of the incoming request, the HTTP version, or the HTTP headers and their values in the request.

Built-in cache redirection policies can be directly bound to a virtual server and do not need further configuration.

Cache redirection policies use the simpler of two NetScaler expressions languages, called *classic expressions*. For a complete description of classic expressions and how to configure them, see

The NetScaler provides the following built-in cache redirection policies

| built in Policy Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bypass-non-get       | Bypass the cache if the request uses an HTTP method other than GET.                                                                                                                                                                                                                                                                                                                                                                           |
| bypass-cache-control | Bypass the cache if the request header contains a Cache-Control: no-cache or Cache-Control: no-store header, or if the HTTP request contains a pragma header.                                                                                                                                                                                                                                                                                 |
| bypass-dynamic-url   | Bypass the cache if the URL suggests that the content is dynamic, as indicated by the presence of any of the following extensions: <ul style="list-style-type: none"><li>• cgi</li><li>• asp</li><li>• exe</li><li>• cfm</li><li>• ex</li><li>• shtml</li><li>• htx</li></ul> Also bypass the cache if the URL starts with any of the following: <ul style="list-style-type: none"><li>• /cgi-bin/</li><li>• /bin/</li><li>• /exec/</li></ul> |
| bypass-urrtokens     | Bypass the cache because the request is dynamic, as indicated by one of the following tokens in the URL: ?, !, or =.                                                                                                                                                                                                                                                                                                                          |
| bypass-cookie        | Bypass the cache for any URL that has a cookie header and an extension other than .gif or .jpg.                                                                                                                                                                                                                                                                                                                                               |

## Displaying the Built-in Cache Redirection Policies

Updated: 2013-08-23

You can display the available cache redirection policies by using the command line interface or the configuration utility.

### To display the built-in cache redirection policies by using the command line interface

At the command prompt, type:

```
show cr policy [<policyName>]
```

#### Example

```
> show cr policy
1) Cache-By-Pass RULE: NS_NON_GET Policy:bypass-non-get
2) Cache-By-Pass RULE: (NS_CACHECONTROL_NOSTORE || NS_CACHECONTROL_NOCACHE || NS_HEADER_PRAGMA) Policy:bypass-cache-control
3) Cache-By-Pass RULE: (NS_EXT_CGI || NS_EXT_ASP || NS_EXT_EXE || NS_EXT_CFM || NS_EXT_EX || NS_EXT_SHTML || NS_EXT_HTX) || (NS_URL_PATH_CGIBIN || NS_URL_PATH_E)
4) Cache-By-Pass RULE: NS_URL_TOKENS Policy:bypass-urrtokens
5) Cache-By-Pass RULE: (NS_HEADER_COOKIE && NS_EXT_NOT_GIF && NS_EXT_NOT_JPEG) Policy:bypass-cookie
Done
>
```

### To display the built-in cache redirection policies by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Policies. The configured cache redirection policies appear in the details pane.
2. Select one of the configured policies to view details.

# Configuring a Cache Redirection Policy

May 14, 2015

A cache redirection policy includes one or more expressions (also called *rules*). Each expression represents a condition that is evaluated when the client request is compared to the policy.

You do not explicitly configure actions for cache redirection policies. By default, the NetScaler appliance considers any request that matches a policy to be non-cacheable and directs the request to the origin server instead of the cache.

Cache redirection uses the *classic policy* format. Each policy has a name and includes an expression or a set of expressions that are combined by using logical operators.

To add a cache redirection policy by using the command line interface

At the command prompt, type the following commands to add a cache redirection policy and verify the configuration:

- add cr policy <policyName> -rule <expression>
- show cr policy [<policyName>]

## Examples

Policy with a simple expression:

```
> add cr policy Policy-CRD-1 -rule "REQ.HTTP.URL != /*.jpeg"
Done
> show cr policy Policy-CRD-1
Cache-By-Pass RULE: REQ.HTTP.URL != /*.jpeg' Policy:Policy-CRD-1
Done
>
```

Policy with a compound expression:

```
> add cr policy Policy-CRD-2 -rule "REQ.HTTP.METHOD == POST && (REQ.HTTP.URL == /*.cgi || REQ.HTTP.URL != /*.gif)"
Done
> show cr policy Policy-CRD-2
Cache-By-Pass RULE: REQ.HTTP.METHOD == POST && (REQ.HTTP.URL == /*.cgi' || REQ.HTTP.URL != /*.gif) Policy:Policy-CRD-2
Done
>
```

Policy that evaluates a header:

```
> add cr policy Policy-CRD-3 -rule "REQ.HTTP.HEADER If-Modified-Since EXISTS"
Done
> show cr policy Policy-CRD-3
Cache-By-Pass RULE: REQ.HTTP.HEADER If-Modified-Since EXISTS Policy:Policy-CRD-3
Done
>
```

To modify or remove a cache redirection policy by using the command line interface

- To modify a cache redirection policy, use the set cr policy command, which is just like add cr policy command, except that you enter the name of an existing policy.
- To remove a policy, use the rm cr policy command, which accepts only the <name> argument. If the policy is bound to a virtual server, you have to unbind the policy, before you can remove it.

For the details of unbinding a cache redirection policy, see "[Unbinding a Policy from a Cache Redirection Virtual Server](#)."

To configure a cache redirection policy with a simple expression by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Policies.
2. In the details pane, click Add.
3. In the Create Cache Redirection Policy dialog box, in the Name\* text box, type the name of the policy, and then in the Expression area, click Add.
4. To configure a simple expression, enter the expression. Following is an example of an expression that checks for a .jpeg extension in a URL:

- Expression Type-General
- Flow Type -REQ
- Protocol -HTTP
- Qualifier -URL
- Operator - !=
- Value\* - /\*.jpeg

The simple expression in the following example checks for an If-Modified-Since header in a request:

- Expression Type -General
- Flow Type -REQ
- Protocol -HTTP
- Qualifier -HEADER
- Operator -EXISTS
- Header Name -If-Modified-Since

5. When you are finished entering the expression, click OK or Create, and then click Close.

To configure a cache redirection policy with a compound expression by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Policies.
2. In the details pane, click Add.
3. In the Name text box, enter a name for the policy.

The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), and underscore ( \_ ) symbols. You should choose a name that will make it easy for others to tell what type of content this policy was created to detect.

4. Choose the type of compound expression that you want to create. Your choices are:
  - **Match Any Expression.** The policy matches the traffic if one or more individual expressions match the traffic.
  - **Match All Expressions.** The policy matches the traffic only if every individual expression matches the traffic.
  - **Tabular Expressions.** Switches the Expressions list to a tabular format with three columns. In the rightmost column, you place one of the following operators:
    - The AND [ && ] operator, to require that, to match the policy, a request must match both the current expression and the following expression.
    - The OR [ || ] operator, to require that, to match the policy, a request must match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.

You can also group expressions in nested subgroups by selecting an existing expression and clicking one of the following operators:

- The BEGIN SUBGROUP [+ ( )] operator, which tells the NetScaler appliance to begin a nested subgroup with the selected expression. (To remove this operator from the expression, click -(.)
- The END SUBGROUP [+ )] operator, which tells the NetScaler appliance to end the current nested subgroup with the selected expression. (To remove this operator from the expression, click -.)
- **Advanced Free-Form.** Switches off the Expressions Editor entirely and turns the Expressions list into a text area in which you can type a compound expression. This is both the most powerful and the most difficult method of creating a policy expression, and is recommended only for those thoroughly familiar with the NetScaler classic expressions language.

For more information about creating classic expressions in the Advanced Free-Form text area, see "[Configuring Classic Policies and Expressions](#)".

Caution: If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression editing mode unless you are sure that you want to use it.

- If you chose Match Any Expression, Match All Expressions, or Tabular Expressions, click **Add** to display the Add Expression dialog box.

You should leave the expression type set to General for cache redirection policies.

- In the Flow Type drop-down list, choose a flow type for your expression.

The flow type determines whether the policy examines incoming or outgoing connections. You have two choices:

- **REQ.** Configures the NetScaler appliance to examine incoming connections, or requests.
- **RES.** Configures the appliance to examine outgoing connections, or responses.

- In the Protocol drop-down list, choose a protocol for your expression.

The protocol determines the type of information that the policy examines in the request or response. Depending upon whether you chose REQ or RES in the previous drop-down list, either all four or only three of the following choices are available:

- **HTTP.** Configures the appliance to examine the HTTP header.
- **SSL.** Configures the appliance to examine the SSL client certificate. Available only if you chose REQ (requests) in the previous drop-down list.
- **TCP.** Configures the appliance to examine the TCP header.
- **IP.** Configures the appliance to examine the source or destination IP address.

- Choose a qualifier for your expression from the Qualifier drop-down list.

The contents of the Qualifier drop-down list depend on which protocol you chose. The following table describes the choices available for each protocol.

**Table 1. Cache Redirection Policy Qualifiers Available for Each Protocol**

| Protocol | Qualifier           | Definition                                        |
|----------|---------------------|---------------------------------------------------|
| HTTP     | METHOD              | HTTP method used in the request.                  |
| HTTP     | URL                 | Contents of the URL header.                       |
|          | URLTOKENS           | URL tokens in the HTTP header.                    |
|          | VERSION             | HTTP version of the connection.                   |
|          | HEADER              | Header portion of the HTTP request.               |
|          | URLLEN              | Length of the contents of the URL header.         |
|          | URLQUERY            | Query portion of the contents of the URL header.  |
|          | URLQUERYLEN         | Length of the query portion of the URL header.    |
| SSL      | CLIENT.CERT         | SSL client certificate as a whole.                |
| SSL      | CLIENT.CERT.SUBJECT | Contents of the client certificate subject field. |
|          | CLIENT.CERT.ISSUER  | Client certificate issuer.                        |

| Protocol | Qualifier                | Definition                                                                  |
|----------|--------------------------|-----------------------------------------------------------------------------|
|          | CLIENT.CERT.SIGALGO      | Signature algorithm used in the client certificate.                         |
|          | CLIENT.CERT.VERSION      | Client certificate version.                                                 |
|          | CLIENT.CERT.VALIDFROM    | Date from which the client certificate is valid. (The start date.)          |
|          | CLIENT.CERT.VALIDTO      | Date after which the client certificate is no longer valid. (The end date.) |
|          | CLIENT.CERT.SERIALNUMBER | Client certificate serial number.                                           |
|          | CLIENT.CIPHER.TYPE       | Encryption method used in the client certificate.                           |
|          | CLIENT.CIPHER.BITS       | Number of significant bits in the encryption key.                           |
|          | CLIENT.SSL.VERSION       | SSL version of the client certificate.                                      |
| TCP      | SOURCEPORT               | Source port of the TCP connection.                                          |
|          | DESTPORT                 | Destination port of the TCP connection.                                     |
|          | MSS                      | Maximum segment size (MSS) of the TCP connection.                           |
| IP       | SOURCEIP                 | Source IP address of the connection.                                        |
|          | DESTIP                   | Destination IP address of the connection.                                   |

9. Choose the operator for your expression from the Operator drop-down list.

Your choices depend on the qualifier you chose in the previous step. The complete list of operators that can appear in this drop-down list is:

- == . Matches the following text string exactly.
- != . Does not match the following text string.
- > . Is greater than the following integer.
- CONTAINS . Contains the following text string.
- CONTENTS . The contents of the designated header, URL, or URL query.
- EXISTS . The specified header or query exists.
- NOTCONTAINS . Does not contain the following text string.
- NOTEXISTS . The specified header or query does not exist.

If you want this policy to operate on requests sent to a specific Host, you can leave the default, the equals (==) sign.

10. If the Value text box is visible, type the appropriate string or number into the text box.

For example, if you want this policy to select requests sent to the host shopping.example.com, you would type that string in the Value text box.

11. If you chose HEADER as the qualifier, type the header you want in the Header Name text box.

12. Click OK to add your expression to the Expression list.

13. Repeat steps 4 through 11 to create additional expressions.
14. Click Close to close the Add Expression dialog box and return to the Create Cache Redirection Policy dialog box.

# Cache Redirection Configurations

Mar 30, 2012

Depending on your deployment and network topology, you can configure one of the following types of cache redirection:

- **Transparent.** A transparent cache can reside on a variety of points along a network backbone to alleviate traffic along the delivery route. In transparent mode, the cache redirection virtual server intercepts all traffic flowing to the NetScaler appliance and applies cache redirection policies to determine whether content should be served from the cache or from the origin server.
- **Forward proxy.** A forward proxy cache server resides on the edge of an enterprise LAN and faces the WAN. In the forward proxy mode, the cache redirection virtual server resolves the hostname of the incoming request by using a DNS server and forwards requests for non-cacheable content to the resolved origin servers. Cacheable requests are sent to the configured cache servers.
- **Reverse proxy.** Reverse proxy caches are configured for specific origin servers. Incoming traffic directed to the reverse proxy, can either be served from a cache server or be sent to the origin server with or without modification to the URL.

# Configuring Transparent Redirection

Sep 07, 2016

When you configure transparent cache redirection, the NetScaler appliance evaluates all traffic it receives, to determine whether it is cacheable. This mode alleviates traffic along the delivery route and is often used when the cache server resides on the backbone of an ISP or carrier.

By default, cacheable requests are sent to a cache server, and non-cacheable requests to the origin server. For example, when the NetScaler appliance receives a request that is directed to a web server, it compares the HTTP headers in the request with a set of policy expressions. If the request does not match the policy, the appliance forwards the request to a cache server. If the request does match a policy, the appliance forwards the request, unchanged, to the web server.

For details on how to modify this default behavior, see "[Directing Policy Hits to the Cache instead of the Origin.](#)"

To configure transparent redirection, first enable cache redirection and load balancing, and configure edge mode. Then, create a cache redirection virtual server with a wildcard IP address (\*), so that this virtual server can receive traffic coming to the NetScaler on any IP address the appliance owns. To this virtual server, bind cache redirection policies that describe the types of requests that should not be cached. Then, create a load balancing virtual server that will receive traffic from the cache redirection virtual server for cacheable requests. Finally, create a service that represents a physical cache server and bind it to the load balancing virtual server.

# Enabling Cache Redirection and Load Balancing

Oct 31, 2013

The NetScaler cache redirection and load balancing features are not enabled by default. They must be enabled before any cache redirection configuration can take effect.

To enable cache redirection and load balancing by using the command line interface

At the command prompt, type the following command to enable cache redirection and load balancing and verify the settings:

- enable ns feature cr lb
- show ns feature

## Example

```
> enable ns feature cr lb
```

```
Done
```

```
> show ns feature
```

|    | Feature           | Acronym | Status |
|----|-------------------|---------|--------|
|    | -----             | -----   | -----  |
| 1) | Web Logging       | WL      | ON     |
| 2) | Surge Protection  | SP      | ON     |
| 3) | Load Balancing    | LB      | ON     |
| 4) | Content Switching | CS      | ON     |
| 5) | Cache Redirection | CR      | ON     |
| 6) | Sure Connect      |         |        |

```
...
```

```
...
```

```
...
```

|     |                |               |    |
|-----|----------------|---------------|----|
| 23) | HTML Injection | HTMLInjection | ON |
| 24) | NetScaler Push | push          | OF |

```
Done
```

```
>
```

To enable cache redirection and load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. To enable cache redirection, in the details pane, under Modes and Features, click Configure advanced features.
  1. In Configure Advanced Features dialog box, select the check box next to the Cache Redirection, and then click OK.
  2. In Enable/Disable Feature(s)? dialog box, click Yes.
3. To enable load balancing, in the details pane, under Modes and Features, click Configure basic features.
  1. In Configure Basic Features dialog box, select the check box next to the Load Balancing, and then click OK.
  2. In Enable/Disable Feature(s)? dialog box, click Yes.

# Configuring Edge Mode

Nov 07, 2016

When deployed at the edge of a network, the NetScaler appliance dynamically learns about the servers on that network. Edge mode enables the appliance to dynamically learn about up to 40,000 HTTP servers and proxy TCP connections for these servers.

This mode turns on the collection of statistics for the dynamically learned services and is typically used in transparent deployments for cache redirection.

To enable edge mode by using the command line interface

At the command prompt, type the following commands to enable edge mode and verify the setting:

- enable ns mode Edge
- show ns mode

## Example

```
> enable ns mode edge
Done
```

```
> show ns mode
```

| Mode                    | Acronym     | Status |
|-------------------------|-------------|--------|
| ...                     | ...         | ...    |
| 6) MAC-based forwarding | MBF         | ON     |
| 7) Edge configuration   | Edge        | ON     |
| 8) Use Subnet IP        | USNIP       | OFF    |
| ...                     | ...         | ...    |
| 16) Bridge BPDUs        | BridgeBPDUs | OFF    |

```
Done
```

```
>
```

To enable edge mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In Configure Modes dialog box, select the check box next to the Edge Configuration, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

# Configuring a Cache Redirection Virtual Server

Sep 10, 2013

By default, a cache redirection virtual server forwards cacheable requests to the load balancing virtual server for the cache, and forwards non-cacheable requests to the origin server (except in a reverse proxy configuration, in which non-cacheable requests are sent to a load balancing virtual server). There are three types of cache redirection virtual servers: transparent, forward proxy, and reverse proxy.

A transparent cache redirection virtual server uses an IP address of \* and a port number, usually 80, that can accept HTTP traffic sent to any IP address that the NetScaler represents. As a result, you can configure only one transparent cache redirection virtual server. Any additional cache redirection virtual servers that you configure must be forward proxy or reverse proxy redirection servers.

To add a cache redirection virtual server in transparent mode by using the command line interface

At the command prompt, type the following commands to add a cache redirection virtual server and verify the configuration:

- `add cr vserver <name> <serviceType> [<IPAddress> <port> ] [-cacheType <cacheType>] [-redirect <redirect>]`
- `show cr vserver [<name>]`

## Example

```
add cr vserver Vserver-CRD-1 HTTP * 80 -cacheType TRANSPARENT -redirect POLICY
```

```
> show cr vserver Vserver-CRD-1
```

```
Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
```

```
State: UP ARP:DISABLED
```

```
Client Idle Timeout: 180 sec
```

```
Down state flush: ENABLED
```

```
Disable Primary Vserver On Down : DISABLED
```

```
Default: Content Precedence: RULE Cache: TRANSPARENT
```

```
On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
```

```
Redirect: POLICY Reuse: ON Via: ON ARP: OFF
```

```
Done
```

```
>
```

To modify or remove a cache redirection virtual server by using the command line interface

- To modify a virtual server, use the `set cr vserver` command, which is just like using the `add cr vserver` command, except that you enter the name of an existing virtual server.
- To remove a virtual server, use the `rm cr vserver` command, which accepts only the `<name>` argument.

To add a cache redirection virtual server in transparent mode by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Cache Redirection) dialog box, specify values for the following parameters as shown:

- Name\*—name

- Port\*—port

\* A required parameter

4. In the Protocol drop-down list, select a supported protocol (for example, **HTTP**). If the virtual server is to receive traffic on a port other than the standard port for the selected protocol, enter a new value in the Port field.
5. Click the Advanced tab.
6. Verify that Cache Type is set to TRANSPARENT and Redirect is set to POLICY.
7. Click Create, and then click Close. The Cache Redirection Virtual Servers pane displays the new virtual server.
8. Select the new cache redirection virtual server to display the details of its configuration.

# Binding Policies to the Cache Redirection Virtual Server

Aug 22, 2013

Cache redirection policies are not automatically bound to the cache redirection virtual server. A policy based cache redirection virtual server cannot function unless you bind at least one policy to it.

To bind policies to a cache redirection virtual server by using the command line interface

At the command prompt, type:

- bind cr vserver <name> -policyName <string>
- show cr vserver [<name>]

## Example

```
> bind cr vserver Vserver-CRD-1 -policyName bypass-cache-control
```

```
Done
```

```
> bind cr vserver Vserver-CRD-1 -policyName bypass-dynamic-url
```

```
Done
```

```
> bind cr vserver Vserver-CRD-1 -policyName bypass-urltokens
```

```
Done
```

```
> bind cr vserver Vserver-CRD-1 -policyName bypass-cookie
```

```
Done
```

```
> show cr vserver Vserver-CRD-1
```

```
Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
```

```
State: UP ARP:DISABLED
```

```
Client Idle Timeout: 180 sec
```

```
Down state flush: ENABLED
```

```
Disable Primary Vserver On Down : DISABLED
```

```
Default: Content Precedence: RULE Cache: TRANSPARENT
```

```
On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
```

```
Redirect: POLICY Reuse: ON Via: ON ARP: OFF
```

```
1) Cache bypass Policy: bypass-cache-control
```

```
2) Cache bypass Policy: bypass-dynamic-url
```

```
3) Cache bypass Policy: bypass-urltokens
```

```
4) Cache bypass Policy: bypass-cookie
```

```
Done
```

```
>
```

To bind a user-defined policy to a cache redirection virtual server by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. Click the virtual server that you want to configure, and click Open.
3. On the Policies tab, select type of the policy and then click Insert Policy.
4. Under Policy Name column, select the policy that you want to bind.

5. Click OK.

# Unbinding a Policy from a Cache Redirection Virtual Server

Aug 23, 2013

When you unbind a policy from the cache redirection virtual server, the NetScaler appliance no longer applies the policy when evaluating client requests.

To unbind a policy from a cache redirection virtual server by using the command line interface

At the command prompt, type:

- `unbind cr vserver <name> -policyName <string>`
- `show cr vserver [<name>]`

## Example

```
unbind cr vserver Vserver-CR-1 -policyName bypass-non-get
```

```
> show cr vserver Vserver-CRD-1
```

```
 Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
```

```
 State: UP ARP:DISABLED
```

```
 Client Idle Timeout: 180 sec
```

```
 Down state flush: ENABLED
```

```
 Disable Primary Vserver On Down : DISABLED
```

```
 Default: Content Precedence: RULE Cache: TRANSPARENT
```

```
 On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
```

```
 Redirect: POLICY Reuse: ON Via: ON ARP: OFF
```

```
1) Cache bypass Policy: bypass-cache-control
```

```
Done
```

```
>
```

To unbind a user-defined policy from a cache redirection virtual server by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. Click the virtual server that you want to configure, and then click Open.
3. On the Policies tab, under Policy Name, select the policy that you want to unbind.
4. Click Unbind Policy, and then click OK.

# Creating a Load Balancing Virtual Server

Sep 10, 2013

The cache redirection virtual server on the NetScaler appliance can send requests to either a cache server farm, if the request is cacheable, or to the origin server farm if the request is not cacheable.

Each cache server is represented on the appliance by a service, which is bound to a load balancing virtual server that receives requests from the cache redirection virtual server and forwards those requests to the servers.

For details on configuring load balancing virtual servers and other configuration options, see "[Load Balancing](#)."

To create a load balancing virtual server by using the command line interface

At the command prompt, type the following commands to create a load balancing virtual server and verify the configuration:

- add lb vserver <name> <serviceType> [<IPAddress>] [<port>]
- show lb vserver [<name>]

## Example

```
> add lb vserver Vserver-LB-CR HTTP 10.102.20.30 80
Done
> show lb vserver Vserver-LB-CR
 Vserver-LB-CR (10.102.20.30:80) - HTTP Type: ADDRESS
 State: DOWN
 Last state change was at Fri Jul 2 08:47:52 2010
 Time since last state change: 0 days, 00:00:08.470
 Effective State: DOWN
 Client Idle Timeout: 180 sec
 Down state flush: ENABLED
 Disable Primary Vserver On Down : DISABLED
 Port Rewrite : DISABLED
 No. of Bound Services : 0 (Total) 0 (Active)
 Configured Method: LEASTCONNECTION
 Mode: IP
 Persistence: NONE
 Vserver IP and Port insertion: OFF
 Push: DISABLED Push VServer:
 Push Multi Clients: NO
 Push Label Rule: none
Done
>
```

To create a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:

- Name\*-name
- IP Address\*- IPAddress
- Port\*-port

\* A required parameter

4. In the Protocol\* drop down list, select a supported protocol (for example, **HTTP**). If the virtual server is to receive traffic on a port other than the well-known port for the selected protocol, enter a new value in the Port field.
5. Click Create, and then click Close. The Load Balancing Virtual Servers pane displays the new virtual server.

# Configuring an HTTP Service

Sep 10, 2013

On the NetScaler appliance, a service represents a physical server on the network. In the transparent cache redirection configuration, the service represents the cache server. Cacheable requests are sent by the cache redirection virtual server to the load balancing virtual server, which in turn forwards each request to the correct service, which passes it on to the cache server.

To configure an HTTP service by using the command line interface

At the command prompt, type the following commands to create an HTTP service and verify the configuration:

- add service <name> <IP> <serviceType> <port> -cacheType <cacheType>
- show service [<name>]

## Example

```
> add service Service-HTTP-1 10.102.29.40 HTTP 80 -cacheType TRANSPARENT
```

```
Done
```

```
> show service Service-HTTP-1
```

```
Service-HTTP-1 (10.102.29.40:80) - HTTP
State: DOWN
Last state change was at Fri Jul 2 09:14:17 2010
Time since last state change: 0 days, 00:00:13.820
Server Name: 10.102.29.40
Server ID : 0 Monitor Threshold : 0
Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive(CKA): NO
Access Down Service: NO
TCP Buffering(TCPB): NO
HTTP Compression(CMP): YES
Idle timeout: Client: 180 sec Server: 360 sec
Client IP: DISABLED
Cache Type: TRANSPARENT Redirect Mode:
Cacheable: NO
SC: OFF
SP: ON
Down state flush: ENABLED
```

```
1) Monitor Name: tcp-default
```

```
State: DOWN Weight: 1
```

```
Probes: 3 Failed [Total: 3 Current: 3]
```

```
Last response: Failure - Time out during TCP connection establishment stage
```

```
Response Time: N/A
```

```
Done
```

```
>
```

To modify or remove a service by using the command line interface

- To modify a service, use the `set service` command, which is just like using the `add service` command, except that you enter the name of an existing service.
- To remove a service, use the `rm service` command, which accepts only the `<name>` argument.

To add an HTTP service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
  - Service Name\*—name
  - Server\*— IP
  - Port\*—port

\* A required parameter
4. In the Protocol\* drop-down list, select a supported protocol (for example, **HTTP**).
5. Click Create, and then click Close.

# Binding/Unbinding a Service to/from a Load Balancing Virtual Server

Aug 22, 2013

You must bind a service to the load balancing virtual server. This enables the load balancer to forward the request to the server that the service represents. If your configuration changes, you can unbind a service from the load balancing virtual server.

To bind a service to a load balancing virtual server by using the command line interface

At the command prompt, type:

- `bind lb vserver <name> <serviceName>`
- `show lb vserver [<name>]`

## Example

```
> bind lb vserver vserver-LB-CR service-HTTP-1
Done
> show lb vserver Vserver-LB-CR
Vserver-LB-CR (10.102.20.30:80) - HTTP Type: ADDRESS
State: DOWN
Last state change was at Fri Jul 2 08:47:52 2010
Time since last state change: 0 days, 00:42:25.610
Effective State: DOWN
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Port Rewrite : DISABLED
No. of Bound Services : 1 (Total) 0 (Active)
Configured Method: LEASTCONNECTION
Mode: IP
Persistence: NONE
Vserver IP and Port insertion: OFF
Push: DISABLED Push VServer:
Push Multi Clients: NO
Push Label Rule: none
```

```
1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
Done
```

>

To unbind a service from a load balancing virtual server by using the command line interface

To unbind a service, use the `unbind lb vserver` command instead of `bind lb vserver`.

To bind/unbind a service from a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers
2. In the details pane, select the virtual server from which you want to bind/unbind the service, and then click Open.

3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

# Disabling the Use the Proxy Port Setting for Transparent Caching

Sep 11, 2013

If the use source IP (USIP) option is disabled on a cache service configured on the NetScaler appliance, the appliance forwards client requests to the cache service by using a NetScaler-owned subnet IP (SNIP) address or mapped IP (MIP) address as the source IP address and a random port as the source port. The randomly selected port is called the proxy port.

However, if you want to configure a fully transparent cache (a cache configuration in which the cache service receives the client's IP address and port number), you must not only enable the USIP option, either globally or on the cache service, but also disable the Use Proxy Port setting, either globally or on the cache service. Disabling the Use Proxy Port setting enables the appliance to use the client's source port as the source port when it connects to the cache service, and ensures a fully transparent cache configuration.

For more information about configuring the Use Proxy Port option globally or on a service, see "[Configuring the Source Port for Server-Side Connections](#)."

# Assigning a Port Range to the NetScaler

Aug 22, 2013

Sharing of the client IP address may create a conflict that makes network devices, such as routers, cache servers, origin servers, and other NetScaler appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

A method to solve this problem is to assign a source port range to the NetScaler appliance. This allotment enables network devices to unambiguously identify the NetScaler appliance that sent the request.

To assign a source port range to a NetScaler appliance by using the command line interface

At the command prompt, type:

```
set ns param -crPortRange <startPortNumber-endPortNumber>
```

To assign a source port range to a NetScaler appliance by using the NetScaler configuration utility

1. In the navigation pane, click System, and then click Settings.
2. In the Settings group, click the Change global system settings link.
3. In the Cache Redirection Port Range group, specify the port range for the NetScaler by typing a port number for Start Port and a port number for End Port.
4. Click OK.

# Enabling Load Balancing Virtual Servers to Redirect Requests to Cache

Aug 23, 2013

If a load balancing virtual server is configured to listen on a particular IP address and port combination, it takes precedence over the cache redirection virtual server for any requests destined for that address-port combination. Therefore, the cache redirection virtual server does not process those requests.

If you want to override this functionality and let the cache redirection virtual server decide whether the request should be served from the cache or not, configure the particular load balancing virtual server to be cacheable.

Such a configuration is typically used when an ISP uses a NetScaler appliance at the edge of its network and all traffic flows through the appliance.

To enable load balancing virtual servers to redirect requests to the cache by using the command line interface

At the command prompt, type:

- `set lb vserver <name> [-cacheable ( YES | NO)]`
- `show lb vserver [<name>]`

## Example

```
set lb vserver Vserver-LB-CR -cacheable YES
> show lb vserver vserver-LB-CR
 Vserver-LB-CR (10.102.20.30:80) - HTTP Type: ADDRESS
 State: DOWN
 Last state change was at Fri Jul 2 08:47:52 2010
 Time since last state change: 0 days, 01:05:51.510
 Effective State: DOWN
 Client Idle Timeout: 180 sec
 Down state flush: ENABLED
 Disable Primary Vserver On Down : DISABLED
 Port Rewrite : DISABLED
 No. of Bound Services : 1 (Total) 0 (Active)
 Configured Method: LEASTCONNECTION
 Mode: IP
 Persistence: NONE
 Cacheable: YES PQ: OFF SC: OFF
 Vserver IP and Port insertion: OFF
 Push: DISABLED Push VServer:
 Push Multi Clients: NO
 Push Label Rule: none

1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
Done
```

For transparent cache redirection, the NetScaler intercepts all traffic and evaluates every request to determine whether it is cacheable. Non-cacheable requests are sent unchanged to the origin server.

When using transparent cache redirection, you may want to turn off cache redirection for load balancing virtual servers that always direct traffic to origin servers.

To turn off caching for a load balancing virtual server by using the command line interface

To turn off caching for a load balancing virtual, use the `unset lb vserver` command instead of `set lb vserver`. Specify a value of `NO` for the **-cacheable** parameter.

To enable or disable load balancing virtual servers to redirect requests to the cache by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server from which you want to enable/disable the caching, and then click Open.
3. On the Advanced tab, select/clear Cache Redirection check box.
4. Click OK.

# Configuring Forward Proxy Redirection

Dec 17, 2013

A forward proxy is a single point of contact for a client or group of clients. In this configuration, the NetScaler appliance redirects non-cacheable requests to an origin server and redirects cacheable requests to either a forward proxy cache or a transparent cache.

When the NetScaler is configured as a forward proxy, users must modify their browsers so that the browser sends requests to the forward proxy instead of the destination servers.

A forward proxy cache redirection virtual server on the NetScaler compares the request with a policy for caching. If the request is not cacheable, the NetScaler queries a DNS load balancing virtual server for resolution of the destination, and then sends the request to the origin server. If the request is cacheable, the NetScaler forwards the request to a load balancing virtual server for the cache.

The NetScaler relies on a host domain name or IP address in the request's HOST header to determine the requested destination. If there is no HOST header in the request, the appliance inserts a HOST header based on the destination IP address in the request.

Typically, the NetScaler appliance acts as a forward proxy in an enterprise LAN. In such a configuration, the appliance resides at the edge of an enterprise LAN and intercepts client requests before they are fanned out to the WAN. Configuring the appliance in the forward proxy mode reduces traffic on the WAN.

To configure forward proxy cache redirection, first enable load balancing and cache redirection on the NetScaler. Then, configure a DNS load balancing virtual server and associated services. Also configure a load balancing virtual server and bind to it appropriate services for the cache. Configure a forward proxy cache redirection virtual server and bind the DNS and load balancing virtual servers to it. You must also configure caching policies and bind them to the cache redirection virtual server. To complete the setup, configure the client browsers to use the forward proxy.

For details on how to enable cache redirection and load balancing on the NetScaler, see "[Enabling Cache Redirection and Load Balancing](#)."

For details on how to create a load balancing virtual server, see "[Creating a Load Balancing Virtual Server](#)."

For details on how to configure services that represent the cache server, see "[Configuring an HTTP Service](#)."

For details on how to bind the service to a virtual server, see "."

For details on how to create a forward proxy cache redirection server, see "[Configuring a Cache Redirection Virtual Server](#)", and create a virtual server of type TRANSPARENT or FORWARD.

For details on binding cache redirection policies to the cache redirection virtual server, see "[Configuring a Cache Redirection Policy](#)."

# Creating a DNS Service

Sep 10, 2013

A DNS service is a representation, on the NetScaler appliance, of a physical DNS server in the network. A DNS load balancing virtual server sends DNS requests to the DNS server in the network through such a service.

To create a DNS service by using the command line interface

At the command line, type the following commands to create a DNS service and verify the configuration :

- add service <name> <IP> <serviceType> <port>
- show service [<name>]

## Example

```
add service Service-DNS-1 10.102.29.41 DNS 53
```

```
show service Service-DNS-1
```

```
Service-DNS-1 (10.102.29.41:53) - DNS
```

```
State: DOWN
```

```
Last state change was at Fri Jul 2 10:14:32 2010
```

```
Time since last state change: 0 days, 00:00:13.550
```

```
Server Name: 10.102.29.41
```

```
Server ID : 0 Monitor Threshold : 0
```

```
Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
```

```
Use Source IP: NO
```

```
Client Keepalive(CKA): NO
```

```
Access Down Service: NO
```

```
TCP Buffering(TCPB): NO
```

```
HTTP Compression(CMP): NO
```

```
Idle timeout: Client: 120 sec Server: 120 sec
```

```
Client IP: DISABLED
```

```
Cacheable: NO
```

```
SC: OFF
```

```
SP: OFF
```

```
Down state flush: ENABLED
```

```
1) Monitor Name: ping-default
```

```
State: DOWN Weight: 1
```

```
Probes: 3 Failed [Total: 3 Current: 3]
```

```
Last response: Failure - Probe timed out.
```

```
Response Time: 2000.0 millisec
```

```
Done
```

To add an DNS service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:

- Service Name\*— name

- Server\*—IP

- Port\*—port

\* A required parameter

4. In the Protocol\* drop down list, select a supported protocol (for example, **DNS**).

5. Click Create, and then click Close.

# Creating a DNS Load Balancing Virtual Server

Aug 23, 2013

The DNS virtual server enables the forward proxy to perform DNS resolution before forwarding a client request to an origin server. The DNS load balancing virtual server is associated with the DNS service that represents the physical DNS server on the network.

To create a DNS load balancing virtual server by using the command line interface

At the command line, type the following commands to create a DNS load balancing virtual server and verify the configuration:

- add lb vserver <name> <serviceType>
- show lb vserver [<name>]

## Example

```
> add lb vserver Vserver-DNS-1 DNS
Done
> show lb vserver Vserver-DNS-1
 Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
 State: DOWN
 Last state change was at Fri Jul 2 10:32:28 2010
 Time since last state change: 0 days, 00:00:08.10
 Effective State: DOWN ARP:DISABLED
 Client Idle Timeout: 120 sec
 Down state flush: ENABLED
 Disable Primary Vserver On Down : DISABLED
 No. of Bound Services : 0 (Total) 0 (Active)
 Configured Method: LEASTCONNECTION
 Mode: IP
 Persistence: NONE
Done
>
```

To create a DNS load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, in the Name box, type a name for the virtual server.
4. In the Protocol\* drop down list, select a supported protocol (for example, **DNS**).
5. Click Create, and then click Close. The DNS Virtual Servers pane displays the new virtual server.

# Binding the DNS Service to the Virtual Server

Aug 22, 2013

For the DNS server to respond to DNS requests, the service representing the DNS server must be bound to the DNS virtual server.

To bind the DNS service to the load balancing virtual server:

At the command prompt, type the following commands to bind the DNS service to the load balancing virtual server and verify the configuration:

- bind lb vserver <name> <serviceName>
- show lb vserver <name>

## Example

```
> bind lb vserver Vserver-DNS-1 Service-DNS-1
Done
> show lb vserver Vserver-DNS-1
 Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
 State: DOWN
 Last state change was at Fri Jul 2 10:32:28 2010
 Time since last state change: 0 days, 00:12:16.80
 Effective State: DOWN ARP:DISABLED
 Client Idle Timeout: 120 sec
 Down state flush: ENABLED
 Disable Primary Vserver On Down : DISABLED
 No. of Bound Services : 1 (Total) 0 (Active)
 Configured Method: LEASTCONNECTION
 Mode: IP
 Persistence: NONE
```

```
1) Service-DNS-1 (10.102.29.41:53) - DNS State: DOWN Weight: 1
Done
```

```
>
```

To unbind a DNS service from the load balancing virtual server:

Use the unbind lb vserver command instead of bind lb vserver.

To Bind/Unbind a DNS service to/from a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers
2. In the details pane, select the virtual server to/from which you want to bind/unbind the DNS service, and then click Open.
3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

# Configuring a Client Web Browser to Use a Forward Proxy

Mar 30, 2012

When you configure the NetScaler appliance as forward proxy cache redirection virtual server in the network, you must configure the client Web browser to send requests to the forward proxy. Typically, when you use a forward proxy, the only route to the servers in the network is through the forward proxy.

Refer the documentation for your browser to configure the browser to use a forward proxy. Specify the IP address and port number of the forward proxy cache redirection virtual server for this configuration.

# Configuring Reverse Proxy Redirection

Dec 17, 2013

A reverse proxy resides in front of one or more Web servers and shields the origin server from client requests. Often, a reverse proxy cache is a front-end for all client requests to a server. An administrator assigns a reverse proxy cache to a specific origin server. This is unlike transparent and forward proxy caches, which cache frequently requested content for all requests to any origin server, and the choice of a server is based on the request.

Unlike a transparent proxy cache, the reverse proxy cache has its own IP address and can replace destination domains and URLs in a non-cacheable request with new destination domains and URLs.

You can deploy reverse proxy cache redirection at the origin-server side or at the edge of a network. When deployed at the origin server, the reverse proxy cache redirection virtual server is a front-end for all requests to the origin server.

In the reverse proxy mode, when the NetScaler receives a request, a cache redirection virtual server evaluates the request and forwards it to either a load balancing virtual server for the cache or a load balancing virtual server for the origin. The incoming request can be transformed by changing the host header or the host URL before they it is sent to the backend server.

To configure reverse proxy cache redirection, first enable cache redirection and load balancing. Then, configure a load balancing virtual server and services to send cacheable requests to the cache servers. Also configure a load balancing virtual server and associated services for the origin servers. Then, configure a reverse proxy cache redirection virtual server and bind relevant cache redirection policies to it. Finally, configure mapping policies and bind them to the reverse proxy cache redirection virtual server.

The mapping policies have an associated action that enables the cache redirection virtual server to forward any non-cacheable request to the load balancing virtual server for the origin.

Be sure to create the default cache server destination.

For details on how to enable cache redirection and load balancing on the NetScaler, see "[Enabling Cache Redirection and Load Balancing](#)."

For details on how to create a load balancing virtual server, see "[Creating a Load Balancing Virtual Server](#)."

For details on how to configure services that represent the cache server, see "[Configuring an HTTP Service](#)."

For details on how to bind the service to a virtual server, see "."

For details on how to create a reverse proxy cache redirection server, see "[Configuring a Cache Redirection Virtual Server](#)", and create a virtual server of type REVERSE.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see "[Binding Policies to the Cache Redirection Virtual Server](#)."

## Configuring Mapping Policies

If an incoming request is non-cacheable, the reverse-proxy cache redirection virtual server replaces the domain and URL in the request with the domain and URL of a target origin server and forwards the request to the load balancing virtual server for the origin.

A mapping policy enables the reverse proxy cache redirection virtual server to replace the destination domain and URL and forward the request to the load balancing virtual server for the origin.

A mapping policy must first translate the domain and the URL, and then pass the request on to the origin load balancing virtual

server.

A mapping policy can map a domain, a URL prefix, and a URL suffix, as follows:

- Domain mapping: You can map a domain without a prefix or suffix. The domain mapping is the default mapping for the virtual server (for example, mapping `www.mycompany.com` to `www.myrealcompany.com`).
- Prefix mapping: You can replace a specified pattern prefixed as part of the URL (for example, mapping `www.mycompany.com/sports/index.html` to `www.mycompany.com/news/index.html`).
- Suffix mapping: You can replace the file suffix in the URL (for example, mapping `www.mycompany.com/sports/index.html` to `www.mycompany.com/sports/index.asp`).

The source and the destination strings being mapped must be similar. If you specify a source domain, you must specify a destination domain, and if you specify a source suffix, you must specify a destination suffix. Similarly, if you specify an exact URL from the source, the target URL must also be an exact URL.

Once you configure mapping policies for the reverse proxy mode, you must bind them to the cache redirection virtual server.

You can use combinations of the source URL, target URL, and source and target domains to configure all three types of domain mapping.

## To configure a mapping policy for reverse proxy mode by using the command line interface

At the command prompt, type the following command to add a policy map and verify the configuration:

- `add policy map <mapPolicyName> -sd <string> [-su <string>] [-td <string>] [-tu <string>]`
- `show policy map [<mapPolicyName>]`

### Example

The following command maps a domain in a client request to a target domain:

```
> add policy map myMappingPolicy -sd www.mycompany.com -td www.myrealcompany.com
Done
> show policy map myMappingPolicy
1) Name: myMappingPolicy
 Source Domain: www.mycompany.com Source Url:
 Target Domain: www.myrealcompany.com Target Url:
Done
>
```

Following is an example of mapping a URL suffix to a different URL suffix:

```
> add policy map myOtherMappingPolicy -sd www.mycompany.com -td www.myrealcompany.com -su /news.html -tu /realnews.html
Done
> show policy map myOtherMappingPolicy
1) Name: myOtherMappingPolicy
 Source Domain: www.mycompany.com Source Url: /news.html
 Target Domain: www.myrealcompany.com Target Url: /realnews.html
Done
>
```

## To configure a mapping policy for reverse proxy mode by using the configuration

## utility

1. Navigate to Traffic Management > Cache Redirection > Map Policies.
2. In the details pane, click Add.
3. In the Create Map Policy dialog box, specify values for the following parameters as shown:

- Name\* - mapPolicyName
- Source Domain\* -sd
- Target Domain\* -td
- Source URL-su
- Target URL-tu

\* A required parameter

4. Click Create, and then click Close. The Map pane displays the new mapping policy.

## To bind the mapping policy to the cache redirection virtual server by using the command line interface

At the command prompt, type the following commands to bind the mapping policy to the cache redirection virtual server and verify the configuration:

- `bind cr vserver <name> -policyName <string> [<targetVserver>]`
- `show cr vserver <name>`

### Example

```
> bind cr vserver Vserver-CRD-3 -policyName myMappingPolicy Vserver-LB-CR
Done
```

```
> show cr vserver Vserver-CRD-3
```

```
Vserver-CRD-3 (10.102.29.50:88) - HTTP Type: CONTENT
State: UP
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Default: Vserver-LB-CR Content Precedence: RULE Cache: REVERSE
On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
Redirect: POLICY Reuse: ON Via: ON ARP: OFF
```

```
1) Policy: Target: Vserver-LB-CR Priority: 0 Hits: 0
```

```
1) Map: myMappingPolicy Target: Vserver-LB-CR
```

```
Done
```

```
>
```

## To bind the mapping policy to the cache redirection virtual server by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server from which you want to bind the mapping policy, and then click Open.
3. In the Configure Virtual Server(Cache Redirection), on the Policies tab, select Map, and then click Insert Policy.
4. In the Policy Name column, select the policy from drop down list.
5. In the Target column, click the down arrow, and then select the vserver from drop down list.

6. Click OK.

# Selective Cache Redirection

Sep 11, 2013

Selective cache redirection sends requests for particular types of content, for example, images, to one cache server or group of cache servers and sends other types of content to a different cache server or group of cache servers. You can configure advanced cache redirection in transparent, reverse proxy, or forward proxy modes.

In selective cache redirection, the NetScaler appliance intercepts a client request and forwards non-cacheable requests to the original destination in the client request. For cacheable requests, the appliance sends the requests to the destination cache server that can serve content of a specific content type.

Selective cache redirection involves configuring content switching policies in addition to cache redirection policies. The NetScaler first evaluates the cache redirection policies that are bound to the cache redirection virtual server. If a request matches a cache redirection policy, the cache redirection virtual server sends the request to the origin server or a load balancing virtual server for the origin. If no cache redirection policies match the request, the NetScaler evaluates the content switching policies bound to the cache redirection virtual server. If a content switching policy matches the request, the cache redirection virtual server redirects the request to a load balancing virtual server for the cache.

To configure selective cache redirection, first enable cache redirection, load balancing, and content switching on the NetScaler appliance. Then, configure a load balancing virtual server for the cache and an associated HTTP service. After this, configure a cache redirection virtual server and bind both the cache redirection and content switching policies to it. Once you have bound the policies, you can configure the virtual server to give precedence to either rule based or URL based content-switching policies.

When configured for transparent mode cache redirection in an edge deployment topology, the NetScaler sends all cacheable HTTP traffic to a transparent cache farm. Clients access the Internet through the NetScaler, which is configured as a Layer 4 switch that receives traffic on port 80.

The NetScaler can direct requests for images (for example, .gif and .jpg files) to one server in the transparent cache farm, and all other requests for static content to other servers in the farm. For this configuration, you configure content switching policies to send images to the image cache and send all other cacheable content to a default cache.

Note: The configuration described here is for transparent selective cache redirection. Therefore, it does not require a load balancing virtual server for the origin, as would a reverse proxy configuration.

To configure this type of selective cache redirection, first enable cache redirection, load balancing, and content switching. Then, configure a load balancing virtual server for the cache and configure an associated HTTP service. Then, configure a cache redirection virtual server and create and bind both cache redirection and content switching policies to this virtual server.

For details on how to enable cache redirection and load balancing on the NetScaler, see "[Configuring Cache Redirection](#)."

# Enabling Content Switching

Nov 08, 2013

To configure selective cache redirection, after you enable both the load balancing and cache redirection features on the NetScaler, you must enable content switching.

To enable content switching by using the command line interface

At the command prompt, type:

- enable ns feature CS
- show ns feature

## Example

```
> enable ns feature cs
```

```
Done
```

```
> show ns feature
```

|     | Feature           | Acronym       | Status |
|-----|-------------------|---------------|--------|
|     | -----             | -----         | -----  |
| 1)  | Web Logging       | WL            | ON     |
| 2)  | Surge Protection  | SP            | ON     |
| 3)  | Load Balancing    | LB            | ON     |
| 4)  | Content Switching | CS            | ON     |
| 5)  | Cache Redirection | CR            | ON     |
|     | ...               |               |        |
|     | ...               |               |        |
|     | ...               |               |        |
| 23) | HTML Injection    | HTMLInjection | ON     |
| 24) | NetScaler Push    | push          | OFF    |

```
Done
```

To enable cache redirection and load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure basic features.
3. In Configure Basic Features dialog box, select the check box next to the Content Switching, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

# Configuring a Load Balancing Virtual Server for the Cache

Dec 17, 2013

Create a load balancing virtual server and an HTTP service for each type of cache server that will be used. For example, if you want to serve JPEG files from one cache server and GIF files from another cache server, and use a third cache server for the rest of the content, create an HTTP service and virtual server for each of the three types of cache servers. Then bind each service to its respective virtual server.

For details on how to create a load balancing virtual server, see "[Creating a Virtual Server](#)Creating a Virtual Server."

For details on how to configure services that represent the cache server, see "[Configuring an HTTP Service](#)."

For details on how to bind the service to a virtual server, see "[Binding/Unbinding a Service to/from a Load Balancing Virtual Server](#)."

For details on how to create a transparent proxy cache redirection server, see "[Configuring a Cache Redirection Virtual Server](#)", and create a virtual server of type TRANSPARENT.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see "[Binding Policies to the Cache Redirection Virtual Server](#)."

## Configuring a Cache Redirection Policy for a Specific Type of Content

To identify requests that contain a .gif or .jpeg extension as cacheable, you configure a cache redirection policy and bind it to the cache redirection virtual server.

Note: If a request matches a policy, the NetScaler appliance forwards it to the origin server. As a result, in the following procedure, you configure policies to match requests that do *not* have ".gif" or ".jpeg" extensions.

To configure cache redirection for a specific type of content, configure a policy that uses a simple expression, as described in "[Configuring a Cache Redirection Policy](#)."

# Configuring Policies for Content Switching

Dec 17, 2013

You must create a content switching policy to identify specific types of content to be cached in one cache server or farm and identify other types of content to serve from another cache server or farm. For example, you can configure a policy to determine the location for image files with .gif and .jpeg extensions.

After defining the content switching policy, you bind it to a cache redirection virtual server and specify a load balancing virtual server. Requests that match the policy are forwarded to the named load balancing virtual server. Requests that do not match the content switching policy are forwarded to the default load balancing virtual server for the cache.

For more details about the content switching feature and configuring content switching policies, see "."

You must first create the content switching policy and then bind it to the cache redirection virtual server.

To create a content switching policy by using the command line interface

At the command line, type:

- add cs policy <policyName> [-url <string> | -rule <expression>]
- show cs policy [<policyName>]

## Examples

```
> add cs policy Policy-CS-JPEG -rule "REQ.HTTP.URL == '/*.*jpeg'"
```

```
Done
```

```
> show cs policy Policy-CS-JPEG
```

```
Rule: REQ.HTTP.URL == '/*.*jpeg' Policy: Policy-CS-JPEG
```

```
Hits: 0
```

```
Done
```

```
>
```

```
> add cs policy Policy-CS-GIF -rule "REQ.HTTP.URL == '/*.*gif'"
```

```
Done
```

```
> show cs policy Policy-CS-GIF
```

```
Rule: REQ.HTTP.URL == '/*.*gif' Policy: Policy-CS-GIF
```

```
Hits: 0
```

```
Done
```

```
>
```

```
> add cs policy Policy-CS-JPEG-URL -url /*.*jpg
```

```
Done
```

```
> show cs policy Policy-CS-JPEG-URL
```

```
URL: /*.*jpg Policy: Policy-CS-JPEG-URL
```

```
Hits: 0
```

```
Done
```

```
>
```

```
> add cs policy Policy-CS-GIF-URL -url /*.gif
Done
> show cs policy Policy-CS-GIF-URL
 URL: /*.gif Policy: Policy-CS-GIF-URL
 Hits: 0
Done
>
```

To create a URL-based content switching policy by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.
4. Select the URL radio button.
5. In the Value text box, type the string value (for example, **/sports**).
6. Click Create and click Close. The policy you created appears in the Content Switching Policies page.

To create a rule-based content switching policy by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.
4. Select the Expression radio button, and then click Configure.
5. In the Create Expression dialog box, choose the expression syntax that you want to use.
  - If you want to use default syntax, accept the default and proceed to the next step.
  - If you want to use classic syntax, click Switch to Classic Syntax.

The Expression portion of the dialog box changes to match your choice. The default syntax Expression view has fewer elements than does the classic syntax Expression view. In the default syntax Expression view, instead of a preview window, a button provides access to an expression evaluator. The evaluator evaluates the expression you entered, to verify that it is valid, and displays an analysis of the expression's effect.

6. Enter your policy expressions.
  - If you are using classic syntax and need further instructions, see "[Configuring Classic Policies and Expressions](#)."
  - If you are using the default syntax and need further instructions, see "[Configuring Default Syntax Expressions: Getting Started](#)."
7. Click Create and click Close. The policy you created appears in the Content Switching Policies pane.

To bind the content switching policy to a cache redirection virtual server by using the command line interface

At the command prompt, type the following commands to bind the content switching policy to a cache redirection virtual server and verify the configuration:

- `bind cs vserver <name> <targetVserver> [-policyName <string>]`
- `show cs vserver [<name>]`

### Example

```
> bind cs vserver Vserver-CR-1 lbcachejpeg -policyName Policy-CS-JPEG
Done
```

```
> bind cs vserver Vserver-CR-1 lbcachegif -policyName Policy-CS-GIF
```

```
Done
```

```
> show cs vserver Vserver-CR-1
```

```
Vserver-CR-1 (10.102.29.60:80) - HTTP Type: CONTENT
```

```
State: UP
```

```
Last state change was at Fri Jul 2 12:53:45 2010
```

```
Time since last state change: 0 days, 00:00:58.920
```

```
Client Idle Timeout: 180 sec
```

```

```

```
State Update: DISABLED
```

```
Default: Content Precedence: RULE
```

```
Cacheable: YES
```

```
Vserver IP and Port insertion: OFF
```

```
Case Sensitivity: ON
```

```
Push: DISABLED Push VServer:
```

```
Push Label Rule: none
```

```
1) Policy: Policy-CS-JPEG Target: lbcachejpeg Priority: 0 Hits: 0
```

```
2) Policy: Policy-CS-GIF Target: lbcachegif Priority: 0 Hits: 0
```

```
Done
```

```
>
```

To bind the content switching policy to a cache redirection virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the policy (for example, **Vserver-CS-1**), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, click CSW, and then click Insert Policy.
4. In the Policy Name column, select the policy that you want to configure for the content switching virtual server.
5. In the Target column, click the green arrow, and select the target load balancing virtual server from the list.
6. Click OK.

# Configuring Precedence for Policy Evaluation

Aug 23, 2013

You can configure a content switching policy based on either a rule, which is a generic configuration to accommodate various content types, or a URL, which is more specific and defines exactly the type of content that has to be sent to a particular cache server. Essentially, the same content can be defined by either a rule based policy or a URL based policy.

Once you bind content switching policies of either type to a cache redirection virtual server, you can configure the virtual server to give precedence to either rule based or URL based policies. This will, in turn, decide which servers the particular requests are directed to.

To configure precedence for policy evaluation, use the precedence parameter, which specifies the type of policy (URL or RULE) that takes precedence on the content redirection virtual server.

Possible values: RULE, URL

Default value: RULE

To configure precedence for policy evaluation by using the command line interface

At the command prompt, type the following commands to configure precedence for policy evaluation and verify the configuration:

- set cr vserver <name> [-precedence (RULE | URL)]
- show cr vserver <name>

## Example

```
> set cr vserver Vserver-CRD-1 -precedence URL
Done
> show cr vserver Vserver-CRD-1
 Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
 State: UP ARP:DISABLED
 Client Idle Timeout: 180 sec
 Down state flush: ENABLED
 Disable Primary Vserver On Down : DISABLED
 Default: Content Precedence: URL Cache: TRANSPARENT
 On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
 Redirect: POLICY Reuse: ON Via: ON ARP: OFF
```

- 1) Cache bypass Policy: bypass-cache-control
  - 2) Cache bypass Policy: Policy-CRD
- Done

>

To configure precedence for policy evaluation by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure precedence, (for example, **Vserver-CS-1**), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, next to Precedence, click Rule or URL, and then click OK.

# Administering a Cache Redirection Virtual Server

Mar 30, 2012

To administer a cache redirection virtual server, you need to view cache redirection statistics. You might need to enable or disable cache redirection servers, or direct policy hits to the cache instead of the origin. Administrative tasks also include backing up a cache redirection virtual server and managing client connections.

# Viewing Cache Redirection Virtual Server Statistics

Aug 23, 2013

You can view properties of a cache redirection virtual server and statistics on the traffic that has passed through a cache redirection virtual server. You can also view the cache redirection virtual servers and policies that you have bound to load balancing virtual servers.

To view statistics for a specific cache redirection virtual servers, use the name parameter to specify the name of the virtual server for which statistics will be displayed. Otherwise, statistics for all cache redirection virtual servers are displayed.

Maximum Length: 127

To view statistics for a cache redirection virtual server by using the command line interface

At the command prompt, type:

```
stat cr vserver [<name>]
```

## Example

```
> stat cr vserver Vserver-CRD-1
```

### Vserver Summary

|              | IP port    | Protocol | State |  |
|--------------|------------|----------|-------|--|
| Vser...CRD-1 | 0.0.0.0 80 | HTTP     | UP    |  |

### VServer Stats:

|                | Rate (/s) | Total |
|----------------|-----------|-------|
| Requests       | 0         | 0     |
| Responses      | 0         | 0     |
| Request bytes  | 0         | 0     |
| Response bytes | 0         | 0     |

Done

>

To view statistics for a cache redirection virtual server by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers
2. In the details pane, select the virtual server for which you want to view statistics, (for example, **Vserver-CRD-1**), and then click Statistics.

Omit the server name to display basic statistics for all cache redirection virtual servers. Include the server name to display detailed statistics for that virtual server, including number and size of requests and responses that pass through the virtual server

To view the statistics of a cache redirection virtual server by using the monitoring and dashboard utilities

1. To view the statistics by using the monitoring utilities, click the Monitoring tab.
2. In the Select Group drop-down menu, choose CR Virtual Servers. A list of cache redirection virtual servers appears.
3. To view the statistics by using the dashboard utilities, click the Dashboard tab.

4. Click Applet Client or Web Start Client next to Statistical Utility.
5. In the Select Group drop-down menu, choose CR Virtual Servers. The dashboard displays summary statistics for the cache redirection virtual servers.
6. To see a chart of virtual server activity, click Chart. A graphical representation of the virtual server statistics appears.

# Enabling or Disabling a Cache Redirection Virtual Server

Aug 23, 2013

When you create a cache redirection virtual server, it is enabled by default. If you disable a cache redirection virtual server, its state changes to OUT OF SERVICE and it stops redirecting cacheable client requests. However, the NetScaler appliance continues to respond to ARP and ping requests for the IP address of this virtual server.

To Enable or Disable a cache redirection virtual servers by using the command line interface

At the command line, type one of the following commands:

- enable cr vserver <name>
- show cr vserver <name>
- disable cr vserver <name>
- show cr vserver <name>

## Examples

```
> enable cr vserver Vserver-CRD-1
```

```
Done
```

```
> show cr vserver Vserver-CRD-1
```

```
Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
State: UP ARP:DISABLED
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Default: Content Precedence: URL Cache: TRANSPARENT
On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
Redirect: POLICY Reuse: ON Via: ON ARP: OFF
```

```
1) Cache bypass Policy: bypass-cache-control
```

```
2) Cache bypass Policy: Policy-CRD
```

```
Done
```

```
>
```

```
> disable cr vserver Vserver-CRD-1
```

```
Done
```

```
> show cr vserver Vserver-CRD-1
```

```
Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
State: OUT OF SERVICE ARP:DISABLED
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Default: Content Precedence: URL Cache: TRANSPARENT
On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
Redirect: POLICY Reuse: ON Via: ON ARP: OFF
```

1) Cache bypass Policy: bypass-cache-control

2) Cache bypass Policy: Policy-CRD

Done

>

To Enable or Disable a cache redirection virtual servers by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.
3. In the details pane, select the virtual server that you want to enable or disable, (for example, **Vserver-CRD-1**), and then click Statistics.
4. In the Proceed dialog box, click Yes.

# Directing Policy Hits to the Cache Instead of the Origin

Aug 23, 2013

By default, when a request matches a policy, the NetScaler appliance forwards the request either to the origin server directly, or to a load balancing virtual server for the origin, depending on how you have configured cache redirection.

You can change the default behavior so that when a request matches a policy, the request is forwarded to a load balancing virtual server for the cache.

To change the destination for a policy hit to the origin or the cache, use the `onPolicyMatch` parameter, which specifies where to send requests that match the cache redirection policy.

The valid options are:

1. CACHE - Directs all matching requests to the cache.
2. ORIGIN - Directs all matching requests to the origin server.

Note: For this option to work, you must select the `cachedirection` type as POLICY.

Possible values: CACHE, ORIGIN

Default value: ORIGIN

To change the destination for a policy hit to the origin or the cache by using the command line interface

At the command prompt, type the following commands to change the destination for a policy hit and verify the configuration:

- `set cr vserver <name> [-onPolicyMatch (ORIGIN | CACHE)]`
- `show cr vserver <name>`

## Example

```
> set cr vserver Vserver-CRD-1 -onPolicyMatch CACHE
Done
> show cr vserver Vserver-CRD-1
Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
State: UP ARP:DISABLED
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Default: Content Precedence: URL Cache: TRANSPARENT
On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
Redirect: POLICY Reuse: ON Via: ON ARP: OFF
```

- 1) Cache bypass Policy: bypass-cache-control
- 2) Cache bypass Policy: Policy-CRD

Done

To change the destination for a policy hit to the origin or the cache by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to change the destination for a policy hit, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, click Advanced tab.
4. Select CACHE or ORIGIN from the Redirect To drop-down list.
5. Click OK.

# Backing Up a Cache Redirection Virtual Server

Aug 22, 2013

Cache redirection can fail if the primary virtual server fails, or if it is unable to handle excessive traffic. You can specify a backup virtual server to take over the processing of traffic when the primary virtual server fails.

To specify a backup cache redirection virtual server, use the backupVServer parameter, which specifies Backup Virtual Server. Maximum Length: 127

To specify a backup cache redirection virtual server by using the command line interface

At the command prompt, type the following commands to specify a backup cache redirection virtual server and verify the configuration:

- set cr vsver <name> [-backupVServer <string>]
- show cr vsver <name>

## Example

```
> set cr vsver Vserver-CRD-1 -backupVServer Vserver-CRD-2
```

Done

```
> show cr vsver Vserver-CRD-1
```

```
Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
State: UP ARP:DISABLED
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Default: Content Precedence: URL Cache: TRANSPARENT
On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
Redirect: POLICY Reuse: ON Via: ON ARP: OFF
Backup: Vserver-CRD-2
```

- 1) Cache bypass Policy: bypass-cache-control
- 2) Cache bypass Policy: Policy-CRD

Done

To specify a backup cache redirection virtual server by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > irtual Servers.
2. In the details pane, select the virtual server for which you want to change the destination for a policy hit, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. In the Backup Virtual Server drop-down list, select the virtual server.
5. Click OK.

# Managing Client Connections for a Virtual Server

Jun 04, 2015

You can configure timeouts on a cache redirection virtual server so that client connections are not kept open indefinitely. You can also insert Via headers in requests. To possibly reduce network congestion, you can reuse open TCP connections. You can enable or disable delayed cleanup of cache redirection virtual server connections.

You can configure the NetScaler to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR\_CNTRLRD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, NetScaler responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds even if one virtual server set to ACTIVE is UP.

This document includes the following information:

- [Configuring Client Timeout](#)
- [Inserting Via Headers in the Requests](#)
- [Reusing TCP Connections](#)
- [Configuring Delayed Connection Cleanup](#)

## Configuring Client Timeout

Updated: 2013-08-22

You can specify expiration of client requests by setting a timeout value for the cache redirection virtual server. The timeout value is the number of seconds for which the cache redirection virtual server waits to receive a response for the client request.

To configure a time-out value, use the `cltTimeout` parameter, which specifies the time, in seconds, after which the NetScaler appliance closes any idle client connections. The default value is 180sec for HTTP/SSL-based services and 9000sec for TCP-based services.

## To configure client timeout by using the command line interface

At the command prompt, type the following commands to configure client timeout and verify the configuration:

- `set cr vserver <name> [-cltTimeout <secs>]`
- `show cr vserver <name>`

### Example

```
> set cr vserver Vserver-CRD-1 -cltTimeout 6000
```

Done

```
> show cr vserver Vserver-CRD-1
Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
State: UP ARP:DISABLED
Client Idle Timeout: 6000 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Default: Content Precedence: URL Cache: TRANSPARENT
On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
Redirect: POLICY Reuse: ON Via: ON ARP: OFF
Backup: Vserver-CRD-2
```

- 1) Cache bypass Policy: bypass-cache-control
- 2) Cache bypass Policy: Policy-CRD

Done

## To configure client timeout by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. In the Client Time-out(secs) text box, enter the time-out value in seconds.
5. Click OK.

## Inserting Via Headers in the Requests

Updated: 2013-08-23

A Via header lists the protocols and recipients between the start and end points for a request or a response and informs the server of proxies through which the request was sent. You can configure the cache redirection virtual server to insert a Via header in each HTTP request. The via parameter is enabled by default when you create a cache redirection virtual server.

To enable or disable Via-header insertion in client requests, use the via parameter, which specifies the state of the system in inserting a Via header in the HTTP requests.

Possible values: ON, OFF

Default value: ON

## To enable or disable Via-header insertion in client requests by using the command line interface

At the command prompt, type:

- set cr vserver <name> [-via (ON | OFF)]
- show cr vserver <name>

### Example

```
> set cr vserver Vserver-CRD-1 -via ON
Done
> show cr vserver Vserver-CRD-1
Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
State: UP ARP:DISABLED
Client Idle Timeout: 6000 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Default: Content Precedence: URL Cache: TRANSPARENT
On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
Redirect: POLICY Reuse: ON Via: ON ARP: OFF
Backup: Vserver-CRD-2
```

- 1) Cache bypass Policy: bypass-cache-control
  - 2) Cache bypass Policy: Policy-CRD
- Done

>

## To enable or disable Via-header insertion in client requests by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. Select the Via check box.
5. Click OK.

### Reusing TCP Connections

Updated: 2013-11-08

You can configure the NetScaler appliance to reuse TCP connections to the cache and origin servers across client connections. This can improve performance by saving the time required to establish a session between the server and the NetScaler. The reuse option is enabled by default when you create a cache redirection virtual server.

To enable or disable the reuse of TCP connections, use the reuse parameter, which specifies the state of reuse of TCP connections to the cache or origin servers across client connections.

Possible values: ON, OFF

Default value: ON

## To enable or disable the reuse of TCP connections by using the command line interface

At the command prompt, type:

- set cr vserver <name> [-reuse (ON | OFF)]
- show cr vserver <name>

## Example

```
> set cr vserver Vserver-CRD-1 -reuse ON
Done
> show cr vserver Vserver-CRD-1
 Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
 State: UP ARP:DISABLED
 Client Idle Timeout: 6000 sec
 Down state flush: ENABLED
 Disable Primary Vserver On Down : DISABLED
 Default: Content Precedence: URL Cache: TRANSPARENT
 On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
 Redirect: POLICY Reuse: ON Via: ON ARP: OFF
 Backup: Vserver-CRD-2
```

- 1) Cache bypass Policy: bypass-cache-control
  - 2) Cache bypass Policy: Policy-CRD
- Done

## To enable or disable the reuse of TCP connections by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. Select the Reuse check box.
5. Click OK.

## Configuring Delayed Connection Cleanup

Updated: 2013-08-22

The down state flush option performs delayed cleanup of connections on a cache redirection virtual server. The down state flush option is enabled by default when you create a cache redirection virtual server.

To enable or disable the down state flush option, set the downStateFlush parameter.

Possible values: ENABLED, DISABLED

Default value: ENABLED

## To enable or disable the down state flush option by using the command line interface

At the command prompt, type the following commands to configure delayed connection clean up and verify the configuration:

- set cr vserver <name> [-downStateFlush (ENABLED | DISABLED)]
- show cr vserver <name>

## Example

```
> set cr vserver Vserver-CRD-1 -downStateFlush ENABLED
Done
> show cr vserver Vserver-CRD-1
 Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
 State: UP ARP:DISABLED
 Client Idle Timeout: 6000 sec
 Down state flush: ENABLED
 Disable Primary Vserver On Down : DISABLED
 Default: Content Precedence: URL Cache: TRANSPARENT
 On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
 Redirect: POLICY Reuse: ON Via: ON ARP: OFF
 Backup: Vserver-CRD-2
```

- 1) Cache bypass Policy: bypass-cache-control
  - 2) Cache bypass Policy: Policy-CRD
- Done

To enable or disable the reuse of TCP connections by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, click Advanced tab.
4. Select the Down state flush check box.
5. Click OK.

# N-Tier Cache Redirection

Mar 30, 2012

To efficiently handle large amounts of cached data, typically several gigabytes per second, an Internet Service Provider (ISP) deploys several dedicated cache servers. The cache redirection feature of the NetScaler appliance can help load balance the cache servers, but a single appliance or a couple of appliances might not efficiently handle the large volume of traffic.

You can solve the problem by deploying the NetScaler appliances in two tiers (layers), where the appliances in the upper tier load balance those in the lower tier and the appliances in the lower tier load balance the cache servers. This arrangement is called *n-tier cache redirection*.

For purposes such as auditing and security, an ISP has to track client details such as the IP address, information provided, and the time of the interaction. Therefore, client connections through a NetScaler appliance have to be fully transparent. However, if you configure transparent cache redirection, with the NetScaler appliances deployed in parallel, the IP address of the client has to be shared among all the appliances. Sharing of the client IP address creates a conflict that makes network devices, such as routers, cache servers, origin servers, and other NetScaler appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

## How N-tier Cache Redirection Is Implemented

To solve the problem, NetScaler n-tier cache redirection splits the source port range among the appliances in the lower tier and includes the client IP address in the request sent to the cache servers. The upper-tier NetScaler appliances are configured to do sessionless load balancing in order to avoid unnecessary load on the appliances.

When the lower-tier NetScaler appliance communicates with a cache server, it uses a mapped IP address (MIP) to represent the source IP address. Therefore, the cache server can identify the NetScaler from which it received the request and send the response to the same NetScaler.

The lower-tier NetScaler appliance inserts the client IP address into the header of the request sent to the cache server. The client IP in the header helps the NetScaler to determine the client to which the packet should be forwarded when it receives the response from a cache server, or the origin server in case of a cache miss. The origin server determines the response to be sent according to the client IP inserted in the request header.

The origin server sends the response to an upper-tier NetScaler, including the source port number from which the origin server received the request. The entire source port range, 1024 to 65535, is distributed among the lower-tier NetScaler appliances. Each lower-tier appliance is exclusively assigned a group of addresses within the range. This allotment enables the upper-tier appliance to unambiguously identify the lower-tier NetScaler appliance that sent the request to the origin server. The upper-tier appliance can therefore forward the response to the correct lower-tier appliance.

The upper-tier NetScaler appliances are configured to do policy-based routing, and the routing policies are defined to determine the IP address of the destination NetScaler from the source port range.

## Setup Necessary for Configuring N-Tier CRD

The following setup is necessary for the functioning of n-tier cache redirection:

For each upper-tier NetScaler appliance:

- Enable Layer 3 mode.
- Define policies for policy-based routes (PBRs) so that traffic is forwarded according to the range of the destination

port.

- Configure a load balancing virtual server.
- Configure the virtual server to listen to all the traffic coming from the client. Set the Service Type/Protocol to be ANY and IP Address as asterisk (\*).
- Enable sessionless load balancing with MAC-based redirection mode to avoid unnecessary load on the upper-tier NetScaler appliances.
- Make sure that the Use Proxy Port option is enabled.
- Create a service for each lower-tier NetScaler and bind all the services to the virtual server.

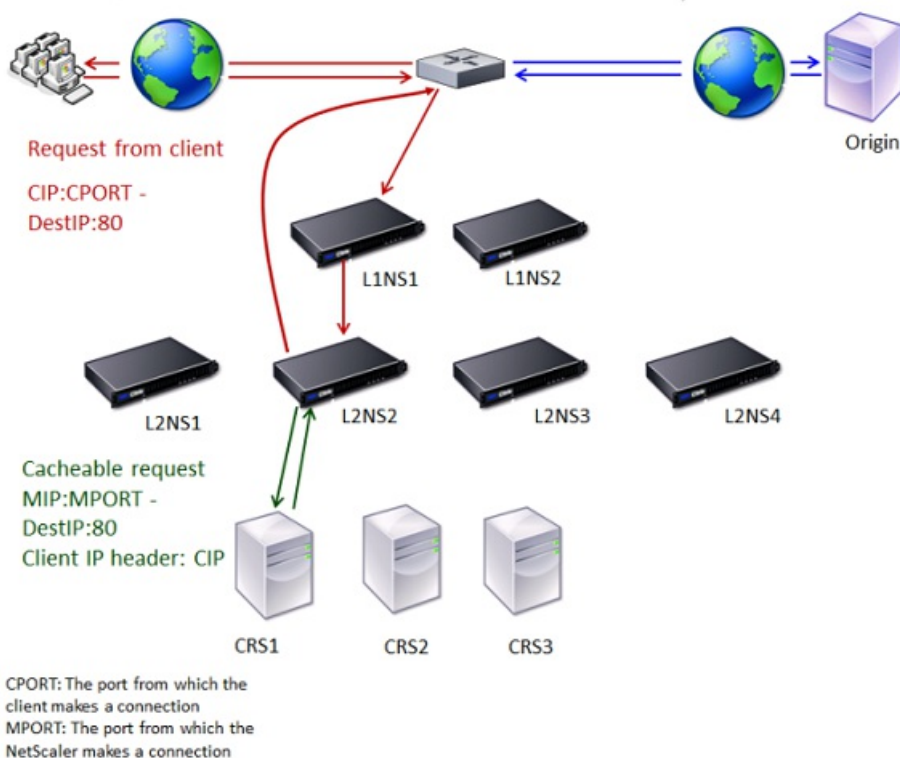

For each lower-tier NetScaler appliance,

- Configure the cache redirection port range on the NetScaler. Assign an exclusive range to each lower-tier NetScaler.
- Configure a load balancing virtual server and enable MAC-based redirection.
- Create a service for each cache server that is to be load balanced by this NetScaler. When creating the service, enable insertion of client IP in the header. Then, bind all the services to the load balancing virtual server.
- Configure a transparent mode cache redirection virtual server with the following settings:
  - Enable the Origin USIP option.
  - Add a source IP expression to include the client IP in the header.
  - Enable the Use Port Range option.

### How N-Tier Cache Redirection Works During a Cache Hit

The following figure shows how cache redirection works when a client request is cacheable and the response is sent from a cache server.

Figure 1. Cache Redirection in Case of a Cache Hit

Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2,

L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

## Traffic Flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. L2NS2 load balances the request to the cache server CRS1, and the request is cacheable. L2NS2 includes the client IP in the request header.
4. CRS1 sends the response to L2NS2 because L2NS2 used its MIP as the source IP address when connecting to CRS1.
5. With the help of the client IP address in the request header, L2NS2 identifies the client from which the request came. L2NS2 directly sends the response to the router, avoiding unnecessary load on the NetScaler in the upper tier.
6. The router forwards the response to Client A.

## How N-Tier Cache Redirection Works During a Cache Bypass

The following figure shows how cache redirection works when a client request is sent to an origin server for a response.

Figure 2. Cache Redirection in Case of a Cache Bypass

Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

## Traffic Flow

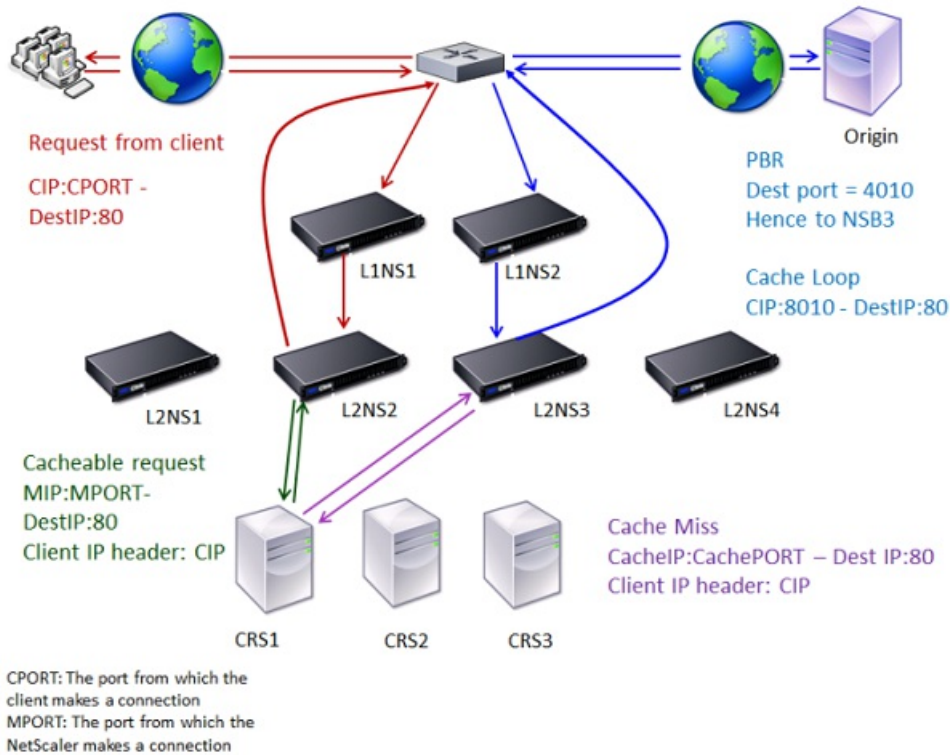

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. The request is uncacheable (cache bypass). Therefore, L2NS2 sends the request to the origin server through the router.
4. The origin server sends the response to an upper-tier NetScaler, L1NS2.

5. According to the PBR policies, L1NS2 forwards the traffic to the appropriate NetScaler in the lower tier, L2NS2.
6. L2NS2 uses the client IP address in the request header to identify the client from which the request came and sends the response directly to the router, avoiding unnecessary load on the NetScaler in the upper tier.
7. The router forwards the response to Client A.

## How N-Tier Cache Redirection Works During a Cache Miss

The following figure shows how cache redirection works when a client request is not cached.

Figure 3. Cache Redirection in Case of a Cache Miss

Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

## Traffic Flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. L2NS2 load balances the request to the cache server CRS1 because the request is cacheable.
4. CRS1 does not have the response (cache miss). CRS1 forwards the request to the origin server through the NetScaler in the lower tier. L2NS3 intercepts the traffic.
5. L2NS3 takes the client IP from the header and forwards the request to the origin server. The source port included in the packet is the L2NS3 port from which the request is sent to the origin server.
6. The origin server sends the response to an upper-tier NetScaler, L1NS2.
7. According to the PBR policies, L1NS2 forwards the traffic to the appropriate NetScaler in the lower tier, L2NS3.
8. L2NS3 forwards the response to the router.
9. The router forwards the response to Client A.

# Configuring the Upper-Tier NetScaler Appliances

Oct 31, 2013

Configure each of the upper-tier NetScaler appliances as follows.

To configure an upper-tier appliance for n-tier cache redirection by using the command line interface

At the command prompt, type the following commands:

- add service <name>@ <serviceIP> <serviceType> <port>  
Run this command for each service to be added.
- add lb vserver <name>@ ANY \* <port> -persistenceType <persistenceMethod> -lbMethod <lbMethod> -m MAC -sessionless ENABLED -cltTimeout <client\_timeout\_value>
- bind lb vserver <name>@ <serviceName>  
Run this command for each service to be bound.
- enable ns mode l3
- add ns pbr <name> <action> -srcPort <sourcePortNumber> -destPort <startPortNumber-endPortNumber> -nextHop <serviceIPAddress> -protocol TCP
- apply ns pbrs  
  
Run this command after adding all the necessary PBRs.

To configure an upper-tier appliance for n-tier cache redirection by using the configuration utility

1. Enable L3 mode:
  1. In the navigation pane, click System, and then click Settings.
  2. In the Settings group, click the Configure modes link.
  3. Select the Layer 3 Mode (IP Forwarding) check box.
  4. Click OK.
2. Configure policy-based routing (PBR):
  1. Navigate to System > Network > PBRs.
  1. In the Policy-Based Routing (PBRs) pane, click Add.
  2. Type a name for the PBR.
  3. Select the action as Allow.
  4. In the Next Hop box, type the IP address of the service, which represents a lower-tier NetScaler.
  5. Select TCP from the Protocol drop-down list.
  6. Type the source port and the range of the destination port corresponding to the lower-tier NetScaler being added.
  7. Click Create.
  8. In the details pane, select the PBR and click Apply.
  9. Repeat Step (i) to Step (vii) for each lower-tier NetScaler.
3. Create a service for each lower-tier NetScaler:
  1. Navigate to Traffic Management > Load Balancing > Services.
  1. In the details pane, click Add.
  2. Specify the name, protocol, IP address, and port. The protocol should be ANY.
  3. Click Create.
4. Configure a load balancing virtual server:
  1. Navigate to Traffic Management > Load Balancing > Virtual Servers.

1. In the details pane, click Add.
2. Specify the name, protocol, IP address, and port. The protocol should be ANY and the IP address should be \*.
3. In the Services tab, select the services that represent the lower-tier NetScaler appliances.
4. In the Advanced tab, select the Redirection Mode as MAC Based and select the Sessionless check box.
5. Click Create.

# Configuring the Lower-Tier NetScaler Appliances

Oct 31, 2013

Configure each of the lower-tier NetScaler appliances as follows.

To configure a lower-tier appliance for n-tier cache redirection by using the command line interface

At the command prompt, type the following commands:

- add service <name>@ <cacheServiceIP> <serviceType> <port> -cip ENABLED "ClientIP" -cachetype transparent  
Repeat for each cache server.
- add lb vserver <name>@ <serviceType> -m MAC
- bind lb vserver <name>@ <cacheServiceName>  
Repeat for each cache server.
- add cr vserver <name> <serviceType> \* <port> -srcIPExpr "HTTP.REQ.HEADER(\"ClientIP\")" -originusip ON –  
usePortRange ON
- set ns param-crPortRange <startPortNumber-endPortNumber>

To configure a lower-tier appliance for n-tier cache redirection by using the configuration utility

1. Create a service for each cache server. To create a service:
  1. Navigate to Traffic Management > Load Balancing > Services.
  1. In the details pane, click Add, and specify the name and protocol. Clear the Directly Addressable check box.
  2. In the Advanced tab, select the Override Global check box and the Client IP check box, and then in the Header box, type ClientIP.
  3. In the Cache Type box, select Transparent Cache.
  4. Click Create.
2. Configure a load balancing virtual server:
  1. Navigate to Traffic Management > Load Balancing > Virtual Services.
  1. In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be an asterisk (\*).
  2. In the Services tab, select the services that represent the cache servers.
  3. In the Advanced tab, for Redirection Mode, select MAC Based.
  4. Click Create.
3. Configure a cache redirection virtual server:
  1. Navigate to Traffic Management > Load Balancing > Virtual Services.
  1. In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be \*.
  2. For Cache Type, select Transparent.
  3. On the Advanced tab, in the Cache Server box, select the new load balancing virtual server and check the Origin USIP and Use Port Range check boxes. In the Source IP Expression box, type HTTP.REQ.HEADER("ClientIP").
  4. Click Create.
4. Assign a source port range for the NetScaler:
  1. In the navigation pane, click System, and then click Settings.
  2. In the Settings group, click the Change global system settings link.
  3. In the Cache Redirection Port Range group, specify the port range for the NetScaler by typing a port number for Start Port and a port number for End Port.

4. Click OK.

# Content Switching

May 25, 2015

In today's complex Web sites, you may want to present different content to different users. For example, you may want to allow users from the IP range of a customer or partner to have access to a special Web portal. You may want to present content relevant to a specific geographical area to users from that area. You may want to present content in different languages to the speakers of those languages. You may want to present content tailored to specific devices, such as smartphones, to those who use the devices. The Citrix NetScaler content switching feature enables the NetScaler appliance to distribute client requests across multiple servers on the basis of specific content that you wish to present to those users.

To configure content switching, first create a basic content switching setup, and then customize it to meet your needs. This entails enabling the content switching feature, setting up load balancing for the server or servers that host each version of the content that is being switched, creating a content switching virtual server, creating policies to choose which requests are directed to which load balancing virtual server, and binding the policies to the content switching virtual server. You can then customize the setup to meet your needs by setting precedence for your policies, protecting your setup by configuring a backup virtual server, and improving the performance of your setup by redirecting requests to a cache.

## How Content Switching Works

Updated: 2013-08-22

Content Switching enables the NetScaler appliance to direct requests sent to the same Web host to different servers with different content. For example, you can configure the appliance to direct requests for dynamic content (such as URLs with a suffix of .asp, .dll, or .exe) to one server and requests for static content to another server. You can configure the appliance to perform content switching based on TCP/IP headers and payload.

You can also use content switching to configure the appliance to redirect requests to different servers with different content on the basis of various client attributes. Some of those client attributes are:

- **Device Type.** The appliance examines the user agent or custom HTTP header in the client request for the type of device from which the request originated. Based on the device type, it directs the request to a specific Web server. For example, if the request came from a cell phone, the request is directed to a server that is capable of serving content that the user can view on his or her cell phone. A request from a computer is directed to a different server that is capable of serving content designed for a computer screen.
- **Language.** The appliance examines the Accept-Language HTTP header in the client request and determines the language used by the client's browser. The appliance then sends the request to a server that serves content in that language. For example, using content switching based on language, the appliance can send someone whose browser is configured to request content in French to a server with the French version of a newspaper. It can send someone else whose browser is configured to request content in English to a server with the English version.
- **Cookie.** The appliance examines the HTTP request headers for a cookie that the server set previously. If it finds the cookie, it directs requests to the appropriate server, which hosts custom content. For example, if a cookie is found that indicates that the client is a member of a customer loyalty program, the request is directed to a faster server or one with special content. If it does not find a cookie, or if the cookie indicates that the user is not a member, the request is directed to a server for the general public.
- **HTTP Method.** The appliance examines the HTTP header for the method used, and sends the client request to the right server. For example, GET requests for images can be directed to an image server, while POST requests can be directed to

a faster server that handles dynamic content.

- **Layer 3/4 Data.** The appliance examines requests for the source or destination IP, source or destination port, or any other information present in the TCP or UDP headers, and directs the client request to the right server. For example, requests from source IPs that belong to customers can be directed to a custom web portal on a faster server, or one with special content.

A typical content switching deployment consists of the entities described in the following diagram.

Figure 1. Content Switching Architecture

A content switching configuration consists of a content switching virtual server, a load balancing setup consisting of load balancing virtual servers and services, and content switching policies. To configure content switching, you must configure a content switching virtual server and associate it with policies and load balancing virtual servers. This process creates a *content group*—a group of all virtual servers and policies involved in a particular content switching configuration.

Content switching can be used with HTTP, HTTPS, TCP, and UDP connections. For HTTPS, you must enable SSL Offload.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. The priority of the policy defines the order in which the policies bound to the content switching virtual server are evaluated. If you are using default syntax policies, when you bind a policy to the content switching virtual server, you must assign a priority to that policy. If you are using NetScaler classic policies, you can assign a priority to your policies, but are not required to do so. If you assign priorities, the policies are evaluated in the order that you set. If you do not, the NetScaler appliance evaluates your policies in the order in which they were created.

In addition to configuring policy priorities, you can manipulate the order of policy evaluation by using Goto expressions and policy bank invocations. For more details about default syntax policy configuration, see "[Configuring Default Syntax Policies](#)."

After it evaluates the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

Content switching virtual servers can only send requests to other virtual servers. If you are using an external load balancer,

you must create a load balancing virtual server for it and bind its virtual server as a service to the content switching virtual server.

# Configuring Basic Content Switching

Jun 09, 2015

Before you configure content switching, you must understand how content switching is set up and how the services and virtual servers are connected.

To configure a basic, functional content switching setup, first enable the content switching feature. Then, create at least one content group. For each content group, create a content switching virtual server to accept requests to a group of web sites that use content switching. Also create a load balancing setup, which includes a group of load balancing virtual servers to which the content switching virtual server directs requests. To specify which requests to direct to which load balancing virtual server, create at least two content switching policies, one for each type of request that is to be redirected. When you have created the virtual servers and policies, bind the policies to the content switching virtual server. You can also bind a policy to multiple content switching virtual servers. When you bind a policy, you specify the load balancing virtual server to which requests that match the policy are to be directed.

In addition to binding individual policies to a content switching virtual server, you can bind policy labels. If you create additional content groups, you can bind a policy or policy label to more than one of the content switching virtual servers.

Note: After creating a content group, you can modify its content switching virtual server to customize the configuration. For information on modifying the configuration of an existing content switching virtual server, see "[Customizing the Basic Content Switching Configuration](#)." For information on disabling and re-enabling entities, unbinding policies, and removing entities, see "[Managing a Content Switching Setup](#)."

This section includes the following details:

- [Creating Content Switching Virtual Servers](#)
- [Configuring a Load Balancing Setup for Content Switching](#)
- [Configuring a Content Switching Action](#)
- [Configuring Content Switching Policies](#)
- [Configuring Content Switching Policy Labels](#)
- [Binding Policies to a Content Switching Virtual Server](#)
- [Configuring Policy Based Logging for Content Switching](#)
- [Verifying the Configuration](#)

# Enabling Content Switching

Oct 31, 2013

To use the content switching feature, you must enable content switching. You can configure content switching entities even though the content switching feature is disabled. However, the entities will not work.

To enable content switching by using the command line interface

At the command prompt, type the following commands to enable content switching and verify the configuration:

- enable ns feature CS
- show ns feature

## Example

```
> enable feature ContentSwitch
Done
> show feature
```

|           | Feature                  | Acronym       | Status    |
|-----------|--------------------------|---------------|-----------|
|           | -----                    | -----         | -----     |
| 1)        | Web Logging              | WL            | OFF       |
| 2)        | Surge Protection         | SP            | ON        |
| 3)        | Load Balancing           | LB            | ON        |
| <b>4)</b> | <b>Content Switching</b> | <b>CS</b>     | <b>ON</b> |
| .         |                          |               |           |
| .         |                          |               |           |
| .         |                          |               |           |
| 22)       | Responder                | RESPONDER     | ON        |
| 23)       | HTML Injection           | HTMLInjection | ON        |
| 24)       | NetScaler Push           | push          | OFF       |

Done

To enable content switching by using the configuration utility

Navigate to System > Settings and, in the Modes and Features group, select Configure Basic Features, and select Content Switching.

# Creating Content Switching Virtual Servers

Apr 07, 2014

You can add, modify, and remove content switching virtual servers. The state of a virtual server is DOWN when you create it, because the load balancing virtual server is not yet bound to it.

To create a virtual server by using the command line interface

At the command prompt, type:

```
add cs vserver <name> <protocol> <IPAddress> <port>
```

## **Example**

```
add cs vserver Vserver-CS-1 HTTP 10.102.29.161 80
```

To add a content switching virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, and add a virtual server.

# Configuring a Load Balancing Setup for Content Switching

Dec 17, 2013

The content switching virtual server redirects all requests to a load balancing virtual server. You must create one load balancing virtual server for each version of the content that is being switched. This is true even when your setup has only one server for each version of the content, and you are therefore not doing any load balancing with those servers. You can also configure actual load balancing with multiple load-balanced servers that mirror each version of the content. In either scenario, the content switching virtual server needs to have a specific load balancing virtual server assigned to each version of the content that is being switched.

The load balancing virtual server then forwards the request to a service. If it has only one service bound to it, it selects that service. If it has multiple services bound to it, it uses its configured load balancing method to select a service for the request, and forwards that request to the service that it selected.

To configure a basic load balancing setup, you need to perform the following tasks:

- Create load balancing virtual servers
- Create services
- Bind services to the load balancing virtual server

For more information on load balancing, see "[Load Balancing](#)." For detailed instructions on setting up a basic load balancing configuration, see "[Setting Up Basic Load Balancing](#)."

# Configuring a Content Switching Action

Sep 30, 2013

You specify the target load balancing virtual server for a content switching policy when binding the policy to the content switching virtual server. Consequently, you have to configure one policy for each load balancing virtual server to which to direct traffic.

However, if your content switching policy uses a default syntax rule, you can configure an action for the policy. In the action, you can specify the name of the target load balancing virtual server, or you can configure a request-based expression that, at run time, computes the name of the load balancing virtual server to which to send the request. The action expression must be specified in the default syntax.

The expression option can drastically reduce the size of your content switching configuration, because you need only one policy per content switching virtual server. Content switching policies that use an action can also be bound to multiple content switching virtual servers, because the target load balancing virtual server is no longer specified in the content switching policy. The ability to bind a single policy to multiple content switching virtual servers helps to further reduce the size of your content switching configuration.

After you create an action, you create a content switching policy and specify the action in the policy, so that the action is performed when that policy matches a request.

Note: You can also, for a content switching policy that uses a default syntax rule, specify the target load balancing virtual server when binding the policy to a content switching virtual server, instead of using a separate action. For domain-based policies, URL-based policies, and rule based policies that use classic expressions, an action is not available. So, for these types of policies, you specify the name of the target load balancing virtual server when binding the policy to a content switching virtual server. For more information, see "[Binding Policies to a Content Switching Virtual Server](#)."

## Configuring an Action that Specifies the Name of the Target Load Balancing Virtual Server

Updated: 2013-08-22

If you choose to specify the name of the target load balancing virtual server in a content switching action, you need as many content switching policies as you have target load balancing virtual servers. Content switching decisions, in this case, are based on the rule in the content switching policy, and the action merely specifies the target load balancing virtual server. When a request matches the policy, the request is forwarded to the specified load balancing virtual server.

## To create and verify a content switching action that specifies the name of the target load balancing virtual server, by using the command line interface

At the command prompt, type:

- add cs action <name> -targetLBVserver <string> [-comment <string>]
- show cs action <name>

Example

```
> add cs action mycsaction -targetLBVserver mylbvserver -comment "Forwards requests to mylbvserver."
Done
> show cs action mycsaction
Name: mycsaction
Target LB Vserver: mylbvserver
```

Hits: 0  
Undef Hits: 0  
Action Reference Count: 0  
Comment: "Forwards requests to mylbvserver."

Done

>

## To configure a content switching action that specifies the name of the target load balancing virtual server, by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Actions.
2. Configure a content switching action, and specify the name of the target load balancing virtual server.

### Configuring an Action that Specifies an Expression for Selecting the Target at Run Time

Updated: 2013-08-22

If you choose to configure a request-based expression that can dynamically compute the name of the target load balancing virtual server, you need to configure only one content switching policy to select the appropriate virtual server. The rule for the policy can be a simple TRUE (the policy matches all requests) because, in this case, content switching decisions are based on the expression in the action. By configuring an expression in an action, you can drastically reduce the size of your content switching configuration.

If you choose to configure a request-based expression for computing the name of the target load balancing virtual server at run time, you must carefully consider how to name the load balancing virtual servers in the configuration. You must be able to derive their names by using the request-based policy expression in the action.

For example, if you are switching requests on the basis of the URL suffix (file extension of the requested resource), when naming the load balancing virtual servers, you can follow the convention of appending the URL suffix to a predetermined string, such as mylb\_. For example, load balancing virtual servers for HTML pages and PDF files could be named mylb\_html and mylb\_pdf, respectively. In that case, the rule that you can use in the content switching action, to select the appropriate load balancing virtual server, is "mylb\_"+HTTP.REQ.URL.SUFFIX. If the content switching virtual server receives a request for an HTML page, the expression returns mylb\_html, and the request is switched to virtual server mylb\_html.

## To create a content switching action that specifies an expression, by using the command line interface

At the command line, type the following commands to create a content switching action that specifies an expression and verify the configuration:

- add cs action <name> -targetVserverExpr <expression> [-comment <string>]
- show cs action <name>

Example

```
> add cs action mycsaction1 -targetvserverExpr "'mylb_' + HTTP.REQ.URL.SUFFIX'
Done
> show cs action mycsaction1
Name: mycsaction1
Target Vserver Expression: "mylb_" + HTTP.REQ.URL.SUFFIX
```

Target LB Vserver: No\_Target

...

Done

>

To configure a content switching action that specifies an expression by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Actions.
2. Configure a content switching action, and specify an expression that will dynamically compute the name of the target load balancing virtual server.

# Configuring Content Switching Policies

Aug 22, 2013

A content switching policy defines a type of request that is to be directed to a load balancing virtual server. These policies are applied in the order of the priorities assigned to them or (if you are using NetScaler classic policies and do not assign priorities when binding them) in the order in which the policies were created.

The policies can be:

- **Domain-based policies.** The NetScaler appliance compares the domain of an incoming URL with the domains specified in the policies. The appliance then returns the most appropriate content. Domain-based policies must be classic policies; default syntax policies are not supported for this type of content switching policy.
- **URL-based policies.** The appliance compares an incoming URL with the URLs specified in the policies. The appliance then returns the most appropriate URL-based content, which is usually the longest matching configured URL. URL-based policies must be classic policies; default syntax policies are not supported for this type of content switching policy.
- **Rule-based policies.** The appliance compares incoming data to expressions specified in the policies. You create rule-based policies by using either a classic expression or a default syntax expression. Both classic and default syntax policies are supported for rule-based content switching policies.

Note: A rule based policy can be configured with an optional action. A policy with an action can be bound to multiple virtual servers or policy labels.

If you set a priority when binding your policies to the content switching virtual server, the policies are evaluated in order of priority. If you do not set specific priorities when binding your policies, the policies are evaluated in the order in which they were created.

For information about NetScaler classic policies and expressions, see "[Configuring Classic Policies and Expressions](#)." For information about Default Syntax policies, see "[Configuring Default Syntax Expressions](#)."

To create a content switching policy by using the command line interface

At the command prompt, type one of the following commands:

- `add cs policy <policyName> -domain <domain>`
- `add cs policy <policyName> -url <URLValue>`
- `add cs policy <policyName> -rule <RULEValue>`
- `add cs policy <policyName> -rule <RULEValue> -action <actionName>`

## Example

```
add cs policy Policy-CS-1 -url "http://example.com"
```

```
add cs policy Policy-CS-1 -domain "example.com"
```

```
add cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(24).EQ(10.217.84.0)"
```

```
add cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2009 Nov,GMT 2009 Dec)"
```

```
add cs policy Policy-CS-3 -rule "http.req.method.eq(GET)" -action act1
```

To rename a content switching policy by using the command line interface

At the command prompt, type:

```
rename cs policy <policyName> <newName>
```

**Example**

```
rename cs policy myCSPolicy myCSPolicy1
```

To rename a content switching policy by using the configuration utility

Navigate to Traffic Management > Content Switching > Policies, select a policy and, in the Action list, select Rename.

To create a content switching policy by using the configuration utility

Navigate to Traffic Management > Content Switching > Policies, and configure a content switching policy.

# Configuring Content Switching Policy Labels

Oct 31, 2013

A policy label is a user-defined bind point to which policies are bound. When a policy label is invoked, all the policies bound to it are evaluated in the order of the priority that you assigned to them. A policy label can include one or more policies, each of which can be assigned its own result. A match on one policy in the policy label can result in proceeding to the next policy, invoking a different policy label or appropriate resource, or an immediate end to policy evaluation and return of control to the policy that invoked the policy label. You can create policy labels for default syntax policies only.

For information about policy labels, see the "[Creating Policy Labels](#)."

A content switching policy label consists of a name, a label type, and a list of policies bound to the policy label. The policy label type specifies the protocol that was assigned to the policies bound to the label. It must match the service type of the content switching virtual server to which the policy that invokes the policy label is bound. For example, you can bind TCP Payload policies to a policy label of type TCP only. Binding TCP Payload policies to a policy label of type HTTP is not supported.

Each policy in a content switching policy label is associated with either a target (which is equivalent to the action that is associated with other types of policies, such as rewrite and responder policies) or a gotoPriorityExpression option and/or an invoke option. That is, for a given policy in a content switching policy label, you can specify a target, or you can set the gotoPriorityExpression option and/or the invoke option. Additionally, if multiple policies evaluate to true, only the target of the last policy that evaluates to true is considered.

You can use either the NetScaler command line or the configuration utility to configure content switching policy labels. In the NetScaler command-line interface (CLI), you first create a policy label by using the add cs policylabel command. Then, you bind policies to the policy label, one policy at a time, by using the bind cs policylabel command. In the NetScaler configuration utility, you perform both tasks in a single dialog box.

To create a content switching policy label by using the command line interface

At the command prompt, type:

```
add cs policylabel <labelName> <cspolicylabelType>
```

## Example

```
add cs policylabel testpollab http
```

To rename a content switching policy label by using the command line interface

At the command prompt, type:

```
rename cs policylabel <labelName> <newName>
```

## Example

```
rename cs policylabel oldPolicyLabelName newPolicyLabelName
```

To rename a content switching policy label by using the configuration utility

Navigate to Traffic Management > Content Switching > Policy Labels, select a policy label and, in the Action list, select Rename.

To bind a policy to a content switching policy label by using the command line interface

At the command prompt, type the following commands to bind a policy to a policy label and verify the configuration:

- `bind cs policylabel <labelName> <policyName> <priority> [ [-targetVserver <string>] | [-gotoPriorityExpression <expression>] | [-invoke <labeltype> <labelName>]]`
- `show cs policylabel <labelName>`

### Example

```
bind cs policylabel testpollab test_Pol 100 -targetVserver LBVIP
```

```
show cs policylabel testpollab
```

```
Label Name: testpollab
```

```
Label Type: HTTP
```

```
Number of bound policies: 1
```

```
Number of times invoked: 0
```

```
1) Policy Name: test_Pol
```

```
Priority: 100
```

```
Target Virtual Server: LBVIP
```

Note: If a policy is configured with an action, the target virtual server (targetVserver), goto priority expression (gotoPriorityExpression), and invoke (invoke) parameters are not required. If a policy is not configured with an action, you need to configure at least one of the following parameters: targetVserver, gotoPriorityExpression, and invoke.

To unbind a policy from a policy label by using the command line interface

At the command prompt, type the following commands to unbind a policy from a policy label and verify the configuration:

- `unbind cs policylabel <labelName> <policyName>`
- `show cs policylabel <labelName>`

### Example

```
unbind cs policylabel testpollab test_Pol
```

```
show cs policylabel testpollab
```

```
Label Name: testpollab
```

```
Label Type: HTTP
```

```
Number of bound policies: 0
```

```
Number of times invoked: 0
```

To remove a policy label by using the command line interface

At the command prompt, type:

```
rm cs policylabel <labelName>
```

To manage a content switching policy label by using the configuration utility

Navigate to Traffic Management > Content Switching > Policy Labels, configure a policy label, bind policies to the label, and optionally specify a priority, gotoPriority expression, and an invoke option.

# Binding Policies to a Content Switching Virtual Server

Sep 03, 2014

After you create your content switching virtual server and policies, you bind each policy to the content switching virtual server. When binding the policy to the content switching virtual server, you specify the target load balancing virtual server.

Note: If your content switching policy uses a default syntax rule, you can configure a content switching action for the policy. If you configure an action, you must specify the target load balancing virtual server when you are configuring the action, not when you are binding the policy to the content switching virtual server. For more information about configuring a content switching action, see [Configuring a Content Switching Action](#).

To bind a policy to a content switching virtual server and select a target load balancing virtual server by using the command line interface

At the command prompt, type:

```
bind cs vserver <name>[-lbvserver<string> -targetLBVServer<string> -policyname <string> -priority <positive_integer>] [-gotoPriorityExpression <expression>] [-type (REQUEST | RESPONSE)] [-invoke (<labelType> <labelName>)]
```

## Example

```
bind cs vserver csw-vip2 -policyname csw-ape-policy2 -priority 14 -gotoPriorityExpression NEXT
```

```
bind cs vserver csw-vip3 -policyname rewrite-policy1 -priority 17 -gotoPriorityExpression 'q.header("a").count' -flowtype REQUEST -invoke policylabel label1
```

```
bind cs vserver Vserver-CS-1 Vserver-LB-1 -policyname Policy-CS-1 -priority 20
```

Note: The parameters, target load balancing virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke method (invoke) cannot be used if a policy has an action.

To bind a policy to a content switching virtual server and select a target load balancing virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, open a virtual server and, in the Content Switching Policy Binding section, bind a policy to the virtual server, and specify a target load balancing virtual server.

# Configuring Policy Based Logging for Content Switching

Jun 05, 2017

You can configure policy based logging for a content switching policy. Policy based logging enables you to specify a format for log messages. The contents of the log message are defined by using a default syntax expression in the content switching policy. When the content switching action specified in the policy is performed, the NetScaler appliance constructs the log message from the expression and writes the message to the log file. Policy based logging is particularly useful if you want to test and troubleshoot a configuration in which content switching actions identify the target load balancing virtual server at run time.

Note: If multiple policies bound to a given virtual server evaluate to TRUE and are configured with an audit message action, the NetScaler appliance does not perform all the audit message actions. It performs only the audit message action that is configured for the policy whose content switching action is performed.

To configure policy based logging for a content switching policy, you must first configure an audit message action. For more information about configuring an audit message action, see [Configuring the NetScaler Appliance for Audit Logging](#). After you configure the audit message action, you specify the action in a content switching policy.

To configure policy based logging for a content switching policy by using the command line interface

At the command line, type the following commands to configure policy based logging for a content switching policy and verify the configuration:

- set cs policy <policyName> -logAction <string>
- show cs policy <policyName>

## Example

```
> set cs policy cspol1 -logAction csLogAction
Done
> show cs policy cspol1
```

```
Policy: cspol1 Rule: TRUE Action: csact1
LogAction: csLogAction
Hits: 0
```

```
1) CS Vserver: csvs1
Priority: 10
Done
>
```

To configure policy based logging for a content switching policy by using the configuration utility

Navigate to Traffic Management > Content Switching > Policies, open a policy and, in the Log Action list, select a log action for the policy.

# Verifying the Configuration

Mar 15, 2012

To verify that your content switching configuration is correct, you need to view the content switching entities. To verify proper operation after your content switching configuration has been deployed, you can view the statistics that are generated as the servers are accessed.

## Viewing the Properties of Content Switching Virtual Servers

Updated: 2013-10-31

You can view the properties of content switching virtual servers that you have configured on the NetScaler. You can use the information to verify whether the virtual server is correctly configured and, if necessary, to troubleshoot. In addition to details such as name, IP address, and port, you can view the various policies bound to a virtual server, and its traffic-management settings.

The content switching policies are displayed in the order of their priority. If more than one policy has the same priority, they are shown in the order in which they are bound to the virtual server.

Note: If you have configured the content switching virtual server to forward traffic to a load balancing virtual server, you can also view the content switching policies by viewing the properties of the load balancing virtual server.

## To view the properties of content switching virtual servers by using the command line interface

To list basic properties of all content switching virtual servers in your configuration, or detailed properties of a specific content switching virtual server, at the command prompt, type one of the following commands:

- show cs vserver
- show cs vserver <name>

### Example

1.

```
show cs vserver Vserver-CS-1
Vserver-CS-1 (10.102.29.161:80) - HTTP Type: CONTENT
State: UP
Last state change was at Thu Jun 30 10:48:59 2011
Time since last state change: 6 days, 20:03:00.760
Client Idle Timeout: 180 sec

## Viewing Content Switching Policies

Updated: 2013-08-22

You can view the properties of the content switching policies that you defined, such as the name, domain, and URL or expression, and use the information to find any mistakes in the configuration, or to troubleshoot if something is not working as it should.

## To view the properties of content switching policies by using the command line interface

To list either basic properties of all content switching policies in your configuration or detailed properties of a specific content switching policy, at the command prompt, type one of the following commands:

- show cs policy
- show cs policy <PolicyName>

### Example

```
show cs policy
```

```
show cs policy Policy-CS-1
```

## To view the properties of content switching policies by using the configuration utility

Navigate to Traffic Management > Content Switching > Policies, select a policy and, in the Action list, select Show Bindings.

## Viewing a Content Switching Virtual Server Configuration by Using the Visualizer

Updated: 2013-08-22

The Content Switching Visualizer is a tool that you can use to view a content switching configuration in graphical format. You can use the visualizer to view the following configuration items:

- A summary of the load balancing virtual servers to which the content switching virtual server is bound.
- All services and service groups that are bound to the load balancing virtual server and all monitors that are bound to the services.
- The configuration details of any displayed element.
- Any policies bound to the content switching virtual server. These policies need not be content switching policies. Many types of policies, such as Rewrite policies, can be bound to a content switching virtual server.

After you configure the various elements in a content switching and load balancing setup, you can export the entire configuration to an application template file.

Note: The Visualizer requires a graphical interface, so it is available only through the configuration utility.

## To view a content switching configuration by using the Visualizer in the

## configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Content Switching Visualizer window, you can adjust the viewable area as follows:
  - Click the Zoom In and Zoom Out icons to increase or decrease the viewable area.
  - Click the Save Image icon to save the graph as an image file.
  - In the Search in text field, begin typing the name of the item you are looking for. When you have typed enough characters to identify the item, its location is highlighted. To restrict the search, click the drop-down menu and select the type of element that you want to search for.
4. To view configuration details for entities that are bound to this virtual server, you can do the following:
  - To view policies that are bound to the virtual server, in the tool bar at the top of the dialog box select one or more feature-specific policy icons. If policy labels are configured, they appear in the main view area.
  - To view the configuration details for a bound service or service group, click the icon for the service, click the Related Tasks tab, and then click Show Member Services.
  - To view the configuration details for a monitor, click the icon for the monitor, click the Related Tasks tab, and then click View Monitor.
5. To view detailed statistics for any virtual server in the content switching configuration, click the virtual server for which you want to view statistics, then click the Related Tasks tab, and then click Statistics.
6. To view a comparative list of the parameters whose values either differ or are not defined across service containers for a load balancing virtual server, click the icon for a container, click the Related Tasks tab, and then click Service Attributes Diff.
7. To view monitor binding details for the services in a container, in the Service Attributes Diff dialog box, in the Group column for the container, click Details. This comparative list helps you determine which service container has the configuration you want to apply to all the service containers.
8. To view the number of requests received per second at a given point in time by the virtual servers in the configuration, and the number of hits per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time. It has to be refreshed manually. To refresh the information, click Refresh Stats.

Note: This option is available only on NetScaler nCore builds.
9. To copy configuration details for an element to a document or spreadsheet, click the icon for that element, click Related Tasks, click Copy Properties, and then paste the information into a document.
10. To export the entire configuration that is displayed in the Visualizer to an application template file, click the icon for the content switching virtual server, click Related Tasks, and then click Create Template. When creating the application template, you can configure variables in some policy expressions and actions. For more information about creating the application template file and configuring variables for a template, see [AppExpert](#).

# Customizing the Basic Content Switching Configuration

Jun 08, 2015

After you configure a basic content switching setup, you might need to customize it to meet your requirements. If your web servers are UNIX-based and rely on case sensitive pathnames, you can configure case sensitivity for policy evaluation. You can also set precedence for evaluation of the content switching policies that you configured. You can configure HTTP and SSL content switching virtual servers to listen on multiple ports instead of creating separate virtual servers. If you want to configure content switching for a specific a virtual LAN, you can configure a content switching virtual server with a listen policy.

To customize the basic content switching configuration, see the following sections:

- [Configuring Case Sensitivity for Policy Evaluation](#)
- [Setting the Precedence for Policy Evaluation](#)
- [Support for Multiple Ports for HTTP and SSL Type Content Switching Virtual Servers](#)
- [Configuring per-VLAN Wildcarded Virtual Servers](#)
- [Configuring the Microsoft SQL Server Version Setting](#)

## Configuring Case Sensitivity for Policy Evaluation

Updated: 2013-10-31

You can configure the content switching virtual server to treat URLs as case sensitive in URL-based policies. When case sensitivity is configured, the NetScaler appliance considers case when evaluating policies. For example, if case sensitivity is off, the URLs /a/1.htm and /A/1.HTM are treated as identical. If case sensitivity is on, those URLs are treated as separate and can be switched to different targets.

## To configure case sensitivity by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -caseSensitive (ON | OFF)
```

### Example

```
set cs vserver Vserver-CS-1 -caseSensitive ON
```

## To configure case sensitivity by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and then select Case Sensitive.

## Setting the Precedence for Policy Evaluation

Updated: 2013-10-31

Precedence refers to the order in which policies that are bound to a virtual server are evaluated. You do not normally have to configure precedence: the default precedence works correctly in many cases. If you want to make sure that one policy or set of policies is applied first, however, and another policy or set of policies is applied only if the first set does not match a request, you can configure either URL-based precedence or rule-based precedence.

## Precedence with URL-Based Policies

If there are multiple matching URLs for the incoming request, the precedence (priority) for URL-based policies is:

1. Domain and exact URL
2. Domain, prefix, and suffix
3. Domain and suffix
4. Domain and prefix
5. Domain only
6. Exact URL
7. Prefix and suffix
8. Suffix only
9. Prefix only
10. Default

If you configure precedence based on URL, the request URL is compared to the configured URLs. If none of the configured URLs match the request URL, then rule-based policies are checked. If the request URL does not match any rule-based policies, or if the content group selected for the request is down, then the request is processed as follows:

- If you configure a default group for the content switching virtual server, then the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, then an “HTTP 404 Not Found” error message is sent to the client.

Note: You should configure URL-based precedence if the content type (for example, images) is the same for all clients. However, if different types of content must be served based on client attributes (such as Accept-Language), you must use rule-based precedence.

## Precedence with Rule-Based Policies

If you configure precedence based on rules, which is the default setting, the request is tested on the basis of the rule-based policies you have configured. If the request does not match any rule-based policies, or if the content group selected for the incoming request is down, the request is processed in the following manner:

- If a default group is configured for the content switching virtual server, the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, an “HTTP 404 Not Found” error message is sent to the client.

To configure precedence by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -precedence (RULE | URL)
```

### Example

```
set cs vserver Vserver-CS-1 -precedence RULE
```

To configure precedence by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and then specify Precedence.

Support for Multiple Ports for HTTP and SSL Type Content Switching Virtual Servers

Updated: 2014-05-21

You can configure the NetScaler ADC so that HTTP and SSL content switching virtual servers listen on multiple ports, without having to configure separate virtual servers. This feature is especially useful if you want to base a content switching decision on a part of the URL and other L7 parameters. Instead of configuring multiple virtual servers with the same IP address and different ports, you can configure one IP address and specify the port as \*. As a result, the configuration size is also reduced.

## To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the command line

At the command prompt, type:

```
add cs vserver <name> <serviceType> <IPAddress> Port *
```

Example

```
> add cs vserver cs1 HTTP 10.102.92.215 *
```

Done

```
> sh cs vserver cs1
```

```
cs1 (10.102.92.215:*) - HTTP Type: CONTENT
State: UP
Last state change was at Tue May 20 01:15:49 2014
Time since last state change: 0 days, 00:00:03.270
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Appflow logging: ENABLED
Port Rewrite : DISABLED
State Update: DISABLED
Default: Content Precedence: RULE
Vserver IP and Port insertion: OFF
L2Conn: OFF Case Sensitivity: ON
Authentication: OFF
401 Based Authentication: OFF
Push: DISABLED Push VServer:
Push Label Rule: none
IcmpResponse: PASSIVE
RHlstate: PASSIVE
TD: 0
```

Done

## To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and create a virtual server of type HTTP or SSL.
2. Use an asterisk (\*) to specify the port.

### Configuring per-VLAN Wildcarded Virtual Servers

Updated: 2013-10-31

If you want to configure content switching for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

## To configure a wildcarded virtual server that listens to a specific VLAN by using the command line interface

At the command prompt, type:

```
add cs vserver <name> <serviceType> IPAddress * Port * -listenpolicy <expression> [-listenpriority <positive_integer>]
```

### Example

```
add cs vserver Vserver-CS-vlan1 ANY * *
-listenpolicy "CLIENT.VLAN.ID.EQ(2)" -listenpriority 10
```

## To configure a wildcarded virtual server that listens to a specific VLAN by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, and configure a virtual server. Specify a listen policy that restricts it to processing traffic only on the specified VLAN.

After you have created this virtual server, you bind it to one or more services as described in [Binding Services to the Virtual Server](#).

## Configuring the Microsoft SQL Server Version Setting

Updated: 2013-08-22

You can specify the version of Microsoft® SQL Server® for a content switching virtual server that is of type MSSQL. The version setting is recommended if you expect some clients to not be running the same version as your Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

## To set the Microsoft SQL Server version parameter by using the command line interface

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a content switching virtual server and verify the configuration:

- set cs vserver <name> -mssqlServerVersion <mssqlServerVersion>
- show cs vserver <name>

Example

```
> set cs vserver myMSSQLcsvip -mssqlServerVersion 2008R2
Done
> show cs vserver myMSSQLcsvip
myMSSQLcsvip (192.0.2.13:1433) - MSSQL Type: CONTENT
State: UP
...
...
Mssql Server Version: 2008R2
```

...

...

Done

>

## To set the Microsoft SQL Server version parameter by using the configuration utility

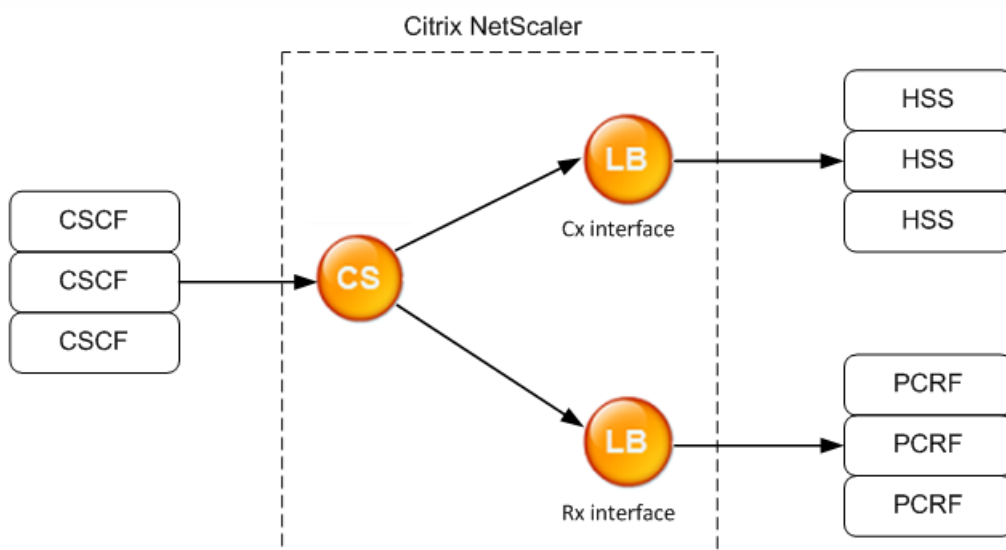

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. In Advanced Settings, select MySQL, and specify the Server Version.

# Content Switching for Diameter Protocol

Jun 26, 2014

For Diameter-protocol traffic, you can configure the NetScaler appliance (or virtual appliance) to act as a relay agent that load balances and forwards a packet to the appropriate destination on the basis of the message content (AVP value in the message). Since the appliance does not perform any application-level processing, it provides relaying services for all diameter applications as specified by the configured content switching policies. Therefore, the appliance advertises the Relay Application ID in the capability exchange answer (CEA) message when the client establishes a diameter connection. You must configure a content switching virtual server, load balancing virtual servers, and services to represent the diameter nodes. When a request reaches the content switching virtual server, the virtual server applies the content switching policies associated with that type of request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

A diameter interface provides a connection between the different diameter nodes. The following sample deployment uses Cx and Rx interfaces. A Cx interface provides a connection between a CSCF and an HSS. An Rx interface provides a connection between a CSCF and a PCRF. All the messages reach the NetScaler appliance. Depending on whether the message is for a Cx or an Rx interface, and on the content switching policies defined, the NetScaler selects an appropriate load balancing server pool.

CSCF=Call Session Control Function  
HSS=Home Subscriber Server  
PCRF=Policy and Charging Rules Function

## Sample Configuration

1. For each entity, create a service, a load balancing server, and bind the service to the virtual server.

```
add service svc_pcrf[1-3] 1.1.1.1[1-3] DIAMETER 3868
add service svc_hss[1-3] 1.1.1.2[1-3] DIAMETER 3868
add lb vserver vs_rx DIAMETER -persistenceType DIAMETER -persistavpno 263
add lb vserver vs_cx DIAMETER -persistenceType DIAMETER -persistavpno 263
bind lb vserver vs_rx svc_pcrf[1-3]
bind lb vserver vs_cx svc_hss[1-3]
```

2. Create a content switching virtual server and two actions (one for each load balancing virtual server). Create two content switching policies and bind these policies to the content switching virtual server, specifying a priority for each policy.

```
add cs vserver cs_diameter DIAMETER 10.1.1.10 3868
```

```
add cs action cx_action -targetLBVserver vs_cx
```

```
add cs action rx_action -targetLBvserver vs_rx
```

```
add cs policy cx_policy -rule "DIAMETER.REQ.AUTH_APPLICATION_ID.EQ(16777216)" -action cx_action
```

```
add cs policy rx_policy -rule "DIAMETER.REQ.AUTH_APPLICATION_ID.EQ(16777236)" -action rx_action
```

```
bind cs vserver cs_diameter -policyName rx_policy -priority 100
```

```
bind cs vserver cs_diameter -policyName cx_policy -priority 110
```

# Protecting the Content Switching Setup against Failure

Jun 08, 2015

Content switching may fail when the content switching virtual server goes DOWN or fails to handle excessive traffic, or for other reasons. To reduce the chances of failure, you can take the following measures to protect the content switching setup against failure:

- [Configure a backup content switching virtual server](#)
- [Configure spillover for preventing the overloading of the primary and diverting excess traffic to the backup virtual server](#)
- [Specify a redirect URL, the URL to which the content is switched if both the primary and backup content switching virtual servers are DOWN](#)
- [Enable the State Update option for marking a content switching virtual server as DOWN when the load balancing virtual server is DOWN](#)
- [Flush the surge queues when the queues become too long](#)

## Configuring a Backup Virtual Server

Updated: 2013-11-08

If the primary content switching virtual server is marked DOWN or DISABLED, the NetScaler appliance can direct requests to a backup content switching virtual server. It can also send a notification message to the client regarding the site outage or maintenance. The backup content switching virtual server is a proxy and is transparent to the client.

When configuring the backup virtual server, you can specify the configuration parameter `Disable Primary When Down` to ensure that, when the primary virtual server comes back up, it remains the secondary until you manually force it to take over as the primary. This is useful if you want to ensure that any updates to the database on the server for the backup are preserved, enabling you to synchronize the databases before restoring the primary virtual server.

You can configure a backup content switching virtual server when you create a content switching virtual server or when you change the optional parameters of an existing content switching virtual server. You can also configure a backup content switching virtual server for an existing backup content switching virtual server, thus creating cascaded backup content switching virtual servers. The maximum depth of cascaded backup content switching virtual servers is 10. The appliance searches for a backup content switching virtual server that is up and accesses that content switching virtual server to deliver the content.

Note: If a content switching virtual server is configured with both a backup content switching virtual server and a redirect URL, the backup content switching virtual server takes precedence over the redirect URL. The redirect is used when the primary and backup virtual servers are down.

## To set up a backup content switching virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -backupVserver <string> -disablePrimaryOnDown (ON | OFF)
```

### Example

```
set cs vserver Vserver-CS-1 -backupVserver Vserver-CS-2 -disablePrimaryOnDown ON
```

## To set up a backup content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MySQL.
2. In Advanced Settings, select Protection, and specify a Backup Virtual Server.

## Diverting Excess Traffic to a Backup Virtual Server

Updated: 2013-11-04

The spillover option diverts new connections arriving at a content switching virtual server to a backup content switching virtual server when the number of connections to the content switching virtual server exceeds the configured threshold value. The threshold value is dynamically calculated, or you can set the value. The number of established connections (in case of TCP) at the virtual server is compared with the threshold value. When the number of connections reaches the threshold, new connections are diverted to the backup content switching virtual server.

If the backup content switching virtual servers reach the configured threshold and are unable to take the load, the primary content switching virtual server diverts all requests to the redirect URL. If a redirect URL is not configured on the primary content switching virtual server, subsequent requests are dropped.

## To configure a content switching virtual server to divert new connections to a backup virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -soMethod <methodType> -soThreshold <thresholdValue> -soPersistence <persistenceValue> -soPersistenceTimeout <timeoutValue>
```

### Example

```
set cs vserver Vserver-CS-1 -soMethod Connection -soThreshold 1000 -soPersistence enabled -soPersistenceTimeout 2
```

## To set a content switching virtual server to divert new connections to a backup virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. In Advanced Settings, select Protection, and configure spillover.

### Configuring a Redirection URL

Updated: 2015-03-19

You can configure a redirect URL to communicate the status of the NetScaler appliance in the event that a content switching virtual server of type HTTP or HTTPS is DOWN or DISABLED. This URL can be local or remote.

Redirect URLs can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL), the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Citrix recommends using an absolute URL. That is, a URL ending in /, for example [www.example.com/](http://www.example.com/) instead of a relative URL. A relative URL redirection might result in the vulnerability scanner reporting a false positive.

Note: If a content switching virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect URL is used when the primary and backup virtual servers are down. When redirection is configured and the content switching virtual server is unavailable, the appliance issues an HTTP 302 redirect to the user's browser.

## To configure a redirect URL for when the content switching virtual server is unavailable by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -redirectURL <URLValue>
```

### Example

```
set cs vserver Vserver-CS-1 -redirectURL http://www.newdomain.com/mysite/maintenance
```

## To configure a redirect URL for when the content switching virtual server is unavailable by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. In Advanced Settings, select Protection, and specify a Redirect URL.

### Configuring the State Update Option

Updated: 2014-12-12

The content switching feature enables the distribution of client requests across multiple servers on the basis of the specific content presented to the users. For efficient content switching, the content switching virtual server distributes the traffic to the load balancing virtual servers according to the content type, and the load balancing virtual servers distribute the traffic to the physical servers according to the specified load balancing method.

For smooth traffic management, it is important for the content switching virtual server to know the status of the load balancing virtual servers. The state update option helps to mark the content switching virtual server DOWN if the load balancing virtual server bound to it is marked DOWN. A load balancing virtual server is marked DOWN if all the physical servers bound to it are marked DOWN.

#### When State Update is disabled:

The status of the content switching virtual server is marked as UP. It remains UP even if there is no bound load balancing virtual server that is UP.

#### When State Update is enabled:

When you add a new content switching virtual server, initially, its status is shown as DOWN. When you bind a load balancing virtual server whose status is UP, the status of the content switching virtual server becomes UP.

If more than one load balancing virtual server is bound and if one of them is specified as the default, the status of the content switching virtual server reflects the status of the default load balancing virtual server.

If more than one load balancing virtual server is bound without any of them being specified as the default, the status of the content switching virtual server is marked UP only if all the bound load balancing virtual servers are UP.

## To configure the state update option by using the command line interface

At the command prompt, type:

```
add cs vserver <name> <protocol> <ipAddress> <port> -stateUpdate ENABLED
```

Example

```
add cs vserver csw_vserver HTTP 10.18.250.154 80 -stateupdate ENABLED -cliTimeout 180
```

## To configure the state update option by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. In Advanced Settings, select Traffic Settings, and then select State Update.

### Flushing the Surge Queue

Updated: 2013-12-04

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which

leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the NetScaler appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.

Note: Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

## To flush a surge queue by using the command line interface

The `flush ns surgeQ` command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]
```

Examples

1.

```
flush ns surgeQ -name SVC1ANZGB -serverName 10.10.10.1 80
```

The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10

2.

flush ns surgeQ

The above command flushes all the surge queues on the appliance.

## To flush a surge queue by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Flush Surge Queue.

# Managing a Content Switching Setup

Jun 08, 2015

After a content switching setup is configured, it may require periodic changes. When operating systems or software are updated, or hardware wears out and is replaced, you may need to take down your setup. Load on your setup may increase, requiring additional resources. You may also modify the configuration to improve performance.

These tasks may require unbinding policies from the content switching virtual server, or disabling or removing content switching virtual servers. After you have made changes to your setup, you may need to re-enable servers and rebind policies. You might also want to rename your virtual servers.

To manage a content switching setup, see the following sections:

- [Unbinding Policies from the Content Switching Virtual Server](#)
- [Removing Content Switching Virtual Servers](#)
- [Disabling and Re-Enabling Content Switching Virtual Servers](#)
- [Renaming Content Switching Virtual Servers](#)
- [Managing Content Switching Policies](#)
- [Modifying a Content Switching Configuration by Using the Visualizer](#)

## Unbinding Policies from the Content Switching Virtual Server

Updated: 2014-09-03

When you unbind a content switching policy from its virtual server, the virtual server no longer includes that policy when determining where to direct requests.

## To unbind a policy from a content switching virtual server by using the command line interface

At the command prompt, type:

```
unbind cs vserver <name> -policyname <string>
```

### Example

```
unbind cs vserver Vserver-CS-1 -policyname Policy-CS-1
```

## To unbind a policy from a content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open the virtual server.
2. Click in the Policies section, select the policy, and click Unbind.

## Removing Content Switching Virtual Servers

Updated: 2013-10-31

You normally remove a content switching virtual server only when you no longer require the virtual server. When you remove a content switching virtual server, the NetScaler appliance first unbinds all policies from the content switching virtual server, and then removes it.

## To remove a content switching virtual server by using the command line interface

At the command prompt, type:

```
rm cs vserver <name>@
```

### Example

```
rm cs vserver Vserver-CS-1
```

## To remove a content switching virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server, and click Delete.

### Disabling and Re-Enabling Content Switching Virtual Servers

Updated: 2013-10-31

Content switching virtual servers are enabled by default when you create them. You can disable a content switching virtual server for maintenance. If you disable the content switching virtual server, the state of the content switching virtual server changes to Out of Service. While out of service, the content switching virtual server does not respond to requests.

## To disable or re-enable a virtual server by using the command line interface

At the command prompt, type one of the following commands:

- `disable cs vserver <name>@`
- `enable cs vserver <name>@`

### Example

```
disable cs vserver Vserver-CS-1
```

```
enable cs vserver Vserver-CS-1
```

## To disable or re-enable a virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Enable or Disable.

### Renaming Content Switching Virtual Servers

Updated: 2013-10-31

You can rename a content switching virtual server without unbinding it. The new name is propagated automatically to all affected parts of the NetScaler configuration.

## To rename a virtual server by using the command line interface

At the command prompt, type:

```
rename cs vserver <name>@ <newName>@
```

### Example

```
rename cs vserver Vserver-CS-1 Vserver-CS-2
```

## To rename a virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Rename.

### Managing Content Switching Policies

Updated: 2013-08-22

You can modify an existing policy by configuring rules or changing the URL of the policy, or you can remove a policy. You can also rename an existing advanced content switching policy. You can create different policies based on the URL. URL-based policies can be of different types, as described in the following table.

**Table 1. Examples of URL-Based Policies**

| Type of URL-Based Policy | Specifies                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Domain and Exact URL     | Requests must match the configured domain name and configured URL (an exact prefix match if only the prefix is configured; or an exact match of the prefix and suffix if both the prefix and suffix are configured).<br><b>Example:</b><br><b>add cs policy Policy-CS-1 -url /sports/tennis/index.html -domain "www.domainxyz.com"</b>                                                             |
| Domain and Wild Card URL | Requests must match the exact domain name and a partial prefix of the configured URL.<br><b>Example:</b><br><b>add cs policy Policy-CS-1 -url /*.jsp -domain "www.domainxyz.com"</b>                                                                                                                                                                                                               |
| Domain Only              | Requests need match only the configured domain name.<br><b>Example:</b><br><b>add cs policy Policy-CS-1 -domain "www.domainxyz.com"</b>                                                                                                                                                                                                                                                            |
| The Exact URL            | The incoming URL must exactly match the URL specified by the policy. If only a URL prefix rule is configured, there must be an exact prefix match with the incoming URL. If a URL prefix and suffix-based rule is configured, there should be an exact match of the prefix and suffix with the incoming URL.<br><b>Example:</b><br><b>add cs policy Policy-CS-1 -url /sports/tennis/index.html</b> |
| Prefix                   | All the incoming URLs must start with the configured prefix.                                                                                                                                                                                                                                                                                                                                       |

|                                           |                                                                                                                                                                                                                          |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Only Type of (Wild Card URL) Based Policy | <p><b>Example:</b><br/> <b>add cs policy Policy-CS-1 -url /sports*</b></p> <p>sports/*” matches all URLs under /sports “/sports*” matches all URLs whose prefix match “/sports” starting from the beginning of a URL</p> |
| Suffix Only (Wild Card URL)               | <p>All incoming URLs must end with the configured URL suffix.</p> <p><b>Example:</b><br/> <b>add cs policy Policy-CS-1 -url /*.jsp</b></p> <p>“/*.jsp” matches all URLs whose file extension is “jsp”</p>                |
| Prefix and Suffix (Wild Card URL)         | <p>All incoming URLs must start with the configured prefix and end with the configured suffix.</p> <p><b>Example:</b><br/> <b>add cs policy Policy-CS-1 -url /sports/*.jsp</b></p>                                       |

Note: You can configure rule-based content switching using classical policy expressions or advanced policy expressions.

## To modify, remove, or rename a policy by using the command line interface

At the command prompt, type one of the following commands:

- `set cs policy <policyName> [-domain <domainValue>] [-rule <ruleValue>] [-url <URLValue>]`
- `rm cs policy <policyName>`
- `rename cs policy <policyName> <newPolicyName>`

### Example

```
set cs policy Policy-CS-1 -domain "www.domainxyz.com"
```

```
set cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(22).EQ(10.100.148.0)"
```

```
set cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2010 Jun,GMT 2010 Jul)"
```

```
set cs policy Policy-CS-1 -url /sports/*
```

```
rename cs policy Policy-CS-1 Policy-CS-11
```

```
rm cs policy Policy-CS-1
```

## To modify, remove, or rename a policy by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. Select the policy, and either delete it, edit it or, in the Action list, click Rename.

## Modifying a Content Switching Configuration by Using the Visualizer

Updated: 2013-08-22

You can use the Visualizer to modify a load balancing virtual server to which the content switching virtual server is bound. You can also modify a service or group of similar services, or a monitor. For more information, see "[The Load Balancing Visualizer](#)."

# Managing Client Connections

May 21, 2015

To ensure efficient management of client connections, you can configure the content switching virtual servers on the NetScaler appliance to use the following features:

- [Redirecting client requests to a cache](#)
- [Enabling delayed cleanup of virtual server connections](#)
- [Rewriting ports and protocols for redirection](#)
- [Inserting the IP address and port of a virtual server in the request header](#)
- [Setting a time-out value for idle client connections](#)
- [Identifying Connections with the 4-tuple and Layer 2 Connection Parameters](#)
- Configuring the ICMP Response. You can configure the NetScaler to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR\_CNTRLRD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, NetScaler responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds even if one virtual server set to ACTIVE is UP.

## Redirecting Client Requests to a Cache

Updated: 2013-10-31

The NetScaler cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the burden of responding to HTTP requests and improve your Web site performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the NetScaler appliance sends cacheable HTTP requests to the cache and non-cacheable HTTP requests to the origin Web server. For more information on cache redirection, see "[Cache Redirection](#)."

## To configure cache redirection on a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -cacheable <Value>
```

### Example

```
set cs vserver Vserver-CS-1 -cacheable yes
```

## To configure cache redirection on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Cacheable.

## Enabling Delayed Cleanup of Virtual Server Connections

Updated: 2013-10-31

Under certain conditions, you can configure the down state flush setting to terminate existing connections when a service or a virtual server is marked DOWNS. Terminating existing connections frees resources and in certain cases speeds recovery of overloaded load balancing setups.

### To configure the down state flush setting on a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -downStateFlush <Value>
```

#### **Example**

```
set cs vserver Vserver-CS-1 -downStateFlush enabled
```

### To configure the down state flush setting on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and then select Down State Flush.

## Rewriting Ports and Protocols for Redirection

Updated: 2013-10-31

Virtual servers and the services that are bound to them may use different ports. When a service responds to an HTTP connection with a redirect, you may need to configure the NetScaler appliance to modify the port and the protocol to ensure that the redirection goes through successfully. You do this by enabling and configuring the redirectPortRewrite setting.

### To configure HTTP redirection on a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -redirectPortRewrite <Value>
```

#### **Example**

```
set cs vserver Vserver-CS-1 -redirectPortRewrite enabled
```

### To configure HTTP redirection on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Rewrite.

## Inserting the IP Address and Port of a Virtual Server in the Request Header

Updated: 2013-10-31

If you have multiple virtual servers that communicate with different applications on the same service, you must configure

the NetScaler appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, you must configure the required header tag on both virtual servers.

Note: This option is not supported for wildcarded virtual servers or dummy virtual servers.

## To insert the IP address and port of the virtual server in the client requests by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -insertVserverIPPort <vServerIPPORT>
```

### Example

```
set cs vserver Vserver-CS-1 -insertVserverIPPort 10.201.25.136:80
```

## To insert the IP address and port of the virtual server in the client requests by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings and, in the Virtual Server IP Port Insertion list, select VIPADDR or V6TOV4MAPPING, and specify a port header in Virtual Server IP Port Insertion Value.

## Setting a Time-out Value for Idle Client Connections

Updated: 2013-10-31

You can configure a virtual server to terminate any idle client connections after a configured time-out period elapses. When you configure this setting, the NetScaler appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection.

## To set a time-out value for idle client connections by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -cltTimeout <Value>
```

### Example

```
set cs vserver Vserver-CS-1 -cltTimeout 100
```

## To set a time-out value for idle client connections by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and specify a Client Idle Time-Out value.

## Identifying Connections with the 4-tuple and Layer 2 Connection Parameters

Updated: 2013-08-22

You can now set the L2Conn option for a content switching virtual server. With the L2Conn option set, connections to the content switching virtual server are identified by the combination of the 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) and Layer 2 connection parameters. The Layer 2 connection parameters are the MAC address, VLAN ID, and channel ID.

## To set the L2Conn option for a content switching virtual server by using the command line interface

At the command line, type the following commands to configure the L2Conn parameter for a content switching virtual server and verify the configuration:

- set cs vserver <name> -l2Conn (**ON** | **OFF**)
- show cs vserver <name>

Example

```
> set cs vserver mycsvserver -l2Conn ON
Done
> show cs vserver mycsvserver
 mycsvserver (192.0.2.56:80) - HTTP Type: CONTENT
 State: UP
 ...
 ...
 L2Conn: ON Case Sensitivity: ON
 ...
 ...
Done
>
```

## To set the L2Conn option for a content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and then select Layer 2 Parameters.

# Troubleshooting

Jul 22, 2013

If the content switching feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

## Resources for Troubleshooting Content Switching

Updated: 2013-07-22

For best results, use the following resources to troubleshoot a content switching issue on a NetScaler appliance:

- Configuration file
- Relevant newslog file
- Trace files
- Network topology diagram for the network setup of the customer
- Citrix documentation, such as release notes, Knowledge Center articles, and eDocs

In addition to the above resources, the following tools expedite troubleshooting:

- The `iehttpheaders` or a similar utility
- The Wireshark application customized for the NetScaler trace files
- An SSH utility for command line access
- A HyperTerminal utility to access the console

## Troubleshooting Content Switching Issues

Updated: 2013-08-02

The most common content switching issues involve the content switching feature not working at all, or working only intermittently, and Service Unavailable responses.

- **Issue**  
The content switching feature is not functioning.

### Resolution

Check the configuration as follows:

- Verify that the appliance is licensed for content switching.
- Verify that the feature is enabled.
- From the configuration file, verify that valid content switching policies are correctly bound to the load balancing virtual servers.

- **Issue**  
Client receives a 503 - Service Unavailable response.

### Resolution

- Verify the URL and policy bindings. The client receives the 503 response when none of the policies you have configured is evaluated and no default load balancing virtual server is defined and bound to the content switching virtual server.
- From the configuration, verify the policies and URL being accessed by the client.
- Verify that for every type of request the respective policy is evaluated. If the policy is not evaluated, check the policy

expression and update it if necessary.

- Verify the URL and HTTP request and response headers. To do so, record an HTTPHeader trace and, if necessary, record the packet traces on the appliance and the client.

- **Issue**

Intermittently, the content switching feature is not working as expected.

**Resolution**

- Study the network topology diagram, if available, of the setup to understand the various devices installed between the client and the server(s).
- Verify the configuration and policy bindings. Make sure that the URL in the policy expression matches to the one in the client request.
- Verify that appropriate priorities are assigned to the policies. An incorrect precedence or priority assigned to a policy can cause a problem.
- Run the following commands to verify the bindings and the values of the policy hit counters in the output of the commands:

```
show cs vserver <CS VServer>
```

```
show cs policy <CS Policy>
```

```
stat cs vserver <CS VServer>
```

- Using `iehttpheaders` or a similar utility, determine whether the HTTP headers for the requests or responses provide any pointers to the issue.
- Check the release notes and Knowledge Center articles.
- If the issue is still not resolved, contact Citrix Technical Support with appropriate data for further investigation.

# Domain Name System

May 26, 2015

You can configure the Citrix NetScaler appliance to function as an authoritative domain name server (ADNS server) for a domain. You can add the DNS resource records that belong to the domain for which the appliance is authoritative and configure resource record parameters. You can also configure the NetScaler appliance as a proxy DNS server that load balances a farm of DNS name servers that are either within your network or outside your network. You can configure the appliance as an end resolver and forwarder. You can configure DNS suffixes that enable name resolution when fully qualified domain names are not configured. The appliance also supports the DNS ANY query that retrieves all the records that belong to a domain.

You can configure the NetScaler appliance to concurrently function as an authoritative DNS server for one domain and a DNS proxy server for another domain. When you configure the NetScaler as the authoritative DNS server or DNS proxy server for a zone, you can enable the appliance to use the Transmission Control Protocol (TCP) for response sizes that exceed the size limit specified for the User Datagram Protocol (UDP).

## How DNS Works on the NetScaler

You can configure the NetScaler appliance to function as an ADNS server, DNS proxy server, end resolver, and forwarder. You can add DNS resource records on the NetScaler, including service (SRV) records, IPv6 (AAAA) records, address (A) records, mail exchange (MX) records, canonical name (CNAME) records, pointer (PTR) records, start of authority (SOA) records, and text (TXT) records. Also, you can configure the NetScaler to load balance external DNS name servers.

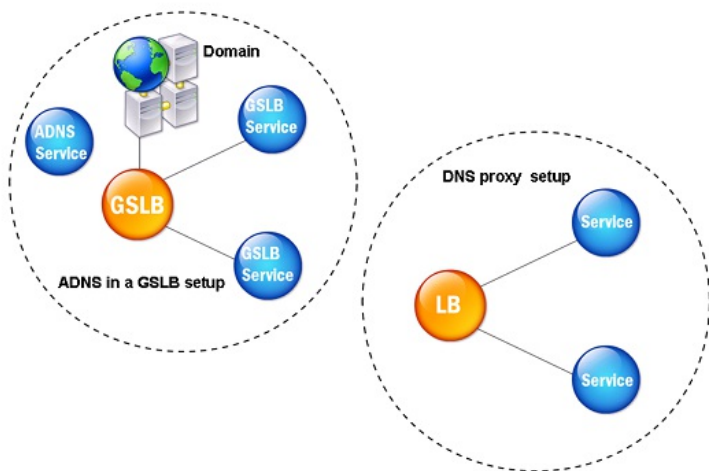

The NetScaler can be configured as the authority for a domain. To do this, you add valid SOA and NS records for the domain.

An ADNS server is a DNS server that contains complete information about a zone.

To configure the NetScaler as an ADNS server for a zone, you must add an ADNS service, and then configure the zone. To do so, you add valid SOA and NS records for the domain. When a client sends a DNS request, the NetScaler appliance searches the configured resource records for the domain name. You can configure the ADNS service to be used with the NetScaler Global Server Load Balancing (GSLB) feature.

You can delegate a subdomain, by adding NS records for the subdomain to the zone of the parent domain. You can then make the NetScaler authoritative for the subdomain, by adding a "glue record" for each of the subdomain name servers. If GSLB is configured, the NetScaler makes a GSLB load balancing decision based on its configuration and replies with the IP address of the selected virtual server. The following figure shows the entities in an ADNS GSLB setup and a DNS proxy setup.

Figure 1. DNS Proxy Entity Model

The NetScaler appliance can function as a DNS proxy. Caching of DNS records, which is an important function of a DNS proxy, is enabled by

default on the NetScaler appliance. This enables the NetScaler to provide quick responses for repeated translations. You must also create a load balancing DNS virtual server, and DNS services, and then bind these services to the virtual server.

The NetScaler provides two options, minimum time to live (TTL) and maximum TTL for configuring the lifetime of the cached data. The cached data times out as specified by your settings for these two options. The NetScaler checks the TTL of the DNS record coming from the server. If the TTL is less than the configured minimum TTL, it is replaced with the configured minimum TTL. If the TTL is greater than the configured maximum TTL, it is replaced with the configured maximum TTL.

The NetScaler also allows caching of negative responses for a domain. A negative response indicates that information about a requested domain does not exist, or that the server cannot provide an answer for the query. The storage of this information is called *negative caching*. Negative caching helps speed up responses to queries on a domain, and can optionally provide the record type.

A negative response can be one of the following:

- NXDOMAIN error message - If a negative response is present in the local cache, the NetScaler returns an error message (NXDOMAIN). If the response is not in the local cache, the query is forwarded to the server, and the server returns an NXDOMAIN error to the NetScaler. The NetScaler caches the response locally, then returns the error message to the client.
- NODATA error message - The NetScaler sends a NODATA error message, if the domain name in query is valid but records of the given type are not available.

The NetScaler supports recursive resolution of DNS requests. In recursive resolution, the resolver (DNS client) sends a recursive query to a name server for a domain name. If the queried name server is authoritative for the domain, it responds with the requested domain name. Otherwise, the NetScaler queries the name servers recursively until the requested domain name is found.

Before you can apply the recursive query option, you must first enable it. You can also set the number of times the DNS resolver must send a resolution request (DNS retries) if a DNS lookup fails.

You can configure the NetScaler as a DNS forwarder. A forwarder passes DNS requests to external name servers. The NetScaler allows you to add external name servers and provides name resolution for domains outside the network. The NetScaler also allows you to set the name lookup priority to DNS or Windows Internet Name Service (WINS).

## Round Robin DNS

When a client sends a DNS request to find the DNS resource record, it receives a list of IP addresses resolving to the name in the DNS request. The client then uses one of the IP addresses in the list, generally, the first record or IP address. Hence, a single server is used for the total TTL of the cache and is overloaded when a large number of requests arrive.

When the NetScaler receives a DNS request, it responds by changing the order of the list of DNS resource records in a round robin method. This feature is called *round robin DNS*. Round robin distributes the traffic equally between data centers. The NetScaler performs this function automatically. You do not have to configure this behavior.

## Functional Overview

If the NetScaler is configured as an ADNS server, it returns the DNS records in the order in which the records are configured. If the NetScaler is configured as a DNS proxy, it returns the DNS records in the order in which it receives the records from the server. The order of the records present in the cache matches the order in which records are received from the server.

The NetScaler then changes the order in which records are sent in the DNS response in a round robin method. The first response contains the first record in sequence, the second response contains the second record in sequence, the third response contains the third record in sequence, and the order continues in the same sequence. Thus, clients requesting the same name can connect to different IP addresses.

### Round Robin DNS Example

As an example of round robin DNS, consider DNS records that have been added as follows:

```
add dns addRec ns1 1.1.1.1 add dns addRec ns1 1.1.1.2 add dns addRec ns1 1.1.1.3 add dns addRec ns1 1.1.1.4
```

The domain, abc.com is linked to an NS record as follows:

```
add dns nsrec abc.com. ns1
```

When the NetScaler receives a query for the A record of ns1, the Address records are served in a round robin method as follows. In the first DNS response, 1.1.1.1 is served as the first record:

|      |         |              |         |              |         |              |         |         |
|------|---------|--------------|---------|--------------|---------|--------------|---------|---------|
| ns1. | 1H IN A | 1.1.1.1 ns1. | 1H IN A | 1.1.1.2 ns1. | 1H IN A | 1.1.1.3 ns1. | 1H IN A | 1.1.1.4 |
|------|---------|--------------|---------|--------------|---------|--------------|---------|---------|

In the second DNS response, the second IP address, 1.1.1.2 is served as the first record:

|      |         |              |         |              |         |              |         |         |
|------|---------|--------------|---------|--------------|---------|--------------|---------|---------|
| ns1. | 1H IN A | 1.1.1.2 ns1. | 1H IN A | 1.1.1.3 ns1. | 1H IN A | 1.1.1.4 ns1. | 1H IN A | 1.1.1.1 |
|------|---------|--------------|---------|--------------|---------|--------------|---------|---------|

In the third DNS response, the third IP address, 1.1.1.2 is served as the first record:

|      |         |              |         |              |         |              |         |         |
|------|---------|--------------|---------|--------------|---------|--------------|---------|---------|
| ns1. | 1H IN A | 1.1.1.3 ns1. | 1H IN A | 1.1.1.4 ns1. | 1H IN A | 1.1.1.1 ns1. | 1H IN A | 1.1.1.2 |
|------|---------|--------------|---------|--------------|---------|--------------|---------|---------|

# Configuring DNS Resource Records

Sep 16, 2016

You configure resource records on the Citrix® NetScaler® appliance when you configure the appliance as an ADNS server for a zone. You can also configure resource records on the appliance if the resource records belong to a zone for which the appliance is a DNS proxy server. On the appliance, you can configure the following record types:

- Service records
- AAAA records
- Address records
- Mail Exchange records
- Name Server records
- Canonical records
- Pointer records
- NAPTR records
- Start of Authority records
- Text records

The following table lists the record types and the number of records (per record type) that you can configure for a domain on the NetScaler.

**Table 1. Record Type and Number Configurable**

| Record Type              | Number of Records |
|--------------------------|-------------------|
| Address (A)              | 25                |
| IPv6 (AAAA)              | 5                 |
| Mail exchange (MX)       | 12                |
| Name server (NS)         | 16                |
| Service (SRV)            | 8                 |
| Pointer (PTR)            | 20                |
| Canonical name (CNAME)   | 1                 |
| Start of Authority (SOA) | 1                 |
| Text (TXT)               | 20                |

|                                  |    |
|----------------------------------|----|
| Naming Authority Pointer (NAPTR) | 20 |
|----------------------------------|----|

**Record Type**

**Number of Records**

## Note

The maximum number of IP addresses for a specific hostname is 25. However, the number of different address records can be more than 25.

# Creating SRV Records for a Service

Nov 21, 2014

The SRV record provides information about the services available on the NetScaler appliance. An SRV record contains the following information: name of the service and the protocol, domain name, TTL, DNS class, priority of the target, weight of records with the same priority, port of the service, and host name of the service. The NetScaler chooses the SRV record that has the lowest priority setting first. If a service has multiple SRV records with the same priority, clients use the weight field to determine which host to use.

To add an SRV record by using the command line interface

At the command prompt, type the following commands to add an SRV record and verify the configuration:

- `add dns srvRec <domain> <target> -priority <positive_integer> -weight <positive_integer> -port <positive_integer> [-TTL <secs>]`
- `sh dns srvRec <domain>`

## Example

```
> add dns srvRec _http._tcp.example.com nameserver1.com -priority 1 -weight 1 -port 80
Done
> show dns srvRec _http._tcp.example.com
1) Domain Name : _http._tcp.example.com
 Target Host : nameserver1.com
 Priority : 1 Weight : 1
 Port : 80 TTL : 3600 secs
Done
>
```

To modify or remove an SRV record by using the command line interface

- To modify an SRV record, type the `set dns srvRec` command, the name of the domain for which the SRV record is configured, the name of the target host that hosts the associated service, and the parameters to be changed, with their new values.
- To remove an SRV record, type the `rm dns srvRec` command, the name of the domain for which the SRV record is configured, and the name of the target host that hosts the associated service.

To configure an SRV record by using the configuration utility

Navigate to Traffic Management > DNS > Records > SRV Records and create an SRV record.

# Creating AAAA Records for a Domain Name

Nov 21, 2014

An AAAA resource record stores a single IPv6 address.

To add an AAAA record by using the command line interface

At the command prompt, type the following commands to add an AAAA record and verify the configuration:

- add dns aaaaRec <hostName> <IPv6Address> ... [-TTL <secs>]
- show dns aaaaRec <hostName>

## Example

```
> add dns aaaaRec www.example.com 2001:0db8:0000:0000:0000:0000:1428:57ab
```

Done

```
> show dns aaaaRec www.example.com
```

```
1) Host Name : www.example.com
 Record Type : ADNS TTL : 5 secs
 IPV6 Address : 2001:db8::1428:57ab
```

Done

>

To remove an AAAA record and all of the IPv6 addresses associated with the domain name, type the `rm dns aaaaRec` command and the domain name for which the AAAA record is configured. To remove only a subset of the IPv6 addresses associated with the domain name in an AAAA record, type the `rm dns aaaaRec` command, the domain name for which the AAAA record is configured, and the IPv6 addresses that you want to remove.

To add an AAAA record by using the configuration utility

Navigate to Traffic Management > DNS > Records > AAAA Records and create an AAAA record.

# Creating Address Records for a Domain Name

Nov 21, 2014

Address (A) records are DNS records that map a domain name to an IPv4 address.

You cannot delete Address records for a host participating in global server load balancing (GSLB). However, the NetScaler deletes Address records added for GSLB domains when you unbind the domain from a GSLB virtual server. Only user-configured records can be deleted manually. You cannot delete a record for a host referenced by records such as NS, MX, or CNAME.

To add an Address record by using the command line interface

At the command prompt, type the following commands to add an Address record and verify the configuration:

- `add dns addRec <hostName> <IPAddress> [-TTL <secs>]`
- `show dns addRec <hostName>`

## Example

```
> add dns addRec ns.example.com 192.0.2.0
Done
> show dns addRec ns.example.com
1) Host Name : ns.example.com
 Record Type : ADNS TTL : 5 secs
 IP Address : 192.0.2.0
Done
>
```

To remove an Address record and all of the IP addresses associated with the domain name, type the `rm dns addRec` command and the domain name for which the Address record is configured. To remove only a subset of the IP addresses associated with the domain name in an Address record, type the `rm dns addRec` command, the domain name for which the Address record is configured, and the IP addresses that you want to remove.

To add an Address record by using the configuration utility

Navigate to Traffic Management > DNS > Records > Address Records and create an Address record.

# Creating MX Records for a Mail Exchange Server

Nov 21, 2014

Mail Exchange (MX) records are used to direct email messages across the Internet. An MX record contains an MX preference that specifies the MX server to be used. The MX preference values range from 0 through 65536. An MX record contains a unique MX preference number. You can set the MX preference and the TTL values for an MX record.

When an email message is sent through the Internet, a mail transfer agent sends a DNS query requesting the MX record for the domain name. This query returns a list of host names of mail exchange servers for the domain, along with a preference number. If there are no MX records, the request is made for the Address record of that domain. A single domain can have multiple mail exchange servers.

To add an MX record by using the command line interface

At the command prompt, type the following commands to add an MX record and verify the configuration:

- `add dns mxRec <domain> -mx <string> -pref <positive_integer> [-TTL <secs>]`
- `show dns mxRec <domain>`

## Example

```
> add dns mxRec example.com -mx mail.example.com -pref 1
Done
> show dns mxRec example.com
1) Domain : example.com MX Name : mail.example.com
 Preference : 1 TTL : 5 secs
Done
>
```

To modify or remove an MX record by using the command line interface

- To modify an MX record, type the `set dns mxRec` command, the name of the domain for which the MX record is configured, the name of the MX record, and the parameters to be changed, with their new values.
- To set the TTL parameter to its default value, type the `unset dns mxRec` command, the name of the domain for which the MX record is configured, the name of the MX record, and `-TTL` without any TTL value. You can use the `unset dns mxRec` command to unset only the TTL parameter.
- To remove an MX record, type the `rm dns mxRec` command, the name of the domain for which the MX record is configured, and the name of the MX record.

To add an MX record by using the configuration utility

Navigate to Traffic Management > DNS > Records > Mail Exchange Records and create an MX record.

# Creating NS Records for an Authoritative Server

Nov 21, 2014

Name Server (NS) records specify the authoritative server for a domain. You can configure a maximum of 16 NS records. You can use an NS record to delegate the control of a subdomain to a DNS server.

To create an NS record by using the command line interface

At the command prompt, type the following commands to create an NS record and verify the configuration:

- add dns nsRec <domain> <nameServer> [-TTL <secs>]
- show dns nsRec <domain>

## Example

```
> add dns nsRec example.com nameserver1.example.com
Done
> show dns nsRec example.com
1) Domain : example.com NameServer : nameserver1.example.com
 TTL : 5 sec
Done
>
```

To remove an NS record, type the `rm dns nsRec` command, the name of the domain to which the NS record belongs, and the name of the name server.

To create an NS record by using the configuration utility

Navigate to Traffic Management > DNS > Records > Name Server Records and create an NS record.

# Creating CNAME Records for a Subdomain

May 26, 2015

A canonical name record (CNAME record) is an alias for a DNS name. These records are useful when multiple services query the DNS server. The host that has an address (A) record cannot have a CNAME record.

In some cases, a NetScaler appliance in proxy mode requests an address record from the cache instead of the server.

To add a CNAME record by using the command line interface

At the command prompt, type the following commands to create a CNAME record and verify the configuration:

- `add dns cnameRec <aliasName> <canonicalName> [-TTL <secs>]`
- `show dns cnameRec <aliasName>`

## Example

```
> add dns cnameRec www.example.com www.examp1enw.com
Done
> show dns cnameRec www.example.com
 Alias Name Canonical Name TTL
1) www.example.com www.examp1enw.com 5 secs
Done
>
```

To remove a CNAME record for a given domain, type the `rm dns cnameRec` command and the alias of the domain name.

To add a CNAME record by using the configuration utility

Navigate to Traffic Management > DNS > Records > Canonical Records and create a CNAME record.

## Caching of CNAME Records

Updated: 2015-05-26

NetScaler ADC when deployed in a proxy mode does not always send the query for an address record to the back-end server. This happens when for a answer to a query for an address record, a partial CNAME chain is present in the cache. There are few conditions in which the ADC caches the partial CNAME record and serves the query from the cache.

Following are the conditions:

- NetScaler should be deployed in a proxy mode
- The response from the back-end server should have a CNAME chain, for which the record type of last entry in the answer section must be a CNAME and the question type not a CNAME
- The response from the back-end server cannot be a No-data or NX-Domain
- The response from the back-end server has to be a authoritative response

# Creating NAPTR Records for Telecommunications Domain

Oct 29, 2014

NAPTR (Naming Address Pointer) is one of the most commonly used DNS record in telecommunications domain. NAPTR records map the Internet telephony address space to the Internet address space. They therefore enable a mobile device to send a request to the correct server. The combination of NAPTR records with Service Records (SRV) allows the chaining of multiple records to form complex rewrite rules that produce new domain labels or uniform resource identifiers (URIs). The DNS code for NAPTR is 35.

NetScaler ADCs support NAPTR in two modes: ADNS mode and proxy mode. In proxy mode, the ADC caches the response from the servers and uses the cached records to server future queries. A maximum of 20 NAPTR records can be added for a particular domain in NetScaler. NetScaler caches the reply to a DNS NAPTR record query. Any subsequent requests for the NAPTR record is served from the cache.

To create a NAPTR record by using command line interface

At the command prompt, type the following commands to add a NAPTR record and verify the configuration:

```
add dns naptrRec <order> <preference>[flags<string>][services<string>](regexp<expressions> | -replacement<string>) [-TTL<secs>]
```

To remove a NAPTR record by using command line interface

```
rm dns naptrRec<domain> (<order> <preference> [-flags <string>] [-services <string>] (-regexp <expression> | -replacement <string>)) | -recordId <positive_integer>@)
```

To configure a NAPTR record using configuration utility

Navigate to Traffic Management > DNS > Records > NAPTR Records and create an NAPTR record.

# Creating PTR Records for IPv4 and IPv6 Addresses

May 26, 2015

A pointer (PTR) record translates an IP address to its domain name. IPv4 PTR records are represented by the octets of an IP address in reverse order with the string "in-addr.arpa." appended at the end. For example, the PTR record for the IP address 1.2.3.4 is 4.3.2.1.in-addr.arpa.

IPv6 addresses are reverse mapped under the domain IP6.ARPA. IPv6 reverse-maps use a sequence of nibbles separated by dots with the suffix ".IP6.ARPA" as defined in RFC 3596. For example, the reverse lookup domain name corresponding to the address, 4321:0:1:2:3:4:567:89ab would be b.a.9.8.7.6.5.0.4.0.0.0.3.0.0.0.2.0.0.0.1.0.0.0.0.0.0.1.2.3.4.IP6.ARPA.

To add a PTR record by using the command line interface

At the command prompt, type the following commands to add a PTR record and verify the configuration:

- add dns ptrRec <reverseDomain> <domain> [-TTL <secs>]
- show dns ptrRec <reverseDomain>

## Example

```
> add dns ptrRec 0.2.0.192.in-addr.arpa example.com
Done
> show dns ptrRec 0.2.0.192.in-addr.arpa
1) Reverse Domain Name : 0.2.0.192.in-addr.arpa
 Domain Name : example.com TTL : 3600 secs
Done
>
```

To remove a PTR record, type the `rm dns ptrRec` command and the reverse domain name associated with the PTR record  
To add a PTR record by using the configuration utility

Navigate to Traffic Management > DNS > Records > PTR Records and create a PTR record.

# Creating SOA Records for Authoritative Information

Nov 21, 2014

A Start of Authority (SOA) record is created only at the zone apex and contains information about the zone. The record includes, among other parameters, the primary name server, contact information (e-mail), and default (minimum) time-to-live (TTL) values for records.

To create an SOA record by using the command line interface

At the command prompt, type the following commands to add an SOA record and verify the configuration:

- add dns soaRec <domain> -originServer <originServerName> -contact <contactName>
- sh dns soaRec <do main>

## Example

```
> add dns soaRec example.com -originServer nameserver1.example.com -contact admin.example.com
```

```
Done
```

```
> show dns soaRec example.com
```

```
1) Domain Name : example.com
Origin Server : nameserver1.example.com
Contact : admin.example.com
Serial No. : 100 Refresh : 3600 secs Retry : 3 secs
Expire : 3600 secs Minimum : 5 secs TTL : 3600 secs
```

```
Done
```

```
>
```

To modify or remove an SOA record by using the command line interface

- To modify an SOA record, type the set dns soaRec command, the name of the domain for which the record is configured, and the parameters to be changed, with their new values.
- To remove an SOA record, type the rm dns soaRec command and the name of the domain for which the record is configured.

To configure an SOA record by using the configuration utility

Navigate to Traffic Management > DNS > Records > SOA Records and create an SOA record.

# Creating TXT Records for Holding Descriptive Text

Nov 21, 2014

Domain hosts store TXT records for informative purposes. A TXT record's RDATA component, which consists of one or more character strings of variable length, can store practically any information that a recipient might need to know about the domain, including information about the service provider, contact person, email addresses, and associated details. SPF (Sender Policy Framework) protection has been the most prominent use case for the TXT record.

All configuration types (authoritative DNS, DNS proxy, end resolver, and forwarder configurations) on the NetScaler appliance support TXT records. You can add a maximum of 20 TXT resource records to a domain. Each resource record is stored with a unique, internally generated record ID. You can view the ID of a record and use it to delete the record. However, you cannot modify a TXT resource record.

To create a TXT resource record by using the command line interface

At the command prompt, type the following commands to create a TXT resource record and verify the configuration:

- `add dns txtRec <domain> <string> ... [-TTL <secs>]`
- `show dns txtRec [<domain> | -type <type>]`

## Example

```
> add dns txtRec www.example.com "Contact: Mark" "Email: mark@example.com" -TTL 36000
Done
> show dns txtRec www.example.com
1) Domain : www.example.com Record id: 13783 TTL : 36000 secs Record Type : ADNS
"Contact: Mark"
"Email: mark@example.com"
Done
```

To remove a TXT resource record by using the command line interface

At the command prompt, type the following commands to remove a TXT resource record and verify the configuration:

- `rm dns txtRec <domain> (<string> ... | -recordId <positive_integer>)`
- `show dns txtRec [<domain> | -type <type>]`

## Example

You can use the `show dns txtRec` command first to view the record ID of the TXT resource record that you want to remove, as shown:

```
> show dns txtRec www.example.com
1) Domain : www.example.com Record id: 36865 TTL : 36000 secs Record Type : ADNS
"Contact: Evan"
"Email: evan@example.com"
2) Domain : www.example.com Record id: 14373 TTL : 36000 secs Record Type : ADNS
"Contact: Mark"
"Email: mark1@example.com"
Done
```

The simpler method of deleting a TXT record is to use the record ID. If you want to provide the strings, enter them in the order in which they are stored in the record. In the following example, the TXT record is deleted by using its record ID.

```
>rm dns txtRec www.example.com -recordID 36865
```

Done

```
> show dns txtRec www.example.com
```

```
1) Domain : www.example.com Record id: 14373 TTL : 36000 secs Record Type : ADNS
```

```
"Contact: Mark"
```

```
"Email: mark1@example.com"
```

Done

To configure a TXT record by using the configuration utility

Navigate to Traffic Management > DNS > Records > TXT Records and create a TXT record.

# Viewing DNS Statistics

Aug 27, 2013

You can view the DNS statistics generated by the Citrix® NetScaler® appliance. The DNS statistics include runtime, configuration, and error statistics.

To view DNS records statistics by using the command line interface

At the command prompt, type:

```
stat dns
```

## Example

```
> stat dns
```

```
DNS Statistics
```

### Runtime Statistics

|             |    |
|-------------|----|
| Dns queries | 21 |
| NS queries  | 8  |
| SOA queries | 18 |

```
.
. .
```

### Configuration Statistics

|              |    |
|--------------|----|
| AAAA records | 17 |
| A records    | 36 |
| MX records   | 9  |

```
.
. .
```

### Error Statistics

|                    |    |
|--------------------|----|
| Nonexistent domain | 17 |
| No AAAA records    | 0  |
| No A records       | 13 |

```
.
. .
```

```
Done
```

```
>
```

To view DNS records statistics by using the configuration utility

1. Navigate to Traffic Management > DNS.
2. In the details pane, click Statistics.

# Configuring a DNS Zone

Oct 29, 2014

A DNS zone entity on the Citrix® NetScaler® appliance facilitates the ownership of a domain on the appliance. A zone on the appliance also enables you to implement DNS Security Extensions (DNSSEC) for the zone, or to offload the zone's DNSSEC operations from the DNS servers to the appliance. DNSSEC sign operations are performed on all the resource records in a DNS zone. Therefore, if you want to sign a zone, or if you want to offload DNSSEC operations for a zone, you must first create the zone on the NetScaler appliance.

You must create a DNS zone on the appliance in the following scenarios:

- The NetScaler appliance owns all the records in a zone, that is, the appliance is operating as the authoritative DNS server for the zone. The zone must be created with the proxyMode parameter set to NO.
- The NetScaler appliance owns only a subset of the records in a zone, and all the other resource records in the zone are hosted on a set of back-end name servers for which the appliance is configured as a DNS proxy server. A typical configuration where the NetScaler appliance owns only a subset of the resource records in the zone is a global server load balancing (GSLB) configuration. Only the GSLB domain names are owned by the NetScaler appliance, while all the other records are owned by the back-end name servers. The zone must be created with the proxyMode parameter set to YES.
- You want to offload DNSSEC operations for a zone from your authoritative DNS servers to the appliance. The zone must be created with the proxyMode parameter set to YES. You might need to configure additional settings for the zone.

The current topic describes how to create a zone for the first two scenarios. For more information about how to configure a zone for offloading DNSSEC operations to the appliance, see [Offloading DNSSEC Operations to the NetScaler Appliance](#).

Note: If the NetScaler is operating as the authoritative DNS server for a zone, you must create Start of Authority (SOA) and name server (NS) records for the zone before you create the zone. If the NetScaler is operating as the DNS proxy server for a zone, SOA and NS records must not be created on the NetScaler appliance. For more information about creating SOA and NS records, see [Configuring DNS Resource Records](#).

When you create a zone, all existing domain names and resource records that end with the name of the zone are automatically treated as a part of the zone. Additionally, any new resource records created with a suffix that matches the name of the zone are implicitly included in the zone.

To create a DNS zone on the NetScaler appliance by using the command line interface

At the command prompt, type the following command to add a DNS zone to the NetScaler appliance and verify the configuration:

- add dns zone <zoneName> -proxyMode ( YES | NO )
- show dns zone [<zoneName> | -type <type>]

## Example

```
> add dns zone example.com -proxyMode Yes
Done
> show dns zone example.com
Zone Name : example.com
```

Proxy Mode : YES

Done

>

To modify or remove a DNS zone by using the command line interface

- To modify a DNS zone, type the set dns zone command, the name of the DNS zone, and the parameters to be changed, with their new values.
- To remove a DNS zone, type the rm dns zone command and the name of the dns zone.

To configure a DNS zone by using the configuration utility

Navigate to Traffic Management > DNS > Zones and create a DNS zone.

# Configuring the NetScaler as an ADNS Server

Aug 29, 2017

You can configure the Citrix® NetScaler® appliance to function as an authoritative domain name server (ADNS) for a domain. As an ADNS server for a domain, the NetScaler resolves DNS requests for all types of DNS records that belong to the domain. To configure the NetScaler to function as an ADNS server for a domain, you must create an ADNS service and configure NS and Address records for the domain on the NetScaler. Normally, the ADNS service uses the Mapped IP address (MIP). However, you can configure the ADNS service with any NetScaler-owned IP address. The following topology diagram shows a sample configuration and the flow of requests and responses.

Figure 1. NetScaler as an ADNS

The following table shows the parameters that are configured for the ADNS service illustrated in the preceding topology diagram.

**Table 1. Example of ADNS Service Configuration**

| Entity type  | Name           | IP address   | Type | Port |
|--------------|----------------|--------------|------|------|
| ADNS Service | Service-ADNS-1 | 10.102.29.51 | ADNS | 53   |

To configure an ADNS setup, you must configure the ADNS service. For instructions on configuring the ADNS service, see "[Load Balancing](#)".

During DNS resolution, the ADNS server directs the DNS proxy or local DNS server to query the NetScaler for the IP address of the domain. Because the NetScaler is authoritative for the domain, it sends the IP address to the DNS proxy or local DNS server. The following diagram describes the placement and role of the ADNS server in a GSLB configuration.

Figure 2. GSLB Entity Model

Note: In ADNS mode, if you remove SOA and ADNS records, the following do not function for the domain hosted by the NetScaler: ANY query (for more information about the ANY query, see [DNS ANY Query](#)), and negative responses, such as NODATA and NXDOMAIN.

This document includes the following information:

- [Creating an ADNS Service](#)
- [Configuring the ADNS Setup to Use TCP](#)
- [Adding DNS Resource Records](#)
- [Removing ADNS Services](#)
- [Configuring Domain Delegation](#)

## Creating an ADNS Service

Updated: 2014-11-14

An ADNS service is used for global service load balancing. For more information about creating a GSLB setup, see "[Global Server Load Balancing](#)". You can add, modify, enable, disable, and remove an ADNS service. For instructions on creating an ADNS service, see [Configuring Services](#).

Note: You can configure the ADNS service to use MIP, SNIP, or any new IP address.

When you create an ADNS service, the NetScaler responds to DNS queries on the configured ADNS service IP and port.

You can verify the configuration by viewing the properties of the ADNS service. You can view properties such as name, state, IP address, port, protocol, and maximum client connections.

## Configuring the ADNS Setup to Use TCP

Updated: 2013-08-26

By default, some clients use the User Datagram Protocol (UDP) for DNS, which specifies a limit of 512 bytes for the payload length of UDP packets. To handle payloads that exceed 512 bytes in size, the client must use the Transmission Control Protocol (TCP). To enable DNS communications over TCP, you must configure the NetScaler appliance to use the TCP protocol for DNS. The NetScaler then sets the truncation bit in the DNS response packets. The truncation bit specifies that the response is too large for UDP and that the client must send the request over a TCP connection. The client then uses the TCP protocol on port 53 and opens a new connection to the NetScaler. The NetScaler listens on port 53 with the

IP address of the ADNS service to accept the new TCP connections from the client.

To configure the NetScaler to use the TCP protocol, you must configure an ADNS\_TCP service. For instructions on creating an ADNS\_TCP service, see "[Load Balancing](#)".

Important: To configure the NetScaler to use UDP for DNS and use TCP only when the payload length of UDP exceeds 512 bytes, you need to configure the ADNS and ADNS\_TCP services. The IP address of the ADNS\_TCP service must be same as the IP address of the ADNS service.

## Adding DNS Resource Records

Updated: 2013-08-26

After you create an ADNS service, you can add DNS records. For instructions on adding DNS records, see [Configuring DNS Resource Records](#).

## Removing ADNS Services

Updated: 2013-08-27

For instructions on removing services, see [Load Balancing](#).

## Configuring Domain Delegation

Domain delegation is the process of assigning responsibility for a part of the domain space to another name server. Therefore, during domain delegation, the responsibility for responding to the query is delegated to another DNS server. Delegation uses NS records.

In the following example, sub1.abc.com is the subdomain for abc.com. The procedure describes the steps to delegate the subdomain to the name server ns2.sub1.abc.com and add an Address record for ns2.sub1.abc.com.

To configure domain delegation, you need to perform the following tasks, which are described in the sections that follow:

1. Create an SOA record for a domain.
2. Create an NS record to add a name server for the domain.
3. Create an Address record for the name server.
4. Create an NS record to delegate the subdomain.
5. Create a glue record for the name server.

## Creating an SOA Record

For instructions on configuring SOA records, see [Creating SOA Records for Authoritative Information](#).

## Creating an NS Record for a Name Server

For instructions on configuring an NS record, see [Creating NS Records for an Authoritative Server](#). In the Name Server drop-down list, select the primary authoritative name server, for example, ns1.abc.com.

## Creating an Address Record

For instructions on configuring Address records, see [Creating Address Records for a Domain Name](#). In the Host Name and IP address text boxes, type the domain name for the DNS Address record and the IP address, for example, ns1.abc.com and 10.102.11.135, respectively.

## Creating an NS Record for Domain Delegation

For instructions on configuring NS records, see [Creating NS Records for an Authoritative Server](#). In the Name Server drop-down list, select the primary authoritative name server, for example, ns2.sub1.abc.com.

## Creating a Glue Record

NS records are usually defined immediately after the SOA record (but this is not a restriction.) A domain must have at least two NS records. If an NS record is defined within a domain, it must have a matching Address record. This Address record is referred to as a glue record. Glue records speed up DNS queries.

For instructions on adding glue records for a subdomain, see the procedure for adding an Address (A) record, [Configuring DNS Resource Records](#).

For instructions on configuring Address records, see [Creating Address Records for a Domain Name](#). In Host Name and IP address text boxes, type the domain name for the DNS Address record and the IP address, for example, ns2.sub1.abc.com and 10.102.12.135, respectively.

# Configuring the NetScaler as a DNS Proxy Server

May 26, 2015

As a DNS proxy server, the Citrix® NetScaler® appliance can function as a proxy for either a single DNS server or a group of DNS servers. The flow of requests and responses is illustrated in the following sample topology diagram.

Figure 1. NetScaler as DNS proxy

By default, the NetScaler appliance caches responses from DNS name servers. When the appliance receives a DNS query, it checks for the queried domain in its cache. If the address for the queried domain is present in its cache, the NetScaler returns the corresponding address to the client. Otherwise, it forwards the query to a DNS name server that checks for the availability of the address and returns it to the NetScaler. The NetScaler then returns the address to the client.

For requests for a domain that has been cached earlier, the NetScaler serves the Address record of the domain from the cache without querying the configured DNS server.

The NetScaler discards a record stored in its cache when the time-to-live (TTL) value of the record reaches the configured value. A client that requests an expired record has to wait until the NetScaler retrieves the record from the server and updates its cache. To avoid this delay, the NetScaler proactively updates the cache by retrieving the record from the server before the record expires.

The following table lists sample names and the values of the entities that need to be configured on the NetScaler.

**Table 1. Example of DNS Proxy Entity Configuration**

| Entity type       | Name          | IP address   | Type | Port |
|-------------------|---------------|--------------|------|------|
| LB virtual server | Vserver-DNS-1 | 10.102.29.40 | DNS  | 53   |
| Services          | Service-DNS-1 | 10.102.29.50 | DNS  | 53   |
|                   | Service-DNS-2 | 10.102.29.51 | DNS  | 53   |

| Entity type | Name | IP address | Type | Port |
|-------------|------|------------|------|------|
|-------------|------|------------|------|------|

The following diagram shows the entities of a DNS Proxy and the values of the parameters to be configured on the NetScaler.

Figure 2. DNS Proxy Entity Model

Note: To configure DNS proxy, you need to know how to configure load balancing services and virtual servers. For information about configuring load balancing services and virtual servers, see "[Load Balancing](#)", and then configure DNS proxy setup.

This document includes the following information:

- [Creating a Load Balancing Virtual Server](#)
- [Creating DNS Services](#)
- [Binding a Load Balancing Virtual Server to DNS Services](#)
- [Configuring the DNS Proxy Setup to Use TCP](#)
- [Enabling Caching of DNS Records](#)
- [Adding DNS Resource Records](#)
- [Removing a Load Balancing DNS Virtual Server](#)
- [Limiting the Number of Concurrent DNS Requests on a Client Connection](#)

## Creating a Load Balancing Virtual Server

Updated: 2014-12-29

To configure a DNS Proxy on the NetScaler ADC, configure a load balancing virtual server of type DNS. To configure a DNS virtual server to load balance a set of DNS servers that support recursive queries, you must set the Recursion Available option. With this option, the RA bit is set to ON in the DNS replies from the DNS virtual server.

For instructions on creating a load balancing virtual server, see "[Load Balancing](#)".

## Creating DNS Services

Updated: 2013-08-26

After creating a load balancing virtual server of type DNS, you must create DNS services. You can add, modify, enable, disable, and remove a DNS service. For instructions on creating a DNS service, see "[Load Balancing](#)".

## Binding a Load Balancing Virtual Server to DNS Services

Updated: 2013-09-13

To complete the DNS Proxy configuration, you must bind the DNS services to the load balancing virtual server. For instructions on binding a service to a load balancing virtual server, see "".

## Configuring the DNS Proxy Setup to Use TCP

Updated: 2013-08-26

Some clients use the User Datagram Protocol (UDP) for DNS communications. However, UDP specifies a maximum packet size of 512 bytes. When payload lengths exceed 512 bytes, the client must use the Transmission Control Protocol (TCP). When a client sends the Citrix® NetScaler® appliance a DNS query, the appliance forwards the query to one of the name servers. If the response is too large for a UDP packet, the name server sets the truncation bit in its response to the NetScaler. The truncation bit indicates that the response is too large for UDP and that the client must send the query over a TCP connection. The NetScaler relays the response to the client with the truncation bit intact and waits for the client to initiate a TCP connection with the IP address of the DNS load balancing virtual server, on port 53. The client sends the request over a TCP connection. The NetScaler appliance then forwards the request to the name server and relays the response to the client.

To configure the NetScaler to use the TCP protocol for DNS, you must configure a load balancing virtual server and services, both of type DNS\_TCP. You can configure monitors of type DNS\_TCP to check the state of the services. For instructions on creating DNS\_TCP virtual servers, services, and monitors, see "[Load Balancing](#)."

For updating the records proactively, the NetScaler uses a TCP connection to the server to retrieve the records.

**Important:** To configure the NetScaler to use UDP for DNS and use TCP only when the payload length of UDP exceeds 512 bytes, you need to configure DNS and DNS\_TCP services. The IP address of the DNS\_TCP service must be same as that of the DNS service.

## Enabling Caching of DNS Records

Updated: 2013-08-27

To complete the process of configuring a DNS proxy on the NetScaler, you must enable caching of DNS records. You must also specify minimum and maximum time-to-live (TTL) values for the records that are cached. The TTL values are measured in seconds.

## To enable caching of DNS records by using the command line interface

At the command prompt, type the following commands to enable caching of DNS records and verify the configuration:

- set dns parameter -cacheRecords Yes
- show dns parameter

### Example

```

> set dns parameter -cacheRecords YES
Done
> show dns parameter
.
.
.
 Cache Records : YES
.
.
.
Done
>

```

## To enable caching of DNS records by using the configuration utility

1. Navigate to Traffic Management > DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, select the Enable records caching check box, and then click OK.

## Configuring Time-to-Live Values for DNS Entries

The TTL is the same for all DNS records with the same domain name and record type. If the TTL value is changed for one of the records, the new value is reflected in all records of the same domain name and type. The default TTL value is 3600 seconds. The minimum is 0, and the maximum is 2147483647. If a DNS entry has a TTL value less than the minimum or greater than the maximum, it is saved as the minimum or maximum TTL value, respectively.

To specify the minimum and/or maximum TTL by using the command line interface

At the NetScaler command prompt, type the following commands to specify the minimum and maximum TTL and verify the configuration:

- set dns parameter [-minTTL <secs>] [-maxTTL <secs>]
- show dns parameter

### Example

```

> set dns parameter -minTTL 1200 -maxTTL 1800
Done
> show dns parameter
 DNS parameters:
 DNS retries: 5
 Minimum TTL: 1200 Maximum TTL: 1800
.
.
.
Done
>

```

To specify the minimum and/or maximum TTL by using the configuration utility

1. Navigate to Traffic Management > DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, in TTL, in the Minimum and Maximum text boxes, type the minimum and maximum time to live (in seconds), respectively, and then click OK.

Note: When the TTL expires, the record is deleted from the cache. The NetScaler proactively contacts the servers and obtains the DNS record just before the DNS record expires.

## Flushing DNS Records

You can delete all DNS records present in the cache. For example, you might want to flush DNS records when a server is restarted after modifications are made.

To delete all proxy records by using the command line interface

At the NetScaler command prompt, type:

```
flush dns proxyRecords
```

To delete all proxy records by using the configuration utility

1. Navigate to Traffic Management > DNS > Records > Address Records.
2. In the details pane, click Flush Proxy Records.

## Adding DNS Resource Records

Updated: 2013-08-26

You can add DNS records to a domain for which the Citrix® NetScaler® appliance is configured as a DNS proxy server. For information about adding DNS records, see [Configuring DNS Resource Records](#).

## Removing a Load Balancing DNS Virtual Server

Updated: 2013-08-27

For information about removing a load balancing virtual server, see [Load Balancing](#).

## Limiting the Number of Concurrent DNS Requests on a Client Connection

Updated: 2013-09-10

You can limit the number of concurrent DNS requests on a single client connection, which is identified by the <clientip:port>-<vserver ip:port> tuple. Concurrent DNS requests are those requests that the NetScaler appliance has forwarded to the name servers and for which the appliance is awaiting responses. Limiting the number of concurrent requests on a client connection enables you to protect the name servers when a hostile client attempts a Distributed Denial of Service (DDoS) attack by sending a flood of DNS requests. When the limit for a client connection is reached, subsequent DNS requests on the connection are dropped till the outstanding request count goes below the limit. This limit does not apply to the requests that the NetScaler appliance serves out of its cache.

The default value for this parameter is 255. This default value is sufficient in most scenarios. If the name servers serve a large number of concurrent DNS requests under normal operating conditions, you can specify either a large value or a value of zero (0). A value of 0 disables this feature and specifies that there is no limit to the number of DNS requests that are allowed on a single client connection. This is a global parameter and applies to all the DNS virtual servers that are configured on the NetScaler appliance.

## To specify the maximum number of concurrent DNS requests allowed on a single client connection by using the command line interface

At the command prompt, type the following commands to specify the maximum number of concurrent DNS requests allowed on a single client connection and verify the configuration:

- set dns parameter -maxPipeline <positive\_integer>
- show dns parameter

### Example

```
> set dns parameter -maxPipeline 1000
Done
> show dns parameter
 DNS parameters:
 DNS retries: 5
 .
 .
 .
 Max DNS Pipeline Requests: 1000
Done
>
```

## To specify the maximum number of concurrent DNS requests allowed on a single client connection by using the configuration utility

1. Navigate to Traffic Management > DNS.
2. In the details pane, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, specify a value for Max DNS Pipeline Requests.
4. Click OK.

# Configuring the NetScaler as an End Resolver

May 26, 2015

A resolver is a procedure that is invoked by an application program that translates a domain/host name to its resource record. The resolver interacts with the LDNS, which looks up the domain name to obtain its IP address. The NetScaler can provide end-to-end resolution for DNS queries.

In recursive resolution, the NetScaler appliance queries different name servers recursively to access the IP address of a domain. When the NetScaler receives a DNS request, it checks its cache for the DNS record. If the record is not present in the cache, it queries the root servers configured in the ns.conf file. The root name server reports back with the address of a DNS server that has detailed information about the second-level domain. The process is repeated until the required record is found.

When you start the NetScaler appliance for the first time, 13 root name servers are added to the ns.conf file. The NS and Address records for the 13 root servers are also added. You can modify the ns.conf file, but the NetScaler does not allow you to delete all 13 records; at least one name server entry is required for the appliance to perform name resolution. The following diagram illustrates the process of name resolution.

Figure 1. Recursive Resolution

In the process shown in the diagram, when the name server receives a query for the address of s1.s2.s3.com, it first checks the root name servers for s1.s2.s3.com. A root name server reports back with the address of the .com name server. If the address of s1.s2.s3.com is found in the name server, it responds with a suitable IP address. Otherwise, it queries other name servers for s3.com, then for s2.s3.com to retrieve the address of s1.s2.s3.com. In this way, resolution always starts from root name servers and ends with the domain's authoritative name server.

Note: For recursive resolution functionality, caching should be enabled.

This document includes the following information:

- [Enabling Recursive Resolution](#)

- [Setting the Number of Retries](#)

## Enabling Recursive Resolution

Updated: 2013-08-27

To configure the NetScaler appliance to function as an end resolver, you must enable recursive resolution on the appliance.

## To enable recursive resolution by using the command line interface

At the command prompt, type the following commands to enable recursive resolution and verify the configuration:

- set dns parameter -recursion ENABLED
- show dns parameter

### Example

```
> set dns parameter -recursion ENABLED
Done
> show dns parameter
 DNS parameters:
.
.
.
 Recursive Resolution : ENABLED
.
.
.
Done
>
```

## To enable recursive resolution by using the configuration utility

1. Navigate to Traffic Management > DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, select the Enable recursion check box, and then click OK.

## Setting the Number of Retries

Updated: 2013-08-27

The NetScaler appliance can be configured to make a preconfigured number of attempts (called DNS retries) when it does not receive a response from the server to which it sends a query. By default, the number of DNS retries is set to 5.

## To set the number of DNS retries by using the command line interface

At the command prompt, type the following commands to set the number of retries and verify the configuration:

- set dns parameter -retries <positive\_integer>
- show dns parameter

### Example

```
> set DNS parameter -retries 3
```

```
Done
```

```
> show dns parameter
```

```
 DNS parameters:
```

```
 DNS retries: 3
```

```
.
```

```
.
```

```
.
```

```
Done
```

```
>
```

## To set the number of retries by using the configuration utility

1. Navigate to Traffic Management > DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, in the DNS Retries text box, type the DNS resolver request retry count, and then click OK.

# Configuring the NetScaler as a Forwarder

Mar 15, 2012

A forwarder is a server that forwards DNS queries to DNS servers that are outside the forwarder server's network. Queries that cannot be resolved locally are forwarded to other DNS servers. A forwarder accumulates external DNS information in its cache as it resolves DNS queries. To configure the NetScaler as a forwarder, you must add an external name server (a name server other than the Citrix NetScaler appliance).

The NetScaler appliance allows you to add external name servers to which it can forward the name resolution queries that cannot be resolved locally. To configure the NetScaler appliance as a forwarder, you must add the name servers to which it should forward name resolution queries. You can specify the lookup priority to specify the name service that the NetScaler appliance must use for name resolution.

# Adding a Name Server

Aug 06, 2017

You can create a name server by specifying its IP address or by configuring an existing virtual server as the name server.

While adding name servers, you can provide an IP address or a virtual IP address (VIP). If you add an IP address, the NetScaler load balances requests to the configured name servers in round robin method. If you add a VIP, you can configure any load balancing method.

**Note:** To verify the configuration, you can also use the `sh dns <recordtype> <domain>` command. If the queried records are not present in the cache, the resource records are fetched from the configured external name servers.

## To add a name server (when the NetScaler appliance acts as a forwarder) by using the command line interface

At the command prompt, type;

```
add dns nameServer ((<IP> | <dnsVserverName>)
```

### Example:

- `add dns nameServer 10.102.9.20`
- `add dns nameServer dnsVirtualNS`

## To add a name server (when the NetScaler appliance acts as a resolver) by using the command line interface

At the command prompt, type:

```
add dns nameServer ((<IP> [-local]) | <dnsVserverName>)
```

### Example

```
add dns nameServer 10.102.9.19 -local
```

### Note

- To remove a name server, at the NetScaler command prompt, type the `rm dns nameServer` command followed by the IP address of the name server.
- To view the details of the DNS nameserver, at the NetScaler command prompt, type `show dns nameServer` command followed by the IP address of the name server.

## To add a name server by using the configuration utility

Navigate to **Traffic Management > DNS > Name Servers** and create a name server.

## Note

Presently, the NetScaler appliance supports name servers over UDP only and thus the DNS response size is limited to 512 bytes. If the DNS response size exceeds 512 bytes, the truncated bit is set in the DNS response. The NetScaler appliance ignores such messages.

# Setting DNS Lookup Priority

Aug 27, 2013

You can set the lookup priority to either DNS or WINS. This option is used in the SSL VPN mode of operation.

To set the lookup priority to DNS by using the command line interface

At the command prompt, type the following commands to set the lookup priority to DNS and verify the configuration:

- set dns parameter -nameLookupPriority (DNS | WINS)
- show dns parameter

## Example

```
> set dns parameter -nameLookupPriority DNS
```

```
Done
```

```
> show dns parameter
```

```
.
```

```
.
```

```
.
```

```
 Name lookup priority : DNS
```

```
.
```

```
.
```

```
.
```

```
Done
```

```
>
```

To set lookup priority to DNS by using the configuration utility

1. Navigate to Traffic Management > DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, under Name Lookup Priority, select DNS or WINS, and then click OK.

Note: If the DNS virtual server that you have configured is DOWN and if you set the -nameLookupPriority to DNS, the NetScaler does not attempt WINS lookup. Therefore, if a DNS virtual server is not configured or is disabled, set the -nameLookupPriority to WINS.

# Disabling and Enabling Name Servers

Aug 27, 2013

The following procedure describes the steps to enable or disable an existing name server.

To enable or disable a name server by using the command line interface

At the command prompt, type the following commands to enable or disable a name server and verify the configuration:

- (enable | disable) dns nameServer <IPAddress>
- show dns nameServer <IPAddress>

## Example

```
> disable dns nameServer 10.102.9.19
```

```
Done
```

```
> show dns nameServer 10.102.9.19
```

```
1) 10.102.9.19: LOCAL - State: OUT OF SERVICE
```

```
Done
```

```
>
```

To enable or disable a name server by using the configuration utility

1. Navigate to Traffic Management > DNS > Name Servers.
2. In the details pane, select the name server that you want to enable or disable.
3. Click Enable or Disable. If a name server is enabled, the Disable option is available. If a name server is disabled, the Enable option is available.

# Configuring DNS Suffixes

Oct 29, 2014

You can configure DNS suffixes that enable the NetScaler appliance to complete non-fully qualified domain names (non-FQDNs) during name resolution. For example, during the process of resolving the domain name abc (which is not fully qualified), if a DNS suffix example.com is configured, the appliance appends the suffix to the domain name (abc.example.com) and resolves it. If DNS suffixes are not configured, the appliance appends a period to the non-FQDNs and resolves the domain name.

## Creating DNS Suffixes

DNS suffixes have significance and are valid only when the NetScaler is configured as an end resolver or forwarder. You can specify a suffix of up to 127 characters.

## To create DNS suffixes by using the command line interface

At the command prompt, type the following commands to create a DNS suffix and verify the configuration:

- add dns suffix <dnsSuffix>
- show dns suffix <dnsSuffix>

### Example

```
> add dns suffix example.com
Done
> show dns suffix example.com
1) Suffix: example.com
Done
>
```

To remove a DNS suffix by using the NetScaler command line, at the NetScaler command prompt, type the rm dns suffix command and the name of the DNS suffix.

## To create DNS suffixes by using the configuration utility

Navigate to Traffic Management > DNS > DNS Suffix and create DNS suffixes.

# DNS ANY Query

Mar 15, 2012

An ANY query is a type of DNS query that retrieves all records available for a domain name. The ANY query must be sent to a name server that is authoritative for a domain.

## Behavior in ADNS Mode

In the ADNS mode, the NetScaler appliance returns the records held in its local cache. If there are no records in the cache, the appliance returns the NXDOMAIN (negative) response.

If the NetScaler can match the domain delegation records, it returns the NS records. Otherwise, it returns the NS records of the root domain.

## Behavior in DNS Proxy Mode

In proxy mode, the NetScaler appliance checks its local cache. If there are no records in the cache, the appliance passes the query to the server.

## Behavior for GSLB Domains

Updated: 2013-08-26

If a GSLB domain is configured on the NetScaler appliance and an ANY query is sent for the GSLB domain (or GSLB site domain), the appliance returns the IP address of the GSLB service that it selects through the Load Balancing decision. If the multiple IP response (MIR) option is enabled, the IP addresses of all GSLB services are sent.

For the NetScaler to return these records when it responds to the ANY query, all records corresponding to a GSLB domain must be configured on the NetScaler.

Note: If records for a domain are distributed between the NetScaler and a server, only records configured on the NetScaler are returned.

The NetScaler provides the option to configure DNS views and DNS policies. These are used for performing global server load balancing. For more information, see [Global Server Load Balancing](#).

# Domain Name System Security Extensions

Aug 27, 2014

DNS Security Extensions (DNSSEC) is an Internet Engineering Task Force (IETF) standard that aims to provide data integrity and data origin authentication in communications between name servers and clients while still transmitting User Datagram Protocol (UDP) responses in clear text. DNSSEC specifies a mechanism that uses asymmetric key cryptography and a set of new resource records that are specific to its implementation.

The DNSSEC specification is described in RFC 4033, "DNS Security Introduction and Requirements," RFC 4034, "Resource Records for the DNS Security Extensions," and RFC 4035, "Protocol Modifications for the DNS Security Extensions." The operational aspects of implementing DNSSEC within DNS are discussed in RFC 4641, "DNSSEC Operational Practices."

You can configure DNSSEC on the Citrix® NetScaler® ADC. You can generate and import keys for signing DNS zones. You can configure DNSSEC for zones for which the NetScaler ADC is authoritative. You can configure the ADC as a DNS proxy server for signed zones hosted on a farm of backend name servers. If the ADC is authoritative for a subset of the records belonging to a zone for which the ADC is configured as a DNS proxy server, you can include the subset of records in the DNSSEC implementation.

# Configuring DNSSEC

May 26, 2015

Configuring DNSSEC involves enabling DNSSEC on the Citrix® NetScaler® appliance, creating a Zone Signing Key and a Key Signing Key for the zone, adding the two keys to the zone, and then signing the zone with the keys.

The NetScaler ADC does not act as a DNSSEC resolver. DNSSEC on the ADC is supported only in the following deployment scenarios:

1. ADNS—NetScaler is the ADNS and generates the signatures itself.
2. Proxy—NetScaler acts as a DNSSEC proxy. It is assumed that the NetScaler is placed in front of the ADNS/LDNS servers in a trusted mode. The ADC acts only as a proxy caching entity and does not validate any signatures.

This document includes the following information:

- [Enabling and Disabling DNSSEC](#)
- [Creating DNS Keys for a Zone](#)
- [Publishing a DNS Key in a Zone](#)
- [Configuring a DNS Key](#)
- [Signing and Unsigning a DNS Zone](#)
- [Viewing the NSEC Records for a Given Record in a Zone](#)
- [Removing a DNS Key](#)

## Enabling and Disabling DNSSEC

Updated: 2014-08-27

You must enable DNSSEC on the NetScaler ADC for the ADC to respond to DNSSEC-aware clients. By default, DNSSEC is enabled.

You can disable the DNSSEC feature if you do not want the NetScaler ADC to respond to clients with DNSSEC-specific information.

## To enable or disable DNSSEC by using the command line interface

At the command prompt, type the following commands to enable or disable DNSSEC and verify the configuration:

- `set dns parameter -dnssec ( ENABLED | DISABLED )`
- `show dns parameter`

### Example

```
> set dns parameter -dnssec ENABLED
Done
> show dns parameter
 DNS parameters:
 DNS retries: 5
.
.
.
 DNSEC Extension: ENABLED
 Max DNS Pipeline Requests: 255
Done
>
```

## To enable or disable DNSSEC by using the configuration utility

1. Navigate to Traffic Management > DNS.
2. In the details pane, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, select or clear the Enable DNSSEC Extension check box.

## Creating DNS Keys for a Zone

Updated: 2014-10-29

For each DNS zone that you want to sign, you must create two pairs of asymmetric keys. One pair, called the Zone Signing Key, is used to sign all the resource record sets in the zone. The second pair is called the Key Signing Key and is used to sign only the DNSKEY resource records in the zone.

When the Zone Signing Key and Key Signing Key are created, the suffix `.key` is automatically appended to the names of the public components of the keys and the suffix `.private` is automatically appended to the names of their private components.

Additionally, the NetScaler ADC also creates a Delegation Signer (DS) record and appends the suffix `.ds` to the name of the record. If the parent zone is a signed zone, you must publish the DS record in the parent zone to establish the chain of trust.

When you create a key, the key is stored in the `/nsconfig/dns/` directory, but it is not automatically published in the zone. After you create a key by using the `create dns key` command,

you must explicitly publish the key in the zone by using the add dns key command. The process of generating a key has been separated from the process of publishing the key in a zone to enable you to use alternative means to generate keys. For example, you can import keys generated by other key-generation programs (such as bind-keygen) by using Secure File Transfer Protocol (SFTP) and then publish the keys in the zone. For more information about publishing a key in a zone, see [Publishing a DNS Key in a Zone](#).

Perform the steps described in this topic to create a Zone Signing Key and then repeat the steps to create a Key Signing Key. The example that follows the command syntax first creates a Zone Signing Key pair for the zone example.com. The example then uses the command to create a Key Signing Key pair for the zone.

## To create a DNS key by using the command line interface

At the NetScaler command prompt, type the following command to create a DNS key:

```
create dns key -zoneName <string> -keyType <keyType> -algorithm RSASHA1 -keySize <positive_integer> -fileNamePrefix <string>
```

### Example

```
> create dns key -zoneName example.com -keyType zsk -algorithm RSASHA1 -keySize 1024 -fileNamePrefix example.com.zsk.rsasha1.1024
File Name: /nsconfig/dns/example.com.zsk.rsasha1.1024.key (public); /nsconfig/dns/example.com.zsk.rsasha1.1024.private (private); /nsconfig/dns/example.com.zsk.rsasha1.1024.ds (ds)
This operation may take some time, Please wait...
Done
> create dns key -zoneName example.com -keyType ksk -algorithm RSASHA1 -keySize 4096 -fileNamePrefix example.com.ksk.rsasha1.4096
File Name: /nsconfig/dns/example.com.ksk.rsasha1.4096.key (public); /nsconfig/dns/example.com.ksk.rsasha1.4096.private (private); /nsconfig/dns/example.com.ksk.rsasha1.4096.ds (ds)
This operation may take some time, Please wait...
Done
>
```

## To create a DNS key by using the configuration utility

1. Navigate to Traffic Management > DNS.

2. In the details area, click **Create DNS Key** and create a DNS key.

Note: For File Name Prefix, if you want to modify the file name prefix of an existing key, click the arrow next to the Browse button, click either Local or Appliance (depending on whether the existing key is stored on your local computer or in the /nsconfig/dns/ directory on the appliance), browse to the location of the key, and then double-click the key. The File Name Prefix box is populated with only the prefix of the existing key. Modify the prefix accordingly.

### Publishing a DNS Key in a Zone

Updated: 2014-10-29

A key (Zone Signing Key or Key Signing Key) is published in a zone by adding the key to the NetScaler ADC. A key must be published in a zone before you sign the zone.

Before you publish a key in a zone, the key must be available in the /nsconfig/dns/ directory. Therefore, if you used other means to generate the key—means other than the create dns key command on the NetScaler ADC (for example, by using the bind-keygen program on another computer)—make sure that the key is added to the /nsconfig/dns/ directory before you publish the key in the zone.

If the key has been generated by another program, you can import the key to your local computer and use the NetScaler configuration utility to add the key to the /nsconfig/dns/ directory. Or, you can use other means to import the key to the directory, such as the Secure File Transfer Protocol (SFTP).

You must use the add dns key command for each public-private key pair that you want to publish in a given zone. If you created a Zone Signing Key pair and a Key Signing Key pair for a zone, use the add dns key command to first publish one of the key pairs in the zone and then repeat the command to publish the other key pair. For each key that you publish in a zone, a DNSKEY resource record is created in the zone.

The example that follows the command syntax first publishes the Zone Signing Key pair (that was created for the example.com zone) in the zone. The example then uses the command to publish the Key Signing Key pair in the zone.

## To publish a key in a zone by using the command line interface

At the command prompt, type the following command to publish a key in a zone and verify the configuration:

- add dns key <keyName> <publickey> <privatekey> [-expires <positive\_integer> [<units>]] [-notificationPeriod <positive\_integer> [<units>]] [-TTL <secs>]
- show dns zone [<zoneName> | -type <type>]

### Example

```
> add dns key example.com.zsk example.com.zsk.rsasha1.1024.key example.com.zsk.rsasha1.1024.private
Done
> add dns key example.com.ksk example.com.ksk.rsasha1.4096.key example.com.ksk.rsasha1.4096.private
Done
> show dns zone example.com
Zone Name : example.com
Proxy Mode : NO
Domain Name : example.com
Record Types : NS SOA DNSKEY
Domain Name : ns1.example.com
Record Types : A
Domain Name : ns2.example.com
Record Types : A
```

Done

>

## To publish a key in a DNS zone by using the NetScaler configuration utility

Navigate to Traffic Management > DNS > Keys.

Note: For Public Key and Private Key, to add a key that is stored on your local computer, click the arrow next to the Browse button, click Local, browse to the location of the key, and then double-click the key.

### Configuring a DNS Key

Updated: 2014-08-27

You can configure the parameters of a key that has been published in a zone. You can modify the key's expiry time period, notification period, and time-to-live (TTL) parameters. If you change the expiry time period of a key, the NetScaler ADC automatically re-signs all the resource records in the zone with the key, provided that the zone is currently signed with the particular key.

## To configure a key by using the command line interface

At the command prompt, type the following command to configure a key and verify the configuration:

- set dns key <keyName> [-expires <positive\_integer> [<units>]] [-notificationPeriod <positive\_integer> [<units>]] [-TTL <secs>]
- show dns key [<keyName>]

### Example

```
> set dns key example.com.ksk -expires 30 DAYS -notificationPeriod 3 DAYS -TTL 3600
```

Done

```
> show dns key example.com.ksk
```

```
1) Key Name: example.com.ksk
```

```
Expires: 30 DAYS Notification: 3 DAYS TTL: 3600
```

```
Public Key File: example.com.ksk.rsasha1.4096.key
```

```
Private Key File: example.com.ksk.rsasha1.4096.private
```

Done

>

## To configure a key by using the configuration utility

1. Navigate to Traffic Management > DNS > Keys.
2. In the details pane, click the key that you want to configure, and then click Open.
3. In the Configure DNS Key dialog box, modify the values of the following parameters as shown:

- Expires—expires
- Notification Period—notificationPeriod
- TTL—TTL

4. Click OK.

## Signing and Unsigning a DNS Zone

Updated: 2014-08-27

To secure a DNS zone, you must sign the zone with the keys that have been published in the zone. When you sign a zone, the NetScaler ADC creates a Next Secure (NSEC) resource record for each owner name. Then, it uses the Key Signing Key to sign the DNSKEY resource record set. Finally, it uses the Zone Signing Key to sign all the resource record sets in the zone, including the DNSKEY resource record sets and NSEC resource record sets. Each sign operation results in a signature for the resource record sets in the zone. The signature is captured in a new resource record called the RRSIG resource record.

After you sign a zone, you must save the configuration.

## To sign a zone by using the command line interface

At the command prompt, type the following command to sign a zone and verify the configuration:

- sign dns zone <zoneName> [-keyName <string> ...]
- show dns zone [<zoneName> | -type (ADNS | PROXY | ALL)]
- save config

### Example

```
> sign dns zone example.com -keyName example.com.zsk example.com.ksk
```

Done

```
> show dns zone example.com
```

```
Zone Name : example.com
```

```
Proxy Mode : NO
```

```
Domain Name : example.com
```

```
Record Types : NS SOA DNSKEY RRSIG NSEC
```

```
Domain Name : ns1.example.com
```

```
Record Types : A RRSIG NSEC
Domain Name : ns2.example.com
Record Types : A RRSIG
Domain Name : ns2.example.com
Record Types : RRSIG NSEC
Done
> save config
Done
>
save config
```

## To unsign a zone by using the command line interface

At the command prompt, type the following command to unsign a zone and verify the configuration:

- `unsign dns zone <zoneName> [-keyName <string> ...]`
- `show dns zone [<zoneName> | -type (ADNS | PROXY | ALL)]`

### Example

```
> unsign dns zone example.com -keyName example.com.zsk example.com.ksk
Done
> show dns zone example.com
Zone Name : example.com
Proxy Mode : NO
Domain Name : example.com
Record Types : NS SOA DNSKEY
Domain Name : ns1.example.com
Record Types : A
Domain Name : ns2.example.com
Record Types : A
Done
>
```

## To sign or unsign a zone by using the configuration utility

1. Navigate to Traffic Management > DNS > Zones.
2. In the details pane, click the zone that you want to sign, and then click Sign/Unsign.
3. In the Sign/Unsign DNS Zone dialog box, do one of the following:
  - To sign the zone, select the check boxes for the keys (Zone Signing Key and Key Signing Key) with which you want to sign the zone. You can sign the zone with more than one Zone Signing Key or Key Signing Key pair.
  - To unsign the zone, clear the check boxes for the keys (Zone Signing Key and Key Signing Key) with which you want to unsign the zone. You can unsign the zone with more than one Zone Signing Key or Key Signing Key pair.
4. Click OK.

### Viewing the NSEC Records for a Given Record in a Zone

Updated: 2014-08-27

You can view the NSEC records that the NetScaler ADC automatically creates for each owner name in the zone.

## To view the NSEC record for a given record in a zone by using the command line interface

At the command prompt, type the following command to view the NSEC record for a given record in a zone:

```
show dns nsecRec [<hostName> | -type (ADNS | PROXY | ALL)]
```

### Example

```
> show dns nsecRec example.com
1) Domain Name : example.com
Next Nsec Name: ns1.example.com
Record Types : NS SOA DNSKEY RRSIG NSEC
Done
>
```

## To view the NSEC record for given record in a zone by using the configuration utility

1. Navigate to Traffic Management > DNS > Records > Next Secure Records.
2. In the details pane, click the name of the record for which you want to view the NSEC record. The NSEC record for the record you select is displayed in the Details area.

### Removing a DNS Key

Updated: 2014-08-27

You remove a key from the zone in which it is published when the key has expired or if the key has been compromised. When you remove a key from the zone, the zone is automatically unsigned with the key. Removing the key with this command does not remove the key files present in the `/nsconfig/dns/` directory. If the key files are no longer needed, they have to be explicitly removed from the directory.

## To remove a key from the NetScaler ADC by using the command line interface

At the command prompt, type the following command to remove a key and verify the configuration:

- `rm dns key <keyName>`
- `show dns key <keyName>`

### Example

```
> rm dns key example.com.zsk
Done
> show dns key example.com.zsk
ERROR: No such resource [keyName, example.com.zsk]
>
```

## To remove a key from the NetScaler ADC by using the configuration utility

1. Navigate to Traffic Management > DNS > Keys.
2. In the details pane, click the name of the key that you want to remove from the ADC, and then click Remove.

# Configuring DNSSEC When the NetScaler ADC is Authoritative for a Zone

Aug 27, 2014

When the Citrix® NetScaler® ADC is authoritative for a given zone, all the resource records in the zone are configured on the ADC. To sign the authoritative zone, you must create keys (the Zone Signing Key and the Key Signing Key) for the zone, add the keys to the ADC, and then sign the zone, as described in [Creating DNS Keys for a Zone](#), [Publishing a DNS Key in a Zone](#), and [Signing and Unsigning a DNS Zone](#), respectively.

If any global server load balancing (GSLB) domains configured on the ADC belong to the zone being signed, the GSLB domain names are signed along with the other records that belong to the zone.

After you sign a zone, responses to requests from DNSSEC-aware clients include the RRSIG resource records along with the requested resource records. DNSSEC must be enabled on the ADC. For more information about enabling DNSSEC, see [Enabling and Disabling DNSSEC](#).

Finally, after you configure DNSSEC for the authoritative zone, you must save the NetScaler configuration.

# Configuring DNSSEC for a Zone for Which the NetScaler ADC Is a DNS Proxy Server

May 26, 2015

The procedure for signing a zone for which the Citrix® NetScaler® ADC is configured as a DNS proxy server depends on whether or not the ADC owns a subset of the zone information owned by the backend name servers. If it does, the configuration is considered a *partial zone ownership configuration*. If the ADC does not own a subset of the zone information, the NetScaler configuration for managing the backend servers is considered a *zone-less DNS proxy server configuration*. The basic DNSSEC configuration tasks for both NetScaler configurations are the same. However, signing the partial zone on the NetScaler ADC requires some additional configuration steps.

Note: The terms *zone-less proxy server configuration* and *partial zone* are used only in the context of the NetScaler appliance.

Important: When configured in proxy mode, the ADC does not perform signature verification on DNSSEC responses before updating the cache.

If you configure the ADC as a DNS proxy to load balance DNSSEC aware resolvers (servers), you must set the Recursion Available option while configuring the DNS virtual server. If a DNSSEC query arrives with Checking Disabled (CD) bit set, the query is passed on to the server with the CD bit retained, and the response from the server is not cached. In releases prior to 10.5.e build xx.x, the ADC unset the CD bit before passing it to the server and also cached the server response.

This document includes the following information:

- [Configuring DNSSEC for a Zone-Less DNS Proxy Server Configuration](#)
- [Configuring DNSSEC for a Partial Zone Ownership Configuration](#)

## Configuring DNSSEC for a Zone-Less DNS Proxy Server Configuration

Updated: 2014-08-27

For a zone-less DNS proxy server configuration, zone signing must be performed on the backend name servers. On the NetScaler ADC, you configure the ADC as a DNS proxy server for the zone. You create a load balancing virtual server of protocol type DNS, configure services on the ADC to represent the name servers, and then bind the services to the load balancing virtual server. For more information about these configuration tasks, see [Configuring the NetScaler as a DNS Proxy Server](#).

When a client sends the ADC a DNS request with the DNSSEC OK (DO) bit set, the ADC checks its cache for the requested information. If the resource records are not available in its cache, the ADC forwards the request to one of the DNS name servers, and then relays the response from the name server to the client. Additionally, the ADC caches the RRSIG resource records along with the response from the name server. Subsequent requests from DNSSEC-aware clients are served from the cache (including the RRSIG resource records), subject to the time-to-live (TTL) parameter. If a client sends a DNS request without setting the DO bit, the ADC responds with only the requested resource records, and does not include the RRSIG resource records that are specific to DNSSEC.

## Configuring DNSSEC for a Partial Zone Ownership Configuration

Updated: 2014-08-27

In some NetScaler configurations, even though the authority for a zone lies with the backend name servers, a subset of the

resource records that belong to the zone might be configured on the NetScaler ADC. The ADC owns (or is authoritative for) only this subset of records. Such a subset of records can be considered to constitute a *partial zone* on the ADC. The ADC owns the partial zone. All other records are owned by the backend name servers.

A typical partial zone configuration on the NetScaler ADC is seen when global server load balancing (GSLB) domains are configured on the ADC, and the GSLB domains are a part of a zone for which the backend name servers are authoritative.

Signing a zone that includes only a partial zone on the ADC involves including the partial zone information in the backend name server zone files, signing the zone on the backend name servers, and then signing the partial zone on the ADC. The same key set must be used to sign the zone on the name servers and the partial zone on the ADC.

## To sign the zone on the backend name servers

1. Include the resource records that are contained in the partial zone, in the zone files of the name servers.
2. Create keys and use the keys to sign the zone on the backend name servers.

## To sign the partial zone on the NetScaler ADC

1. Create a zone with the name of the zone that is owned by the backend name servers. When configuring the partial zone, set the proxyMode parameter to YES. This zone is the partial zone that contains the resource records owned by the ADC.

For example, if the name of the zone that is configured on the backend name servers is example.com, you must create a zone named example.com on the ADC, with the proxyMode parameter set to YES. For more information about adding a zone, see [Configuring a DNS Zone](#).

Note: Do not add SOA and NS records for the zone. These records should not exist on the ADC for a zone for which the ADC is not authoritative.

2. Import the keys (from one of the backend name servers) to the ADC and then add them to the /nsconfig/dns/ directory. For more information about how you can import a key and add it to the ADC, see [Publishing a DNS Key in a Zone](#).
3. Sign the partial zone with the imported keys. When you sign the partial zone with the keys, the ADC generates RRSIG and NSEC records for the resource record sets and individual resource records in the partial zone, respectively. For more information about signing a zone, see [Signing and Unsigning a DNS Zone](#).

# Configuring DNSSEC for GSLB Domain Names

Aug 27, 2014

If global server load balancing (GSLB) is configured on the Citrix® NetScaler® ADC and the ADC is authoritative for the zone to which the GSLB domain names belong, all GSLB domain names are signed when the zone is signed. For more information about signing a zone for which the ADC is authoritative, see [Configuring DNSSEC When the NetScaler Appliance Is Authoritative for a Zone](#).

If the GSLB domains belong to a zone for which the backend name servers are authoritative, you must first sign the zone on the name servers, and then sign the partial zone on the ADC to complete the DNSSEC configuration for the zone. For more information, see [Configuring DNSSEC for a Partial Zone Ownership Configuration](#).

# Zone Maintenance

May 26, 2015

From a DNSSEC perspective, zone maintenance involves rolling over Zone Signing Keys and Key Signing Keys when key expiry is imminent. These zone maintenance tasks have to be performed manually. The process of re-signing a zone is performed automatically and does not require manual intervention.

This document includes the following information:

- [Re-Signing an Updated Zone](#)
- [Rolling Over DNSSEC Keys](#)

## Re-Signing an Updated Zone

Updated: 2014-08-27

When a zone is updated, that is, when new records are added to the zone or existing records are changed, the process of re-signing the new (or modified) record is performed automatically by the Citrix® NetScaler® ADC. If a zone contains multiple Zone Signing Keys, the ADC re-signs the new (or modified) record with the key with which the zone is signed at the point in time when the re-signing is to be performed.

## Rolling Over DNSSEC Keys

Updated: 2014-08-27

On the NetScaler ADC, you can use the pre-publish and double signature methods to perform a rollover of the Zone Signing Key and Key Signing Key. More information about these two rollover methods is available in RFC 4641, “DNSSEC Operational Practices.”

The following topics map commands on the ADC to the steps in the rollover procedures discussed in RFC 4641.

The key expiry notification is sent through an SNMP trap called `dnskeyExpiry`. Three MIB variables, `dnskeyName`, `dnskeyTimeToExpire`, and `dnskeyUnitsOfExpiry` are sent along with the `dnskeyExpiry` SNMP trap. For more information, see [Citrix NetScaler SNMP OID Reference](#) at .

## Pre-Publish Key Rollover

RFC 4641, “DNSSEC Operational Practices” defines four stages for the pre-publish key rollover method: initial, new DNSKEY, new RRSIGs, and DNSKEY removal. Each stage is associated with a set of tasks that you must perform on the ADC. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here can be used for both Key Signing Keys and Zone Signing Keys.

- **Stage 1: Initial.** The zone contains only those key sets with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.

### Example

Consider the key, `example.com.zsk1`, with which the zone `example.com` is currently signed. The zone contains only those RRSIGs that were generated by the `example.com.zsk1` key, which is due for expiry. The Key Signing Key is `example.com.ksk1`.

- **Stage 2: New DNSKEY.** A new key is created and published in the zone (that is, the key is added to the ADC), but the zone is not signed with the new key until the pre-roll phase is complete. In this stage, the zone contains the old key, the new key, and the RRSIGs generated by the old key. Publishing the new key for the complete duration of the pre-roll phase gives the DNSKEY resource record (that corresponds to the new key) enough time to propagate to the secondary name servers.

#### Example

A new key `example.com.zsk2` is added to the `example.com` zone. The zone is not signed with `example.com.zsk2` until the pre-roll phase is complete. The `example.com` zone contains DNSKEY resource records for both `example.com.zsk1` and `example.com.zsk2`.

#### NetScaler commands

Perform the following tasks on the ADC:

- Create a new DNS key by using the `create dns key` command.  
For more information about creating a DNS key, including an example, see [Creating DNS Keys for a Zone](#).
- Publish the new DNS key in the zone by using the `add dns key` command.  
For more information about publishing the key in the zone, including an example, see [Publishing a DNS Key in a Zone](#).
- **Stage 3: New RRSIGs.** The zone is signed with the new DNS key and then unsigned with the old DNS key. The old DNS key is not removed from the zone and remains published until the RRSIGs that were generated by the old key expire.

#### Example

The zone is signed with `example.com.zsk2` and then unsigned with `example.com.zsk1`. The zone continues to publish `example.com.zsk1` until the RRSIGs that were generated by `example.com.zsk1` expire.

#### NetScaler commands

Perform the following tasks on the ADC:

- Sign the zone with the new DNS key by using the `sign dns zone` command.
- Unsign the zone with the old DNS key by using the `unsign dns zone` command.  
For more information about signing and unsigned a zone, including examples, see [Signing and Unsigning a DNS Zone](#).
- **Stage 4: DNSKEY Removal.** When the RRSIGs that were generated by the old DNS key expire, the old DNS key is removed from the zone.

#### Example

The old DNS key `example.com.zsk1` is removed from the `example.com` zone.

#### NetScaler commands

On the ADC, you remove the old DNS key by using the `rm dns key` command. For more information about removing a key from a zone, including an example, see [Removing a DNS Key](#).

## Double Signature Key Rollover

RFC 4641, “DNSSEC Operational Practices” defines three stages for double signature key rollover: initial, new DNSKEY, and DNSKEY removal. Each stage is associated with a set of tasks that you must perform on the ADC. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here can be used for both Key Signing Keys and Zone Signing Keys.

- **Stage 1: Initial.** The zone contains only those key sets with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.

#### Example

Consider the key, `example.com.zsk1`, with which the zone `example.com` is currently signed. The zone contains only those RRSIGs that were generated by the `example.com.zsk1` key, which is due for expiry. The Key Signing Key is `example.com.ksk1`.

- **Stage 2: New DNSKEY.** The new key is published in the zone and the zone is signed with the new key. The zone contains the RRSIGs that are generated by the old and the new keys. The minimum duration for which the zone must contain both sets of RRSIGs is the time required for all the RRSIGs to expire.

#### Example

A new key `example.com.zsk2` is added to the `example.com` zone. The zone is signed with `example.com.zsk2`. The `example.com` zone now contains the RRSIGs generated from both keys.

#### NetScaler commands

Perform the following tasks on the ADC:

- Create a new DNS key by using the `create dns key` command.  
For more information about creating a DNS key, including an example, see [Creating DNS Keys for a Zone](#).
- Publish the new key in the zone by using the `add dns key` command.  
For more information about publishing the key in the zone, including an example, see [Publishing a DNS Key in a Zone](#).
- Sign the zone with the new key by using the `sign dns zone` command.  
For more information about signing a zone, including examples, see [Signing and Unsigning a DNS Zone](#).
- **Stage 3: DNSKEY Removal.** When the RRSIGs that were generated by the old DNS key expire, the old DNS key is removed from the zone.

#### Example

The old DNS key `example.com.zsk1` is removed from the `example.com` zone.

#### NetScaler commands

On the ADC, you remove the old DNS key by using the `rm dns key` command.

For more information about removing a key from a zone, including an example, see [Removing a DNS Key](#).

# Offloading DNSSEC Operations to the NetScaler ADC

Nov 21, 2014

For DNS zones for which your DNS servers are authoritative, you can offload DNSSEC operations to the NetScaler ADC. In a DNSSEC offloading deployment, a DNS server sends unsigned responses. The ADC signs the response on the fly before relaying it to the client. The ADC also caches the signed response. Apart from reducing the load on the DNS servers, offloading DNSSEC operations to the ADC gives you the following benefits:

- You can sign records that the DNS servers generate programmatically. Such records cannot be signed by routine zone signing operations performed on the DNS servers.
- You can serve signed responses to clients even if you have not implemented DNSSEC on your servers.

For setting up DNSSEC offloading, you must configure a DNS load balancing virtual server, configure services that represent the DNS servers, and then bind the services to the virtual server. For information about configuring a DNS load balancing virtual server, configuring services, and binding the services to the virtual server, see [Configuring a DNS Zone](#).

You must create a zone entity on the ADC for each DNS zone whose DNSSEC operations you want to offload. For each DNS zone, you must enable the Proxy Mode and DNSSEC Offload parameters. You can optionally configure NSEC record generation for an offloaded zone. To create a DNS zone entity for DNSSEC offloading, follow the instructions in this topic.

To complete the configuration, you must generate DNS keys for the zone, add the keys to the zone, and then sign the zone with the keys. This process is the same as for normal DNSSEC. For information about creating keys, adding keys to a zone, and signing the zone, see [Domain Name System Security Extensions](#).

After you configure DNS offloading, you must flush the DNS cache on the ADC. Flushing the DNS cache ensures that any unsigned records in the cache are removed and subsequently replaced by signed records. For information about flushing the DNS cache, see [Enabling Caching of DNS Records](#).

Note: DNSSEC offloading is supported on all NetScaler MPX platforms, except the NetScaler MPX 9700/10500/12500/15500 FIPS platform. The feature is also supported on NetScaler virtual appliances hosted on NetScaler SDX platforms.

To enable DNSSEC offloading for a zone by using the command line interface

At the command line, type the following commands to enable DNSSEC offloading for a zone and verify the configuration:

- add dns zone <zoneName> -proxyMode YES -dnssecOffload ENABLED [-nsec ( ENABLED | DISABLED )
- show dns zone

## Example

```
> add dns zone example.com -proxyMode YES -dnssecOffload ENABLED nsec ENABLED
Done
> show dns zone example.com
Zone Name : example.com
Proxy Mode : YES
DNSSEC Offload: ENABLED NSEC: ENABLED
Done
>
```

To enable DNSSEC offloading for a zone by using the configuration utility

1. Navigate to Traffic Management > DNS > Zones.
2. In the details pane, do one of the following:
  - To create a zone on the ADC, click Add.
  - To configure DNSSEC offloading for an existing zone, double-click the zone.
3. In the Create DNS Zone or Configure DNS Zone dialog box, select the Proxy Mode and DNSSEC Offload check boxes.
4. Optionally, if you want the ADC to generate NSEC records for the zone, select the NSEC check box.

# DataStream

May 25, 2015

The NetScaler DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests based on the SQL query being sent.

When deployed in front of database servers, a NetScaler ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and on the basis of database names, usernames, character sets, and packet size.

You can either configure load balancing to switch requests based on load balancing algorithms or elaborate the switching criteria by configuring content switching to make a decision based on an SQL query parameters. You can further configure monitors to track the state of database servers.

Note: NetScaler DataStream is supported only for MySQL and MS SQL databases. For information about the supported protocol version, character sets, special queries, and transactions, see DataStream Reference.

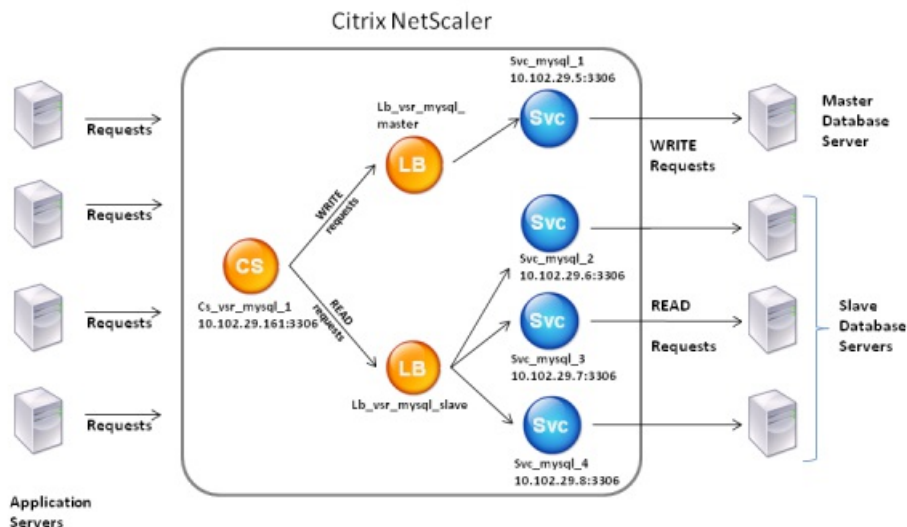

## How NetScaler DataStream Works

Updated: 2013-09-18

In DataStream, the NetScaler is placed in-line between the application and/or Web servers and the database servers. On the NetScaler appliance, the database servers are represented by services.

A typical DataStream deployment consists of the entities described in the following diagram.

Figure 1. *DataStream Entity Model*

As shown in this figure, a DataStream configuration can consist of an optional content switching virtual server (CS), a load balancing setup consisting of load balancing virtual servers (LB1 and LB2) and services (Svc1, Svc2, Svc3, and Svc4), and content switching policies (optional).

The clients (application or Web servers) send requests to the IP address of a content switching virtual server (CS) configured on the NetScaler appliance. The NetScaler, then, authenticates the clients using the database user credentials configured on the NetScaler appliance. The content switching virtual server (CS) applies the associated content switching policies to the requests. After evaluating the policies, the content switching virtual server (CS) routes the requests to the appropriate load balancing virtual server (LB1 or LB2), which, then, distributes the requests to the appropriate database servers (represented by services on the NetScaler) based on the load balancing algorithm. The NetScaler uses the same database user credentials to authenticate the connection with the database server.

If a content switching virtual server is not configured on the NetScaler, the clients (application or Web servers) send their requests to the IP address of a load balancing virtual server configured on the NetScaler appliance. The NetScaler authenticates the client by using the database user credentials configured on the NetScaler appliance, and then uses the same credentials to authenticate the connection with the database server. The load balancing virtual server distributes the requests to the database servers according to the load balancing algorithm. The most effective load balancing algorithm for database switching is the least connection method.

DataStream uses connection multiplexing to enable multiple client-side requests to be made over the same server-side connection. The following connection properties are considered:

- User name
- Database name
- Packet size
- Character set

# Configuring Database Users

Dec 28, 2016

In databases, a connection is always stateful, which means that as soon as a connection is established, it must be authenticated.

You need to configure your database user name and password on the NetScaler ADC. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. When you add the database user names and passwords on the ADC, these are added to the nsconfig file.

Note: Names are case sensitive.

The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

To add a database user by using the command line interface

At the command prompt, type

```
add db user <username> - password <password>
```

## Example

```
> add db user nsdbuser -password dd260427edf
```

To add a database user by using the configuration utility

Navigate to System > User Administration > Database Users, and configure a database user.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the NetScaler.

To reset the password of a database user by using the command line interface

At the command prompt, type

```
set db user <username> -password <password>
```

## Example

```
> set db user nsdbuser -password dd260538abs
```

To reset the password of database users by using the configuration utility

Navigate to System > User Administration > Database Users, select a user, and enter new values for the password.

If a database user no longer exists on the database server, you can remove the user from the NetScaler. However, if the user continues to exist on the database server and you remove the user from the NetScaler, any request from the client with this user name does not get authenticated, and therefore, does not get routed to the database server.

To remove a database user by using the command line interface

At the command prompt, type

```
rm db user <username>
```

## Example

```
> rm db user nsdbuser
```

## To remove a database user by using the configuration utility

Navigate to System > User Administration > Database Users, select a user, and click Delete.

# Configuring a Database Profile

Sep 03, 2014

A database profile is a named collection of parameters that is configured once but applied to multiple virtual servers that require those particular parameter settings. After creating a database profile, you bind it to load balancing or content switching virtual servers. You can create as many profiles as you need.

To create a database profile by using the command line interface

At the command line, type the following commands to create a database profile and verify the configuration:

- `add db dbProfile <name> [-interpretQuery ( YES | NO )] [-stickiness (YES | NO )] [-kcdAccount <string>]`
- `show db dbProfile`

## Example

```
> add dbProfile myDBProfile -interpretQuery YES -stickiness YES -kcdAccount mykcdacct
Done
> show dbProfile myDBProfile
Name: myDBProfile
Interpret Query: YES
Stickyness: YES
KCD Account: mykcdacct
Reference count: 0
```

Done

>

To create a database profile by using the configuration utility

Navigate to System > Profiles and, on the Database Profiles tab, configure a database profile.

To bind a database profile to a load balancing or content switching virtual server by using the command line interface

At the command line, type:

```
set (lb | cs) vserver <name> -dbProfileName <string>
```

To bind a database profile to a load balancing or content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers or Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Profiles and, in the DB Profile list, select a profile to bind to the virtual server. To create a new profile, click plus (+).

# Configuring Load Balancing for DataStream

May 15, 2015

Before configuring a load balancing setup, you must enable the load balancing feature. Then, begin by creating at least one service for each database server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server and bind the services to the virtual server.

Parameter values specific to DataStream

## Protocol

Use the MYSQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see <http://dev.mysql.com/doc/internals/en/client-server-protocol.html>. For information about the TDS protocol, see [http://msdn.microsoft.com/en-us/library/dd304523\(v=prot.13\).aspx](http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx).

## Port

Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

## Method

It is recommended that you use the Least Connection method for better load balancing and lower server load. However, other methods, such as Round Robin, Least Response Time, Source IP Hash, Source IP Destination IP Hash, Least Bandwidth, Least Packets, and Source IP Source Port Hash, are also supported.

Note: URL Hash method is not supported for DataStream.

## MS SQL Server Version

If you are using the Microsoft SQL Server, and you expect some clients to not be running the same version as your Microsoft SQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see [Configuring the MySQL and Microsoft SQL Server Version Setting](#).

## MySQL Server Version

If you are using the MySQL Server, and you expect some clients to not be running the same version as your MySQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see [Configuring the MySQL and Microsoft SQL Server Version Setting](#).

# Configuring Content Switching for DataStream

May 15, 2015

You can segment traffic according to information in the SQL query, on the basis of database names, user names, character sets, and packet size.

You can configure content switching policies with default syntax expressions to switch content based on connection properties, such as user name and database name, command parameters, and the SQL query to select the server.

The default syntax expressions evaluate traffic associated with MySQL and MS SQL database servers. You can use request-based expressions in default syntax policies to make request switching decisions at the content switching virtual server bind point and response-based expressions (expressions that begin with MYSQL.RES) to evaluate server responses to user-configured health monitors.

Note: For information about default syntax expressions, see [Default Syntax Expressions: DataStream](#).

Parameter values specific to DataStream

## **Protocol**

Use the MySQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see <http://dev.mysql.com/doc/internals/en/client-server-protocol.html>. For information about the TDS protocol, see [http://msdn.microsoft.com/en-us/library/dd304523\(v=prot.13\).aspx](http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx).

## **Port**

Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

## **MS SQL Server Version**

If you are using Microsoft SQL Server, and you expect some clients to not be running the same version as your Microsoft SQL Server product, set the Server Version parameter for the content switching virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see [Configuring the Microsoft SQL Server Version Setting](#).

# Configuring Monitors for DataStream

Oct 10, 2016

To track the state of each load balanced database server in real time, you need to bind a monitor to each service. The monitor is configured to test the service by sending periodic probes to the service. (This is sometimes referred to as performing a health check.) If the monitor receives a timely response to its probes, it marks the service as UP. If it does not receive a timely response to the designated number of probes, it marks the service as DOWN.

For DataStream, you need to use the built-in monitors, MYSQL-ECV and MSSQL-ECV. This monitor provides the ability to send an SQL request and parse the response for a string.

Before configuring monitors for DataStream, you must add database user credentials to your NetScaler. For information about configuring monitors, see [Monitors](#).

When you create a monitor, a TCP connection is established with the database server, and the connection is authenticated by using the user name provided while creating the monitor. You can then run an SQL query to the database server and evaluate the server response to check whether it matches the configured rule.

The following examples are for MYSQL servers.

## Examples

In the following example, the value of the error message is evaluated to determine the state of the server.

```
add lb monitor lb_mon1 MYSQL-ECV -sqlQuery "select * from
table2;" -evalrule "mysql.res.error.message.contains('\Invalid
User')"-database "NS" -userName "user1"
```

In the following example, the number of rows in the response is evaluated to determine the state of the server.

```
add lb monitor lb_mon4 MYSQL-ECV -sqlQuery "select * from
table4;" -evalrule "mysql.res.atleast_rows_count(7)" -database "NS" -userName "user2"
```

In the following example, the value of a particular column is evaluated to determine the state of the server.

```
add lb monitor lb_mon3 MYSQL-ECV
-sqlQuery "select * from ABC;" -evalrule "mysql.res.row(1).double_elem(2) == 345.12"
-database "NS" -userName "user3"
```

The following examples are for MSSQL servers.

## Examples

In the following example, the value of the error message is evaluated to determine the state of the server.

```
add lb monitor lb_mon1 MSSQL_ECV -sqlQuery "select * from
table2;" -evalrule "mssql.res.error.message.contains('\Invalid
User')"-database "NS" -userName "user1"
```

In the following example, the number of rows in the response is evaluated to determine the state of the server.

```
add lb monitor lb_mon4 MSSQL_ECV -sqlQuery "select * from
table4;" -evalrule "mssql.res.atleast_rows_count(7)" -database "NS" -userName "user2"
```

In the following example, the value of a particular column is evaluated to determine the state of the server.

```
add lb monitor lb_mon3 MSSQL_ECV
-sqlQuery "select * from ABC;" -evalrule "mssql.res.row(1).double_elem(2) == 345.12"
-database "NS" -userName "user3"
```

# Use Case 1: Configuring DataStream for a Master/Slave Database Architecture

May 15, 2015

A commonly used deployment scenario is the master/slave database architecture where the master database replicates all information to the slave databases.

For master/slave database architecture, you may want all WRITE requests to be sent to the master database and all READ requests to the slave databases.

The following figure shows the entities and the values of the parameters you need to configure on the appliance.

Figure 1. *DataStream Entity Model for Master/Slave Database Setup*

In this example scenario, a service (Svc\_mysql\_1) is created to represent the master database and is bound to a load balancing virtual server (Lb\_vsr\_mysql\_master). Three more services (Svc\_mysql\_2, Svc\_mysql\_3, and Svc\_mysql\_4) are created to represent the three slave databases, and they are bound to another load balancing virtual server (Lb\_vsr\_mysql\_slave).

A content switching virtual server (Cs\_vsr\_mysql\_1) is configured with associated policies to send all WRITE requests to the load balancing virtual server, Lb\_vsr\_mysql\_master, and all READ requests to the load balancing virtual server, Lb\_vsr\_mysql\_slave.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

The following table lists the names and values of the entities and the policy configured on the NetScaler.

**Table 1. Entity and Policy Names and Values**

| Entity Type | Name | IP Address | Protocol | Port | Expression |
|-------------|------|------------|----------|------|------------|
|             |      |            |          |      |            |

| Services Entity Type             | Svc_mysql_1 Name    | 10.102.29.5 IP Address | MYSQL Protocol | 3306 Port | NA Expression                                 |
|----------------------------------|---------------------|------------------------|----------------|-----------|-----------------------------------------------|
|                                  | Svc_mysql_2         | 10.102.29.6            | MYSQL          | 3306      | NA                                            |
|                                  | Svc_mysql_3         | 10.102.29.7            | MYSQL          | 3306      | NA                                            |
|                                  | Svc_mysql_4         | 10.102.29.8            | MYSQL          | 3306      | NA                                            |
| Load balancing virtual servers   | Lb_vsr_mysql_master | 10.102.29.201          | MYSQL          | 3306      | NA                                            |
|                                  | Lb_vsr_mysql_slave  | 10.102.29.202          | MYSQL          | 3306      | NA                                            |
| Content switching virtual server | Cs_vsr_mysql_1      | 10.102.29.161          | MYSQL          | 3306      | NA                                            |
| Content switching policy         | Cs_select           | NA                     | NA             | NA        | "MYSQLREQ.QUERY.COMMAND.contains(\"select\")" |

To configure DataStream for a master/slave database setup by using the command line interface

At the command prompt, type

- add service Svc\_mysql\_1 10.102.29.5 mysql 3306
- add service Svc\_mysql\_2 10.102.29.6 mysql 3306
- add service Svc\_mysql\_3 10.102.29.7 mysql 3306
- add service Svc\_mysql\_4 10.102.29.8 mysql 3306
- add lb vserver Lb\_vsr\_mysql\_master mysql 10.102.29.201 3306
- add lb vserver Lb\_vsr\_mysql\_slave mysql 10.102.29.202 3306
- bind lb vserver Lb\_vsr\_mysql\_master svc\_mysql\_1
- bind lb vserver Lb\_vsr\_mysql\_slave svc\_mysql\_2
- bind lb vserver Lb\_vsr\_mysql\_slave svc\_mysql\_3
- bind lb vserver Lb\_vsr\_mysql\_slave svc\_mysql\_4
- add cs vserver Cs\_vsr\_mysql\_1 mysql 10.102.29.161 3306
- add cs policy Cs\_select –rule "MYSQLREQ.QUERY.COMMAND.contains(\"select\")"
- bind cs vserver Cs\_vsr\_mysql\_1 Lb\_vsr\_mysql\_master
- bind cs vserver Cs\_vsr\_mysql\_1 Lb\_vsr\_mysql\_slave –policy Cs\_select –priority 10

# Use Case 2: Configuring the Token Method of Load Balancing for DataStream

May 15, 2015

You can configure the token method of load balancing for DataStream to base the selection of database servers on the value of the token extracted from the client (application or web server) requests. These tokens are defined by using SQL expressions. For subsequent requests with the same token, the NetScaler sends the requests to the same database server that handled the initial request. Requests with the same token are sent to the same database server until the maximum connection limit is reached or the session entry has aged out.

You can use the following sample SQL expressions to define tokens:

| <b>MySQL</b>              | <b>MS SQL</b>           |
|---------------------------|-------------------------|
| MYSQL.REQ.QUERY.TEXT      | MSSQL.REQ.QUERY.TEXT    |
| MYSQL.REQ.QUERY.TEXT(n)   | MSSQL.REQ.QUERY.TEXT(n) |
| MYSQL.REQ.QUERY.COMMAND   | MSSQL.REQ.QUERY.COMMAND |
| MYSQL.CLIENT.USER         | MSSQL.CLIENT.USER       |
| MYSQL.CLIENT.DATABASE     | MSSQL.CLIENT.DATABASE   |
| MYSQL.CLIENT.CAPABILITIES |                         |

The following example shows how the NetScaler DataStream feature works when you configure the token method of load balancing.

Figure 1. How DataStream Works with the Token Method of Load Balancing

In this example, the token is the name of the database. A request with token books is sent to Database Server1 and a request with token music is sent to Database Server2. All subsequent requests with token books are sent to Database Server1 and requests with token music are sent to Database Server2. This configuration provides pseudo persistence with the database servers.

To configure this example by using the command line interface

At the command prompt, type:

- add service Service1 192.0.2.9 MYSQL 3306
- add service Service2 192.0.2.11 MYSQL 3306
- add lb vserver token\_lb\_vserver MYSQL 192.0.2.15 3306 -lbmethod token -rule MYSQL.CLIENT.DATABASE
- bind lb vserver token\_lb\_vserver Service1
- bind lb vserver token\_lb\_vserver Service2

To configure this example by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. Click in the Service section, and configure two services specifying the protocol as MYSQL. Bind these services to the virtual server.
3. In Advanced Settings, click Method and, in the Load Balancing Method list, select TOKEN and specify the expression as MYSQL.CLIENT.DATABASE.

# Use Case 3: Logging MSSQL Transactions in Transparent Mode

Jun 09, 2015

You can configure the NetScaler appliance to operate transparently between MSSQL clients and servers, and to only log or analyze details of all client-server transactions. Transparent mode is designed so that the NetScaler appliance only forwards MSSQL requests to the server, and then relays the server's responses to the clients. As the requests and responses pass through the appliance, the appliance logs information gathered from them, as specified by the audit logging or AppFlow configuration, or collects statistics, as specified by the Action Analytics configuration. You do not have to add database users to the appliance.

When operating in transparent mode, the NetScaler appliance does not perform load balancing, content switching, or connection multiplexing for the requests. However, it responds to a client's pre-login packet on behalf of the server so that it can prevent encryption from being agreed upon during the pre-login handshake. The login packet and subsequent packets are forwarded to the server.

This section includes the following details:

- [Summary of Configuration Tasks](#)
- [Configuring Transparent Mode by Using a Wildcard Virtual Server](#)
- [Configuring Transparent Mode by Using MSSQL Services](#)

## Summary of Configuration Tasks

Updated: 2015-05-25

For logging or analyzing MSSQL requests in transparent mode, you have to do the following:

- Configure the NetScaler appliance as the default gateway for both clients and servers.
- Do one of the following on the NetScaler appliance:
  - **If you can configure the use source IP address (USIP) option globally**, create a load balancing virtual server with a wildcard IP address and the port number on which the MSSQL servers listen for requests (a port-specific wildcard virtual server). Then, enable the USIP option globally. If you configure a port-specific wildcard virtual server, you do not have to create MSSQL services on the appliance. The appliance discovers the services on the basis of the destination IP address in the client requests. For instructions, see [Configuring Transparent Mode by Using a Wildcard Virtual Server](#).
  - **If you do not want to configure the USIP option globally**, create MSSQL services with the USIP option enabled on each of them. If you configure services, you do not have to create a port-specific wildcard virtual server. For instructions, see [Configuring Transparent Mode by Using MSSQL Services](#).
- Configure audit logging, AppFlow, or Action Analytics to log or collect statistics about the requests. If you configure a virtual server, you can bind your policies either to the virtual server or to the global bind point. If you do not configure a virtual server, you can bind your policies to only the global bind point.

## Configuring Transparent Mode by Using a Wildcard Virtual Server

Updated: 2013-11-04

You can configure transparent mode by configuring a port-specific wildcard virtual server and enabling Use Source IP (USIP) mode globally. When a client sends its default gateway (the NetScaler appliance) a request with the IP address of an MSSQL server in the destination IP address header, the appliance checks whether the destination IP address is available. If

the IP address is available, the virtual server forwards the request to the server. Otherwise, it drops the request.

## To create a wildcard virtual server by using the command line

At the command prompt, type the following commands to create a wildcard virtual server and verify the configuration:

1. add lb vserver <name> <serviceType> <IPAddress> <port>
2. show lb vserver <name>

Example

```
> add lb vserver wildcardLbVs MSSQL * 1433
Done
> show lb vserver wildcardLbVs
wildcardLbVs (*:1433) - MSSQL Type: ADDRESS
State: UP
...
```

Done

>

## To create a wildcard virtual server by using the NetScaler configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server. Specify MSSQL as the protocol and \* as the IP address.

## To enable Use Source IP (USIP) mode globally by using the command line

At the command prompt, type the following commands to enable USIP mode globally and verify the configuration:

- enable ns mode USIP
- show ns mode

Example

```
> enable ns mode USIP
Done
> show ns mode
```

| Mode             | Acronym | Status |
|------------------|---------|--------|
| .....            | .....   | .....  |
| ...              |         |        |
| 3) Use Source IP | USIP    | ON     |
| ...              |         |        |

Done

>

## To enable USIP mode globally by using the NetScaler configuration utility

1. Navigate to System > Settings and, in Modes and Features, select Configure Modes.
2. Select Use Source IP.

Configuring Transparent Mode by Using MSSQL Services

Updated: 2013-08-23

You can configure transparent mode by configuring MSSQL services and enabling USIP on each service. When a client sends its default gateway (the NetScaler appliance) a request with the IP address of an MSSQL server in the destination IP address header, the appliance forwards the request to the destination server.

## To create an MSSQL service and enable USIP mode on the service by using the command line interface

At the command prompt, type the following commands to create an MSSQL service, with USIP enabled, and verify the configuration:

- add service <name> (<IP> | <serverName>) <serviceType> <port> -usip YES
- show service <name>

Example

```
> add service myDBservice 192.0.2.0 MSSQL 1433 -usip YES
```

```
Done
```

```
> show service myDBservice
```

```
myDBservice (192.0.2.0:1433) - MSSQL
```

```
State: UP
```

```
...
```

```
Use Source IP: YES Use Proxy Port: YES
```

```
...
```

```
Done
```

```
>
```

## To create an MSSQL service, with USIP enabled, by using the NetScaler configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and configure a service.
2. Specify protocol as MSSQL and, in Settings, select Use Source IP.

# Use Case 4: Database Specific Load Balancing

Nov 28, 2016

A database server farm should be load balanced not only on the basis of the states of the servers, but also on the basis of the availability of the database on each server. A service might be up, and a load balancing device might show it as being in the UP state, but the requested database might be unavailable on that service. If a query is forwarded to a service on which the database is unavailable, the request is not served. Therefore, a load balancing device must be aware of the availability of a database on each service and, when making a load balancing decision, it must consider only those services on which the database is available.

As an example, consider that database servers server1, server2, and server3 host databases mydatabase1 and mydatabase2. If mydatabase1 becomes unavailable on server2, the load balancing device must be aware of that change in state, and it must load balance requests for mydatabase1 across only server1 and server3. After mydatabase1 becomes available on server2, the load balancing device must include server2 in load balancing decisions. Similarly, if mydatabase2 becomes unavailable on server3, the device must load balance requests for mydatabase2 across only server1 and server2, and it must include server3 in its load balancing decisions only when mydatabase2 becomes available. This load balancing behavior must be consistent across all the databases that are hosted on the server farm.

The Citrix NetScaler appliance implements this behavior by retrieving a list of all the databases that are active on a service. To retrieve the list of active databases, the appliance uses a monitor that is configured with an appropriate SQL query. If the requested database is unavailable on a service, the appliance excludes the service from load balancing decisions until it becomes available. This behavior ensures uninterrupted service to clients.

Note: Database specific load balancing is currently supported for only MSSQL and MySQL service types. This support is also available for Microsoft SQL Server 2012 high availability deployment.

To set up database specific load balancing, you must enable the load balancing feature, configure a load balancing virtual server of type MSSQL or MySQL, configure the services that host the database, and bind the services to the virtual server. The monitor needs valid user credentials to log on to the database server, so you must configure a database user account on each of the servers and then add the user account to the NetScaler appliance. Then, you configure an MSSQL-ECV or MYSQL-ECV monitor and bind the monitor to each service. Finally, you must test the configuration to ensure that it is working as intended. Before you perform these configuration tasks, make sure you understand how database specific load balancing works.

This section includes the following details:

- [How Database Specific Load Balancing Works](#)
- [Enabling Load Balancing](#)
- [Configuring a Load Balancing Virtual Server for Database Specific Load Balancing](#)
- [Configuring Services](#)
- [Configuring Database Users](#)
- [Configuring a Monitor to Retrieve the Names of Active Databases](#)
- [Availability Groups Deployment Support for MSSQL](#)

## How Database Specific Load Balancing Works

For database specific load balancing, you configure a monitor that periodically queries each database server for the names of all the active databases on it. The Citrix NetScaler appliance stores the results, and regularly updates the records on the basis of the information retrieved through monitoring. When a client queries a particular database, the appliance uses the configured load balancing method to select a service, and then checks its records to determine whether the database is

available on that service. If the records indicate that the database is not available, it uses the configured load balancing method to select the next available service, and then repeats the check. The appliance forwards the query to the first available service on which the database is active.

## Enabling Load Balancing

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

## To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

### Example

```
> enable ns feature LoadBalancing
Done
> show ns feature
```

|           | Feature               | Acronym   | Status    |
|-----------|-----------------------|-----------|-----------|
|           | -----                 | -----     | -----     |
| 1)        | Web Logging           | WL        | OFF       |
| 2)        | Surge Protection      | SP        | ON        |
| <b>3)</b> | <b>Load Balancing</b> | <b>LB</b> | <b>ON</b> |
| .         |                       |           |           |
| .         |                       |           |           |
| .         |                       |           |           |
| 24)       | NetScaler Push        | push      | OFF       |

Done

## To enable load balancing by using the configuration utility

Navigate to System > Settings and, in Configure Basic Features, select Load Balancing.

### Configuring a Load Balancing Virtual Server for Database Specific Load Balancing

To configure a virtual server to load balance databases on the basis of availability, you enable the database specific load balancing parameter on the virtual server. Enabling the parameter modifies the load balancing logic so that the NetScaler appliance refers the results of the monitoring probe sent to the selected service, before forwarding the query to that service.

### Note

For configuration examples related to MSSQL or MySQL, refer to the following topics:

- [Configuration examples for MSSQL virtual server](#)
- [Configuration examples for MySQL virtual server](#)

## To configure a load balancing virtual server for database specific load balancing

At the command prompt, type the following command to configure a load balancing virtual server for database specific load balancing and verify the configuration:

- add lb vserver <name> <serviceType> <ipAddress> <port> -dbsLb ENABLED
- show lb vserver <name>

## Configuring Services

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the NetScaler appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server's name instead of its IP address when you create a service.

## Configuring Database Users

In databases, a connection is always stateful, which means that as soon as a connection is established, it must be authenticated.

You need to configure your database user name and password on the NetScaler ADC. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. When you add the database user names and passwords on the ADC, these are added to the nsconfig file.

Note: Names are case sensitive.

The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

## To add a database user by using the command line interface

At the command prompt, type

```
add db user <username> - password <password>
```

### Example

```
> add db user nsdbuser -password dd260427edf
```

## To add a database user by using the configuration utility

Navigate to System > User Administration > Database Users, and configure a database user.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the NetScaler.

## To reset the password of a database user by using the command line interface

At the command prompt, type

```
set db user <username> -password <password>
```

#### Example

```
> set db user nsdbuser -password dd260538abs
```

## To reset the password of database users by using the configuration utility

Navigate to System > User Administration > Database Users, select a user, and enter new values for the password.

If a database user no longer exists on the database server, you can remove the user from the NetScaler. However, if the user continues to exist on the database server and you remove the user from the NetScaler, any request from the client with this user name does not get authenticated, and therefore, does not get routed to the database server.

To remove a database user by using the command line interface

At the command prompt, type

```
rm db user <username>
```

#### Example

```
> rm db user nsdbuser
```

## To remove a database user by using the configuration utility

Navigate to System > User Administration > Database Users, select a user, and click Delete.

### Configuring a Monitor to Retrieve the Names of Active Databases

To retrieve a list of all the active databases on a database instance, you create a monitor that logs on to the database server by using a valid user credentials and runs an appropriate SQL query. The SQL query you need to use depends on your SQL server deployment. For example, in an MSSQL database mirroring setup, you can use the following query to retrieve a list of active databases available on a server instance.

```
select name from sys.databases where state=0
```

In a **MySQL** database setup you can use the following queries to retrieve a list of active databases available on a server instance.

#### show databases

You also configure the monitor to evaluate the response for an error condition, and to store the results if there is no error. If the response contains an error, the monitor marks the service as DOWN, and the appliance excludes the service from load balancing decisions until an error is no longer returned.

**Note:** The database specific load balancing feature is supported only for the MSSQL and MySQL service types. Therefore, the monitor type must be MSSQL-ECV or MYSQL-ECV.

## To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line

At the command prompt, type the following commands to retrieve the names of all the active databases hosted on a service and verify the configuration:

- **add lb monitor** <monitorName> <type> -userName <string> -sqlQuery <text> -evalRule <expression> -storedb **ENABLED**

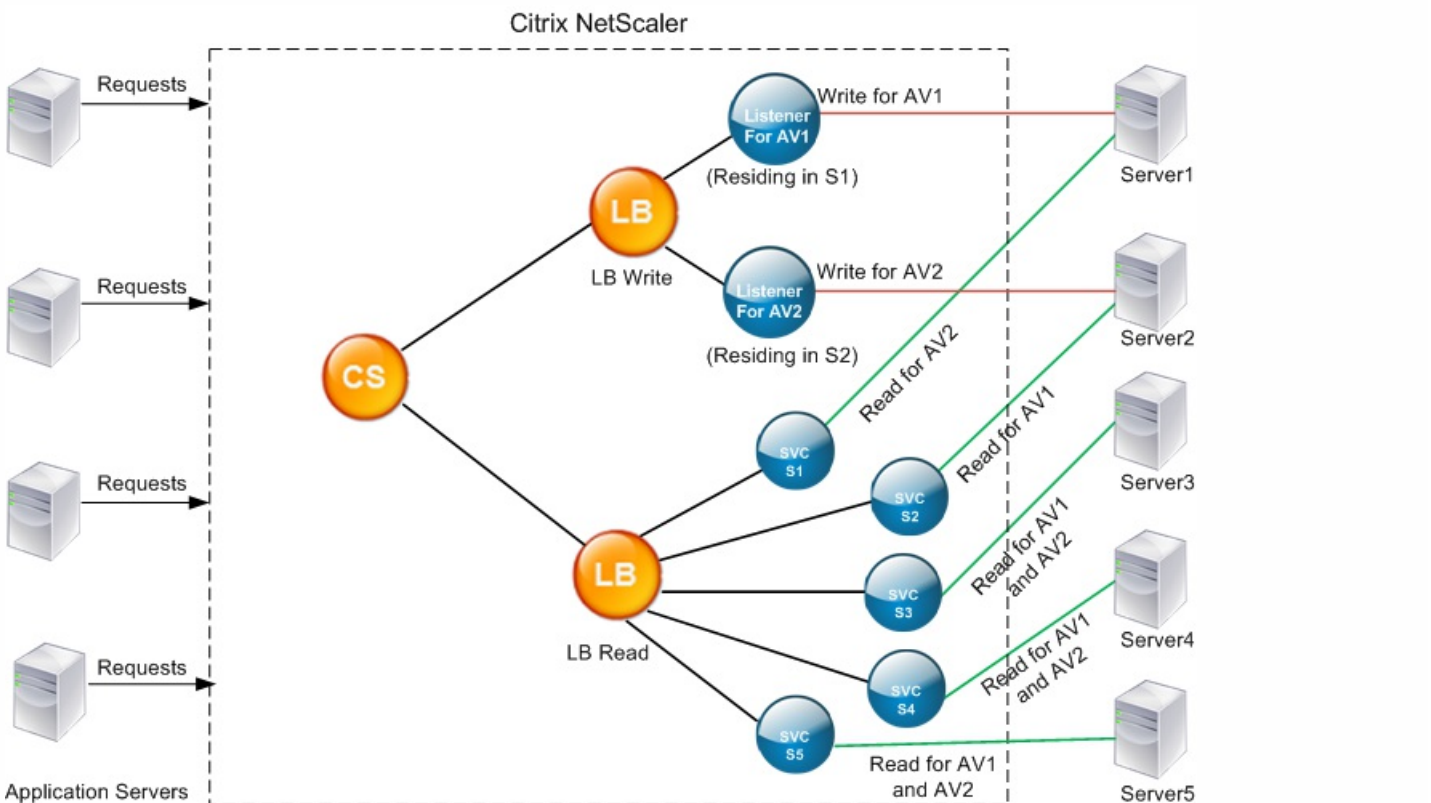

- **show lb monitor** <monitorName>

To configure a monitor to retrieve the names of all the active databases hosted on a service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Monitors** and configure a monitor of type **MSSQL-ECV** or **MYSQL-ECV**.
2. In **Special Parameters**, specify a user name, query, and a rule.
  - For example, for MSSQL-ECV, the query should be "select name from sys.databases where state=0" and a rule should be MSSQL.RES.TYPE.NE(ERROR).
  - For MYSQL-ECV, the query should be "show databases" and a rule should be MYSQL.RES.TYPE.NE(ERROR).

### Availability Groups Deployment Support for MSSQL

Consider the following scenario in which database specific load balancing is configured in a high availability group deployment. S1 through S5 are the services on the NetScaler. DB1 through DB4 are the databases on the servers represented by the services S1 through S5. AV1 and AV2 are the availability groups. Each availability group contains up to one primary database server instance and up to four secondary database server instances. A service, representing the servers in the availability group, can be primary for one availability group and secondary for another availability group. Each availability group contains different databases and one listener, which is a service. All requests arrive on the listener service that resides on the primary database. AV1 contains databases DB1 and DB2. AV2 contains databases DB3 and DB4. L1 and L2 are the listeners on AV1 and AV2 respectively. S1 is the primary service for AV1 and S2 is the primary service for AV2.

| Service | List of Active Databases on the Service |
|---------|-----------------------------------------|
| S1      | DB1, DB2, DB3, DB4                      |
| S2      | DB3, DB4                                |

| Service | List of Active Databases on the Service |
|---------|-----------------------------------------|
| S3      | DB3, DB4                                |
| S4      | DB1, DB2                                |
| S5      | DB1, DB2                                |

| Availability Group | Databases | Services representing the Servers in Availability Group |
|--------------------|-----------|---------------------------------------------------------|
| AV1                | DB1, DB2  | S1, S4, S5                                              |
| AV2                | DB3, DB4  | S1, S2, S3                                              |

Queries flow as follows:

1. A READ query for AV1 is load balanced between S4 and S5. S1 is the primary for AV1.
2. A WRITE query for AV1 is directed to L1.
3. A READ query for AV2 is load balanced between S1 and S3. S2 is the primary for AV2.
4. A WRITE query for AV1 is directed to L2.

## Sample Configuration

1. Configure load balancing and content switching virtual servers.
  - add lb vserver lbwrite -dbslb enabled
  - add lbvserver lbread MSSQL -dbslb enabled
  - add csvserver csv MSSQL 1.1.1.10 1433
2. Configure two listener services, one for each availability group, and five services S1 through S5 representing databases DB1 through DB4.
  - add service L1 1.1.1.11 MSSQL 1433
  - add service L2 1.1.1.12 MSSQL 1433
  - add service s1 1.1.1.13 MSSQL 1433
  - add service s2 1.1.1.14 MSSQL 1433
  - add service s3 1.1.1.15 MSSQL 1433
  - add service s4 1.1.1.16 MSSQL 1433
  - add service s5 1.1.1.17 MSSQL 1433
3. Bind the services to the load balancing virtual servers.
  - bind lbvserver lbwrite L1
  - bind lbvserver lbwrite L2
  - bind lbvserver lbread s1
  - bind lbvserver lbread s2
  - bind lbvserver lbread s3
  - bind lbvserver lbread s4
  - bind lbvserver lbread s5
4. Configure database users.
  - add db user nsdbuser1 -password dd260427edf

- add db user nsdbuser2 -password ccd1234xyzw
5. Configure two monitors, monitor\_L1 and monitor\_L2 for each listener service, to retrieve the list of active databases in that availability group. Add a monitor, monitor1 to retrieve the list of databases for the secondary database server instance.
    - add lb monitor monitor\_L1 MSSQL-ECV -userName user1 -sqlQuery "SELECT name FROM sys.databases a INNER JOIN sys.dm\_hadr\_availability\_replica\_states b ON a.replica\_id=b.replica\_id INNER JOIN sys.availability\_group\_listeners c on b.group\_id = c.group\_id INNER JOIN sys.availability\_group\_listener\_ip\_addresses d on c.listener\_id = d.listener\_id WHERE b.role = 1 and d.ip\_address like '1.1.1.11'" -evalRule "MSSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED
    - add lb monitor monitor\_L2 MSSQL-ECV -userName user1 -sqlQuery "SELECT name FROM sys.databases a INNER JOIN sys.dm\_hadr\_availability\_replica\_states b ON a.replica\_id=b.replica\_id INNER JOIN sys.availability\_group\_listeners c on b.group\_id = c.group\_id INNER JOIN sys.availability\_group\_listener\_ip\_addresses d on c.listener\_id = d.listener\_id WHERE b.role = 1 and d.ip\_address like '1.1.1.12'" -evalRule "MSSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED
    - add lb monitor monitor1 MSSQL-ECV -userName user1 -sqlQuery "SELECT name FROM sys.databases a INNER JOIN sys.dm\_hadr\_availability\_replica\_states b ON a.replica\_id=b.replica\_id WHERE b.role = 2" -evalRule "MSSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED
  6. Configure read and write policies.
    - add cs policy pol\_write -rule "MSSQL.REQ.QUERY.TEXT.CONTAINS(\"insert\")"
    - add cs policy pol\_read -rule "MSSQL.REQ.QUERY.TEXT.CONTAINS(\"select\")"
  7. Bind the policies to the content switching virtual server.
    - bind cs server csv -target LB server lbwrite -policyName pol\_write -priority 11
    - bind cs server csv -target LB server lbread -policyName pol\_read -priority 12
  8. Bind monitors to the services. Bind monitors to services L1 and L2 to get the list of active databases for the availability group for which it is the listener. Bind monitors to all the services that are bound to the read-only virtual server.
    - bind service L1 -monitorName monitor\_L1
    - bind service L2 -monitorName monitor\_L2
    - bind service s1 -monitorName monitor1
    - bind service s2 -monitorName monitor1
    - bind service s3 -monitorName monitor1
    - bind service s4 -monitorName monitor1
    - bind service s5 -monitorName monitor1

## Configuration examples for MSSQL virtual server

### To configure a load balancing virtual server for database specific load balancing:

```
> add lb vserver DBSpecificLB1 MSSQL 192.0.2.10 1433 -dbsLb ENABLED
```

```
Done
```

```
> show lb vserver DBSpecificLB1
```

```
DBSpecificLB1 (192.0.2.10:1433) - MSSQL Type: ADDRESS
```

```
...
```

```
DBS_LB: ENABLED
```

```
Done
```

```
>
```

### To configure services:

```
add service msservice1 5.5.5.5 MSSQL 1433
```

### To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line:

```
> add lb monitor mssql-monitor1 MSSQL-ECV -userName user1 -sqlQuery "select name from sys.databases where state=0" -evalRule "MSSQL.RES.TYPE.NE(ERROR)" -storedb EN
```

**Done**

```
> show lb monitor mssql-monitor1
```

```
1) Name.....: mssql-monitor1 Type.....: MSSQL-ECV
```

...

```
Special parameters: Database.....:""
```

```
User name.....:"user1"
```

```
Query...:select name from sys.databases where state=0 EvalRule...:MSSQL.RES.TYPE.NE(ERROR)
```

```
Version...:70 STORE_DB...:ENABLED
```

**Done**

```
>
```

### Configuration examples for MySQL virtual server

#### To configure a load balancing virtual server for database specific load balancing:

```
> add lb vserver DBSpecificLB1 MYSQL 192.0.2.10 3306 -dbsLb ENABLED
```

**Done**

```
> show lb vserver DBSpecificLB
```

```
DBSpecificLB1 (192.0.2.10:3306) - MYSQL Type: ADDRESS
```

...

```
DBS_LB: ENABLED
```

**Done**

```
>
```

### To configure services:

```
add service msservice1 5.5.5.5 MYSQL 3306
```

### To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line

```
> add lb monitor mysql-monitor1 MYSQL-ECV -userName user1 -sqlQuery "show databases" -evalRule "MYSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED
```

**Done**

```
> show lb monitor mysql-monitor1
```

```
1) Name.....: mysql-monitor1 Type.....: MYSQL-ECV State....: ENABLED
```

```
...
```

```
Special parameters: Database.....:""
```

```
User name.....:"user1" Query...:show databases
```

```
EvalRule...:MYSQL.RES.TYPE.NE(ERROR) STORE_DB...:ENABLED
```

**Done**

```
>
```

# DataStream Reference

Jun 15, 2017

This reference describes the MySQL and TDS protocols, the database versions, the authentication methods, and the character sets supported by the DataStream feature. It also describes how NetScaler handles transaction requests and special queries that modify the state of a connection.

You can also configure the NetScaler appliance to generate audit log messages for the DataStream feature.

## Supported Database Versions, Protocols, and Authentication Methods

|                        | MySQL Database                                                                                                                                                                                                                | MS SQL Database                                                                                                                                                                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Database Versions      | MySQL database versions 4.1, 5.0, 5.1, 5.4, 5.5, and 5.6.                                                                                                                                                                     | MS SQL database versions 2000, 2000SP1, 2005, 2008, 2008R2, and 2012.                                                                                                                                                                                     |
| Protocols              | MySQL protocol version 10.<br>For information about the MySQL protocol, see <a href="http://dev.mysql.com/doc/internals/en/client-server-protocol.html">http://dev.mysql.com/doc/internals/en/client-server-protocol.html</a> | Tabular Data Stream (TDS) protocol version 7.1 and higher.<br>For information about the TDS protocol, see <a href="http://msdn.microsoft.com/en/us/library/dd304523(v=prot.13).aspx">http://msdn.microsoft.com/en/us/library/dd304523(v=prot.13).aspx</a> |
| Authentication Methods | MySQL native authentication is supported.                                                                                                                                                                                     | SQL server authentication and Windows Authentication (Kerberos/NTLM) are supported.                                                                                                                                                                       |

## Character Sets

The DataStream feature supports only the UTF-8 charset.

The character set used by the client while sending a request may be different from the character set used in the database server responses. Although the charset parameter is set during the connection establishment, it can be changed at any time by sending an SQL query. The character set is associated with a connection, and therefore, requests on connections with one character set cannot be multiplexed onto a connection with a different character set.

NetScaler parses the queries sent by the client and the responses sent by the database server.

The character set associated with a connection can be changed after the initial handshake by using the following two queries:

- SET NAMES <charset> COLLATION <collation>
- SET CHARACTER SET <charset>

## Transactions

In MySQL, transactions are identified by using the connection parameter AUTOCOMMIT or the BEGIN:COMMIT queries. The AUTOCOMMIT parameter can be set during the initial handshake, or after the connection is established by using the query SET AUTOCOMMIT.

NetScaler explicitly parses each and every query to determine the beginning and end of a transaction.

In MySQL protocol, the response contains two flags to indicate whether the connection is a transaction, the TRANSACTION and AUTOCOMMIT flags.

If the connection is a transaction, the TRANSACTION flag is set. Or, if the AutoCommit mode is OFF, the AUTOCOMMIT flag is not set. NetScaler parses the response, and if either the TRANSACTION flag is set or the AUTOCOMMIT flag is not set, it does not do connection multiplexing. When these conditions are no longer true, the NetScaler begins connection multiplexing.

## Note

Transactions are also supported for MS SQL.

## Special Queries

Updated: 2014-05-21

There are special queries, such as SET and PREPARE, that modify the state of the connection and may break request switching, and therefore, these need to be handled differently.

On receiving a request with special queries, NetScaler sends an OK response to the client and additionally, stores the request in the connection.

When a non-special query, such as INSERT and SELECT, is received along with a stored query, the NetScaler first, looks for the server-side connection on which the stored query has already been sent to the database server. If no such connections exist, NetScaler creates a new connection, and sends the stored query first, and then, sends the request with the non-special query.

In case of SET, USE db, and INIT\_DB special queries, the appliance modifies a field in the server side connection corresponding to the special query. This results in better reuse of the server side connection.

Only 16 queries are stored in each connection.

The following is a list of the special queries for which NetScaler has a modified behavior.

### **SET query**

The SET SQL queries define variables that are associated with the connection. These queries are also used to define global variables, but as of now, NetScaler is unable to differentiate between local and global variables. For this query, the NetScaler uses the 'store and forward' mechanism described earlier .

### **USE <db> query**

Using this query, the user can change the database associated with a connection. In this case, NetScaler parses the <db> value sent and modifies a field in the server side connection to reflect the new database to be used.

### **INIT\_DB command**

Using this query, the user can change the database associated with a connection. In this case, NetScaler parses the <init\_db> value sent and modifies a field in the server side connection to reflect the new database to be used.

### **COM\_PREPARE**

NetScaler stops request switching on receiving this command.

## **PREPARE query**

This query is used to create prepared statements that are associated with a connection. For this query, the NetScaler uses the 'store and forward' mechanism described earlier in this section.

## Audit Log Message Support

Updated: 2013-09-30

You can now configure the NetScaler appliance to generate audit log messages for the DataStream feature. Audit log messages are generated when client-side and server-side connections are established, closed, or dropped. The categories of messages that you can log and view are ERROR and INFO. Error messages for client-side connections begin with "CS" and error messages for server-side connections begin with "SS." Additional information is provided where necessary. For example, log messages for closed connections (CS\_CONN\_CLOSED) include only the connection ID. However, log messages for established connections (CS\_CONN\_ESTD) include information such as the user name, database name, and the client IP address in addition to the connection ID.

# Firewall Load Balancing

Jun 29, 2012

Firewall load balancing distributes traffic across multiple firewalls, providing fault tolerance and increased throughput.

Firewall load balancing protects your network by:

- Dividing the load between the firewalls, which eliminates a single point of failure and allows the network to scale.
- Increasing high availability.

Configuring a NetScaler appliance for firewall load balancing is similar to configuring load balancing, with the exception that the recommended service type is ANY, recommended monitor type is PING, and the load balancing virtual server mode is set to MAC.

You can set up firewall load balancing in a sandwich, an enterprise, or multiple-firewall environment configuration. The sandwich environment is used for load balancing traffic entering the network from outside and traffic leaving the network to the internet and involves configuring two NetScaler appliances, one on each side of a set of firewalls. You configure an enterprise environment for load balancing traffic leaving the network to the internet. The enterprise environment involves configuring a single NetScaler appliance between the internal network and the firewalls that provide access to the Internet. The multiple-firewall environment is used for load balance traffic coming from another firewall. Having firewall load balancing enabled on both the sides of NetScaler improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic. The multiple-firewall environment involves configuring a NetScaler appliance sandwiched between two firewalls.

Important: If you configure static routes on the NetScaler for the destination IP address and enable L3 mode, the NetScaler uses its routing table to route the traffic instead of sending the traffic to the load balancing vserver.

Note: For FTP to work, an additional virtual server or service should be configured on the NetScaler with IP address and port as \* and 21 respectively, and the service type specified as FTP. In this case, the NetScaler manages the FTP protocol by accepting the FTP control connection, modifying the payload, and managing the data connection, all through the same firewall.

Firewall Load Balancing supports only some of the load balancing methods supported on the NetScaler. Also, you can configure only a few types of persistence and monitors.

## Firewall Load Balancing Methods

The following load balancing methods are supported for firewall load balancing.

- Least Connections
- Round Robin
- Least Packets
- Least Bandwidth
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port hash
- Least Response Time Method (LRTM)
- Custom Load

## Firewall Persistence

Only SOURCEIP, DESTIP, and SOURCEIPDESTIP based persistence are supported for firewall load balancing.

## Firewall Server Monitoring

Only PING and transparent monitors are supported in firewall load balancing. You can bind a PING monitor (default) to the backend service that represents the firewall. If a firewall is configured not to respond to ping packets, you can configure transparent monitors to monitor hosts on the trusted side through individual firewalls.

# Sandwich Environment

Apr 08, 2013

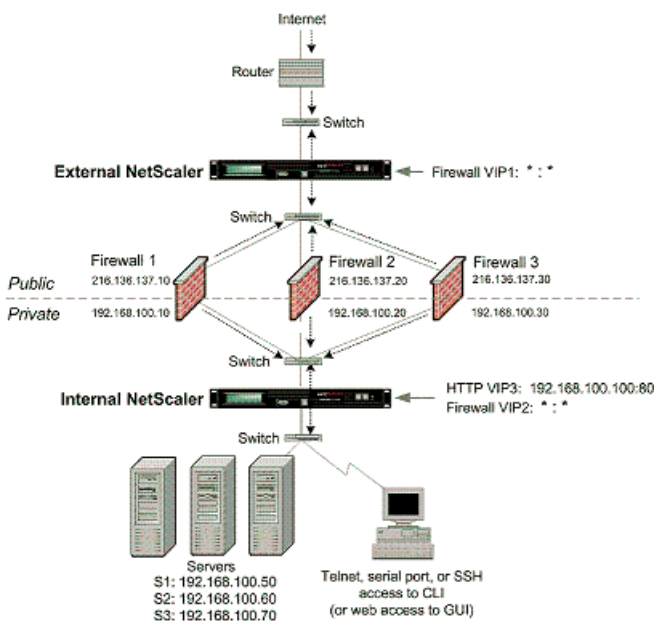

A NetScaler deployment in a sandwich mode is capable of load balancing network traffic through firewalls in both directions: ingress (traffic entering the network from the outside, such as the internet) and egress (traffic leaving the network to the internet).

In this setup, a NetScaler is located on each side of a set of firewalls. The NetScaler placed between the firewalls and the Internet, called the external NetScaler that handles ingress traffic selects the best firewall, based on the configured method. The NetScaler between the firewalls and the private network, called the internal NetScaler tracks the firewall from which the initial packet for a session is received. It then makes sure that all subsequent packets for that session are sent to the same firewall.

The internal NetScaler can be configured as a regular traffic manager to load balance traffic across the private network servers. This configuration also allows traffic originating from the private network (egress) to be load balanced across the firewalls.

The following diagram shows the sandwich firewall load balancing environment.

Figure 1. Firewall Load Balancing (Sandwich)

The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.

## Configuring the External NetScaler in a Sandwich Environment

Updated: 2015-05-22

Perform the following tasks to configure the external NetScaler in a sandwich environment

- [Enable the load balancing feature.](#)

- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server for traffic coming from the Internet.
- Configure the virtual server in MAC rewrite mode.
- Bind services to the wildcard virtual server.
- Save and Verify the Configuration.

## Enable the load balancing feature

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

### Example

```
> enable ns feature LoadBalancing
Done
> show ns feature
```

|     | Feature               | Acronym   | Status    |
|-----|-----------------------|-----------|-----------|
|     | -----                 | -----     | -----     |
| 1)  | Web Logging           | WL        | OFF       |
| 2)  | Surge Protection      | SP        | ON        |
| 3)  | <b>Load Balancing</b> | <b>LB</b> | <b>ON</b> |
| .   |                       |           |           |
| .   |                       |           |           |
| .   |                       |           |           |
| 24) | NetScaler Push        | push      | OFF       |

Done

To enable load balancing by using the configuration utility

Navigate to System > Settings and, in **Configure Basic Features**, select **Load Balancing**.

## Configure a wildcard service for each firewall

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> ANY *
```

### Example

```
add service Service-HTTP-1 10.102.29.5 ANY *
```

To configure a wildcard service for each firewall by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services and add a service. Specify **ANY** in the **Protocol** field and **\*** in the Port field.

## Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- add lb monitor <monitorName> <type> [-destIP <ip\_addr|ipv6\_addr|\*>] [-transparent (YES | NO )]
- bind lb monitor <monitorName> <serviceName>

### Example

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
```

```
bind monitor monitor-HTTP-1 fw-svc1
```

To bind a PING monitor, type the following command:

```
bind monitor PING fw-svc1
```

To create and bind a transparent monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and then create and bind a transparent monitor.

## Configure a wildcard virtual server for traffic coming from the Internet

To configure a wildcard virtual server for traffic coming from the Internet by using the command line interface

At the command prompt, type:

```
add lb vserver <name> ANY * *
```

### Example

```
add lb vserver Vserver-LB-1 ANY * *
```

To configure a wildcard virtual server for traffic coming from the Internet by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers and create a wildcard virtual server. Specify **ANY** in the **Protocol** field and **\*** in the Port field.

## Configure the virtual server in MAC rewrite mode

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -m <RedirectionMode>
```

### Example

```
set lb vserver Vserver-LB-1 -m MAC
```

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1).
2. Edit the **Basic Settings** section and click **more**.
3. From the **Redirection Mode** drop-down list, select **MAC Based**.

## Bind services to the wildcard virtual server

To bind a service to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

### Example

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind a service to the wildcard virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server for which you want to bind the service.
2. Click in the **Services** section and select a service to bind.

## Save and Verify the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

### Example

```
save config
```

```
sh lb vserver FWLBVIP1
```

```
FWLBVIP1 (*:*) - ANY Type: ADDRESS

## Configuring the Internal NetScaler ADC in a Sandwich Environment

Updated: 2015-06-04

Perform the following tasks to configure the internal NetScaler in a sandwich environment

For traffic from the server (egress)

- [Enable the load balancing feature.](#)
- [Configure a wildcard service for each firewall.](#)

- [Configure a monitor for each wildcard service.](#)
- [Configure a wildcard virtual server to load balance the traffic sent to the firewalls.](#)
- [Configure the virtual server in MAC rewrite mode.](#)
- [Bind firewall services to the wildcard virtual server.](#)

For traffic across private network servers

- [Configure a service for each virtual server .](#)
- [Configure a monitor for each service.](#)
- [Configure an HTTP virtual server to balance traffic sent to the servers.](#)
- [Bind HTTP services to the HTTP virtual server .](#)
- [Save and Verify the Configuration.](#)

## Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

### Example

```
> enable ns feature LoadBalancing
Done
> show ns feature
```

|           | Feature               | Acronym   | Status    |
|-----------|-----------------------|-----------|-----------|
|           | -----                 | -----     | -----     |
| 1)        | Web Logging           | WL        | OFF       |
| 2)        | Surge Protection      | SP        | ON        |
| <b>3)</b> | <b>Load Balancing</b> | <b>LB</b> | <b>ON</b> |
| .         |                       |           |           |
| .         |                       |           |           |
| .         |                       |           |           |
| 24)       | NetScaler Push        | push      | OFF       |

```
Done
```

To enable load balancing by using the configuration utility

Navigate to System > Settings and, in Configure Basic Features, select Load Balancing.

## Configure a wildcard service for each firewall

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

add service <name> <serverName> ANY \*

### Example

```
add service Service-HTTP-1 10.102.29.5 ANY *
```

To configure a wildcard service for each firewall by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services and add a service. Specify **ANY** in the **Protocol** field and **\*** in the Port field.

## Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- add lb monitor <monitorName> <type> [-destIP <ip\_addr|ipv6\_addr|\*>] [-transparent (YES | NO )]
- bind lb monitor <monitorName> <serviceName>

### Example

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
```

```
bind monitor monitor-HTTP-1 fw-svc1
```

To create and bind a transparent monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors and create a monitor.
2. In the **Create Monitor** dialog box, enter the required parameters and select **Transparent**.

## Configure a wildcard virtual server to load balance the traffic sent to the firewalls

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the command line interface

At the command prompt, type:

```
add lb vserver <name> ANY * *
```

### Example

```
add lb vserver Vserver-LB-1 ANY * *
```

To configure a wildcard virtual server for traffic coming from the Internet by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers and create a wildcard virtual server. Specify **ANY** in the

Protocol field and \* in the Port field.

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
  - Name—name
4. In Protocol, select ANY, and in IP Address and Port, select \*.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

## Configure the virtual server in MAC rewrite mode

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -m <RedirectionMode>
```

### Example

```
set lb vserver Vserver-LB-1 -m MAC
```

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1).
2. Edit the **Basic Settings** section and click **more**.
3. From the **Redirection Mode** drop-down list, select **MAC Based**.

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.
3. On the Advanced tab, under Redirection Mode, click MAC-Based.
4. Click OK.

## Bind firewall services to the wildcard virtual server

To bind firewall services to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

### Example

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind firewall services to the wildcard virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

## Configure a service for each virtual server

To configure a service for each virtual server by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> HTTP <port>
```

#### Example

```
add service Service-HTTP-1 10.102.29.5 HTTP 80
```

To configure a service for each virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services and configure a service for each virtual server. Specify **HTTP** in the **Protocol** field and select **HTTP** under **Available Monitors**.

1.

To configure a service for each virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
  - Service Name— name
  - Server— serverName
  - Port— port
4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.
5. Click Create, and then click Close. The service you created appears in the Services pane.

## Configure a monitor for each service

To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
bind lb monitor <monitorName> <ServiceName>
```

#### Example

```
bind mon monitor-HTTP-1 Service-HTTP-1
```

To bind a monitor to a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, double-click a service and add a monitor.

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and add a monitor.

## Configure an HTTP virtual server to balance traffic sent to the servers

To configure an HTTP virtual server to balance traffic sent to the servers by using the command line interface

At the command prompt, type:

```
add lb vserver <name> HTTP <ip> <port>
```

#### Example

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Services and configure an HTTP virtual server. Specify **HTTP** in the **Protocol** field.

1.

To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
  - Name—name
  - IP Address—IPAddress  
Note: If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, **1000:0000:0000:0000:0005:0600:700a:888b**).
  - Port—port
4. Under Protocol, select HTTP.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

## Save and Verify the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

### Example

```
save config
```

```
show lb vserver FWLBVIP2
```

```
FWLBVIP2 (*:*) - ANY Type: ADDRESS
State: UP
Last state change was at Mon Jun 14 07:22:54 2010
Time since last state change: 0 days, 00:00:32.760
Effective State: UP
Client Idle Timeout: 120 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
No. of Bound Services : 2 (Total) 2 (Active)
Configured Method: LEASTCONNECTION
Current Method: Round Robin, Reason: A new service is bound
Mode: MAC
Persistence: NONE
Connection Failover: DISABLED
```

1) fw-int-svc1 (10.102.29.5: \*) - ANY State: UP Weight: 1

2) fw-int-svc2 (10.102.29.9: \*) - ANY State: UP Weight: 1

Done

show service fw-int-svc1

fw-int-svc1 (10.102.29.5:\*) - ANY

State: DOWN

Last state change was at Thu Jul 8 14:44:51 2010

Time since last state change: 0 days, 00:01:50.240

Server Name: 10.102.29.5

Server ID : 0 Monitor Threshold : 0

Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits

Use Source IP: NO

Client Keepalive(CKA): NO

Access Down Service: NO

TCP Buffering(TCPB): NO

HTTP Compression(CMP): NO

Idle timeout: Client: 120 sec Server: 120 sec

Client IP: DISABLED

Cacheable: NO

SC: OFF

SP: OFF

Down state flush: ENABLED

1) Monitor Name: monitor-HTTP-1

State: DOWN Weight: 1

Probes: 9 Failed [Total: 9 Current: 9]

Last response: Failure - Time out during TCP connection establishment stage

Response Time: 2000.0 millisec

2) Monitor Name: ping

State: UP Weight: 1

Probes: 3 Failed [Total: 0 Current: 0]

Last response: Success - ICMP echo reply received.

Response Time: 1.275 millisec

Done

To save and verify the configuration by using the configuration utility

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
5. Navigate to Traffic Management > Load Balancing > Services.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.

## Monitoring a Firewall Load Balancing Setup in a Sandwich Environment

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

## Viewing the Statistics of a Virtual Server

Updated: 2013-09-05

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
```

### Example

```
>stat lb vserver -detail
```

```
Virtual Server(s) Summary
```

|               | vsvrIP       | port | Protocol | State | Req/s | Hits/s |  |
|---------------|--------------|------|----------|-------|-------|--------|--|
| One           | *            | 80   | HTTP     | UP    | 5/s   | 0/s    |  |
| Two           | *            | 0    | TCP      | DOWN  | 0/s   | 0/s    |  |
| Three         | *            | 2598 | TCP      | DOWN  | 0/s   | 0/s    |  |
| dnsVirtualINS | 10.102.29.90 | 53   | DNS      | DOWN  | 0/s   | 0/s    |  |
| BRVSERV       | 10.10.1.1    | 80   | HTTP     | DOWN  | 0/s   | 0/s    |  |
| LBVIP         | 10.102.29.66 | 80   | HTTP     | UP    | 0/s   | 0/s    |  |

Done

To display virtual server statistics by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers > Statistics.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

## Viewing the Statistics of a Service

Updated: 2013-08-28

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

```
stat service <name>
```

**Example**

```
stat service Service-HTTP-1
```

To view the statistics of a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

# Enterprise Environment

Mar 22, 2012

In the enterprise setup, the NetScaler is placed between the firewalls connecting to the public Internet and the internal private network and handles egress traffic. The NetScaler selects the best firewall based on the configured load balancing policy.

The following diagram shows the enterprise firewall load balancing environment

Figure 1. Firewall Load Balancing (Enterprise)

The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and vserver with type HTTP or TCP. For FTP to work, configure the service with type FTP.

## Configuring the NetScaler in an Enterprise Environment

Updated: 2013-11-08

Perform the following tasks to configure a NetScaler in an enterprise environment.

For traffic from the server (egress)

- [Enable the load balancing feature.](#)
- [Configure a wildcard service for each firewall.](#)
- [Configure a monitor for each wildcard service.](#)
- [Configure a wildcard virtual server to load balance the traffic sent to the firewalls .](#)
- [Configure the virtual server in MAC rewrite mode.](#)
- [Bind firewall services to the wildcard virtual server.](#)

For traffic across private network servers

- [Configure a service for each virtual server](#) .
- [Configure a monitor for each service](#).
- [Configure an HTTP virtual server to balance traffic sent to the servers](#).
- [Bind HTTP services to the HTTP virtual server](#) .
- [Save and Verify the Configuration](#).

## Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

### Example

```
> enable ns feature LoadBalancing
Done
> show ns feature
```

|     | Feature               | Acronym   | Status    |
|-----|-----------------------|-----------|-----------|
|     | -----                 | -----     | -----     |
| 1)  | Web Logging           | WL        | OFF       |
| 2)  | Surge Protection      | SP        | ON        |
| 3)  | <b>Load Balancing</b> | <b>LB</b> | <b>ON</b> |
| .   |                       |           |           |
| .   |                       |           |           |
| .   |                       |           |           |
| 24) | NetScaler Push        | push      | OFF       |

```
Done
```

To enable load balancing by using the configuration utility

Navigate to System > Settings and, in Configure Basic Features, select Load Balancing.

## Configure a wildcard service for each firewall

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> ANY *
```

### Example

```
add service Service-HTTP-1 10.102.29.5 ANY *
```

To configure a wildcard service for each firewall by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
  - Service Name— name
  - Server— serverName
4. In Protocol, select ANY, and in Port, select \*.
5. Click Create, and then click Close. The service you created appears in the Services pane.

## Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- add lb monitor <monitorName> <type> [-destIP <ip\_addr| ipv6\_addr| \*>] [-transparent (YES | NO )]
- bind lb monitor <monitorName> <serviceName>

### Example

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
bind monitor monitor-HTTP-1 fw-svc1
```

To create and bind a transparent monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify values as shown:
  - Name\*
  - Type\*— type
  - Destination IP
  - Transparent

\* A required parameter
4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

## Configure a wildcard virtual server to load balance the traffic sent to the firewalls

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the command line interface

At the command prompt, type:

```
add lb vserver <name> ANY * *
```

#### **Example**

```
add lb vserver Vserver-LB-1 ANY * *
```

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
  - Name—name
4. In Protocol, select ANY, and in IP Address and Port, select \*.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

## Configure the virtual server in MAC rewrite mode

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -m <RedirectionMode>
```

#### **Example**

```
set lb vserver Vserver-LB-1 -m MAC
```

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.
3. On the Advanced tab, under Redirection Mode, click MAC-Based.
4. Click OK.

## Bind firewall services to the wildcard virtual server

To bind firewall services to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

#### **Example**

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind firewall services to the wildcard virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

## Configure a service for each virtual server

To configure a service for each virtual server by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> HTTP <port>
```

#### Example

```
add service Service-HTTP-1 10.102.29.5 HTTP 80
```

To configure a service for each virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
  - Service Name— name
  - Server— serverName
  - Port— port
4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.
5. Click Create, and then click Close. The service you created appears in the Services pane.

## Configure a monitor for each service

To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
bind lb monitor <monitorName> <ServiceName>
```

#### Example

```
bind mon monitor-HTTP-1 Service-HTTP-1
```

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and add a monitor.

## Configure an HTTP virtual server to balance traffic sent to the servers

To configure an HTTP virtual server to balance traffic sent to the servers by using the command line interface

At the command prompt, type:

```
add lb vserver <name> HTTP <ip> <port>
```

#### Example

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
  - Name— name
  - IP Address— IPAddress

Note: If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, **1000:0000:0000:0000:0005:0600:700a:888b**).

- Port—port
4. Under Protocol, select HTTP.
  5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

## Bind HTTP services to the HTTP virtual server

To bind HTTP services to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

### Example

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind HTTP services to the wildcard virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

## Save and Verify the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

### Example

```
save config
```

```
show lb vserver FWLBVIP2
```

```
FWLBVIP2 (*:*) - ANY Type: ADDRESS
State: UP
Last state change was at Mon Jun 14 07:22:54 2010
Time since last state change: 0 days, 00:00:32.760
Effective State: UP
Client Idle Timeout: 120 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
No. of Bound Services : 2 (Total) 2 (Active)
Configured Method: LEASTCONNECTION
Current Method: Round Robin, Reason: A new service is bound
Mode: MAC
Persistence: NONE
Connection Failover: DISABLED
```

```
1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
```

2) fw-int-svc2 (10.102.29.9: \*) - ANY State: UP Weight: 1

Done

show service fw-int-svc1

fw-int-svc1 (10.102.29.5:\*) - ANY

State: DOWN

Last state change was at Thu Jul 8 14:44:51 2010

Time since last state change: 0 days, 00:01:50.240

Server Name: 10.102.29.5

Server ID : 0 Monitor Threshold : 0

Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits

Use Source IP: NO

Client Keepalive(CKA): NO

Access Down Service: NO

TCP Buffering(TCPB): NO

HTTP Compression(CMP): NO

Idle timeout: Client: 120 sec Server: 120 sec

Client IP: DISABLED

Cacheable: NO

SC: OFF

SP: OFF

Down state flush: ENABLED

1) Monitor Name: monitor-HTTP-1

State: DOWN Weight: 1

Probes: 9 Failed [Total: 9 Current: 9]

Last response: Failure - Time out during TCP connection establishment stage

Response Time: 2000.0 millisecc

2) Monitor Name: ping

State: UP Weight: 1

Probes: 3 Failed [Total: 0 Current: 0]

Last response: Success - ICMP echo reply received.

Response Time: 1.275 millisecc

Done

To save and verify the configuration by using the configuration utility

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
5. Navigate to Traffic Management > Load Balancing > Services.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.

## Monitoring a Firewall Load Balancing Setup in an Enterprise Environment

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

## Viewing the Statistics of a Virtual Server

Updated: 2013-09-05

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
```

### Example

```
>stat lb vserver -detail
```

Virtual Server(s) Summary

|               | vsvrIP       | port | Protocol | State | Req/s | Hits/s |  |
|---------------|--------------|------|----------|-------|-------|--------|--|
| One           | *            | 80   | HTTP     | UP    | 5/s   | 0/s    |  |
| Two           | *            | 0    | TCP      | DOWN  | 0/s   | 0/s    |  |
| Three         | *            | 2598 | TCP      | DOWN  | 0/s   | 0/s    |  |
| dnsVirtualINS | 10.102.29.90 | 53   | DNS      | DOWN  | 0/s   | 0/s    |  |
| BRVSERV       | 10.10.1.1    | 80   | HTTP     | DOWN  | 0/s   | 0/s    |  |
| LBVIP         | 10.102.29.66 | 80   | HTTP     | UP    | 0/s   | 0/s    |  |

Done

To display virtual server statistics by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers > Statistics.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

## Viewing the Statistics of a Service

Updated: 2013-08-28

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

```
stat service <name>
```

**Example**

```
stat service Service-HTTP-1
```

To view the statistics of a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

# Multiple-Firewall Environment

Sep 06, 2012

Note: This feature is available in NetScaler release 9.3.e and 10.

In a multiple-firewall environment, the NetScaler appliance is placed between two sets of firewalls, the external set connecting to the public Internet, and the internal set connecting to the internal private network. The external set typically handles the egress traffic. These firewalls mainly implement access control lists to allow or deny access to external resources. The internal set typically handles the ingress traffic. These firewalls implement security to safeguard the intranet from malicious attacks apart from load-balancing the ingress traffic. The multiple-firewall environment allows you to load-balance traffic coming from another firewall. By default, the traffic coming from a firewall is not load balanced on the other firewall across a NetScaler. Having firewall load balancing enabled on both the sides of NetScaler improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic.

Figure 1 shows a multiple-firewall load balancing environment

Figure 1. Firewall Load Balancing (multiple-firewall)

With a configuration like the one shown in Figure 1, you can configure the NetScaler to load balance the traffic through the an internal firewall even if it is load balanced by an external firewall. For example, with this feature configured, the traffic coming from the external firewalls (firewalls 1, 2, and 3) is load balanced on the internal firewalls (firewalls 4, 5, and 6) and vice versa.

Firewall load balancing is supported only for MAC mode LB virtual server.

The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.

## Configuring the NetScaler in a Multiple-Firewall Environment

Updated: 2015-05-18

To configure a NetScaler appliance in a multiple-firewall environment, you have to enable the load balancing feature, configure a virtual server to load balance the egress traffic across the external firewalls, configure a virtual server to load balance the ingress traffic across the internal firewalls, and enable firewall load balancing on the NetScaler. To configure a virtual server to load balance traffic across a firewall in the multiple-firewall environment, you need to:

1. [Configure a wildcard service for each firewall](#)
2. [Configure a monitor for each wildcard service](#)
3. [Configure a wildcard virtual server to load balance the traffic sent to the firewalls](#)
4. [Configure the virtual server in MAC rewrite mode](#)
5. [Bind firewall services to the wildcard virtual server](#)

## Enabling the load balancing feature

To configure and implement load balancing entities such as services and virtual servers, you need to enable the load balancing feature on the NetScaler device.

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature <featureName>
- show ns feature

### Example

```
enable ns feature LoadBalancing
```

```
Done
```

```
show ns feature
```

```
Feature Acronym Status
```

```

```

```
1) Web Logging WL OFF
```

```
2) Surge Protection SP ON
```

```
3) Load Balancing LB ON
```

```
.
```

```
.
```

```
.
```

```
24) NetScaler Push push OFF
```

```
Done
```

To enable load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the Settings pane, under Modes and Features, click Change basic features.

3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click Ok.

## Configuring a wildcard service for each firewall

To accept traffic from all the protocols, you need to configure wildcard service for each firewall by specifying support for all the protocols and ports.

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type the following command to configure support for all the protocols and ports:

```
add service <name>@ <serverName> <serviceType> <port_number>
```

### Example

```
add service fw-svc1 10.102.29.5 ANY *
```

To configure a wildcard service for each firewall by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Services dialog box, specify values for the following parameters as shown:
  - Service Name—name
  - Server—serverName
  - \* A required parameter
4. In Protocol, select Any and in Port, select \*.
5. Click Create, and then click Close. The service you created appears in the Services pane.

## Configuring a monitor for each service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- add lb monitor <monitorName> <type> [-destIP <ip\_addr|ipv6\_addr|\*>] [-transparent (YES | NO )]
- bind lb monitor <monitorName> <serviceName>

### Example

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
```

```
bind monitor monitor-HTTP-1 fw-svc1
```

To create and bind a transparent monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
  2. In the details pane, click Add.
  3. In the Create Monitor dialog box, specify values for the following parameters as shown:
    - Name\*
    - Type\*—type
    - Destination IP
    - Transparent
- \* A required parameter
4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

## Configuring a virtual server to load balance the traffic sent to the firewalls

To load balance any kind of traffic, you need to configure a wildcard virtual server specifying the protocol and port as any value.

To configure a virtual server to load balance the traffic sent to the firewalls by using the command line interface

At the command prompt, type the following command:

```
add lb vserver <name>@ <serviceType> <IPAddress> <port_number>
```

### Example

```
add lb vserver Vserver-LB-1 ANY * *
```

To configure a virtual server to load balance the traffic sent to the firewalls by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In Protocol, select Any, and in IP Address and Port, select \*.
4. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

## Configuring the virtual server to MAC rewrite mode

To configure the virtual server to use MAC address for forwarding the incoming traffic, you need to enable the MAC rewrite mode.

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type the following command:

```
set lb vserver <name>@ -m <RedirectionMode>
```

### Example

```
set lb vserver Vserver-LB-1 -m MAC
```

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click Open.

3. On the Advanced tab, under the Redirection Mode mode, click Open.
4. Click Ok.

## Binding firewall services to the virtual server

To access a service on NetScaler, you need to bind it to a wildcard virtual server. To bind firewall services to the virtual server by using the command line interface

At the command prompt, type the following command:

```
bind lb vserver <name>@ <serviceName>
```

### Example

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind firewall services to the virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server (for example, Service-HTTP-1).
4. Click Ok.

## Configuring the multiple-firewall load balancing on the NetScaler Appliance

To load balance traffic on both the sides of a NetScaler using firewall load balancing, you need to enable multiple-firewall load balancing by using the `vServerSpecificMac` parameter.

To configure multiple-firewall load balancing by using the command line interface

At the command prompt, type the following command:

```
set lb parameter -vServerSpecificMac <status>
```

### Example

```
set lb parameter -vServerSpecificMac ENABLED
```

To configure multiple-firewall load balancing by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Configure Load Balancing parameters).
3. In the Set Load Balancing Parameters dialog box, select the Virtual Server Specific MAC check box.
4. Click Ok.

## Saving and Verifying the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

### Example

save config

show lb vserver FWLBVIP2

```
FWLBVIP2 (*:*) - ANY Type: ADDRESS
State: UP
Last state change was at Mon Jun 14 07:22:54 2010
Time since last state change: 0 days, 00:00:32.760
Effective State: UP
Client Idle Timeout: 120 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
No. of Bound Services : 2 (Total) 2 (Active)
Configured Method: LEASTCONNECTION
Current Method: Round Robin, Reason: A new service is bound
Mode: MAC
Persistence: NONE
Connection Failover: DISABLED
```

- 1) fw-int-svc1 (10.102.29.5: \*) - ANY State: UP Weight: 1
  - 2) fw-int-svc2 (10.102.29.9: \*) - ANY State: UP Weight: 1
- Done

show service fw-int-svc1

```
fw-int-svc1 (10.102.29.5:*) - ANY
State: DOWN
Last state change was at Thu Jul 8 14:44:51 2010
Time since last state change: 0 days, 00:01:50.240
Server Name: 10.102.29.5
Server ID : 0 Monitor Threshold : 0
Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive(CKA): NO
Access Down Service: NO
TCP Buffering(TCPB): NO
HTTP Compression(CMP): NO
Idle timeout: Client: 120 sec Server: 120 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: OFF
Down state flush: ENABLED
```

- 1) Monitor Name: monitor-HTTP-1
  - State: DOWN Weight: 1
  - Probes: 9 Failed [Total: 9 Current: 9]
  - Last response: Failure - Time out during TCP connection establishment stage

Response Time: 2000.0 millisec

2) Monitor Name: ping

State: UP Weight: 1

Probes: 3 Failed [Total: 0 Current: 0]

Last response: Success - ICMP echo reply received.

Response Time: 1.275 millisec

Done

To save and verify the configuration by using the configuration utility

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
5. Navigate to Traffic Management > Load Balancing > Services.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.

## Monitoring a Firewall Load Balancing Setup in a Multiple-Firewall Environment

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

## Viewing the Statistics of a Virtual Server

Updated: 2013-09-05

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
```

### Example

```
>stat lb vserver -detail
```

Virtual Server(s) Summary

|     | vsvrIP | port | Protocol | State | Req/s | Hits/s |
|-----|--------|------|----------|-------|-------|--------|
| One | *      | 80   | HTTP     | UP    | 5/s   | 0/s    |

```
Two * 0 TCP DOWN 0/s 0/s
Three * 2598 TCP DOWN 0/s 0/s
dnsVirtualINS 10.102.29.90 53 DNS DOWN 0/s 0/s
BRVSERVER 10.10.1.1 80 HTTP DOWN 0/s 0/s
LBVIP 10.102.29.66 80 HTTP UP 0/s 0/s
Done
```

To display virtual server statistics by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers > Statistics.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

## Viewing the Statistics of a Service

Updated: 2013-08-28

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

```
stat service <name>
```

### Example

```
stat service Service-HTTP-1
```

To view the statistics of a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

# Global Server Load Balancing

Mar 22, 2012

NetScaler appliances configured for global server load balancing (GSLB) provide for disaster recovery and ensure continuous availability of applications by protecting against points of failure in a wide area network (WAN). GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers in case of an outage.

Following are some typical GSLB configurations:

- **Active-active data center setup.** Consists of multiple active data centers. Client requests are load balanced across active data centers.
- **Active-standby data center setup.** Consists of an active and a standby data center. When a failover occurs as a result of a disaster event, the standby data center becomes operational.
- **Proximity setup.** Directs client requests to the data center that is closest in geographical distance or network distance.

In a typical configuration, a local DNS server sends client requests to a GSLB virtual server, to which are bound GSLB services. A GSLB service identifies a load balancing or content switching virtual server, which can be at the local site or a remote site. If the GSLB virtual server selects a load balancing or content switching virtual server at a remote site, it sends the virtual server's IP address to the DNS server, which sends it to the client. The client then resends the request to the new virtual server at the new IP.

The GSLB entities that you must configure are the GSLB sites, the GSLB services, the GSLB virtual servers, load balancing or content switching virtual servers, and authoritative DNS (ADNS) services. You must also configure MEP. You can also configure DNS views to expose different parts of your network to clients accessing the network from different locations.

Note: To take full advantage of the NetScaler GSLB features, you should use NetScaler appliances for load balancing or content switching at each data center, so that your GSLB configuration can use the proprietary Metric Exchange Protocol (MEP) to exchange site metrics.

# How GSLB Works

May 20, 2015

With ordinary DNS, when a client sends a domain name system (DNS) request, it receives a list of IP addresses of the domain or service. Generally, the client chooses the first IP address in the list and initiates a connection with that server. The DNS server uses a technique called DNS round robin to rotate through the IPs on the list, sending the first IP address to the end of the list and promoting the others after it responds to each DNS request. This technique ensures equal distribution of the load, but it does not support disaster recovery, load balancing based on load or proximity of servers, or persistence.

When you configure GSLB on NetScaler appliances and enable Metric Exchange Protocol (MEP), the appliances use the DNS infrastructure to connect the client to the data center that best meets the criteria that you set. The criteria can designate the least loaded data center, the closest data center, the data center that responds most quickly to requests from the client's location, a combination of those metrics, and SNMP metrics. An appliance keeps track of the location, performance, load, and availability of each data center and uses these factors to select the data center to which to send a client request.

A GSLB configuration consists of a group of GSLB entities on each appliance in the configuration. These entities include GSLB sites, GSLB services, GSLB virtual servers, load balancing and/or content switching servers, and ADNS services.

This document includes the following information:

- [GSLB Sites](#)
- [GSLB Services](#)
- [GSLB Virtual Servers](#)
- [Load Balancing or Content Switching Virtual Servers](#)
- [ADNS Services](#)
- [DNS VIPs](#)

## GSLB Sites

A typical GSLB setup consists of data centers, each of which has various network appliances that may or may not be NetScaler appliances. The data centers are called GSLB sites. Each GSLB site is managed by a NetScaler appliance that is local to that site. Each of these appliances treats its own site as the local site and all other sites, managed by other appliances, as remote sites.

If the appliance that manages a site is the only NetScaler appliance in that data center, the GSLB site hosted on that appliance acts as a bookkeeping placeholder for auditing purposes, because no metrics can be collected. Typically, this happens when the appliance is used only for GSLB, and other products in the data center are used for load balancing or content switching.

## GSLB Services

A GSLB service is usually a representation of a load balancing or content switching virtual server, although it can represent any type of virtual server. The GSLB service identifies the virtual server's IP address, port number, and service type. GSLB services are bound to GSLB virtual servers on the NetScaler appliances managing the GSLB sites. A GSLB service bound to a GSLB virtual server in the same data center is local to the GSLB virtual server. A GSLB service bound to a GSLB virtual server in

a different data center is remote from that GSLB virtual server.

## GSLB Virtual Servers

A GSLB virtual server has one or more GSLB services bound to it, and load balances traffic among those services. It evaluates the configured GSLB methods (algorithms) to select the appropriate service to which to send a client request. Because the GSLB services can represent either local or remote servers, selecting the optimal GSLB service for a request has the effect of selecting the data center that should serve the client request.

The domain for which global server load balancing is configured must be bound to the GSLB virtual server, because one or more services bound to the virtual server will serve requests made for that domain.

Unlike other virtual servers configured on a NetScaler appliance, a GSLB virtual server does not have its own virtual IP address (VIP).

## Load Balancing or Content Switching Virtual Servers

Updated: 2013-09-13

A load balancing or content switching virtual server represents one or many physical servers on the local network. Clients send their requests to the load balancing or content switching virtual server's virtual IP (VIP) address, and the virtual server balances the load across the physical servers. After a GSLB virtual server selects a GSLB service representing either a local or a remote load balancing or content switching virtual server, the client sends the request to that virtual server's VIP address.

For more information about load balancing or content switching virtual servers and services, see [Load Balancing](#), or [Content Switching](#).

## ADNS Services

An ADNS service is a special kind of service that responds only to DNS requests for domains for which the NetScaler appliance is authoritative. When an ADNS service is configured, the appliance owns that IP address and advertises it. Upon reception of a DNS request by an ADNS service, the appliance checks for a GSLB virtual server bound to that domain. If a GSLB virtual server is bound to the domain, it is queried for the best IP address to which to send the DNS response.

## DNS VIPs

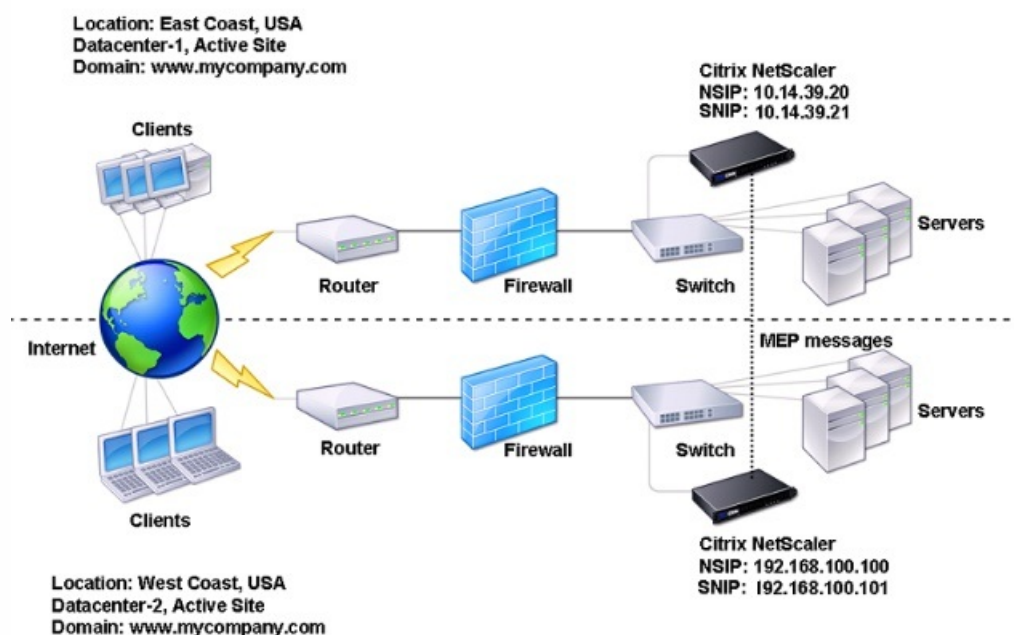

A DNS virtual IP is a virtual IP (VIP) address that represents a load balancing DNS virtual server on the NetScaler appliance. DNS requests for domains for which the NetScaler appliance is authoritative can be sent to a DNS VIP.

# Configuring Global Server Load Balancing (GSLB)

Oct 06, 2016

Global server load balancing is used to manage traffic flow to a web site hosted on two separate server farms that ideally are in different geographic locations. For example, consider a Web site, [www.mycompany.com](http://www.mycompany.com), which is hosted on two geographically separated server farms or data centers. Both server farms use NetScaler appliances. The NetScaler appliances in these server farms are set up in one-arm mode and function as authoritative DNS servers for the [www.mycompany.com](http://www.mycompany.com) domain. The following figure illustrates this configuration.

Figure 1. Basic GSLB Topology

To configure such a GSLB setup, you must first configure a standard load balancing setup for each server farm or data center. This enables you to balance load across the different servers in each server farm. Then, configure both NetScaler appliances as authoritative DNS (ADNS) servers. Next, create a GSLB site for each server farm, configure GSLB virtual servers for each site, create GLSB services, and bind the GSLB services to the GSLB virtual servers. Finally, bind the domain to the GSLB virtual servers. The GSLB configurations on the two appliances at the two different sites are identical, although the load-balancing configurations for each site is specific to that site.

Note: To configure a GSLB site in a NetScaler cluster setup, see [Setting Up GSLB in a Cluster](#).

Configuring a Standard Load Balancing Setup

Updated: 2013-08-30

A load balancing virtual server balances the load across different physical servers in the data center. These servers are represented as services on the NetScaler appliance, and the services are bound to the load balancing virtual server.

For details on configuring a basic load balancing setup, see [Load Balancing](#).

# Configuring an Authoritative DNS Service

Nov 24, 2014

When you configure the NetScaler appliance as an authoritative DNS server, it accepts DNS requests from the client and responds with the IP address of the data center to which the client should send requests.

Note: For the NetScaler to be authoritative, you must also create SOA and NS records. For more information about SOA and NS records, see "[Domain Name System](#)".

To create an ADNS service by using the command line interface

At the command prompt, type the following commands to create an ADNS service and verify the configuration:

- add service <name> <IP>@ ADNS <port>
- show service <name>

## Example

```
add service Service-ADNS-1 10.14.39.21 ADNS 53
show service Service-ADNS-1
```

To modify an ADNS service by using the command line interface

At the command prompt, type the following command:

```
set service <name> <IPAddress> ADNS <port>
```

## Example

```
set service Service-ADNS-1 10.14.39.21 ADNS 53
```

To remove an ADNS service by using the command line interface

At the command prompt, type the following command:

```
rm service <name>
```

## Example

```
rm service Service-ADNS-1
```

To configure an ADNS service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Add a new ADNS service, or select an existing service and edit its settings.

# Configuring a Basic GSLB Site

Nov 24, 2014

A GSLB site is a representation of a data center in your network and is a logical grouping of GSLB virtual servers, services, and other network entities. Typically, in a GSLB set up, there are many GSLB sites that are equipped to serve the same content to a client. These are usually geographically separated to ensure that the domain is active even if one site goes down completely. All of the sites in the GSLB configuration must be configured on every NetScaler appliance hosting a GSLB site. In other words, at each site, you configure the local GSLB site and each remote GSLB site.

Once GSLB sites are created for a domain, the NetScaler appliance sends client requests to the appropriate GSLB site as determined by the GSLB algorithms configured.

To create a GSLB site by using the command line interface

At the command prompt, type the following commands to create a GSLB site and verify the configuration:

- add gslb site <siteName> <siteIPAddress>
- show gslb site <siteName>

## Example

```
add gslb site Site-GSLB-East-Coast 10.14.39.21
```

```
show gslb site Site-GSLB-East-Coast
```

To modify or remove a GSLB Site by using the command line interface

- To modify a GSLB site, use the set gslb site command, which is just like using the add gslb site command, except that you enter the name of an existing GSLB Site.
- To unset a site parameter, use the unset gslb site command, followed by the siteName value and the name of the parameter to be reset to its default value.
- To remove a GSLB site, use the rm gslb site command, which accepts only the <name> argument.

To configure a basic GSLB site by using the configuration utility

1. Navigate to Traffic Management > GSLB > Sites.
2. Add a new GSLB site, or select an existing GSLB site and edit its settings.

To view the statistics of a GSLB site by using the command line interface

At the command prompt, type:

```
stat gslb site <siteName>
```

## Example

```
stat gslb site Site-GSLB-East-Coast
```

To view the statistics of a GSLB site by using the configuration utility

1. Navigate to Traffic Management > GSLB > Sites.
2. Select the GSLB site and click **Statistics**.

# Configuring a GSLB Service

Nov 24, 2014

A GSLB service is a representation of a load balancing or content switching virtual server. A local GSLB service represents a local load balancing or content switching virtual server. A remote GSLB service represents a load balancing or content switching virtual server configured at one of the other sites in the GSLB setup. At each site in the GSLB setup, you can create one local GSLB service and any number of remote GSLB services.

## Creating GSLB Services

### To create a GSLB service by using the command line interface

At the command prompt, type the following commands to create a GSLB service and verify the configuration:

- add gslb service <serviceName> <serverName | IP> <serviceType> <port>-siteName <string>
- show gslb service <serviceName>

#### Example

```
add gslb service Service-GSLB-1 10.14.39.14 HTTP 80 --siteName Site-GSLB-East-Coast
show gslb service Service-GSLB-1
```

### To modify or remove a GSLB service by using the command line interface

- To modify a GSLB service, use the set gslb service <serviceName> command. For this command, specify the name of the GSLB service whose configuration you want to modify. You can change the existing values of the parameters either specified by you or set by default. You can change the value of more than one parameter in the same command. Refer to the add gslb service command for details about the parameters. Example  
> set gslb service SKP\_GSLB\_NOTCNAME\_SVC2 -maxBandWidth 25 -maxClient 8  
Done  
> sh gslb service SKP\_GSLB\_NOTCNAME\_SVC2  
SKP\_GSLB\_NOTCNAME\_SVC2 (21.211.21.21: 80)- HTTP  
...  
Max Conn: 8 Max Bandwidth: 25 kbits
- To reset a parameter to its default value, you can use the unset gslb service <serviceName> command and the parameters to be unset. Example  
> unset gslb service SKP\_GSLB\_NOTCNAME\_SVC2 maxBandWidth  
Done  
> sh gslb service SKP\_GSLB\_NOTCNAME\_SVC2  
SKP\_GSLB\_NOTCNAME\_SVC2 (21.211.21.21: 80)- HTTP  
...  
Max Conn: 8 Max Bandwidth: 0 kbits
- To remove a GSLB service, use the rm gslb service <serviceName> command.

### To create a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Add a new GSLB service, or select an existing service and edit its settings.

## To view the statistics of a GSLB service by using the command line interface

At the command prompt, type:

```
stat gslb service <serviceName>
```

### **Example**

```
stat gslb service Service-GSLB-1
```

## To view the statistics of a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Select the GSLB Service and click **Statistics**.

# Configuring a GSLB Virtual Server

Jun 06, 2017

A GSLB virtual server is an entity that represents one or more GSLB services and balances traffic between them. It evaluates the configured GSLB methods or algorithms to select a GSLB service to which to send the client request.

## Note

A GSLB virtual server protocol requirement is mainly to create a relation between the virtual server and the services that are bound to the virtual server. This also keeps CLI/APIs consistent with respect to other types of virtual servers. The Service Type parameter on a service or a virtual server is not leveraged while serving the DNS requests. It is instead referenced during site persistence, monitoring, and for the purpose of doing lookups via MEP.

## Creating GSLB Virtual Servers

### To create a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to add a GSLB virtual server and verify the configuration:

- `add gslb vserver <name> <serviceType> -ipType (IPv4 | IPv6)`
- `show gslb vserver <name>`

#### Example

```
add gslb vserver Vserver-GSLB-1 HTTP -ipType IPv4
add gslb vserver Vserver-GSLB-2 HTTP -ipType IPv6
show gslb vserver Vserver-GSLB-1
show gslb vserver Vserver-GSLB-2
```

### To modify or remove a GSLB virtual server by using the command line interface

- To modify a GSLB virtual server, use the `set gslb vserver` command, which is just like using the `add gslb vserver` command, except that you enter the name of an existing GSLB virtual server.
- To reset a parameter to its default value, you can use the `unset gslb vserver` command followed by the `vserverName` value and the name of the parameter to be unset.
- To remove a GSLB virtual server, use the `rm gslb vserver` command, which accepts only the `<name>` argument.

### To configure a GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. Add a new GSLB virtual server, or select an existing GSLB virtual server and edit its settings.

### To view the statistics of a GSLB virtual server by using the command line interface

At the command prompt, type:

```
stat gslb vserver <name>
```

#### Example

```
stat gslb vserver Vserver-GSLB-1
```

## To view the statistics of a GSLB virtual server by using the configuration utility

Navigate to Traffic Management > GSLB > Virtual Servers, select the virtual server and click **Statistics**.

### Statistics of a GSLB service

When you run the `stat gslb service` command from the command line or click on the Statistics link from the configuration utility, the following details of the service will be displayed:

- **Request bytes.** Total number of request bytes received on this service or virtual server.
- **Response bytes.** Number of response bytes received by this service or virtual server.
- **Current client established connections.** Number of client connections in ESTABLISHED state.
- **Current load on the service.** Load on the service (Calculated from the load monitor bound to the service).

The data of number of requests and responses, and the number of current client and server connections may not be displayed or may not be synchronized with the data of the corresponding load balancing virtual server.

### Clearing the GSLB virtual server or service statistics

Note: This feature is available in NetScaler release 10.5.e.

You can now clear the statistics of a GSLB virtual server and service. NetScaler ADC provides the following two options to clear the statistics:

- **Basic:** Clears the statistics that are specific to the virtual server but retains the statistics that are contributed by the bound GSLB service.
- **Full:** Clears both the virtual server and the bound GSLB service statistics.

## To clear the statistics of a GSLB virtual server by using the command line interface

At the command prompt, type:

```
stat gslb vserver <name> -clearstats <basic | full>
```

### Example

```
stat gslb vserver Vserver-GSLB-1 --clearstats basic
```

## To clear the statistics of a GSLB service by using the command line interface

At the command prompt, type:

```
stat gslb service <name> -clearstats <basic | full>
```

### Example

```
stat gslb service service-GSLB-1 --clearstats basic
```

## To clear the statistics of a GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. Select the GSLB virtual server and, click **Statistics**, and then click **Clear**.
3. From the **Clear** drop-down list, select **Basic** or **Full**, and then click **OK**.

## To clear the statistics of a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Select the GSLB service and, click **Statistics**, and then click **Clear**.
3. From the **Clear** drop-down list, select **Basic** or **Full**, and then click **OK**.

### Enabling and Disabling GSLB Virtual Servers

Updated: 2014-11-21

When you create a GSLB virtual server, it is enabled by default. If you disable it, it cannot process traffic. A disabled GSLB virtual server is not included in GSLB configuration but is not removed from the NetScaler appliance.

## To enable or disable a GSLB virtual server by using the command line interface

At the command prompt, type one of the following commands:

- `enable gslb vserver <name>@`
- `disable gslb vserver <name>@`

### Example

```
enable gslb vserver Vserver-GSLB-1
disable gslb vserver Vserver-GSLB-1
```

## To enable or disable a GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. Select a virtual server and, from the **Action** list, select **enable** or **disable**.

# Binding GSLB Services to a GSLB Virtual Server

Nov 21, 2014

Once the GSLB services and virtual server are configured, relevant GSLB services must be bound to the GSLB virtual server to activate the configuration.

To bind a GSLB service to a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to bind a GSLB service to a GSLB virtual server and verify the configuration:

- `bind gslb vserver <name> -serviceName <string>`
- `show gslb vserver <name>`

## Example

```
bind gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1
show gslb vserver Vserver-GSLB-1
```

To unbind a GSLB service from a GSLB virtual server by using the command line interface

At the command prompt, type:

```
unbind gslb vserver <name> -serviceName <string>
```

To bind GSLB services by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click a virtual server.
2. Click in the **Domains** section, and configure a domain and bind the domain.

# Binding a Domain to a GSLB Virtual Server

Dec 09, 2014

To make a NetScaler appliance the authoritative DNS server for a domain, you must bind the domain to the GSLB virtual server. When you bind a domain to a GSLB virtual server, the NetScaler adds an address record for the domain, containing the name of the GSLB virtual server. The start of authority (SOA) and name server (NS) records for the GSLB domain must be added manually.

For details on configuring SOA and NS records, see "[Domain Name System](#)".

To bind a domain to a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to bind a domain to a GSLB virtual server and verify the configuration:

- `bind gslb vserver <name> -domainName <string>`
- `show gslb vserver <name>`

## Example

```
bind gslb vserver Vserver-GSLB-1 -domainName www.mycompany.com
show gslb vserver Vserver-GSLB-1
```

To unbind a GSLB domain from a GSLB virtual server by using the command line interface

At the command prompt, type:

```
unbind gslb vserver <name> -domainName <string>
```

To bind a domain to a GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server to which you want to bind the domain (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, do one of the following:
  - To create a new Domain, click Add.
  - To modify an existing Domain, select the domain, and then click Open.
4. In the Create GSLB Domain or Configure GSLB Domain dialog box, specify values for the following parameters as shown:
  - Domain Name\*—domainName (for example, www.mycompany.com)

\* A required parameter
5. Click Create.
6. Click OK.

To view the statistics of a domain by using the command line interface

At the command prompt, type:

```
stat gslb domain <name>
```

## Example

```
stat gslb domain www.mycompany.com
```

Note: To view statistics for a particular GSLB domain, enter the name of the domain exactly as it was added to the

NetScaler appliance. If you do not specify the domain name, or if you specify an incorrect domain name, statistics for all configured GSLB domains are displayed.

To view the statistics of a domain by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, select the domain, and then click Statistics.

To view the configuration details of the entities bound to a GSLB domain using the command line

Note: This feature is available in NetScaler release 10.5.e.

At the command prompt, type:

```
show gslb domain <name>
```

#### **Example**

```
show gslb domain gslb1.com
```

```
gslb1.com
```

```
gvs1 - HTTP state: DOWN
```

```
DNS Record Type: A
```

```
Configured Method: LEASTCONNECTION
```

```
Backup Method: ROUNDROBIN
```

```
Persistence Type: NONE
```

```
Empty Down Response: DISABLED
```

```
Multi IP Response: DISABLED
```

```
Dynamic Weights: DISABLED
```

```
gsvc1 (10.102.239.165: 80)- HTTP State: DOWN Weight: 1
```

```
Dynamic Weight: 0 Cumulative Weight: 1
```

```
Effective State: DOWN
```

```
Threshold : BELOW
```

```
Monitor Name : http
```

```
State: DOWN Weight: 1
```

```
Probes: 144 Failed [Total: 144 Current: 144]
```

```
Last response: Failure - TCP syn sent, reset received.
```

```
Response Time: 2000 millisec
```

```
gsvc2 (10.102.239.179: 80)- HTTP State: DOWN Weight: 1
```

```
Dynamic Weight: 0 Cumulative Weight: 1
```

```
Effective State: DOWN
```

```
Threshold : BELOW
```

```
Monitor Name : http-ecv
```

```
State: DOWN Weight: 1
```

```
Probes: 141 Failed [Total: 141 Current: 141]
```

```
Last response: Failure - TCP syn sent, reset received.
```

```
Response Time: 2000 millisec
```

```
Done
```

To view the configuration details of the entities bound to a GSLB domain by using the configuration utility

Note: This feature is available in NetScaler release 10.5.e.

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click a virtual server.
2. Click the field below the **Domains** pane.
3. In the **GSLB Virtual Server Domain Binding** dialog box, select a domain, and then click **Show Bindings**.

# Synchronizing a Configuration in a GSLB Setup

May 11, 2017

Typically, a GSLB setup has a few data centers with a GSLB site configured for each data center. In each NetScaler, participating in GSLB, configure one GSLB site as a local site and the others as remote sites. When you add another GSLB site at a later point of time, ensure that all the GSLB sites have the same configuration. To have the same configuration on all the GSLB sites, you can use the NetScaler appliance's GSLB configuration synchronization option.

The NetScaler appliance from which you use the synchronization option is referred to as the 'master node' and the GSLB sites on which the configuration is copied as 'slave nodes'. When you synchronize a GSLB configuration, the configurations on all the GSLB sites participating in the GSLB setup are made similar to that on the master node.

Synchronization (may also be referred to as 'auto sync') is carried out in the following manner:

- The master node finds the differences between the configuration of the master node and slave node, and changes the configuration of the slave node to make it similar to the master node.  
If you force a synchronization (use the 'force sync' option), the NetScaler deletes the GSLB configuration from the slave node and then configures the slave to make it similar to the master node.
- During synchronization, if a command fails, synchronization is not aborted.
- Synchronization is done only on the parent sites. If a GSLB site is configured as a child site, its configuration is not affected by synchronization.

Note:

- On the remote GSLB site RPC node, configure the firewall to accept auto-sync connections by specifying the remote site IP (cluster IP address for cluster setup) and port (3010 for RPC and 3008 for secure RPC). The source IP address that will be used for auto-sync is the NSIP of the master node (NSIP of the configuration coordinator in a cluster setup). The destination IP is the site IP (remote site IP).
- The Source IP address cannot be synchronized across the sites participating in GSLB because the source IP address for a RPC node is specific to each NetScaler appliance. Therefore, after you force a synchronization (using the `sync gslb config -forceSync` command or by selecting the ForceSync option in the NetScaler GUI), you have to manually change the source IP addresses on the other NetScaler appliances.
- Port 22 is also required for synchronizing the database files to the remote site.

If you use the `saveconfig` option, the sites that participate in the synchronization process automatically save their configuration, in the following way:

1. The master node saves its configuration immediately before it initiates the process of synchronization.
2. After the process of synchronization is complete, the slave nodes save their configuration. A slave node saves its configuration only if the configuration difference was applied successfully on it. If synchronization fails on a slave node, you must manually investigate the cause of the failure and take corrective action.

Limitations of synchronization:

- On the master node, the names of the remote GSLB sites must be identical to the names of sites configured on the NetScaler appliances hosting those sites.
- During the synchronization, traffic disruptions may occur.
- NetScaler can synchronize only up to 80000 lines of the configuration.
- Synchronization may fail:

- If the spill over method is changed from CONNECTION to DYNAMIC CONNECTION.
- If you interchange the site prefix of the GSLB services bound to a GSLB virtual server on the master node and then try to synchronize.
- If the RPC node passwords are different for NetScaler IP address (NSIP) and loopback IP address.
- If you have configured the GSLB sites as High Availability (HA) pairs, the RPC node passwords of primary and secondary nodes should be same.
- If you rename any GLSB entity that are part of your GSLB configuration (use "show gslb runningConfig" command to display the GSLB configuration). You need to use the force sync option to synchronize the configuration to other GSLB sites.

Note: To overcome the limitations due to some settings in the GSLB configuration, you can use the force sync option. But, if you use the force sync option the GSLB entities are removed and re-added to the configuration and the GSLB statistics are reset to zero. Hence the traffic is disrupted during the configuration change.

Before you start the synchronization of a GSLB setup, make sure that:

- On all the GSLB sites including the master node, management access should be enabled for the IP address of the corresponding GSLB site. The IP address of a GSLB site must be an IP address owned by the NetScaler. For more information about adding the GSLB site IP addresses and enabling Management Access, see "[Configuring a Basic GSLB Site](#)" and "[Configuring NetScaler-Owned IP Addresses](#)".
- The GSLB configuration on the NetScaler appliance that is considered as the master node is complete and appropriate to be copied on all the sites.
- If you are synchronizing the GSLB configuration for the first time, all the sites participating in GSLB need to have the GSLB site entity of their respective local sites.
- You are not synchronizing sites that, by design, do not have the same configuration.

Important: After a GSLB configuration is synchronized, the configuration cannot be rolled back on any of the GSLB sites. Run the sync gslb config command only if you are sure that the synchronization process will not overwrite the configuration on the remote site. Site synchronization is undesirable when the local and remote sites have different configurations by design, and can lead to site outage. If some commands fail and some commands succeed, the successful commands cannot be rolled back.

To synchronize a GSLB configuration by using the command line interface

At the command prompt, type the following commands to synchronize GSLB sites and verify the configuration:

- sync gslb config [-preview | -forceSync <string> | -nowarn | -saveconfig] [-debug]
- show gslb syncStatus

## Example

```
> sync gslb config
[WARNING]: Syncing config may cause configuration loss on other site.
Please confirm whether you want to sync-config (Y/N)? [N]:y
Sync Time: Dec 9 2011 10:56:9
Retrieving local site info: ok
Retrieving all participating gslb sites info: ok
Gslb_site1[Master]:
 Getting Config: ok
Gslb_site2[Slave]:
```

Getting Config: ok  
Comparing config: ok  
Applying changes: ok

Done

To synchronize a GSLB configuration by using the configuration utility

1. Navigate to Traffic Management > GSLB and, under GSLB Configuration, click **Synchronize configuration on remote sites** and synchronize the GSLB configuration.

# Configuring the Metrics Exchange Protocol (MEP)

May 21, 2015

The data centers in a GSLB setup exchange metrics with each other through the metrics exchange protocol (MEP), which is a proprietary protocol for Citrix NetScaler appliances. The exchange of the metric information begins when you create a GSLB site. These metrics comprise load, network, and persistence information.

MEP is required for health checking of data centers to ensure their availability. A connection for exchanging network metrics (round-trip time) can be initiated by either of the data centers involved in the exchange, but a connection for exchanging site metrics is always initiated by the data center with the lower IP address. By default, the data center uses a subnet IP (SNIP) address (SNIP) or a mapped IP (MIP) address to establish a connection to the IP address of a different data center. However, you can configure a specific SNIP, MIP, or virtual IP (VIP) address, or the NetScaler IP (NSIP) address as the source IP address for metrics exchange. The communication process between GSLB sites uses TCP port 3011 or 3009, so this port must be open on firewalls that are between the NetScaler appliances.

**Note:** You cannot configure a GSLB site IP address as the source IP address for site metrics exchange.

If the source and target sites (the site that initiates a MEP connection and the site that receives the connection request, respectively) have both private and public IP addresses configured, the sites exchange MEP information by using the public IP addresses.

You can also bind monitors to check the health of remote services as described in "[Monitoring GSLB Services](#)." When monitors are bound, metric exchange does not control the state of the remote service. If a monitor is bound to a remote service and metric exchange is enabled, the monitor controls the health status. Binding the monitors to the remote service enables the NetScaler appliance to interact with a non-NetScaler load balancing device. The NetScaler can monitor non-NetScaler devices but cannot perform load balancing on them unless monitors are bound to all GSLB services and only static load balancing methods (such as the round robin, static proximity, or hash-based methods) are used.

This document includes the following information:

- [Enabling Site Metric Exchange](#)
- [Enabling Network Metric Information Exchange](#)
- [Enabling Persistence Information Exchange](#)

## Enabling Site Metric Exchange

Updated: 2014-11-24

Site metrics exchanged between the GSLB sites include the status of each load balancing and content switching virtual server, the current number of connections, the current packet rate, and current bandwidth usage information.

The NetScaler appliance needs this information to perform load balancing between the sites. The site metric exchange interval is 1 second. A remote GSLB service must be bound to a local GSLB virtual server to enable the exchange of site metrics with the remote service.

## To enable or disable site metric exchange by using the command line interface

At a command prompt, type the following commands to enable or disable site metric exchange and verify the

configuration:

- `set gslb site <siteName> -metricExchange(ENABLED | DISABLED)`
- `show gslb site <siteName>`

### Example

```
set gslb site Site-GSLB-East-Coast -metricExchange ENABLED
set gslb site Site-GSLB-East-Coast -metricExchange DISABLED
show gslb site Site-GSLB-East-Coast
```

## To enable or disable site metric exchange by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Sites**, select the site.
2. In the **Configure GSLB Site** dialog box, select the **Metric Exchange** option.

### Enabling Network Metric Information Exchange

Updated: 2014-11-24

If your GSLB sites use the round trip time (RTT) load balancing method, you can enable or disable the exchange of RTT information about the client's local DNS service. This information is exchanged every 5 seconds.

For details about changing the GSLB method to RTT, see "[Changing the GSLB Method.](#)"

## To enable or disable network metric information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable network metric information exchange and verify the configuration:

- `set gslb site <siteName> -nwmetricExchange (ENABLED | DISABLED)`
- `show gslb site <<siteName>`

### Example

```
set gslb site Site-GSLB-East-Coast -nwmetricExchange ENABLED
set gslb site Site-GSLB-East-Coast -nwmetricExchange DISABLED
show gslb site Site-GSLB-East-Coast
```

## To enable or disable network metric information exchange by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Sites**.
2. In the **Configure GSLB Site** dialog box, select the **Network Metric Exchange** option.

### Enabling Persistence Information Exchange

Updated: 2014-11-24

You can configure NetScaler appliance to provide persistent connections, so that a client transmission to any virtual server

in a group can be directed to a server that has received previous transmissions from the same client.

You can enable or disable the exchange of persistence information at each site. This information is exchanged every 5 seconds between NetScaler appliances participating in GSLB.

For details about configuring persistence, see "[Configuring Persistent Connections](#)".

## To enable/disable persistence information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable persistence information exchange and verify the configuration:

- **set gslb site** <siteName> **-sessionExchange (ENABLED| DISABLED)**
- **show gslb site** <siteName>

### Example

```
set gslb site Site-GSLB-East-Coast -sessionExchange ENABLED
set gslb site Site-GSLB-East-Coast -sessionExchange DISABLED
show gslb site Site-GSLB-East-Coast
```

## To enable/disable persistence information exchange by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Sites**, and double-click the site.
2. In the **Configure GSLB Site** dialog box, select the **Persistence Session Entry Exchange** option.

# Configuring Site-to-Site Communication

May 11, 2017

GSLB site-to-site communication is between the remote procedure call (RPC) nodes that are associated with the communicating sites. A master GSLB site establishes connections with slave sites to synchronize GSLB configuration information and to exchange site metrics.

An RPC node is created automatically when a GSLB site is created, and is assigned an internally generated user name and password. The NetScaler appliance uses this user name and password to authenticate itself to remote GSLB sites during connection establishment. No configuration steps are necessary for an RPC node, but you can specify a password of your choice, enhance security by encrypting the information that GSLB sites exchange, and specify a source IP address for the RPC node.

The appliance needs a NetScaler-owned IP address to use as the source IP address when communicating with other GSLB sites. By default, the RPC nodes use either a subnet IP (SNIP) address or a mapped IP (MIP) address, but you might want to specify an IP address of your choice.

The following topics describe the behavior and configuration of RPC nodes on the NetScaler appliance:

- [Changing the Password of an RPC Node](#)
- [Encrypting the Exchange of Site Metrics](#)
- [Configuring the Source IP Address for an RPC Node](#)

## Changing the Password of an RPC Node

Updated: 2014-11-21

You can secure the communication between sites in your GSLB setup by changing the password of each RPC node. After you change the password for the RPC node of the local site, you must manually propagate the change to the RPC node at each of the remote sites.

The password is stored in encrypted form. You can verify that the password has changed by using the `show rpcNode` command to compare the encrypted form of the password before and after the change.

## To change the password of an RPC node by using the command line interface

At the command line, type the following commands to change the password of an RPC node:

- `set ns rpcNode <IPAddress> {-password}`
- `show ns rpcNode`

### Example

```
> set ns rpcNode 192.0.2.4 -password mypassword
Done
> show ns rpcNode
.
.
.
2) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e
SrcIP: * Secure: OFF
```

Done  
>

## To unset the password of an RPC node by using the command line interface

To unset the password of an RPC node by using the NetScaler command line, type the `unset rpcNode` command, the IP address of the RPC node, and the password parameter, without a value.

## To change the password of an RPC node by using the configuration utility

Navigate to `System > Network > RPC`, select the RPC node, and change the password.

### Encrypting the Exchange of Site Metrics

Updated: 2014-11-24

You can secure the information that is exchanged between GSLB sites by setting the secure option for the RPC nodes in the GSLB setup. With the secure option set, the NetScaler appliance encrypts all communication sent from the node to other RPC nodes.

## To encrypt the exchange of site metrics by using the command line interface

At the command prompt, type the following commands to encrypt the exchange of site metrics and verify the configuration:

- `set ns rpcNode <IPAddress> [-secure ( YES | NO )]`
- `show rpcNode`

### Example

```
> set rpcNode 192.0.2.4 -secure YES
Done
>
> show rpcNode
.
.
.
3) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP: 192.0.2.3 Secure: ON
Done
>
```

## To unset the secure parameter by using the command line interface

To unset the secure parameter by using the NetScaler command line, type the `unset rpcNode` command, the IP address of the RPC node, and the secure parameter, without a value.

## To encrypt the exchange of site metrics by using the NetScaler configuration utility

1. Navigate to `System > Network > RPC` and double-click a RPC node.
2. Select the **Secure** option, and click **OK**.

### Configuring the Source IP Address for an RPC Node

Updated: 2014-11-24

By default, the NetScaler appliance uses a NetScaler-owned subnet IP (SNIP) address or mapped IP (MIP) address as the source IP address for an RPC node, but you can configure the appliance to use a specific SNIP address or MIP address. If neither a SNIP address nor a MIP address is available, the GSLB site cannot communicate with other sites. In such a scenario, you must configure either the NetScaler IP (NSIP) address or a virtual IP (VIP) address as the source IP address for an RPC node. A VIP address can be used as the source IP address of an RPC node only if the RPC node is a remote node. If you configure a VIP address as the source IP address and remove the VIP address, the appliance uses a SNIP address or a MIP address.

## To specify a source IP address for an RPC node by using the command line interface

At the command prompt, type the following commands to change the source IP address for an RPC node and verify the configuration:

- `set ns rpcNode <IPAddress> [-srcIP <ip_addr | ipv6_addr | *>]`
- `show ns rpcNode`

### Example

```
> set rpcNode 192.0.2.4 -srcIP 192.0.2.3
Done
> show rpcNode
.
.
.
2) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP: 192.0.2.3 Secure: OFF
Done
>
```

## To unset the source IP address parameter by using the command line interface

To unset the source IP address parameter by using the NetScaler command line, type the `unset rpcNode` command, the IP address of the RPC node, and the `srcIP` parameter, without a value.

## To specify a source IP address for an RPC node by using the NetScaler configuration utility

1. Navigate to **System > Network > RPC** and double-click a RPC node.
2. In the **Source IP Address** field, enter the IP address that you want the RPC node to use as the source IP address and click **OK**.

### Important

The source IP address cannot be synchronized across the sites participating in GSLB because the source IP address for a RPC node is specific to each NetScaler appliance. Therefore, after you force a synchronization (using the `sync gslb config -forceSync` command or by selecting the ForceSync option in the NetScaler GUI), you have to manually change the source IP addresses on the other NetScaler appliances.

# Customizing Your GSLB Configuration

May 21, 2015

Once your basic GSLB configuration is operational, you can customize it by modifying the bandwidth of a GSLB service, configuring CNAME based GSLB services, static proximity, dynamic RTT, persistent connections, or dynamic weights for services, or changing the GSLB Method.

You can also configure monitoring for GSLB services to determine their states.

These settings depend on your network deployment and the types of clients you expect to connect to your servers.

This document includes the following information:

- [Modifying Maximum Connections or Maximum Bandwidth for a GSLB Service](#)
- [Creating CNAME-Based GSLB Services](#)
- [Configuring Transition Out-Of-Service State \(TROFS\) in GSLB](#)
- [Configuring Dynamic Weights for Services](#)

## Modifying Maximum Connections or Maximum Bandwidth for a GSLB Service

Updated: 2014-11-26

You can restrict the number of new clients that can simultaneously connect to a load balancing or content switching virtual server by configuring the maximum number of clients and/or the maximum bandwidth for the GSLB service that represents the virtual server.

## To modify the maximum clients or bandwidth of a GSLB service by using the command line interface

At the command prompt, type the following command to modify the maximum number of client connections or the maximum bandwidth of a GSLB service and verify the configuration:

- `set gslb service <serviceName> [-maxClients <positive_integer>] [-maxBandwidth <positive_integer>]`
- `show gslb service <serviceName>`

### Example

```
set gslb service Service-GSLB-1 -maxBandwidth 100 -maxClients 100
show gslb service Service-GSLB-1
```

## To modify the maximum clients or bandwidth of a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services, and double-click a service.
2. Click in the **Other Settings** section and set the following parameters:
  - Max Clients—maxClients
  - Max Bandwidth—maxBandwidth

## Creating CNAME-Based GSLB Services

Updated: 2014-11-24

To configure a GSLB service, you can use the IP address of the server or a canonical name of the server. If you want to run multiple services (like an FTP and a Web server, each running on different ports) from a single IP address or run multiple HTTP services on the same port, with different names, on the same physical host, you can use canonical names (CNAMES) for the services.

For example, you can have two entries in DNS as ftp.example.com and www.example.com for FTP services and HTTP services on the same domain, example.com. CNAME-based GSLB services are useful in a multilevel domain resolver configuration or in multilevel domain load balancing. Configuring a CNAME-based GSLB service can also help if the IP address of the physical server is likely to change.

If you configure CNAME-based GSLB services for a GSLB domain, when a query is sent for the GSLB domain, the NetScaler appliance provides a CNAME instead of an IP address. If the A record for this CNAME record is not configured, the client must query the CNAME domain for the IP address. If the A record for this CNAME record is configured, the NetScaler provides the CNAME with the corresponding A record (IP address). The NetScaler appliance handles the final resolution of the DNS query, as determined by the GSLB method. The CNAME records can be maintained on a different NetScaler appliance or on a third-party system.

In an IP-address-based GSLB service, the state of a service is determined by the state of the server that it represents. However, a CNAME-based GSLB service has its state set to UP by default; the virtual server IP (VIP) address or metric exchange protocol (MEP) are not used for determining its state. If a desktop-based monitor is bound to a CNAME-based GSLB service, the state of the service is determined according to the result of the monitor probes.

You can bind a CNAME-based GSLB service only to a GSLB virtual server that has the DNS Record Type as CNAME. Also, a NetScaler appliance can contain at most one GSLB service with a given CNAME entry.

The following are some of the features supported for a CNAME-based GSLB service:

- GSLB-policy based site affinity is supported, with the CNAME as the preferred location.
- Source IP persistence is supported. The persistency entry contains the CNAME information instead of the IP address and port of the selected service.

The following are the limitations of CNAME-based GSLB services:

- Site persistence is not supported, because the service referenced by a CNAME can be present at any third-party location.
- Multiple-IP-address response is not supported because one domain cannot have multiple CNAME entries.
- Source IP Hash and Round Robin are the only load balancing methods supported. The Static Proximity method is not supported because a CNAME is not associated with an IP address and static proximity can be maintained only according to the IP addresses.

Note: The Empty-Down-Response feature should be enabled on the GSLB virtual server to which you bind the CNAME-based GSLB service. If you enable the Empty-Down-Response feature, when a GSLB virtual server is DOWN or disabled, the response to a DNS query, for the domains bound to this virtual server, contains an empty record without any IP addresses, instead of an error code.

## To create a CNAME-based GSLB service by using the command line interface

At the command prompt, type:

```
add gslb service <serviceName> -cnameEntry <string> -siteName <string>
```

### Example

```
add gslb service Service-GSLB-1 -cnameEntry transport.mycompany.com -siteName Site-GSLB-East-Coast
add gslb service Service-GSLB-2 -cnameEntry finance.mycompany.com -siteName Site-GSLB-West-Coast
```

## To create a CNAME-based GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Create a service, and set the **Type to Canonical Name Based**.

### Configuring Transition Out-Of-Service State (TROFS) in GSLB

When you configure persistence on a GSLB virtual server to which a service is bound, the service continues to serve requests from the client even after it is disabled, accepting new requests or connections only to honor persistence. After a configured period of time, known as the graceful shutdown period, no new requests or connections are directed to the service, and all of the existing connections are closed.

When disabling a service, you can specify a graceful shutdown period, in seconds, by using the delay argument. During the graceful shutdown period, if the service is bound to a virtual server, its state appears as Out of Service.

### Configuring Dynamic Weights for Services

Updated: 2015-06-02

In a typical network, there are servers that have a higher capacity for traffic than others. However, with a regular load balancing configuration, the load is evenly distributed across all services even though different services represent servers with different capacities.

To optimize your GSLB resources, you can configure dynamic weights on a GSLB virtual server. The dynamic weights can be based on either the total number of services bound to the virtual server or the sum of the weights of the individual services bound to the virtual server. Traffic distribution is then based on the weights configured for the services.

When dynamic weights are configured on the GSLB virtual server, requests are distributed according to the load balancing method, the weight of the GSLB service, and the dynamic weight. The product of the weight of the GSLB service and the dynamic weight is known as the cumulative weight. Therefore, when dynamic weight is configured on the GSLB virtual server, requests are distributed on the basis of the load balancing method and the cumulative weight.

When dynamic weight for a virtual server is disabled, the numerical value is set to 1. This ensures that the cumulative weight is a non-zero integer at all times.

Dynamic weight can be based on the total number of active services bound to load balancing virtual servers or on the weights assigned to the services.

Consider a configuration with two GSLB sites configured for a domain and each site has two services that can serve the client. If a service at either site goes down, the other server in that site has to handle twice as much traffic as a service at the other site. If dynamic weight is based on the number of active services, the site with both services active has twice the weight of the site with one service down and therefore receives twice as much traffic.

Alternatively, consider a configuration in which the services at the first site represent servers that are twice as powerful as servers at the second site. If dynamic weight is based on the weights assigned to the services, twice as much traffic can be

sent to the first site as to the second.

Note: For details on assigning weights to load balancing services, see "[Assigning Weights to Services](#)".

As an illustration of how dynamic weight is calculated, consider a GSLB virtual server that has a GSLB service bound to it. The GSLB service represents a load balancing virtual server that in turn has two services bound to it. The weight assigned to the GSLB service is 3. The weights assigned to the two services are 1 and 2 respectively. In this example, when dynamic weight is set to:

- **Disabled:** The cumulative weight of the GSLB virtual server is the product of the dynamic weight (disabled = 1) and the weight of the GSLB service (3), so the cumulative weight is 3.
- **SERVICECOUNT:** The count is the sum of the number of services bound to the load balancing virtual servers corresponding to the GSLB service (2), and the cumulative weight is the product of the dynamic weight (2) and the weight of the GSLB service (3), which is 6.
- **SERVICEWEIGHT:** The dynamic weight is the sum of the number of services bound to the GSLB service (2), and the cumulative weight is the product of the dynamic weight (2) and the weight of the GSLB service (3), which is 6.

Note: Dynamic weights are not applicable when content switching virtual servers are configured.

## To configure a GSLB virtual server to use dynamic weights by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -dynamicWeight SERVICECOUNT | SERVICEWEIGHT
```

### Example

```
set gslb vserver vserver-GSLB-1 -dynamicWeight SERVICECOUNT
```

## To set GSLB virtual server to use dynamic weights by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers, double-click the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
2. Click the **Method** section and, from the **Dynamic Weight** drop-down list, select **SERVICECOUNT** or **SERVICEWEIGHT**.

# Changing the GSLB Method

Mar 22, 2012

Unlike traditional DNS servers that simply respond with the IP addresses of the configured servers, a NetScaler appliance configured for GSLB responds with the IP addresses of the services, as determined by the configured GSLB method. By default, the GSLB virtual server is set to the least connection method. If all GSLB services are down, the NetScaler responds with the IP addresses of all the configured GSLB services.

GSLB methods are algorithms that the GSLB virtual server uses to select the best-performing GSLB service. After the host name in the Web address is resolved, the client sends traffic directly to the resolved service IP address.

The NetScaler appliance provides the following GSLB methods:

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

For GSLB methods to work with a remote site, either MEP must be enabled or explicit monitors must be bound to the remote services. If MEP is disabled, RTT, Least Connections, Least Bandwidth, Least Packets and Least Response Time methods default to Round Robin.

The Static Proximity and RTT load balancing methods are specific to GSLB.

Specifying a GSLB Method Other than Static Proximity or Dynamic (RTT)

Updated: 2013-11-11

For information about the Round Robin, Least Connections, Least Response Time, Least Bandwidth, Least Packets, Source IP Hash, or Custom Load method, see "[Load Balancing](#)."

## To change the GSLB method by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -lbMethod GSLBMethod
```

### Example

```
set gslb vserver Vserver-GSLB-1 -lbMethod ROUNDROBIN
```

## To change the GSLB method by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the details pane, select a GSLB virtual server and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Method and Persistence tab, under Method, select a method from the Choose Method list.

4. Click OK, and verify that the method you selected appears under Details at the bottom of the screen.

# Configuring Static Proximity

May 22, 2015

The static proximity method for GSLB uses an IP-address based static proximity database to determine the proximity between the client's local DNS server and the GSLB sites. The NetScaler appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the NetScaler appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

For the static proximity method to work, you must either configure the NetScaler appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the GSLB method.

This document includes the following information:

- [Adding a Location File to Create a Static Proximity Database](#)
- [Adding Custom Entries to a Static Proximity Database](#)
- [Setting the Location Qualifiers](#)
- [Specifying the Proximity Method](#)
- [Synchronizing GSLB Static Proximity Database](#)

# Adding a Location File to Create a Static Proximity Database

Oct 09, 2016

A static proximity database is a UNIX-based ASCII file. Entries added to this database from a location file are called static entries. Only one location file can be loaded on a NetScaler appliance. Adding a new location file overrides the existing file. The number of entries in the static proximity database is limited by the configured memory in the NetScaler appliance.

The static proximity database can be created in the default format or in a format derived from commercially configured third party databases (such as [www.maxmind.com](http://www.maxmind.com) and [www.ip2location.com](http://www.ip2location.com)).

The NetScaler ADC includes an IP geolocation database, GeoLite2 (published by MaxMind). The database is available in a format supported by NetScaler ADC at: `/var/netscaler/inbuilt_db/Citrix_Netscaler_InBuilt_GeoIP_DB.csv`. You can use this IP geolocation database as the location file for the static proximity based GSLB method or in location based policies.

**Note:** The ADC includes the GeoLite2 database available from <http://www.maxmind.com>.

These databases vary in the details they provide. There is no strict enforcement of the database file format, except that the default file has format tags. The database files are ASCII files that use a comma as the field delimiter. There are differences in the structure of fields and the representation of IP addresses in the locations.

The format parameter describes the structure of the file to the NetScaler appliance. Specifying an incorrect value for the format option can corrupt the internal data.

Note: The default location of the database file is `/var/netscaler/locdb`, and on a high availability (HA) setup, an identical copy of the file must be present in the same location on both NetScaler appliances.

The following abbreviations are used in this section:

- **CSHN.** Short name of a country based on the country code standard of ISO-3166.
- **LCN.** Long name of the country.
- **RC.** Region code based on ISO-3166-2 (for US and Canada). The region code "FIPS-10-4" is used for the other regions.

Note: Some databases provide short country names according to ISO-3166 and long country names as well. The NetScaler uses short names when storing and matching qualifiers.

To create a static proximity database, log on to the UNIX shell of the NetScaler appliance and use an editor to create a file with the location details in one of the NetScaler-supported formats.

To add a static location file by using the command line interface

At the command prompt, type:

- `add locationFile <locationFile> [-format <format>]`
- `show locationFile`

## Example

```
> add locationFile /var/nsmapi/locdb/nsgeo1.0 -format netscaler
Done
> show locationFile
Location File: /var/nsmapi/locdb/nsgeo1.0
```

Format: netscaler

Done

>

To add a static location file by using the configuration utility

1. Navigate to AppExpert > Location, click the **Static Database** tab.
2. Click **Add** to add a static location file.

You can view an imported location file database by using the View Database dialog box in the configuration utility. There is no NetScaler command line equivalent.

To view a static location file by using the configuration utility

1. Navigate to AppExpert > Location, click the **Static Database** tab.
2. Select a static location file, and from the **Action** list, click **View Database**.

To convert a location file into the netscaler format

By default, when you add a location file, it is saved in the netscaler format. You can convert a location file of other formats into the netscaler format.

Note: The nsmmap option can be accessed only from the command line interface. The conversion is possible only into the netscaler format.

To convert the static database format, at the NetScaler command prompt, type the following command:

```
nsmmap -f <inputFileFormat> -o <outputFileName> <inputFileName>
```

## Example

```
nsmmap -f ip-country-region-city -o nsfile.ns ip-country-region-city.csv
```

# Adding Custom Entries to a Static Proximity Database

Jan 22, 2015

Custom entries take precedence over static entries in the proximity database. You can add a maximum of 500 custom entries. For a custom entry, denote all omitted qualifiers with an asterisk (\*) and, if qualifiers have a period or space in the name, enclose the parameter in double quotation marks. The first 31 characters are evaluated for each qualifier. You can also provide the longitude and latitude of the geographical location of the IP address-range for selecting a service with the static proximity GSLB method.

To add custom entries by using the command line interface

At the command prompt, type the following commands to add a custom entry to the static proximity database and verify the configuration:

- add location < IPfrom> < IPTo> <preferredLocation> [-longitude <integer>][-latitude <integer>]]
- show location

## Example

```
>add location 192.168.100.1 192.168.100.100 *.us.ca.mycity
>show location
```

Parameters for adding custom entries

### IPfrom

First IP address in the range, in dotted decimal notation. This is a mandatory argument.

### IPto

Last IP address in the range, in dotted decimal notation. This is a mandatory argument.

### preferredLocation

String of qualifiers, in dotted notation, describing the geographical location of the IP address range. Each qualifier is more specific than the one that precedes it, as in continent.country.region.city.isp.organization. For example, "NA.US.CA.San Jose.ATT.citrix".

Note: A qualifier that includes a dot (.) or space ( ) must be enclosed in double quotation marks.

This is a mandatory argument. Maximum Length: 197

### longitude

Numerical value, in degrees, specifying the longitude of the geographical location of the IP address-range.

Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location.

Maximum value: 180

### latitude

Numerical value, in degrees, specifying the latitude of the geographical location of the IP address-range.

Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location.

Maximum value: 180

To add custom entries by using the configuration utility

Navigate to AppExpert > Location, click the **Custom Entries** tab, and add the custom entries.

# Setting the Location Qualifiers

Nov 24, 2014

The database used to implement static proximity contains the location of the GSLB sites. Each location contains an IP address range and up to six qualifiers for that range. The qualifiers are literal strings and are compared in a prescribed order at run time. Every location must have at least one qualifier. The meaning of the qualifiers (context) is defined by the qualifier labels, which are user defined. The NetScaler has two built-in contexts:

Geographic context, which has the following qualifier labels:

- Qualifier 1 – “Continent”
- Qualifier 2 – “Country”
- Qualifier 3 – “State”
- Qualifier 4 – “City”
- Qualifier 5 – “ISP”
- Qualifier 6 – “Organization”

Custom entries, which have the following qualifier labels:

- Qualifier 1 – “Qualifier 1”
- Qualifier 2 – “Qualifier 2”
- Qualifier 3 – “Qualifier 3”
- Qualifier 4 – “Qualifier 4”
- Qualifier 5 – “Qualifier 5”
- Qualifier 6 – “Qualifier 6”

If the geographic context is set with no Continent qualifier, Continent is derived from Country. Even the built-in qualifier labels are based on the context, and the labels can be changed. These qualifier labels specify the locations mapped with the IP addresses used to make static proximity decisions.

To perform a static proximity-based decision, the NetScaler appliance compares the location attributes (qualifiers) derived from the IP address of the local DNS server resolver with the location attributes of the participating sites. If only one site matches, the appliance returns the IP address of that site. If there are multiple matches, the site selected is the result of a round robin on the matching GSLB sites. If there is no match, the site selected is a result of a round robin on all configured sites. A site that does not have any qualifiers is considered a match.

To set the location qualifiers by using the command line interface

At the command prompt, type:

```
set locationparameter -context <context> -q1label <string> [-q2label <string>] [-q3label <string>] [-q4label <string>] [-q5label <string>] [-q6label <string>]
```

## Example

```
set locationparameter -context custom -q1label asia
```

To set the location qualifiers by using the configuration utility

1. Navigate to AppExpert > Location.
2. From the **Action** list, click **Location Parameters** and set the location qualifiers.

# Specifying the Proximity Method

Nov 24, 2014

When you have configured the static proximity database, you are ready to specify static proximity as the GSLB method. To specify static proximity by using the command line interface

At the command prompt, type the following commands to configure static proximity and verify the configuration:

- `set gslb vserver <name> -lbMethod STATICPROXIMITY`
- `show gslb vserver <name>`

## Example

```
set gslb vserver Vserver-GSLB-1 -lbMethod STATICPROXIMITY
show gslb vserver
```

To specify static proximity by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server.
2. Click the **Method** section and from the **Choose Method** drop-down list, select **STATICPROXIMITY**.

# Synchronizing GSLB Static Proximity Database

Apr 08, 2014

Synchronizing a global server load balancing (GSLB) static proximity database requires that one of the sites be identified as the master GSLB node. Any site in the topology can be designated as the master node. The rest of the GSLB nodes are automatically designated as slave nodes.

Synchronizing GSLB static proximity databases synchronizes the files in the `/var/netscaler/locdb` directory across the slave nodes. During the synchronization process, the master node fetches the running configuration from each of the slave nodes and compares it to the configuration on the master node. The master GSLB node uses the `rsync` program to synchronize the static proximity database across the slave nodes. To speed up the synchronization process, the `rsync` program makes only enough changes to eliminate the differences between the two files. The synchronization process cannot be rolled back.

The following example synchronizes Site2, which is a slave site, to master site Site1. The administrator enters the **sync gslb config** command on Site1:

```
sync gslb config -nowarn
Sync Time: Feb 24 2014 14:56:16
Retrieving local site info: ok
Retrieving all participating gslb sites info:
0 bytes in 0 blocks
ok
site1[Master]:
 Getting Config: ok
site2[Slave]:
 Syncing gslb static proximity database: ok
 Getting Config: ok
 Comparing config: ok
 Applying changes: ok
Done
```

# Configuring the Dynamic Method (RTT)

May 22, 2015

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client's local DNS server and a data resource. To measure dynamic RTT, the NetScaler appliance probes the client's local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value.

When a client's DNS request for a domain comes to the NetScaler appliance configured as the authoritative DNS for that domain, the appliance uses the RTT value to select the IP address of the best performing site to send it as a response to the DNS request.

The NetScaler appliance uses different mechanisms, such as ICMP echo request / reply (PING), UDP, and TCP to gather the RTT metrics for connections between the local DNS server and participating sites. The appliance first sends a ping probe to determine the RTT. If the ping probe fails, a DNS UDP probe is used. If that probe also fails, the appliance uses a DNS TCP probe.

These mechanisms are represented on the Netscaler appliance as Load Balancing Monitors and are easily identified due to their use of the "ldns" prefix. The three monitors, in their default order, are:

- ldns-ping
- ldns-dns
- ldns-tcp

These monitors are built in to the appliance and are set to safe defaults, but may be customized just like any other monitor on the appliance.

The default order may also be changed by setting it explicitly as a GSLB parameter. For example, to set the order to be the DNS UDP query followed by the PING and then TCP, type the following command:

```
set gslb parameter -ldnsprobeOrder DNS PING TCP
```

Unless they have been customized, the NetScaler appliance performs UDP and TCP probing on port 53, however unlike regular load balancing monitors the probes need not be successful in order to provide valid RTT information. ICMP port unavailable messages, TCP Resets and DNS error responses, which would usually constitute a failure are all acceptable for calculating the RTT value.

Once the RTT data has been compiled, the Netscaler uses the proprietary metrics exchange protocol (MEP) to exchange RTT values between participating sites. After calculating RTT metrics, the appliance sorts the RTT values to identify the data center with the best (smallest) RTT metric."

If RTT information is not available (for example, when a client's local DNS server accesses the site for the first time), the NetScaler appliance selects a site by using the round robin method and directs the client to the site.

To configure the dynamic method, you configure the site's GSLB virtual server for dynamic RTT. You can also set the interval at which local DNS servers are probed to a value other than the default.

This document includes the following information:

- [Configuring a GSLB Virtual Server for Dynamic RTT](#)

- [Setting the Probing Interval of Local DNS Servers](#)

## Configuring a GSLB Virtual Server for Dynamic RTT

Updated: 2014-11-24

To configure a GSLB virtual server for dynamic RTT, you specify the RTT load balancing method.

The NetScaler appliance regularly validates the timing information for a given local server. If a change in latency exceeds the configured tolerance factor, the appliance updates its database with the new timing information and sends the new value to other GSLB sites by performing a MEP exchange. The default tolerance factor is 5 milliseconds (ms).

The RTT tolerance factor must be the same throughout the GSLB domain. If you change it for a site, you must configure identical RTT tolerance factors on all NetScaler appliances deployed in the GSLB domain.

## To configure a GSLB virtual server for dynamic RTT by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -lbMethod RTT -tolerance <value>
```

### Example

```
set gslb vserver Vserver-GSLB-1 -lbMethod RTT -tolerance 10
```

## To configure a GSLB virtual server for dynamic RTT by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server.

## Setting the Probing Interval of Local DNS Servers

Updated: 2014-11-24

The NetScaler appliance uses different mechanisms, such as ICMP echo request / reply (PING), TCP, and UDP to obtain RTT metrics for connections between the local DNS server and participating GSLB sites. By default, the appliance uses a ping monitor and probes the local DNS server every 5 seconds. The appliance then waits 2 seconds for the response and, if a response is not received in that time, it uses the TCP DNS monitor for probing.

However, you can modify the time interval for probing the local DNS server to accommodate your configuration.

## To modify the probing interval by using the command line interface

At the command prompt, type:

```
set lb monitor <monitorName> <type> -interval <integer> <units> -resptimeout <integer> <units>
```

### Example

```
set lb monitor monitor-HTTP-1 HTTP -interval 10 sec -resptimeout 5 sec
```

## To modify the probing interval by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and double-click the monitor that you want to modify (for example, ping).

# Configuring Persistent Connections

Jun 04, 2015

Persistence ensures that a series of client requests for a particular domain name is sent to the same data center instead of being load balanced. If persistence is configured for a particular domain, it takes precedence over the configured GSLB method. Persistence is useful for deployments that deal with e-commerce, such as shopping card usage, where the server needs to maintain the state of the connection to track the transaction. To maintain the state of connection, you must configure persistence on a virtual server. With persistence configured, NetScaler selects a data center to process a client request and forwards the IP address of the selected data center for all subsequent DNS requests. If the configured persistence applies to a site that is down, the NetScaler appliance uses a GSLB method to select a new site, and the new site becomes persistent for subsequent requests from the client.

The GSLB virtual server is responsible for DNS-based site persistence, and it controls the site persistence for a remote GSLB service. The NetScaler appliance supports persistence based on the source IP address or on HTTP cookies.

When you bring a physical service DOWN with a delay time, the physical service goes into the transition out of service (TROFS) state. Site persistence is supported as long as the service is in the TROFS state. That is, if the same client sends a request for the same service within the specified delay time after a service is marked TROFS, the same GSLB site (data center) services the request.

Note: If connection proxy is specified as the site persistence method and if you also want to configure persistence of the physical servers, do not configure SOURCEIP persistence. When the connection is proxied, an IP address owned by the NetScaler is used, and not the actual IP address of the client. Configure methods such as cookie persistence or rule-based persistence on the load balancing virtual server.

This document includes the following information:

- [Configuring Persistence Based on Source IP Address](#)
- [Configuring Persistence Based on HTTP Cookies](#)

## Configuring Persistence Based on Source IP Address

Updated: 2014-11-24

With source-IP persistence, when a DNS request is received at a data center, the NetScaler appliance first looks for an entry in the persistence table and, if an entry for the local DNS server exists and the server mentioned in the entry is configured, the IP address of that server is sent as the DNS response.

For the first request from a particular client, the NetScaler appliance selects the best GSLB site for the request and sends its IP address to the client. Since persistence is configured for the source IP address of the client, all subsequent requests by that client or another local DNS server in the same IP subnet are sent the IP address of the GSLB site that was selected for the first request.

For source-IP address based persistence, the same set of persistence identifiers must be configured on the GSLB virtual servers in all data centers. A persistence identifier is a number used by the data centers to identify a particular GSLB virtual server. A cookie transmits the persistence identifier, enabling the NetScaler appliance to identify the domain so that it can forward all appropriate requests to the same domain. When persistence is enabled, the persistence information is also exchanged as part of metrics exchange.

For the NetScaler appliance to support persistence across sites, persistence must be enabled on the GSLB virtual servers of

all participating sites. When you use source IP address persistence on the network identifier, you must configure a subnet mask. For any domain, persistence takes precedence over any other configured GSLB method.

## To configure persistence based on source IP address by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -persistenceType (SOURCEIP | NONE) -persistenceId <positive_integer> [-persistMask <netmask>] -
[timeout <mins>]
```

### Example

```
set gslb vserver vserver-GSLB-1 -persistenceType SOURCEIP -persistenceId 23 -persistMask 255.255.255.255 -timeout 2
```

## To configure persistence based on source IP address by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
2. Click the **Persistence** section and, from the **Persistence** drop-down list, select **SOURCEIP** and set the following parameters:
  - Persistence Id—persistenceId
  - Time-out—timeout
  - IPv4 Netmask or IPv6 Mask length—persistMask

## Configuring Persistence Based on HTTP Cookies

Updated: 2014-11-26

The NetScaler appliance provides persistence at the HTTP-request level by using connection proxy and HTTP redirect. With these persistence methods, the appliance uses an HTTP cookie (known as a “site cookie”) to reconnect the client to the same server. The NetScaler inserts the site cookie in the first HTTP response.

The site cookie contains information about the selected GSLB service on which the client has a persistent connection. The cookie expiration is based on the cookie timeout configured on the NetScaler appliance. If the virtual server names are not identical on all the sites, you must use the persistence identifier. Cookies inserted are compliant with RFC 2109.

When the NetScaler appliance responds to a client DNS request by sending the IP address of the selected GSLB site, the client sends an HTTP request to that GSLB site. The physical server in that GSLB site adds a site cookie to the HTTP header, and connection persistence is in effect.

If the DNS entry in the client cache expires, and then the client sends another DNS query and is directed to a different GSLB site, the new GSLB site uses the site cookie present in the client request header to implement persistence. If the GSLB configuration at the new site uses connection-proxy persistence, the new site creates a connection to the GSLB site that inserted the site cookie, proxies the client request to the original site, receives a response from the original GSLB site, relays that response back to the client, and closes the connection. If the GSLB configuration uses HTTP redirect persistence, the new site redirects the request to the site that originally inserted the cookie.

Note: Connection proxy persistence can be configured only for local services. However, connection proxy persistence must

be enabled on both local and remote GSLB services that are configured for the GSLB virtual server.

Connection proxy occurs when the following conditions are satisfied:

- Requests are sent from a domain participating in GSLB. The domain is obtained from the URL/Host header.
- Requests are sent from a local GSLB service whose public IP address matches the public IP address of an active service bound to the GSLB virtual server.
- The local GSLB service has connection proxy enabled.
- The request includes a valid cookie that contains the IP address of an active remote GSLB service.

If one of the conditions is not met, connection proxy does not occur, but a site cookie is added if the local GSLB service has connection proxy enabled AND:

- No site cookie is supplied; OR,
- The site cookie refers to an IP address that is not an active GSLB remote service; OR,
- The cookie refers to the IP address of the virtual server on which the request is received.

The following are the limitations of using connection proxy site cookies:

- Site cookies do not work for non-HTTP(S) protocols.
- If an HTTP request is sent to a back-up virtual server, the virtual server does not add a cookie.
- Site cookies do not work if SSL client authentication is required.
- At the local site, the statistics for a GSLB service on a remote site are not the same as the statistics recorded for that service at the remote site. At the local site, the statistics for a remote GSLB service are slightly higher than the statistics that the remote site records for that same service.

Redirect persistence can be used only:

- For HTTP or HTTPS protocols.
- If the domain name is present in the request (either in the URL or in the HOST header), and the domain is a GSLB domain.
- When the request is received on a backup VIP or a GSLB local service that is in the down state.

## To set persistence based on HTTP cookies by using the command line interface

At the command prompt, type:

```
set gslb service <serviceName> -sitePersistence (ConnectionProxy [-sitePrefix <prefix>] | HTTPRedirect -sitePrefix <prefix>)
```

### Example

```
set gslb service service-GSLB-1 -sitePersistence ConnectionProxy
set gslb service service-GSLB-1 -sitePersistence HTTPRedirect -sitePrefix vserver-GSLB-1
```

## To set persistence based on cookies by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services and select the service that you want to configure for site persistence (for example, service-GSLB-1).
2. Click the **Site Persistence** section and set persistence based on cookies.

# Overriding Static Proximity Behavior by Configuring Preferred Locations

Mar 22, 2012

You might want to direct traffic from a local DNS (LDNS) server or network to a GSLB service other than the GSLB service that the static proximity method selects for that traffic. That is, you have a *preferred location* for that traffic. To override the static proximity method with preferred locations, you can do the following:

1. Configure a DNS action that consists of a list of preferred locations. For more information about configuring a DNS action, see [Configuring a DNS Action](#).
2. Configure a DNS policy to identify the traffic arriving from the LDNS server or network for which you want to override static proximity, and apply the action in the policy.
3. Bind the policy to the global request bind point.

In the DNS action, you can configure a list of up to 8 preferred locations. The locations must be provided in the dotted qualifier notation, which is the notation in which you add custom locations to the static proximity database. The locations can include wildcards for qualifiers that you want to omit. For information about the dotted qualifier notation for locations, see [Adding Custom Entries to a Static Proximity Database](#). When entering the preferred locations, you must enter them in the descending order of priority.

When a policy evaluates to TRUE, the NetScaler appliance matches the preferred locations, in priority order, with the locations of GSLB services. Matches are of the following two types:

- If all the non-wildcard qualifiers in a preferred location match the corresponding qualifiers in the location of a GSLB service, the match is considered a perfect match. For example, a GSLB service location of \*.UK.\* or Europe.UK.\* is a perfect match for the preferred location \*.UK.\*.
- If only a subset of the non-wildcard qualifiers match, the match is considered a partial match. For example, a GSLB service location of Europe.EG is a partial match for the preferred location Europe.UK.

When a DNS policy evaluates to TRUE, the following algorithm is used to select a GSLB service:

1. The appliance evaluates the preferred location that has the highest priority and moves down the priority order until a perfect match is found between a preferred location and the location of a GSLB service.

If a perfect match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple perfect matches are found (which can happen when one or more wildcards are used in a preferred location), the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

2. If a perfect match is not found for any of the preferred locations, the appliance returns to the preferred location that has the highest priority and moves down the priority order until a partial match is found between a preferred location and the location of a GSLB service.

If a partial match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple partial matches are found, the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

3. If none of the perfect and partial matches are up, the appliance load balances all other available GSLB services.

In this way, the appliance implements a type of site affinity for traffic that matches the DNS policy.

## Example

Consider a GSLB configuration that consists of the following eight GSLB services:

- Asia.IN
- Asia.JPN
- Asia.HK
- Europe.UK
- Europe.RU
- Europe.EG
- Africa.SD
- Africa.ZMB

Further consider the following DNS action and policy configuration:

```
> add dns action prefLoc11 GslbPrefLoc -preferredLocList "Asia.HK" "Europe.UK"
Done
> add dns policy dnsPolPrefLoc "CLIENT.IP.SRC.MATCHES_LOCATION("*ZMB.*")" prefLoc11
Done
```

When the appliance receives a request from the location \*.ZMB.\*, the preferred locations are evaluated as follows:

1. The appliance attempts to find a GSLB service whose location is a perfect match for Asia.HK, which is the preferred location that has the highest priority. It finds that the GSLB service at Asia.HK is a perfect match. If the GSLB service is up, it sends the client the IP address of the GSLB service.
2. If the GSLB service at Asia.HK is down, the appliance attempts to find a perfect match for the second preferred location, Europe.UK. It finds that the GSLB service at Europe.UK is a perfect match. If the GSLB service is up, it sends the client the IP address of the service.
3. If the GSLB service at Europe.UK is down, it returns to the preferred location that has the highest priority, Asia.HK, and looks for partial matches. For Asia.HK, it finds that Asia.IN and Asia.JPN are partial matches. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
4. If all partial matches for Asia.HK are down, the appliance looks for partial matches for Europe.UK. It finds that Europe.RU and Europe.EG are partial matches for the preferred location. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
5. If all partial matches for Europe.UK are down, the appliance load balances all other available GSLB services. In the current example, the appliance load balances Africa.SD and Africa.ZMB because the remaining six GSLB services have been found to be down.

# Monitoring GSLB Services

May 22, 2015

When you bind a remote service to a GSLB virtual server, the GSLB sites exchange metric information, including network metric information, which is the round-trip-time and persistence information.

If a metric exchange connection is momentarily lost between any of the participating sites, the remote site is marked as DOWN and load balancing is performed on the remaining sites that are UP. When metric exchange for a site is DOWN, the remote services belonging to the site are marked DOWN as well.

The NetScaler appliance periodically evaluates the state of the remote GSLB services by using either MEP or monitors that are explicitly bound to the remote services. Binding explicit monitors to local services is not required, because the state of the local GSLB service is updated by default using the MEP. However, you can bind explicit monitors to a remote service. When monitors are explicitly bound, the state of the remote service is not controlled by the metric exchange.

By default, when you bind a monitor to a remote GSLB service, the NetScaler appliance uses the state of the service reported by the monitor. However, you can configure the NetScaler appliance to use monitors to evaluate services in the following situations:

- Always use monitors (default setting).
- Use monitors when MEP is DOWN.
- Use monitors when remote services and MEP are DOWN.

The second and third of the above settings enable the NetScaler to stop monitoring when MEP is UP. For example, in a hierarchical GSLB setup, a GSLB site provides the MEP information about its child sites to its parent site. Such an intermediate site may evaluate the state of the child site as DOWN because of network issues, though the actual state of the site is UP. In this case, you can bind monitors to the services of the parent site and disable MEP to determine the actual state of the remote service. This option enables you to control the manner in which the states of the remote services are determined.

To use monitors, first create them, and then bind them to GSLB services.

This document includes the following information:

- [Adding or Removing Monitors](#)
- [Binding Monitors to a GSLB Service](#)

## Adding or Removing Monitors

Updated: 2014-11-24

To add a monitor, you specify the type and the port. You cannot remove a monitor that is bound to a service. You must first unbind the monitor from the service.

## To add a monitor by using the command line interface

At the command prompt, type the following commands to create a monitor and verify the configuration:

- `add lb monitor <monitorName> -type <monitorType> -destPort <portNumber>`
- `show lb monitor <monitorName>`

### Example

```
add lb monitor monitor-HTTP-1 -type HTTP -destPort 80
show lb monitor monitor-HTTP-1
```

## To remove a monitor by using the command line interface

At the command prompt, type:

```
rm lb monitor <monitorName>
```

## To add a monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and add or delete a monitor.

### Binding Monitors to a GSLB Service

Updated: 2014-11-24

Once you create monitors, you must bind them to GSLB services. When binding monitors to the services, you can specify a weight for the monitor. After binding one or more weighted monitors, you can configure a monitor threshold for the service. This threshold takes the service down if the sum of the bound monitor weights falls below the threshold value.

Note: In the configuration utility, you can set both the weight and the monitoring threshold at the same time that you bind the monitor. When using the command line, you must issue a separate command to set the service's monitoring threshold.

## To bind the monitor to the GSLB service by using the command line interface

At the command prompt, type:

```
bind monitor <name> <serviceName> [-state (Enabled | Disabled)] -weight <positiveInteger>
```

### Example

```
bind monitor monitor-HTTP-1 service-GSLB-1 -state enabled -weight 2
```

## To set the monitoring threshold for a GSLB service by using the command line interface

At the command prompt, type:

```
set gslb service <ServiceName> -monThreshold <PositiveInteger>
```

### Example

```
set gslb service service-GSLB-1 -monThreshold 9
```

## To bind the monitor to the GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Click the **Monitor** section and bind the monitor to the GSLB service.

## To set the monitoring threshold for a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Click the **Monitor Threshold** section and enter a threshold value.

# Monitoring GSLB Sites

Nov 24, 2014

The NetScaler appliance uses MEP or monitors to determine the state of the GSLB sites. You can configure a GSLB site to always use monitors (the default), use monitors when MEP is down, or use monitors when both the remote service and MEP are down. In the latter two cases, the NetScaler appliance stops monitoring when MEP returns to the UP state.

To configure monitor triggering by using the command line interface

At the command prompt, type:

```
set gslb site <siteName> -triggerMonitor (ALWAYS | MEPDOWN | MEPDOWN_SVCDOWN)
```

## Example

```
> set gslb site Site-GSLB-North-America -triggerMonitor Always
```

```
Done
```

To configure monitor triggering by using the configuration utility

1. Navigate to Traffic Management > GSLB > Sites and double-click the site.
2. In the **Trigger Monitors** drop-down list, select an option for when to trigger monitoring.

# Protecting the GSLB Setup Against Failure

May 22, 2015

You can protect your GSLB setup against failure of a GSLB site or a GSLB virtual server by configuring a backup GSLB virtual server, configuring the NetScaler appliance to respond with multiple IP addresses, or configuring a Backup IP address for a GSLB domain. You can also divert excess traffic to a backup virtual server by using spillover.

This document includes the following information:

- [Configuring a Backup GSLB Virtual Server](#)
- [Configuring a GSLB Setup to Respond with Multiple IP Addresses](#)
- [Configuring a GSLB Virtual Server to Respond with an Empty Address Record When DOWN](#)
- [Configuring a Backup IP Address for a GSLB Domain](#)
- [Diverting Excess Traffic to a Backup Virtual Server](#)

## Configuring a Backup GSLB Virtual Server

Updated: 2015-05-04

Configuring a backup entity for a GSLB virtual server ensures that DNS traffic to a site is not interrupted if the GSLB virtual server goes down. The backup entity can be another GSLB virtual server, or it can be a backup IP address. With a backup entity configured, if the primary GSLB virtual server goes down, the backup entity handles DNS requests. To specify what should happen when the primary GSLB virtual server comes back up again, you can configure the backup entity to continue handling traffic until you manually enable the primary virtual server to take over (using the `disablePrimaryOnDown` option), or you can configure a timeout period after which the primary takes over.

If you configure both the timeout and the `disablePrimaryOnDown` option for the backup entity, the backup session time-out takes precedence over the `disablePrimaryOnDown` setting.

## To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server as a backup virtual server and verify the configuration:

- `set gslb vserver <name> -backupVServer <name> [-backupSessionTimeout <timeoutValue>] [-disablePrimaryOnDown (ENABLED | DISABLED)]`
- `show gslb vserver <name>`

### Example

```
set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2 -backupSessionTimeout 3 -disablePrimaryOnDown ENABLED
show gslb vserver vserver-GSLB-1
```

## To set GSLB virtual server as a backup virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers, and double-click the GSLB virtual server.
2. Click the **Backup Virtual Server** section and select the backup virtual server.

## Configuring a GSLB Setup to Respond with Multiple IP Addresses

Updated: 2014-11-24

A typical DNS response contains the IP address of the best performing GSLB service. However, if you enable multiple IP response (MIR), the NetScaler appliance sends the best GSLB service as the first record in the response and adds the remaining active services as additional records. If MIR is disabled (the default), the NetScaler appliance sends the best service as the only record in the response.

## To configure a GSLB virtual server for multiple IP responses by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server for multiple IP responses and verify the configuration:

- `set gslb vserver<name> -MIR (ENABLED | DISABLED)`
- `show gslb vserver <name>`

### Example

```
set gslb vserver vserver-GSLB-1 -MIR ENABLED
show gslb vserver <vserverName>
```

## To set a GSLB virtual server for multiple IP responses by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
2. On the Advanced tab, under When this VServer is "UP," select the Send all "active" service IP in response (MIR) check box, and click OK.

## Configuring a GSLB Virtual Server to Respond with an Empty Address Record When DOWN

Updated: 2014-11-24

A DNS response can contain either the IP address of the requested domain or an answer stating that the IP address for the domain is not known by the DNS server, in which case the query is forwarded to another name server. These are the only possible responses to a DNS query.

When a GSLB virtual server is disabled or in a DOWN state, the response to a DNS query for the GSLB domain bound to that virtual server contains the IP addresses of all the services bound to the virtual server. However, you can configure the GSLB virtual server to in this case send an empty down response (EDR). When this option is set, a DNS response from a GSLB virtual server that is in a DOWN state does not contain IP address records, but the response code is successful. This prevents clients from attempting to connect to GSLB sites that are down.

Note: You must configure this setting for each virtual server to which you want it to apply.

## To configure a GSLB virtual server for empty down responses by using the command line interface

At the command prompt, type:

```
set gslb vserver<name> -EDR (ENABLED | DISABLED)
```

### Example

```
> set gslb vserver vserver-GSLB-1 -EDR ENABLED
Done
```

## To set a GSLB virtual server for empty down responses by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
2. On the Advanced tab, under When this VServer is “Down,” select the Do not send any service’s IP address in response (EDR) check box.
3. Click OK.

### Configuring a Backup IP Address for a GSLB Domain

Updated: 2014-11-24

You can configure a backup site for your GSLB configuration. With this configuration in place, if all of the primary sites go DOWN, the IP address of the backup site is provided in the DNS response.

Typically, if a GSLB virtual server is active, that virtual server sends a DNS response with one of the active site IP addresses as selected by the configured GSLB method. If all the configured primary sites in the GSLB virtual server are inactive (in the DOWN state), the authoritative domain name system (ADNS) server or DNS server sends a DNS response with the backup site’s IP address.

Note: When a backup IP address is sent, persistence is not honored.

## To set a backup IP address for a domain by using the command line interface

At the command prompt, type the following commands to set a backup IP address and verify the configuration:

- `set gslb vserver <name> -domainName <string> -backupIP <IPAddress>`
- `show gslb vserver <name>`

### Example

```
set gslb vserver vserver-GSLB-1 -domainName www.abc.com -backupIP 10.102.29.66
show gslb vserver vserver-GSLB-1
```

## To set a backup IP address for a domain by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server to which you want to bind the backup domain (for example, vserver-GSLB-1).
2. Click the **Domains** section, configure the GSLB domain and specify the IP address of the backup domain in the **Backup IP** field.

### Diverting Excess Traffic to a Backup Virtual Server

Updated: 2014-11-24

Once the number of connections to a primary GSLB virtual server exceeds the configured threshold value, you can use the spillover option to divert new connections to a backup GSLB virtual server. This threshold value can be calculated dynamically or set manually. Once the number of connections to the primary virtual server drops below the threshold, the primary GSLB virtual server resumes serving client requests.

You can configure persistence with spillover. When persistence is configured, new clients are diverted to the backup virtual server if that client is not already connected to a primary virtual server. When persistence is configured, connections that were diverted to the backup virtual server are not moved back to the primary virtual server after the number of connections to the primary virtual server drops below the threshold. Instead, the backup virtual server continues to process those connections until they are terminated by the user. Meanwhile, the primary virtual server accepts new clients.

The threshold can be measured either by the number of connections or by the bandwidth.

If the backup virtual server reaches the configured threshold and is unable to take any additional load, the primary virtual server diverts all requests to the designated redirect URL. If a redirect URL is not configured on the primary virtual server, subsequent requests are dropped.

The spillover feature prevents the remote backup GSLB service (backup GSLB site) from getting flooded with client requests when the primary GSLB virtual server fails. This occurs when a monitor is bound to a remote GSLB service, and the service experiences a failure that causes its state to go DOWN. The monitor continues to keep the state of the remote GSLB service UP, however, because of the spillover feature.

As part of the resolution to this problem, two states are maintained for a GSLB service, the primary state and effective state. The primary state is the state of the primary virtual server and the effective state is the cumulative state of the virtual servers (primary and backup chain). The effective state is set to UP if any of the virtual servers in the chain of virtual servers is UP. A flag that indicates that the primary VIP has reached the threshold is also provided. The threshold can be measured by either the number of connections or the bandwidth.

A service is considered for GSLB only if its primary state is UP. Traffic is directed to the backup GSLB service only when all the primary virtual servers are DOWN. Typically, such deployments will have only one backup GSLB service.

Adding primary and effective states to a GSLB service has the following effects:

- When source IP persistence is configured, the local DNS is directed to the previously selected site only if the primary virtual server on the selected site is UP and below threshold. Persistence can be ignored in the round robin mode.
- If cookie-based persistence is configured, client requests are redirected only when the primary virtual server on the selected site is UP.
- If the primary virtual server has reached its saturation and the backup VIP(s) is absent or down, the effective state is set to DOWN.
- If external monitors are bound to an HTTP-HTTPS virtual server, the monitor decides the primary state.
- If there is no backup virtual server to the primary virtual server and the primary virtual server has reached its threshold, the effective state is set to DOWN.

## To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a backup GSLB virtual server and verify the configuration:

- `set gslb vserver <name> -soMethod <method> -soThreshold <threshold> -soPersistence ( ENABLED | DISABLED ) -soPersistenceTimeout <timeout>`
- `show gslb vserver <name>`

### Example

```
set gslb vserver Vserver-GSLB-1 -soMethod CONNECTION -soThreshold 1000 -soPersistence ENABLED -soPersistenceTimeout 2
show gslb vserver Vserver-GSLB-1
```

## To configure a backup GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server that you want to configure as a backup (for example, Vserver-LB-1).
2. Click the **Spillover** section and set the following parameters:
  - Method— soMethod
  - Threshold— soThreshold
  - Persistence Time-out (min) — soPersistenceTimeout
3. Select the Persistence option and click **OK**.

# Managing Client Connections

Aug 07, 2017

To facilitate management of client connections, you can enable delayed cleanup of connections to the virtual server. You can then manage local DNS traffic by configuring DNS policies.

This document includes the following information:

- [Enabling Delayed Cleanup of Virtual Server Connections](#)
- [Managing Local DNS Traffic by Using DNS Policies](#)
- [Adding DNS Views](#)

## Enabling Delayed Cleanup of Virtual Server Connections

Updated: 2014-11-24

The state of a virtual server depends on the states of the services bound to it, and the state of each service depends on the monitors bound to it. If a server is slow or down, the monitoring probes time out and the service that represents the server is marked as DOWN. A virtual server is marked as DOWN only when all services bound to it are marked as DOWN. You can configure services and virtual servers to either terminate all connections when they go down, or allow the connections to go through. The latter setting is for situations in which a service is marked as DOWN because of a slow server.

When you configure the down state flush option, the NetScaler appliance performs a delayed cleanup of connections to a GSLB service that is down.

## To enable delayed cleanup of virtual server connections by using the command line interface

At the command prompt, type the following commands to configure delayed connection cleanup and verify the configuration:

- `set gslb service <name> -downStateFlush (ENABLED | DISABLED)`
- `show gslb service <name>`

### Example

```
> set gslb service Service-GSLB-1 -downStateFlush ENABLED
Done
> show gslb service Service-GSLB-1
Done
```

## To enable delayed cleanup of virtual server connections by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services and double-click the service.
2. Click the **Other Settings** section and select the **Down State Flush** option.

## Managing Local DNS Traffic by Using DNS Policies

Updated: 2015-05-22

You can use DNS policies to implement site affinity by directing traffic from the IP address of a local DNS resolver or network to a predefined target GSLB site. This is configured by creating DNS policies with DNS expressions and binding the policies globally on the NetScaler appliance.

This document includes the following information:

- [DNS Expressions](#)
- [Configuring DNS Actions](#)
- [Configuring DNS Policies](#)
- [Binding DNS Policies](#)

## DNS Expressions

Updated: 2013-07-18

The NetScaler appliance provides certain predefined DNS expressions that can be used for configuring actions specific to a domain. Such actions can, for example, drop certain requests, select a specific view for a specific domain, or redirect certain requests to a specific location.

These DNS expressions (also called *rules*) are combined to create DNS policies that are then bound globally on the NetScaler appliance.

Following is the list of predefined DNS qualifiers available on the NetScaler appliance:

- CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
- CLIENT.UDP.DNS.IS\_AREC
- CLIENT.UDP.DNS.IS\_AAAAREC
- CLIENT.UDP.DNS.IS\_SRVREC
- CLIENT.UDP.DNS.IS\_MXREC
- CLIENT.UDP.DNS.IS\_SOAREC
- CLIENT.UDP.DNS.IS\_PTRREC
- CLIENT.UDP.DNS.IS\_CNAME
- CLIENT.UDP.DNS.IS\_NSREC
- CLIENT.UDP.DNS.IS\_ANYREC

The CLIENT.UDP.DNS.DOMAIN DNS expression can be used with string expressions. If you are using domain names as part of the expression, they must end with a period (.). For example, CLIENT.UDP.DNS.DOMAIN.ENDSWITH("abc.com.")

To create an expression by using the configuration utility

1. Click the icon next to the Expression text box. Click Add. (Leave the Flow Type and Protocol drop-down list boxes empty.) Follow these steps to create a rule.
2. In the Qualifier box, select a qualifier (for example, LOCATION).
3. In the Operator box, select an operator (for example, ==).
4. In the Value box, type a value (for example, Asia, Japan...).
5. Click OK. Click Create and click Close. The rule is created.
6. Click OK.

## Configuring DNS Actions

Updated: 2014-11-24

A DNS policy includes the name of a DNS action to be performed when the policy rule evaluates to TRUE. A DNS action can do one of the following:

- Send the client an IP address for which you have configured a DNS view. For more information about DNS views, see [Adding DNS Views](#).
- Send the client the IP address of a GSLB service after referring to a list of preferred locations that overrides static proximity behavior. For more information about preferred locations, see [Overriding Static Proximity Behavior by Configuring Preferred Locations](#).
- Send the client a specific IP address as determined by the evaluation of the DNS query or response (DNS response rewrite).
- Forward a request to the name server without performing a lookup in the appliance's DNS cache.
- Drop a request.

You cannot create a DNS action for dropping a DNS request or for bypassing the DNS cache on the appliance. If you want to drop a DNS request, use the built-in action, `dns_default_act_Drop`. If you want to bypass the DNS cache, use the built-in action, `dns_default_act_Cachebypass`. Both actions are available along with custom actions in the Create DNS Policy and the Configure DNS Policy dialog boxes. These built-in actions cannot be modified or removed.

To configure a DNS action by using the command line interface

At the command prompt, type the following commands to configure a DNS action and verify the configuration:

- `add dns action <actionName> <actionType> (-IPAddress <ip_addr | ipv6_addr> ... | -viewName <string> | -preferredLocList <string> ...) [-TTL <secs>]`
- `show dns action [<actionName>]`

## Examples

**Example 1: Configuring DNS Response Rewrite.** The following DNS action sends the client a preconfigured IP address when the policy to which the action is bound evaluates to true:

```
> add dns action dns_act_response_rewrite Rewrite_Response -IPAddress 192.0.2.20 192.0.2.56 198.51.100.10
Done
> show dns action dns_act_response_rewrite
1) ActionName: dns_act_response_rewrite ActionType: Rewrite_Response TTL: 3600 IPAddress: 192.0.2.20 192.0.2.56 198.51.100.10
Done
```

**Example 2: Configuring a DNS-View Based Response.** The following DNS action sends the client an IP address for which you have configured a DNS view:

```
> add dns action send_ip_from_view_internal_ip ViewName -viewName view_internal_ip
Done
> show dns action send_ip_from_view_internal_ip
1) ActionName: send_ip_from_view_internal_ip ActionType: ViewName ViewName: view_internal_ip
Done
```

**Example 3: Configuring a Response Based on a Preferred Location List.** The following DNS action sends the client the IP address that corresponds to the preferred location that it selects from the specified list of locations:

```
> add dns action send_preferred_location GslbPrefLoc -preferredLocList NA.tx.ns1.*.* NA.tx.ns2.*.* NA.tx.ns3.*.*
Done
> show dns action send_preferred_location
1) ActionName: send_preferred_location ActionType: GslbPrefLoc PreferredLocList: "NA.tx.ns1.*.*" "NA.tx.ns2.*.*" "NA.tx.ns3.*.*"
Done
```

To configure a DNS action by using the NetScaler configuration utility

1. Navigate to Traffic Management > DNS > Actions, create or edit a DNS action.
2. In the Create DNS Action or Configure DNS Action dialog box, set the following parameters:
  - Action Name (cannot be changed for an existing DNS action)
  - Type (cannot be changed for an existing DNS action)  
To set the Type parameter, do one of the following:
    - To create a DNS action that is associated with a DNS view, select View Name. Then, from the View Name list, select the DNS view that you want to use in the action.
    - To create a DNS action with a preferred location list, select Preferred Location List. In Preferred Location, enter a location, and then click Add. Add as many DNS locations as you want.
    - To configure a DNS action for rewriting a DNS response on the basis of policy evaluation, select Rewrite Response. In IP Address, enter an IP address, and then click Add. Add as many IP addresses as you want.
  - TTL (applicable only to the Rewrite Response action type)

## Configuring DNS Policies

Updated: 2014-11-24

DNS policies operate on a location database that uses static and custom IP addresses. The attributes of the incoming local DNS request are defined as part of an expression, and the target site is defined as part of a DNS policy. While defining actions and expressions, you can use a pair of single quotation marks (") as a wildcard qualifier to specify more than one location. When a DNS policy is configured and a GSLB request is received, the custom IP address database is first queried for an entry that defines the location attributes for the source:

- When a DNS query comes from an LDNS, the characteristics of the LDNS are evaluated against the configured policies. If they match, an appropriate action (site affinity) is executed. If the LDNS characteristics match more than one site, the request is load balanced between the sites that match the LDNS characteristics.
- If the entry is not found in the custom database, the static IP address database is queried for an entry, and if there is a match, the above policy evaluation is repeated.
- If the entry is not found in either the custom or static databases, the best site is selected and sent in the DNS response on the basis of the configured load balancing method.

The following restrictions apply to DNS policies created on the NetScaler appliance.

- A maximum of 64 policies are supported.
- DNS policies are global to the NetScaler and cannot be applied to a specific virtual server or domain.
- Domain or virtual server specific binding of policy is not supported.

You can use DNS policies to direct clients that match a certain IP address range to a specific site. For example, if you have a GSLB setup with multiple GSLB sites that are separated geographically, you can direct all clients whose IP address is within a specific range to a particular data center.

Both TCP-based and UDP-based DNS traffic can be evaluated. Policy expressions are available for UDP-based DNS traffic on the server and for both UDP-based DNS traffic and TCP-based DNS traffic on the client side. Additionally, you can configure expressions to evaluate queries and responses that involve only the following DNS question types (or QTYPE values):

- A
- AAAA
- NS
- SRV
- PTR
- CNAME
- SOA
- MX
- ANY

The following response codes (RCODE values) are also supported:

- NOERROR - No error
- FORMERR - Format error
- SERVFAIL - Server failure
- NXDOMAIN - Non-existent domain
- NOTIMP - Query type not implemented
- REFUSED - Query refused

You can configure expressions to evaluate DNS traffic. A DNS expression begins with the DNS.REQ or DNS.RES prefixes. Functions are available for evaluating the queried domain, the query type, and the carrier protocol. For more information about DNS expressions, see "Expressions for Evaluating a DNS Message and Identifying Its Carrier Protocol" in ["Policy Configuration and Reference"](#).

To add a DNS policy by using the command line interface

At the command prompt, type the following commands to create a DNS policy and verify the configuration:

- add dns policy <name> <rule> <actionName>
- show dns policy <name>

### Example

```
> add dns policy policy-GSLB-1 'CLIENT.UDP.DNS.DOMAIN.EQ("domainname")' my_dns_action
Done
> show dns policy policy-GSLB-1
Name: policy-GSLB-1
Rule: CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
Action Name: my_dns_action
Hits: 0
Undef Hits: 0
```

Done

To remove a configured DNS policy by using the command line interface

At the command prompt, type:

```
rm dns policy <name>
```

To configure a DNS policy by using the NetScaler configuration utility

1. Navigate to Traffic Management > DNS > Policies and create a DNS policy.
2. In the Create DNS Policy or Configure DNS Policy dialog box, set the following parameters:
  - Policy Name (cannot be changed for an existing policy)
  - Action
  - Expression
 

To specify an expression, do the following:

    1. Click Add, and then, in the drop-down box that appears, select the expression element with which you want to begin the expression. A second list appears. The list contains a set of expression elements that you can use immediately after the first expression element.
    2. In the second list, select the expression element that you want, and then enter a period.
    3. After each selection, if you enter a period, the next set of valid expression elements appear in a list. Select expression elements and fill in arguments to functions until you have the expression you want.
3. Click Create or OK, and then click Close.

## Binding DNS Policies

Updated: 2013-08-29

DNS policies are bound globally on the NetScaler appliance and are available for all configured GSLB virtual servers. Even though DNS policies are globally bound, policy execution can be limited to a specific GSLB virtual server by specifying the domain in the expression.

Note: Even though the bind dns global command accepts REQ\_OVERRIDE and RES\_OVERRIDE as valid bind points, those bind points are redundant, because DNS policies can be bound only globally. Bind your DNS policies only to the REQ\_DEFAULT and RES\_DEFAULT bind points.

To bind a DNS policy globally by using the command line interface

At the command prompt, type the following commands to bind a DNS policy globally and verify the configuration:

- bind dns global <policyName> <priority> [-gotoPriorityExpression <string>] [-type <type>]
- show dns global -type <type>

### Example

```
> bind dns global policy-GSLB-1 10 -gotoPriorityExpression END
Done
> show dns global -type REQ_DEFAULT
1) Policy Name: policy-GSLB-1
Priority: 10
GotoPriorityExpression: END
```

Done

To bind a DNS policy globally by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind DNS Policy(s) to Global dialog box, click Insert Policy.
4. In the Policy Name column, select, from the list, the policy that you want to bind. Alternatively, in the list, click New Policy, and then create a DNS policy by setting parameters in the Create DNS Policy dialog box.
5. To modify a policy that is already bound globally, click the name of the policy, and then click Modify Policy. Then, in the Configure DNS Policy dialog box, modify the policy, and then click OK.
6. To unbind a policy, click the name of the policy, and then click Unbind Policy.
7. To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
8. To regenerate assigned priorities, click Regenerate Priorities. The priority values are modified to begin at 100, with increments of 10, without affecting the order of evaluation.
9. Click OK.

To view the global bindings of a DNS policy by using the command line interface

At the command prompt, type:

```
show dns global
```

To view the global bindings of a DNS policy by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings. The global bindings of all DNS policies appear in this dialog box.

## Adding DNS Views

Updated: 2014-11-24

You can configure DNS views to identify various types of clients and provide an appropriate IP address to a group of clients who query for the same GSLB domain. DNS views are configured by using DNS policies that select the IP addresses sent back to the client.

For example, if you have configured GSLB for your company's domain and have the server hosted in your company's network, clients querying for the domain from within your company's internal network can be provided with the server's internal IP address instead of the public IP address. Clients that query DNS for the domain from the Internet, on the other hand, can be provided the domain's public IP address.

To add a DNS view, you assign it a name of up to 31 characters. The leading character must be a number or letter. The following characters are also allowed: @ \_ - . (period) : (colon) # and space ( ). After adding the view, you configure a policy to associate it with clients and a part of the network, and you bind the policy globally. To configure and bind a DNS policy, see [Configuring DNS Policies](#) and [Binding DNS Policies](#).

## To add a DNS view by using the command line interface

At the command prompt, type the following commands to create a DNS view and verify the configuration:

- add dns view <viewName>
- show dns view <viewName>

### Example

```
add dns view PrivateSubnet
show dns view PrivateSubnet
```

## To remove a DNS view by using the command line interface

At the command prompt, type:

```
rm dns view <viewName>
```

## To add a DNS view by using the configuration utility

Navigate to Traffic Management > DNS > Views and add a DNS view.

For details on how to create a DNS policy, see [Configuring DNS Policies](#) and for details on how to bind DNS policies globally, see [Binding DNS Policies](#).

# Configuring GSLB for Disaster Recovery

Aug 06, 2017

Disaster recovery capability is critical, because downtime is costly. A NetScaler appliance configured for GSLB forwards traffic to the least-loaded or the best-performing data center. This configuration, referred to as an active-active setup, not only improves performance, but also provides immediate disaster recovery by routing traffic to other data centers if a data center that is part of the setup goes down. Alternatively, you can configure an active-standby GSLB setup for disaster recovery only.

This document includes the following information:

- [Configuring GSLB for Disaster Recovery in an Active-Standby Data Center Setup](#)
- [Configuring for Disaster Recovery in an Active-Active Data Center Setup](#)
- [Configuring for Disaster Recovery with Weighted Round Robin](#)
- [Configuring for Disaster Recovery with Data Center Persistence](#)

## Configuring GSLB for Disaster Recovery in an Active-Standby Data Center Setup

Updated: 2014-11-24

A conventional disaster recovery setup includes an active data center and a standby data center. The standby data center is a remote site. When a failover occurs as a result of a disaster event that causes the primary active data center to be inactive, the standby data center becomes operational.

Configuring disaster recovery in an active-standby data-center setup consists of the following tasks.

- Create the active data center.
  - Add a local GSLB site.
  - Add a GSLB vserver, which represents the active data center.
  - Bind the domain to the GSLB virtual server.
  - Add gslb services and bind the services to active GSLB virtual server.
- Create the standby data center.
  - Add a remote gslb site.
  - Add a gslb vserver, which represents standby data center.
  - Add gslb services which represents standby data center and bind the services to the standby gslb vserver.
  - Designate the standby data center by configuring the standby GSLB virtual server as the backup virtual server for the active GSLB virtual server.

Once you have configured the primary data center, replicate the configuration for the backup data center and designate it as the standby GSLB site by designating a GSLB virtual server at that site as the backup virtual server.

For details on how to configure a basic GSLB setup, see [Configuring Global Server Load Balancing \(GSLB\)](#).

## To designate the standby GSLB site by using the command line interface

At both the active site and the remote site, at the command prompt, type:

```
set gslb vserver <name> -backupVserver <string>
```

### Example

```
set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2
```

## To configure the standby site by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the GSLB virtual server for the primary site.
2. Click the **Backup Virtual Server** section and select a backup virtual server.

By default, once the primary virtual server becomes active, it starts receiving traffic. However, if you want the traffic to be directed to the backup virtual server even after the primary virtual server becomes active, use the 'disable primary on down' option.

### Configuring for Disaster Recovery in an Active-Active Data Center Setup

An active-active GSLB deployment, in which both GSLB sites are active, removes any risk that may arise in having a standby data center. With such a setup, web or application content can be mirrored in geographically separate locations. This ensures that data is consistently available at each distributed data center.

To configure GSLB for disaster recovery in an active-active data center set up, you must first configure the basic GSLB setup on the first data center and then configure all other data centers.

First create at least two GSLB sites. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server in the local site. Finally, at the local site, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Once you have configured the first data center, replicate the configuration for other data centers part of the setup.

For details on how to configure a basic GSLB setup, see [Configuring Global Server Load Balancing \(GSLB\)](#).

### Configuring for Disaster Recovery with Weighted Round Robin

Updated: 2014-11-24

When you configure GSLB to use the weighted round robin method, weights are added to the GSLB services and the configured percentage of incoming traffic is sent to each GSLB site. For example, you can configure your GSLB setup to forward 80 percent of the traffic to one site and 20 percent of the traffic to another. After you do this, the NetScaler appliance will send four requests to the first site for each request that it sends to the second.

To set up the weighted round robin method, first create two GSLB sites, local and remote. Next, for the local site create a GSLB virtual server and GSLB services, and bind the services to the virtual server. Configure the GSLB method as round robin. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Each service that represents a physical server in the network has weights associated with it. Therefore the GSLB service is assigned a dynamic weight that is the sum of weights of all services bound to it. Traffic is then split between the GSLB services based on the ratio of the dynamic weight of the particular service to the total weight. You can also configure individual weights for each GSLB service instead of the dynamic weight.

If the services do not have weights associated with them, you can configure the GSLB virtual server to use the number of services bound to it to calculate the weight dynamically.

For details on how to configure a basic GSLB setup, see [Configuring Global Server Load Balancing \(GSLB\)](#).

Once you configure a basic GSLB setup, you must configure the weighted round robin method such that the traffic is split between the configured GSLB sites according to the weights configured for the individual services.

## To configure a virtual server to assign weights to services by using the command line interface

At the command prompt, type one of the following commands, depending upon whether you want to create a new load balancing virtual server or configure an existing one:

- `add lb vserver <name>@ -weight <WeightValue> <ServiceName>`
- `set lb vserver <name>@ -weight <WeightValue> <ServiceName>`

### Example

```
add lb vserver Vserver-LB-1 -weight 4 Service-HTTP-1
set lb vserver Vserver-LB-1 -weight 4 Service-HTTP-1
```

## To set dynamic weight by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -dynamicWeight DynamicWeightType
```

### Example

```
set gslb vserver Vserver-GSLB-1 -dynamicWeight ServiceWeight
```

## To add weights to the GSLB services by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -serviceName GSLBServiceName -weight WeightValue
```

### Example

```
set gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1 -weight 1
```

## To configure a virtual server to assign weights to services by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and double-click the virtual server (for example, Vserver-LB-1).
2. Click the **Services** section and set the weight of a service.

## To add weights to the GSLB services by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the virtual server (for example, vserver-GSLB-1)
2. Click the **Services** section and set the weight of the service in the **Weight** field.

## To set dynamic weight by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the virtual server (for example, vserver-

GSLB-1).

2. Click the **Method** section and, from the **Dynamic Weight** drop-down list select **SERVICEWEIGHT**.

## Configuring for Disaster Recovery with Data Center Persistence

Updated: 2014-11-24

Data center persistence is required for web applications that require maintaining a connection with the same server instead of having the requests load balanced. For example, in an e-commerce portal, maintaining a connection between the client and the same server is critical. For such applications, HTTP redirect persistence can be configured in an active-active setup.

To configure GSLB for disaster recovery with data center persistence, you must first configure the basic GSLB set up and then configure HTTP redirect persistence.

First create two GSLB sites, local and remote. Next, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Next, create a load balancing virtual server with the same virtual server IP address as the GSLB service. Finally, duplicate the previous steps for the remote configuration, or configure the NetScaler appliance to autosynchronize your GSLB configuration.

For details on how to configure a basic GSLB setup, see [Configuring Global Server Load Balancing \(GSLB\)](#).

Once you have configured a basic GSLB setup, configure HTTP redirect precedence to enable data center persistence.

## To configure HTTP redirect by using the command line interface

At the command prompt, type the following commands to configure HTTP redirect and verify the configuration:

- `set gslb service <serviceName> -sitePersistence <sitePersistence> -sitePrefix <string>`
- `show gslb service <serviceName>`

### Example

```
set gslb service Service-GSLB-1 -sitePersistence HTTPRedirect -sitePrefix vserver-GSLB-1
show gslb service Service-GSLB-1
```

## To configure HTTP redirect by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Services** and double-click the GSLB service to be configured.
2. Click the **Site Persistence** section, select the **HTTPRedirect** option, and in the **Site Prefix** text box, enter the site prefix (for example, vserver-GSLB-1).

### Note

When site persistence is not configured and if a load balancing virtual server that is configured as a local GSLB service is DOWN, the HTTP requests are redirected to other healthy GSLB sites using a 302 redirect.

# Configuring GSLB for Proximity

Aug 30, 2013

When you configure GSLB for proximity, client requests are forwarded to the closest data center. The main benefit of the proximity-based GSLB method is faster response times resulting from the selection of the closest available data center. Such a deployment is critical for applications that require fast access to large volumes of data.

You can configure GSLB for proximity based on the round trip time (RTT), static proximity, or a combination of the two.

## Configuring Dynamic Method (RTT)

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client's local DNS server and a data resource. To measure dynamic RTT, the NetScaler appliance probes the client's local DNS server and gathers RTT metric information. The NetScaler then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value

To configure GSLB for proximity with dynamic method, you must first configure the basic GSLB set up and then configure dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see [Configuring Global Server Load Balancing \(GSLB\)](#).

Once you have configured a basic GSLB setup, configure the dynamic RTT method.

For details on how to configure the GSLB virtual server to use the dynamic RTT method for load balancing, see [Configuring Dynamic RTT](#).

## Configuring Static Proximity

The static proximity method for GSLB uses an IP address-based static proximity database to determine the proximity between the client's local DNS server and the GSLB sites. The NetScaler appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the NetScaler appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

To configure GSLB for proximity with static proximity, you must first configure the basic GSLB set up and then configure static proximity.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see [Configuring Global Server Load Balancing \(GSLB\)](#).

Once you have configured a basic GSLB setup, configure static proximity.

For details on how to configure the GSLB virtual server to use static proximity for load balancing, see [Configuring Static Proximity](#).

### Configuring Static Proximity and Dynamic RTT

You can configure the GSLB virtual server to use a combination of static proximity and dynamic RTT when you have some clients coming from an internal network like a branch office. You can configure GSLB such that the clients coming from the branch office or any other internal network are directed to a particular GSLB site that is geographically close to the client network. For all other requests, you can use dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see [Configuring Global Server Load Balancing \(GSLB\)](#).

Once you have configured a basic GSLB setup, configure the GSLB virtual server to use static proximity for all traffic originating from an internal network and then use dynamic RTT for all other traffic.

For details on how to configure static proximity, see [Configuring Static Proximity](#) and for details on how to configure dynamic RTT, see [Configuring Dynamic RTT](#).

# Configuring Parent-Child Topology

Nov 07, 2016

NetScaler appliances configured for global server load balancing (GSLB) provide for disaster recovery and ensure continuous availability of applications by protecting against points of failure in a wide area network (WAN). GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers in the event of an outage.

There are three fundamental entities that must be configured for GSLB:

- **Site:** A GSLB site represents a NetScaler or a high availability (HA) pair of NetScaler appliances that maintain GSLB state information and provide information about how the NetScaler nodes should communicate. A site can also represent a data center.
- **GSLB virtual server:** A GSLB virtual server represents a group of resources to which users can be directed, and the logic used to select one resource versus another.
- **GSLB service:** A GSLB service represents a target resource and is bound to a GSLB virtual server. The target resource might be a load balancing virtual server on a NetScaler, or it could represent a third party server.

Sites and services are inherently linked to indicate proximity between the two. That is, all services must belong to a site, and are assumed to be in the same location as the GSLB site for proximity purposes. Likewise, services and virtual servers are linked, so that the logic is linked to the resources that are available.

## Relationships among GSLB Sites

The concept of sites is central to NetScaler GSLB implementations. Unless otherwise specified, sites form a peer relationship among themselves. This relationship is used first to exchange health information and then to distribute load as determined by the selected algorithm. In many situations, however, a peer relationship among all GSLB sites is not desirable. Reasons for not having an all-peer implementation could be

1. To clearly separate GSLB sites. For example, to separate sites that participate in resolving DNS queries from the traffic management sites.
2. To reduce the volume of Metric Exchange Protocol (MEP) traffic, which increases exponentially with an increasing number of peer sites.

These goals can be achieved by using parent and child GSLB sites. Parent-child relationships can be used to build a two-level hierarchical GSLB design with the following characteristics:

- At the top level are parent sites that have peer relationships with other parents.
- Each parent can have multiple children, but each child can have only one parent.
- Each parent site exchanges health information with its children and with other parent sites.
- A child communicates only with its parent.

Note:

- In a parent-child relationship for GSLB, only the parent site responds to ADNS queries. The child sites act as normal load balancing sites.
- ADNS service or DNS load balancing virtual servers should be configured only in the parent site.
- A parent site can have a normal GSLB configuration, that is, services from local and all remote sites but a child site can have local services only.

Limitations of GSLB Parent-Child site configuration:

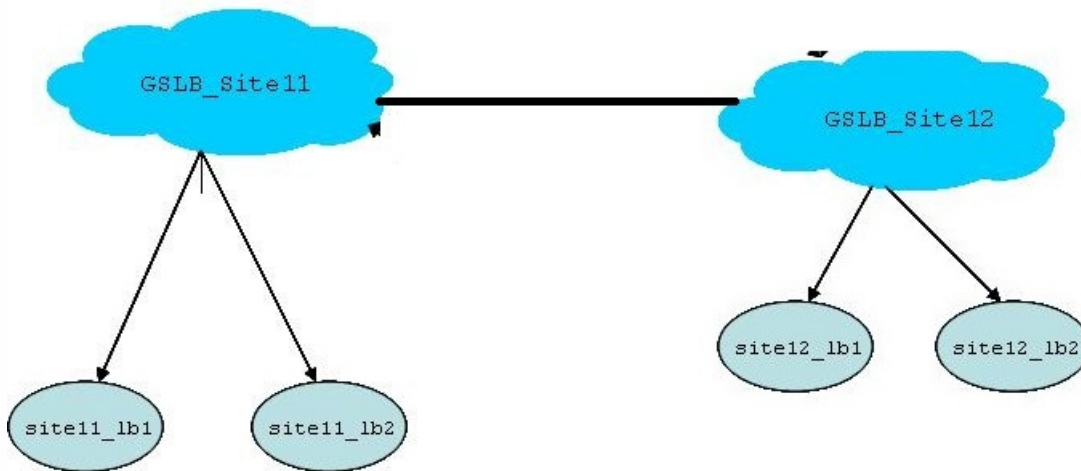

- You can configure up to 32 Parent sites and a total of 1024 Child sites.

- On the Child site, by default, the nwmetricExchange and sessionExchange options are disabled.
- Round Trip Time (RTT) GSLB method is not recommended for GSLB Parent-Child site configuration.

### Setting Up a Parent-Child Configuration for Global Server Load Balancing

If you have a firewall configured at a GSLB site, make sure that port 3011 is open. Follow the procedures at the following location to create services and virtual servers: [Configuring Global Server Load Balancing \(GSLB\)](#)

Figure 1. GSLB Parent-Child Topology

In the above figure:

- GSLB\_Site11 and GSLB\_Site12 are parent sites in a peer relationship.
- site11\_lb1 and site11\_lb2 are the child sites of GSLB\_Site11, while site12\_lb1 and site12\_lb2 are the child sites of GSLB\_Site12.

The configuration of each parent site includes the information about all the child sites associated with it, but the configuration of each child site pertains only to that child and its parent. A child site is not aware about any other parent site or other child sites in the configuration. For example, in the above figure, the configuration of child site site11\_lb1 would include only information about its parent site, GSLB\_Site11.

Note: GSLB auto sync syncs only the GSLB configuration across the parent sites. It does not sync any configuration to the child sites.

To set up a parent-child configuration for GSLB by using the NetScaler command line

1. On each parent site, enter the following command: `add gslb site<siteName><siteIPAddress> [-publicIP<ip_addr|ipv6_addr|*>] [-parentSite<string>]` For example: `# add gslb site gslb_site11 1.1.1.1 -publicIP 1.1.1.1`  
`# add gslb site site11_lb1 1.1.1.2 -publicIP 1.1.1.2 -parentSite gslb_site11`  
`# add gslb site site11_lb2 1.1.1.3 -publicIP 1.1.1.3 -parentSite gslb_site11`  
`# add gslb site gslb_site12 3.3.3.1 -publicIP 3.3.3.1`  
`# add gslb site site12_lb1 3.3.3.2 -publicIP 3.3.3.2 -parentSite gslb_site12`  
`# add gslb site site12_lb2 3.3.3.3 -publicIP 3.3.3.3 -parentSite gslb_site12`

The above command makes the parent site aware of its child sites as well as of the other parent site in the configuration.

2. On each child site, enter the following command: `add gslb site<siteName><siteIPAddress> [-publicIP<ip_addr | ipv6_addr | *>] [-parentSite<string>]` For example: `# add gslb site gslb_site11 1.1.1.1 -publicIP 1.1.1.1`  
`# add gslb site site11_lb1 1 1.1.1.2 -publicIP 1.1.1.2 -parentSite gslb_site11`

The above command creates the child site and adds the parent-site information to child site's configuration.

In the child sites, only the child site and its respective parent site needs to be configured and not other parent or child sites.

Network metrics, such as RTT and persistence session information, are synced only across the parent sites. Therefore, parameters like `nwMetric` and `sessionExchange` are disabled by default on all the child sites.

To verify correct parent-child configuration, check the states of all the GSLB services bound to the parent sites.

# Link Load Balancing

May 19, 2015

Link load balancing (LLB) balances outbound traffic across multiple Internet connections provided by different service providers. LLB enables the Citrix® NetScaler® appliance to monitor and control traffic so that packets are transmitted seamlessly over the best possible link. Unlike with server load balancing, where a service represents a server, with LLB, a service represents a router or the next hop. A link is a connection between the NetScaler and the router.

To configure link load balancing, many users begin by configuring a basic setup with default settings. Configuring a basic setup involves configuring services, virtual servers, monitors, routes, an LLB method, and, optionally, configuring persistence. Once a basic setup is operational, you can customize it for your environment.

Load balancing methods that are applicable to LLB are round robin, destination IP hash, least bandwidth, and least packets. You can optionally configure persistence for connections to be sustained on a specific link. The available persistence types are source IP address-based, destination IP address-based, and source IP and destination IP address-based. PING is the default monitor but configuring a transparent monitor is recommended.

You can customize your setup by configuring reverse NAT (RNAT) and backup links.

This document includes the following information:

- [Configuring a Basic LLB Setup](#)
- [Configuring RNAT with LLB](#)
- [Configuring a Backup Route](#)
- [Resilient LLB Deployment Scenario](#)
- [Monitoring an LLB Setup](#)

# Configuring a Basic LLB Setup

Dec 22, 2016

To configure LLB, you first create services representing each router to the Internet Service Providers (ISPs). A PING monitor is bound by default to each service. Binding a transparent monitor is optional but recommended. Then, you create a virtual server, bind the services to the virtual server, and configure a route for the virtual server. The route identifies the virtual server as the gateway to the physical routers represented by the services. The virtual server selects a router by using the load balancing method that you specify. Optionally, you can configure persistence to make sure that all traffic for a particular session is sent over a specific link.

To configure a basic LLB setup, do the following:

- [Configure services](#)
- [Configure an LLB virtual server and binding a service](#)
- [Configure the LLB method and persistence](#)
- [Configure an LLB route](#)
- [Create and bind a transparent monitor](#)

## Configuring Services

Updated: 2014-10-27

A default monitor (PING) is automatically bound to a service type of ANY when the service is created, but you can replace the default monitor with a transparent monitor, as described in "[Creating and Binding a Transparent Monitor](#)."

## To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port>
- show service <name>

### Example

```
add service ISP1R_svc_any 10.10.10.254 any *
show service ISP1R_svc_any
 ISP1R_svc_any (10.10.10.254:*) - ANY
 State: DOWN
 Last state change was at Tue Aug 31 04:31:13 2010
 Time since last state change: 2 days, 05:34:18.600
 Server Name: 10.10.10.254
 Server ID : 0 Monitor Threshold : 0
 Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
 Use Source IP: NO
 Client Keepalive(CKA): NO
 Access Down Service: NO
 TCP Buffering(TCPB): YES
```

HTTP Compression(CMP): NO  
Idle timeout: Client: 120 sec Server: 120 sec  
Client IP: DISABLED  
Cacheable: NO  
SC: OFF  
SP: OFF  
Down state flush: ENABLED

- 1) Monitor Name: ping  
State: UP Weight: 1  
Probes: 244705 Failed [Total: 0 Current: 0]  
Last response: Success - ICMP echo reply received.  
Response Time: 1.322 millisec

Done

## To create services by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create a service.

## To create services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters:
  - Service Name\*—name
  - Server—IP
  - Protocol\*—serviceType (Select ANY from the drop-down list.)
  - Port\*—port\* A required parameter
4. Click Create.
5. Repeat Steps 2-4 to create another service.
6. Click Close.
7. In the Services pane, select the services that you just configured and verify that the settings displayed at the bottom of the screen are correct.

## Configuring an LLB Virtual Server and Binding a Service

Updated: 2014-10-28

After you create a service, create a virtual server and bind services to the virtual server. The default LB method of least connections is not supported in LLB. For information about changing the LB method, see "[Configuring the LLB Method and Persistence](#)."

## To create a link load balancing virtual server and bind a service by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType>
- bind lb vserver < name> <serviceName>

- show lb vserver < name>

## Example

```
add lb vserver LLB-vip any
bind lb vserver LLB-vip ISP1R_svc_any
sh lb vserver LLB-vip
 LLB-vip (0.0.0.0:0) - ANY Type: ADDRESS
 State: DOWN
 Last state change was at Thu Sep 2 10:51:32 2010
 Time since last state change: 0 days, 17:51:46.770
 Effective State: DOWN
 Client Idle Timeout: 120 sec
 Down state flush: ENABLED
 Disable Primary Vserver On Down : DISABLED
 No. of Bound Services : 1 (Total) 0 (Active)
 Configured Method: ROUNDROBIN
 Mode: IP
 Persistence: NONE
 Connection Failover: DISABLED
```

```
1) ISP1R_svc_any (10.10.10.254: *) - ANY State: DOWN Weight: 1
Done
```

## To create a link load balancing virtual server and bind a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.  
Note: Make sure that **Directly Addressable** is unchecked.
2. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

## Configuring the LLB Method and Persistence

Updated: 2014-10-28

By default, the NetScaler appliance uses the least connections method to select the service for redirecting each client request, but you should set the LLB method to one of the supported methods. You can also configure persistence, so that different transmissions from the same client are directed to the same server.

## To configure the LLB method and/or persistence by using the command line interface

At the command prompt, type the following command:

- set lb vserver <name> -lbMethod <lbMethod> -persistenceType <persistenceType>
- show lb vserver <name>

## Example

```
set lb vserver LLB-vip -lbmethod ROUNDROBIN -persistencetype SOURCEIP
```

```
show lb vserver LLB-vip
```

```
LLB-vip (0.0.0.0:0) - ANY Type: ADDRESS
```

```
State: DOWN
```

```
Last state change was at Fri Sep 3 04:46:48 2010
```

```
Time since last state change: 0 days, 00:52:21.200
```

```
Effective State: DOWN
```

```
Client Idle Timeout: 120 sec
```

```
Down state flush: ENABLED
```

```
Disable Primary Vserver On Down : DISABLED
```

```
No. of Bound Services : 0 (Total) 0 (Active)
```

```
Configured Method: ROUNDROBIN
```

```
Mode: IP
```

```
Persistence: SOURCEIP
```

```
Persistence Mask: 255.255.255.255 Persistence v6MaskLength: 128 Persistence Timeout: 2 min
```

```
Connection Failover: DISABLED
```

## To configure the link load balancing method and/or persistence by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server for which you want to configure the load balancing method and/or persistence settings.
2. In the **Advanced** section, select Method and configure the load balancing method.
3. In the **Advanced** section, select **Persistence** and configure the persistence parameters.

### Configuring an LLB Route

Updated: 2014-10-28

After configuring the IPv4 or IPv6 services, virtual servers, LLB methods, and persistence, you configure an IPv4 or IPv6 LLB route for the network specifying the LLB virtual server as the gateway. A route is a collection of links that are load balanced. Requests are sent to the LLB virtual server IP address that acts as the gateway for all outbound traffic and selects the router based on the LLB method configured.

## To configure an IPv4 LLB route by using the command line interface

At the command prompt, type:

- add lb route <network> <netmask> <gatewayName>
- show lb route [<network> <netmask>]

### Example

```
add lb route 0.0.0.0 0.0.0.0 LLB-vip
```

```
show lb route 0.0.0.0 0.0.0.0
```

|    | Network | Netmask | Gateway/VIP | Flags |
|----|---------|---------|-------------|-------|
|    | -----   | -----   | -----       | ----- |
| 1) | 0.0.0.0 | 0.0.0.0 | LLB-vip     | UP    |

## To configure an IPv6 LLB route by using the command line interface

At the command prompt, type:

- add lb route6 <network> <gatewayName>
- show lb route6

```
add lb route6 ::/0 llb_vs show lb route6 Network VIP Flags ----- 1) ::/0 llb_vs UP
```

### Example

## To configure an LLB route by using the configuration utility

Navigate to System > Network > Routes, and select **LLB**, and configure the LLB route.

Note: Select LLBV6 to configure an IPV6 route.

## To configure an LLB route by using the configuration utility

1. Navigate to System > Network > Routes.
2. In the details pane, select one of the following:
  - Click LLB to configure an IPv4 route.
  - Click LLBV6 to configure an IPv4 route.
3. In the Create LB Route or Create LB IPV6 Routedialog box, set the following parameters:
  - Network\*
  - Netmask\*— Required for IPV4 routes.
  - Gateway Name\*—gatewayName\* A required parameter
4. Click Create, and then click Close. The route that you just created appears on the LLB or the LLB6 tab in the Routes pane.

The following diagram shows a basic LLB setup. A service is configured for each of the two links (ISPs) and PING monitors are bound by default to these services. A link is selected based on the LLB method configured.

Figure 1. Basic LLB Setup

## Note

If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

## Creating and Binding a Transparent Monitor

Updated: 2014-10-28

You create a transparent monitor to monitor the health of upstream devices, such as routers. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the router is UP but one of the next hop devices from that router is down, the appliance includes the router while performing load balancing and forwards the packet to the router. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the router) are down, the service is marked as DOWN and the router is not included when the appliance performs link load balancing.

## To create a transparent monitor by using the command line interface

At the command prompt, type:

- add lb monitor <monitorName> <type> -destIP <ip\_addr|\*> -transparent YES
- show lb monitor [<monitorName>]

### Example

```
add lb monitor monitor-1 PING -destIP 10.10.10.11 -transparent YES
```

```
> show lb monitor monitor-1
```

```
1) Name.....: monitor-1 Type.....: PING State.....: ENABLED
```

Standard parameters:

```
Interval.....: 5 sec Retries.....: 3
Response timeout.: 2 sec Down time.....: 30 sec
Reverse.....: NO Transparent.....: YES
Secure.....: NO LRTM.....: ENABLED
Action.....: Not applicable Deviation.....: 0 sec
Destination IP...: 10.10.10.11
Destination port.: Bound service
Iptunnel.....: NO
TOS.....: NO TOS ID.....: 0
SNMP Alert Retries: 0 Success Retries...: 1
Failure Retries...: 0
```

## To create a transparent monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors and configure a transparent monitor.

## To create a transparent monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the Monitors pane, click Add.
3. In the Create Monitor dialog box, set the following parameters:

- Name\*
- Type\*
- Destination IP
- Transparent

\* A required parameter

4. Click Create, and then click Close.
5. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed in the Details pane are correct.

## To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. On the **Monitors** tab, under **Available**, select the monitor that you want to bind to the service, and then click **Add**.

## To bind a monitor to a service by using the command line interface

At the command prompt, type:

- bind lb monitor <monitorName> <serviceName>
- show service <name>

## Example

```
bind lb monitor monitor-HTTP-1 ISP1R_svc_any
```

```
Done
```

```
> show service ISP1R_svc_any
```

```

## To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select a service to which you want to bind a monitor, and then click Open.
3. In the Configure Service dialog box, on the Monitors tab, under Available, select the monitor that you want to bind to the service, and then click Add.
4. Click OK.
5. In the Services pane, select the service that you just configured and verify that the settings displayed in the Details pane are correct.

# Configuring RNAT with LLB

Dec 15, 2016

You can configure an LLB setup for reverse network address translation (RNAT) for outbound traffic. This ensures that the return network traffic for a specific flow is routed through the same path. First configure basic LLB, as described in "[Configuring a Basic LLB Setup](#)", and then configure RNAT. You must then enable use subnet IP (USNIP) mode.

To add SNIPs for ISP routers by using the command line interface

At the command prompt, type:

- **Add IP NS** <network><subnet of first ISP in the IP router> <subnet mask> **-type SNIP**
- **Add IP NS** <in the IP subnet of second ISP router> <subnet mask> **-type SNIP**

example

COPY

```
add ns ip 10.140.23.1 255.255.255.0 -type snip
```

```
add ns ip 10.141.23.1 255.255.255.0 -type snip
```

To configure RNAT by using the command line interface

At the command prompt, type:

- set mat <network> <netmask>
- show mat

example

COPY

```

> set rnat 10.102.29.0 255.255.255.0 -natIP 10.140.23.1

> set rnat 10.102.29.0 255.255.255.0 -natIP 10.141.23.1

> show rnat

1) Network: 10.102.29.0 Netmask: 255.255.255.0

 NatIP: 10.140.23.1

2) Network: 10.102.29.0 Netmask: 255.255.255.0

 NatIP: 10.141.23.1

```

To configure RNAT by using the configuration utility

1. Navigate to System > Network > Routes.
2. On the **RNAT** tab, from the **Actions** drop-down list, select **Configure RNAT**.
3. Specify the network on which to perform RNAT.

## Note

You can also configure RNAT by using Access Control Lists (ACLs). Refer [Configuring RNAT](#) for details.

To enable Use Subnet IP mode by using the command line interface

At the command prompt, type:

- enable ns mode USNIP
- show ns mode

At the command prompt, type:

- **enable ns mode USNIP**
- **show ns mode**

## Example

```

enable ns mode USNIP
> show ns mode

```

| Mode | Acronym | Status |
|------|---------|--------|
|------|---------|--------|

|                  |       |    |
|------------------|-------|----|
| 1) Fast Ramp     | FR    | ON |
| 2) ....          |       |    |
| 8) Use Subnet IP | USNIP | ON |
| 9) ...           |       |    |

To enable Use Subnet IP mode by using the configuration utility

1. Navigate to System > Settings and, under **Modes and Features**, click **Configure Modes**.
2. In the **Configure Modes** dialog box, select **Use Subnet IP**, and then click **OK**.

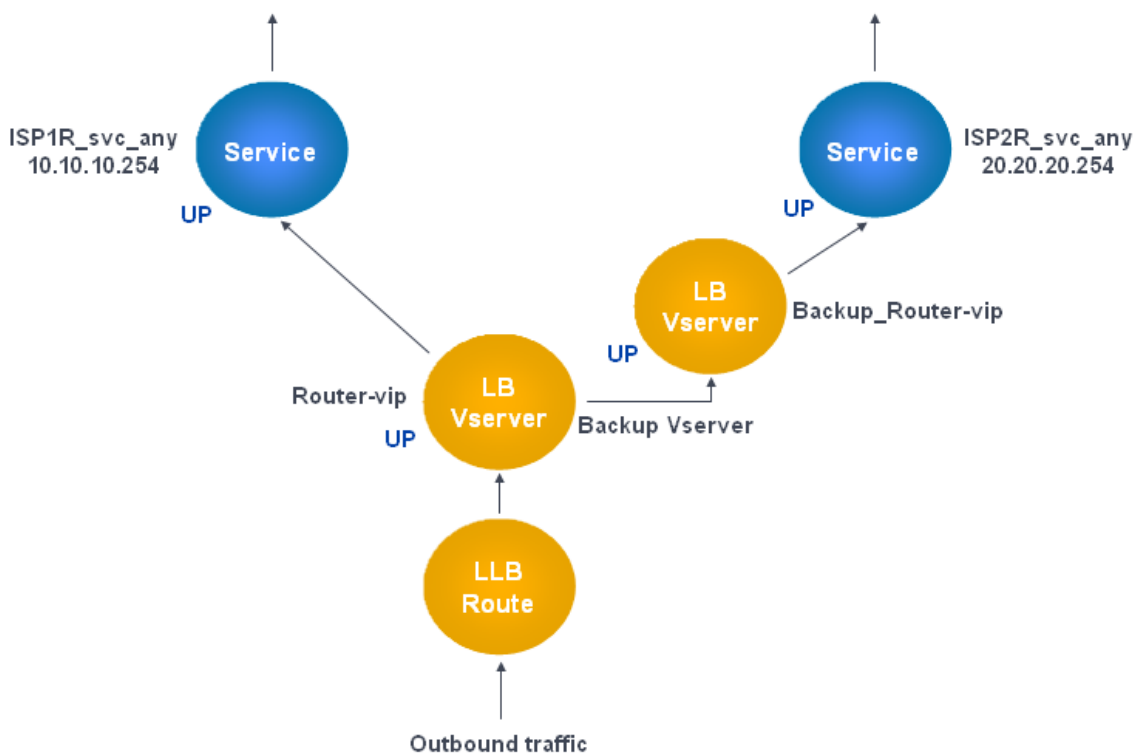

# Configuring a Backup Route

Oct 28, 2014

To prevent disruption in services when the primary route is down, you can configure a backup route. Once the backup route is configured, the NetScaler appliance automatically uses it when the primary route fails. First create a primary virtual server as described in "Configuring an LLB Virtual Server and Binding a Service." To configure a backup route, create a secondary virtual server similar to a primary virtual server and then designate this virtual server as a backup virtual server (route).

In the following diagram, **Router-vip** is the primary virtual server, and **Backup\_Router-vip** is the secondary virtual server designated as the backup virtual server.

Figure 1. Backup Route Setup

Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

By default, all traffic is sent through the primary route. However, when the primary route fails, all traffic is diverted to the backup route as shown in the following diagram.

Figure 2. Backup Routing in Operation

Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

To set the secondary virtual server as the backup virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -backupVserver <string>
```

**Example**

```
set lb vserver Router-vip -backupVServer Backup_Router-vip
```

```
> show lb vserver Router-vip
```

```
Router-vip (0.0.0.0:0) - ANY Type: ADDRESS
State: UP
Last state change was at Fri Sep 3 04:46:48 2010
Time since last state change: 0 days, 03:09:45.600
Effective State: UP
Client Idle Timeout: 120 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
No. of Bound Services : 1 (Total) 1 (Active)
Configured Method: ROUNDROBIN
Mode: IP
Persistence: DESTIP Persistence Mask: 255.255.255.255 Persistence v6MaskLength: 128 Persistence Timeout: 2 min
Backup: Router2-vip
Connection Failover: DISABLED
```

Done

To set the secondary virtual server as the backup virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the secondary virtual server for which you

want to configure the backup virtual server.

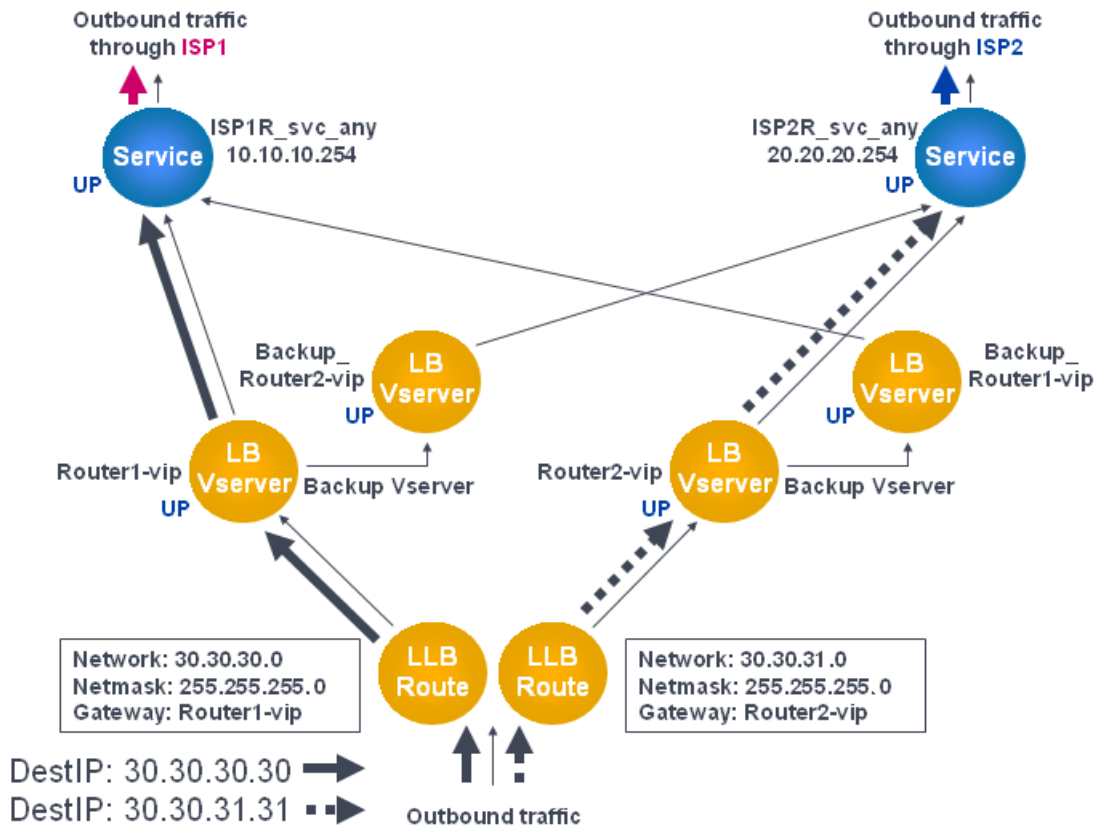

2. In the **Load Balancing Virtual Server** dialog box, under **Advanced**, select **Protection**.
3. In the **Backup Virtual Server** drop-down list, select the secondary backup virtual server, and then click **OK**.

# Resilient LLB Deployment Scenario

Mar 22, 2012

In the following diagram, there are two networks: 30.30.30.0 and 30.30.31.0. Link load balancing is configured based on the destination IP address. Two routes are configured with gateways **Router1-vip** and **Router2-vip**, respectively. **Router1-vip** is configured as a backup to **Router2-vip** and vice versa. All traffic with the destination IP specified as 30.30.30.30 is sent through **Router1-vip** and traffic with the destination IP specified as 30.30.31.31 is sent through **Router2-vip**.

Figure 1. Resilient LLB Deployment Setup

Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

However, if any one of the gateways (**Router1-vip** or **Router2-vip**) is DOWN, traffic is routed through the backup router. In the following diagram, **Router1-vip** for ISP1 is DOWN, so all traffic with the destination IP specified as 30.30.30.30 is also sent through ISP2.

Figure 2. Resilient LLB Deployment Scenario

Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

# Monitoring an LLB Setup

Sep 20, 2010

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

## Viewing the Statistics of a Virtual Server

Updated: 2013-09-05

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

## To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
```

### Example

```
>stat lb vserver -detail
```

Virtual Server(s) Summary

|              | vsvrIP       | port | Protocol | State | Req/s | Hits/s |  |
|--------------|--------------|------|----------|-------|-------|--------|--|
| One          | *            | 80   | HTTP     | UP    | 5/s   | 0/s    |  |
| Two          | *            | 0    | TCP      | DOWN  | 0/s   | 0/s    |  |
| Three        | *            | 2598 | TCP      | DOWN  | 0/s   | 0/s    |  |
| dnsVirtualNS | 10.102.29.90 | 53   | DNS      | DOWN  | 0/s   | 0/s    |  |
| BRVSERV      | 10.10.1.1    | 80   | HTTP     | DOWN  | 0/s   | 0/s    |  |
| LBVIP        | 10.102.29.66 | 80   | HTTP     | UP    | 0/s   | 0/s    |  |

Done

## To display virtual server statistics by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers > Statistics.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

## Viewing the Statistics of a Service

Updated: 2013-08-28

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

## To view the statistics of a service by using the command line interface

At the command prompt, type:

```
stat service <name>
```

### **Example**

```
stat service Service-HTTP-1
```

## To view the statistics of a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

# Load Balancing

Oct 12, 2016

The load balancing feature distributes user requests for web pages and other protected applications across multiple servers that all host (or mirror) the same content. You use load balancing primarily to manage user requests to heavily used applications, preventing poor performance and outages and ensuring that users can access your protected applications. Load balancing also provides fault tolerance; when one server that hosts a protected application becomes unavailable, the feature distributes user requests to the other servers that host the same application.

You can configure the load balancing feature to:

- Distribute all requests for a specific protected website, application, or resource between two or more identically configured servers.
- Use any of several different algorithms to determine which server should receive each incoming user request, basing the decision on different factors, such as which server has the fewest current user connections or which server has the lightest load.

The load balancing feature is a core feature of the NetScaler appliance. Most users first set up a working basic configuration and then customize various settings, including persistence for connections. In addition, you can configure features for protecting the configuration against failure, managing client traffic, managing and monitoring servers, and managing a large scale deployment.

# How Load Balancing Works

Nov 04, 2016

In a basic load balancing setup, clients send their requests to the IP address of a virtual server configured on the NetScaler appliance. The virtual server distributes them to the load-balanced application servers according to a preset pattern, called the load balancing algorithm. In some cases, you might want to assign the load balancing virtual server a wildcard address instead of a specific IP address. For instructions about specifying a global HTTP port on the appliance, see [Global HTTP Ports](#).

To understand how load balancing works, see the following sections:

- [Load Balancing Basics](#)
- [Understanding the Topology](#)
- [Use of Wildcards Instead of IP Addresses and Ports](#)
- [Configuring Global HTTP Ports](#)

## Load Balancing Basics

Updated: 2013-06-18

A load balancing setup includes a load-balancing virtual server and multiple load-balanced application servers. The virtual server receives incoming client requests, uses the load balancing algorithm to select an application server, and forwards the requests to the selected application server. The following conceptual drawing illustrates a typical load balancing deployment. Another variation involves assigning a global HTTP port.

Figure 1. Load Balancing Architecture

The load balancing virtual server can use any of a number of algorithms (or methods) to determine how to distribute load among the load-balanced servers that it manages. The default load balancing method is the least connection method, in which the NetScaler appliance forwards each incoming client connection to whichever load-balanced application server currently has the fewest active user connections.

The entities that you configure in a typical NetScaler load balancing setup are:

- **Load balancing virtual server.** The IP address, port, and protocol combination to which a client sends connection requests for a particular load-balanced website or application. If the application is accessible from the Internet, the virtual server IP (VIP) address is a public IP address. If the application is accessible only from the local area network (LAN) or wide area network (WAN), the VIP is usually a private (ICANN non-routable) IP address.
- **Service.** The IP address, port, and protocol combination used to route requests to a specific load-balanced application server. A service can be a logical representation of the application server itself, or of an application running on a server that hosts multiple applications. After creating a service, you bind it to a load balancing virtual server.
- **Server object.** A virtual entity that enables you to assign a name to a physical server instead of identifying the server by its IP address. If you create a server object, you can specify its name instead of the server's IP address when you create a service. Otherwise, you must specify the server's IP address when you create a service, and the IP address becomes the name of the server.
- **Monitor.** An entity on the NetScaler appliance that tracks a service and ensures that it is operating correctly. The monitor periodically probes (or performs a health check on) each service to which you assign it. If the service does not respond within the time specified by the time-out, and a specified number of health checks fail, that service is marked DOWN. The NetScaler appliance then skips that service when performing load balancing, until the issues that caused the service to quit responding are fixed.

The virtual server, services, and load balanced application servers in a load balancing setup can use either Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) IP addresses. You can mix IPv4 and IPv6 addresses in a single load balancing setup.

For variations in the load balancing setup, see the following use cases:

- [Configuring Load Balancing in Direct Server Return Mode](#)
- [Configuring LINUX Servers in DSR Mode](#)
- [Configuring DSR Mode When Using TOS](#)
- [Configuring Load Balancing in DSR Mode by Using IP Over IP](#)
- [Configuring Load Balancing in One-arm Mode](#)
- [Configuring Load Balancing in the Inline Mode](#)
- [Load Balancing of Intrusion Detection System Servers](#)
- [Load Balancing RDP services](#)

## Understanding the Topology

In a load balancing setup, the load balancing server is logically located between the client and the server farm, and manages traffic flow to the servers in the server farm. On the NetScaler appliance, the application servers are represented by virtual entities called services. The following diagram shows the topology of a basic load balancing configuration.

Figure 2. Basic Load Balancing Topology

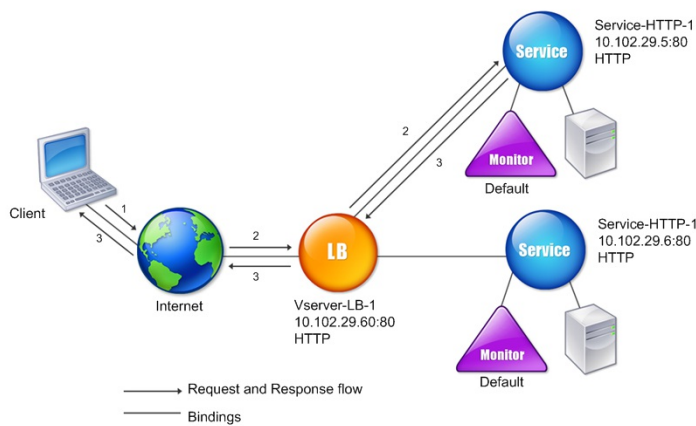

In the diagram, load balancing is used to manage traffic flow to the servers. The virtual server selects the service and assigns it to serve client requests. Consider a scenario where the services Service-HTTP-1 and Service-HTTP-2 are created and bound to the virtual server named Vserver-LB-1. Vserver-LB-1 forwards the client request to either Service-HTTP-1 or Service-HTTP-2. The NetScaler appliance uses the least connection load balancing method to select the service for each

request. The following table lists the names and values of the basic entities that must be configured on the appliance.

| Entity         | Mandatory Parameters and Sample Values |              |      |          |
|----------------|----------------------------------------|--------------|------|----------|
|                | Name                                   | IP Address   | Port | Protocol |
| Virtual server | Vserver-LB-1                           | 10.102.29.60 | 80   | HTTP     |
| Services       | Service-HTTP-1                         | 10.102.29.5  | 80   | HTTP     |
|                | Service-HTTP-2                         | 10.102.29.6  | 80   | HTTP     |
| Monitors       | Default                                | None         | None | None     |

The following diagram shows the load balancing sample values and mandatory parameters that are described in the preceding table.

Figure 3. Load Balancing Entity Model

## Use of Wildcards Instead of IP Addresses and Ports

Updated: 2013-11-20

In some cases you might need to use a wildcard for the IP address or the port of a virtual server or for the port of a service. The following cases may require using a wildcard:

- If the NetScaler appliance is configured as a transparent pass through, which must accept all traffic that is sent to it regardless of the IP or port to which it is sent.
- If one or more services listen on ports that are not well known.

- If one or more services, over time, change the ports that they listen on.
- If you reach the limit for the number of IP addresses and ports that you can configure on a single NetScaler appliance.
- If you want to create virtual servers that listen for all traffic on a specific virtual LAN.

When a wildcard-configured virtual server or service receives traffic, the NetScaler appliance determines the actual IP address or port and creates new records for the service and associated load balanced application server. These dynamically created records are called dynamically learned server and service records.

For example, a firewall load balancing configuration can use wildcards for both the IP address and port. If you bind a wildcard TCP service to this type of load balancing virtual server, the virtual server receives and processes all TCP traffic that does not match any other service or virtual server.

The following table describes some of the different types of wildcard configurations and when each should be used.

| IP         | Port | Protocol         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------|------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| *          | *    | TCP              | A general wildcard virtual server that accepts traffic sent to any IP address and port on the NetScaler appliance. When using a wildcarded virtual server, the appliance dynamically learns the IP and port of each service and creates the necessary records as it processes traffic.                                                                                                                                                                                                                                                                                                                                                   |
| *          | *    | TCP              | A firewall load balancing virtual server. You can bind firewall services to this virtual server, and the NetScaler appliance passes traffic through the firewall to the destination.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| IP Address | *    | TCP,UDP, and ANY | A virtual server that accepts all traffic that is sent to the specified IP address, regardless of the port. You must explicitly bind to this type of virtual server the services to which it will redirect traffic. It will not dynamically learn them.<br><br>Note: You do not configure services or virtual servers for a global HTTP port. In this case, you configure a specific port as a global HTTP port (for example, set ns param -httpPort 80). The appliance then accepts all traffic that matches the port number, and processes it as HTTP traffic. The appliance dynamically learns and creates services for this traffic. |
| *          | port | SSL, SSL_TCP     | A virtual server that accepts all traffic sent to any IP address on a specific port. Used for global transparent SSL offloading. All SSL, HTTP, and TCP processing that usually is performed for a service of the same protocol type is applied to traffic that is directed to this specific port. The appliance uses the port to dynamically learn the IP of the service it should use. If -cleartext is not specified, the NetScaler appliance uses end-to-end SSL.                                                                                                                                                                    |
| *          | port | Not applicable   | All other virtual servers that can accept traffic to the port. You do not bind services to these virtual servers; the NetScaler appliance learns them dynamically.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Note: If you have configured your NetScaler appliance as a transparent pass through that makes use of global (wildcard) ports, you may want to turn on Edge mode. For more information, see "[Configuring Edge Mode](#)."

The NetScaler appliance attempts to locate virtual servers and services by first attempting an exact match. If none is found, it continues to search for a match based on wildcards, in the following order:

1. Specific IP address and specific port number
2. Specific IP address and a \* (wildcard) port
3. \* (wildcard) IP address and a specific port
4. \* (wildcard) IP address and a \* (wildcard) port

If the appliance is unable to select a virtual server by IP address or port number, it searches for a virtual server on the basis of the protocol used in the request, in the following order:

1. HTTP
2. TCP
3. ANY

## Configuring Global HTTP Ports

Updated: 2013-10-23

You do not configure services or virtual servers for a global HTTP port. Instead, you configure a specific port by using the `set ns param` command. After configuring this port, the NetScaler appliance accepts all traffic that matches the port number, and processes it as HTTP traffic, dynamically learning and creating services for that traffic.

You can configure more than one port number as a global HTTP port. If you are specifying more than one port number in a single `set ns param` command, separate the port numbers by a single white space. If one or more ports have already been specified as global HTTP ports, and you want to add one or more ports without removing the ports that are currently configured, you must specify all the port numbers, current and new, in the command. Before you add port numbers, use the `show ns param` command to view the ports that are currently configured.

## To configure a global HTTP port by using the command line interface

At the command prompt, type the following commands to configure a global HTTP port and verify the configuration:

- `set ns param -httpPort <port>`
- `show ns param`

### Example 1: Configuring a port as a global HTTP port

In this example, port 80 is configured as a global HTTP port.

```
> set ns param -httpPort 80
Done
> show ns param
Global configuration settings:
 HTTP port(s): 80
 Max connections: 0
 Max requests per connection: 0
 Client IP insertion: DISABLED
 Cookie version: 0
 Persistence Cookie Secure Flag: ENABLED
...
...
```

### Example 2: Adding ports when one or more global HTTP ports are already configured

In this example, port 8888 is added to the global HTTP port list. Port 80 is already configured as a global HTTP port.

```
> show ns param
```

```
Global configuration settings:
 HTTP port(s): 80
 Max connections: 0
 Max requests per connection: 0
 Client IP insertion: DISABLED
 Cookie version: 0
 Persistence Cookie Secure Flag: ENABLED
 Min Path MTU: 576
```

```
...
```

```
...
```

```
Done
```

```
> set ns param -httpPort 80 8888
```

```
Done
```

```
> show ns param
```

```
Global configuration settings:
 HTTP port(s): 80,8888
 Max connections: 0
 Max requests per connection: 0
 Client IP insertion: DISABLED
 Cookie version: 0
 Persistence Cookie Secure Flag: ENABLED
 Min Path MTU: 576
```

```
...
```

```
...
```

```
Done
```

```
>
```

## To configure a global HTTP port by using the configuration utility

1. Navigate to System > Settings > Change HTTP Parameters, and then add an HTTP port number.

# Setting Up Basic Load Balancing

Nov 10, 2016

Before configuring your initial load balancing setup, enable the load balancing feature. Then begin by creating at least one service for each server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server, and bind each service to the virtual server. That completes the initial setup. Before proceeding with further configuration, verify your configuration to make sure that each element was configured properly and is operating as expected.

To set up basic load balancing, see the following sections:

- [Enabling Load Balancing](#)
- [Configuring a Server Object](#)
- [Configuring Services](#)
- [Creating a Virtual Server](#)
- [Binding Services to the Virtual Server](#)
- [Verifying the Configuration](#)

## Enabling Load Balancing

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

## To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

Example

COPY

```
> enable ns feature LoadBalancing
```

```
Done
```

```
> show ns feature
```

|     | Feature               | Acronym   | Status    |
|-----|-----------------------|-----------|-----------|
|     | -----                 | -----     | -----     |
| 1)  | Web Logging           | WL        | OFF       |
| 2)  | Surge Protection      | SP        | ON        |
| 3)  | <b>Load Balancing</b> | <b>LB</b> | <b>ON</b> |
| .   |                       |           |           |
| .   |                       |           |           |
| .   |                       |           |           |
| 24) | NetScaler Push        | push      | OFF       |

```
Done
```

## To enable load balancing by using the configuration utility

Navigate to **System > Settings** and, in **Configure Basic Features**, select **Load Balancing**.

### Configuring a Server Object

Create an entry for your server on the NetScaler appliance. The NetScaler appliance supports IP address based servers and domain-based servers. If you create an IP address based server, you can specify the name of the server instead of its IP address when you create a service. For information about setting up DNS for a domain-based server, see [Domain Name System](#).

### To create a server object by using the NetScaler command line

At the command prompt, type:

```
add server <name>@ <IPAddress>@ | <domain>
```

### To create a server object by using the NetScaler GUI

Navigate to **Traffic Management > Load Balancing > Servers**, and add a server object.

```
add server web_serv 10.102.27.150
```

## Configuring Services

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the NetScaler appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server's name instead of its IP address when you create a service.

When you create a service that uses UDP as the transport layer protocol, a ping monitor is automatically bound to the service. A ping monitor is the most basic of the built-in monitors. When you create a service that uses TCP as the transport layer protocol, a TCP\_default monitor is automatically bound to the service. When you develop a strategy for managing your load balancing setup, you might decide to bind a different type of monitor, or multiple monitors, to the service.

## Creating a Service

Before you create a service, you need to understand the different service types and how each is used. The following list describes the types of services supported on the NetScaler appliance.

### HTTP

Used for load-balanced servers that accept HTTP traffic, such as standard web sites and web applications. The HTTP service type enables the NetScaler appliance to provide compression, content filtering, caching, and client keep-alive support for your Layer 7 web servers. This service type also supports virtual server IP port insertion, redirect port rewriting, Web 2.0 Push, and URL redirection support.

Because HTTP is a TCP-based application protocol, you can also use the TCP service type for web servers. If you do so, however, the NetScaler appliance is able to perform only Layer 4 load balancing. It cannot provide any of the Layer 7 support described earlier.

### SSL

Used for servers that accept HTTPS traffic, such as ecommerce web sites and shopping cart applications. The SSL service type enables the NetScaler appliance to encrypt and decrypt SSL traffic (perform SSL offloading) for your secure web applications. It also supports HTTP persistence, content switching, rewrite, virtual server IP port insertion, Web 2.0 Push, and URL redirection.

You can also use the SSL\_BRIDGE, SSL\_TCP, or TCP service types. If you do so, however, the NetScaler performs only Layer 4 load balancing. It cannot provide SSL offloading or any of the Layer 7 support described above.

### FTP

Used for servers that accept FTP traffic. The FTP service type enables the NetScaler appliance to support specific details of the FTP protocol.

You can also use TCP or ANY service types for FTP servers.

### **TCP**

Used for servers that accept many different types of TCP traffic, or that accept a type of TCP traffic for which a more specific type of service is not available.

You can also use the ANY service type for these servers.

### **SSL\_TCP**

Used for servers that accept non-HTTP-based SSL traffic, to support SSL offloading.

You can also use the TCP service type for these services. If you do so, the NetScaler appliance performs both the Layer 4 load balancing and SSL offloading.

### **UDP**

Used for servers that accept UDP traffic. You can also use the ANY service type.

### **SSL\_BRIDGE**

Used for servers that accept SSL traffic when you do not want the NetScaler appliance to perform SSL offloading. Alternatively, you can use the SSL\_TCP service type.

### **NNTP**

Used for servers that accept Network News Transfer Protocol (NNTP) traffic, typically Usenet sites.

### **DNS**

Used for servers that accept DNS traffic, typically nameservers. With the DNS service type, the NetScaler appliance validates the packet format of each DNS request and response. It can also cache DNS responses. You can apply DNS policies to DNS services.

You can also use the UDP service type for these services. If you do, however, the NetScaler appliance can only perform Layer 4 load balancing. It cannot provide support for DNS-specific features.

### **ANY**

Used for servers that accept any type of TCP, UDP, or ICMP traffic. The ANY parameter is used primarily with firewall load balancing and link load balancing.

### **SIP-UDP**

Used for servers that accept UDP-based Session Initiation Protocol (SIP) traffic. SIP initiates, manages, and terminates multimedia communications sessions, and has emerged as the standard for Internet telephony (VoIP).

You can also use the UDP service type for these services. If you do, however, the NetScaler appliance performs only Layer 4 load balancing. It cannot provide support for SIP-specific features.

## DNS-TCP

Used for servers that accept DNS traffic, where the NetScaler appliance acts as a proxy for TCP traffic sent to DNS servers. With services of the DNS-TCP service type, the NetScaler appliance validates the packet format of each DNS request and response and can cache DNS responses, just as with the DNS service type.

You can also use the TCP service type for these services. If you do, however, the NetScaler appliance only performs Layer 4 load balancing of external DNS name servers. It cannot provide support for any DNS-specific features.

## RTSP

Used for servers that accept Real Time Streaming Protocol (RTSP) traffic. RTSP provides delivery of multimedia and other streaming data. Select this type to support audio, video, and other types of streamed media.

You can also use the TCP service type for these services. If you do, however, the NetScaler appliance performs only Layer 4 load balancing. It cannot parse the RTSP stream or provide support for RTSPID persistence or RTSP NATting.

## DHCPRA

Used for servers that accept DHCP traffic. The DHCPRA service type can be used to relay DHCP requests and responses between VLANs.

## DIAMETER

Used for load balancing Diameter traffic among multiple Diameter servers. Diameter uses message-based load balancing.

## SSL\_DIAMETER

Used for load balancing Diameter traffic over SSL.

Services are designated as DISABLED until the NetScaler appliance connects to the associated load-balanced server and verifies that it is operational. At that point, the service is designated as ENABLED. Thereafter, the NetScaler appliance periodically monitors the status of the servers, and places any that fail to respond to monitoring probes (called health checks) back in the DISABLED state until they respond.

Note: You can create a range of services from a single CLI command or the same dialog box. The names in the range vary by a number used as a suffix/prefix. For example, service1, service2, and so on. From the configuration utility, you can specify a range only in the last octet of the IP address, which is the fourth in case of an IPv4 address and the eighth in case of an IPv6 address. From the command line, you can specify the range in any octet of the IP address.

## To create a service by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> <serviceType> <port>
```

Example

COPY

```
add service Service-HTTP-1 web_serv HTTP 80
```

## To create a service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, click **Add**.
3. In the **Create Service** dialog box, specify values for the following parameters:
  - Service Name—name
  - Server—serverName
  - Protocol—serviceType
  - Port—port
4. Click **Create**, and then click **Close**. The service you created appears in the **Services** pane.

## Creating a Virtual Server

After you create your services, you must create a virtual server to accept traffic for the load balanced Web sites, applications, or servers. Once load balancing is configured, users connect to the load-balanced Web site, application, or server through the virtual server's IP address or FQDN.

Note: The virtual server is designated as DOWN until you bind the services that you created to it, and until the NetScaler appliance connects to those services and verifies that they are operational. Only then is the virtual server designated as UP.

## To create a virtual server by using the command line interface

At the command prompt, type:

```
add lb vserver <name> <serviceType> <ip> <port>
```

```
Example COPY

add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

## To create a virtual server by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and then create a virtual server.

## Binding Services to the Virtual Server

Note: A service can be bound to a maximum of 500 virtual servers.

After you have created services and a virtual server, you must bind the services to the virtual server. In most cases, services are bound to virtual servers of the same type, but you can bind certain types of services to certain different types of virtual servers, as shown below.

| Virtual Server Type | Service Type | Comment                                                                            |
|---------------------|--------------|------------------------------------------------------------------------------------|
| HTTP                | SSL          | You would normally bind an SSL service to an HTTP virtual server to do encryption. |

| SSL Virtual Server Type | HTTP Service Type | Comment                                                                                                                                                                                                                                     |
|-------------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SSL_TCP                 | TCP               | You would normally bind an HTTP service to an SSL virtual server to do SSL offloading.<br>You would normally bind a TCP service to an SSL_TCP virtual server to do SSL offloading for other TCP (SSL decryption without content awareness). |

The state of the services bound to a virtual server determines the state of the virtual server: if all of the bound services are DOWN, the virtual server is marked DOWN, and if any of the bound services is UP or OUT OF SERVICE, the state of the virtual server is UP.

## To bind a service to a load balancing virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

Example
COPY

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

## To bind a service to a load balancing virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select a virtual server.
2. Click in the **Service** section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

### Verifying the Configuration

After finishing your basic configuration, you should view the properties of each service and load balancing virtual server in your load balancing setup to verify that each is configured correctly. After the configuration is up and running, you should view the statistics for each service and load balancing virtual server to check for possible problems.

## Viewing the Properties of a Server Object

You can view properties such as the name, state, and IP address of any server object in your NetScaler appliance configuration.

### To view the properties of server objects by using the command line interface

At the command prompt, type:

```
show server <serverName>
```

Example
COPY

```
show server server-1
```

### To view the properties of server objects by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Servers**. The parameter values of the available servers appear in the details pane.

## Viewing the Properties of a Virtual Server

You can view properties such as the name, state, effective state, IP address, port, protocol, method, and number of bound services for your virtual servers. If you have configured more than the basic load balancing settings, you can view the persistence settings for your virtual servers, any policies that are bound to them, and any cache redirection and content switching virtual servers that have been bound to the virtual servers.

### To view the properties of a load balancing virtual server by using the command line interface

At the command prompt, type:

```
show lb vserver <name>
```

Example

COPY

```
show lb vserver Vserver-LB-1
```

### To view the properties of a load balancing virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, click a virtual server to display its properties at the bottom of the details pane.
3. To view cache redirection and content switching virtual servers that are bound to this virtual server, click **Show CS/CR Bindings**.

## Viewing the Properties of a Service

You can view the name, state, IP address, port, protocol, maximum client connection, maximum requests per connection, and server type of the configured services, and use this information to troubleshoot any mistake in the service configuration.

### To view the properties of services by using the command line interface

At the command prompt, type:

```
show service <name>
```

Example

COPY

```
show service Service-HTTP-1
```

### To view the properties of services by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Services**. The details of the available services appear on the **Services** pane.

## Viewing the Bindings of a Service

You can view the list of virtual servers to which the service is bound. The binding information also provides the name, IP address, port and state of the virtual servers to which the services are bound. You can use the binding information to troubleshoot any problem with binding the services to virtual servers.

### To view the bindings of a service by using the command line

At the command prompt, type:

```
show service bindings <name>
```

Example

COPY

```
show service bindings Service-HTTP-1
```

### To view the bindings of a service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, select the service whose binding information you want to view.
3. In the **Action** tab, click **Show Bindings**.

## Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name

- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

### To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the appliance, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
```

Example
COPY

```

>stat lb vserver -detail

Virtual Server(s) Summary

vsrvIP port Protocol State Req/s Hits/s

One * 80 HTTP UP 5/s 0/s

Two * 0 TCP DOWN 0/s 0/s

Three * 2598 TCP DOWN 0/s 0/s

dnsVirtualINS 10.102.29.90 53 DNS DOWN 0/s 0/s

BRVSERV 10.10.1.1 80 HTTP DOWN 0/s 0/s

LBVIP 10.102.29.66 80 HTTP UP 0/s 0/s

Done

```

### To display virtual server statistics by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.

3. In the details pane, click **Statistics**.

## Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

### To view the statistics of a service by using the command line interface

At the command prompt, type:

```
stat service <name>
```

A terminal window with a dark background. The title bar at the top left says "Example" and at the top right is a "COPY" button. The terminal content shows the command "stat service Service-HTTP-1" entered at the prompt.

```
Example COPY
stat service Service-HTTP-1
```

### To view the statistics of a service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).
3. Click **Statistics**. The statistics appear in a new window.

# Load Balancing Virtual Server and Service States

Jul 28, 2016

A load balancing virtual server that does not have a backup virtual server can take the following states, depending on the states of the service(s) bound to it and whether it is administratively disabled:

- **UP:** At least one of the services bound to the virtual server is UP.
- **DOWN:** All the services bound to the virtual server are DOWN, or the load balancing feature is not enabled.
- **Out of Service (OFS):** If you administratively disable the virtual server, it enters the OFS state but its effective state is DOWN. Transitioning to the OFS state from the DOWN or UP state, or to the DOWN or UP state from the OFS state, is controlled by the administrator.

The state and effective state of a virtual server are the same if a backup virtual server is not configured. However, if a backup virtual server or a chain of backup virtual servers is configured, the effective state is derived from the states of the services that are bound to the primary virtual server and the backup virtual server(s). If any of the backup virtual servers in the chain is UP, the effective state of the primary virtual server is UP, even if all the services bound to the primary virtual server are DOWN.

The following diagrams show the conditions under which a virtual server transitions from one state to another.

A service can take the following states:

- **UP:** If probes from all the monitors bound to the service are successful.
- **DOWN:** If monitoring probes to the service are not answered within the configured time limit.
- **OUT OF SERVICE:** If you administratively disable the service, or if you gracefully shut down the service and there are no active transactions to the service

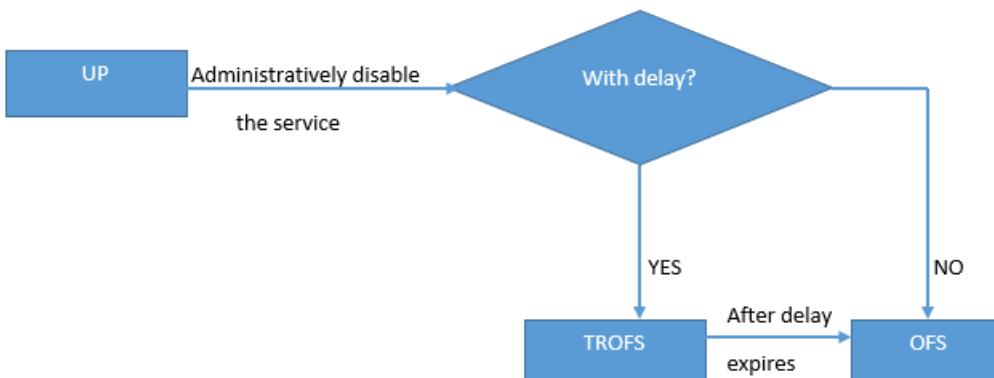

- **GOING OUT OF SERVICE (TROFS):** If you administratively disable the service with delay, or gracefully shut down the service and there are active transactions to the service. For more information, see <http://docs.citrix.com/en-us/netscaler/11/traffic-management/load-balancing/load-balancing-advanced-settings/graceful-shutdown.html>.
- **DOWN WHEN GOING OUT OF SERVICE (TROFS\_DOWN):** A monitoring probe fails while the service is in the GOING OUT OF SERVICE state.

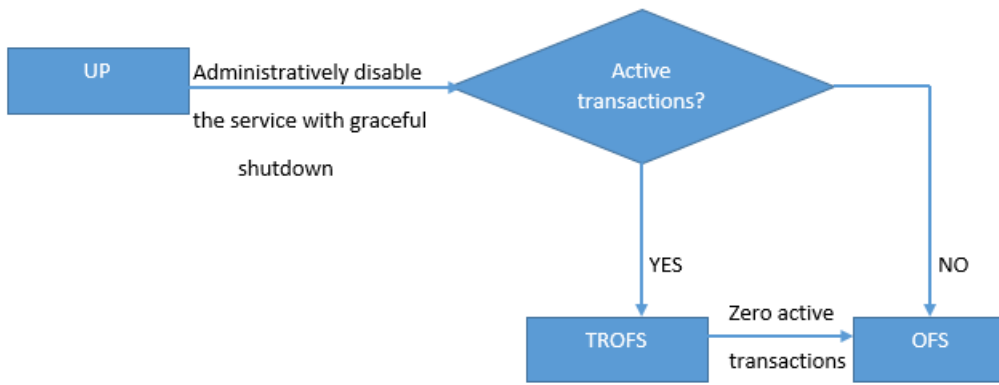

A service in the process of transitioning from UP to OFS is in the GOING OUT OF SERVICE state. A service transitioning from DOWN to OFS is in the DOWN WHEN GOING OUT OF SERVICE state. For example, if a service is DOWN and you disable it with delay, the service transitions to DOWN WHEN GOING OUT OF SERVICE and then to the OUT OF SERVICE state. If a service is UP and you disable it with delay, the service transitions to GOING OUT OF SERVICE. During this time, if a monitoring probe to the server fails, the service transitions to DOWN WHEN GOING OUT OF SERVICE and, after the delay time expires, enters the OFS state.

## Note

You can configure spillover to a backup virtual server by setting the "healthThreshold" parameter to a non-zero positive value. Then, if a single service bound to the primary virtual server transitions to the DOWN WHEN GOING OUT OF SERVICE state and the health threshold is not reached, the primary virtual server is marked DOWN and new connections are directed to the backup virtual server.

The following diagrams show the conditions under which a service transitions from one state to another.

# Load Balancing Algorithms

Aug 29, 2013

The load balancing algorithm defines the criteria that the NetScaler appliance uses to select the service to which to redirect each client request. Different load balancing algorithms use different criteria. For example, the least connection algorithm selects the service with the fewest active connections, while the round robin algorithm maintains a running queue of active services, distributes each connection to the next service in the queue, and then sends that service to the end of the queue.

Some load balancing algorithms are best suited to handling traffic on websites, others to managing traffic to DNS servers, and others to handling complex web applications used in e-commerce or on company LANs or WANs. The following table lists each load balancing algorithm that the NetScaler appliance supports, with a brief description of how each operates.

| Name              | Server Selection Based On                                                                                                               |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| LEASTCONNECTION   | Which service currently has the fewest client connections. This is the default load balancing algorithm.                                |
| ROUNDROBIN        | Which service is at the top of a list of services. After that service is selected for a connection, it moves to the bottom of the list. |
| LEASTRESPONSETIME | Which load balanced server currently has the quickest response time.                                                                    |
| URLHASH           | A hash of the destination URL.                                                                                                          |
| DOMAINHASH        | A hash of the destination domain.                                                                                                       |
| DESTINATIONIPHASH | A hash of the destination IP address.                                                                                                   |
| SOURCEIPHASH      | A hash of the source IP address.                                                                                                        |
| SRCIPDESTIPHASH   | A hash of the source and destination IP addresses.                                                                                      |
| CALLIDHASH        | A hash of the call ID in the SIP header.                                                                                                |
| SRCIPSRCPORHASH   | A hash of the client's IP address and port.                                                                                             |
| LEASTBANDWIDTH    | Which service currently has the fewest bandwidth constraints.                                                                           |
| LEASTPACKETS      | Which service currently is receiving the fewest packets.                                                                                |

|                           |                                                                 |
|---------------------------|-----------------------------------------------------------------|
| <b>Name</b><br>CUSTOMLOAD | <b>Server Selection Based On</b><br>Data from a load monitor.   |
| TOKEN                     | The configured token.                                           |
| LRTM                      | Fewest active connections and the lowest average response time. |

Depending on the protocol of the service that it is load balancing, the NetScaler appliance sets up each connection between client and server to last for a different time interval. This is called load balancing granularity, of which are three types: request-based, connection-based, and time-based granularity. The following table describes each type of granularity and when each is used.

| Granularity      | Types of Load Balanced Service              | Specifies                                                                                                                                                                                                                                                                                                              |
|------------------|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Request - based  | HTTP or HTTPS                               | A new service is chosen for each HTTP request, independent of TCP connections. As with all HTTP requests, after the Web server fulfills the request, the connection is closed.                                                                                                                                         |
| Connection-based | TCP and TCP-based protocols other than HTTP | A service is chosen for every new TCP connection. The connection persists until terminated by either the service or the client.                                                                                                                                                                                        |
| Time-based       | UDP and other IP protocols                  | A new service is chosen for each UDP packet. Upon selection of a service, a session is created between the service and a client for a specified period of time. When the time expires, the session is deleted and a new service is chosen for any additional packets, even if those packets come from the same client. |

During startup of a virtual server, or whenever the state of a virtual server changes, the virtual server can initially use the round robin method to distribute the client requests among the physical servers. This type of distribution, referred to as *startup round robin*, helps prevent unnecessary load on a single server as the initial requests are served. After using the round robin method at the startup, the virtual server switches to the load balancing method specified on the virtual server.

The Startup RR Factor works in the following manner:

- If the Startup RR Factor is set to zero, the NetScaler switches to the specified load balancing method depending on the request rate.
- If the Startup RR Factor is any number other than zero, NetScaler uses the round robin method for the specified number of requests before switching to the specified load balancing method.
- By default, the Startup RR Factor is set to zero.

Note: You cannot set the startup RR Factor for an individual virtual server. The value you specify applies to all the virtual servers on the NetScaler appliance.

### **To set the startup round-robin factor by using the command line interface**

At the command prompt, type:

```
set lb parameter -startupRRFactor <positive_integer>
```

Example

```
set lb parameter -startupRRFactor 25000
```

### **To set the startup round-robin factor by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing Parameters, and set the Startup RR Factor.

# The Least Connection Method

Nov 11, 2016

When a virtual server is configured to use the least connection load balancing algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.

For TCP, HTTP, HTTPS, and SSL\_TCP services, the NetScaler appliance includes the following connection types in its list of existing connections:

- **Active connections to a service.** Connections representing requests that a client has sent to the virtual server and that the virtual server has forwarded to a service. For HTTP and HTTPS services, active connections represent only those HTTP or HTTPS requests that have not yet received a response.
- **Waiting connections in the surge queue.** Any connections to the virtual server that are waiting in a surge queue and have not yet been forwarded to a service. Connections can build up in the surge queue at any time, for any of the following reasons:
  - Your services have connection limits, and all services in your load balancing configuration are at that limit.
  - The surge protection feature is configured and has been activated by a surge in requests to the virtual server.
  - The load-balanced server has reached an internal limit and therefore does not open any new connections. (For example, an Apache server's connection limit is reached.)

When a virtual server uses the least connection method, it considers the waiting connections as belonging to the specific service. Therefore, it does not open new connections to those services.

For UDP services, the connections that the least connection algorithm considers include all sessions between the client and a service. These sessions are logical, time-based entities. When the first UDP packet in a session arrives, the NetScaler appliance creates a session between the source IP address and port and the destination IP address and port.

For Real-Time Streaming Protocol (RTSP) connections, the NetScaler appliance uses the number of active control connections to determine the lowest number of connections to an RTSP service.

The following example shows how a virtual server selects a service for load balancing by using the least connection method. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions.
- Service-HTTP-2 is handling 15 active transactions.
- Service-HTTP-3 is not handling any active transactions.

The following diagram illustrates how the NetScaler appliance forwards incoming requests when using the least connection method.

Figure 1. Mechanism of the Least Connections Load Balancing Method

In this diagram, the virtual server selects the service for each incoming connection by choosing the server with the fewest active transactions.

Connections are forwarded as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.

Note: The service with no active transaction is selected first.

- Service-HTTP-3 receives the second and third requests because the service has the next least number of active transactions.
- Service-HTTP-1 receives the fourth request. Because Service-HTTP-1 and Service-HTTP-3 have same number of active transactions, the virtual server uses the round robin method to choose between them.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-1 receives the sixth request, and so on, until both Service-HTTP-1 and Service-HTTP-3 are handling the same number of requests as Service-HTTP-2. At that time, the NetScaler appliance starts forwarding requests to Service-HTTP-2 when it is the least loaded service or its turn comes up in the round robin queue.

Note: If connections to Service-HTTP-2 close, it might get new connections before each of the other two services has 15 active transactions.

The following table explains how connections are distributed in the three-service load balancing set up described above.

| Incoming Connection | Service Selected          | Current Number of Active Connections | Remarks                                           |
|---------------------|---------------------------|--------------------------------------|---------------------------------------------------|
| Request-1           | Service-HTTP-3<br>(N = 0) | 1                                    | Service-HTTP-3 has the fewest active connections. |
| Request-2           | Service-                  | 2                                    |                                                   |

| Incoming Connection                                                                                                                                                                                                               | HTTP-3 Service Selected<br>(N = 1) | Current Number of Active Connections | Remarks                                                                       |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|--------------------------------------|-------------------------------------------------------------------------------|
| Request-3                                                                                                                                                                                                                         | Service-HTTP-3<br>(N = 2)          | 3                                    |                                                                               |
| Request-4                                                                                                                                                                                                                         | Service-HTTP-1<br>(N = 3)          | 4                                    | Service-HTTP-1 and Service-HTTP-3 have the same number of active connections. |
| Request-5                                                                                                                                                                                                                         | Service-HTTP-3<br>(N = 3)          | 4                                    |                                                                               |
| Request-6                                                                                                                                                                                                                         | Service-HTTP-1<br>(N = 4)          | 5                                    |                                                                               |
| Request-7                                                                                                                                                                                                                         | Service-HTTP-3<br>(N = 4)          | 5                                    |                                                                               |
| Request-8                                                                                                                                                                                                                         | Service-HTTP-1<br>(N = 5)          | 6                                    |                                                                               |
| Service-HTTP-2 is selected for load balancing when it completes its active transactions and the current connections to it close, or when the other services (Service-HTTP-1 and Service-HTTP-3) have 15 or more connections each. |                                    |                                      |                                                                               |

The NetScaler appliance can also use the least connection method when weights are assigned to services. It selects a service by using the value (Nw) of the following expression:

$$Nw = (\text{Number of active transactions}) * (10000 / \text{weight})$$

The following example shows how the NetScaler appliance selects a service for load balancing by using the least connection method when weights are assigned to services. In the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. Connections are forwarded as follows:

- Service-HTTP-3 receives the first because the service is not handling any active transactions.

Note: If services are not handling any active transactions, the NetScaler appliance uses the round robin method regardless of the weights assigned to each of the services.

- Service-HTTP-3 receives the second, third, fourth, fifth, sixth, and seventh requests because the service has lowest Nw value.
- Service-HTTP-1 receives the eighth request. Because Service-HTTP-1 and Service-HTTP-3 now have same Nw value, the NetScaler performs load balancing in a round robin manner. Therefore, Service-HTTP-3 receives the ninth request.

The following table explains how connections are distributed on the three-service load balancing setup that is described above.

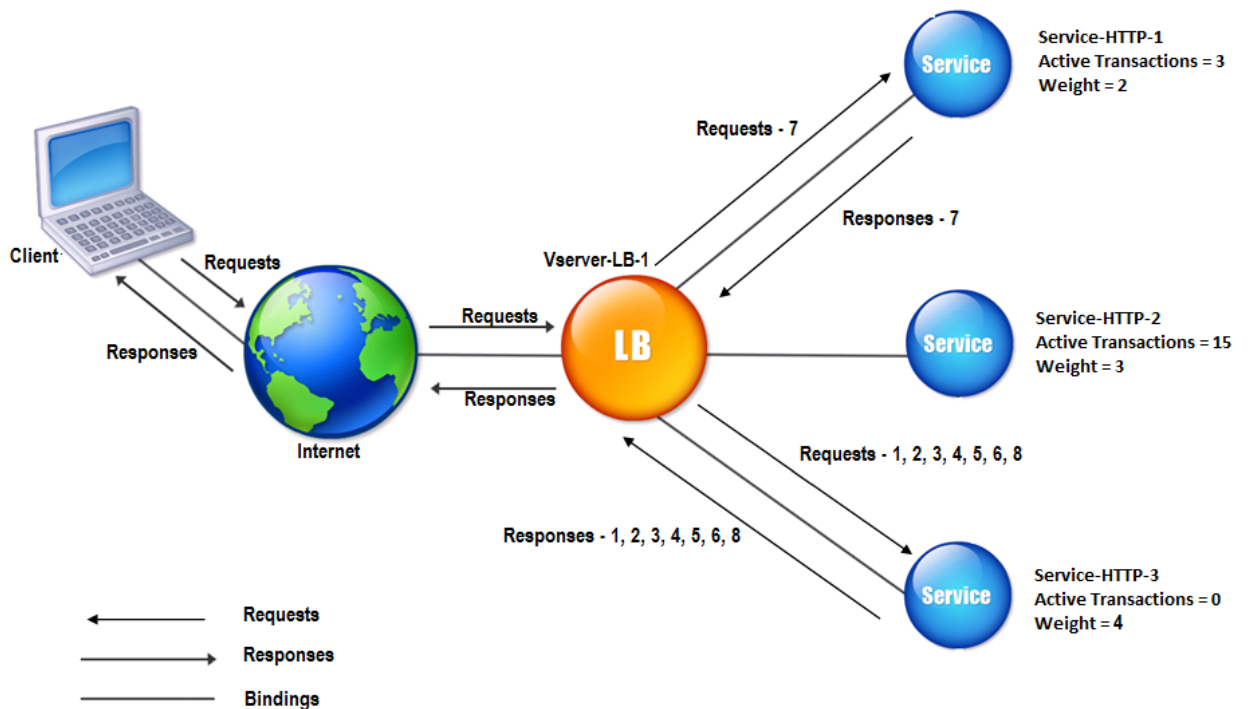

| Request Received | Service Selected                   | Current Nw (Number of active transactions) * (10000 / weight) value | Remarks                                 |
|------------------|------------------------------------|---------------------------------------------------------------------|-----------------------------------------|
| Request-1        | Service-HTTP-3<br><br>(Nw = 0)     | Nw = 2500                                                           | Service-HTTP-3 has the lowest Nw value. |
| Request-2        | Service-HTTP-3<br><br>(Nw = 2500)  | Nw = 5000                                                           |                                         |
| Request-3        | Service-HTTP-3<br><br>(Nw = 5000)  | Nw = 7500                                                           |                                         |
| Request-4        | Service-HTTP-3<br><br>(Nw = 7500)  | Nw = 10000                                                          |                                         |
| Request-5        | Service-HTTP-3<br><br>(Nw = 10000) | Nw = 12500                                                          |                                         |
| Request-6        | Service-HTTP-3                     | Nw = 15000                                                          |                                         |

| Request Received | (Nw = Service Selected)<br>(12500) | Current Nw (Number of active transactions) * (10000 / weight) value | Remarks                                                   |
|------------------|------------------------------------|---------------------------------------------------------------------|-----------------------------------------------------------|
| Request-7        | Service-HTTP-1<br><br>(Nw = 15000) | Nw = 20000                                                          | Service-HTTP-1 and Service-HTTP-3 have the same Nw values |
| Request-8        | Service-HTTP-3<br><br>(Nw = 15000) | Nw = 17500                                                          |                                                           |

Service-HTTP-2 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-1 and Service-HTTP-3) is equal to 50000.

The following diagram illustrates how the NetScaler appliance uses the least connection method when weights are assigned to the services.

Figure 2. Mechanism of the Least Connections Load Balancing Method when Weights are Assigned

To configure the least connection method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

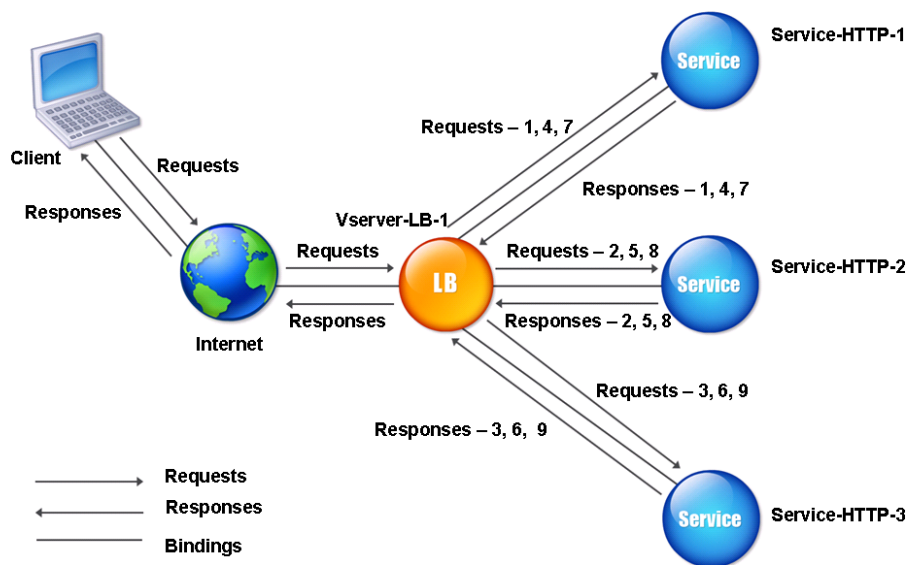

# The Round Robin Method

Mar 16, 2012

When a load balancing virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.

The following diagram illustrates how the NetScaler appliance uses the round robin method with a load balancing setup that contains three load-balanced servers and their associated services.

Figure 1. How the Round Robin Load Balancing Method Works

If you assign a different weight to each service, the NetScaler appliance performs weighted round robin distribution of incoming connections. It does this by skipping the lower-weighted services at appropriate intervals.

For example, assume that you have a load balancing setup with three services. You set Service-HTTP-1 to a weight of 2, Service-HTTP-2 to a weight of 3, and Service-HTTP-3 to a weight of 4. The services are bound to Vserver-LB-1, which is configured to use the round robin method. With this setup, incoming requests are delivered as follows:

- Service-HTTP-1 receives the first request.
- Service-HTTP-2 receives the second request.
- Service-HTTP-3 receives the third request.
- Service-HTTP-1 receives the fourth request.
- Service-HTTP-2 receives the fifth request.
- Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh request.
- Service-HTTP-3 receives both the eighth and the ninth requests.

Note: You can also configure weights on services to prevent multiple services from using the same server and overloading

the server.

A new cycle then begins, using the same pattern.

The following diagram illustrates the weighted round robin method.

Figure 2. How the Round Robin Load Balancing Method Works with Weighted Services

To configure the round robin method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

# The Least Response Time Method

Jul 10, 2013

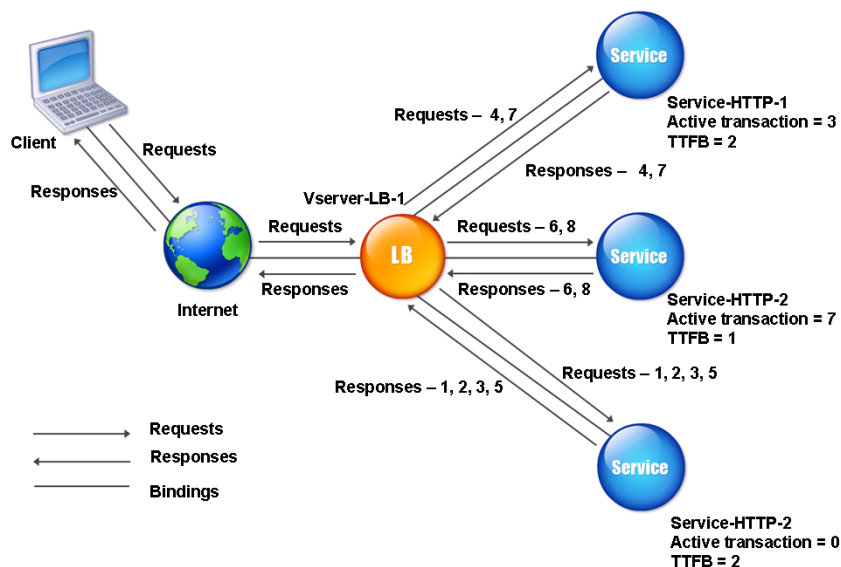

When the load balancing virtual server is configured to use the least response time method, it selects the service with the fewest active connections and the lowest average response time. You can configure this method for HTTP and Secure Sockets Layer (SSL) services only. The response time (also called Time to First Byte, or TTFB) is the time interval between sending a request packet to a service and receiving the first response packet from the service. The NetScaler appliance uses response code 200 to calculate TTFB.

The following example shows how a virtual server selects a service for load balancing by using the least response time method. Consider the following three services:

- Service-HTTP-1 is handling three active transactions and TTFB is two seconds.
- Service-HTTP-2 is handling seven active transactions and TTFB is one second.
- Service-HTTP-3 is not handling any active transactions and TTFB is two seconds.

The following diagram illustrates how the NetScaler appliance uses the least response time method to forward the connections.

Figure 1. How the Least Response Time Load Balancing Method Works

The virtual server selects a service by multiplying the number of active transactions by the TTFB for each service and then selecting the service with the lowest result. For the example shown above, the virtual server forwards requests as follows:

- Service-HTTP-3 receives the first request, because the service is not handling any active transactions.
- Service-HTTP-3 also receives the second and third requests, because the result is lowest of the three services.
- Service-HTTP-1 receives the fourth request. Since Service-HTTP-1 and Service-HTTP-3 have the same result, the NetScaler appliance chooses between them by applying the Round Robin method.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-2 receives the sixth request, because at this point it has the lowest result.
- Because Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all have the same result at this point, the NetScaler

switches to the round robin method, and continues to distribute connections using that method.

The following table explains how connections are distributed in the three-service load balancing setup described above.

| Request Received | Service Selected          | Current N Value (Number of Active Transactions * TTFB) | Remarks                                                                    |
|------------------|---------------------------|--------------------------------------------------------|----------------------------------------------------------------------------|
| Request-1        | Service-HTTP-3<br>(N = 0) | N = 2                                                  | Service-HTTP-3 has the lowest N value.                                     |
| Request-2        | Service-HTTP-3<br>(N = 2) | N = 4                                                  |                                                                            |
| Request-3        | Service-HTTP-3<br>(N = 3) | N = 6                                                  |                                                                            |
| Request-4        | Service-HTTP-1<br>(N = 6) | N = 8                                                  | Service-HTTP-1 and Service-HTTP-3 have the same N values.                  |
| Request-5        | Service-HTTP-3<br>(N = 6) | N = 8                                                  |                                                                            |
| Request-6        | Service-HTTP-2<br>(N = 7) | N = 8                                                  | Service-HTTP-2 has the lowest N value.                                     |
| Request-7        | Service-HTTP-1<br>(N = 8) | N = 15                                                 | Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values. |
| Request-8        | Service-HTTP-2<br>(N = 8) | N = 9                                                  |                                                                            |

| Request Received                                                                                           | Service Selected | Current N Value (Number of Active Transactions) * TFB (Nw) | Remarks |
|------------------------------------------------------------------------------------------------------------|------------------|------------------------------------------------------------|---------|
| The NetScaler selects a service based on the following expression:<br>$Nw = (N) * (10000 / \text{weight})$ |                  |                                                            |         |

Suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned weight of 3, and Service-HTTP-3 is assigned weight of 4.

The NetScaler appliance distributes requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.

If services are not handling any active transactions, the NetScaler selects them regardless of the weights assigned to them.

- Service-HTTP-3 receives the second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and therefore the highest Nw value, so the virtual server does not select it for load balancing.

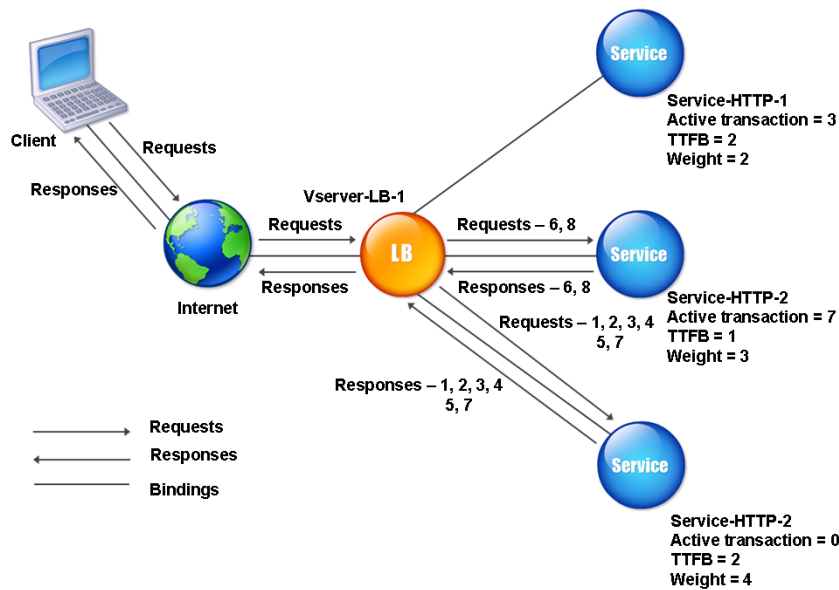

The following table explains how connections are distributed in the three-service load balancing set up described above.

| Request Received | Service Selected               | Current Nw Value (Number of Active Transactions) * (10000 / Weight) | Remarks                                 |
|------------------|--------------------------------|---------------------------------------------------------------------|-----------------------------------------|
| Request-1        | Service-HTTP-3<br>(Nw = 0)     | Nw = 2500                                                           | Service-HTTP-3 has the lowest Nw value. |
| Request-2        | Service-HTTP-3<br>(Nw = 2500)  | Nw = 5000                                                           |                                         |
| Request-3        | Service-HTTP-3<br>(Nw = 5000)  | Nw = 15000                                                          |                                         |
| Request-4        | Service-HTTP-3<br>(Nw = 15000) | Nw = 20000                                                          |                                         |

| Request Received                                                                                                                                                                         | Service Selected                  | Current Nw Value (Number of Active Transactions) * (10000 / Weight) | Remarks                                 |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|---------------------------------------------------------------------|-----------------------------------------|
| Request-5                                                                                                                                                                                | Service-HTTP-1<br>(Nw = 20000)    | Nw = 25000                                                          |                                         |
| Request-6                                                                                                                                                                                | Service-HTTP-2<br>(Nw = 23333.34) | Nw = 26666.67                                                       | Service-HTTP-2 has the lowest Nw value. |
| Request-7                                                                                                                                                                                | Service-HTTP-3<br>(Nw = 25000)    | Nw = 30000                                                          | Service-HTTP-3 has the lowest Nw value. |
| Request-8                                                                                                                                                                                | Service-HTTP-2<br>(Nw = 26666.67) | Nw = 33333.34                                                       | Service-HTTP-2 has the lowest Nw value. |
| Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw values of other services (Service-HTTP-2 and Service-HTTP-3) are equal to 105000. |                                   |                                                                     |                                         |

The following diagram illustrates how the NetScaler appliance uses the least response time method when weights are assigned.

Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned

To configure the least response time method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

When a load balancing virtual server is configured to use the least response time method with monitors, it uses the existing monitoring infrastructure to select the service with the smallest number of active transactions and the fastest average response time. Before you use the least response time method with monitoring, you must bind application-specific monitors to each service and enable least response time method mode on these monitors. The NetScaler appliance then makes load balancing decisions based on the response times it calculates from monitoring probes. For more information about configuring monitors, see [Configuring Monitors in a Load Balancing Setup](#).

You can use the least response time method with monitors to select non-HTTP and non-HTTPS services. You can also use this method when several monitors are bound to a service. Each monitor determines the response time by using the protocol that it measures for the service that it is bound to. The virtual server then calculates an average response time for that service by averaging the results.

The following table summarizes how response times are calculated for various monitors.

| Monitor | Response Time Calculation                                                                                                                                                                               |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PING    | Time difference between the ICMP ECHO request and the ICMP ECHO response.                                                                                                                               |
| TCP     | Time difference between the SYN request and the SYN+ACK response.                                                                                                                                       |
| HTTP    | Time difference between the HTTP request (after the TCP connection is established) and the HTTP response.                                                                                               |
| TCP-ECV | Time difference between the time the data send string is sent and the data receive string is returned.<br><br>A tcp-ecv monitor without the send and receive strings is considered to have an incorrect |

| Monitor                             | configuration.<br>Response Time Calculation                                                                                                                                   |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HTTP-ECV                            | Time difference between the HTTP request and the HTTP response.                                                                                                               |
| UDP-ECV                             | Time difference between the UDP send string and the UDP receive string.<br><br>A udp-ecv monitor without the receive string is considered to have an incorrect configuration. |
| DNS                                 | Time difference between a DNS query and the DNS response.                                                                                                                     |
| TCPS                                | Time difference between a SYN request and the SSL handshake completion.                                                                                                       |
| FTP                                 | Time difference between the sending of the user name and the completion of user authentication.                                                                               |
| HTTPS (monitors HTTPS requests)     | Time difference is same as for the HTTP monitor.                                                                                                                              |
| HTTPS-ECV (monitors HTTPS requests) | Time difference is same as for the HTTP-ECV monitor                                                                                                                           |
| USER                                | Time difference between the time when a request is sent to the dispatcher and the time when the dispatcher response is received.                                              |

The following example shows how the NetScaler appliance selects a service for load balancing by using the least response time method with monitors. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions and the response time is five seconds.
- Service-HTTP-2 is handling 7 active transactions and the response time is one second.
- Service-HTTP-3 is not handling any active transactions and the response time is two seconds.

The following diagram illustrates the process that the NetScaler appliance follows when it forwards requests.

Figure 3. How the Least Response Time Load Balancing Method Works When Using Monitors

The virtual server selects a service by using the value (N) in the following expression:

$N = \text{Number of active transactions} * \text{Response time}$  that is determined by the monitor

The virtual server delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service is not handling any active transaction.
- Service-HTTP-3 receives the second, third, and fourth requests, because this service has the lowest N value.
- Service-HTTP-2 receives the fifth request, because this service has the lowest N value.
- Since both Service-HTTP-2 and Service-HTTP-3 currently have the same N value, the NetScaler appliance switches to the round robin method. Therefore, Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh and eighth requests, because this service has the lowest N value.

Service-HTTP-1 is not considered for load balancing, because it is more heavily loaded (has the highest N value) when compared to the other two services. However, if Service-HTTP-1 completes its active transactions, the NetScaler appliance again considers that service for load balancing.

The following table summarizes how N is calculated for the services.

| Request Received | Service Selected          | Current N Value (Number of Active Transactions) | Remarks                                |
|------------------|---------------------------|-------------------------------------------------|----------------------------------------|
| Request-1        | Service-HTTP-3<br>(N = 0) | N = 2                                           | Service-HTTP-3 has the lowest N value. |
| Request-2        | Service-HTTP-3<br>(N = 2) | N = 4                                           |                                        |

| Request Received                                                                                                                                                                            | Service Selected          | Current N Value (Number of Active Transactions) | Remarks                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|-------------------------------------------------|-----------------------------------------------------------|
| Request-3                                                                                                                                                                                   | Service-HTTP-3<br>(N = 4) | N = 6                                           |                                                           |
| Request-4                                                                                                                                                                                   | Service-HTTP-3<br>(N = 6) | N = 8                                           |                                                           |
| Request-5                                                                                                                                                                                   | Service-HTTP-2<br>(N = 7) | N = 8                                           | Service-HTTP-1 and Service-HTTP-3 have the same N values. |
| Request-6                                                                                                                                                                                   | Service-HTTP-3<br>(N = 8) | N = 10                                          |                                                           |
| Request-7                                                                                                                                                                                   | Service-HTTP-2<br>(N = 8) | N = 9                                           | Service-HTTP-2 has the lowest N value.                    |
| Request-8                                                                                                                                                                                   | Service-HTTP-1<br>(N = 9) | N = 10                                          |                                                           |
| Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when the N value of the other services (Service-HTTP-2 and Service-HTTP-3) is equal to 15. |                           |                                                 |                                                           |

The NetScaler appliance also performs load balancing by using the number of active transactions, response time, and weights if different weights are assigned to services. The NetScaler appliance selects the service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4.

The NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.
- Service-HTTP-3 receives the second, third, and fourth requests, because this service has the lowest Nw value.

- Service-HTTP-2 receives the fifth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the seventh and the eighth requests, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and the highest Nw value, so the NetScaler appliance does not select it for load balancing.

The following table summarizes how Nw is calculated for various monitors.

| Request Received | Service Selected                  | Current Nw Value (Number of Active Transactions) * (10000 / Weight) | Remarks                                 |
|------------------|-----------------------------------|---------------------------------------------------------------------|-----------------------------------------|
| Request-1        | Service-HTTP-3<br>(Nw = 0)        | Nw = 5000                                                           | Service-HTTP-3 has the lowest Nw value. |
| Request-2        | Service-HTTP-3<br>(Nw = 5000)     | Nw = 10000                                                          |                                         |
| Request-3        | Service-HTTP-3<br>(Nw = 15000)    | Nw = 20000                                                          |                                         |
| Request-4        | Service-HTTP-3<br>(Nw = 20000)    | Nw = 25000                                                          |                                         |
| Request-5        | Service-HTTP-2<br>(Nw = 23333.34) | Nw = 26666.67                                                       | Service-HTTP-2 has the lowest Nw value. |
| Request-6        | Service-HTTP-3<br>(Nw = 25000)    | Nw = 30000                                                          | Service-HTTP-3 has the lowest Nw value. |

|                                                                                                                                                                                           |                                                   |                                                                                     |                                         |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|-------------------------------------------------------------------------------------|-----------------------------------------|
| Request-7<br>Request Received                                                                                                                                                             | Service-HTTP-2<br>Selected<br><br>(Nw = 23333.34) | Nw= 26666.67<br>Current Nw Value (Number of Active Transactions) * (10000 / Weight) | Service-HTTP-2 has the lowest Nw value. |
| Request-8                                                                                                                                                                                 | Service-HTTP-2<br><br>(Nw = 25000)                | Nw = 30000                                                                          | Service-HTTP-2 has the lowest Nw value. |
| Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw value of the other services (Service-HTTP-2 and Service-HTTP-3) is equal to 75000. |                                                   |                                                                                     |                                         |

The following diagram illustrates how the virtual server uses the least response time method when weights are assigned.

Figure 4. How the Least Response Time Load Balancing Method with Monitors Works When Weights Are Assigned

To configure the least response time method using monitors, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

# About Hashing Methods

Mar 16, 2012

Load balancing methods based on hashes of certain connection information or header information constitute the majority of the NetScaler appliance's load balancing methods. Hashes are shorter and easier to use than the information that they are based on, while retaining enough information to ensure that no two different pieces of information generate the same hash and are therefore confused with one another.

You can use the hashing load balancing methods in an environment where a cache serves a wide range of content from the Internet or specified origin servers. Caching requests reduces request and response latency, and ensures better resource (CPU) utilization, making caching popular on heavily used Web sites and application servers. Since these sites also benefit from load balancing, hashing load balancing methods are widely useful.

The NetScaler provides the following hashing methods:

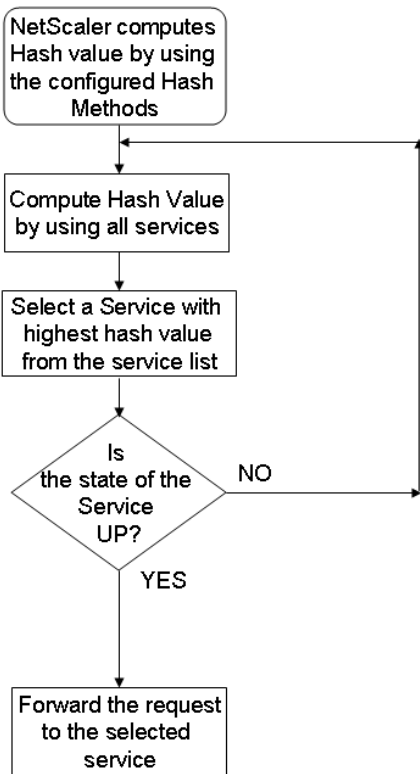

- URL hash method
- Domain hash method
- Destination IP hash method
- Source IP hash method
- Source IP Destination IP hash method
- Source IP Source Port hash method
- Call ID hash method
- Token method

These hashing algorithms ensure minimal disruption when services are added to or deleted from your load balancing setup. Most of them calculate two hash values:

- A hash of the service's IP address and port.
- A hash of the incoming URL, the domain name, the source IP address, the destination IP address, or the source and destination IP addresses, depending on the configured hash method.

The NetScaler appliance then generates a new hash value by using both of those hash values. Finally, it forwards the request to the service with highest hash value. As the appliance computes a hash value for each request and selects the service that will process the request, it populates a cache. Subsequent requests with the same hash value are sent to the same service. The following flow chart illustrates this process.

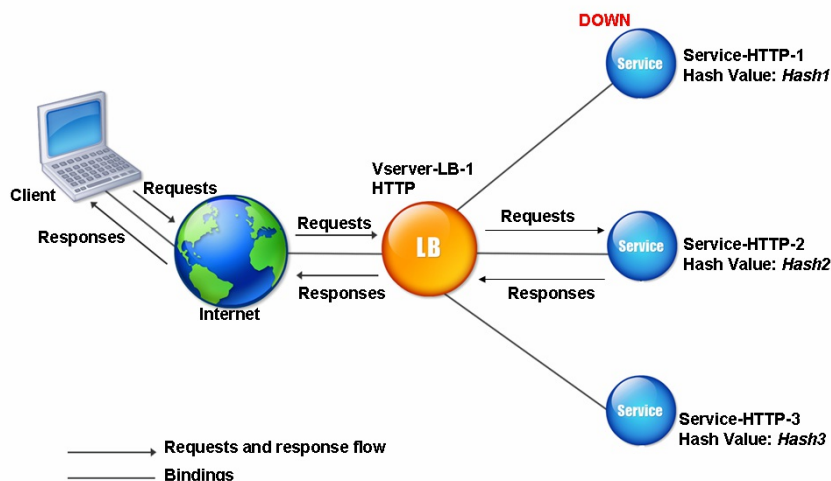

Figure 1. How the Hashing Methods Distribute Requests

Hashing methods can be applied to IPv4 and IPv6 addresses.

Consider a scenario where three services (Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3) are bound to a virtual server, any hash method is configured, and the hash value is Hash1. When the configured services are UP, the request is sent to Service-HTTP-1. If Service-HTTP-1 is down, the NetScaler appliance calculates the hash value for the last log of the number of services. The NetScaler then selects the service with the highest hash value, such as Service-HTTP-2. The following diagram illustrates this process.

Figure 2. Entity Model for Hashing Methods

Note: If the NetScaler appliance fails to select a service by using a hashing method, it defaults to the least connection method to select a service for the incoming request. You should adjust server pools by removing services during periods of low traffic to enable the caches to repopulate without affecting performance on your load balancing setup.

The URL Hash Method

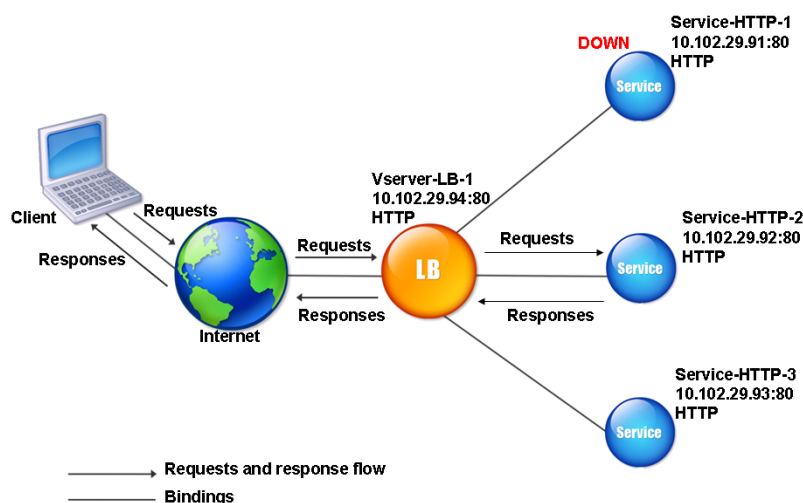

When you configure the NetScaler appliance to use the URL hash method for load balancing the services, for selecting a service, the NetScaler generates a hash value of the HTTP URL present in the incoming request. If the service selected by the hash value is DOWN, the algorithm has a method to select another service from the list of active services. The NetScaler caches the hashed value of the URL, and when it receives subsequent requests that use the same URL, it forwards them to the same service. If the NetScaler cannot parse an incoming request, it uses the round robin method for load balancing instead of the URL hash method.

For generating the hash value, NetScaler uses a specific algorithm and considers a part of the URL. By default, the NetScaler considers the first 80 bytes of the URL. If the URL is of less than 80 bytes, the complete URL is used. You can specify a different length. The hash length can be from 1 to 4096 bytes. Generally, if long URLs are used where only a small number of characters are different, it is a good idea to make the hash length as high as possible to try to ensure a more even load distribution.

Consider a scenario where three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3, are bound to a virtual server, and the load balancing method configured on the virtual server is the URL hash method. The virtual server receives a request and the hash value of the URL is U1. NetScaler selects Service-HTTP-1. If Service-HTTP-1 is DOWN, the NetScaler selects Service-HTTP-2.

The following diagram illustrates this process.

Figure 3. How URL Hashing Operates

If both Service-HTTP-1 and Service-HTTP-2 are DOWN, NetScaler sends requests with hash value U1 to Service-HTTP-3.

If Service-HTTP-1 and Service-HTTP-2 are down, requests that generate the hash URL1 are sent to Service-HTTP-3. If these services are UP, requests that generate the hash URL1 are distributed in the following manner:

- If the Service-HTTP-2 is up, the request is sent to Service-HTTP-2.
- If the Service-HTTP-1 is up, the request is sent to Service-HTTP-1.
- If Service-HTTP-1 and Service-HTTP-2 are up at the same time, the request is sent to Service-HTTP-1.

To configure the URL hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#). Select the load balancing method as URL Hash, and set the hash length to the number of bytes to be used for generating the hash

value.

## The Domain Hash Method

A load balancing virtual server configured to use the domain hash method uses the hashed value of the domain name in the HTTP request to select a service. The domain name is taken from either the incoming URL or the Host header of the HTTP request. If the domain name appears in both the URL and the Host header, the NetScaler gives preference to the URL.

If you configure domain name hashing, and an incoming HTTP request does not contain a domain name, the NetScaler appliance defaults to the round robin method for that request.

The hash-value calculation uses the name length or hash length value, whichever is smaller. By default, the NetScaler appliance calculates the hash value from the first 80 bytes of the domain name. To specify a different number of bytes in the domain name when calculating the hash value, you can set the hashLength parameter (Hash Length in the configuration utility) to a value of from 1 to 4096 (bytes).

To configure the domain hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## The Destination IP Hash Method

Updated: 2013-09-03

A load balancing virtual server configured to use the destination IP hash method uses the hashed value of the destination IP address to select a server. You can mask the destination IP address to specify which part of it to use in the hash value calculation, so that requests that are from different networks but destined for the same subnet are all directed to the same server. This method supports IPv4 and IPv6-based destination servers.

This load balancing method is appropriate for use with the cache redirection feature.

To configure the destination IP hash method for an IPv4 destination server, you set the netMask parameter. To configure this method for an IPv6 destination server, you use the v6NetMaskLen parameter. In the configuration utility, text boxes for setting these parameters appear when you select the Destination IP Hash method.

To configure the destination IP hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## The Source IP Hash Method

A load balancing virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## The Source IP Destination IP Hash Method

A load balancing virtual server configured to use the source IP destination IP hash method uses the hashed value of the source and destination IP addresses (either IPv4 or IPv6) to select a service. Hashing is symmetric; the hash-value is the same regardless of the order of the source and destination IPs. This ensures that all packets flowing from a particular client to the same destination are directed to the same server.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP destination IP hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

### The Source IP Source Port Hash Method

A load balancing virtual server configured to use the source IP source port hash method uses the hash value of the source IP (either IPv4 or IPv6) and source port to select a service. This ensures that all packets on a particular connection are directed to the same service.

This method is used in connection mirroring and firewall load balancing. For more information about connection mirroring, see [Connection Failover](#).

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP source port hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

### The Call ID Hash Method

A load balancing virtual server configured to use the call ID hash method uses the hash value of the call ID in the SIP header to select a service. Packets for a particular SIP session are therefore always directed to the same proxy server.

This method is applicable to SIP load balancing. For more information about SIP load balancing, see [Monitoring SIP Services](#).

To configure the call ID hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

# The Least Bandwidth Method

Jan 17, 2014

A load balancing virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps). The following example shows how the virtual server selects a service for load balancing by using the least bandwidth method.

Consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has 3 Mbps bandwidth.
- Service-HTTP-2 has 5 Mbps bandwidth.
- Service-HTTP-3 has 2 Mbps bandwidth.

The following diagram illustrates how the virtual server uses the least bandwidth method to forward requests to the three services.

Figure 1. How the Least Bandwidth Load Balancing Method Works

The virtual server selects the service by using the bandwidth value (N), which is the sum of the number of bytes transmitted and received over the previous 14 seconds. If each request requires 1 Mbps bandwidth, the NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Since Service-HTTP-1 and Service-HTTP-3 now have same N value, the virtual server switches to the round robin method for these servers, alternating between them. Service-HTTP-1 receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 now all have same N value, the virtual server includes Service-HTTP-2 in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

| Request Received | Service Selected          | Current N Value | Remarks                                                                    |
|------------------|---------------------------|-----------------|----------------------------------------------------------------------------|
| Request-1        | Service-HTTP-3<br>(N = 2) | N = 3           | Service-HTTP-3 has the lowest N value.                                     |
| Request-2        | Service-HTTP-1<br>(N = 3) | N = 4           | Service-HTTP-1 and Service-HTTP-3 have the same N values.                  |
| Request-3        | Service-HTTP-3<br>(N = 3) | N = 4           |                                                                            |
| Request-4        | Service-HTTP-1<br>(N = 4) | N = 5           |                                                                            |
| Request-5        | Service-HTTP-3<br>(N = 4) | N = 5           |                                                                            |
| Request-6        | Service-HTTP-1<br>(N = 5) | N = 6           | Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values. |
| Request-7        | Service-HTTP-2<br>(N = 5) | N = 6           |                                                                            |
| Request-8        | Service-HTTP-3<br>(N = 5) | N = 6           |                                                                            |

Note: If you enable the RTSP NAT option on the virtual server, the NetScaler appliance uses the number of data and control bytes exchanged to determine the bandwidth usage for RTSP services. For more information about RTSP NAT

option, see [Managing RTSP Connections](#).

The NetScaler appliance also performs load balancing by using the bandwidth and weights if different weights are assigned to the services. It selects a service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.

| Request Received | Service Selected                   | Current Nw Value (Number of Active Transactions) * (10000 / Weight) | Remarks                                 |
|------------------|------------------------------------|---------------------------------------------------------------------|-----------------------------------------|
| Request-1        | Service-HTTP-3<br><br>(Nw = 5000)  | Nw = 5000                                                           | Service-HTTP-3 has the lowest Nw value. |
| Request-2        | Service-HTTP-3<br><br>(Nw = 5000)  | Nw = 7500                                                           |                                         |
| Request-3        | Service-HTTP-3<br><br>(Nw = 7500)  | Nw = 10000                                                          |                                         |
| Request-4        | Service-HTTP-3<br><br>(Nw = 10000) | Nw = 12500                                                          |                                         |
| Request-5        | Service-HTTP-3<br><br>(Nw =        | Nw = 15000                                                          |                                         |

| Request Received | Service Selected                  | Current Nw Value (Number of Active Transactions) * (10000 / Weight) | Remarks                                                   |
|------------------|-----------------------------------|---------------------------------------------------------------------|-----------------------------------------------------------|
| Request-6        | Service-HTTP-1<br>(Nw = 15000)    | Nw = 20000                                                          | Service-HTTP-1 and Service-HTTP-3 have the same Nw value. |
| Request-7        | Service-HTTP-3<br>(Nw = 15000)    | Nw = 17500                                                          |                                                           |
| Request-8        | Service-HTTP-2<br>(Nw = 16666.67) | Nw = 20000                                                          | Service-HTTP-2 has the lowest Nw value.                   |

The following diagram illustrates how the virtual server uses the least bandwidth method when weights are assigned to the services.

Figure 2. How the Least Bandwidth Load Balancing Method Works When Weights Are Assigned

To configure the least bandwidth method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

# The Least Packets Method

Jan 17, 2014

A load balancing virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has handled three packets in last 14 seconds.
- Service-HTTP-2 has handled five packets in last 14 seconds.
- Service-HTTP-3 has handled two packets in last 14 seconds.

The following diagram illustrates how the NetScaler appliance uses the least packets method to choose a service for each request that it receives.

Figure 1. How the Least Packets Load Balancing Method Works

The NetScaler appliance selects a service by using the number of packets (N) transmitted and received by each service in the last 14 seconds. Using this method, it delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Since Service-HTTP-1 and Service-HTTP-3 now have the same N value, the virtual server switches to the round robin method. Service-HTTP-1 therefore receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have same N value, the virtual server switches to the round robin method for Service-HTTP-2 as well, including it in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

| Request Received | Service Selected          | Current N Value | Remarks                                                                    |
|------------------|---------------------------|-----------------|----------------------------------------------------------------------------|
| Request-1        | Service-HTTP-3<br>(N = 2) | N = 3           | Service-HTTP-3 has the lowest N value.                                     |
| Request-2        | Service-HTTP-1<br>(N = 3) | N = 4           | Service-HTTP-1 and Service-HTTP-3 have the same N values.                  |
| Request-3        | Service-HTTP-3<br>(N = 3) | N = 4           |                                                                            |
| Request-4        | Service-HTTP-1<br>(N = 4) | N = 5           |                                                                            |
| Request-5        | Service-HTTP-3<br>(N = 4) | N = 5           |                                                                            |
| Request-6        | Service-HTTP-1<br>(N = 5) | N = 6           | Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values. |
| Request-7        | Service-HTTP-2<br>(N = 5) | N = 6           |                                                                            |
| Request-8        | Service-HTTP-3<br>(N = 5) | N = 6           |                                                                            |

Note: If you enable the RTSP NAT option on the virtual server, the NetScaler uses the number of data and control packets to calculate the number of packets for RTSP services. For more information about RTSP NAT option, see [Managing RTSP](#)

## Connections.

The NetScaler appliance also performs load balancing by using the number of packets and weights when a different weight is assigned to each service. It selects a service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.

| Request Received | Service Selected                   | Current Nw Value (Number of Active Transactions) * (10000 / weight) | Remarks                                 |
|------------------|------------------------------------|---------------------------------------------------------------------|-----------------------------------------|
| Request-1        | Service-HTTP-3<br><br>(Nw = 5000)  | Nw = 5000                                                           | Service-HTTP-3 has the lowest Nw value. |
| Request-2        | Service-HTTP-3<br><br>(Nw = 5000)  | Nw = 7500                                                           |                                         |
| Request-3        | Service-HTTP-3<br><br>(Nw = 7500)  | Nw = 10000                                                          |                                         |
| Request-4        | Service-HTTP-3<br><br>(Nw = 10000) | Nw = 12500                                                          |                                         |
| Request-5        | Service-HTTP-3<br><br>(Nw =        | Nw = 15000                                                          |                                         |

| Request Received | Service Selected                  | Current Nw Value (Number of Active Transactions) * (10000 / weight) | Remarks                                                   |
|------------------|-----------------------------------|---------------------------------------------------------------------|-----------------------------------------------------------|
| Request-6        | Service-HTTP-1<br>(Nw = 15000)    | Nw = 20000                                                          | Service-HTTP-1 and Service-HTTP-3 have the same Nw value. |
| Request-7        | Service-HTTP-3<br>(Nw = 15000)    | Nw = 17500                                                          |                                                           |
| Request-8        | Service-HTTP-2<br>(Nw = 16666.67) | Nw = 20000                                                          | Service-HTTP-2 has the lowest Nw value.                   |

The following diagram illustrates how the virtual server uses the least packets method when weights are assigned.

Figure 2. How the Least Packets Method Works When Weights Are Assigned

To configure the least packets method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

# The Custom Load Method

Feb 24, 2015

Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the NetScaler appliance usually selects a service that is not handling any active transactions. If all of the services in the load balancing setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the load balancing decision when those services are not UP.

For more information about load monitors, see [Understanding Load Monitors](#). The following diagram illustrates how a load monitor operates.

Figure 1. How Load Monitors Operate

The load monitor uses Simple Network Management Protocol (SNMP) probes to calculate load on each service by sending an SNMP GET request to the service. This request contains one or more object IDs (OIDs). The service responds with an SNMP GET response, with metrics corresponding to the SNMP OIDs. The load monitor uses the response metrics, described below, to calculate the load on the service.

The load monitor calculates the load on a service by using the following parameters:

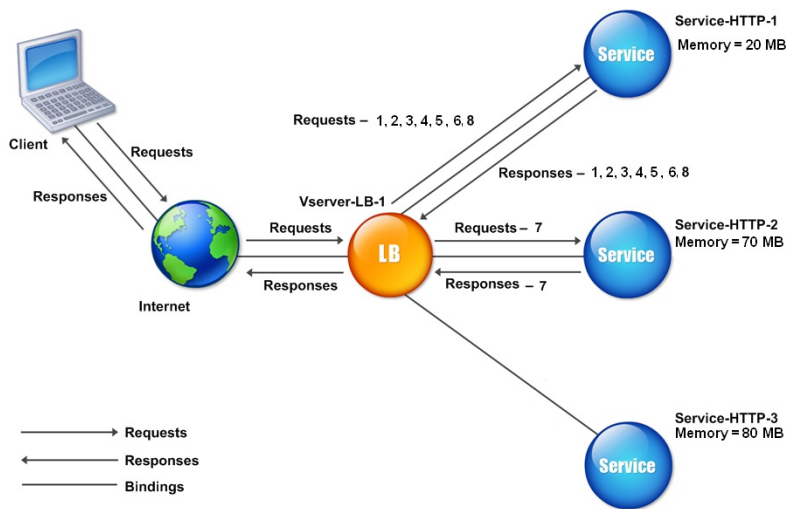

- Metrics values retrieved through SNMP probes that exist as tables in the NetScaler.
- Threshold value set for each metric.
- Weight assigned to each metric.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 is using 20 megabytes (MB) of memory.
- Service-HTTP-2 is using 70 MB of memory.
- Service-HTTP-3 is using 80 MB of memory.

The load balanced servers can export metrics such as CPU and memory usage to the services, which can in turn provide them to the load monitor. The load monitor sends an SNMP GET request containing the OIDs 1.3.6.1.4.1.5951.4.1.1.41.1.5, 1.3.6.1.4.1.5951.4.1.1.41.1.4, and 1.3.6.1.4.1.5951.4.1.1.41.1.3 to the services. SNMP OIDs of type STRING are not supported, because you cannot calculate the load by using a STRING OID. Loads can be calculated by using other data types, such as INT and gauge32. The three services respond to the request. The NetScaler appliance compares the exported metrics, and then selects Service-HTTP-1 because it has more available memory. The following diagram illustrates this process.

Figure 2. How the Custom Load Method Works

If each request uses 10 MB memory, the NetScaler appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, and fifth requests, because this service has the lowest N value.
- Service-HTTP-1 and Service-HTTP-2 now have the same load, so the virtual server reverts to the round robin method for these servers. Therefore, Service-HTTP-2 receives the sixth request, and Service-HTTP-1 receives the seventh request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have same load, the virtual server reverts to the round robin method for Service-HTTP-3 as well. Therefore, Service-HTTP-3 receives the eighth request.

The following table summarizes how N is calculated.

| Request received | Service selected           | Current N Value (Number of Active Transactions) | Remarks                                |
|------------------|----------------------------|-------------------------------------------------|----------------------------------------|
| Request-1        | Service-HTTP-1<br>(N = 20) | N = 30                                          | Service-HTTP-3 has the lowest N value. |
| Request-2        | Service-HTTP-1<br>(N = 30) | N = 40                                          |                                        |

| Request received | Service selected           | Current N Value (Number of Active Transactions) | Remarks                                                                    |
|------------------|----------------------------|-------------------------------------------------|----------------------------------------------------------------------------|
| Request-3        | Service-HTTP-1<br>(N = 40) | N = 50                                          |                                                                            |
| Request-4        | Service-HTTP-1<br>(N = 50) | N = 60                                          |                                                                            |
| Request-5        | Service-HTTP-1<br>(N = 60) | N = 70                                          |                                                                            |
| Request-6        | Service-HTTP-1<br>(N = 70) | N = 80                                          | Service-HTTP-2 and Service-HTTP-3 have the same N values.                  |
| Request-7        | Service-HTTP-2<br>(N = 70) | N = 80                                          |                                                                            |
| Request-8        | Service-HTTP-1<br>(N = 80) | N = 90                                          | Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values. |

If different weights are assigned to the services, the custom load algorithm considers both the load on each service and the weight assigned to each service. It selects a service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 4, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 2. If each request uses 10 MB memory, the NetScaler appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, fifth, sixth, seventh, and eighth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the ninth request, because this service has the lowest Nw value.

Service-HTTP-3 has the highest Nw value, and is therefore not considered for load balancing.

The following table summarizes how Nw is calculated.

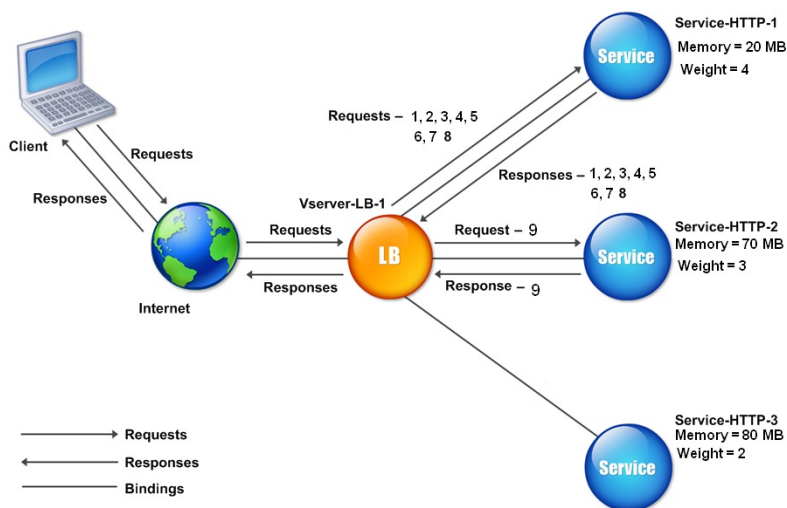

| Request received | Service selected                       | Current Nw Value (Number of Active Transactions) * (10000 / Weight) | Remarks                                 |
|------------------|----------------------------------------|---------------------------------------------------------------------|-----------------------------------------|
| Request-1        | Service-HTTP-1<br><br>(Nw = 50000)     | Nw = 75000                                                          | Service-HTTP-1 has the lowest Nw value. |
| Request-2        | Service-HTTP-1<br><br>(Nw = 5000)      | Nw = 100000                                                         |                                         |
| Request-3        | Service-HTTP-1<br><br>(Nw = 15000)     | Nw = 125000                                                         |                                         |
| Request-4        | Service-HTTP-1<br><br>(Nw = 20000)     | Nw = 150000                                                         |                                         |
| Request-5        | Service-HTTP-1<br><br>(Nw = 23333.34)) | Nw = 175000                                                         |                                         |
| Request-6        | Service-HTTP-1<br><br>(Nw = 25000)     | Nw = 200000                                                         |                                         |
| Request-7        | Service-HTTP-1<br><br>(Nw = 23333.34)  | Nw = 225000                                                         |                                         |
| Request-8        | Service-                               | Nw = 250000                                                         |                                         |

| Request received | HTTP-1 Service selected (Nw = 25000) | Current Nw Value (Number of Active Transactions) * (10000 / Weight) | Remarks                                 |
|------------------|--------------------------------------|---------------------------------------------------------------------|-----------------------------------------|
| Request-9        | Service-HTTP-2 (Nw = 233333.34)      | Nw = 266666.67                                                      | Service-HTTP-2 has the lowest Nw value. |

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-2 and Service-HTTP-3) is equal to 400,000.

The following diagram illustrates how the NetScaler appliance uses the custom load method when weights are assigned.

Figure 3. How the Custom Load Method Works When Weights Are Assigned

To configure the custom load method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

# Configuring the Token Method

Jul 15, 2014

A load balancing virtual server configured to use the token method bases its selection of a service on the value of a data segment extracted from the client request. The data segment is called the token. You configure the location and size of the token. For subsequent requests with the same token, the virtual server chooses the same service that handled the initial request.

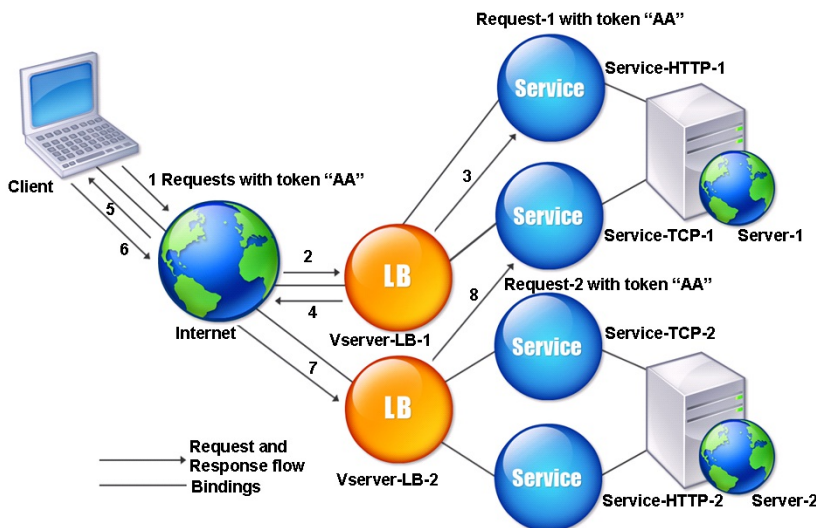

This method is content aware; it operates differently for TCP, HTTP, and HTTPS connections. For HTTP or HTTPS services, the token is found in the HTTP headers, the URL, or the BODY. To locate the token, you specify or create a classic or advanced expression. For more information on classic or advanced expressions, see [Policy Configuration and Reference](#).

For HTTP services, the virtual server searches for the configured token in the first 24 kilobytes (KB) of the TCP payload. For non-HTTP (TCP, SSL, and SSL\_TCP) services, the virtual server searches for the configured token in the first 16 packets if the total size of the 16 packets is less than 24 KB. But if the total size of the 16 packets is greater than 24 KB, the NetScaler searches for the token in the first 24 KB of payload. You can use this load balancing method across virtual servers of different types to make sure that requests presenting the same token are directed to appropriate services, regardless of the protocol used.

For example, consider a load balancing setup consisting of servers that contain Web content. You want to configure the NetScaler appliance to search for a specific string (the token) inside the URL query portion of the request. Server-1 has two services, Service-HTTP-1 and Service-TCP-1, and Server-2 has two services, Service-HTTP-2 and Service-TCP-2. The TCP services are bound to Vserver-LB-2, and the HTTP services are bound to Vserver-LB-1.

If Vserver-LB-1 receives a request with the token AA, it selects the service Service-HTTP-1 (bound to server-1) to process the request. If Vserver-LB-2 receives a different request with the same token (AA), it directs this request to the service Service-TCP-1. The following diagram illustrates this process.

Figure 1. How the Token Method Works

To configure the Token load balancing method by using the command line interface

At the command prompt, type the following commands to configure the token load balancing method and verify the configuration:

- `set lb vserver <name> -lbMethod TOKEN -rule <rule> -datalength <length> -dataoffset <offset>`
- `show lb vserver <name>`

### Example

```
set lb vserver LB-VServer-1 -lbMethod TOKEN -rule 'AA' -datalength 2 -dataoffset 25
```

```
show lb vserver LB-VServer-1
```

To configure the token load balancing method by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, click Method
3. In the Load Balancing Method list, select Token, and specify an expression.

# Configuring a Load Balancing Method That Does Not Include a Policy

Jul 16, 2014

After you select a load balancing algorithm for your load balancing setup, you must configure the NetScaler appliance to use that algorithm. You can configure it by using the NetScaler command line or by using the configuration utility.

Note:

The token method is policy based and requires more configuration than is described here. To configure the token method, see [Configuring the Token Method](#).

For some hash-based methods, you can mask an IP address to direct requests belonging to the same subnet to the same server. For more information, see [The Destination IP Hash Method](#), [The Source IP Hash Method](#), [The Source IP Destination IP Hash Method](#), and [The Source IP Source Port Hash Method](#).

To set the load balancing method by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -lbMethod <method>
```

## **Example**

```
set lb vserver Vserver-LB-1 -lbMethod LeastConnection
```

To set the load balancing method by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, click Method, and in the Load Balancing Method list, select a method.

# Persistence and Persistent Connections

Mar 16, 2012

Unless you configure persistence, a load balancing stateless protocol, such as HTTP, disrupts the maintenance of state information about client connections. Different transmissions from the same client might be directed to different servers even though all of the transmissions are part of the same session. You must configure persistence on a load balancing virtual server that handles certain types of Web applications, such as shopping cart applications.

Before you can configure persistence, you need to understand the different types of persistence, how they are used, and what the implications of each type is. You then need to configure the NetScaler appliance to provide persistent connections for those Web sites and Web applications that require them.

You can also configure backup persistence, which takes effect in the event that the primary type of persistence configured for a load balancing virtual server fails. You can configure persistence groups, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

For information about persistence with RADIUS load balancing, see [Configuring RADIUS Load Balancing with Persistence](#).

# About Persistence

Mar 16, 2012

You can choose from among any of several types of persistence for a given load balancing virtual server, which then routes to the same service all connections from the same user to your shopping cart application, Web-based email, or other network application. The persistence session remains in effect for a period of time, which you specify.

If a server participating in a persistence session goes DOWN, the load balancing virtual server uses the configured load balancing method to select a new service, and establishes a new persistence session with the server represented by that service. If the server goes OUT OF SERVICE, it continues to process existing persistence sessions, but the virtual server does not direct any new traffic to it. After the shutdown period elapses, the virtual server ceases to direct connections from existing clients to the service, closes existing connections, and redirects those clients to new services if necessary.

Depending on the persistence type you configure, the NetScaler appliance might examine the source IPs, destination IPs, SSL session IDs, Host or URL headers, or some combination of these things to place each connection in the proper persistence session. It might also base persistence on a cookie issued by the Web server, on an arbitrarily assigned token, or on a logical rule. Almost anything that allows the appliance to match connections with the proper persistence session and be used as the basis for persistence.

The following table summarizes the persistence types available on the NetScaler appliance.

**Table 1. Types of Persistence**

| Persistence Type | Description                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------|
| Source IP        | SOURCEIP. Connections from the same client IP address are parts of the same persistence session.                 |
| HTTP Cookie      | COOKIEINSERT. Connections that have the same HTTP Cookie header are parts of the same persistence session.       |
| SSL Session ID   | SSLSESSION. Connections that have the same SSL Session ID are parts of the same persistence session.             |
| URL Passive      | URLPASSIVE. Connections to the same URL are treated as parts of the same persistence session.                    |
| Custom Server ID | CUSTOMSERVERID. Connections with the same HTTP HOST header are treated as parts of the same persistence session. |
| Destination IP   | DESTIP. Connections to the same destination IP are treated as parts of the same persistence session.             |
| Source and       | SRCIPDESTIP. Connections that are both from the same source IP and to the same destination IP                    |

| <b>Persistence Type</b>        | <b>Description</b>                                                                                                                                                              |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Destination IPs<br>SIP Call ID | are treated as parts of the same persistence session.<br>CALLID. Connections that have the same call ID in the SIP header are treated as parts of the same persistence session. |
| RTSP Session ID                | RTSPSID. Connections that have the same RTSP Session ID are treated as parts of the same persistence session.                                                                   |
| User-Defined Rule              | RULE. Connections that match a user-defined rule are treated as parts of the same persistence session.                                                                          |

Depending on the type of persistence that you have configured, the virtual server can support either 250,000 simultaneous persistent connections or any number of persistent connections up to the limits imposed by the amount of RAM on your NetScaler appliance. The following table shows which types of persistence fall into each category.

**Table 2. Persistence Types and Numbers of Simultaneous Connections Supported**

| <b>Persistence Type</b>                                                                                 | <b>Number of Simultaneous Persistent Connections Supported</b>                                              |
|---------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Source IP, SSL Session ID, Rule, destination IP, source IP/destination IP, SIP Call ID, RTSP Session ID | 250 K                                                                                                       |
| Cookie, URL Server ID, Custom Server ID                                                                 | Memory limit. In case of CookieInsert, if timeout is not 0, the number of connections is limited by memory. |

Some types of persistence are specific to particular types of virtual server. The following table lists each type of persistence and indicates which types of persistence are supported on which types of virtual server.

**Table 3. Relationship of Persistence Type to Virtual Server Type**

| <b>Persistence Type</b> | <b>HTTP</b> | <b>HTTPS</b> | <b>TCP</b> | <b>UDP/IP</b> | <b>SSL_Bridge</b> | <b>SSL_TCP</b> | <b>RTSP</b> | <b>SIP_UDP</b> |
|-------------------------|-------------|--------------|------------|---------------|-------------------|----------------|-------------|----------------|
| <b>SOURCEIP</b>         | YES         | YES          | YES        | YES           | YES               | YES            | NO          | NO             |
| <b>COOKIEINSERT</b>     | YES         | YES          | NO         | NO            | NO                | NO             | NO          | NO             |
| <b>SSLSESSION</b>       | NO          | YES          | NO         | NO            | YES               | YES            | NO          | NO             |
| <b>URLPASSIVE</b>       | YES         | YES          | NO         | NO            | NO                | NO             | NO          | NO             |

| <b>CUSTOMSERVERID</b><br>Persistence Type | <b>YES</b><br>HTTP | <b>YES</b><br>HTTPS | <b>NO</b><br>TCP | <b>NO</b><br>UDP/IP | <b>NO</b><br>SSL_Bridge | <b>NO</b><br>SSL_TCP | <b>NO</b><br>RTSP | <b>NO</b><br>SIP_UDP |
|-------------------------------------------|--------------------|---------------------|------------------|---------------------|-------------------------|----------------------|-------------------|----------------------|
| <b>RULE</b>                               | YES                | YES                 | YES              | NO                  | NO                      |                      | NO                | NO                   |
| <b>SRCIPDESTIP</b>                        | YES                | YES                 | YES              | YES                 | YES                     | YES                  | NO                | NO                   |
| <b>DESTIP</b>                             | YES                | YES                 | YES              | YES                 | YES                     | YES                  | NO                | NO                   |
| <b>CALLID</b>                             | NO                 | NO                  | NO               | NO                  | NO                      | NO                   | NO                | YES                  |
| <b>RTSPID</b>                             | NO                 | NO                  | NO               | NO                  | NO                      | NO                   | YES               | NO                   |

# Persistence Based on Source IP Address

Mar 16, 2012

When source IP persistence is configured, the load balancing virtual server uses the configured load balancing method to select a service for the initial request, and then uses the source IP address (client IP address) to identify subsequent requests from that client and send them to the same service. You can set a time-out value, which specifies the maximum inactivity period for the session. When the time-out value expires, the session is discarded, and the configured load balancing algorithm is used to select a new server.

Caution: In some circumstances, using persistence based on source IP address can overload your servers. All requests to a single Web site or application are routed through the single gateway to the NetScaler appliance, even though they are then redirected to multiple locations. In multiple proxy environments, client requests frequently have different source IP addresses even when they are sent from the same client, resulting in rapid multiplication of persistence sessions where a single session should be created. This issue is called the “Mega Proxy problem.” You can use HTTP cookie-based persistence instead of Source IP-based persistence to prevent this from happening.

To configure persistence based on Source IP Address, see [Configuring Persistence Types That Do Not Require a Rule](#).

Note: If all incoming traffic comes from behind a Network Address Translation (NAT) device or proxy, the traffic appears to the NetScaler appliance to come from a single source IP address. This prevents Source IP persistence from functioning properly. Where this is the case, you must select a different persistence type.

# Persistence Based on HTTP Cookies

Feb 11, 2015

When HTTP cookie persistence is configured, the NetScaler appliance sets a cookie in the HTTP headers of the initial client request. The cookie contains the IP address and port of the service selected by the load balancing algorithm. As with any HTTP connection, the client then includes that cookie with any subsequent requests.

When the NetScaler appliance detects the cookie, it forwards the request to the service IP and port in the cookie, maintaining persistence for the connection. You can use this type of persistence with virtual servers of type HTTP or HTTPS. This persistence type does not consume any NetScaler resources and therefore can accommodate an unlimited number of persistent clients.

Note: If the client's Web browser is configured to refuse cookies, HTTP cookie-based persistence will not work. It might be advisable to configure a cookie check on the Web site, and warn clients that do not appear to be storing cookies properly that they will need to enable cookies for the Web site if they want to use it.

The format of the cookie that the NetScaler appliance inserts is:

```
NSC_XXXX=<ServiceIP ><ServicePort>
```

where:

- NSC\_XXXX is the virtual server ID that is derived from the virtual server name.
- ServiceIP and ServicePort are encoded representations of the service IP address and service port, respectively. The IP address and port are encoded separately.

You can set a time-out value for this type of persistence to specify an inactivity period for the session. When the connection has been inactive for the specified period of time, the NetScaler appliance discards the persistence session. Any subsequent connection from the same client results in a new server being selected based on the configured load balancing method, and a new persistence session being established.

Note: If you set the time-out value to 0, the NetScaler appliance does not specify an expiration time, but sets a session cookie that is not saved when the client's browser is shut down.

By default, the NetScaler appliance sets HTTP version 0 cookies for maximum compatibility with client browsers. (Only certain HTTP proxies understand version 1 cookies; most commonly used browsers do not.) You can configure the appliance to set HTTP version 1 cookies, for compliance with RFC2109. For HTTP version 0 cookies, the appliance inserts the cookie expiration date and time as an absolute Coordinated Universal Time (GMT). It calculates this value as the sum of the current GMT time on the appliance and the time-out value. For HTTP version 1 cookies, the appliance inserts a relative expiration time by setting the "Max-Age" attribute of the HTTP cookie. In this case, the client's browser calculates the actual expiration time.

To configure persistence based on a cookie inserted by the appliance, see [Configuring Persistence Types That Do Not Require a Rule](#).

In the HTTP cookie, the appliance by default sets the httponly flag to indicate that the cookie is nonscriptable and should not be revealed to the client application. Therefore, a client-side script cannot access the cookie, and the client is not susceptible to cross-site scripting.

Certain browsers, however, do not support the httponly flag and, therefore, might not return the cookie. As a result, persistence is broken. For browsers that do not support the flag, you can omit the httponly flag in the persistence cookie.

To change the httponly flag setting by using the command line interface

At the command prompt, type:

```
set lb parameter -httpOnlyCookieFlag (ENABLED | DISABLED)
```

**Example**

```
> set lb parameter -httpOnlyCookieFlag disabled
Done
> show lb parameter
Global LB parameters:
 Persistence Cookie HttpOnly Flag: DISABLED
 Use port for hash LB: YES
Done
```

To change the httponly flag setting by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing Parameters, and select or clear the Persistence Cookie HTTPOnly Flag.

### Encrypting the Cookie

From release 10.5 build 55.8, you can encrypt the cookie in addition to any SSL encryption.

To encrypt the cookie by using the command line interface, at the command prompt, type:

```
set lb parameter -useSecuredPersistenceCookie ENABLED -cookiePassphrase test
```

To encrypt the cookie by using the configuration utility, navigate to Traffic Management > Change Load Balancing Parameters, and select Use Secured Persistence Cookie and Cookie Passphrase and enter a passphrase.

# Persistence Based on SSL Session IDs

Aug 22, 2016

When SSL Session ID persistence is configured, the NetScaler appliance uses the SSL Session ID, which is part of the SSL handshake process, to create a persistence session before the initial request is directed to a service. The load balancing virtual server directs subsequent requests that have the same SSL session ID to the same service. This type of persistence is used for SSL bridge services.

## Note:

There are two issues that users should consider before choosing this type of persistence. First, this type of persistence consumes resources on the NetScaler appliance, which limits the number of concurrent persistence sessions that it can support. If you expect to support a very large number of concurrent persistence sessions, you might want to choose another type of persistence.

Second, if the client and the load-balanced server should renegotiate the session ID during their transactions, persistence is not maintained, and a new persistence session is created when the client's next request is received. This may result in the client's activity on the Web site being interrupted and the client being required to reauthenticate or restart the session. It may also result in large numbers abandoned sessions if the timeout is set to too large a value.

To configure persistence based on SSL session ID, see [Configuring Persistence Types That Do Not Require a Rule](#).

# Persistence Based on Diameter AVP Number

Aug 25, 2016

You can use persistence based on the (Attribute-Value Pair) AVP number of a Diameter message to create persistent Diameter sessions. When the NetScaler appliance finds the AVP in the Diameter message, it creates a persistence session based on the value of the AVP. All subsequent messages that match the value of the AVP are directed to the previously selected server. If the value of the AVP does not match the persistence session, a new session is created for the new value.

Note: If the AVP number is not defined in Diameter base-protocol RFC 6733, and if the number is nested inside a grouped AVP, you must define a sequence of AVP numbers (maximum of 3) in parent-to-child order. For example, if persist AVP number X is nested inside AVP Y, which is nested in Z, define the list as Z Y X.

## To configure Diameter-based persistence on a virtual server by using the command line interface

At the command prompt, type the following command:

```
set lb vserver <name> -PersistenceType <type-> persistAVPno <positive_integer>
```

### Example

```
set lb vserver diameter_vs -persistenceType DIAMETER -persistAVPno 263
```

# Custom Server ID Persistence

Nov 07, 2016

In the Custom Server ID persistence method, the Server ID specified in the client request is used to maintain persistence. For this type of persistence to work, you must first set a server ID on the services. The NetScaler appliance checks the URL of the client request and connects to the server associated with the specified server ID. The service provider should make sure that the users are aware of the server IDs to be provided in their requests for specific services.

For example, if your site provides different types of data, such as images, text, and multimedia, from different servers, you can assign each server a server ID. On the NetScaler appliance, you specify those server IDs for the corresponding services, and you configure custom server ID persistence on the corresponding load balancing virtual server. When sending a request, the client inserts the server ID into the URL indicating the required type of data.

To configure custom server ID persistence:

- In your load balancing setup, assign a server ID to each service for which you want to use the user-defined server ID to maintain persistence. Alphanumeric server IDs are allowed.
- Specify rules, in the default-syntax expression language, to examine the URL queries for the server ID and forward traffic to the corresponding server.
- Configure custom server ID persistence.

Note: The persistence time-out value does not affect the Custom Server ID persistence type. There is no limit on the maximum number of persistent clients because this persistence type does not store any client information.

## Example

In a load balancing setup with two services, assign server ID 2345-photo-56789 to Service-1, and server ID 2345-drawing-abb123 to Service-2. Bind these services to a virtual server named Web11.

```
set service Service-1 10.102.29.5 -CustomServerID 2345-photo-56789
set service Service-2 10.102.29.6 -CustomServerID 2345-drawing-abb123
```

On virtual server Web11, enable Custom Server ID persistence.

Create the following expression so that all URL queries containing the string "sid=" are examined.

```
HTTP.REQ.URL.AFTER_STR("sid=")
```

## Example

```
set lb vserver Web11 -persistenceType customserverID -rule "HTTP.REQ.URL.AFTER_STR(\"sid=\")"
bind lb vserver Web11 Service-[1-2]
```

When a client sends a request with the following URL to the IP address of Web11, the NetScaler directs the request to Service-2 and honors persistence.

## Example

```
http://www.example.com/index.asp?&sid=2345-drawing-abb123
```

For more information about default-syntax policy expressions, see the [Policy Configuration and Reference](#).

To configure custom server ID persistence by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service and set a server ID.

3. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
4. In Advanced Settings, select Persistence.
5. Select CUSTOMESERVERID, and specify an expression.

# Persistence Based on IP Addresses

Jun 03, 2015

You can base persistence on Destination IP addresses, or on both Source IP and Destination IP Addresses.

## Persistence Based on Destination IP Addresses

Updated: 2013-09-24

With destination IP address-based persistence, when the NetScaler appliance receives a request from a new client, it creates a persistence session based on the IP address of the service selected by the virtual server (the destination IP address). Subsequently, it directs requests to the same destination IP to the same service. This type of persistence is used with link load balancing. For more information about link load balancing, see [Link Load Balancing](#).

The time-out value for destination IP persistence is the same as that for source IP persistence, described in [Persistence Based on Source IP Address](#).

To configure persistence based on the destination IP address, see [Configuring Persistence Types That Do Not Require a Rule](#).

## Persistence Based on Source and Destination IP Addresses

With source and destination IP address-based persistence, when the NetScaler appliance receives a request, it creates a persistence session based on both the IP address of the client (the source IP address) and the IP address of the service selected by the virtual server (the destination IP address). Subsequently, it directs requests from the same source IP and to the same destination IP to the same service.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in [Persistence Based on Source IP Address](#).

To configure persistence based on both source and destination IP addresses, see [Configuring Persistence Types That Do Not Require a Rule](#).

# Persistence Based on SIP Call ID

Mar 16, 2012

With SIP Call ID persistence, the NetScaler appliance chooses a service based on the call ID in the SIP header. This enables it to direct packets for a particular SIP session to the same service and, therefore, to the same load balanced server. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see [Monitoring SIP Services](#).

To configure persistence based on SIP Call ID, see [Configuring Persistence Types That Do Not Require a Rule](#).

# Persistence Based on RTSP Session IDs

Aug 29, 2013

With RTSP Session ID persistence, when the NetScaler appliance receives a request from a new client, it creates a new persistence session based on the Real-Time Streaming Protocol (RTSP) session ID in the RTSP packet header, and then directs the request to the RTSP service selected by the configured load balancing method. It directs subsequent requests that contain the same session ID to the same service. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see [Monitoring SIP Services](#).

Note: RTSP Session ID persistence is configured by default on RTSP virtual servers, and you cannot modify that setting. Sometimes different RTSP servers issue the same session IDs. When this happens, unique sessions cannot be created between the client and the RTSP server by using only the RTSP session ID. If you have multiple RTSP servers that may issue the same session IDs, you can configure the appliance to append the server IP address and port to the session ID, creating a unique token that can be used to establish persistence. This is called session ID mapping.

To configure persistence based on RTSP Session IDs, see [Configuring Persistence Types That Do Not Require a Rule](#).

Important: If you need to use session ID mapping, you must set the following parameter when configuring each service within the load balancing setup. Also, make sure that no non-persistent connections are routed through the RTSP virtual server.

# Configuring URL Passive Persistence

Nov 23, 2015

With URL Passive persistence, when the NetScaler appliance receives a request from a client, it extracts the server IP address-port information (expressed as a single hexadecimal number) from the client request.

URL passive persistence requires configuring an advanced expression that specifies the query element that contains the server IP address-port information. For more information about classic and advanced policy expressions, see [Policy Configuration and Reference](#).

The following expression configures the appliance to examine requests for URL queries that contain the string "urlp=", extract the server IP address-port information, convert it from a hexadecimal string to an IP and port number, and forward the request to the service configured with this IP address and port number.

```
HTTP.REQ.URL.AFTER_STR("urlp=")
```

If URL passive persistence is enabled and the above expression is configured, a request with the following URL and server IP address-port string is directed to 10.102.29.10:80.

```
http://www.example.com/index.asp?urlp=0A661D0A0050
```

The persistence time-out value does not affect this persistence type; persistence is maintained as long as the server IP address-port information can be extracted from client requests. This persistence type does not consume any NetScaler resources, so it can accommodate an unlimited number of persistent clients.

To configure URL passive persistence, you first configure persistence as described in [Configuring Persistence Types That Do Not Require a Rule](#). You set the persistence type to URLPASSIVE. You then perform the procedures provided below.

## To configure URL passive persistence by using the command line interface

At the command prompt, type:

```
set lb vserver <vserverName> [-persistenceType <persistenceType>] [-rule <expression>]
```

### Example

```
set lb vserver LB-VServer-1 -persistenceType URLPASSIVE -rule HTTP.REQ.URL.AFTER_STR("urlp=")
```

## To configure URL passive persistence by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, select Persistence, and specify URLPASSIVE.

# Configuring Persistence Based on User-Defined Rules

Aug 29, 2013

When rule based persistence is configured, the NetScaler appliance creates a persistence session based on the contents of the matched rule before directing the request to the service selected by the configured load balancing method.

Subsequently, it directs all requests that match the rule to the same service. You can configure rule based persistence for services of type HTTP, SSL, RADIUS, ANY, TCP, and SSL\_TCP.

Rule based persistence requires a classic or default syntax expression. You can use a classic expression to evaluate request headers, or you can use a default syntax expression to evaluate request headers, Web form data in a request, response headers, or response bodies. For example, you could use a classic expression to configure persistence based on the contents of the HTTP Host header. You could also use a default syntax expression to configure persistence based on application session information in a response cookie or custom header. For more information on creating and using classic and default syntax expressions, see [Policy Configuration and Reference](#).

The expressions that you can configure depends on the type of service for which you are configuring rule based persistence. For example, certain RADIUS-specific expressions are not allowed for protocols other than RADIUS, and TCP-option based expressions are not allowed for service types other than the ANY type. For TCP and SSL\_TCP service types, you can use expressions that evaluate TCP/IP protocol data, Layer 2 data, TCP options, and TCP payloads.

Note: For a use case that involves configuring rule based persistence on the basis of Financial Information eXchange ("FIX") Protocol data transmitted over TCP, see [Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream](#).

Rule based persistence can be used for maintaining persistence with entities such as Branch Repeater appliances, Branch Repeater plug-ins, cache servers, and application servers.

Note: On an ANY virtual server, you cannot configure rule-based persistence for the responses.

To configure persistence based on a user-defined rule, you first configure persistence as described in [Configuring Persistence Types That Do Not Require a Rule](#), and set the persistence type to RULE. You then perform the procedures provided below. You can configure rule based persistence by using the configuration utility or the NetScaler command line.

To configure persistence based on user-defined rules by using the command line interface

At the command prompt, type:

```
set lb vserver <vserverName> [-rule <expression>][-resRule <expression>]
```

## Example

```
set lb vserver vsvr_name --rule http.req.header("cookie").value(0).typecast_nvlist_t(=';').value("server")
```

```
set lb vserver vsvr_name --resrule http.res.header("set-cookie").value(0).typecast_nvlist_t(=';').value("server")
```

To configure persistence based on user-defined rules by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, select Persistence, select RULE, and specify an expression.

## Example: Classic Expression for a Request Payload

The following classic expression creates a persistence session based on the presence of a User-Agent HTTP header that contains the string, "MyBrowser", and directs any subsequent client requests that contain this header and string to the

same server that was selected for the initial request.

http header User-Agent contains MyBrowser

**Example: Default syntax Expression for a Request Header**

The following default syntax expression does exactly the same thing as the previous classic expression.

```
HTTP.REQ.HEADER("User-Agent").CONTAINS ("MyBrowser")
```

**Example: Default syntax Expression for a Response Cookie**

The following expression examines responses for “server” cookies, and then directs any requests that contain that cookie to the same server that was selected for the initial request.

```
HTTP.RES.HEADER("SET-COOKIE").VALUE(0).TYPECAST_NVLIST_T(';',:').VALUE("server")
```

# Configuring Persistence Types That Do Not Require a Rule

Apr 28, 2016

To configure persistence, you must first set up a load balancing virtual server, as described in [Setting Up Basic Load Balancing](#). You then configure persistence on the virtual server.

To configure persistence on a virtual server by using the command line interface

At the command prompt, type the following commands to configure persistence and verify the configuration:

- `set lb vserver <name> -PersistenceType <type> [-timeout <integer>]`
- `show lb vserver`

Timeout is the time period for which a persistence session is in effect. Default value: 2. Maximum value: 1440.

## Example

```
set lb vserver Vserver-LB-1 -persistenceType SOURCEIP
```

```
show lb vserver
```

Note: For IP-based persistence, you can also set the `persistMask` parameter.

To configure persistence on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, select Persistence, and specify a persistence type other than RULE.

# Configuring Backup Persistence

Nov 12, 2013

The NetScaler appliance uses backup persistence to choose a new type of persistence when the primary persistence type fails. For example, if the primary persistence type is set to Cookie Insert, and backup persistence is set to Source IP, the NetScaler appliance uses Source IP-based persistence when the cookie is missing from the HTTP header or when the client browser does not support cookies.

You can set a time-out value for backup persistence only when the primary persistence type is HTTP Cookie-based or RTSP session ID-based persistence, and the backup persistence type is Source IP-based.

To set backup persistence for a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -persistenceType <PersistenceType> -persistenceBackup <BackupPersistenceType>
```

## Example

```
set lb vserver Vserver-LB-1 -persistenceType CookieInsert -persistenceBackup SourceIP
```

To set backup persistence for a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, select Persistence, and specify a backup persistence type.

# Configuring Persistence Groups

Aug 29, 2013

When you have load-balanced servers that handle several different types of connections (such as Web servers that host multimedia), you can configure a virtual server group to handle these connections. To create a virtual server group, you bind different types of virtual servers, one for each type of connection that your load balanced servers accept, into a single group. You then configure a persistence type for the entire group.

You can configure either source IP-based persistence or HTTP cookie-based persistence for persistence groups. After you set persistence for the entire group, you cannot change it for individual virtual servers in the group. If you configure persistence on a group and then add a new virtual server to the group, the persistence of the new virtual server is changed to match the persistence setting of the group.

When persistence is configured on a group of virtual servers, persistence sessions are created for initial requests, and subsequent requests are directed to the same service as initial request, regardless of the virtual server in the group that receives each client request.

If you configure HTTP cookie-based persistence, the domain attribute of the HTTP cookie is set. This setting causes the client software to add the HTTP cookie into client requests if different virtual servers have different public host names. For more information about CookieInsert persistence type, see [Persistence Based on HTTP Cookies](#).

To create a virtual server persistency group by using the command line interface

At the command prompt, type:

```
bind lb group <vServerGroupName> <vServerName> -persistenceType <PersistenceType>
```

## Example

```
bind lb group Vserver-Group-1 Vserver-LB-1 -persistenceType CookieInsert
```

To modify a virtual server group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Persistency Groups, create a persistency group, and specify the virtual servers that must be part of this group.

To modify a virtual server group by using the command line interface

At the command prompt, type:

```
set lb group <vServerGroupName> -PersistenceBackup <BackupPersistenceType> -persistMask <SubnetMaskAddress>
```

## Example

```
set lb group vserver-Group-1 -PersistenceBackup SourceIP -persistMask 255.255.255.255
```

# Configuring RADIUS Load Balancing with Persistence

Jun 08, 2015

Today's complex networking environment often requires coordinating a high-volume, high-capacity load balancing configuration with robust authentication and authorization. Application users may connect to a VPN through mobile access points such as consumer-grade DSL or Cable connections, WiFi, or even dial-up nodes. Those connections usually use dynamic IPs, which can change during the connection.

If you configure RADIUS load balancing on the NetScaler appliance to support persistent client connections to RADIUS authentication servers, the appliance uses the user logon or the specified RADIUS attribute instead of the client IP as the session ID, directing all connections and records associated with that user session to the same RADIUS server. Users are therefore able to log on to your VPN from mobile access locations without experiencing disconnections when the client IP or WiFi access point changes.

To configure RADIUS load balancing with persistence, you must first configure RADIUS authentication for your VPN. For information and instructions, see the Authentication, Authorization, Auditing (AAA) chapter in [AAA Application Traffic](#). You must also choose either the Load Balancing or Content Switching feature as the basis for your configuration, and make sure that the feature you chose is enabled. The configuration process with either feature is almost the same.

Then, you configure either two load balancing, or two content switching, virtual servers, one to handle RADIUS authentication traffic and the other to handle RADIUS accounting traffic. Next, you configure two services, one for each load balancing virtual server, and bind each load balancing virtual server to its service. Finally, you create a load balancing persistency group and set the persistency type to RULE.

To configure RADIUS load balancing with persistence, see the following sections:

- [Enabling the Load Balancing or Content Switching Feature](#)
- [Configuring Virtual Servers](#)
- [Configuring Services](#)
- [Binding Virtual Servers to Services](#)
- [Configuring a Persistency Group for Radius](#)

## Enabling the Load Balancing or Content Switching Feature

Updated: 2013-08-29

To use the Load Balancing or Content Switching feature, you must first ensure that the feature is enabled. If you are configuring a new NetScaler appliance that has not previously been configured, both of these features are already enabled, so you can skip to the next section. If you are configuring a NetScaler appliance with a previous configuration on it, and you are not certain that the feature you will use is enabled, you must do that now.

- For instructions on enabling the load balancing feature, see [Enabling Load Balancing](#).
- For instructions on enabling the content switching feature, see [Enabling Content Switching](#).

## Configuring Virtual Servers

Updated: 2013-09-13

After enabling the load balancing or content switching feature, you must next configure two virtual servers to support RADIUS authentication:

- **RADIUS authentication virtual server.** This virtual server and its associated service will handle authentication traffic to your RADIUS server. Authentication traffic consists of connections associated with users logging onto your protected application or virtual private network (VPN).
- **RADIUS accounting virtual server.** This virtual server and its associated service will handle accounting connections to your RADIUS server. Accounting traffic consists of connections that track an authenticated user's activities on your protected application or VPN.

Important: You must create either a pair of load balancing virtual servers or a pair of content switching virtual servers to use in your RADIUS persistence configuration. You cannot mix virtual server types.

## To configure a load balancing virtual server by using the command line interface

At the command prompt type the following commands to create a new load balancing virtual server and verify the configuration:

- `add lb vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule <rule>`
- `show lb vserver <name>`

To configure an existing load balancing virtual server, replace the above add lb virtual server command with the set lb vserver command, which takes the same arguments.

## To configure a content switching virtual server by using the command line interface

At the command prompt type the following commands to create a new content switching virtual server and verify the configuration:

- `add cs vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule <rule>`
- `show cs vserver <name>`

To configure an existing content switching virtual server, replace the above add cs vserver command with the set cs vserver command, which takes the same arguments.

### Example

```
add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812
-lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813
-lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
set lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812
-lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
set lb vserver radius_auth_vs1 RADIUS 192.168.46.34 1813
-lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
```

## To configure a load balancing or content switching virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers or navigate to Traffic Management > Content Switching > Virtual Servers>>, and configure a virtual server.

## Configuring Services

Updated: 2013-09-17

After configuring your virtual servers, you must next configure two services, one for each of the virtual servers that you created. For instructions, see [Configuring Services](#).

Note: Once configured, these services are in the DISABLED state until the NetScaler appliance can connect to your RADIUS server's authentication and accounting IPs and monitor their status.

### Binding Virtual Servers to Services

After configuring your services, you must next bind each of the virtual servers that you created to the appropriate service. For instructions, see [Binding Services to the Virtual Server](#).

## Configuring a Persistency Group for Radius

Updated: 2013-09-17

After binding your load balancing virtual servers to the corresponding services, you must set up your RADIUS load balancing configuration to support persistence. To do so, you configure a load balancing persistency group that contains your RADIUS load balancing virtual servers and services, and configure that load balancing persistency group to use rule-based persistence. For instructions, see [Configuring Persistence Groups](#).

# Viewing Persistence Sessions

Sep 13, 2013

You can view the different persistence sessions that are in effect globally or for a particular virtual server.

Note: A NetScaler nCore appliance uses multiple CPU cores for packet handling. Every session on the appliance is owned by a CPU core. If the appliance receives a request for which a session does not already exist, a session is created, and one of the cores is designated as the owner of that session. Subsequent requests that belong to that session might not always arrive at and be handled by the owner core. In that case, inter-core messaging ensures that the session information on the owner core is always current. However, when a core receives a request that belongs to a persistence session owned by another core, the inter-core messaging does not refresh the timeout value for the persistence session. Consequently, in the output of successively executed `show lb persistentSessions` commands, which display timeout values from owner cores only, the timeout value for a persistence session might diminish to 0 (zero), even if the persistence session continues to be active.

To view a persistence session by using the command line interface

At the command prompt, to view all persistence sessions type:

```
show lb persistentSessions [<vServer>]
```

## **Example**

```
show lb persistentSessions myVserver
```

To view persistence sessions by using the configuration utility

Navigate to Traffic Management > Virtual server persistent sessions.

# Clearing Persistence Sessions

Nov 12, 2013

You might need to clear persistence sessions from the NetScaler if sessions fail to time out. You can do one of the following:

- Clear all sessions for all virtual servers at once.
- Clear all sessions for a given virtual server at once.
- Clear a particular session that is associated with a given virtual server.

Note: The functionality for clearing a particular session that is associated with a given virtual server is available only on NetScaler 10.e.

To clear a persistence session by using the command line interface

At the command prompt, type the following commands to clear persistence sessions and verify the configuration:

- `clear lb persistentSessions [<vServer> [-persistenceParam <string>]]`
- `show persistentSessions <vServer>`

## Examples

Example 1 clears all persistence sessions for load balancing virtual server lbvip1. Example 2 first displays the persistence sessions for load balancing virtual server lbvip1, clears the session with persistence parameter xls, and then displays the persistence sessions to verify that the session was cleared.

### Example

```
> clear persistentSessions lbvip1
```

```
Done
```

```
> show persistentSessions
```

```
Done
```

```
>
```

### Example 2

```
> show persistentSessions lbvip1
```

```
Type SRC-IP ... PERSISTENCE-PARAMETER
```

```
RULE 0.0.0.0 ... xls
```

```
RULE 0.0.0.0 ... txt
```

```
RULE 0.0.0.0 ... html
```

```
Done
```

```
> clear persistentSessions lbvip1 -persistenceParam xls
```

```
Done
```

```
> show persistentSessions lbvip1
```

```
Type SRC-IP ... PERSISTENCE-PARAMETER
```

```
RULE 0.0.0.0 ... txt
```

```
RULE 0.0.0.0 ... html
```

```
Done
```

```
>
```

To clear persistence sessions by using the configuration utility

1. Navigate to Traffic Management > Clear Persistent Sessions.

# Overriding Persistence Settings for Overloaded Services

Aug 29, 2013

When a service is loaded or is otherwise unavailable, service to clients is degraded. To work around this situation, you might have to configure the NetScaler appliance to temporarily forward to other services the requests that would otherwise be included in the persistence session that is associated with the overloaded service. In other words, you might have to override the persistence setting that is configured for the load balancing virtual server. You can achieve this functionality by setting the `skippersistency` parameter. With the parameter set, when the virtual server receives new connections for an overloaded service, the virtual server disregards any existing persistence sessions that are associated with that service, until the service returns to a state at which it can accept requests. Persistence sessions associated with other services are not affected. The functionality is available for only virtual servers whose type is `ANY` or `UDP`.

In Branch Repeater load balancing configurations, you must also configure a load monitor and bind it to the service. The monitor takes the service out of subsequent load balancing decisions until the load on the service is brought below the configured threshold. For information about configuring a load monitor for your virtual server, see [Understanding Load Monitors](#).

You can configure the virtual server to perform one of the following actions with the requests that would otherwise form a part of the persistence session:

- **Send each request to one of the other services.** The virtual server takes a load balancing decision and sends each request to one of the other services on the basis of the configured load balancing method. If all the services are overloaded, requests are dropped until a service becomes available.  
Both wildcard and IP address–based virtual servers support this option. This action is appropriate for all deployments, including deployments in which the virtual server is load balancing Branch Repeater appliances or firewalls.
- **Bypass the virtual server-service configuration.** The virtual server does not take a load balancing decision. Instead, it simply bridges each request through to a physical server on the basis of the destination IP address in the request. Only wildcard virtual servers of type `ANY` and `UDP` support the bypass option. Wildcard virtual servers have a `*.*` IP and port combination. This action is appropriate for deployments in which you are using the virtual server to load balance Branch Repeater appliances or firewalls. In these deployments, the NetScaler appliance first forwards a request to a Branch Repeater appliance or firewall, and then forwards the processed response to a physical server. If you configure the virtual server to bypass the virtual server–service configuration for overloaded services, if a Branch Repeater appliance or firewall gets overloaded, the virtual server bridges requests directly to their destination IP addresses until the Branch Repeater appliance or firewall can accept requests.

To override persistence settings for overloaded services by using the command line interface

At the command prompt, type the following commands to override persistence settings for overloaded services and verify the configuration:

- `set lb vserver <name> -skippersistency <skippersistency>`
- `show lb vserver <name>`

## Example

```
> set lb vserver mylbvserver -skippersistency ReLb
```

Done

```
> show lb vserver mylbvserver
```

```
mylbvserver (*:*) - ANY Type: ADDRESS
```

```
...
```

```
...
```

```
Skip Persistence: ReLb
```

```
...
```

Done

```
>
```

To override persistence settings for overloaded services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server of type UDP or ANY.
2. In the Advanced Settings pane, select Traffic Settings, and specify the type of Skip Persistence.

# Troubleshooting

Feb 28, 2014

**The statistics from the NetScaler VPX appliance indicate that the appliance has reached the session persistence limit. As a result, persistence sessions are failing. Is possible to increase the session persistence limit?**

**Cause:** The NetScaler appliance has the system limit of 250,000 persistence session for a core.

**Resolution:** To resolve this issue, you can perform any of the following tasks:

- Reduce the time out value for persistence
- Increase the number of cores for the appliance

**After configuring Cookie Insert persistence on the NetScaler appliance, the users report that the connections work fine for some time, but then start getting disconnected. What best practice should I follow when configuring persistence?**

**Cause:** By default, the time-out value for Cookie Insert persistence is 120 seconds.

**Resolution:** When you configure persistence for applications for which idle time cannot be determined, set the Cookie Insert persistence time-out value to 0. With this setting, the connection does not time out.

**After configuring an HTTP virtual server on the NetScaler appliance, I need to make sure that a user always connects to the same server for the requested content, so I configured SourceIP persistence. Now, increasing the time-out value for persistence introduces latency. How can I increase the timeout value without affecting performance?**

**Resolution:** Consider using Cookie Insert persistence with the time-out value set to 0. This setting enables long-duration persistence settings, because the appliance does not specify a time for expiring the cookie.

**After configuring Cookie Insert persistence on the NetScaler appliance, it works as expected when clients from the same time zone access the content. However, when a client from another time zone makes an attempt to connect, the connection is immediately timed out.**

**Cause:** Time based Cookie Insert persistence works as expected when a client from the same time zone makes a connection. However, when the client machine and NetScaler appliance are in different time zones, the cookie is not valid. For example, when a client in EST time zone sends a cookie at 11:00 AM EST to a NetScaler appliance in the PST time zone, the appliance receives the cookie at 2:00 PM PST. As a result of the difference in time, the cookie is not valid, and the connection is immediately timed-out.

**Resolution:** Set the time-out value for Cookie Insert persistence to 0.

**A NetScaler appliance is used to load balance application servers, such as Oracle Weblogic server. To make sure that clients get persistent connections to these servers, SourceIP persistence is configured. It works as expected when a connection is made from a computer. However, when thin clients attempt a connection through a terminal server and, as a result, the appliance receives requests from multiple clients from the same IP address (the terminal server IP address). Therefore, the connections from all thin clients are directed to the same application server. Is it possible to configure persistency for requests from individual thin clients based on the client IP address?**

**Cause:** The NetScaler appliance receives requests from the terminal server and the source IP address of the request remains the same. As a result, the appliance cannot distinguish among the requests received from the thin clients and provide persistence according to the requests from thin clients.

**Resolution:** To avoid this problem, you can configure Rule persistence based on some unique parameter value for each thin client.

**The NetScaler appliance is used to load balance Web Interface servers. When accessing the servers, the user receives the “State Error” error message. Additionally, when one of the Web Interface servers is shut down or not available, some of the users receive an error message.**

**Cause:** Lack of persistence to the Web Interface servers can result in error messages when a user attempts to connect to the server.

**Resolution:** Citrix recommends that you specify the Cookie Insert persistence method on the NetScaler appliance when load balancing Web Interface servers.

# Customizing a Load Balancing Configuration

Jun 09, 2015

After you configure a basic load balancing setup, you can make a number of modifications to it so that it distributes load exactly as you need. The load balancing feature is complex. You can modify the basic elements by changing the load balancing algorithm, configuring load balancing groups and using them to create your load balancing configuration, configuring persistent client-server connections, configuring the redirection mode, and assigning different weights to different services that have different capacities.

The default load balancing algorithm on the NetScaler appliance is the least connection method, which configures the appliance to send each incoming connection to the service that is currently handling the fewest connections. You can specify different load balancing algorithms, each of which is suited to different conditions.

To accommodate applications such as shopping carts, which require that all requests from the same user be directed to the same server, you can configure the appliance to maintain persistent connections between clients and servers. You can also specify persistence for a group of virtual servers, causing the appliance to direct individual client requests to the same service regardless of which virtual server in the group receives the client request.

You can enable and configure the redirection mode that the appliance uses when redirecting user requests, choosing between IP-based and MAC-based forwarding. You can assign weights to different services, specifying what percentage of incoming load should be directed to each service, so that you can include servers with different capacities in the same load balancing setup without overloading the lower-capacity servers or allowing the higher-capacity servers to sit idle.

This section includes the following details:

- [Customizing the Hash Algorithm for Persistence across Virtual Servers](#)

- [Configuring per-VLAN Wildcarded Virtual Servers](#)
- [Assigning Weights to Services](#)
- [Configuring the MySQL and Microsoft SQL Server Version Setting](#)

# Customizing the Hash Algorithm for Persistence across Virtual Servers

Aug 29, 2013

The NetScaler appliance uses hash-based algorithms for maintaining persistence across virtual servers. By default, the hash-based load balancing method uses a hash value of the IP address and port number of the service. If a service is made available at different ports on the same server, the algorithm generates different hash values. Therefore, different load balancing virtual servers might send requests for the same application to different services, breaking the pseudo-persistence.

As an alternative to using the port number to generate the hash value, you can specify a unique hash identifier for each service. For a service, the same hash identifier value must be specified on all the virtual servers. If a physical server serves more than one type of application, each application type should have a unique hash identifier.

The algorithm for computing the hash value for a service works as follows:

- By default, a global setting specifies the use of port number in a hash calculation.
- If you configure a hash identifier for a service, it is used, and the port number is not, regardless of the global setting.
- If you do not configure a hash identifier, but change the default value of the global setting so that it does not specify use of the port number, the hash value is based only on the IP address of the service.
- If you do not configure a hash identifier or change the default value of the global setting to use the port number, the hash value is based on the IP address and the port number of the service.

You can also specify hash identifiers when using the NetScaler command line to bind services to a service group. In the configuration utility, you can open a service group and add hash identifiers on the Members tab.

To change the use-port-number global setting by using the command line interface

At the command prompt, type:

```
set lb parameter -usePortForHashLb (YES | NO)
```

## Example

```
> set lb parameter -usePortForHashLb NO
```

```
Done
```

```
>show lb parameter
```

```
Global LB parameters:
```

```
 Persistence Cookie HttpOnly Flag: DISABLED
```

```
 Use port for hash LB: NO
```

```
Done
```

To change the use-port-number global setting by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing parameters.
2. Select or clear Use Port for Hash Based LB Methods.

To create a new service and specify a hash identifier for a service by using the command line interface

At the command prompt, type the following commands to set the hash ID and verify the setting:

```
add service < name > (< ip > |< serverName >) < serviceType > < port > -hashId < positive_integer >
```

```
show service <name>
```

### Example

```
> add service flbkng 10.101.10.1 http 80 -hashId 12345
```

```
Done
```

```
>show service flbkng
```

```
flbkng (10.101.10.1:80) - HTTP
```

```
State: DOWN
```

```
Last state change was at Thu Nov 4 10:14:52 2010
```

```
Time since last state change: 0 days, 00:00:15.990
```

```
Server Name: 10.101.10.1
```

```
Server ID : 0 Monitor Threshold : 0
```

```
Down state flush: ENABLED
```

```
Hash Id: 12345
```

```
1) Monitor Name: tcp-default
```

```
State: DOWN Weight: 1
```

```
Done
```

To specify a hash identifier for an existing service by using the command line interface

Type the set service command, the name of the service, and **-hashID** followed by the ID value.

To specify a hash identifier while adding a service group member

To specify a hash identifier for each member to be added to the group and verify the setting, at the command prompt, type the following commands (Be sure to specify a unique hashID for each member.):

```
bind servicegroup <serviceName> <memberName> <port> -hashId <positive_integer>
```

```
show servicegroup <serviceName>
```

### Example

```
bind servicegroup http_svc_group 10.102.27.153 80 -hashId 2222222
```

```
>show servicegroup SRV
```

```
SRV - HTTP
```

```
State: ENABLED Monitor Threshold : 0
```

```
...
```

```
1) 1.1.1.1:80 State: DOWN Server Name: 1.1.1.1 Server ID: 123 Weight: 1
```

```
Hash Id: 32211
```

```
Monitor Name: tcp-default State: DOWN
```

```
...
```

2) 2.2.2.2:80 State: DOWN Server Name: 2.2.2.2 Server ID: 123 Weight: 1  
Hash Id: 12345

Monitor Name: tcp-default State: DOWN

...

Done

To specify a hash identifier for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Create a new service, or open an existing service and specify the hash ID.

To specify a hash identifier for an already configured service group member by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a member and type a unique hash ID.

# Configuring the Redirection Mode

Nov 12, 2013

The redirection mode configures the method used by a virtual server to determine where to forward incoming traffic. The NetScaler appliance supports the following redirection modes:

- IP-Based forwarding (the default)
- MAC-Based forwarding

You can configure MAC-Based forwarding on networks that use direct server return (DSR) topology, link load balancing, or firewall load balancing. For more information on MAC-Based forwarding, see [Configuring MAC-Based Forwarding](#).

To configure the redirection mode by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -m <RedirectionMode>
```

## Example

```
set lb vserver Vserver-LB-1 -m MAC
```

## Note

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

To configure the redirection mode by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server and select the redirection mode.

# Configuring per-VLAN Wildcarded Virtual Servers

Nov 12, 2013

If you want to configure load balancing for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

To configure a wildcarded virtual server that listens to a specific VLAN by using the command line interface

At the command prompt, type the following commands to configure a wildcarded virtual server that listens to a specific VLAN and verify the configuration:

- `add lb vserver <name> <serviceType> IPAddress * Port * -listenpolicy <expression> [-listenpriority <positive_integer>]`
- `show vserver`

## Example

```
add lb vserver Vserver-LB-vlan1 ANY -listenpolicy "CLIENT.VLAN.ID.EQ(2)" -listenpriority 10
```

```
show vserver Vserver-LB-vlan1
```

To configure a wildcarded virtual server that listens to a specific VLAN by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Create a new virtual server or open an existing virtual server.
3. Specify a listen policy priority and expression.

After you have created this virtual server, you bind it to one or more services as described in [Setting Up Basic Load Balancing](#).

# Assigning Weights to Services

Nov 12, 2013

In a load balancing configuration, you assign weights to services to indicate the percentage of traffic that should be sent to each service. Services with higher weights can handle more requests; services with lower weights can handle fewer requests. Assigning weights to services allows the NetScaler appliance to determine how much traffic each load balanced server can handle, and therefore more effectively balance load.

Note: If you use a load balancing method that supports weighting of services (for example, the round robin method), you can assign a weight to the service.

The following table describes the load balancing methods that support weighting, and briefly describes the manner in which weighting affects how a service is selected for each one.

| <b>Load Balancing Methods</b>                                     | <b>Service Selection with Weights</b>                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Round Robin                                                       | The virtual server prioritizes the queue of available services such that services with the highest weights come to the front of the queue more frequently than those with the lowest weights and receive proportionately more traffic. For a complete description, see <a href="#">The Round Robin Method</a> . |
| Least Connection                                                  | The virtual server selects the service with the best combination of fewest active transactions and highest weight. For a complete description, see <a href="#">The Least Connection Method</a> .                                                                                                                |
| Least Response Time and Least Response Time Method using Monitors | The virtual server selects the service with the best combination of fewest active transactions and fastest average response time. For a complete description, see <a href="#">The Least Response Time Method</a> .                                                                                              |
| Least Bandwidth                                                   | The virtual server selects the service with the best combination of least traffic and highest bandwidth. For a complete description, see <a href="#">The Least Bandwidth Method</a> .                                                                                                                           |
| Least Packets                                                     | The virtual server selects the service with the best combination of fewest packets and highest weight. For a complete description, see <a href="#">The Least Packets Method</a> .                                                                                                                               |
| Custom Load                                                       | The virtual server selects the service with the best combination of lowest load and highest weight. For a complete description, see <a href="#">The Custom Load Method</a> .                                                                                                                                    |
| Hashing methods and Token method                                  | Weighting is not supported by these load balancing methods.                                                                                                                                                                                                                                                     |

To configure a virtual server to assign weights to services by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -weight <Value> <ServiceName>
```

**Example**

```
set lb vserver Vserver-LB-1 -weight 10 Service-HTTP-1
```

To configure a virtual server to assign weights to services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open the virtual server, and then click in the Services section.
3. In the weight column for the service, assign a weight to the service.

# Configuring the MySQL and Microsoft SQL Server Version Setting

Mar 24, 2015

You can specify the version of Microsoft® SQL Server® and the MySQL server for a load balancing virtual server that is of type MSSQL and MySQL respectively. The version setting is recommended if you expect some clients to not be running the same version as your MySQL or Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

To set the Microsoft SQL Server version parameter by using the command line interface

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a load balancing virtual server and verify the configuration:

- `set lb vserver <name> -mssqlServerVersion <mssqlServerVersion>`
- `show lb vserver <name>`

## Example

```
> set lb vserver myMSSQLvip -mssqlServerVersion 2008R2
Done
> show lb vserver myMSSQLvip
myMSSQLvip (190.0.2.12:1433) - MSSQL Type: ADDRESS
...
...
Mssql Server Version: 2008R2
...
...
Done
>
```

To set the MySQL Server version parameter by using the command line interface

At the command prompt, type the following commands to set the MySQL Server version parameter for a load balancing virtual server and verify the configuration:

- `set lb vserver <name> -mysqlServerVersion <string>`
- `show lb vserver <name>`

## Example

```
> set lb vserver mysqlsvr -mysqlserverversion 5.5.30
Done
> sh lb vserver mysqlsvr
mysqlsvr (2.22.2.222:3306) - MYSQL Type: ADDRESS
...
...
Mysql Server Version: 5.5.30
...
...

```

...

Done

>

To set the MySQL or Microsoft SQL Server version parameter by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server of type MySQL or MSSQL, and set the server version.

# Configuring Diameter Load Balancing

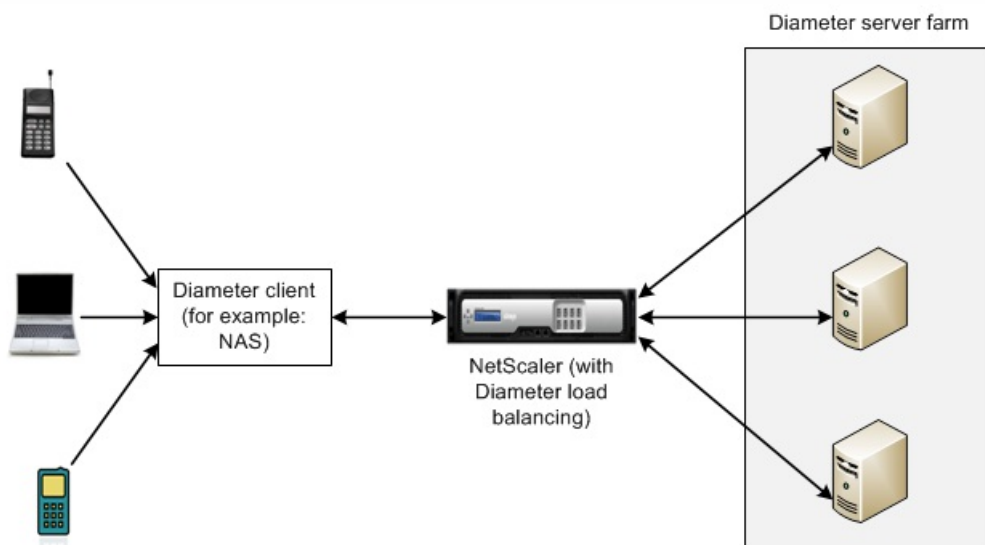

Mar 18, 2013

The Diameter protocol is a next generation Authentication, Authorization, and Accounting (AAA) signaling protocol used mainly on mobile devices such as laptops and mobile phones. It is a peer-to-peer protocol, as opposed to the traditional client-server model used by most other protocols. However, in most Diameter deployments, the clients originates the request and the server responds to the request.

When Diameter messages are exchanged, the Diameter server usually does much more processing than does the Diameter client. With the increase in control plane signaling volume, the Diameter server becomes a bottleneck. Therefore, Diameter messages must be load balanced to multiple servers. A virtual server performing load balancing of Diameter messages provides the following benefits:

- Lighter load on Diameter servers, which translates to faster response time to end users.
- Server health monitoring and better failover capabilities.
- Better scalability in terms of server addition without changing client configuration.
- High availability.
- SSL-Diameter offloading.

The following figure shows a Diameter system in a NetScaler deployment:

A Diameter system has the following components:

- **Diameter client.** Supports Diameter client applications in addition to the base protocol. Diameter clients are often implemented in devices situated at the edge of a network and provide access control services for that network. Typical examples of Diameter clients are a Network Access Server (NAS) and the Mobile IP Foreign Agent (FA).
- **Diameter agent.** Provides relay, proxy, redirect, or translation services. The NetScaler appliance (configured with a Diameter load balancing virtual server) plays the role of a Diameter agent.
- **Diameter server.** Handles the authentication, authorization, and accounting requests for a particular realm. A Diameter server must support Diameter server applications in addition to the base protocol.

In a typical Diameter topology, when an end-user device (such as a mobile phone) needs a service, it sends a request to a

Diameter client. Each Diameter client establishes a single connection (TCP connection—SCTP is not yet supported) with a Diameter server as specified by the Diameter base-protocol RFC 6733. The connection is long-lived and all messages between the two Diameter nodes (client and server) are exchanged over this connection. The NetScaler uses message based load balancing .

### **Example**

A mobile service provider uses Diameter for its billing system. When a subscriber uses a prepaid number, the Diameter client repeatedly sends requests to the server to check the available balance. The Diameter protocol establishes a connection between the client and the server, and all requests are exchanged over that connection. Connection based load balancing would be pointless, because there is only one connection. However, with the large number of messages on the connection, message based load balancing expedites the process of billing the prepaid mobile subscriber.

### **How Diameter Load Balancing Works**

A Diameter client opens a connection to the NetScaler appliance and sends a Diameter capability exchange (CER) message. Diameter messages are composed of command codes and each command has a set of Attribute-Value Pairs (AVPs), such as Origin-Host and Host-IP-Address.

The NetScaler selects a Diameter server, opens a connection to the server, and forwards the CER message to the server. The server reads the client identity and determines that it is directly connected to the client.

The Diameter server prepares the Diameter handshake reply and sends it to the NetScaler appliance. The appliance modifies the handshake and inserts its own identity. At this point, the Diameter client determines that it is directly connected to the NetScaler (the agent).

Note: Until the Diameter handshake is complete, all Diameter request messages from the client are queued on the selected server. The packets are forwarded to the server when the handshake is complete.

### **Load Balancing Diameter Traffic**

When a client sends a request to the NetScaler appliance, the appliance parses the request and contextually load balances it to a Diameter server on the basis of a persist AVP. The NetScaler has advertised the client identity to the server, so it does not add route entries, because the server is expecting messages directly from client.

Server initiated requests are not as frequent as client requests. Server initiated requests are similar to client initiated requests, except:

- Since messages are received from multiple servers, the NetScaler maintains the transaction state by adding a unique Hop by Hop (HbyH) number to each forwarded request message. When the message response arrives (with same HbyH number), the appliance translates this HbyH number to the HbyH number that was received on the server when the request arrived.
- NetScaler adds a route entry by putting its identity, because the client sees the NetScaler as a relay agent.

Note: If a Diameter message spans more than one packet, the NetScaler accumulates the packets in an incomplete header queue and forwards them to the server when the full message is accumulated. Similarly, if a single packet contains more than one Diameter message, the NetScaler splits the packet and forwards the messages to servers as determined by the load balancing virtual server.

### **Disconnecting a Session**

A Disconnect Peer Request (DPR) indicates the peer's intention of closing the connection, with the reason for closing the connection. The peer replies with a DPA (TCP always provides successful DPA).

- When the NetScaler receives a DPR from the client, it broadcasts the DPR to all servers and immediately replies with a DPA to the client. The servers reply with DPAs, but the NetScaler ignores them. The client sends a FIN, which the NetScaler broadcasts to all servers.
- When the NetScaler receives a DPR from the server, it replies with a DPA to that server alone, and does not remove the server from the reuse pool. When the server sends a FIN, the NetScaler replies with FIN/ACK and removes connections from the reuse pool.
- If the NetScaler receives a FIN from the client, it sends the client a FIN/ACK, broadcasts the FIN, and immediately removes the server connection from the reuse pool.
- If the NetScaler receives a FIN from the server, it sends a FIN/ACK and removes it from reuse pool. Any new message for this server is sent on a new connection.

## Configuring Load Balancing for Diameter Traffic

Updated: 2013-11-12

To configure the NetScaler appliance to load balance Diameter traffic, you must first set the Diameter parameters on the appliance, then add the Diameter monitor, add the Diameter services, bind the services to the monitor, add the Diameter load balancing virtual server, and bind the services to the virtual server.

### To configure load balancing for Diameter traffic by using the command line interface

1. Configure the Diameter parameters.  
`set ns diameter -identity <string> -realm <string> -serverClosePropagation <YES | NO>`

#### Example

```
set ns diameter -identity mydomain.org -realm org -serverClosePropagation YES
```

2. Add a Diameter monitor.  
`add lb monitor <monitorName> DIAMETER -originHost <string> -originRealm <string>`

#### Example

```
add lb monitor diameter_mon DIAMETER -originHost mydomain.org -originRealm org
```

3. Create the Diameter services.  
`add service <name>@ <IP>@ DIAMETER <port>`

#### Example

```
add service diameter_svc0 10.102.82.86 DIAMETER 3868
add service diameter_svc1 10.102.82.87 DIAMETER 3868
add service diameter_svc2 10.102.82.88 DIAMETER 3868
add service diameter_svc3 10.102.82.89 DIAMETER 3868
```

4. Bind the Diameter services to the Diameter monitor.  
`bind service <name>@ monitorName <monitorName>`

#### -Example

```
bind service diameter_svc0 -monitorName diameter_mon
bind service diameter_svc1 -monitorName diameter_mon
bind service diameter_svc2 -monitorName diameter_mon
bind service diameter_svc3 -monitorName diameter_mon
```

5. Add a Diameter load balancing virtual server with Diameter persistence.  
`add lb vserver <name>@ DIAMETER <IPAddress> <port> -persistenceType DIAMETER -persistAVPno <positive_integer>`

### Example

```
add lb vserver diameter_vs DIAMETER 10.102.112.152 3868 -persistenceType DIAMETER -persistAVPno 263
```

6. Bind the Diameter services to the Diameter load balancing virtual server.

```
bind lb vserver <name>@ <serviceName>
```

### Example

```
bind lb vserver diameter_vs diameter_svc0
```

```
bind lb vserver diameter_vs diameter_svc1
```

```
bind lb vserver diameter_vs diameter_svc2
```

```
bind lb vserver diameter_vs diameter_svc3
```

7. Save the configuration.

```
save ns config
```

Note: You can also configure load balancing of Diameter traffic over SSL by using the **SSL\_DIAMETER** service type.

## To configure load balancing for Diameter traffic by using the configuration utility

1. Navigate to System > Settings > Change Diameter Parameters and set the diameter parameters.
2. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a load balancing virtual server of type Diameter.
3. Create a service of type Diameter.
4. Create a monitor of type Diameter. In Special parameters, set the origin host and origin realm.
5. Bind the monitor to the service, and bind the service to the Diameter virtual server.
6. In Advanced Settings, click Persistence, specify Diameter and enter a persistence AVP number.
7. Click Save, and click Done.

# Protecting a Load Balancing Configuration against Failure

Jun 03, 2015

When a load balancing virtual server fails, or when the virtual server is unable to handle excessive traffic, the load balancing setup can fail. You can protect your load balancing setup against failure by configuring the NetScaler appliance to redirect excess traffic to an alternate URL, configuring a backup load balancing virtual server, and configuring stateful connection failover.

To protect a load balancing configuration against failure, see the following sections:

- [Redirecting Client Requests to an Alternate URL](#)
- [Configuring a Backup Load Balancing Virtual Server](#)
- [Configuring Spillover](#)
- [Connection Failover](#)
- [Flushing the Surge Queue](#)

# Redirecting Client Requests to an Alternate URL

Sep 02, 2013

In the event that a load balancing virtual server of type HTTP or type HTTPS goes DOWN or is disabled, you can redirect requests to an alternate URL by using an HTTP 302 redirect. The alternate URL can provide information about the status of the server.

You can redirect to a page on the local server or a remote server. You can redirect to a relative URL or an absolute URL. If you configure a redirect to a relative URL consisting of a domain name with no path, the NetScaler appliance appends the path of the incoming URL to the domain. If you use an absolute URL, the HTTP redirect is sent to that URL with no modification.

Note: If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when both the primary and backup virtual servers are DOWN.

To configure a virtual server to redirect the client request to a URL by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -redirectURL <URLValue>
```

## **Example**

```
set lb vserver Vserver-LB-1 -redirectURL http://www.newdomain.com/mysite/maintenance
```

To configure a virtual server to redirect the client request to a URL by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Protection, and specify a redirect URL.

# Configuring a Backup Load Balancing Virtual Server

Sep 02, 2013

You can configure the NetScaler appliance to direct requests to a backup virtual server in the event that the primary load balancing virtual server is DOWN or unavailable. The backup virtual server is a proxy and is transparent to the client. The appliance can also send a notification message to the client regarding the site outage.

You can configure a backup load balancing virtual server when you create it, or you can change the optional parameters of an existing virtual server. You can also configure a backup virtual server for an existing backup virtual server, thus creating cascading backup virtual servers. The maximum depth of cascading backup virtual servers is 10.

If you have multiple virtual servers that connect to two servers, you have a choice for what happens if the primary virtual server goes DOWN and then comes back up. The default behavior is for the primary virtual server to resume its role as primary. However, you may want to configure the backup virtual server to remain in control in the event that it takes over. For example, you may want to sync updates on the backup virtual server to the primary virtual server and then manually force the original primary server to resume its role. In this case, you can designate the backup virtual server to remain in control in the event that the primary virtual server goes DOWN and then comes back up.

You can configure a redirect URL on the primary load balancing virtual server as a fallback for when both the primary and the backup virtual servers are DOWN or have reached their threshold for handling requests. When services bound to virtual servers are OUT OF SERVICE, the appliance uses the redirect URL.

Note: If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when the primary and backup virtual servers are down. To set a backup virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -backupVserver <BackupVServerName> [-disablePrimaryOnDown]
```

## Example

```
set lb vserver Vserver-LB-1 -backupVserver Vserver-LB-2 -disablePrimaryOnDown
```

To set a backup virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Protection, and select a backup virtual server.
3. If you want the backup virtual server to remain in control until you manually enable the primary virtual server even if the primary virtual server comes back up, select Disable Primary When Down.

# Configuring Spillover

Sep 02, 2013

A spillover configuration on the appliance consists of a primary virtual server that is configured with a spillover method, a spillover threshold, and a backup virtual server. Backup virtual servers can also be configured for spillover, creating a chain of backup virtual servers.

The spillover method specifies the operational condition on which you want to base your spillover configuration (for example, the number of established connections, bandwidth, or combined health of the server farm). When a new connection arrives, the appliance verifies that the primary virtual server is up and compares the operational condition with the configured spillover threshold. If the threshold is reached, the spillover feature diverts new connections to the first available virtual server in the backup chain. The backup virtual server manages the connections it receives until the load on the primary falls below the threshold.

If you configure spillover persistence, the backup virtual server continues to process the connections it received, even after the load on the primary falls below the threshold. If you configure spillover persistence and a spillover persistence timeout, the backup virtual server processes connections for only the specified period of time after the load on the primary falls below the threshold.

Note: In most cases, spillover is triggered if the value associated with the spillover method exceeds the threshold (for example, number of connections). Keep in mind, however, that with the server-health spillover method, spillover is triggered if the health of the server farm falls below the threshold.

You can configure spillover in one of the following ways:

- Specify a predefined spillover method. Four predefined methods are available, and they fulfill common spillover requirements.
- Configure policy based spillover. In policy based spillover, you use a NetScaler rule to specify the conditions that should be met for spillover to occur. NetScaler rules give you the flexibility to configure spillover for various operational conditions.

Use policy based spillover if a predefined method does not satisfy your requirements. If you configure both for a primary virtual server, the policy based spillover configuration takes precedence over the predefined method.

First, you create the primary virtual server and the virtual servers that you need for the backup chain. You set up the backup chain by specifying one virtual server as the backup for the primary (that is, you create a secondary virtual server), a virtual server as the backup for the secondary (that is, you create a tertiary virtual server), and so on. Then, you configure spillover by either specifying a predefined spillover method or creating and binding spillover policies.

For instructions for assigning a virtual server as the backup for another virtual server, see [Configuring a Backup Load Balancing Virtual Server](#).

## Configuring a Predefined Spillover Method

Updated: 2013-09-02

Predefined spillover methods fulfill some of the more common spillover requirements. To use one of the predefined spillover methods, you configure spillover parameters on the primary virtual server. To create a chain of backup virtual servers, you also configure spillover parameters on backup virtual servers.

If the backup virtual servers reach their own threshold values, and the service type is TCP, the NetScaler appliance sends clients a TCP reset. For service types HTTP, SSL, and RTSP, it diverts new requests to the redirect URL configured for the primary virtual server. A redirect URL can be specified for only HTTP, SSL, and RTSP virtual servers. If a redirect URL is not configured, the NetScaler appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).

Note: With RTSP virtual servers, the NetScaler appliance uses only data connections for spillover. If the backup RTSP virtual server is not available, the requests are redirected to an RTSP URL and an RTSP redirect message is sent to the client.

## To configure a predefined spillover method for a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -soMethod <spilloverType> -soThreshold <positiveInteger> -soPersistence ENABLED -soPersistenceTimeout <positiveInteger>
```

Example

```
set lb vserver Vserver-LB-1 -soMethod Connection -soThreshold 1000 -soPersistence enabled -soPersistenceTimeout 2
```

## To configure a predefined spillover method for a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Protection, and set the spillover parameters.

## Configuring Policy Based Spillover

Updated: 2013-09-02

Spillover policies, which are based on rules (expressions), enable you to configure the appliance for a wider range of spillover scenarios. For example, you can configure spillover on the basis of the virtual server's response time, or on the basis of number of connections in the virtual server's surge queue.

To configure policy based spillover, first create a spillover action. You then select the expression that you want to use in the spillover policy, configure the policy, and associate the action with it. Finally, you bind the spillover policy to a load balancing, content switching, or global server load balancing virtual server. You can bind multiple spillover policies to a virtual server, with priority numbers. The appliance evaluates the spillover policies in ascending order of priority numbers and performs the action associated with the last policy to evaluate to TRUE.

A virtual server can also have a backup action. The backup action is performed if the virtual server does not have one or more backup virtual servers, or if all of the backup virtual servers are DOWN, disabled, or have reached their own spillover limits.

When a spillover policy results in an UNDEF condition (an exception thrown when the result of policy evaluation is undefined), an UNDEF action is performed. The UNDEF action is always ACCEPT. You cannot specify an UNDEF action of your choice.

## Configuring a Spillover Action

Updated: 2013-09-13

A spillover action is performed when the spillover policy with which it is associated evaluates to TRUE. Currently, SPILLOVER is the only supported spillover action.

To configure policy based spillover by using the command line interface

At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

- add spillover action <name> -action SPILLOVER
- show spillover action <name>

Example

```
> add spillover action mySoAction -action SPILLOVER
Done
> show spillover action mySoAction
1) Name: mySoAction Action: SPILLOVER
Done
>
```

## Selecting an Expression for the Spillover Policy

Updated: 2013-09-02

In the policy expression, you can use any virtual-server based expression that returns a Boolean value. For example, you could use one of the following expressions:

SYS.VSERVER("vserver").RESPTIME.GT(<int>), SYS.VSERVER("vserver").STATE.EQ("<string>"), and SYS.VSERVER("vserver").THROUGHPUT.LT(<int>).

In addition to the existing functions such as RESPTIME, STATE, and THROUGHPUT, you can use the following virtual server based functions that have been introduced with this feature:

### Averagesurgecount

Returns the average number of requests in the surge queues of active services. Returns 0 (zero) if there are no active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

### Activeservices

Returns the number of active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

### Activetransactions

Returns the value of the virtual-server-level counter for current active transactions.

### is\_dynamic\_limit\_reached

Returns a Boolean TRUE if the number of connections being managed by the virtual server equals the dynamically calculated threshold. The dynamic threshold is the sum of the maximum client (Max Clients) settings of the bound services that are UP.

You can use a policy expression to implement any of the predefined spillover methods. The following table maps the predefined spillover methods to the expressions you can use to implement them:

Table 1. Converting predefined spillover methods to policy expressions

| Predefined spillover method | Corresponding expression                                                                                                                                                                                                                                                                                         |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CONNECTION                  | SYS.VSERVER("<vserver-name>").CONNECTIONS, used with the GT(int) arithmetic function.                                                                                                                                                                                                                            |
| BANDWIDTH                   | SYS.VSERVER("<vserver-name>").THROUGHPUT, used with the GT(int) arithmetic function.                                                                                                                                                                                                                             |
| HEALTH                      | SYS.VSERVER("<vserver-name>").HEALTH, used with the LT(int) arithmetic function.                                                                                                                                                                                                                                 |
| DYNAMICCONNECTION           | SYS.VSERVER("<vserver-name>").IS_DYNAMIC_LIMIT_REACHED<br>Note: If you implement policy based spillover by using the IS_DYNAMIC_LIMIT_REACHED function, you must also configure the predefined DYNAMICCONNECTION method for the virtual server, so that statistics required for spillover to work are collected. |

## Configuring a Spillover Policy

Updated: 2013-09-13

A spillover policy uses a Boolean expression as a rule to specify the conditions that must be met for spillover to occur.

To configure a spillover policy by using the command line interface

At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

- add spillover policy <name> -rule <expression> -action <string> [-comment <string>]
- show spillover policy <name>

Example

```
> add spillover policy mySoPolicy -rule SYS.VSERVER("v1").RESPTIME.GT(50) -action mySoAction -comment "Triggers spillover when the vserver's response time is greater than 50 ms."
Done
> show spillover policy mySoPolicy
1) Name: mySoPolicy Rule: "SYS.VSERVER("v1").RESPTIME.GT(50)" Action: mySoAction Hits: 0 ActivePolicy: 0
```

Comment: "Triggers spillover when the vserver's response time is greater than 50 ms."

Done

>

## Binding a Spillover Policy to a Virtual Server

Updated: 2013-09-13

You can bind a spillover policy to load balancing, content switching, or global server load balancing virtual servers). You can bind multiple policies to a virtual server, with Goto expressions controlling the flow of evaluation.

To bind a spillover policy to a virtual server by using the command line interface

At the command prompt, type the following commands to bind a spillover policy to a load balancing, content switching, or global server load balancing virtual server and verify the configuration:

- bind (lb | cs | gslb) vserver <name> -policyName <string> -priority <positive\_integer> [-gotoPriorityExpression <expression>]
- show (lb | cs | gslb) vserver <name>

### Example

```
> bind lb vserver vserver1 -policyName mySoPolicy -priority 5
```

Done

```
> show lb vserver vserver1
```

```
vserver1 (2.2.2.12:80) - HTTP Type: ADDRESS
```

```
...
```

```
1) Spillover Policy Name: mySoPolicy Priority: 5
```

```
GotoPriority Expression: END
```

```
Flowtype: REQUEST
```

Done

>

## Configuring a Backup Action for a Spillover Event

Updated: 2013-09-02

A backup action specifies what to do in the event that the spillover threshold is reached but one or more backup virtual servers are either not configured or are down, disabled, or have reached their own thresholds.

Note: For the predefined spillover methods that are configured directly on the virtual server (as values of the Spillover Method parameter), the backup action is not configurable. By default, the appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).

The backup action is configured on the virtual server. You can configure the virtual server to accept requests (after the threshold specified by the policy is reached), redirect clients to a URL, or simply drop requests until the number of requests falls below the threshold.

To configure a backup action for spillover by using the command line interface

At the command prompt, type the following commands to configure a backup action and verify the configuration:

- set lb vserver <name> -soBackupAction <soBackupAction>
- show lb vserver <name>

### Example

```
> set lb vserver vs1 -soBackupAction REDIRECT -redirectURL http://www.mysite.com/maintenance
```

Done

```
> show lb vserver vs1
```

```
vs1 (10.102.29.76:80) - HTTP Type: ADDRESS
```

```
State: UP
```

```
...
```

```
Redirect URL: http://www.mysite.com/maintenance
```

```
...
```

Done

>

To configure a backup action for spillover by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Protection, and then specify a spillover backup action.

# Connection Failover

Nov 10, 2016

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. In a NetScaler High Availability (HA) setup, *connection failover* (or *connection mirroring-CM*) refers to keeping active an established TCP or UDP connection when a failover occurs. The new primary NetScaler appliance has information about the connections established before the failover and continues to serve those connections. After failover, the client remains connected to the same physical server. The new primary appliance synchronizes the information with the new secondary appliance by using the SSF framework. If the L2Conn parameter is set, Layer 2 connection parameters are also synchronized with the secondary.

You can set up connection failover in either stateless or stateful mode. In the stateless connection failover mode, the HA nodes do not exchange any information about the connections that are failed over. This method has no runtime overhead.

In the stateful connection failover mode, the primary appliance synchronizes the data of the failed-over connections with the new secondary appliance.

Connection failover is helpful if your deployment has long lasting connections. For example, if you are downloading a large file over FTP and a failover occurs during the download, the connection breaks and the download is aborted. However, if you configure connection failover in stateful mode, the download continues even after the failover.

## How Connection Failover Works on NetScaler Appliances

In stateless connection failover, the new primary appliance tries to re-create the packet flow according to the information contained in the packets it receives.

In stateful failover, to maintain current information about the mirrored connections, the primary appliance sends messages to the secondary appliance. The secondary appliance maintains the data related to the packets but uses it only in the event of a failover. If a failover occurs, the new primary (old secondary) appliance starts using the stored data about the mirrored connections and accepting traffic. During the transition period, the client and server may experience a brief disruption and retransmissions.

Note:

Verify that the primary appliance is able to authorize itself on the secondary appliance. To verify correct configuration of the passwords, use the `show rpcnode` command from command line or use the RPC option of the Network menu from the configuration utility.

A basic HA configuration with connection failover contains the entities shown in the following figure.

Figure 1. Connection Failover Entity Diagram

## Note

Connection failover is not supported after either of the following events:

- An upgrade to a later release.
- An upgrade to a later build within the same release, if the new build uses a different HA version.

## Supported Setup

Connection failover can be configured only on load balancing virtual servers. It cannot be configured on content switching virtual servers. If you enable connection failover on load balancing virtual servers that are attached to a content switching virtual server, connection failover will not work because the load balancing virtual servers do not initially accept the traffic.

The following table describes the setup supported for connection failover.

**Table 1. Connection Failover - Supported Setup**

| Setting                | Stateless                                                                                                                                 | Stateful                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| Service type           | ANY.                                                                                                                                      | ANY, UDP, TCP, FTP, SSL_BRIDGE.                                    |
| Load balancing methods | All methods supported for the service type ANY.<br>However, if Source IP persistence is not set, the SRCIPSRCPORHASH method must be used. | All methods applicable to the supported service types.             |
| Persistence types      | SOURCEIP persistence.                                                                                                                     | All types applicable to the supported service types are supported. |

| <b>Setting</b>                  | <b>Stateless</b>                                 | <b>Stateful</b>                                      |
|---------------------------------|--------------------------------------------------|------------------------------------------------------|
| USIP                            | Must be ON.                                      | No restriction.                                      |
|                                 |                                                  | It can be ON or OFF.                                 |
| Service bindings                | Service can be bound to only one virtual server. | Service can be bound to one or more virtual servers. |
| Internet Protocol (IP) versions | IPv4 and IPv6                                    | IPV4                                                 |
| Redundancy support              | Clustering and high availability                 | High availability                                    |

### Features Affected by Connection Failover

The following table lists the features affected if connection failover is configured.

**Table 2. How Connection Failover Affects NetScaler Features**

| <b>Feature</b>        | <b>Impact of Connection Failover</b>                                                                                                                                                                                                       |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SYN protection        | For any connection, if a failover occurs after the NetScaler issues SYN-ACK but before it receives the final ACK, the connection is not supported by connection failover. The client must reissue the request to establish the connection. |
| Surge protection      | If the failover occurs before a connection with the server is established, the new primary NetScaler tries to establish the connection with the server. It also retransmits all the packets held in the course of surge protection.        |
| Access down           | If enabled, the access-down functionality takes precedence over connection failover.                                                                                                                                                       |
| Application Firewall™ | The Application Firewall feature is not supported.                                                                                                                                                                                         |
| INC                   | Independent network configuration is not supported in the high availability (HA) mode.                                                                                                                                                     |
| TCP buffering         | TCP buffering is not compatible with connection mirroring.                                                                                                                                                                                 |
| Close on              | After failover, the NATPCBs may not be closed on response.                                                                                                                                                                                 |

| response<br>Feature  | Impact of Connection Failover |
|----------------------|-------------------------------|
| IPv6 virtual servers | Not yet supported.            |

To configure connection failover by using the configuration utility, navigate to Traffic Management > Load Balancing > Virtual Servers. Open the virtual server, and in Advanced Settings click Protection, and select Connection Failover as Stateful.

To configure connection failover by using the command line interface, enter the following command:

```
set lb vserver <vServerName> -connFailover <Value>
```

Example

```
set lb vserver Vserver-LB-1 -connFailover stateful
```

When connection failover is disabled on a virtual server, the resources allocated to the virtual server are freed.

To disable connection failover by using the configuration utility, navigate to Traffic Management > Load Balancing > Virtual Servers. Open the virtual server, under Protection, select Connection Failover as Disabled.

To disable connection failover by using the command line interface, enter the following command:

```
set lb vserver <vServerName> -connFailover <Value>
```

Example

```
set lb vserver Vserver-LB-1 -connFailover disable
```

# Flushing the Surge Queue

Dec 04, 2013

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the NetScaler appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.

Note: Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

To flush a surge queue by using the command line interface

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]
```

## Examples

1.

```
flush ns surgeQ --name SVC1ANZGB --serverName 10.10.10.1 80
```

The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10

2.

```
flush ns surgeQ
```

The above command flushes all the surge queues on the appliance.

To flush a surge queue by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Flush Surge Queue.

# Managing a Load Balancing Setup

Jun 09, 2015

An existing Load Balancing setup does not require a great deal of work to maintain as long as it is unchanged, but most do not remain unchanged for long. Increasing load requires new load-balanced servers and eventually new NetScaler appliances, which must be configured and added to the existing setup. Old servers wear out and need to be replaced, requiring removal of some servers and addition of others. Upgrades to your networking equipment or changes to topology may also require modifications to your load balancing setup. Therefore, you will need to perform operations on server objects, services, and virtual servers. The Visualizer can display your configuration graphically, and you can perform operations on the entities in the display. You can also take advantage of a number of other features that facilitate management of the traffic through your load balancing setup.

This section includes the following details:

- [Managing Server Objects](#)
- [Managing Services](#)
- [Managing a Load Balancing Virtual Server](#)

# Managing Server Objects

Nov 12, 2013

During basic load balancing setup, when you create a service, a server object with the IP address of the service is created, if one does not already exist. If you prefer for your service objects named with domain names rather than IP addresses, you might also have created one or more server objects manually. You can enable, disable, or remove any server object.

When you enable or disable a server object, you enable or disable all services associated with the server object. When you refresh the NetScaler appliance after disabling a server object, the state of its service appears as OUT OF SERVICE. If you specify a wait time when disabling a server object, the server object continues to handle established connections for the specified amount of time, but rejects new connections. If you remove a server object, the service to which it is bound is also deleted.

To enable a server by using the command line interface

At the command prompt, type:

```
enable server <name>@
```

## Example

```
enable server 10.102.29.5
```

To enable or disable a server object by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Servers.
2. Select the server and, in the Action list, select Enable or Disable.

To disable a server object by using the command line interface

At the command prompt, type:

```
disable server <name>@ <delay>
```

## Example

```
disable server 10.102.29.5 30
```

To remove a server object by using the command line interface

At the command prompt, type:

```
rm server <name>@
```

## Example

```
rm server 10.102.29.5
```

To remove a server object by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Servers.
2. Select a server, and click Remove.

# Managing Services

Nov 12, 2013

Services are enabled by default when you create them. You can disable or enable each service individually. When disabling a service, you normally specify a wait time during which the service continues to handle established connections, but rejects new ones, before shutting down. If you do not specify a wait time, the service shuts down immediately. During the wait time, the service's state is OUT OF SERVICE.

You can remove a service when it is no longer used. When you remove a service, it is unbound from its virtual server and deleted from the NetScaler configuration.

To enable or disable a service by using the command line interface

At the command prompt, type:

- enable service <name>
- disable service <name>@ <DelayInSeconds>

## Examples

```
enable service Service-HTTP-1
```

```
disable service Service-HTTP-1 30
```

To enable or disable a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service and, in the Action list, select Enable or Disable.

# Managing a Load Balancing Virtual Server

Feb 17, 2014

Virtual servers are enabled by default when you create them. You can disable and enable virtual servers manually. If you disable a virtual server, the virtual server's state appears as OUT OF SERVICE. When this happens, the virtual server terminates all connections, either immediately or after allowing existing connections to complete, depending on the setting of the `downStateFlush` parameter. If `downStateFlush` is ENABLED (default), all the connections are flushed. If DISABLED, the virtual server continues to serve requests on existing connections.

You remove a virtual server only when you no longer require the virtual server. Before you remove it, you must unbind all services from it.

To enable or disable a virtual server by using the command line interface

At the command prompt, type:

- `enable lb vserver <name>@`
- `disable lb vserver`  
SYNOPSIS  
`disable lb vserver <name>`

## Examples

```
enable lb vserver Vserver-LB-1
```

```
disable lb vserver Vserver-LB-1
```

To enable or disable a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Select a virtual server, and in the Action list, select Enable or Disable.

To unbind a service from a virtual server by using the command line interface

At the command prompt, type:

```
unbind lb vserver <name>@ <serviceName>
```

## Example

```
unbind lb vserver Vserver-LB-1 Service-HTTP-1
```

To unbind a service from a virtual server by using the configuration utility

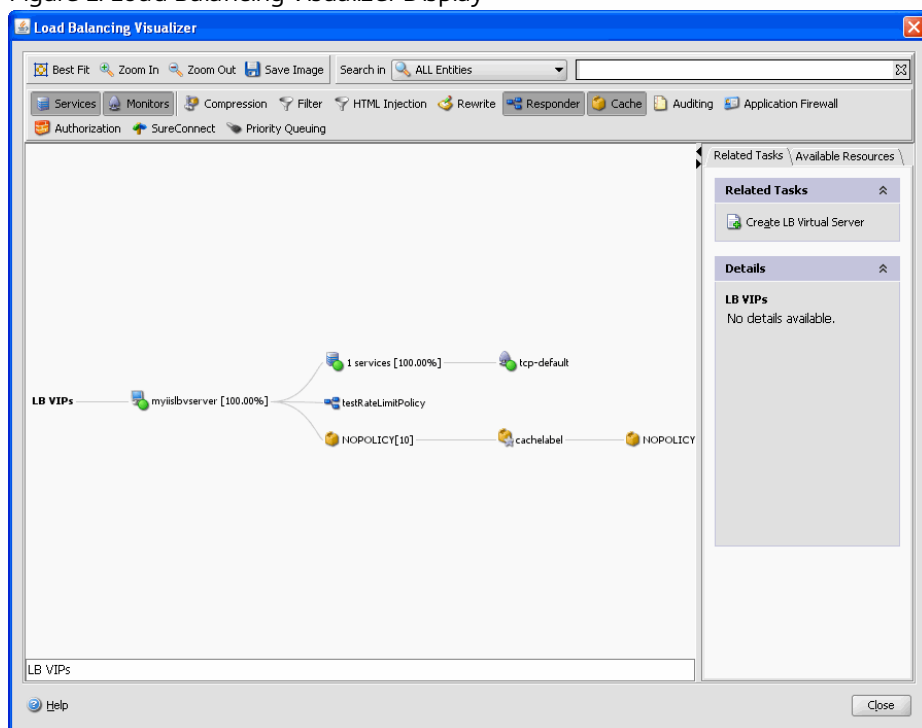

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, and click in the Services section.
3. Select a service and click Unbind.

# The Load Balancing Visualizer

Sep 03, 2013

The Load Balancing Visualizer is a tool that you can use to view and modify the load balancing configuration in graphical format. Following is an example of the Visualizer display

Figure 1. Load Balancing Visualizer Display

You can use the visualizer to view the following:

- The services and service groups that are bound to a virtual server.
- The monitors that are bound to each service.
- The policies that are bound to the virtual server.
- The policy labels, if configured.
- Configuration details of any displayed element.
- Load balancing virtual server statistics.
- Statistical information such as the number of requests received per second by the virtual server and the number of hits per second for rewrite, responder, and cache policies.
- A comparative list of all the parameters whose values either differ or are not defined across service containers.

You can also use the Visualizer to add and bind new objects, modify existing ones, and enable or disable objects. Most configuration elements displayed in the Visualizer appear under the same names as in other parts of the configuration utility. However, unlike the rest of the configuration utility, the Visualizer groups services that have the same configuration details and monitor bindings into an entity called a service container.

A service container is set of similar services and service groups that are bound to a single load balancing virtual server. Next to the service container is a number that shows the number of services in the group. The services in the container have the same properties, with the exception of the name, IP address, and port, and their monitor bindings should have the same weight and binding state. When you bind a new service to a virtual server, it is placed into an existing container if its configuration and monitor bindings match those of other services; otherwise, it is placed in its own container.

The service container display can help you troubleshoot your configuration if something is not functioning as you expect. More than one container for a particular virtual server is an indication that something is wrong with the configuration of that virtual server and its services. To correct the problem, you must first identify the container that has the desired configuration. You can do so by using the Service Attributes Diff feature, described below. After you identify the container, you right-click the container and click Apply Configuration.

The following procedures provide only basic steps for using the Visualizer. Because the Visualizer duplicates functionality in other areas of the Load Balancing feature, other methods of viewing or configuring all of the settings that can be configured in the Visualizer are provided throughout the Load Balancing documentation.

Note: The Visualizer requires a graphic interface, so it is available only through the configuration utility.

#### To view load balancing virtual server properties by using the Visualizer

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, you can adjust the viewable area as follows:
  - Click the Zoom In and Zoom Out icons to increase or decrease the size of the viewed objects. You can click and drag the viewable area if an item that you want to see disappears from view after zooming in.
  - Click the Best Fit icon to optimize the viewing area.
  - Click the Save Image icon to save the graph as an image file.
  - Click the image, hold down the mouse button, and drag the image to pan the view.
  - In the Search in text field, begin typing the name of the item you are looking for. The item's location is then highlighted. To restrict the search, click the drop-down menu and select the type of element that you want to search for

#### To view configuration details for services, service groups, and monitors by using the Visualizer

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, to view configuration details for entities that are bound to this virtual server, you can do the following:
  - To view a summary of bound services, position the cursor over the virtual server icon.
  - To view services in a service container, click the icon for a service group, click the Related Tasks tab, click Show Member Services, and then click the service group name. To view additional details about the services click Open.
  - To view common properties of services in a service group, click the icon for the service group, click the Related Tasks tab, and view the Details section of the tab.
  - To view a comparative list of the parameters whose values either differ or are not defined across service containers, click the icon for a container, click the Related Tasks tab, and then click Service Attributes Diff. To view monitor binding details for the services in a container, in the Service Attributes Diff dialog box, in the Group column for the container, click Details.
  - To view the details for a monitor, position the cursor over the icon or click the icon for the monitor. For additional details, click the icon, click the Related Tasks tab, and then click View Monitor.
  - To view binding details of a monitor, click the connecting line between the monitor and its related service.

#### To view configuration details for policies and policy labels by using the Visualizer in the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.

3. In the Load Balancing Visualizer dialog box, to view configuration details for entities that are bound to this virtual server, you can do the following:
  - To view policies that are bound to this virtual server, select one or more policy icons in the tool bar at the top of the dialog box. For example, you can select Compression, Filter, Rewrite, and Responder. If policy labels are configured, they appear in the main view area.
  - For bound policies that appear in the view pane of the Visualizer, to view a policy's expression and actions, position the cursor over the policy icon. To view binding details, position the cursor over the line that connects the policy to the virtual server. To view these details, click the policy. The details of the policy appear in the details pane.

#### To view statistical information by using the Visualizer

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, to view statistical information, you can do the following:
  - To view detailed statistics for the load balancing virtual server, click the icon for the virtual server, click the Related Tasks tab, and then click Statistics.
  - To view the number of requests received per second at a given point in time by the load balancing virtual server and the number of hits per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time and has to be refreshed manually. To refresh this information, click Refresh Stats.

Note: The Show Stats option is available only on NetScaler nCore builds.

#### To save configuration properties for any entity by using the Visualizer

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. To copy configuration details for an element to a document or spreadsheet, click the icon for that element, click Related Tasks.
4. In the Related Tasks tab, click Copy Properties and then paste the information into a document.

#### To bind a resource to a load balancing configuration by using the Visualizer

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure bindings, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, click the Available Resources tab, select a resource type in the drop-down menu, and do one or more of the following:
  - To bind a new monitor to a service, select Monitors, click a particular monitor, and then drag it to the service container icon. Use CONTROL + click to select multiple monitors and drag them to the service.
  - To bind a service or service group, select Services or Service Groups, respectively, click a particular service or service group, and then drag it to the virtual server icon. To bind multiple services or service groups at one time, press CONTROL + click to select multiple services and drag them over the virtual server.
  - To bind a policy, select one of the policy groups, click a particular policy, and then drag it to a virtual server. To bind multiple policies (classic policies only) at one time, press CONTROL + policies and drag them over the virtual server. For details on classic and advanced policies, see [Policy Configuration and Reference](#).

#### To unbind a resource by using the Visualizer

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server from which you want to unbind a service, policy, or monitor, and then click

Visualizer.

3. In the Load Balancing Visualizer dialog box, on the Visualizer image, click the connecting line between the resources that you want to unbind, and then click Unbind. For example, to unbind a monitor, you would click the link between the monitor and its bound service and click Unbind.
4. In the Unbind dialog box, click Yes.

To modify a resource in a load balancing configuration by using the Visualizer

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, on the Visualizer image, double-click the resource that you want to modify.  
Note: Alternatively, on the Available Resources tab, select the resource type from the drop-down menu, select the particular resource that you want to configure and then click Open.
4. In the modify dialog box, enter new settings for the resource.

To add, remove, or disable a resource in a load balancing configuration by using the Visualizer

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, right-click the icon for the resource that you want to add, remove, or disable, and then select the corresponding option from the menu.  
Note: Alternatively, on the Available Resources tab, click the resource type from the drop-down menu, and then click Add to add an entity, or select the particular resource that you want to configure and then click Open.  
Note: These options are not available for service groups or policies.

# Managing Client Traffic

Jun 03, 2015

Managing client connections properly helps to ensure that your applications remain available to users even when your NetScaler appliance is experiencing high loads. A number of load balancing features and other features available on the appliance can be integrated into a load balancing setup to process load more efficiently, divert it when necessary, and prioritize the tasks that the appliance must perform:

- **Sessionless load balancing.** You can configure sessionless load balancing virtual servers and perform load balancing without creating sessions in configurations that use DSR or intrusion detection systems (IDS).
- **Integrated caching.** You can redirect HTTP requests to a cache.
- **Priority queuing.** You can direct requests based on priority, by integrating your configuration with the Priority Queuing feature.
- **SureConnect.** You can use load balancing with the SureConnect feature to redirect important requests to a custom Web page, insulating them from delays due to network congestion.
- **Delayed cleanup.** You can configure delayed cleanup of virtual server connections to prevent the cleanup process from using CPU cycles during periods when the NetScaler appliance is experiencing high loads.
- **Rewrite.** You can use the Rewrite feature to modify port and protocol when performing HTTP redirection, or insert the virtual server IP address and port into a custom Request header.
- **RTSP NAT.**
- **Rate-based monitoring.** You can enable rate-based monitoring to divert excess traffic.
- **Layer 2 Parameters.** You can configure a virtual server to use the L2 parameters to identify a connection.
- **ICMP Response.** You can configure the NetScaler to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR\_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, NetScaler responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds even if one virtual server set to ACTIVE is UP.

To manage client traffic, see the following sections:

- [Configuring Sessionless Load Balancing Virtual Servers](#)
- [Redirecting HTTP Requests to a Cache](#)
- [Directing Requests According to Priority](#)
- [Directing Requests to a Custom Web Page](#)
- [Enabling Cleanup of Virtual Server Connections](#)
- [Graceful Shut down of Services](#)
- [Rewriting Ports and Protocols for HTTP Redirection](#)
- [Inserting the IP Address and Port of a Virtual Server in the Request Header](#)
- [Using a Specified Source IP for Backend Communication](#)
- [Setting a Timeout Value for Idle Client Connections](#)
- [Managing RTSP Connections](#)
- [Managing Client Traffic on the Basis of Traffic Rate](#)
- [Identifying a connection with Layer 2 Parameters](#)

- [Configuring the Prefer Direct Route Option](#)

# Configuring Sessionless Load Balancing Virtual Servers

Nov 11, 2013

When the NetScaler appliance performs load balancing, it creates and maintains sessions between clients and servers. The maintenance of session information places a significant load on the NetScaler resources, and sessions might not be needed in scenarios such as a direct server return (DSR) setup and the load balancing of intrusion detection systems (IDS). To avoid creating sessions when they are not necessary, you can configure a virtual server on the appliance for sessionless load balancing. In sessionless load balancing, the appliance carries out load balancing on a per-packet basis.

Sessionless load balancing can operate in MAC-based forwarding mode or IP-based forwarding mode.

For MAC-based forwarding, the IP address of the sessionless virtual server must be specified on all the physical servers to which the traffic is forwarded.

For IP-based forwarding in sessionless load balancing, the IP address and port of the virtual server need not be specified on the physical servers, because this information is included in the forwarded packets. When forwarding a packet from the client to the physical server, the appliance leaves client details such as IP address and port unchanged and adds the IP address and port of the destination.

## Supported Setup

NetScaler sessionless load balancing supports the following service types and load balancing methods:

### Service Types

- ANY for MAC-based redirection
- ANY, DNS, and UDP for IP-based redirection

### Load Balancing Methods

- Round Robin
- Least Bandwidth
- LRTM (Least response time method)
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port Hash
- Custom Load

## Limitations

Sessionless load balancing has the following limitations:

- The NetScaler must be deployed in two-arm mode.
- A service must be bound to only one virtual server.
- Sessionless load balancing is not supported for service groups.
- Sessionless load balancing is not supported for domain based services (DBS services).
- Sessionless load balancing in the IP mode is not supported for a virtual server that is configured as a backup to a primary virtual server.
- You cannot enable spillover mode.

- For all the services bound to a sessionless load balancing virtual server, the Use Source IP (USIP) option must be enabled.
- For a wildcard virtual server or service, the destination IP address will not be changed.

Note: While configuring a virtual server for sessionless load balancing, explicitly specify a supported load balancing method. The default method, Least Connection, cannot be used for sessionless load balancing.

Note: To configure sessionless load balancing in MAC-based redirection mode on a virtual server, the MAC-based forwarding option must be enabled on the NetScaler.

To add a sessionless virtual server by using the command line interface

At the command prompt, type the following commands to add a sessionless virtual server and verify the configuration:

- add lb vserver <name>@ <serviceType> <IPAddress>@ <port> -m <redirectionMode> -sessionless <(ENABLED | DISABLED)> -lbMethod <load\_balancing\_method>
- show lb vserver <name>

### Example

```
add lb vserver sesslessv1 any 11.11.12.123 54 -sessionless ENABLED -lbMethod roundrobin -m ip
Done
show lb vserver sesslessv1
sesslessv1 (11.11.12.123:54) - ANY Type: ADDRESS
State: DOWN
...
Effective State: DOWN
Client Idle Timeout: 120 sec
Down state flush: ENABLED
...
Persistence: NONE
Sessionless LB: ENABLED
Connection Failover: DISABLED
L2Conn: OFF
1) Policy : cmp_text Priority:8680 Inherited
2) Policy : cmp_nocmp_ie60 Priority:8690 Inherited
```

## To configure sessionless load balancing on an existing virtual server

At the command prompt, type:

```
set lb vserver <name>@ -m <redirectionMode> -sessionless <(ENABLED | DISABLED)> -lbMethod <load_balancing_method>
```

Example

```
set lb vserver sesslessv1 -m mac -sessionless ENABLED -lbmethod lrtm
Done
```

### Note

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

To configure a sessionless virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open the virtual server, and in Advanced Settings, click Traffic Settings, and then select Sessionless Load Balancing.

# Redirecting HTTP Requests to a Cache

Nov 11, 2013

The NetScaler cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the impact of responding to HTTP requests and improve your Web site performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the NetScaler appliance sends cacheable HTTP requests to the cache, and non-cacheable HTTP requests to the origin Web server.

To configure cache redirection on a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -cacheable <Value>
```

## **Example**

```
set lb vserver Vserver-LB-1 -cacheable yes
```

To configure cache redirection on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Cacheable.

# Directing Requests According to Priority

Nov 11, 2013

The NetScaler appliance supports prioritization of client requests with its priority queuing feature. This feature allows you to designate certain requests, such as those from important clients, as priority requests and sends them to the “front of the line,” so that the appliance responds to them first. This allows you to provide uninterrupted service to those clients through demand surges or DDoS attacks on your Web site.

To configure priority queuing on a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -pq <Value>
```

## **Example**

```
set lb vserver Vserver-LB-1 -pq yes
```

To configure priority queuing on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Priority Queuing.

Note: You must configure priority queuing globally for it to function correctly.

# Directing Requests to a Custom Web Page

Nov 11, 2013

The NetScaler appliance provides the SureConnect option to ensure that web applications respond despite delays caused by limited server capacity or processing speed. SureConnect does this by displaying an alternative web page of your choice when the server that hosts the primary web page is either unavailable or responding slowly.

To configure SureConnect on a virtual server, you must first configure the alternative content. For information about configuring a SureConnect website, see [SureConnect](#). After you configure the website, enable SureConnect on the load balancing virtual server to put your SureConnect custom web page in use.

Note: For SureConnect to function correctly, you must configure it globally.

To enable SureConnect on a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -sc <Value>
```

## Example

```
set lb vserver Vserver-LB-1 -sc yes
```

To enable SureConnect on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server..
2. In Advanced Settings, click Traffic Settings, and select SureConnect.

# Enabling Cleanup of Virtual Server Connections

Nov 11, 2013

Under certain conditions, you can configure the `downStateFlush` setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes and health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN.

A virtual server is marked DOWN only when all services bound to it are marked DOWN. When a virtual server goes DOWN, it terminates all connections, either immediately or after allowing existing connections to complete.

You must not enable the `downStateFlush` setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, `Vserver-LB-1`, with two services bound to it, `Service-TCP-1` and `Service-TCP-2`. The virtual server intercepts two connections, `C1` and `C2`, and redirects them to `Service-TCP-1` and `Service-TCP-2`, respectively. In the table, E and D denote the state of the `downStateFlush` setting: E means Enabled, and D means Disabled.

| <b>Vserver-LB-1</b> | <b>Service-TCP-1</b> | <b>State of connections</b>                                                                                                                                                                                                                 |
|---------------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E                   | E                    | Both client and server connections are terminated.                                                                                                                                                                                          |
| E                   | D                    | Both client and server connections are terminated. In case of HTTP services, both client and server connections are terminated only if the transaction is active. If the transaction is not active, only client connections are terminated. |
| D                   | E                    | Both client and server connections are terminated. In case of HTTP services, both client and server connections are terminated only if the transaction is active. If the transaction is not active, only server connections are terminated. |
| D                   | D                    | Neither client nor server connections are terminated.                                                                                                                                                                                       |

Note: In case of HTTP services, the `downStateFlush` setting is effective only when the client is connected to the server. If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown of a service, see [Graceful Shutdown of Services](#).

To configure the down state flush setting on a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -downStateFlush <Value>
```

**Example**

```
set lb vserver Vserver-LB-1 -downStateFlush enabled
```

To configure the down state flush setting on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server..
2. In Advanced Settings, click Traffic Settings, and select Down State Flush.

# Graceful Shut down of Services

Feb 08, 2016

During scheduled network outages such as system upgrades or hardware maintenance, you may have to close or disable some services. To avoid disrupting sessions that have already been established, you can specify a wait time, which places a service in the transition out of service (TROFS) state until the specified wait time expires. The service then enters the out of service (OFS) state.

Often, however, you cannot estimate the amount of time needed for all the connections to a service to complete the existing transactions. If a transaction is unfinished when the wait time expires, shutting down the service may result in data loss. In this case, you can specify graceful shutdown for the service, so that the service is disabled only when all the current active client connections are closed by either the server or the client. See the following table for behavior if you specify a wait time in addition to graceful shutdown.

Persistence is maintained according to the specified method even if you enable graceful shutdown. The system continues to serve all the persistent clients, including new connections from the clients, unless the service is marked DOWN during the graceful shutdown state as a result of the checks made by a monitor.

The following table describes graceful shut down options.

**Table 1. Graceful Shut down Options**

| State                                                        | Results                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Graceful shutdown is enabled and a wait time is specified.   | Service is shut down after the last of the current active client connections is served, even if the wait time has not expired. The appliance checks the status of the connections once every second. If the wait time expires, any open sessions are closed. |
| Graceful shutdown is disabled and a wait time is specified.  | Service is shut down only after the wait time expires, even if all established connections are served before expiration.                                                                                                                                     |
| Graceful shutdown is enabled and no wait time is specified.  | Service is shut down only after the last of the previously established connections is served, regardless of the time taken to serve the last connection.                                                                                                     |
| Graceful shutdown is disabled and no wait time is specified. | No graceful shutdown. Service is shut down immediately after the disable option is chosen or the disable command is issued. (The default wait time is zero seconds.)                                                                                         |

To terminate existing connections when a service or a virtual server is marked DOWN, you can use the Down State Flush option. For more information, see [Enabling Cleanup of Virtual Server Connections](#).

To configure graceful shutdown for a service by using the command line interface

At the command prompt, type the following commands to shut down a service gracefully and verify the configuration:

- `disable service <name>@ [<delay>] [-graceFul (YES | NO)]`
- `show service <name>`

### Example

```
> disable service svc1 6000 -graceFul YES
Done
>show service svc1
svc1 (10.102.80.41:80) - HTTP
State: GOING OUT OF SERVICE (Graceful, Out Of Service in 5998 seconds)
Last state change was at Mon Nov 15 22:44:15 2010
Time since last state change: 0 days, 00:00:01.160
...
Down state flush: ENABLED
```

```
1 bound monitor:
1) Monitor Name: tcp-default
State: UP Weight: 1
Probes: 13898 Failed [Total: 0 Current: 0]
Last response: Probe skipped - live traffic to service.
Response Time: N/A
Done
```

```
>show service svc1
svc1 (10.102.80.41:80) - HTTP
State: OUT OF SERVICE
Last state change was at Mon Nov 15 22:44:19 2010
Time since last state change: 0 days, 00:00:03.250
Down state flush: ENABLED
```

```
1 bound monitor:
1) Monitor Name: tcp-default
State: UNKNOWN Weight: 1
Probes: 13898 Failed [Total: 0 Current: 0]
Last response: Probe skipped - service state OFS.
Response Time: N/A
Done
```

To configure graceful shutdown for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and from the Action list, click Disable. Enter a wait time, and select Graceful.

# Rewriting Ports and Protocols for HTTP Redirection

Nov 11, 2013

Virtual servers and the services that are bound to them may use different ports. When a service responds to an HTTP connection with a redirect, you might need to configure the NetScaler appliance to modify the port and the protocol to make sure that the redirection goes through successfully. You do this by enabling and configuring the `redirectPortRewrite` setting.

This setting affects only HTTP and HTTPS traffic. If this setting is enabled on a virtual server, the virtual server rewrites the port on redirects, replacing the port used by the service with the port used by the virtual server.

If the virtual server or service is of type SSL, you must enable SSL redirect on the virtual server or service. If both the virtual server and service are of type SSL, enable SSL redirect on the virtual server.

The `redirectPortRewrite` setting can be used in the following scenarios:

- The virtual server is of type HTTP and the services are of type SSL.
- The virtual server is of type SSL and the services are of type HTTP.
- The virtual server is of type HTTP and the services are of type HTTP.
- The virtual server is of type SSL and the services are of type SSL.

Scenario 1: The virtual server is of type HTTP and services are of type SSL. SSL redirect, and optionally port rewrite, is enabled on the service. If port rewrite is enabled, the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

| Redirect URL from the Server                                                            | Redirect URL sent to the Client      |
|-----------------------------------------------------------------------------------------|--------------------------------------|
| Only SSL redirect is enabled. The virtual server can be configured on any port.         |                                      |
| <code>http://domain.com/</code>                                                         | <code>http://domain.com/</code>      |
| <code>http://domain.com:8080/</code>                                                    | <code>http://domain.com:8080/</code> |
| <code>https://domain.com/</code>                                                        | <code>https://domain.com/</code>     |
| <code>https://domain.com:444/</code>                                                    | <code>https://domain.com:444/</code> |
| SSL redirect and port rewrite are enabled. The virtual server is configured on port 80. |                                      |
| <code>http://domain.com/</code>                                                         | <code>http://domain.com/</code>      |
| <code>http://domain.com:8080/</code>                                                    | <code>http://domain.com:8080/</code> |
| <code>https://domain.com/</code>                                                        | <code>https://domain.com/</code>     |

| <b>Redirect URL from the Server</b>                                                   | <b>Redirect URL sent to the Client</b> |
|---------------------------------------------------------------------------------------|----------------------------------------|
| https://domain.com:444/                                                               | https://domain.com/                    |
| SSL redirect and port rewrite are enabled. Virtual server is configured on port 8080. |                                        |
| http://domain.com/                                                                    | http://domain.com/                     |
| http://domain.com:8080/                                                               | http://domain.com:8080/                |
| https://domain.com/                                                                   | http://domain.com:8080/                |
| https://domain.com:444/                                                               | http://domain.com:8080/                |

Scenario 2: The virtual server is of type SSL and services are of type HTTP. If port rewrite is enabled, only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

| <b>Redirect URL from the Server</b>                                                                            | <b>Redirect URL sent to the Client</b> |
|----------------------------------------------------------------------------------------------------------------|----------------------------------------|
| SSL redirect is enabled on the virtual server. The virtual server can be configured on any port.               |                                        |
| http://domain.com/                                                                                             | https://domain.com/                    |
| http://domain.com:8080/                                                                                        | https://domain.com:8080/               |
| https://domain.com/                                                                                            | https://domain.com/                    |
| https://domain.com:444/                                                                                        | https://domain.com:444/                |
| SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443. |                                        |
| http://domain.com/                                                                                             | https://domain.com/                    |
| http://domain.com:8080/                                                                                        | https://domain.com/                    |
| https://domain.com/                                                                                            | https://domain.com/                    |
| https://domain.com:444/                                                                                        | https://domain.com:444/                |
| SSL redirect and port rewrite are enabled. The virtual server is configured on port 444.                       |                                        |

| <b>Redirect URL from the Server</b> | <b>Redirect URL sent to the Client</b> |
|-------------------------------------|----------------------------------------|
| http://domain.com/                  | https://domain.com:444/                |
| http://domain.com:8080/             | https://domain.com:444/                |
| https://domain.com/                 | https://domain.com/                    |
| https://domain.com:445/             | https://domain.com:445/                |

Scenario 3: The virtual server and service are of type HTTP. Port rewrite must be enabled on the virtual server. Only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

| <b>Redirect URL from the Server</b>            | <b>Redirect URL sent to the Client</b> |
|------------------------------------------------|----------------------------------------|
| The virtual server is configured on port 80.   |                                        |
| http://domain.com/                             | http://domain.com/                     |
| http://domain.com:8080/                        | http://domain.com/                     |
| https://domain.com/                            | https://domain.com/                    |
| https://domain.com:444/                        | https://domain.com:444/                |
| The virtual server is configured on port 8080. |                                        |
| http://domain.com/                             | http://domain.com:8080/                |
| http://domain.com:8080/                        | http://domain.com:8080/                |
| https://domain.com/                            | https://domain.com/                    |
| https://domain.com:445/                        | https://domain.com:445/                |

Scenario 4: The virtual server and service are of type SSL. If port rewrite is enabled, only the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

| <b>Redirect URL from the Server</b>                                                              | <b>Redirect URL sent to the Client</b> |
|--------------------------------------------------------------------------------------------------|----------------------------------------|
| SSL redirect is enabled on the virtual server. The virtual server can be configured on any port. |                                        |

| Redirect URL from the Server                                                                                   | Redirect URL sent to the Client |
|----------------------------------------------------------------------------------------------------------------|---------------------------------|
| http://domain.com/                                                                                             | http://domain.com/              |
| http://domain.com:8080/                                                                                        | http://domain.com:8080/         |
| https://domain.com/                                                                                            | https://domain.com/             |
| https://domain.com:444/                                                                                        | https://domain.com:444/         |
| SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443. |                                 |
| http://domain.com/                                                                                             | http://domain.com/              |
| http://domain.com:8080/                                                                                        | http://domain.com:8080/         |
| https://domain.com/                                                                                            | https://domain.com/             |
| https://domain.com:444/                                                                                        | https://domain.com/             |
| SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 444. |                                 |
| http://domain.com/                                                                                             | http://domain.com/              |
| http://domain.com:8080/                                                                                        | http://domain.com:8080/         |
| https://domain.com/                                                                                            | https://domain.com:444/         |
| https://domain.com:445/                                                                                        | https://domain.com:444/         |

To configure HTTP redirection on a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -redirectPortRewrite (ENABLED | DISABLED)
```

**Example**

```
set lb vserver Vserver-LB-1 -redirectPortRewrite enabled
```

To configure HTTP redirection on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open the virtual server, and in the Advanced Settings pane, click Traffic Settings, and then select Rewrite.

To configure SSL Redirect on an SSL virtual server or service by using the command line interface

At the command prompt, type:

- set ssl vserver <vServerName> - sslRedirect (ENABLED | DISABLED)
- set ssl service <serviceName> - sslRedirect (ENABLED | DISABLED)

### Example

```
set ssl vserver Vserver-SSL-1 -sslRedirect enabled
```

```
set ssl service service-SSL-1 -sslRedirect enabled
```

To configure SSL redirection and SSL port rewrite on an SSL virtual server or service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click SSL Parameters, and select SSL Redirect.

# Inserting the IP Address and Port of a Virtual Server in the Request Header

Nov 11, 2013

If you have multiple virtual servers that communicate with different applications on the same service, you must configure the NetScaler appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, then you must configure the required header tag on both virtual servers.

Note: This option is not supported for wild card virtual servers or dummy virtual servers.

To insert the IP address and port of the virtual server in the client requests by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -insertVserverIPPort <insertVserverIPPort> [<vipHeader>]
```

## Example

```
set lb vserver Vserver-LB-1 -insertVserverIPPort VipAddr
```

To insert the IP address and port of the virtual server in the client requests by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open the virtual server, and in the Advanced Settings pane, click Traffic Settings, and then select Virtual Server IP Port Insertion and specify a virtual server IP port header.

# Using a Specified Source IP for Backend Communication

Jun 17, 2014

For communication with the physical servers or other peer devices, the NetScaler appliance uses an IP address owned by it as the source IP address. NetScaler maintains a pool of its IP addresses, and dynamically selects an IP address while connecting with a server. Depending on the subnet in which the physical server is placed, NetScaler decides which IP address to use. This address pool is used for sending traffic as well as monitor probes.

In many situations, you may want the NetScaler to use a specific IP address or any IP address from a specific set of IP addresses for backend communications. The following are a few examples:

- A server can distinguish monitor probes from traffic if the source IP address used for monitor probes belongs to a specific set.
- To improve server security, a server may be configured to respond to requests from a specific set of IP addresses or, sometimes, from a single specific IP address. In such a case, the NetScaler can use only the IP addresses accepted by the server as the source IP address.
- The NetScaler can manage its internal connections efficiently if it can distribute its IP addresses into IP sets and use an address from a set only for connecting to a specific service.

To configure the NetScaler to use a specified source IP address, create net profiles (network profiles) and configure the NetScaler entities to use the profile. A net profile can be bound to load balancing or content switching virtual servers, services, service groups, or monitors. A net profile has NetScaler owned IP addresses (SNIPs and VIPs) that can be used as the source IP address. It can be a single IP address or a set of IP addresses, referred to as an IP set. If a net profile has an IP set, NetScaler dynamically selects an IP address from the IP set at the time of connection. If a profile has a single IP address, the same IP address is used as the source IP.

If a net profile is bound to a load balancing or content switching virtual server, the profile will be used for sending traffic to all the services bound to it. If a net profile is bound to a service group, NetScaler uses the profile for all the members of the service group. If a net profile is bound to a monitor, NetScaler uses the profile for all the probes sent from the monitor. Note: When a NetScaler appliance uses a VIP address to communicate with a server, it uses session entries to identify whether the traffic destined to the VIP address is a response from a server or a request from a client.

## **Usage of a net profile for sending traffic:**

If the Use Source IP Address (USIP) option is enabled, NetScaler uses the IP address of the client and ignores all the net profiles. If the USIP option is not enabled, NetScaler selects the source IP in the following manner:

- If there is no net profile on the virtual server or the service/service group, NetScaler uses the default method.
- If there is a net profile only on the service/service group, NetScaler uses that net profile.
- If there is a net profile only on the virtual server, NetScaler uses the net profile.
- If there is a net profile both on the virtual server and service/service group, NetScaler uses the net profile bound to the service/service group.

## **Usage of a net profile for sending monitor probes:**

For monitor probes, NetScaler selects the source IP in the following manner:

- If there is a net profile bound to the monitor, NetScaler uses the net profile of the monitor. It ignores the net profiles

bound to the virtual server or service/service group.

- If there is no net profile bound to the monitor,
  - If there is a net profile on the service/service group, NetScaler uses the net profile of the service/service group.
  - If there is no net profile even on the service/service group, NetScaler uses the default method of selecting a source IP.

Note: If there is no net profile bound to a service, NetScaler looks for a net profile on the service group if the service is bound to a service group.

To use a specified source IP address for communication, go through the following steps:

1. Create IP sets from the pool of SNIPs and VIPs owned by the NetScaler. An IP set can consist of both SNIP and VIP addresses. For instructions, see [Creating IP Sets](#).
2. Create net profiles. For instructions, see [Creating a Net Profile](#).
3. Bind the net profiles to NetScaler entities. For instructions, see [Binding a Net Profile to a NetScaler Entity](#).

Note: A net profile can have only the IP addresses specified as SNIP and VIP on the NetScaler.

## Managing Net Profiles

A net profile (or network profile) contains an IP address or an IP set. During communication with physical servers or peers, the NetScaler appliance uses the addresses specified in the profile as the source IP address. For more information on the use of net profiles, see [Using a User-specified Source IP Address for Backend Communication](#).

- For instructions on creating a network profile, see [Creating a Network Profile](#).
- For instructions on binding a network profile to a NetScaler entity, see [Binding a Network Profile](#).

## Creating an IP Set

Updated: 2014-06-17

An IP set is a set of IP addresses, which are configured on the NetScaler appliance as Subnet IP addresses (SNIPs) or Virtual IP addresses (VIPs). An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it. To create an IP set, add an IP set and bind NetScaler owned IP addresses to it. SNIP addresses and VIP addresses can be present in the same IP set. For more information about the use of IP sets, see [Using a User-specified Source IP Address for Backend Communication](#).

## To create an IP set by using the command line interface

At the command prompt, type the following commands:

- `add ipset <name>`
- `bind ipset <name> <IPAddress>@`  
or
- `bind ipset <name> <IPAddress>@`
- `show ipset [<name>]`

The above command shows the names of all the IP sets on the NetScaler if you do not pass any name. It shows the IP addresses bound to the specified IP set if you pass a name.

### Examples

1.  
> `add ipset skpnwipset`

```
Done
> bind ipset skpnwipset 21.21.20.1
Done
```

## 2.

```
> add ipset testnwipset
Done
> bind ipset testnwipset 21.21.21.[21-25]
IPAddress "21.21.21.21" bound
IPAddress "21.21.21.22" bound
IPAddress "21.21.21.23" bound
IPAddress "21.21.21.24" bound
IPAddress "21.21.21.25" bound
Done
```

## 3.

```
> bind ipset skipipset 11.11.11.101
ERROR: Invalid IP address
[This IP address could not be added because this is not an IP address owned by the NetScaler]
> add ns ip 11.11.11.101 255.255.255.0 -type SNIP
ip "11.11.11.101" added
Done
> bind ipset skipipset 11.11.11.101
IPAddress "11.11.11.101" bound
Done
```

## 4.

```
> sh ipset
1) Name: ipset-1
2) Name: ipset-2
3) Name: ipset-3
4) Name: skpnewipset
Done
```

## 5.

```
> sh ipset skpnewipset
IP:21.21.21.21
IP:21.21.21.22
IP:21.21.21.23
IP:21.21.21.24
IP:21.21.21.25
Done
```

## To create an IP set by using the configuration utility

Navigate to System > Network > IP Sets, and create an IP set.

### Creating a Net Profile

Updated: 2014-06-17

A net profile (network profile) consists of one or more SNIP or VIP addresses of the NetScaler. For more information about the usage of net profiles, see [Using a User-specified Source IP Address for Backend Communication](#).

## To create a net profile by using the command line interface

At the command prompt, type:

`add netprofile <name> [-srclp <srclpVal>]` If the `srclpVal` is not provided in this command, it can be provided later by using the `set netprofile` command.

Examples

```
> add netprofile skpnetprofile1 -srclp 21.21.20.1
Done
```

```
> add netprofile baksnp -srclp bakipset
Done
```

```
> set netprofile yahnp -srclp 12.12.23.1
Done
```

```
> set netprofile citkbnp -srclp citkbipset
Done
```

### Binding a Net Profile to a NetScaler Entity

Updated: 2013-11-12

A net profile can be bound to a load balancing virtual server, service, service group, or a monitor. For more information about the effect of binding a net profile to a NetScaler entity, see [Using a User-specified Source IP Address for Backend Communication](#).

Note: You can bind a net profile at the time of creating a NetScaler entity or bind it to an already existing entity.

## To bind a net profile to a server by using the command line interface

You can bind a net profile to load balancing virtual servers and content switching virtual servers. Specify the appropriate virtual server.

At the command prompt, type:

- `set lb vserver <name>@ -netProfile <net_profile_name>`  
or
- `set cs vserver <name> -netProfile <net_profile_name>`

Examples

```
set lb vserver skpnwvs1 -netProfile gntnp
Done
set cs vserver mmdcsv -netProfile mmdnp
Done
```

## To bind a net profile to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.

2. In Advanced Settings, click Profiles, and set a net profile.

## To bind a net profile to a service by using the command line interface

At the command prompt, type:

```
set service <name>@ -netProfile <net_profile_name>
```

Example

```
set service brnssvc1 -netProfile brnsnp
```

Done

## To bind a net profile to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, click Profiles, and set a net profile.

## To bind a net profile to a service group by using the command line interface

At the command prompt, type:

```
set servicegroup <serviceGroupName>@ -netProfile <net_profile_name>
```

Example

```
set servicegroup ndhsvcgrp -netProfile ndhnp
```

Done

## To bind a net profile to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups, and open a service group.
2. In Advanced Settings, click Profiles, and set a net profile.

## To bind a net profile to a monitor by using the command line interface

At the command prompt, type:

```
set monitor <monitor_name> -netProfile <net_profile_name>
```

Example

```
set monitor brnsecvmon1 -netProfile brnsmonnp
```

Done

## To bind a net profile to a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Open a monitor, and set the net profile.

# Setting a Timeout Value for Idle Client Connections

Nov 04, 2016

You can configure a virtual server to terminate any idle client connections after a configured timeout period (in seconds) elapses. When you configure this setting, the NetScaler appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection.

To set a time-out value for idle client connections by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -cltTimeout <Value>
```

## **Example**

```
set lb vserver Vserver-LB-1 -cltTimeout 100
```

To set a time-out value for idle client connections by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, click Traffic Settings, and set the client idle time-out value in seconds.

# Managing RTSP Connections

Nov 11, 2013

The NetScaler appliance can use either of two topologies—NAT-on mode or NAT-off mode—to load balance RTSP servers. In NAT-on mode, Network Address Translation (NAT) is enabled and configured on the appliance. RTSP requests and responses both pass through the appliance. You must therefore configure the appliance to perform network address translation (NAT) to identify the data connection.

For more information about enabling and configuring NAT, see "[IP Addressing](#)."

In NAT-off mode, NAT is not enabled and configured. The appliance receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. The load balanced RTSP servers send their responses directly to the client, bypassing the appliance. You must therefore configure the appliance to use Direct Server Return (DSR) mode, and assign publicly accessible FQDNs in DNS to your load balanced RTSP servers.

For more information about enabling and configuring DSR mode, see "[Configuring Load Balancing in Direct Server Return Mode](#)." For more information about configuring DNS, see "[Domain Name System](#)."

In either case, when you configure RTSP load balancing, you must also configure `rtspNat` to match the topology of your load balancing setup.

To configure RTSP NAT by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@-RTSPNAT <ValueOfRTSPNAT>
```

## Example

```
set lb vserver vserver-LB-1 -RTSPNAT ON
```

To configure RTSP NAT by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server of type RTSP.
2. In Advanced Settings, click Traffic Settings, and select RTSP Natting.

# Managing Client Traffic on the Basis of Traffic Rate

Sep 30, 2015

You can monitor the rate of traffic that flows through load balancing virtual servers and control the behavior of the NetScaler appliance based on the traffic rate. You can throttle the traffic flow if it is too high, cache information based on the traffic rate, and if the traffic rate is too high redirect excess traffic to a different load balancing virtual server. You can apply rate-based monitoring to HTTP and Domain Name System (DNS) requests.

For more information on rate-based policies, see [Rate Limiting](#).

# Identifying a connection with Layer 2 Parameters

Nov 12, 2013

Generally, to identify a connection, the NetScaler uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.

Enabling the L2Conn parameter for a load balancing virtual server allows multiple TCP and non-TCP connections with the same 4-tuple (<source IP>:<source port>:<destination IP>:<destination port>) to co-exist on the NetScaler appliance. The appliance uses both the 4-tuple and the Layer 2 parameters to identify TCP and non-TCP connections.

You can enable the L2Conn option in the following scenarios:

- Multiple VLANs are configured on the NetScaler appliance, and a firewall is set up for each VLAN.
- You want the traffic originating from the servers in one VLAN and bound for a virtual server in another VLAN to pass through the firewalls configured for both VLANs.

Therefore, when an nCore NetScaler appliance on which the l2Conn parameter is set for one or more load balancing virtual servers is downgraded to a Classic build or to an nCore build that does not support the l2Conn parameter, the load balancing configurations that use the l2Conn parameter become ineffective.

To configure the L2 connection option by using the command line interface

At the command prompt, type:

```
add lb vserver <name>@ <serviceType> <IPAddress>@ <port> -l2Conn ON
```

## Example

```
add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -l2Conn ON
```

To configure the L2 connection option by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Layer 2 Parameters.

# Configuring the Prefer Direct Route Option

Aug 29, 2013

On a wildcard load balancing virtual server if you explicitly configure a route to a destination, by default, the NetScaler appliance forwards traffic according to the configured route. If you want the NetScaler to not look up for the configured route, you can set the Prefer Direct Route option to NO.

If a device is directly connected to a NetScaler appliance, the NetScaler directly forwards traffic to the device. For example, if the destination of a packet is a firewall, the packet need not be routed through another firewall. However, in some cases, you may want the traffic to go through the firewall even if the device is directly connected to it. In such cases, you can set the Prefer Direct Route Option to NO.

Note: The preferDirectRoute setting is applicable to all the wildcard virtual servers on the NetScaler appliance. To set the prefer direct route option by using the command line interface

At the command prompt, type:

```
set lb parameter -preferDirectRoute (YES | NO)
```

## Example

```
set lb parameter -preferDirectRoute YES
```

To set the prefer direct route option by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing parameters.
2. Select Prefer Direct Route.

# Advanced Load Balancing Settings

Jun 03, 2015

In addition to configuring virtual servers, you can configure advanced settings for services.

To configure advanced load balancing settings, see the following sections:

- [Gradually Stepping Up the Load on a New Service with Virtual Server–Level Slow Start](#)
- [The No-Monitor Option for Services](#)
- [Protecting Applications on Protected Servers Against Traffic Surges](#)
- [Enabling Cleanup of Service Connections](#)
- [Directing Requests to a Custom Web Page](#)
- [Enabling Access to Services When Down](#)
- [Enabling TCP Buffering of Responses](#)
- [Enabling Compression](#)
- [Maintaining Client Connection for Multiple Client Requests](#)

# Gradually Stepping Up the Load on a New Service with Virtual Server–Level Slow Start

Mar 16, 2012

You can configure the NetScaler appliance to gradually increase the load on a service (the number of requests that the service receives per second) immediately after the service is either added to a load balancing configuration or has a state change from DOWN to UP (hereafter, the term “new service” is used for both situations). You can either increase the load manually with load values and intervals of your choice (manual slow start) or configure the appliance to increase the load at a specified interval (automated slow start) until the service is receiving as many requests as the other services in the configuration. During the ramp-up period for the new service, the appliance uses the configured load balancing method.

This functionality is not available globally. It has to be configured for each virtual server. The functionality is available only for virtual servers that use one of the following load balancing methods:

- Round robin
- Least connection
- Least response time
- Least bandwidth
- Least packets
- LRTM (Least Response Time Method)
- Custom load

For this functionality, you need to set the following parameters:

- The new service request rate, which is the amount by which to increase the number or percentage of requests sent to a new service each time the rate is incremented. That is, you specify the size of the increment in terms of either the number of requests per second or the percentage of the load being borne, at the time, by the existing services. If this value is set to 0 (zero), slow start is not performed on new services.

Note: In automated slow start mode, the final increment is smaller than the specified value if the specified value would place a heavier load on the new service than on the other services.

- The increment interval, in seconds. If this value is set to 0 (zero), the load is not incremented automatically. You have to increment it manually.

With automated slow start, a service is taken out of the slow start phase when one of the following conditions applies:

- The actual request rate is less than the new service request rate.
- The service does not receive traffic for three successive increment intervals.
- The request rate has been incremented 200 times.
- The percentage of traffic that the new service must receive is greater than or equal to 100.

With manual slow start, the service remains in the slow start phase until you take it out of that phase.

## Manual Slow Start

If you want to manually increase the load on a new service, do not specify an increment interval for the load balancing virtual server. Specify only the new service request rate and the units. With no interval specified, the appliance does not increment the load periodically. It maintains the load on the new service at the value specified by the combination of the new service request rate and units until you manually modify either parameter. For example, if you set the new service request rate and unit parameters to 25 and “per second,” respectively, the appliance maintains the load on the new service at 25 requests per second until you change either parameter. When you want the new service to exit the slow start mode

and receive as many requests as the existing services, set the new service request rate parameter to 0.

As an example, assume that you are using a virtual server to load balance 2 services, Service1 and Service2, in round robin mode. Further assume that the virtual server is receiving 240 requests per second, and that it is distributing the load evenly across the services. When a new service, Service3, is added to the configuration, you might want to increase the load on it manually through values of 10, 20, and 40 requests per second before sending it its full share of the load. The following table shows the values to which you set the three parameters.

**Table 1. Parameter Values**

| Parameter                              | Value                                           |
|----------------------------------------|-------------------------------------------------|
| Interval in seconds                    | 0                                               |
| New service request rate               | 10, 20, 40, and 0, at intervals that you choose |
| Units for the new service request rate | Requests per second                             |

When you set the new service request rate parameter to 0, Service3 is no longer considered a new service, and receives its full share of the load.

Assume that you add another service, Service4, during the ramp-up period for Service3. In this example, Service4 is added when the new service request rate parameter is set to 40. Therefore, Service4 begins receiving 40 requests per second.

The following table shows the load distribution on the services during the period described in this example.

**Table 2. Load Distribution on Services when Manually Stepping Up the Load**

|                                            | new service request rate = 10 req/sec<br>(Service3added) | new service request rate = 20 req/sec | new service request rate = 40 req/sec<br>(Service4added) | new service request rate = 0 req/sec<br>(new services exit slow start mode) |
|--------------------------------------------|----------------------------------------------------------|---------------------------------------|----------------------------------------------------------|-----------------------------------------------------------------------------|
| Service1                                   | 115                                                      | 110                                   | 80                                                       | 60                                                                          |
| Service2                                   | 115                                                      | 110                                   | 80                                                       | 60                                                                          |
| Service3                                   | 10                                                       | 20                                    | 40                                                       | 60                                                                          |
| Service4                                   | -                                                        | -                                     | 40                                                       | 60                                                                          |
| Total req/sec (load on the virtual server) | 240                                                      | 240                                   | 240                                                      | 240                                                                         |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                               |                                              |                                                               |                                                                                 |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|----------------------------------------------|---------------------------------------------------------------|---------------------------------------------------------------------------------|
| Automated Slow Start                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | <b>new service request rate = 10 req/sec (Service3 added)</b> | <b>new service request rate = 20 req/sec</b> | <b>new service request rate = 40 req/sec (Service4 added)</b> | <b>new service request rate = 0 req/sec (new services exit slow start mode)</b> |
| If you want the appliance to increase the load on a new service automatically at specified intervals until the service can be considered capable of handling its full share of the load, set the new service request rate parameter, the units parameter, and the increment interval. When all the parameters are set to values other than 0, the appliance increments the load on a new service by the value of the new service request rate, at the specified interval, until the service is receiving its full share of the load. |                                                               |                                              |                                                               |                                                                                 |

As an example, assume that four services, Service1, Service2, Service3, and Service4, are bound to a load balancing virtual server, vserver1. Further assume that vserver1 receives 100 requests per second, and that it distributes the load evenly across the services (25 requests per second per service). When you add a fifth service, Service5, to the configuration, you might want the appliance to send the new service 4 requests per second for the first 10 seconds, 8 requests per second for the next 10 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters:

**Table 3. Parameter Values**

| Parameter                              | Value               |
|----------------------------------------|---------------------|
| Interval in seconds                    | 10                  |
| Increment value                        | 4                   |
| Units for the new service request rate | Requests per second |

With this configuration, the new service begins receiving as many requests as the existing services 50 seconds after it is added or its state has changed from DOWN to UP. During each interval in this period, the appliance distributes to the existing servers the excess of requests that would have been sent to the new service in the absence of stepwise increments. For example, in the absence of stepwise increments, each service, including Service5, would have received 20 requests each per second. With stepwise increments, during the first 10 seconds, when Service5 receives only 4 requests per second, the appliance distributes the excess of 16 requests per second to the existing services, resulting in the distribution pattern shown in the following table and figure over the 50-second period. After the 50-second period, Service5 is no longer considered a new service, and it receives its normal share of traffic.

**Table 4. Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added**

|                            | 0 sec | 10 sec | 20 sec | 30 sec | 40 sec | 50 sec |
|----------------------------|-------|--------|--------|--------|--------|--------|
| <b>Req/sec forService1</b> | 25    | 24     | 23     | 22     | 21     | 20     |
| <b>Req/sec forService2</b> | 25    | 24     | 23     | 22     | 21     | 20     |
| <b>Req/sec forService3</b> | 25    | 24     | 23     | 22     | 21     | 20     |

|                                                   |                        |                         |                         |                         |                         |                         |
|---------------------------------------------------|------------------------|-------------------------|-------------------------|-------------------------|-------------------------|-------------------------|
| <b>Req/sec forService4</b>                        | <sup>25</sup><br>0 sec | <sup>24</sup><br>10 sec | <sup>23</sup><br>20 sec | <sup>22</sup><br>30 sec | <sup>21</sup><br>40 sec | <sup>20</sup><br>50 sec |
| <b>Req/sec forService5</b>                        | 0                      | 4                       | 8                       | 12                      | 16                      | 20                      |
| <b>Total req/sec (load on the virtual server)</b> | 100                    | 100                     | 100                     | 100                     | 100                     | 100                     |

Figure 1. A Graph of the Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added

An alternative requirement might be for the appliance to send Service5 25% of the load on the existing services in the first 5 seconds, 50% in the next 5 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters.

**Table 5. Parameter Values**

| Parameter                              | Value   |
|----------------------------------------|---------|
| Interval in seconds                    | 5       |
| Increment value                        | 25      |
| Units for the new service request rate | Percent |

With this configuration, the service begins receiving as many requests as the existing services 20 seconds after it is added or its state has changed from DOWN to UP. The traffic distribution during the ramp-up period for the new service is identical to the one described earlier, where the unit for the step increments was “requests per second.”

### Setting the Slow Start Parameters

Updated: 2013-12-04

You set the slow start parameters by using either the `set lb vserver` or the `add lb vserver` command. The following command is for setting slow start parameters when adding a virtual server.

To configure stepwise load increments for a new service by using the command

## line interface

At the command prompt, type the following commands to configure stepwise increments in the load for a service and verify the configuration:

- add lb vserver <name> <serviceType> <IPAddress> <port> [-newServiceRequest <positive\_integer>] [<newServiceRequestUnit>] [-newServiceRequestIncrementInterval <positive\_integer>]
- show lb vserver <name>

Example

```
> set lb vserver BR_LB -newServiceRequest 5 PER_SECOND -newServiceRequestIncrementInterval 10
Done
> show lb vserver BR_LB
BR_LB (192.0.2.33:80) - HTTP Type: ADDRESS
State: UP
...
...
New Service Startup Request Rate: 5 PER_SECOND, Increment Interval: 10
...
...
Done
>
```

## To configure stepwise load increments for a new service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Method, and set the following slow start parameters:
  - New Service Startup Request Rate.
  - New Service Request Unit.
  - Increment Interval.

# The No-Monitor Option for Services

Nov 11, 2013

If you use an external system to perform health checks on the services and do not want the NetScaler appliance to monitor the health of a service, you can set the no-monitor option for the service. If you do so, the appliance does not send probes to check the health of the service but shows the service as UP. Even if the service goes DOWN, the appliance continues to send traffic from the client to the service as specified by the load balancing method.

The monitor can be in the ENABLED or DISABLED state when you set the no-monitor option, and when you remove the no-monitor option, the earlier state of the monitor is resumed.

You can set the no-monitor option for a service when creating the service. You can also set the no-monitor option on an existing service.

The following are the consequences of setting the no-monitor option:

- If a service for which you enabled the no-monitor option goes down, the NetScaler continues to show the service as UP and continues to forward traffic to the service. A persistent connection to the service can worsen the situation. In that case, or if many services shown as UP are actually DOWN, the system may fail. To avoid such a situation, when the external mechanism that monitors the services reports that a service that is DOWN, remove the service from the NetScaler configuration.
- If you configure the no-monitor option on a service, you cannot configure load balancing in the Direct Server Return (DSR) mode. For an existing service, if you set the no-monitor option, you cannot configure the DSR mode for the service.

To set the no-monitor option for a new service by using the command line interface

At the command prompt, type the following commands to create a service with the health monitor option, and verify the configuration:

```
add service <serviceName> <IP | serverName> <serviceType> <port> -healthMonitor (YES | NO)
```

## Example

```
>add service nomonsvc 10.102.21.21 http 80
-healthMonitor no
Done
> show service nomonsvc
nomonsvc (10.102.21.21:80) - HTTP
State: UP
Last state change was at Mon Nov 15 22:41:29 2010
Time since last state change: 0 days, 00:00:00.970
Server Name: 10.102.21.21
Server ID : 0 Monitor Threshold : 0
...
Access Down Service: NO
...
Down state flush: ENABLED
Health monitoring: OFF
```

1 bound monitor:

1) Monitor Name: tcp-default

State: UNKNOWN Weight: 1

Probes: 3 Failed [Total: 3 Current: 3]

Last response: Probe skipped - Health monitoring is turned off.

Response Time: N/A

Done

To set the no-monitor option for an existing service by using the command line interface

At the command prompt, type the following command to set the health monitor option:

```
set service <name> -healthMonitor (YES | NO)
```

### Example

By default, the state of a service and the state of the corresponding monitor are UP.

```
>show service LB-SVC1
```

LB-SVC1 (10.102.29.5:80) - HTTP

State: UP

1) Monitor Name: http-ecv

State: UP Weight: 1

Probes: 99992 Failed [Total: 0 Current: 0]

Last response: Success - Pattern found in response.

Response Time: 3.76 millisec

Done

When the no-monitor option is set on a service, the state of the monitor changes to UNKNOWN.

```
> set service LB-SVC1 -healthMonitor NO
```

Done

```
> show service LB-SVC1
```

LB-SVC1 (10.102.29.5:80) - HTTP

State: UP

Last state change was at Fri Dec 10 10:17:37 2010.

Time since last state change: 5 days, 18:55:48.710

Health monitoring: OFF

1) Monitor Name: http-ecv

State: UNKNOWN Weight: 1

Probes: 100028 Failed [Total: 0 Current: 0]

Last response: Probe skipped - Health monitoring is turned off.

Response Time: 0.0 millisec

Done

When the no-monitor option is removed, the earlier state of the monitor is resumed.

```
> set service LB-SVC1 -healthMonitor YES
```

Done

```
>show service LB-SVC1
```

LB-SVC1 (10.102.29.5:80) - HTTP

State: UP

Last state change was at Fri Dec 10 10:17:37 2010

Time since last state change: 5 days, 18:57:47.880

1) Monitor Name: http-ecv

State: UP Weight: 1

Probes: 100029 Failed [Total: 0 Current: 0]

Last response: Success - Pattern found in response.

Response Time: 5.690 millisec

Done

To set the no-monitor option for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and clear Health Monitoring.

# Protecting Applications on Protected Servers Against Traffic Surges

Jun 08, 2015

The NetScaler provides the surge protection option to maintain the capacity of a server or cache. The NetScaler regulates the flow of client requests to servers and controls the number of clients that can simultaneously access the servers. The NetScaler blocks any surges passed to the server, thereby preventing overloading of the server.

For surge protection to function correctly, you must enable it globally. For more information about surge protection, see "[Surge Protection](#)."

To set surge protection on the service by using the command line interface

At the command prompt, type:

```
set service <name>@ -sp <Value>
```

## **Example**

```
set service Service-HTTP-1 -sp ON
```

To set surge protection on the service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a source.
2. In Advanced Settings, select Traffic Settings, and select Surge Protection.

# Enabling Cleanup of Service Connections

Nov 25, 2013

When cleanup of service connections is enabled, the NetScaler performs a cleanup of the connections on a service that is down. This setting is described in [Enabling Cleanup of Virtual Server Connections](#).

To set down state flush on the service by using the command line interface

At the command prompt, type:

```
set service <name> -downStateFlush <Value>
```

## **Example**

```
set service Service-HTTP-1 -downStateFlush enabled
```

To set down state flush on the service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Down State Flush.

# Directing Requests to a Custom Web Page

Jun 08, 2015

For SureConnect to function correctly, you must set it globally. The NetScaler provides the SureConnect option to ensure the response from an application. For more information about the SureConnect option, see "[Sure Connect](#)."

To set SureConnect on the service by using the command line interface

At the command prompt, type:

```
set service <name>@ -sc <Value>
```

## **Example**

```
set service Service-HTTP-1 -sc ON
```

To set SureConnect on the service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Sure Connect.

# Enabling Access to Services When Down

Jun 08, 2015

You can enable access to a service when it is disabled or in a DOWN state by configuring the NetScaler appliance to use Layer 2 mode to bridge the packets sent to the service. Normally, when requests are forwarded to services that are DOWN, the request packets are dropped. When you enable the Access Down setting, however, these request packets are sent directly to the load balanced servers.

For more information about Layer 2 and Layer 3 modes, see [IP Addressing](#).

For the appliance to bridge packets sent to the DOWN services, enable Layer 2 mode with the accessDown parameter.

To enable access down on a service by using the command line interface

At the command prompt, type:

```
set service <name>@ -accessDown <Value>
```

## **Example**

```
set service Service-HTTP-1 -accessDown YES
```

To enable access down on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Access Down.

# Enabling TCP Buffering of Responses

Jun 08, 2015

The NetScaler appliance provides a TCP buffering option that buffers only responses from the load balanced server. This enables the appliance to deliver server responses to the client at the maximum speed that the client can accept them. The appliance allocates from 0 through 4095 megabytes (MB) of memory for TCP buffering, and from 4 through 20480 kilobytes (KB) of memory per connection.

Note: TCP buffering set at the service level takes precedence over the global setting. For more information about configuring TCP buffering globally, see "[TCP Buffering](#)."

To enable TCP Buffering on a service by using the command line interface

At the command prompt, type:

```
set service <name>@ -TCPB <Value>
```

## Example

```
set service Service-HTTP-1 -TCPB YES
```

To enable TCP Buffering on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select TCP Buffering.

# Enabling Compression

Jun 08, 2015

The NetScaler appliance provides a compression option to transparently compress HTML and text files by using a set of built-in compression policies. Compression reduces bandwidth requirements and can significantly improve server responsiveness in bandwidth-constrained setups. The compression policies are associated with services bound to the virtual server. The policies determine whether a response can be compressed and send compressible content to the appliance, which compresses it and sends it to the client.

Note: For compression to function correctly, you must enable it globally. For more information about configuring compression globally, see [Compression](#).

To enable compression on a service by using the command line interface

At the command prompt, type:

```
set service <name> -CMP <YES | NO>
```

## Example

```
set service Service-HTTP-1 -CMP YES
```

To enable compression on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Compression.

# Maintaining Client Connection for Multiple Client Requests

Jun 08, 2015

You can set the client keep-alive parameter to configure an HTTP or SSL service to keep a client connection to a Web site open across multiple client requests. If client keep-alive is enabled, even when the load balanced Web server closes a connection, the NetScaler appliance keeps the connection between the client and itself open. This setting allows services to serve multiple client requests on a single client connection.

If you do not enable this setting, the client will open a new connection for every request that it sends to the Web site. The client keep-alive setting saves the packet round trip time required to establish and close connections. This setting also reduces the time to complete each transaction. Client keep-alive can be enabled only on HTTP or SSL service types.

Client keep-alive set at the service level takes precedence over the global client keep-alive setting. For more information about client keep-alive, see [Client Keep-Alive](#).

To enable client keep-alive on a service by using the command line interface

At the command prompt, type:

```
set service <name>@ -CKA <Value>
```

## **Example**

```
set service Service-HTTP-1 -CKA YES
```

To enable client keep-alive on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Client Keep-Alive.

# Inserting the IP Address of the Client in the Request Header

Oct 06, 2016

A NetScaler uses the subnet IP (SNIP) address to connect to the server. The server need not be aware of the client.

However, in some situations, the server needs to be aware of the client it has to serve. When you enable the client IP setting, the NetScaler inserts the client's IPv4 or IPv6 address while forwarding the requests to the server. The server inserts this client IP in the header of the responses. The server is thus aware of the client.

To insert client IP address in the client request by using the command line interface

At the command prompt, type:

```
set service <name>@ -CIP <Value> <cipHeader>
```

## **Example**

```
set service Service-HTTP-1 -CIP enabled X-forwarded-for
```

To insert client IP address in the client request by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Client IP Address.

# Using the Source IP Address of the Client When Connecting to the Server

Jun 08, 2015

You can configure the NetScaler appliance to forward packets from the client to the server without changing the source IP address. This is useful when you cannot insert the client IP address into a header, such as when working with non-HTTP services.

For more information about configuring USIP globally, see "[Enabling Use Source IP Mode.](#)"

For information about using the port of the client when connecting to the server, see [Using the Client Port When Connecting to the Server.](#)

To enable USIP mode for a service by using the command line interface

At the command prompt, type:

```
set service <name>@ -usip (YES | NO)
```

## **Example**

```
set service Service-HTTP-1 -usip YES
```

To enable USIP mode for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Use Source IP Address.

# Configuring the Source Port for Server-Side Connections

Jun 08, 2015

When the NetScaler appliance connects to a physical server, it can use the source port from client's request, or it can use a proxy port as the source port for the connection. You can set the Use Proxy Port parameter to YES to handle situations such as the following scenario:

- The NetScaler appliance is configured with two load balancing virtual servers, LBVS1 and LBVS2.
- Both the virtual servers are bound to the same service, S-ANY.
- Use (the client's) source IP address (USIP) is enabled on the service.
- Client C1 sends two requests, Req1 and Req2, for the same service.
- Req1 is received by LBVS1 and Req2 is received by LBVS2.
- LBVS1 and LBVS2 forward the request to S-ANY, and when S-ANY sends the response, they forward the response to the client.
- Consider two cases:
  - Use the client port. When the NetScaler uses the client port, both the virtual servers use the client's IP address (because USIP is ON) and the client's port when connecting to the server. Therefore, when the service sends the response, the NetScaler cannot determine which virtual server should receive the response.
  - Use proxy port. When the NetScaler uses a proxy port, the virtual servers use the client's IP address (because USIP is ON), but different ports when connecting to the server. Therefore, when the service sends the response, the port number identifies the virtual server that should receive the response.

However, if you require a fully transparent configuration, such as a fully transparent cache redirection configuration, you must disable the Use Proxy port Setting so that the NetScaler appliance can use the source port from the client's request.

The Use Proxy Port option becomes relevant if the use source IP (USIP) option is enabled. For TCP-based service types, such as TCP, HTTP, and SSL, the option is enabled by default. For UDP-based service types, such as UDP and DNS, including ANY, the option is disabled by default. For more information about the USIP option, see "[Enabling Use Source IP Mode.](#)"

You can configure the Use Proxy Port setting either globally or on a given service.

## Configuring the Use Proxy Port Setting on a Service

Updated: 2013-11-11

You configure the Use ProxyPort setting on the service if you want to override the global setting.

## To configure the Use Proxy Port setting on a service by using the command line interface

At the command prompt, type:

```
set service <name>@ -useProxyPort (YES | NO)
```

### Example

```
> set service svc1 -useproxyport YES
Done > show service svc1
```

```
svc1 (10.102.29.30:80) - HTTP
State: UP
...
Use Source IP: YES Use Proxy Port: YES
...
Done
>
```

## To configure the Use Proxy Port setting on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Use Proxy Port.

### Configuring the Use Proxy Port Setting Globally

Updated: 2013-09-13

You configure the Use Proxy Port setting globally if you want to apply the setting to all the services on the NetScaler appliance. The global setting is overridden by service-specific Use Proxy Port settings.

## To configure the Use Proxy Port setting globally by using the command line interface

At the command prompt, type the following commands to configure the Use Proxy Port setting globally and verify the configuration:

- set ns param -useproxyport ( ENABLED | DISABLED )
- show ns param

Example

```
> set ns param -useproxyport ENABLED
Done
> show ns param
Global configuration settings:
...
Use Proxy Port: ENABLED
Done
>
```

## To configure the Use Proxy Port setting globally by using the configuration utility

Navigate to System > Settings > Change global system settings, and select or clear Use Proxy Port.

# Setting a Limit on the Number of Client Connections

Nov 11, 2013

You can specify a maximum number of client connections that each load balanced server can handle. The NetScaler appliance then opens client connections to a server only until this limit is reached. When the load balanced server reaches its limit, monitor probes are skipped, and the server is not used for load balancing until it has finished processing existing connections and frees up capacity.

For more information on the Maximum Client setting, see "[Load Balancing Domain-Name Based Services](#)."

Note: Connections that are in the process of closing are not considered for this limit.

To set a limit to the number of client connections by using the command line interface

At the command prompt, type:

```
set service <name> -maxclient <Value>
```

## **Example**

```
set service Service-HTTP-1 -maxClient 1000
```

To set a limit to the number of client connections by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Maximum Clients.

# Setting a Limit on Number of Requests Per Connection to the Server

Aug 29, 2013

The NetScaler appliance can be configured to reuse connections to improve performance. In some scenarios, however, load balanced Web servers may have issues when connections are reused for too many requests. For HTTP or SSL services, use the max request option to limit the number of requests sent through a single connection to a load balanced Web server.

Note: You can configure the max request option for HTTP or SSL services only.

To limit the number of client requests per connection by using the command line interface

At the command prompt, type:

```
set service <ServiceName> -maxReq <Value>
```

## **Example**

```
set service Service-HTTP-1 -maxReq 100
```

To limit the number of client requests per connection by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Maximum Requests.

# Setting a Threshold Value for the Monitors Bound to a Service

Nov 11, 2013

The NetScaler appliance designates a service as UP only when the sum of the weights of all monitors bound to it and that are UP is equal to or greater than the threshold value configured on the service. The weight for a monitor specifies how much that monitor contributes to designating the service to which it is bound as UP.

For example, assume that three monitors, named Monitor-HTTP-1, Monitor-HTTP-2, and Monitor-HTTP-3 respectively, are bound to Service-HTTP-1, and that the threshold configured on the service is three. Suppose the following weights are assigned to each monitor:

- The weight of Monitor-HTTP-1 is 1.
- The weight of Monitor-HTTP-2 is 3.
- The weight of Monitor-HTTP-3 is 1.

The service is marked UP only when one of the following is true:

- Monitor-HTTP-2 is UP.
- Monitor-HTTP-2 and Monitor-HTTP-1 or Monitor-HTTP-3 are UP
- All three monitors are UP.

To set the monitor threshold value on a service by using the command line interface

At the command prompt, type:

```
set service <name> -monThreshold <Value>
```

## Example

```
set service Service-HTTP-1 -monThreshold 100
```

To set the monitor threshold value on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Monitor Threshold.

# Setting a Timeout Value for Idle Client Connections

Nov 11, 2013

You can configure the service with a time-out value to terminate any idle client connections when the configured time elapses. If the client is idle during the configured time, the NetScaler closes the client connection.

To set a timeout value for idle client connections by using the command line interface

At the command prompt, type:

```
set service <name> -cltTimeout <Value>
```

## **Example**

```
set service Service-HTTP-1 -cltTimeout 100
```

To set a timeout value for idle client connections by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Client Idle Time-out.

# Setting a Timeout Value for Idle Server Connections

Nov 04, 2016

You can configure a service with a timeout value to terminate any idle server connections when the configured time (in seconds) elapses. If the server is idle for the configured amount of time, the NetScaler appliance closes the server connection.

To set a timeout value for idle server connections by using the command line interface

At the command prompt, type:

```
set service <name>@ -svrTimeout <Value>
```

## **Example**

```
set service Service-HTTP-1 -svrTimeout 100
```

To set a timeout value for idle server connections by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Server Idle Time-out.

# Setting a Limit on the Bandwidth Usage by Clients

Jun 29, 2017

In some cases, servers may have limited bandwidth to handle client requests and may become overloaded. To prevent overloading a server, you can specify a maximum limit on the bandwidth, in Kbps, processed by the server. The NetScaler appliance forwards requests to a load balanced server only until this limit is reached.

To set a maximum bandwidth limit on a service by using the command line interface

At the command prompt, type:

```
set service <name> -maxBandwidth <Value>
```

## **Example**

```
set service Service-HTTP-1 -maxBandwidth 100
```

To set a maximum bandwidth limit on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Maximum Bandwidth.

# Redirecting Client Requests to a Cache

Nov 11, 2013

You can configure a service to redirect client requests to a cache, and forward only those requests that are cache misses to a service chosen by the configured load balancing method.

To set cache redirection on a service by using the command line interface

At the command prompt, type:

```
set service <name>@ -cacheable <Value>
```

## **Example**

```
set service Service-HTTP-1 -cacheable YES
```

To set cache redirection on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service, and set the Cache Type.

# Retaining the VLAN Identifier for VLAN Transparency

Aug 29, 2013

You can configure a load balancing virtual server to retain the client's VLAN identifier in packets that are to be forwarded to servers. The virtual server must be a wildcard virtual server of type ANY, and must be functioning in MAC mode.

To configure a load balancing virtual server to retain the client VLAN ID by using the command line interface

At the command prompt, type the following command to configure a load balancing virtual server to retain the client VLAN ID and verify the configuration:

- `set lb vserver <name> -m MAC -macmodeRetainvlan ENABLED`
- `show lb vserver <name>`

## Note

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

To configure a load balancing virtual server to retain the client VLAN ID by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Retain VLAN ID.

# Configuring Automatic State Transition Based on Percentage Health of Bound Services

Nov 11, 2013

You can configure a load balancing virtual server to automatically transition from the UP state to the DOWN state if the percentage of active services falls below a configured threshold. For example, if you bind 10 services to a load balancing virtual server and configure a threshold of 50% for that virtual server, it transitions from UP to DOWN if six or more services are DOWN. When the percentage health rises above the threshold value, the virtual server returns to the UP state.

You can also enable an SNMP alarm called ENTITY-STATE if you want the NetScaler appliance to notify you when the percentage health of bound services causes a virtual server to change state.

To configure percentage based automatic state transition by using the command line interface

At the command prompt, type the following commands to configure automatic state transition for a virtual server and verify the configuration:

- `set lb vserver <name>@ -healthThreshold <positive_integer>`
- `show lb vserver <name>`

To configure percentage based automatic state transition by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and set a Health Threshold.

To enable the ENTITY-STATE alarm by using the command line interface

At the command prompt, type the following commands to enable the ENTITY-STATE SNMP alarm and verify the configuration:

- `enable snmp alarm ENTITY-STATE`
- `show snmp alarm`

To enable the ENTITY-STATE alarm by using the configuration utility

1. Navigate to System > SNMP > Alarms.
2. Select ENTITY-STATE and, in the Action list, select Enable.

# The Built-in Monitors

Jun 09, 2015

The NetScaler appliance contains a number of built-in monitors that you can use to monitor your services. These built-in monitors handle most of the common protocols. You cannot modify or remove the built-in monitors; you can only bind a built-in monitor to a service and unbind it from the service.

Note: You can create a custom monitor based on a built-in monitor. To learn how to create custom monitors, see [Configuring Monitors in a Load Balancing Setup](#).

This section includes the following details:

- [Monitoring TCP-based Applications](#)
- [Monitoring SSL Services](#)
- [Monitoring FTP Services](#)
- [Monitoring SIP Services](#)
- [Monitoring RADIUS Services](#)
- [Monitoring Accounting Information Delivery from a RADIUS Server](#)
- [Monitoring DNS and DNS-TCP Services](#)
- [Monitoring LDAP Services](#)
- [Monitoring MySQL Services](#)
- [Monitoring SNMP Services](#)
- [Monitoring NNTP Services](#)
- [Monitoring POP3 Services](#)
- [Monitoring SMTP Services](#)
- [Monitoring RTSP Servers](#)
- [Monitoring the XML Broker Services](#)
- [Monitoring ARP Requests](#)
- [Monitoring the XenDesktop Delivery Controller Services](#)
- [Monitoring Web Interface Services](#)
- [Monitoring Citrix StoreFront Stores](#)

# Monitoring TCP-based Applications

Apr 03, 2014

The NetScaler appliance has two built-in monitors that monitor TCP-based applications: tcp-default and ping-default. When you create a service, the appropriate default monitor is bound to it automatically, so that the service can be used immediately if it is UP. The tcp-default monitor is bound to all TCP services; the ping-default monitor is bound to all non-TCP services.

You cannot delete or modify default monitors. When you bind any other monitor to a TCP service, the default monitor is unbound from the service. The following table lists the monitor types, and the parameters and monitoring processes associated with each type.

| Monitor type | Specific parameters                                                                                                                                                                                                                          | Process                                                                                                                                                                                                                                                                                                              |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tcp          | Not applicable                                                                                                                                                                                                                               | <p>The NetScaler appliance establishes a 3-way handshake with the monitor destination, and then closes the connection.</p> <p>If the appliance observes TCP traffic to the destination, it does not send TCP monitoring requests. This occurs if LRTM is disabled. By default, LRTM is disabled on this monitor.</p> |
| http         | <p>httrequest ["HEAD /"] - HTTP request that is sent to the service.</p> <p>respcode [200] - A set of HTTP response codes are expected from the service.</p>                                                                                 | <p>The NetScaler appliance establishes a 3-way handshake with the monitor destination.</p> <p>After the connection is established, the appliance sends HTTP requests, and then compares the response code with the configured set of response codes.</p>                                                             |
| tcp-ecv      | <p>send [""] - is the data that is sent to the service. The maximum permissible length of the string is 512 K bytes.</p> <p>recv [""] - expected response from the service. The maximum permissible length of the string is 128 K bytes.</p> | <p>The NetScaler appliance establishes a 3-way handshake with the monitor destination.</p> <p>When the connection is established, the appliance uses the send parameter to send specific data to the service and expects a specific response through the receive parameter.</p>                                      |

| <b>Monitor type</b> | <b>Specific parameters</b>                                                                                              | <b>Process</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| http-ecv            | send ["" ] - HTTP data that is sent to the service<br><br>recv ["" ] - the expected HTTP response data from the service | The NetScaler appliance establishes a 3-way handshake with the monitor destination.<br><br>When the connection is established, the appliance uses the send parameter to send the HTTP data to the service and expects the HTTP response that the receive parameter specifies. | ping                | Not Applicable                                                                                                          | The NetScaler appliance sends an ICMP echo request to the destination of the monitor and expects an ICMP echo response.                                                                                                                                                                                                                                                                                                                                         |

To configure built-in monitors for TCP-based applications, see [Configuring Monitors in a Load Balancing Setup](#).

# Monitoring SSL Services

Jun 16, 2014

The NetScaler appliance has built-in secure monitors, TCPS and HTTPS. You can use the secure monitors to monitor HTTP as well as non-HTTP traffic. To configure a secure HTTP monitor, select the monitor type as HTTP, and then set the secure flag. To configure a secure TCP monitor, select the monitor type as TCP, and then set the secure flag. The secure monitors work as described below:

- **Secure TCP monitoring.** The NetScaler appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. After the handshake is over, the appliance closes the connection.
- **Secure HTTP monitoring.** The NetScaler appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. When the SSL connection is established, the appliance sends HTTP requests over the encrypted channel and checks the response codes.

The following table describes the available built-in monitors for monitoring SSL services.

| Monitor type | Probe                                                                    | Success criteria (Direct condition)                                                                                                                    |
|--------------|--------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCP          | TCP connection<br>SSL handshake                                          | Successful TCP connection established and successful SSL handshake.                                                                                    |
| HTTP         | TCP connection<br>SSL handshake<br>Encrypted HTTP request                | Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP response code in server HTTP response is encrypted. |
| TCP-ECV      | TCP connection<br>SSL handshake<br>(Data sent to a server is encrypted.) | Successful TCP connection is established, successful SSL handshake is performed, and expected TCP data is received from the server.                    |
| HTTP-ECV     | TCP connection<br>SSL handshake<br>(Encrypted HTTP request)              | Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP data is received from the server.                   |

# Monitoring FTP Services

Mar 24, 2015

To monitor FTP services, the NetScaler appliance opens two connections to the FTP server. It first connects to the control port, which is used to transfer commands between a client and an FTP server. After it receives the expected response, it connects to the data port, which is used to transfer files between a client and an FTP server. Only when the FTP server responds as expected on both connections is it marked UP.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

The NetScaler appliance has two built-in monitors for FTP services: the FTP monitor and the FTP-EXTENDED monitor. The FTP monitor checks basic functionality; the FTP-EXTENDED monitor also verifies that the FTP server is able to transmit a file correctly.

| Parameter | Specifies                                                                      |
|-----------|--------------------------------------------------------------------------------|
| userName  | User name used in the probe. Applies to both the FTP and FTP-EXTENDED monitor. |
| password  | Password used in monitoring. Applies to both the FTP and FTP-EXTENDED monitor  |
| fileName  | File name to be used for FTP-EXTENDED monitor only.                            |

To configure built-in monitors to check the state of FTP services, see [Configuring Monitors in a Load Balancing Setup](#).

# Monitoring SIP Services

Oct 14, 2014

Note: Support for load balancing SIP traffic over TCP or TLS is available in Netscaler release 10.5.e.

A NetScaler ADC has two built-in monitors that you can use to monitor SIP services: the **SIP-UDP** and **SIP-TCP** monitors. A SIP monitor periodically checks the SIP service to which the SIP monitor is bound, by sending SIP request methods to the SIP service. If the SIP service replies with a response code, the monitor marks the service as UP. If the SIP service does not respond, or responds incorrectly, it is marked as DOWN.

| Parameter | Specifies                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sipURI    | SIP addressing schema of the SIP server.                                                                                                                                                            |
| sipmethod | Type of SIP request used to probe the SIP service. Specify one of the following methods: <ul style="list-style-type: none"><li>• INVITE</li><li>• OPTION (the default)</li><li>• REGISTER</li></ul> |
| respcode  | SIP response code with which the SIP service responds the probe request.<br><br>Default: 200.                                                                                                       |

# Monitoring RADIUS Services

Aug 01, 2013

The NetScaler appliance RADIUS monitor periodically checks the state of the RADIUS service to which it is bound by sending an authentication request to the service. The RADIUS server authenticates the RADIUS monitor and sends a response. By default, the monitor expects to receive a response code of 2, the default Access-Accept response, from the RADIUS server. As long as the monitor receives the appropriate response, it marks the service UP.

Note: RADIUS monitor supports only PAP type authentication.

- If the client authenticated successfully, the RADIUS server sends an Access-Accept response. The default access-accept response code is 2, and this is the code that the appliance uses.
- If the client fails to authenticate successfully (such as when there is a mismatch in the user name, password, or secret key), the RADIUS server sends an Access-Reject response. The default access-reject response code is 3, and this is the code that the appliance uses.

| Parameter | Specifies                                                                                                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| userName  | User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.                                                                                                           |
| password  | Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.                                                                                                                               |
| radKey    | Shared secret key value that the RADIUS server uses during client authentication.                                                                                                                               |
| radNASid  | NAS-ID that is encapsulated in the payload when an access request is made.                                                                                                                                      |
| radNASip  | The IP address that is encapsulated in the payload when an access-request is made. When radNASip is not configured, the NetScaler sends the mapped IP address (MIP) to the RADIUS server as the NAS IP address. |

To monitor a RADIUS service, you must configure the RADIUS server to which it is bound as follows:

1. Add the user name and password of the client that the monitor will use for authentication to the RADIUS authentication database.
2. Add the IP address and secret key of the client to the appropriate RADIUS database.
3. Add the IP addresses that the appliance uses to send RADIUS packets to the RADIUS database. If the NetScaler appliance has more than one mapped IP address, or if a subnet IP address (SNIP) is used, you must add the same secret key for all of the IP addresses.

Caution: If the IP address used by the appliance are not added to the RADIUS database, the RADIUS server will discard all packets.

To configure built-in monitors to check the state of RADIUS server, see [Configuring Monitors in a Load Balancing Setup](#).

# Monitoring Accounting Information Delivery from a RADIUS Server

Sep 13, 2013

You can configure a monitor called a *RADIUS accounting* monitor to determine whether the Radius server used for Authentication, Authorization, and Accounting (AAA) is delivering accounting information as expected. The monitor is of type `RADIUS_ACCOUNTING`. The probe is generated by a Perl script called `nsbmradius.pl`, which is located in the `/nsconfig/monitors/` directory. The script sends successive accounting request probes to the RADIUS server. The probe is considered successful only if the RADIUS accounting server responds with a packet whose Code field is set to 5, which, according to RFC 2866, indicates an Accounting-Response packet.

When configuring a RADIUS accounting monitor, you must specify a secret key. You can specify optional parameters, each of which represents a RADIUS attribute, such as `Acct-Status-Type` and `Framed-IP-Address`. For information about these attributes, see RFC 2865, "Remote Authentication Dial In User Service (RADIUS)," and RFC 2866, "RADIUS Accounting."

To configure a RADIUS accounting monitor by using the command line interface

At the command prompt, type the following commands to configure a RADIUS accounting monitor and verify the configuration:

- `add lb monitor <monitorName> RADIUS_ACCOUNTING [-userName <string>] {-password } {-radKey } [-radNASip <ip_addr>] [-radAccountType <positive_integer>] [-radFramedIP <ip_addr>] [-radAPN <string>] [-radMSISDN <string>] [-radAccountSession <string>]`
- `show lb monitor <monitorName>`

## Example

```
add lb monitor radAcctMon RADIUS_ACCOUNTING -radKey "8d#>9jr4rV)L7%a2-zW13sM"
```

# Monitoring DNS and DNS-TCP Services

Mar 19, 2012

The NetScaler appliance has two built-in monitors that can be used to monitor DNS services: DNS and DNS-TCP. When bound to a service, either monitor periodically checks the state of that DNS service by sending a DNS query to it. The query resolves to an IPv4 or IPv6 address. That IP address is then checked against the list of test IP addresses that you configure. The list can contain up to five IP addresses. If the resolved IP address matches at least one IP address on the list, the DNS service is marked as up. If the resolved IP does not match any IP addresses on the list, the DNS service is marked as down.

| Parameter | Parameter                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| query     | The DNS query (domain name) sent to the DNS service that is being monitored. Default value: “\007” If the DNS query succeeds, the service is marked as UP; otherwise, it is marked as DOWN.<br><br>For a reverse monitor, if the DNS query succeeds, the service is marked as DOWN; otherwise, it is marked as UP. If no response is received, the service is marked as DOWN. |
| queryType | The type of DNS query that is sent. Possible values: Address, Zone.                                                                                                                                                                                                                                                                                                           |
| IPAddress | List of IP addresses that are checked against the response to the DNS monitoring probe.                                                                                                                                                                                                                                                                                       |
| IPv6      | Select this check box if the IP address uses IPv6 format.                                                                                                                                                                                                                                                                                                                     |

To configure the built-in DNS or DNS-TCP monitors, see [Configuring Monitors in a Load Balancing Setup](#).

# Monitoring LDAP Services

Mar 24, 2015

The NetScaler appliance has one built-in monitor that can be used to monitor LDAP services: the LDAP monitor. It periodically checks the LDAP service to which it is bound by authenticating and sending a search query to it. If the search is successful, the service is marked UP. If the LDAP server does not locate the entry, a failure message is sent to the LDAP monitor, and the service is marked DOWN.

You configure the LDAP monitor to define the search that it should perform when sending a query. You can use the Base DN parameter to specify a location in the directory hierarchy where the LDAP server should start the test query. You can use the Attribute parameter to specify an attribute of the target entity.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

| Parameter | Specifies                                                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| baseDN    | Base name for the LDAP monitor from where the LDAP search must start. If the LDAP server is running locally, the default value of base is dc=netScaler, dc=com. |
| bindDN    | BDN name for the LDAP monitor.                                                                                                                                  |
| filter    | Filter for the LDAP monitor.                                                                                                                                    |
| password  | Password used in monitoring LDAP servers.                                                                                                                       |
| attribute | Attribute for the LDAP monitor.                                                                                                                                 |

To configure the built-in LDAP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

# Monitoring MySQL Services

Mar 24, 2015

The NetScaler appliance has one built-in monitor that can be used to monitor MySQL services: the MySQL monitor. It periodically checks the MySQL service to which it is bound by sending a search query to it. If the search is successful, the service is marked UP. If the MySQL server does not respond or the search fails, a failure message is sent to the MySQL monitor, and the service is marked DOWN.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

| Parameter | Specifies                                     |
|-----------|-----------------------------------------------|
| database  | Database that is used for the MySQL monitor.  |
| sqlQuery  | SQL query that is used for the MySQL monitor. |

To configure built-in MySQL monitor, see [Configuring Monitors in a Load Balancing Setup](#).

# Monitoring SNMP Services

Mar 24, 2015

The NetScaler appliance has one built-in monitor that can be used to monitor SMNP services: the SNMP monitor. It periodically checks the SNMP agent on the service to which it is bound by sending a query for the enterprise identification ID (OID) that you configure for monitoring. If the query is successful, the service is marked UP. If the SNMP service finds the OID that you specified, the query succeeds and the SNMP monitor marks the service UP. If it does not find the OID, the query fails and the SNMP monitor marks service DOWN.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

| Parameter     | Specifies                                                               |
|---------------|-------------------------------------------------------------------------|
| SNMPOID       | OID that is used for the SNMP monitor.                                  |
| snmpCommunity | Community that is used for the SNMP monitor.                            |
| snmpThreshold | Threshold that is used for the SNMP monitor.                            |
| snmpVersion   | SNMP version that is used for load monitoring. Possible Values: V1, V2. |

To configure the built-in SNMP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

# Monitoring NNTP Services

Mar 24, 2015

The NetScaler appliance has one built-in monitor that can be used to monitor NNTP services: the NNTP monitor. It periodically checks the NNTP service to which it is bound by connecting to the service and checking for the existence of the newsgroup that you specify. If the newsgroup exists, the search is successful and the service is marked UP. If the NNTP service does not respond or the search fails, the service is marked DOWN.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

The NNTP monitor can optionally be configured to post a test message to the newsgroup as well.

| Parameter | Specifies                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------|
| userName  | User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe. |
| password  | Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.                     |
| group     | Group name to be queried for NNTP monitor.                                                            |

To configure the built-in NNTP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

# Monitoring POP3 Services

Mar 24, 2015

The NetScaler appliance has one built-in monitor that can be used to monitor POP3 services: the POP3 monitor. It periodically checks the POP3 service to which it is bound by opening a connection with a POP3 server. If the POP3 server responds with the correct response codes within the configured time period, it marks the service UP. If the POP3 service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

| Parameter      | Specifies                                                    |
|----------------|--------------------------------------------------------------|
| userName       | User name POP3 server. This user name is used in the probe.  |
| password       | Password used in monitoring POP3 servers.                    |
| scriptName     | The path and name of the script to execute.                  |
| dispatcherIP   | The IP address of the dispatcher to which the probe is sent. |
| dispatcherPort | The port of the dispatcher to which the probe is sent.       |

To configure the built-in POP3 monitor, see [Configuring Monitors in a Load Balancing Setup](#).

# Monitoring SMTP Services

Mar 24, 2015

The NetScaler appliance has one built-in monitor that can be used to monitor SMTP services: the SMTP monitor. It periodically checks the SMTP service to which it is bound by opening a connection with it and conducting a series of handshakes to ensure that the server is operating correctly. If the SMTP service completes the handshakes properly, the monitor marks the service UP. If the SMTP service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

| Parameter      | Specifies                                                    |
|----------------|--------------------------------------------------------------|
| userName       | User name SMTP server. This user name is used in the probe.  |
| password       | Password used in monitoring SMTP servers.                    |
| scriptName     | The path and name of the script to execute.                  |
| dispatcherIP   | The IP Address of the dispatcher to which the probe is sent. |
| dispatcherPort | The port of the dispatcher to which the probe is sent.       |

To configure the built-in SMTP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

# Monitoring RTSP Servers

Apr 08, 2013

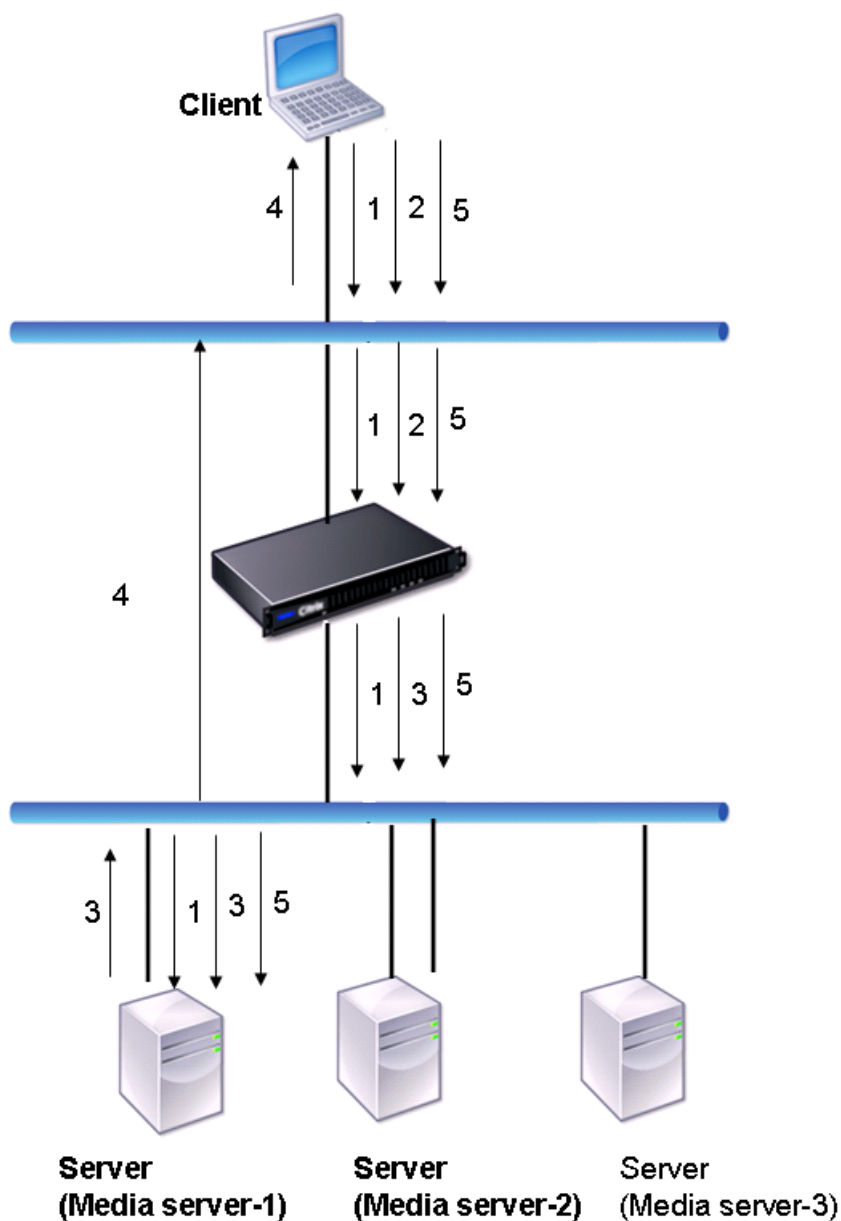

The NetScaler appliance has one built-in monitor that can be used to monitor RTSP services: the RTSP monitor. It periodically checks the RTSP service to which it is bound by opening a connection with the load balanced RTSP server. The type of connection that it opens, and the response that it expects, differs depending upon the network configuration. If the RTSP service responds as expected within the configured time period, it marks the service UP. If the service does not respond, or responds incorrectly, it marks the service DOWN.

The NetScaler appliance can be configured to load balance RTSP servers using two topologies: NAT-off and NAT-on. RTSP servers send their responses directly to the client, bypassing the appliance. The appliance must be configured to monitor RTSP services differently depending upon which topology your network uses. The appliance can be deployed either in inline or non-inline mode in both NAT-off and NAT-on mode.

In NAT-off mode, the appliance operates as a router: it receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. If your load balanced RTSP servers are assigned publicly accessible FQDNs in DNS, the load balanced servers send their responses directly to the client, bypassing the appliance. The following figure demonstrates this configuration.

Figure 1. RTSP in NAT-off Mode

The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:
  - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
  - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request may be sent to a different service.
3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.

Note: The appliance does not perform NAT to identify the RTSP connection, because the RTSP connections bypass it.

4. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the media server. Media Server-1 performs the requested actions, such as play, forward, or rewind.

In NAT-on mode, the appliance receives RTSP requests from the client and routes those requests to the appropriate media server using the configured load balancing method. The media server then sends its responses to the client through the appliance, as illustrated in the following diagram.

Figure 2. RTSP in NAT-on Mode

The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using the RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:

- If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
  - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request may be sent to a different service.
3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.
  4. The appliance performs NAT to identify the client for RTSP data connections, and the RTSP connections pass through the appliance and are routed to the correct client.
  5. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the appliance. The appliance uses RTSPSID persistence to identify the appropriate service, and routes the request to Media Server-1. Media Server-1 performs the requested action, such as play, forward, or rewind.

The RTSP monitor uses the RTSP protocol to evaluate the state of the RTSP services. The RTSP monitor connects to the RTSP server and conducts a sequence of handshakes to ensure that the server is operating correctly.

| Parameter   | Specifies                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rtspRequest | The RTSP request string that is sent to the RTSP server (for example, OPTIONS *). The default value is 07. The length of the request must not exceed 163 characters. |
| respCode    | Set of response codes that are expected from the service.                                                                                                            |

For instructions on configuring an RTSP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

# Monitoring the XML Broker Services

Sep 13, 2013

The NetScaler appliance has a built-in monitor type, CITRIX-XML-SERVICE, with which you can create monitors to monitor the XML Broker services. The XML Broker services are used by Citrix XenApp. The monitor opens a connection to the service and periodically probes the XML services to which it is bound. If the server responds as expected within the configured time period, the monitor marks the service UP. If the service does not respond, or responds incorrectly, the monitor marks the service DOWN.

To configure a CITRIX-XML-SERVICE monitor, you need to specify the application name in addition to setting the standard parameters. The application name is the name of the application that has to be run to monitor the state of the XML Broker service. The default application is Notepad.

To configure monitors for XML Broker services, see "[Configuring Monitors in a Load Balancing Setup](#)."

## Note

The parameter "Application Name" for Citrix-XML-Service monitor is invalid for XA and XD versions 7 and later. The probing criteria is different from XA/XD 7. However, you can still use application name for versions below XA/XD 7.

# Monitoring ARP Requests

Mar 19, 2012

The NetScaler appliance has one built-in monitor that can be used to monitor ARP requests: the ARP monitor. This monitor periodically sends an ARP request to the service to which it is bound, and listens for the expected response. If it receives the expected response, it marks the service UP. If it receives no response or the wrong response, it marks the service DOWN.

ARP locates a hardware address for a load balanced server when only the network layer address is known. ARP works with IPv4 to translate IP addresses to Ethernet MAC addresses. ARP monitoring is not relevant to IPv6 networks, and is therefore not supported on those networks.

There are no special parameters for the ARP monitor.

For instructions on configuring an ARP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

# Monitoring the XenDesktop Delivery Controller Services

Nov 26, 2013

In desktop virtualization, the NetScaler appliance can be used to load balance the Web Interface (WI) servers and the XenDesktop Delivery Controller servers deployed by Citrix XenDesktop environment. The NetScaler provides a built-in monitor, CITRIX-XD-DDC monitor, which monitors the XenDesktop Delivery Controller servers. In addition to the health check, you can also verify whether the probe is sent by a valid user of the XenDesktop Delivery Controller server.

The monitor sends a probe to the XenDesktop Delivery Controller server in the form of an XML message. If the server responds to the probe with the identity of the server farm, the probe is considered to be successful and the server's status is marked as UP. If the HTTP response does not have a success code or the identity of the server farm is not present in the response, the probe is considered to be a failure and the server's status is marked as DOWN.

The Validate Credentials option determines the probe to be sent by the monitor to the XenDesktop Delivery Controller server, that is, whether to request only the server name or to also validate the login credentials.

Note: Regardless of whether or not the user credentials (user name, password and domain) are specified on the CITRIX-XD-DDC monitor, the XenDesktop Delivery Controller server validates the user credentials only if the option to validate credentials is enabled on the monitor.

If you use the wizard for configuring the load balancing of the XenDesktop servers, the CITRIX-XD-DDC monitor is automatically created and bound to the XenDesktop Delivery Controller services. If you do not use the wizard, add a monitor of the type CITRIX-XD-DDC.

- For instructions on using the wizard, see [Configuring the load balancing of XenDesktop](#).
- For instructions on adding a monitor, see [Creating Monitors](#).
- For instructions on binding a monitor to a service, see [Binding Monitors to Services](#).

To add an XD-DDC monitor with the validate credentials option by using the command line interface

At the command prompt, type the following commands to add an XD-DDC monitor and verify the configuration:

- add lb monitor <monitorName> <monitorType> -userName <userName> -password <password> -ddcDomain <ddc\_domain\_name> -validateCred YES
- show lb monitor <monitorName>

## Example

```
> add lb monitor xdddcmon Citrix-xd-ddc -userName Administrator -password E12Dc35450a1 -ddcDomain dhop -validateCred YES
Done
> show lb monitor xdddcmon
1) Name.....:xdddcmon Type.....:CITRIX-XD-DDC State.....: ENABLED
```

### Standard parameters:

```
Interval.....:5 sec...Retries.....:3
Response timeout.....:2 sec...Down time.....:30 sec
Reverse.....:NO...Transparent.....:NO
Secure.....:NO...LRTM.....:ENABLED
Action.....:Not applicable...Deviation.....:0 sec
Destination IP.....:Bound service
Destination port.....:Bound service
Iptunnel.....:NO
TOS.....:NO...TOS ID.....:0
SNMP Alert Retries.....:0...Success Retries.....:1
Failure Retries.....:0
```

### Special parameters:

```
User Name.....:"Administrator"
Password.....:*****
DDC Domain.....: "dhop"
Done
```

To specify the validate credentials option on an XD-DDC monitor by using the command line interface

At the command prompt, type:

```
set lb monitor <monitorName> <monitorType> -userName -password -ddcDomain <ddc_domain_name> -validateCred YES
```

## Example

```
> set lb monitor XD_DDC_21.21.21.22_443_mn CITRIX-xd-ddc -userName Administrator -password D123S1R2A123 -ddcDomain dhop -validateCred YES
Done
```

To configure an XD-DDC monitor with the validate credentials option by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type Citrix-XD-DDC.

# Monitoring Web Interface Services

May 07, 2015

In desktop virtualization, the NetScaler appliance can be used to load balance the Web Interface (WI) servers and Dynamic Desktop Controller (DDC) servers deployed in the Citrix XenApp and Citrix XenDesktop and environments. The NetScaler appliance has two built-in monitor types for monitoring the WI servers used in these environments.

A CITRIX-WEB-INTERFACE monitor can monitor the Web Interface services efficiently because it monitors a dynamic page at the location specified by the site path. The monitor checks for critical failures in resource availability.

To mark a service as UP, the appliance expects the following response from the server:

1. For the first GET request, 200 OK .
2. For the POST request with credentials, 302 Found with the required WIAuthID.
3. For the last GET request with session cookie, 200 OK.

Note: If a redirect URL is configured, 302 Found is expected in the first request before 200 OK.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

When you configure a CITRIX-WEB-INTERFACE monitor, specify the site path to the location of the http page that displays the data collected by the monitor. To monitor the status of the service, in the specified site path, you can view the data updated dynamically by the monitoring script `auth/nocookies.aspx`.

Note: End the site path with a slash (/) to indicate that the monitored resource is dynamic.

Note: When you configure the WI-EXTENDED monitor, when specifying the site path, do not enter a slash (/) at the end of the path as the software internally adds a slash at the end of the path. For example, note the following command:

```
add monitor wi CITRIX-WI-EXTENDED -sitepath "/Citrix/DesktopWeb" -username aaa -password bbb -domain ccc
```

A CITRIX-WI-EXTENDED monitor verifies the logging process with the Web Interface service. This monitor accesses the login page and passes the user name, password, domain, and site path that were specified while configuring the monitor. It verifies the validity of the login credentials, correct configuration of the monitor (for example, the site path), and the connection with the IIS server.

Note: The CITRIX-WI-EXTENDED monitor is supported only for the .NET version of the WI servers. This monitor will not work for the JSP version of the WI servers.

If you use the wizard for configuring load balancing of the XenDesktop servers, a CITRIX-WEB-INTERFACE monitor is automatically created and bound to the WI services. The wizard adds and binds a CITRIX-WEB-INTERFACE monitor by default. If you want to add and bind a CITRIX-WI-EXTENDED monitor, select the Validate Credentials check box and type the necessary data. If you do not use the wizard, add a monitor corresponding to the WI services and bind it to each WI service that you create.

- For instructions on using the wizard, see [Configuring XenDesktop for Load Balancing](#) or [Configuring XenApp for Load Balancing](#).
- For instructions on adding a CITRIX-WEB-INTERFACE monitor, see [Creating Monitors](#).
- For instructions on binding a monitor to a service, see [Binding Monitors to Services](#).

To add a WI monitor by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> <monitorType> -sitePath <site_path> -dispatcherIP 127.0.0.1 -dispatcherPort 3013
```

-userName <username> -password <password> -domain <domain\_name>

## Examples

```
add lb monitor mwie CITRIX-WEB-INTERFACE -sitePath "/Citrix/XDWI"
```

```
add lb monitor mwie CITRIX-WI-EXTENDED -sitePath "/Citrix/XDWI"
```

```
-dispatcherIP 127.0.0.1 -dispatcherPort 3013 -userName administrator
```

```
-password d83d154575d426 -encrypted -domain wi
```

To add a WI monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and create a WI monitor of type CITRIX-WEB-INTERFACE or CITRIX-WI-EXTENDED.

# Monitoring Citrix StoreFront Stores

Sep 30, 2015

You can configure a user monitor for a Citrix Storefront store. The monitor determines the state of the StoreFront store by successively probing the account service, authentication service, and discovery document (in that order). If any of those services do not respond to the probe, the monitor probe fails, and the StoreFront store is marked as DOWN. The monitor sends probes to the IP address and port of the bound service.

Note: Monitor probes originate from the NetScaler IP (NSIP) address. However, if the subnet of a StoreFront server is different from that of the appliance, then the subnet IP (SNIP) address is used.

Beginning with build 120.13, you can also bind a StoreFront monitor to a service group. A monitor is bound to each member of the service group and probes are sent to the IP address and port of the bound member (service). Also, because each member of a service group is now monitored by using the member's IP address, you can now use the StoreFront monitor to monitor StoreFront cluster nodes that are added as members of the service group.

The hostname parameter for StoreFront monitors is deprecated. The secure parameter is now used to determine whether to use HTTP (the default) or HTTPS to send monitor probes.

To use HTTPS, set the secure option to Yes.

To create a StoreFront monitor by using the command line interface

At the command prompt, type the following commands to configure a StoreFront monitor and verify the configuration:

- `add lb monitor <monitorName> STOREFRONT <string> -storeName <string> [-storefrontacctservice ( YES | NO )] -secure ( YES | NO )`
- `show lb monitor <monitorName>`

## Example

```
add lb monitor storefront_ssl STOREFRONT -storename myStore -storefrontacctservice YES -secure YES
```

To create a StoreFront monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and create a WI monitor of type STOREFRONT.

# Custom Monitors

Jun 09, 2015

In addition to built-in monitors, you can use custom monitors to check the state of your services. The NetScaler appliance provides several types of custom monitors based on scripts that are included with NetScaler operating system that can be used to determine the state of services based on the load on the service or network traffic sent to the service. These are the inline monitors, user monitors, and load monitors.

With any of these types of monitors, you can use the supplied functionality, or you can create your own scripts and use those scripts to determine the state of the service to which the monitor is bound.

This section includes the following details:

- [Configuring HTTP-Inline Monitors](#)
- [Understanding User Monitors](#)
- [How to Use a User Monitor to Check Web Sites](#)
- [Understanding the Internal Dispatcher](#)
- [Configuring a Custom User Monitor](#)
- [Understanding Load Monitors](#)
- [Configuring Load Monitors](#)
- [Unbinding Metrics from a Metrics Table](#)

# Configuring HTTP-Inline Monitors

Apr 15, 2015

Inline monitors analyze and probe the responses from the services to which they are bound only when those services receive client requests. The inline monitor is of type HTTP-INLINE and can only be configured to work with HTTP and HTTPS services. An inline monitor determines that the service to which it is bound is UP by checking its responses to the requests that are sent to it. When no client requests are sent to the service, the inline monitor probes the service by using the configured URL.

Note: Inline monitors cannot be bound to HTTP or HTTPS Global Server Load Balancing (GSLB) remote or local services because these services represent virtual servers rather than actual load balanced Web servers.

Inline monitors have a time-out value and a retry count when probes fail. You can select any of the following action types for the NetScaler appliance to take when a failure occurs:

- **NONE.** No explicit action is taken. You can view the service and monitor, and the monitor indicates the number of current contiguous error responses and cumulative responses checked.
- **LOG.** Logs the event in ns/syslog and displays the counters.
- **DOWN.** Marks the service down and does not direct any traffic to the service. This setting breaks any persistent connections to the service. This action also logs the event and displays counters.

After the service is down, the service remains DOWN for the configured down time. After the DOWN time elapses, the inline monitor uses the configured URL to probe the service to see if it is available again. If the probe succeeds, the state of the service is changed to UP. Traffic is directed to the service, and monitoring resumes as before.

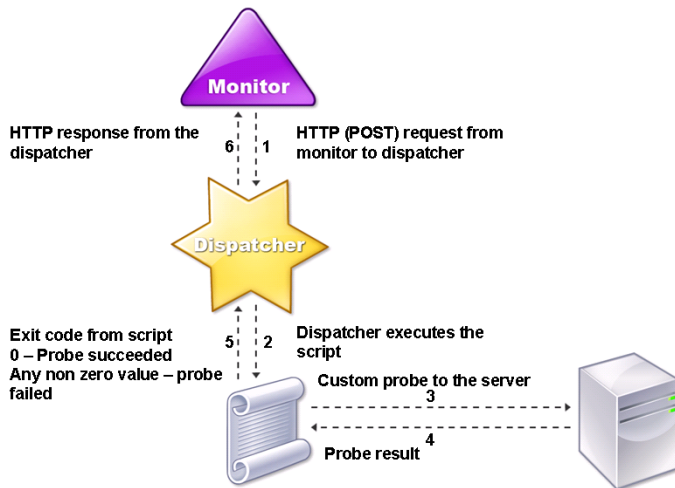

To configure inline monitors, see [Configuring Monitors in a Load Balancing Setup](#).

# Understanding User Monitors

Jul 19, 2017

User monitors extend the scope of custom monitors. You can create user monitors to track the health of customized applications and protocols that the NetScaler appliance does not support. The following diagram illustrates how a user monitor works.

Figure 1. User Monitors

A user monitor requires the following components.

- **Dispatcher.** A process, on the appliance, that listens to monitoring requests. A dispatcher can be on the loopback IP address (127.0.0.1) and port 3013. Dispatchers are also known as internal dispatchers. A dispatcher can also be a web server that supports Common Gateway Interface (CGI). Such dispatchers are also known as external dispatchers. They are used for custom scripts that do not run on the FreeBSD environment, such as .NET scripts.

Note: You can configure the monitor and the dispatcher to use HTTPS instead of HTTP by enabling the “secure” option on the monitor and configure it as an external dispatcher. However, an internal dispatcher understands only HTTP, and cannot use HTTPS.

In a HA setup, the dispatcher runs on both the primary and secondary NetScaler appliances. The dispatcher remains inactive on the secondary appliance.

**Script.** The script is a program that sends custom probes to the load balanced server and returns the response code to the dispatcher. The script can return any value to the dispatcher, but if a probe succeeds, the script must return a value of zero (0). The dispatcher considers any other value as probe failure.

The NetScaler appliance is bundled with sample scripts for commonly used protocols. The scripts exist in the /nsconfig/monitors directory. If you want to add a new script, add it there. If you want to customize an existing script, create a copy with a new name and modify it.

Important: Starting with release 10.1 build 122.17, the script files for user monitors are in a new location.

If you upgrade an MPX or VPX virtual appliance to release 10.1 build 122.17 or later, the changes are as follows:

- A new directory named `conflicts` is created in `/nsconfig/monitors/` and all the built-in scripts of the previous builds are moved to this directory.
- All new built-in scripts are available in the `/netscaler/monitors/` directory. All custom scripts are available in the `/nsconfig/monitors/` directory.
- You must save a new custom script in the `/nsconfig/monitors/` directory.
- After the upgrade is completed, if a custom script is created and saved in the `/nsconfig/monitors/` directory, with the same name as that of a built-in script, the script in the `/netscaler/monitors/` directory takes priority. That is, the custom script does not run.

If you provision a virtual appliance with release 10.1 build 122.17 or later, the changes are as follows:

- All built-in scripts are available in the `/netscaler/monitors/` directory.
- The `/nsconfig/monitors/` directory is empty.
- If you create a new custom script, you must save it in the `/nsconfig/monitors/` directory.

For the scripts to function correctly,

- The maximum number of characters in the name of the script must not exceed 63.
- The maximum number of script arguments that can be provided to a script must not exceed 512.
- The maximum number of characters that can be provided in the parameter script arguments must not exceed 639.

To debug the script, you must run it by using the `nsumon-debug.pl` script from the NetScaler command line. You use the script name (with its arguments), IP address, and the port as the arguments of the `nsumon-debug.pl` script. Users must use the script name, IP address, port, time-out, and the script arguments for the `nsumon-debug.pl` script.

At the NetScaler command line, type:

```
nsumon-debug.pl <scriptname> <IP> <port> <timeout> [scriptarguments] [is_secure]
```

**Important:** Starting with release 10.5 build 57.x, script files for user monitors support IPv6 addresses and include the following changes:

- For the following protocols, new `pm` files have been included for IPv6 support.
  - Radius
  - NNTP
  - POP3
  - SMTP
- The following sample scripts in `/netscaler/monitors/` has been updated for IPv6 support:
  - `nsbmradius.pl`
  - `nsldap.pl`
  - `nsnntp.pl`
  - `nspop3 nssf.pl`
  - `nssnmp.pl`
  - `nswi.pl`
  - `nstftp.pl`

- nssmtp.pl
- nsrdp.pl
- nsntlm-lwp.pl
- nsftp.pl
- nsappc.pl

After upgrading to release 10.5 build 57.x, if you want to use your existing custom scripts with IPv6 services, make sure that you update the existing custom scripts with the changes provided in the updated sample scripts in `/netscaler/monitors/`.

Note: The sample script `nsmysql.pl` does not support IPv6 address. If an IPv6 service is bound to a user monitor that uses `nsmysql.pl`, the probe will fail.

- The following LB monitor types have been updated to support IPv6 addresses:

- USER
- SMTP
- NNTP
- LDAP
- SNMP
- POP3
- FTP\_EXTENDED
- STOREFRONT
- APPC
- CITRIX\_WI\_EXTENDED

If you are creating a new custom script that uses one of these LB monitors types, make sure that you include IPv6 support in the custom script. Refer to the associated sample script in `/netscaler/monitors/` for the changes that you have to make in the custom script for IPv6 support.

To track the status of the server, the monitor sends an HTTP POST request to the configured dispatcher. This POST request contains the IP address and port of the server, and the script that must be executed. The dispatcher executes the script as a child process, with user-defined parameters (if any). Then, the script sends a probe to the server. The script sends the status of the probe (response code) to the dispatcher. The dispatcher converts the response code to an HTTP response and sends it to the monitor. Based on the HTTP response, the monitor marks the service as up or down.

The appliance logs the error messages to the `/var/nslog/nsumond.log` file when user monitor probes fail. The following table lists the user monitors and the possible reasons for failure.

| User monitor type | Probe failure reasons |
|-------------------|-----------------------|
|-------------------|-----------------------|

| Monitor type | Problem description                                                                                       |
|--------------|-----------------------------------------------------------------------------------------------------------|
| SMTP         | Monitor fails to establish a connection to the server.                                                    |
| NNTP         | Monitor fails to establish a connection to the server.                                                    |
|              | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|              | Monitor fails to find the NNTP group.                                                                     |
| LDAP         | Monitor fails to establish a connection to the server.                                                    |
|              | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|              | Monitor fails to bind to the LDAP server.                                                                 |
|              | Monitor fails to locate an entry for the target entity in the LDAP server.                                |
| FTP          | The connection to the server times out.                                                                   |
|              | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|              | Logon fails.                                                                                              |
|              | Monitor fails to find the file on the server.                                                             |
| POP3         | Monitor fails to establish a connection to the database.                                                  |
|              | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|              | Logon fails.                                                                                              |
| POP3         | Monitor fails to establish a connection to the database.                                                  |
|              | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |

| User monitor type             | Probe failure reasons                                                                                     |
|-------------------------------|-----------------------------------------------------------------------------------------------------------|
|                               | LOGON fails.                                                                                              |
|                               | Preparation of SQL query fails.                                                                           |
|                               | Execution of SQL query fails.                                                                             |
| SNMP                          | Monitor fails to establish a connection to the database.                                                  |
|                               | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|                               | Logon fails.                                                                                              |
|                               | Monitor fails to create the SNMP session.                                                                 |
|                               | Monitor fails to find the object identifier.                                                              |
|                               | The monitor threshold value setting is greater than or equal to the actual threshold of the monitor.      |
| RDP (Windows Terminal Server) | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|                               | Monitor fails to create a socket.                                                                         |
|                               | Mismatch in versions.                                                                                     |
|                               | Monitor fails to confirm connection.                                                                      |

You can view the log file from the NetScaler command line by using the following commands, which open a BSD shell, display the log file on the screen, and then close the BSD shell and return you to the NetScaler command prompt:

```
> shell
root@ns# cat /var/nslog/nsumond.log
root@ns# exit
>
```

User monitors also have a time-out value and a retry count for probe failures. You can use user monitors with non-user monitors. During high CPU utilization, a non-user monitor enables faster detection of a server failure.

If the user monitor probe times out during high CPU usage, the state of the service remains unchanged.

## Note

For scriptable monitors, the response timeout must be configured to a value equal to expected timeout + 1 second.

For example, if you expect the timeout to be 4 seconds, configure the response timeout as 5 seconds.

### **Example command:**

```
add lb monitor <name> USER -scriptname <script-name> -resptimeout 5 seconds
```

# How to Use a User Monitor to Check Web Sites

Mar 19, 2012

You can configure a user monitor to check for specific Web site problems that are reported by HTTP servers using specific HTTP codes. The following table lists the HTTP response codes that this user monitor expects.

| HTTP response code          | Meaning                                                                                                                                                                  |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200 - success               | Probe success.                                                                                                                                                           |
| 503 - service unavailable   | Probe failure.                                                                                                                                                           |
| 404 - not found             | Script not found or cannot execute.                                                                                                                                      |
| 500 - Internal server error | Internal error/resource constraints in dispatcher (out of memory, too many connections, unexpected system error, or too many processes). The service is not marked DOWN. |
| 400 - bad request           | Error parsing HTTP request.                                                                                                                                              |
| 502 - bad gateway           | Error decoding script's response.                                                                                                                                        |

You configure the user monitor for HTTP by using the following parameters.

| Parameter      | Specifies                                                                             |
|----------------|---------------------------------------------------------------------------------------|
| scriptName     | The path and name of the script to execute.                                           |
| scriptArgs     | The strings that are added in the POST data. They are copied to the request verbatim. |
| dispatcherIP   | The IP address of the dispatcher to which the probe is sent.                          |
| dispatcherPort | The port of the dispatcher to which the probe is sent.                                |
| localfileName  | The name of a monitor script file on the local system.                                |

| Parameter | Specifies                                                                                 |
|-----------|-------------------------------------------------------------------------------------------|
| destPath  | A particular location on the NetScaler appliance where the uploaded local file is stored. |

To create a user monitor to monitor HTTP, see [Configuring Monitors in a Load Balancing Setup](#).

# Understanding the Internal Dispatcher

Mar 19, 2012

You can use a custom user monitor with the internal dispatcher. Consider a case where you need to track the health of a server based on the presence of a file on the server. The following diagram illustrates this scenario.

Figure 1. Using a User Monitor with the Internal Dispatcher

A possible solution is to use a Perl script that initiates an FTP session with the server and checks for the presence of the file. You can then create a user monitor that uses the Perl script. The NetScaler includes such a Perl script (nsftp.pl), in the /nsconfig/monitors/ directory.

You can use a user monitor with an external dispatcher. Consider a case where you must track the health of a server based on the state of an SMTP service on another server. This scenario is illustrated in the following diagram.

Figure 2. Using a User Monitor with an External Dispatcher

A possible solution would be to create a Perl script that checks the state of the SMTP service on the server. You can then create a user monitor that uses the Perl script.

# Configuring a Custom User Monitor

Aug 24, 2016

To configure a custom user monitor, you must first write the script that performs the action that the monitor will use to check the service that is bound to it, and upload the script to the /nsconfig/monitors directory on the NetScaler appliance. Then you create the monitor on the appliance, as described below.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

To configure a user monitor by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> USER -scriptname <NameOfScript> -scriptargs <Arguments>
```

## **Example**

```
add monitor Monitor-User-1 USER -scriptname nsftp.pl -scriptargs "file=/home/user/sample.txt;user=root;password=passwd"
```

# Understanding Load Monitors

Mar 19, 2012

Load monitors use SNMP polled OIDs to calculate load. The load monitor uses the IP address of the service to which it is bound (the destination IP address) for polling. It sends an SNMP query to the service, specifying the OID for a metric. The metrics can be CPU, memory, or number of server connections. The server responds to the query with a metric value. The metric value in the response is compared with the threshold value. The NetScaler appliance considers the service for load balancing only if the metric is less than the threshold value. The service with the lowest load value is considered first.

The following diagram illustrates a load monitor configured for the services described in the basic load balancing setup discussed in [Setting Up Basic Load Balancing](#).

Figure 1. Operation of Load Monitors

Note: The load monitor does not determine the state of the service. It only enables the appliance to consider the service for load balancing.

After you configure the load monitor, you must then configure the metrics that the monitor will use. For load assessment, the load monitor considers server parameters known as metrics, which are defined within the metric tables in the appliance configuration. Metric tables can be of two types:

- **Local.** By default, this table exists in the appliance. It consists of four metrics: connections, packets, response time, and bandwidth. The appliance specifies these metrics for a service, and SNMP queries are not originated for these services. These metrics cannot be changed.
- **Custom.** A user-defined table. Each metric is associated with an OID.

By default, the appliance generates the following tables:

- NetScaler
- RADWARE
- CISCO-CSS
- LOCAL

- FOUNDRY
- ALTEON

You can either add the appliance-generated metric tables, or you can add tables of your own choosing, as shown in the following table. The values in the metric table are provided only as examples. In an actual scenario, consider the real values for the metrics.

| Metric name | OIDs    | Weight | Threshold |
|-------------|---------|--------|-----------|
| CPU         | 1.2.3.4 | 2      | 70        |
| Memory      | 4.5.6.7 | 3      | 80        |
| Connections | 5.6.7.8 | 4      | 90        |

To calculate the load for one or more metrics, you assign a weight to each metric. The default weight is 1. The weight represents the priority given to each metric. If the weight is high, the priority is high. The appliance chooses a service based on the SOURCEIPDESTIP hash algorithm.

You can also set the threshold value for each metric. The threshold value enables the appliance to select a service for load balancing if the metric value for the service is less than the threshold value. The threshold value also determines the load on each service.

# Configuring Load Monitors

Nov 12, 2013

To configure a load monitor, first create the load monitor. For instructions on creating a monitor, see [Creating Monitors](#). Next, select or create the metric table to define a set of metrics that determine the state of the server, and (if you create a metric table) bind each metric to the metric table.

To create a metric table by using the command line interface

At the command prompt, type the following commands:

- `add lb metricTable <metricTableName>`
- `bind lb metricTable <metricTableName> <metric> <SNMPOID>`

## Example

```
add metricTable Table-Custom-1
```

```
bind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5 11
```

To create a metric table and bind metrics to it by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Metric Tables and create a metric table.
2. To bind metrics, click Bind and specify a metric and an SNMP OID.

# Unbinding Metrics from a Metrics Table

Nov 12, 2013

You can unbind metrics from a metrics table if the metrics need to be changed, or if you want to remove the metrics table entirely.

To unbind metrics from a metric table by using the command line interface

At the command prompt, type:

```
unbind lb metricTable <metricTable> <metric>
```

## **Example**

```
unbind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5
```

To unbind metrics from a metric table by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Metric Tables.
2. Open a metric table, select a metric, and click Delete.

You can view the detail of all configured metric tables, such as name and type, to determine whether the metric table is internal or created and configured.

# Configuring Monitors in a Load Balancing Setup

Jun 09, 2015

To configure monitors on a Web site, you first decide whether to use a built-in monitor or create your own monitor. If you create a monitor, you can choose between creating a monitor based on a built-in monitor, or creating a custom monitor that uses a script that you write to monitor the service. For more information about creating custom monitors, see [Custom Monitors](#). Once you have chosen or created a monitor, you then bind it to the appropriate service. The following conceptual diagram illustrates a basic load balancing setup with monitors.

Figure 1. How Monitors Operate

As shown above, each service has a monitor bound to it. The monitor probes the load balanced server via its service. As long as the load balanced server responds to the probes, the monitor marks it UP. If the load balanced server should fail to respond to the designated number of probes within the designated time period, the monitor marks it DOWN.

This section includes the following details:

- [Creating Monitors](#)
- [Binding Monitors to Services](#)
- [Modifying Monitors](#)
- [Enabling and Disabling Monitors](#)
- [Unbinding Monitors](#)
- [Removing Monitors](#)
- [Viewing Monitors](#)
- [Closing Monitor Connections](#)
- [Ignoring the Upper Limit on Client Connections for Monitor Probes](#)

# Creating Monitors

Nov 12, 2013

The NetScaler appliance provides a set of built-in monitors. It also allows you to create custom monitors, either based on the built-in monitors or from scratch.

To create a monitor by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> <monitorType> [<interval>]
```

## **Example**

```
add lb mon monitor-HTTP-1 HTTP
```

```
add lb mon monitor-HTTP-2 TCP 2
```

To create a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor.

# Binding Monitors to Services

Nov 12, 2013

After creating a monitor, you bind it to a service. You can bind one or multiple monitors to a service. If you bind one monitor to a service, that monitor determines whether the service is marked UP or DOWN. If you bind multiple monitors to a service, the NetScaler appliance checks all monitors bound to that service using a calculation that you control, and marks the service UP or DOWN depending on the results.

Note: The destination IP address of a monitor probe can be different than the server IP address and port.  
To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
bind lb monitor <monitorName> <ServiceName>
```

## **Example**

```
bind mon monitor-HTTP-1 Service-HTTP-1
```

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and add a monitor.

# Modifying Monitors

Nov 12, 2013

You can modify the settings for any monitor that you created.

Note: Two sets of parameters apply to monitors: those that apply to all monitors, regardless of type, and those that are specific to a monitor type. For information on parameters for a specific monitor type, see the description for that type of monitor.

To modify an existing monitor by using the command line interface

At the command prompt, type:

```
set lb monitor <monitorName> <type> -interval <interval> -resptimeout <resptimeout>
```

## **Example**

```
set mon monitor-HTTP-1 HTTP -interval 50 milli
-resptimeout 20 milli
```

To modify an existing monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and open a monitor to modify.

# Enabling and Disabling Monitors

Nov 12, 2013

By default, monitors bound to services and service groups are enabled. When you enable a monitor, the monitor begins probing the services to which it is bound. If you disable a monitor bound to a service, the state the service is determined using the other monitors bound to the service. If the service is bound to only one monitor, and if you disable the monitor, the state of the service is determined using the default monitor.

To enable a monitor by using the command line interface

At the command prompt, type:

```
enable lb monitor <monitorName>
```

**Example**

```
enable lb mon monitor-HTTP-1
```

To enable a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Select a monitor, and from the Action list, select Enable or Disable.

To disable a monitor by using the command line interface

At the command prompt, type:

```
disable lb monitor <monitorName>
```

**Example**

```
disable lb mon monitor-HTTP-1
```

# Unbinding Monitors

Nov 12, 2013

You can unbind monitors from a service and service group. When you unbind a monitor from the service group, the monitors are unbound from the individual services that constitute the service group. When you unbind a monitor from a service or a service group, the monitor does not probe the service or the service group.

Note: When you unbind all user-configured monitors from a service or a service group, the default monitor is bound to the service and the service group. The default monitors then probes the service or the service groups.

To unbind a monitor from a service by using the command line interface

At the command prompt, type:

```
unbind lb monitor <monitorName>
```

## **Example**

```
unbind mon monitor-HTTP-1 Service-HTTP-1
```

To unbind a monitor from a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service to modify.
2. Click in the Monitors section, select a monitor, and click Unbind.

# Removing Monitors

Nov 12, 2013

After you unbind a monitor that you created from its service, you can remove that monitor from the NetScaler configuration. (If a monitor is bound to a service, it cannot be removed.)

Note: When you remove monitors bound to a service, the default monitor is bound to the service. You cannot remove default monitors.

To remove a monitor by using the command line interface

At the command prompt, type:

```
rm lb monitor <monitorName> <type>
```

## **Example**

```
rm lb monitor monitor-HTTP-1 HTTP
```

To remove a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Select a monitor, and click Delete.

# Viewing Monitors

Nov 12, 2013

You can view the services and service groups that are bound to a monitor. You can verify the settings of a monitor to troubleshoot your NetScaler configuration. The following procedure describes the steps to view the bindings of a monitor to the services and service groups.

To view monitor bindings by using the command line interface

At the command prompt, type:

```
show lb monbindings <MonitorName>
```

## Example

```
show lb monbindings monitor-HTTP-1
```

To view monitor bindings by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Select a monitor, and in the Action list, click Show Bindings.

To view monitors by using the command line interface

At the command prompt, type:

```
show lb monitor <monitorName>
```

## Example

```
show lb mon monitor-HTTP-1
```

To view monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors. The details of the available monitors appear in the Monitors pane.

# Closing Monitor Connections

Aug 29, 2013

The NetScaler appliance sends probes to the services through the monitors bound to the services. By default, the monitor on the NetScaler and the physical server follow the complete handshake procedure even for monitor probes. However, this procedure adds overhead to the monitoring process and may not be always necessary.

For the TCP monitors, you can configure the NetScaler to close a monitor-probe connection after receiving SYN-ACK from the service. To do so, set the value of the `monitorConnectionClose` parameter to `RESET`. If you want the monitor-probe connection to go through the complete procedure, set the value to `FIN`.

Note: The `monitorConnectionClose` setting is applicable to all the monitors bound to all the services configured on the NetScaler appliance.

To configure monitor-connection closure by using the command line interface

At the command prompt, type:

```
set lb parameter -monitorConnectionClose <monitor_conn_close_option>
```

## **Example**

```
set lb parameter -monitorConnectionClose RESET
```

To configure monitor-connection closure by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing Parameters.
2. Select `FIN` or `Reset`.

# Ignoring the Upper Limit on Client Connections for Monitor Probes

Aug 29, 2013

Depending on considerations such as the capacity of a physical server, you can specify a limit on the maximum number of client connections made to any service. If you have set such a limit on a service, the NetScaler appliance stops sending requests to the service when the threshold is reached and resumes sending connections to the service after the number of existing connections falls to within the limits. You can configure the NetScaler to skip this check when it sends monitor-probe connections to a service.

Note: You cannot skip the maximum-client-connections check for an individual service. If you specify this option, it applies to all the monitors bound to all the services configured on the NetScaler appliance.

To set the Skip MaxClients for Monitor Connections option by using the command line interface

At the command prompt, type:

```
set lb parameter -monitorSkipMaxClient (ENABLED | DISABLED)
```

## **Example**

```
set lb parameter -monitorSkipMaxClient enabled
```

To set the Skip MaxClients for Monitor Connections option by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing Parameters.
2. Select Skip MaxClients for Monitoring Connections.

# Managing a Large Scale Deployment

Mar 19, 2012

The NetScaler appliance contains several features that are helpful when you are configuring a large load balancing deployment. Instead of configuring virtual servers and services individually, you can create groups of virtual servers and services. You can also create a range of virtual servers and services, and you can translate or mask virtual server and service IP addresses.

You can set persistence for a group of virtual servers. You can bind monitors to a group of services. Creating a range of virtual servers and services of identical type allows you to set up and configure those servers in a single procedure, which significantly shortens the time required to configure those virtual servers and services.

By translating or masking IP addresses, you can take down virtual servers and services, and make changes to your infrastructure, without extensive reconfiguration of your service and virtual server definitions.

# Ranges of Virtual Servers and Services

Mar 19, 2012

When you configure load balancing, you can create ranges of virtual servers and services, eliminating the need to configure virtual servers and services individually. For example, you can use a single procedure to create three virtual servers with three corresponding IP addresses. When more than one argument uses a range, all of the ranges must be of the same size.

The following are the types of ranges you can specify when adding services and virtual servers to your configuration:

- **Numeric ranges.** Instead of typing a single number, you can specify a range of consecutive numbers.

For example, you can create a range of virtual servers by specifying a starting IP address, such as 10.102.29.30, and then typing a value for the last byte that indicates the range, such as 34. In this example, five virtual servers will be created with IP addresses that range between 10.102.29.30 and 10.102.29.34.

Note: The IP addresses of the virtual servers and services must be consecutive.

- **Alphabetic ranges.** Instead of typing a literal letter, you can substitute a range for any single letter, for example, [C-G]. This results in all letters in the range being included, in this case C, D, E, F, and G.

For example, if you have three virtual servers named Vserver-x, Vserver-y, and Vserver-z, instead of configuring them separately, you can type vserver [x-z] to configure them all.

## Creating a Range of Virtual Servers

Updated: 2013-11-12

You create a range of virtual servers as described below.

## To create range of virtual servers by using the command line interface

At the command prompt, type one of the following commands:

- `add lb vserver <name>@ <protocol> -range <rangeValue> <IPAddress> [<port>]`
- `add lb vserver <name>@[<rangeValue>] <protocol> <IPAddress[<rangeValue>]> [<port>]`

### Example

```
add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
```

OR

```
> add lb vserver vserver[P-R] http 10.102.29.[26-28] 80
vserver "vserverP" added
vserver "vserverQ" added
vserver "vserverR" added
Done
```

## To create range of virtual servers by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Add a virtual server, and specify a range.

## Creating a Range of Services

Updated: 2013-11-12

You create a range of services as described below. If you specify a range for the service name, specify a range for the IP address too.

### To create range of services by using the command line interface

At the command prompt, type the command:

```
add service <name>@ <IP>@ <protocol> <port>
```

#### **Example**

```
> add service serv[1-3] 10.102.29.[102-104] http 80
service "serv1" added
service "serv2" added
service "serv3" added
Done
```

# Configuring Service Groups

Mar 19, 2012

Configuring a service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable any option, such as compression, health monitoring or graceful shutdown, for a service group, the option gets enabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to service groups.

The members of a service group can be identified by IP address or server name.

Using domain-name based service (DBS) group members is advantageous because you need not reconfigure the member on the NetScaler appliance if the IP address of the member changes. The appliance automatically senses such changes through the configured name server. This feature is particularly useful in cloud scenarios, where the service provider can change a physical server or change the IP address for a service. If you specify a DBS group member, the NetScaler learns the IP address dynamically.

You can bind both IP-based and DBS members to the same service group.

Note: If you use DBS service group members, make sure that either a name server is specified or a DNS server is configured on the NetScaler. A domain name will be resolved into an IP address only if the corresponding address record is present on the NetScaler or the name server.

## Creating Service Groups

Updated: 2013-09-04

You can configure up to 8192 service groups on the NetScaler appliance.

## To create a service group by using the command line

At the command prompt, type:

```
add servicegroup <ServiceGroupName> <Protocol>
```

### Example

```
add servicegroup Service-Group-1 HTTP
```

## To create a service group by using the configuration utility

Navigate to Traffic Management > Load Balancing > Service Groups, and add a service group.

## Binding a Service Group to a Virtual Server

Updated: 2013-11-12

When you bind a service group to a virtual server, the member services are bound to the virtual server.

## To bind a service group to a virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name>@ <serviceGroupName>
```

### Example

```
bind lb vserver Vserver-LB-1 Service-Group-1
```

## To bind a service group to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Service Groups.

### Binding a Member to a Service Group

Updated: 2013-11-12

Adding services to a service group enables the service group to manage the servers. You can add the servers to a service group by specifying the IP addresses or the names of the servers.

In the configuration utility, if you want to add a domain-name based service group member, select Server Based.

With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.

## To add members to a service group by using the command line interface

To configure a service group, at the command prompt, type:

```
bind servicegroup <serviceGroupName> (<IP>@ | <serverName>) <port>
```

### Examples

```
bind servicegroup Service-Group-1 10.102.29.30 80
```

```
bind servicegroup Service-Group-2 1000:0000:0000:0000:0005:0600:700a:888b 80
```

```
bind servicegroup CitrixEdu s1.citrite.net
```

## To add members to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups and open a service group.
2. Click in the Service Group section, and do one of the following:
  - To add a new IP based service group member, select IP Based.
  - To add a server-name based service group member, select Server Based.

If you want to add a domain-name based service group member, select **Server Based**. With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.

3. If adding a new IP based member, in the IP Address text box, type the IP address. If the IP address uses IPv6 format, select the IPv6 check box and then enter the address in the IP Address text box.

Note: You can add a range of IP addresses. The IP addresses in the range must be consecutive. Specify the range by entering the starting IP address in the IP Address text box (for example, 10.102.29.30). Specify the end byte of the IP address range in the text box under Range (for example, 35). In the Port text box type the port (for example, 80), and then click Add.

4. Click Create.

## Binding a Monitor to a Service Group

Updated: 2013-12-10

When you create a service group, the default monitor of the type appropriate for the group is automatically bound to it. Monitors periodically probe the servers in the service group to which they are bound and update the state of the service groups.

You can bind a different monitor of your own choice to the service group.

### To bind a monitor to a service group by using the command line interface

At the command prompt, type:

```
bind serviceGroup <serviceName> -monitorName <string> -monState (ENABLED | DISABLED)
```

#### **Example**

```
bind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
```

### To a bind monitor to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a service group and, in Advanced Settings, click Monitors.

# Managing Service Groups

Jun 04, 2015

You can change the settings of the services in a service group, and you can perform tasks such as enabling, disabling, and removing service groups. You can also unbind members from a service group.

To manage service groups, see the following sections:

- [Modifying a Service Group](#)
- [Removing a Service Group](#)
- [Unbinding a Member from a Service Group](#)
- [Unbinding a Service Group from a Virtual Server](#)
- [Unbinding Monitors from Service Groups](#)
- [Enabling or Disabling a Service Group](#)
- [Viewing the Properties of a Service Group](#)
- [Viewing Service Group Statistics](#)
- [Load Balancing Virtual Servers Bound to a Service Group](#)

## Modifying a Service Group

Updated: 2013-11-12

You can modify attributes of service group members. You can set several attributes of the service group, such as maximum client, SureConnect, and compression. The attributes are set on the individual servers in the service group. You cannot set parameters on the service group such as transport information (IP address and port), weight, and server ID.

Note: A parameter you set for a service group is applied to the member servers in the group, not to individual services.

## To modify a service group by using the command line interface

At the command prompt, type the following command with one or more of the optional parameters:

```
set servicegroup <serviceGroupName> [-type <type>] [-maxClient <maxClient>] [-maxReq <maxReq>] [-cacheable (YES | NO)] [-cip (ENABLED | DISABLED)] [-cipHeader <cipHeader>] [-usip (YES | NO)] [-sc (ON | OFF)] [-sp (ON | OFF)] [-cltTimeout <cltTimeout>] [-svrTimeout <svrTimeout>] [-cka (YES | NO)] [-TCPB (YES | NO)] [-CMP (YES | NO)] [-maxBandwidth <maxBandwidth>] [-maxThreshold <maxThreshold>] [-state (ENABLED | DISABLED)] [-downStateFlush (ENABLED | DISABLED)]
```

### Example

```
set servicegroup Service-Group-1 -type TRANSPARENT
```

```
set servicegroup Service-Group-1 -maxClient 4096
```

```
set servicegroup Service-Group-1 -maxReq 16384
```

```
set servicegroup Service-Group-1 -cacheable YES
```

## To modify a service group by using the configuration utility

Navigate to Traffic Management > Load Balancing > Service Groups, and open the service group to modify.

## Removing a Service Group

Updated: 2013-09-04

When you remove a service group, the servers bound to the group retain their individual settings and continue to exist on the NetScaler.

## To remove a service group by using the command line interface

At the command prompt, type:

```
rm servicegroup <ServiceGroupName>
```

### **Example**

```
rm servicegroup Service-Group-1
```

## To remove a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and click Delete.

### Unbinding a Member from a Service Group

Updated: 2013-11-12

When you unbind a member from the service group, the attributes set on the service group will no longer apply to the member that you unbound. The member services retains its individual settings, however, and continues to exist on the NetScaler.

## To unbind members from a service group by using the command line interface

At the command prompt, type:

```
unbind servicegroup <serviceGroupName> <IP>@ [<port>]
```

### **Example**

```
unbind servicegroup Service-Group-1 10.102.29.30 80
```

## To unbind members from a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a service group, and click in the Service Group Members section.
3. Select a service group member, and click Unbind.

### Unbinding a Service Group from a Virtual Server

Updated: 2013-11-12

When you unbind a service group from a virtual server, the member services are unbound from the virtual server and continue to exist on the NetScaler appliance.

## To unbind a service group from a virtual server by using the command line interface

At the command prompt, type:

```
unbind lb vserver <name>@ <ServiceGroupName>
```

### Example

```
unbind lb vserver Vserver-LB-1 Service-Group-1
```

## To unbind a service group from a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open the virtual server, and click in the Service Group section.
3. Select the service group, and click Unbind.

### Unbinding Monitors from Service Groups

Updated: 2013-12-10

When you unbind a monitor from a service group, the monitor that you unbound no longer monitors the individual services that constitute the group.

## To unbind a monitor from a service group using the command line interface

At the command prompt, type:

```
unbind serviceGroup <serviceName> -monitorName <string>
```

### Example

```
unbind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
```

## To unbind a monitor from a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a service group, and click in the Monitors section.
3. Select a monitor, and click Unbind.

### Enabling or Disabling a Service Group

Updated: 2013-09-04

When you enable a service group and the servers, the services belonging to the service group are enabled. Similarly, when a service belonging to a service group is enabled, the service group and the service are enabled. By default, service groups are enabled.

After disabling an enabled service, you can view the service using the configuration utility or the command line to see the amount of time that remains before the service goes DOWN.

## To disable a service group by using the command line interface

At the command prompt, type:

```
disable servicegroup <ServiceGroupName>
```

### Example

```
disable servicegroup Service-Group-1
```

## To disable a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and in the Action list, click Disable.

## To enable a service group by using the command line interface

At the command prompt, type:

```
enable servicegroup <ServiceGroupName>
```

### Example

```
enable servicegroup Service-Group-1
```

## To enable a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and in the Action list, click Enable.

### Viewing the Properties of a Service Group

Updated: 2013-09-04

You can view the following settings of the configured service groups: name, IP address, state, protocol, maximum client connections, maximum requests per connection, maximum bandwidth, and monitor threshold. Viewing the details of the configuration can be helpful for troubleshooting your configuration.

## To view the properties of a service group by using the command line interface

At the command prompt, type one of the following commands to display the group properties or the properties and the group members:

- show servicegroup <ServiceGroupName>
- show servicegroup <ServiceGroupName> -includemembers

### Example

```
show servicegroup Service-Group-1
```

## To view the properties of a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Click the arrow next to the service group.

### Viewing Service Group Statistics

Updated: 2013-09-04

You can view service-group statistical data, such as rate of requests, responses, request bytes, and response bytes. The NetScaler appliance uses the statistics of a service group, such as these, to balance the load on the services.

## To view the statistics of a service group by using the command line interface

At the command prompt, type:

```
stat servicegroup <ServiceGroupName>
```

## Example

```
stat servicegroup Service-Group-1
```

## To view the statistics of a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and click Statistics.

### Load Balancing Virtual Servers Bound to a Service Group

Updated: 2013-09-04

In large-scale deployments, the same service group can be bound to multiple load balancing virtual servers. In such a case, instead of viewing each virtual server to see the service group it is bound to, you can view a list of all the load balancing virtual servers bound to a service group. You can view the following details of each virtual server:

- Name
- State
- IP address
- Port

## To display the virtual servers bound to a service group by using the command line interface

At the command prompt, type the following command to display the virtual servers bound to a service group:

```
show servicegroupbindings <serviceGroupName>
```

Example

```
> show servicegroupbindings SVCGRPDTLS
SVCGRPDTLS - State :ENABLED
1) Test-pers (10.10.10.3:80) - State : DOWN
2) BRVSERV (10.10.1.1:80) - State : DOWN
3) OneMore (10.102.29.136:80) - State : DOWN
4) LBVIP1 (10.102.29.66:80) - State : UP
Done
>
```

## To display the virtual servers bound to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and in the Action list, click Show Bindings.

# Configuring Automatic Domain Based Service Group Scaling

Nov 03, 2016

A domain based service group consists of members whose IP addresses are obtained by resolving the domain names of servers that are bound to the service group. The domain names are resolved by a name server whose details you configure on the appliance. A domain based service group can also include IP-address based members.

The process of name resolution for a domain based server might return more than one IP address. The number of IP addresses in the DNS response is determined by the number of address (A) records configured for the domain name, on the name server. Even if the name resolution process returns multiple IP addresses, only one IP address is bound to the service group. To scale up or scale down a service group, you need to manually bind and unbind additional domain based servers to and from the service group, respectively.

However, you can configure a domain based service group to scale automatically on the basis of the complete set of IP addresses returned by a DNS name server for a domain based server. To configure automatic scaling, when binding a domain based server to a service group, enable the automatic scaling option. Following are the steps for configuring a domain based service group that scales automatically:

- Add a name server for resolving domain names. For more information about configuring a name server on the appliance, see [Adding a Name Server](#).
- Add a domain based server. For information about adding a domain based server, see [Adding a Server](#).
- Add a service group and associate the domain based server to the service group, with the autoscale option set to DNS. For information about adding a service group, see [Configuring Service Groups](#).

When a domain based server is bound to a service group and the automatic scaling option is set on the binding, a UDP monitor and a TCP monitor are automatically created and bound to the domain based server. The two monitors function as resolvers. The TCP monitor is disabled by default, and the appliance uses the UDP monitor to send DNS queries to the name server to resolve the domain name. If the DNS response is truncated (has the TC flag set to 1), the appliance falls back to TCP and uses the TCP monitor to send the DNS queries over TCP. Thereafter, the appliance continues to use only the TCP monitor.

The DNS response from the name server might contain multiple IP addresses for the domain name. With the automatic scaling option set, the appliance polls each of the IP addresses by using the default monitor, and then includes in the service group only those IP addresses that are up and available. After the IP address records expire, as defined by their time-to-live (TTL) values, the UDP monitor (or the TCP monitor, if the appliance has fallen back to using the TCP monitor) queries the name server for domain resolution and includes any new IP addresses in the service group. If an IP address that is part of the service group is not present in the DNS response, the appliance removes that address from the service group after gracefully closing existing connections to the group member, a process during which it does not allow any new connections to be established with the member. If a domain name that resolved successfully in the past results in an NXDOMAIN response, all the service group members associated with that domain are removed.

Static (IP-address based) members and dynamically scaling domain based members can coexist in a service group. You can also bind members with different domain names to a service group with the automatic scaling option set. However, each domain name associated with a service group must be unique within the service group. You must enable the automatic scaling option for each domain based server that you want to use for automatic service group scaling. If an IP address is common to one or more domains, the IP address is added to the service group only once.

To configure a service group to scale automatically by using the command line interface

At the command prompt, type the following commands to configure the service group and verify the configuration:

- add serviceGroup <serviceGroupName> <serverName> <port> -autoScale **(YES | NO)**
- show serviceGroup <serviceGroupName>

## Example

In the following example, server1 is a domain based server. The DNS response contains multiple IP addresses. Five addresses are available and are added to the service group.

```
> add serviceGroup servGroup server1 80 -autoScale YES
Done
> sh servicegroup servGroup
servGroup - HTTP
State: ENABLED Monitor Threshold : 0
...
...
1) 192.0.2.31:80 State: UP Server Name: server1 (Auto scale) Server ID: None Weight: 1

Monitor Name: tcp-default State: UP
Probes: 2 Failed [Total: 0 Current: 0]
Last response: Success - TCP syn+ack received.

2) 192.0.2.32:80 State: UP Server Name: server1 (Auto scale) Server ID: None Weight: 1

Monitor Name: tcp-default State: UP
Probes: 2 Failed [Total: 0 Current: 0]
Last response: Success - TCP syn+ack received.

3) 192.0.2.36:80 State: UP Server Name: server1 (Auto scale) Server ID: None Weight: 1

Monitor Name: tcp-default State: UP
Probes: 2 Failed [Total: 0 Current: 0]
Last response: Success - TCP syn+ack received.

4) 192.0.2.55:80 State: UP Server Name: server1 (Auto scale) Server ID: None Weight: 1

Monitor Name: tcp-default State: UP
Probes: 2 Failed [Total: 0 Current: 0]
Last response: Success - TCP syn+ack received.

5) 192.0.2.80:80 State: UP Server Name: server1 (Auto scale) Server ID: None Weight: 1

Monitor Name: tcp-default State: UP
Probes: 2 Failed [Total: 0 Current: 0]
Last response: Success - TCP syn+ack received.
```

Done

To configure a service group to scale automatically by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Create a service group, and set the autoscale mode to DNS.

# Translating the IP Address of a Domain-Based Server

Nov 12, 2013

To simplify maintenance on the NetScaler appliance and on the domain-based servers that are connected to it, you can configure IP address masks and translation IP addresses. These functions work together to parse incoming DNS packets and substitute a new IP address for a DNS-resolved IP address.

When configured for a domain-based server, IP address translation enables the appliance to locate an alternate server IP address in the event that you take the server down for maintenance or if you make any other infrastructure changes that affect the server.

When configuring the mask, you must use standard IP mask values (a power of two, minus one) and zeros, for example, 255.255.0.0. Non-zero values are only permitted in the starting octets.

When you configure a translation IP for a server, you create a 1:1 correspondence between a server IP address and an alternate server that shares leading or trailing octets in its IP address. The mask blocks particular octets in the original server's IP address. The DNS-resolved IP address is transformed to a new IP address by applying the translation IP address and the translation mask.

For example, you can configure a translation IP address of 10.20.0.0 and a translation mask of 255.255.0.0. If a DNS-resolved IP address for a server is 40.50.27.3, this address is transformed to 10.20.27.3. In this case, the translation IP address supplies the first two octets of the new address, and the mask passes through the last two octets from the original IP address. The reference to the original IP address, as resolved by DNS, is lost. Monitors for all services to which the server is bound also report on the transformed IP address.

When configuring a translation IP address for a domain-based server, you specify a mask and an IP address to which the DNS-resolved IP address is to be translated.

Note: Translation of the IP address is only possible for domain-based servers. You cannot use this feature for IP-based servers. The address pattern can be based on IPv4 addresses only.

To configure a translation IP address for a server by using the command line interface

At the command prompt, type:

```
add server <name>@ <serverDomainName> -translationIp <translationIPAddress> -translationMask <netMask> -state <ENABLED | DISABLED>
```

## Example

```
add server myMaskedServer www.example.com -translationIp 10.10.10.10 -translationMask 255.255.0.0 -state ENABLED
```

To configure a translation IP address for a server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Servers, create a domain-based server, and specify a translation IP address.

# Masking a Virtual Server IP Address

Nov 12, 2013

You can configure a mask and a pattern instead of a fixed IP address for a virtual server. This enables traffic that is directed to any of the IP addresses that match the mask and pattern to be rerouted to a particular virtual server. For example, you can configure a mask that allows the first three octets of an IP address to be variable, so that traffic to 111.11.11.198, 22.22.22.198, and 33.33.33.198 is all sent to the same virtual server.

By configuring a mask for a virtual server IP address, you can avoid reconfiguration of your virtual servers due to a change in routing or another infrastructure change. The mask allows the traffic to continue to flow without extensive reconfiguration of your virtual servers.

The mask for a virtual server IP address works somewhat differently from the IP pattern definition for a server described in [Translating the IP Address of a Domain-Based Server](#). For a virtual server IP address mask, a non-zero mask is interpreted as an octet that is considered. For a service, the non-zero value is blocked.

Additionally, for a virtual server IP address mask, either leading or trailing values can be considered. If the virtual server IP address mask considers values from the left of the IP address, this is known as a forward mask. If the mask considers the values to the right side of the address, this is known as a reverse mask.

Note: The NetScaler appliance evaluates all forward mask virtual servers before evaluating reverse mask virtual servers. When masking a virtual server IP address, you also need to create an IP address pattern for matching incoming traffic with the correct virtual server. When the appliance receives an incoming IP packet, it matches the destination IP address in the packet with the bits that are considered in the IP address pattern, and after it finds a match, it applies the IP address mask to construct the final destination IP address.

Consider the following example:

- Destination IP address in the incoming packet: 10.102.27.189
- IP address pattern: 10.102.0.0
- IP mask: 255.255.0.0
- Constructed (final) destination IP address: 10.102.27.189.

In this case, the first 16 bits in the original destination IP address match the IP address pattern for this virtual server, so this incoming packet is routed to this virtual server.

If a destination IP address matches the IP patterns for more than one virtual server, the longest match takes precedence. Consider the following example:

- Virtual Server 1: IP pattern 10.10.0.0, IP mask 255.255.0.0
- Virtual Server 2: IP pattern 10.10.10.0, IP mask 255.255.255.0
- Destination IP address in the packet: 10.10.10.45.
- Selected virtual server: Virtual Server 2.

The pattern associated with Virtual Server 2 matches more bits than that associated with Virtual Server 1, so IPs that match it will be sent to Virtual Server 2.

Note: Ports are also considered if a tie-breaker is required.

To configure a virtual server IP address mask by using the command line interface

At the command prompt, type:

```
add lb vserver <name>@ http -ipPattern <ipAddressPattern> -ipMask <ipMask> <listenPort>
```

**Example**

Pattern matching based on prefix octets:

```
add lb vserver myLBVserver http -ippattern 10.102.0.0 -ipmask 255.255.0.0 80
```

Pattern matching based on trailing octets:

```
add lb vserver myLBVserver1 http -ippattern 0.0.22.74 -ipmask 0.0.255.255 80
```

Modify a pattern-based virtual server:

```
set lb vserver myLBVserver1 -ippattern 0.0.22.74 -ipmask 0.0.255.255
```

To configure a virtual server IP address mask by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Address Type list, select IP Pattern, and specify an IP pattern and IP mask.

# Configuring Load Balancing for Commonly Used Protocols

Jun 05, 2015

In addition to Web sites and Web-based applications, other types of network-deployed applications that use other common protocols often receive large amounts of traffic and therefore benefit from load balancing. Several of these protocols require specific configurations for load balancing to work properly. Among them are FTP, DNS, SIP, and RTSP.

If you configure your NetScaler appliance to use domain names for your servers rather than IPs, you may also need to set up IP translation and masking for those servers.

To configure load balancing for commonly used protocols, see the following sections:

- [Load Balancing for a Group of FTP Servers](#)
- [Load Balancing DNS Servers](#)
- [Load Balancing Domain-Name Based Services](#)
- [Load Balancing a Group of SIP Servers](#)
- [Load Balancing RTSP Servers](#)
- [Load Balancing of Remote Desktop Protocol \(RDP\) Servers](#)

# Load Balancing for a Group of FTP Servers

Feb 11, 2015

The NetScaler appliance can be used to load balance FTP servers. FTP requires that the user initiate two connections on two different ports to the same server: the control connection, through which the client sends commands to the server, and the data connection, through which the server sends data to the client. When the client initiates an FTP session by opening a control connection to the FTP server, the appliance uses the configured load balancing method to select an FTP service, and forwards the control connection to it. The load balanced FTP server then opens a data connection to the client for information exchange.

The following diagram describes the topology of a load balancing configuration for a group of FTP servers.

Figure 1. Basic Load Balancing Topology for FTP Servers

In the diagram, the services Service-FTP-1, Service-FTP-2, and Service-FTP-3 are bound to the virtual server Vserver-LB-1. Vserver-LB-1 forwards the client's connection request to one of the services using the least connection load balancing method. Subsequent requests are forwarded to the service that the appliance initially selected for load balancing.

The following table lists the names and values of the basic entities configured on the appliance.

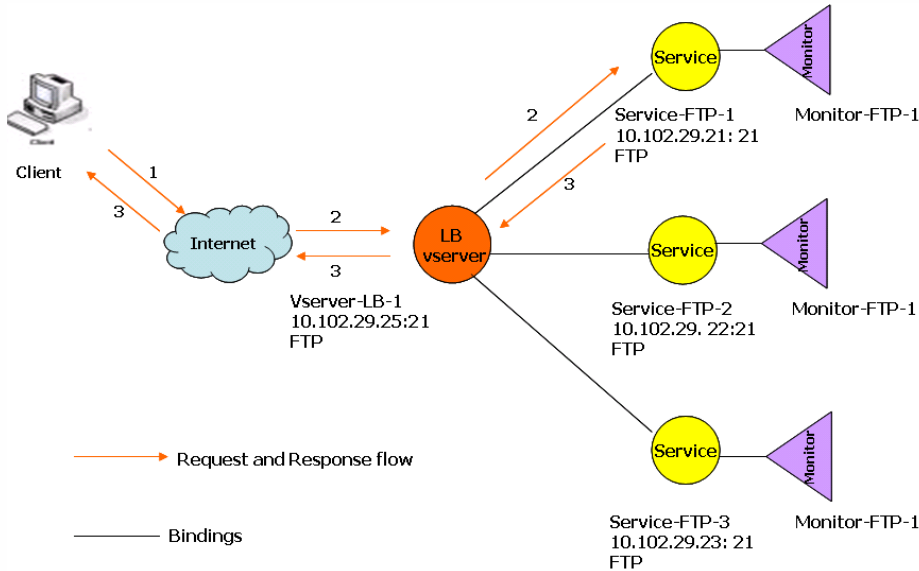

| Entity type | Name          | IP address   | Port | Protocol |
|-------------|---------------|--------------|------|----------|
| Vserver     | Vserver-LB-1  | 10.102.29.25 | 21   | FTP      |
| Services    | Service-FTP-1 | 10.102.29.21 | 21   | FTP      |
|             | Service-FTP-2 | 10.102.29.22 | 21   | FTP      |
|             | Service-FTP-3 | 10.102.29.23 | 21   | FTP      |

| Entity type | Name | IP address | Port | Protocol |
|-------------|------|------------|------|----------|
| Monitors    | FTP  | None       | None | None     |

The following diagram shows the load balancing entities, and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing FTP Servers Entity Model

The appliance can also provide a passive FTP option to access FTP servers from outside of a firewall. When a client uses the passive FTP option and initiates a control connection to the FTP server, the FTP server also initiates a control connection to the client. It then initiates a data connection to transfer a file through the firewall.

To create services and virtual servers of type FTP, see [Setting Up Basic Load Balancing](#). Name the entities and set the parameters to the values described in the columns of the previous table. When you configure a basic load balancing setup, a default monitor is bound to the services.

Next, bind the FTP monitor to the services by following the procedure described in the section [Binding Monitors to Services](#).

To create FTP monitors by using the command line interface

At the command prompt, type:

```
add lb monitor <MonitorName> FTP -interval <Interval> -userName <UserName> -password <Password>
```

**Example**

```
add lb monitor monitor-FTP-1 FTP -interval 360 -userName User -password User
```

To create FTP monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor of type FTP, and in Special Parameters, specify a user name and password.

# Load Balancing DNS Servers

Sep 03, 2013

When you request DNS resolution of a domain name, the NetScaler appliance uses the configured load balancing method to select a DNS service. The DNS server to which the service is bound then resolves the domain name and returns the IP address as the response. The appliance can also cache DNS responses and use the cached information to respond to future requests for resolution of the same domain name. Load balancing DNS servers improves DNS response times.

The following diagram describes the topology of a load balancing configuration that load balances a group of DNS services.

Figure 1. Basic Load Balancing Topology for DNS Servers

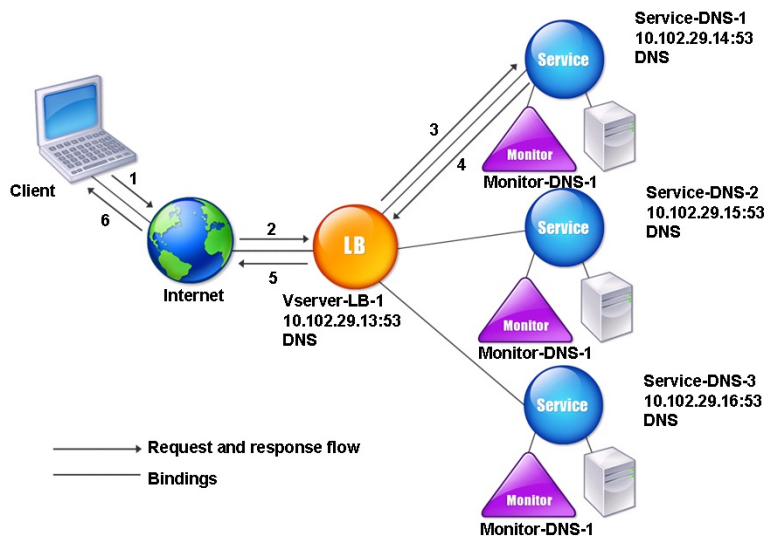

In the diagram, the services Service-DNS-1, Service-DNS-2, and Service-DNS-3 are bound to the virtual server Vserver-LB-1. The virtual server Vserver-LB-1 forwards client requests to a service using the least connection load balancing method. The following table lists the names and values of the basic entities configured on the appliance.

| Entity type    | Name          | IP address   | Port | Protocol |
|----------------|---------------|--------------|------|----------|
| Virtual Server | Vserver-LB-1  | 10.102.29.13 | 53   | DNS      |
| Services       | Service-DNS-1 | 10.102.29.14 | 53   | DNS      |
|                | Service-DNS-2 | 10.102.29.15 | 53   | DNS      |
|                | Service-DNS-3 | 10.102.29.16 | 53   | DNS      |
| Monitors       | monitor-DNS-1 | None         | None | None     |

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DNS Servers Entity Model

To configure a basic DNS load balancing setup, see [Setting Up Basic Load Balancing](#). Follow the procedures to create services and virtual servers of type DNS, naming the entities and setting the parameters using the values described in the previous table. When you configure a basic load balancing setup, the default ping monitor is bound to the services. For instructions on binding a DNS monitor to DNS services, you can also see [Binding Monitors to Services](#).

The following procedure describes the steps to create a monitor that maps a domain name to the IP address based on a query.

To configure DNS monitors by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> DNS -query <domainName> -queryType <Address | ZONE> -IPAddress <ipAddress>
```

**Example**

```
add lb monitor monitor-DNS-1 DNS -query www.citrix.com -queryType Address -IPAddress 10.102.29.66
```

```
add lb monitor monitor-DNS-2 DNS -query www.citrix2.com -queryType Address -IPAddress 1000:0000:0000:0000:0005:0600:700a::888b-888d
```

To configure DNS monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor of type DNS, and in Special Parameters, specify a query and query type.

# Load Balancing Domain-Name Based Services

Aug 06, 2017

When you create a service for load balancing, you can provide an IP address. Alternatively, you can create a server using a domain name. The server name (domain name) can be resolved using an IPv4 or IPv6 name server, or by adding an authoritative DNS record (A record for IPv4 or AAAA record for IPv6) to the NetScaler configuration.

When you configure services with domain names instead of IP addresses, and if the name server resolves the domain name to a new IP address, the monitor bound to the service runs a health check on the new IP address, and updates the service IP address only when the IP address is found to be healthy. The monitor could be the default monitor bound to the service or you can bind any other supported monitor. It probes the service at regular intervals defined in the monitor parameters. If the domain name resolves to a new IP address, the monitor sends a fresh probe to check the health of the service. All subsequent probes are at the predefined interval.

Note: When you change the IP address of a server, the corresponding service is marked down for the first client request. The name server resolves the service IP address to the changed IP address for the next request, and the service is marked UP.

Domain-name based services have the following restrictions:

- The maximum domain name length is 255 characters.
- The Maximum Client parameter is used to configure a service that represents the domain name-based server. For example, a maxClient of 1000 is set for the services bound to a virtual server. When the connection count at the virtual server reaches 2000, the DNS resolver changes the IP address of the services. However, because the connection counter on the service is not reset, the virtual server cannot take any new connections until all the old connections are closed.
- When the IP address of the service changes, persistence is difficult to maintain.
- If the domain name resolution fails due to a timeout, the appliance uses the old information (IP address).
- When monitoring detects that a service is down, the appliance performs a DNS resolution on the service (representing the domain name-based server) to obtain a new IP address.
- Statistics are collected on a service and are not reset when the IP address changes.
- If a DNS resolution returns a code of "name error" (3), the appliance marks the service down and changes the IP address to zero.

When the appliance receives a request for a service, it selects the target service. This way, the appliance balances load on your services. The following diagram describes the topology of a load balancing configuration that load balances a group of domain-name based servers (DBS).

Figure 1. Basic Load Balancing Topology for DBS Servers

The services Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 are bound to the virtual server Vserver-LB-1. The vserver Vserver-LB-1 uses the least connection load balancing method to choose the service. The IP address of the service is resolved using the name server Vserver-LB-2.

The following table lists the names and values of the basic entities configured on the appliance.

| Entity type    | Name           | IP address     | Port | Protocol |
|----------------|----------------|----------------|------|----------|
| Virtual Server | Vserver-LB-1   | 10.102.29.17   | 80   | HTTP     |
|                | Vserver-LB-2   | 10.102.29.20   | 53   | DNS      |
| Servers        | server-1       | 10.102.29.18   | 80   | HTTP     |
|                | server-2       | www.citrix.com | 80   | HTTP     |
| Services       | Service-HTTP-1 | server-1       | 80   | HTTP     |
|                | Service-HTTP-2 | server-2       | 80   | HTTP     |
|                | Service-HTTP-2 | 10.102.29.19   | 80   | HTTP     |
| Monitors       | Default        | None           | None | None     |
| Name Server    | None           | 10.102.29.19   | None | None     |

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DBS Servers Entity Model

To configure a basic load balancing setup, see [Setting Up Basic Load Balancing](#). Create the services and virtual servers of type HTTP, and name the entities and set the parameters using the values described in the previous table.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

To add a name server by using the command line interface

At the command prompt, type:

```
add dns nameServer <dnsVserverName>
```

#### Example

```
add dns nameServer Vserver-LB-2
```

To add a name server by using the configuration utility

1. Navigate to **Traffic Management > DNS > Name Servers**.
2. Create a DNS name server of type DNS Virtual Server, and select a server from the DNS Virtual Server list.

You can also add an authoritative name server that resolves the domain name to an IP address.

## Note

You can add a name server of type TCP, UDP or UDP\_TCP to resolver DBS probes. However, if TCP and UDP name servers coexists, and a UDP name server receives a response with truncated bit, this response is not retried over TCP name server.

# Load Balancing a Group of SIP Servers

Dec 09, 2014

Note: Support for load balancing SIP traffic over TCP or TLS is available in NetScaler release 10.5.e.

The Session Initiation Protocol (SIP) is designed to initiate, manage, and terminate multimedia communications sessions. It has emerged as the standard for Internet telephony (VoIP). SIP messages can be transmitted over TCP or UDP. SIP messages are of two types: request messages and response messages.

The traffic in a SIP based communication system is routed through dedicated devices and applications (entities). In a multimedia communication session, these entities exchange messages. The following figure shows a basic SIP based communication system:

Figure 1. SIP Based Communication System

A NetScaler ADC enables you to load balance SIP messages over UDP or over TCP (including TLS). You can configure the NetScaler ADC to load balance SIP requests to a group of SIP proxy servers. To do so, you create a load balancing virtual server with the load balancing method and the type of persistence set to one of the following combinations:

- Call-ID hash load balancing method with no persistence setting
- Call-ID based persistence with least connection or round robin load balancing method
- Rule based persistence with least connection or round robin load balancing method

Also, by default, the NetScaler ADC appends RPORT to the via header of the SIP request, so that the server sends the response back to the source IP address and port from which the request originated.

Note: For load balancing to work, you must configure the SIP proxies so that they do not add private IP addresses or private domains to the SIP header/payload. SIP proxies must add to the SIP header a domain name that resolves to the IP address of the SIP virtual server. Also, the SIP proxies must communicate with a common database to share registration information.

## Server Initiated Traffic

For SIP-server initiated outbound traffic, configure RNAT on the NetScaler ADC so that the private IP addresses used by the clients are translated into public IP addresses.

If you have configured SIP parameters that include the RNAT source or destination port, the appliance compares the values of the source and destination ports of the request packets with the RNAT source port and RNAT destination port. If one of the values matches, the appliance updates the VIA header with RPORT. The SIP response from the client then traverses the same path as the request.

For server-initiated SSL traffic, the NetScaler ADC uses a built-in certificate-key pair. If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named **nsrnat sip-127.0.0.1-5061**.

## Support for Policies and Expressions

The NetScaler default expressions language contains a number of expressions that operate on Session Initiation Protocol (SIP) connections. These expressions can be bound only to SIP based (`sip_udp`, `sip_tcp` or `sip_ssl`) virtual servers, and to global bind points. You can use these expressions in content switching, rate limiting, responder, and rewrite policies.

For more information, see [SIP Expressions](#).

## Configuring Load Balancing for SIP Signaling Traffic over TCP or UDP

The NetScaler ADC can load balance SIP servers that send requests over UDP or TCP, including TCP traffic secured by TLS. The ADC provides the following service types to load balance the SIP servers:

- `SIP_UDP` – Used when SIP servers send SIP messages over UDP.
- `SIP_TCP` – Used when SIP servers send SIP messages over TCP.
- `SIP_SSL` – Used to secure SIP signaling traffic over TCP by using SSL or TLS. The NetScaler ADC supports the following modes:
  - End-to-end TLS connection between the client, the ADC, and the SIP server.
  - TLS connection between the client and the ADC, and TCP connection between the ADC and the SIP server.
  - TCP connection between the client and the ADC, and TLS connection between the ADC and the SIP server.

The following figure shows the topology of a setup configured to load balance a group of SIP servers sending SIP messages over TCP or UDP.

Figure 2. SIP Load Balancing Topology

| Entity type    | Name          | IP address   | Port | Service type / Protocol     |
|----------------|---------------|--------------|------|-----------------------------|
| Virtual Server | Vserver-LB-1  | 10.102.29.65 | 80   | SIP_UDP / SIP_TCP / SIP_SSL |
| Services       | Service-SIP-1 | 192.168.1.6  | 80   | SIP_UDP / SIP_TCP / SIP_SSL |
|                | Service-SIP-2 | 192.168.1.5  | 80   | SIP_UDP / SIP_TCP / SIP_SSL |
| Monitors       | Default       | None         | 80   | SIP_UDP / SIP_TCP / SIP_SSL |

Following is an overview of configuring basic load balancing for SIP traffic:

1. Configure services, and configure a virtual server for each type of SIP traffic that you want to load balance:

- **SIP\_UDP** – If you are load balancing the SIP traffic over UDP.
- **SIP\_TCP** – If you are load balancing the SIP traffic over TCP.
- **SIP\_SSL** – If you are load balancing and securing the SIP traffic over TCP.

Note: If you use SIP\_SSL, be sure to create an SSL certificate-key pair. For more information, see Adding a Certificate Key Pair.

2. Bind the services to the virtual servers.

3. If you want to monitor the states of the services with a monitor other than the default (**tcp-default**), create a custom monitor and bind it to the services. The NetScaler ADC provides two custom monitor types, **SIP-UDP** and **SIP-TCP**, for monitoring SIP services.

4. If using a SIP\_SSL virtual server, bind an SSL certificate-key pair to the virtual server.

5. If you are using the NetScaler ADC as the gateway for the SIP servers in your deployment, configure RNAT.
6. If you want to append RPORT to the SIP messages that are initiated from the SIP server, configure the SIP parameters.

To configure a basic load balancing setup for SIP traffic by using the command line interface

1. Create one or more services. At the command prompt, type:  
add service <name> <serverName> (SIP\_UDP | SIP\_TCP | SIP\_SSL) <port>

**Example**

```
add service Service-SIP-UDP-1 192.0.2.5 SIP_UDP 80
```

2. Create as many virtual servers as necessary to handle the services that you created. The virtual server type must match the type of services that you will bind to it. At the command prompt, type:  
add lb vserver <name> <serverName> (SIP\_UDP | SIP\_TCP | SIP\_SSL) <port>

**Example**

```
add lb vserver Vserver-LB-1 SIP_UDP 10.102.29.60 80
```

3. Bind each service to a virtual server. At the command prompt, type:  
bind lb vserver <name> <serverName>

**Example**

```
bind lb vserver Vserver-LB-1 Service-SIP-UDP-1
```

4. (Optional) Create a custom monitor of type SIP-UDP or SIP-TCP, and bind the monitor to the service. At the command prompt, type:  
add lb monitor <monitorName> <monitorType> [<interval>]

```
bind lb monitor <monitorName> <ServiceName>
```

**Example**

```
add lb monitor mon1 sip-UDP -sipMethod REGISTER -sipURI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200
```

```
bind monitor mon1 Service-SIP-UDP-1
```

5. If you created a SIP\_SSL virtual server, bind an SSL certificate key pair to the virtual server. At the command prompt, type: At the command prompt, type:  
bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -CA -skipCAName

**Example**

```
bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1
```

6. Configure RNAT as required by your network topology. At the command prompt, type one of the following commands to create, respectively, an RNAT entry that uses a network address as the condition and a MIP or SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a MIP or SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:

```
set nat <IPAddress> <netmask>
```

```
set nat <IPAddress> <netmask> -natip <NATIPAddress>
```

```
set nat <aclname> [-redirectPort <port>]
```

```
set nat <aclname> [-redirectPort <port>] -natIP <NATIPAddress>
```

#### Example

```
set nat 192.168.1.0 255.255.255.0 -natip 10.102.29.50
```

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named **nsrnatsip-127.0.0.1-5061**.

```
add ssl certKey <certkeyName> -cert <string> [-key <string>]
```

```
bind ssl service <serviceName> -certkeyName <string>
```

#### Example

```
add ssl certKey c1 -cert cert.epm -key key.ky
```

```
bind ssl service nsrnatsip-127.0.0.1-5061 -certkeyName c1
```

7. If you want to append RPORT to the SIP messages that the SIP server initiates, type the following command at the command prompt:

```
set lb sipParameters -natSrcPort <natSrcPort> -natDstPort<natDstPort> -retryDur <integer> -addRportVip <addRportVip> - sip503RateThreshold <sip503_rate_threshold_value>
```

#### Sample Configuration for load balancing the SIP traffic over UDP

```
> add service service-UDP-1 10.102.29.5 SIP_UDP 80
```

Done

```
> add lb vserver vserver-LB-1 SIP_UDP 10.102.29.60 80
```

Done

```
> bind lb vserver vserver-LB-1 service-UDP-1
```

Done

```
> add lb mon mon1 sip-udp -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200
```

Done

```
> bind mon mon1 service-UDP-1
```

Done

```
> set nat 192.168.1.0 255.255.255.0
```

Done

```
> set lb sipParameters -natSrcPort 5060 -natDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 1000
```

Done

## Sample Configuration for load balancing the SIP traffic over TCP

```
> add service service-TCP-1 10.102.29.5 SIP_TCP 80
```

Done

```
> add lb vserver vserver-LB-1 SIP_TCP 10.102.29.60 80
```

Done

```
> bind lb vserver vserver-LB-1 service-TCP-1
```

Done

```
> add lb mon mon1 sip-tcp -sipMethod REGISTER -sipURI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200
```

Done

```
> bind mon mon1 service-TCP-1
```

Done

```
> set nat 192.168.1.0 255.255.255.0
```

Done

```
> set lb sipParameters -natSrcPort 5060 -natDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 1000
```

Done

## Sample Configuration for load balancing and securing SIP traffic over TCP

```
> add service service-SIP-SSL-1 10.102.29.5 SIP_SSL 80
```

Done

```
> add lb vserver vserver-LB-1 SIP_SSL 10.102.29.60 80
```

Done

```
> bind lb vserver vserver-LB-1 service-SIP-SSL
```

Done

```
> add lb mon mon1 sip-tCP -sipMethod REGISTER -sipURI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200
```

Done

```
> bind mon mon1 service-SIP-SSL
```

Done

```
> bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1
```

Done

```
> set nat 192.168.1.0 255.255.255.0
```

Done

```
> set lb sipParameters -natSrcPort 5060 -natDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 1000
```

Done

To configure a basic load balancing setup for SIP traffic by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a virtual server of type SIP\_UDP, SIP\_TCP, or SIP\_SSL.
2. Click the Service section, and add a service of type SIP\_UDP, SIP\_TCP, or SIP\_SSL.
3. (Optional) Click the Monitor section, and add a monitor of type: SIP-UDP or SIP-TCP.
4. Bind the monitor to the service, and bind the service to the virtual server.
5. If you created a SIP\_SSL virtual server, bind an SSL certificate key pair to the virtual server. Click the Certificates section, and bind a certificate key pair to the virtual server.
6. Configure RNAT as required by your network topology. To configure RNAT:
  1. Navigate to System > Network > Routes.
  2. On the Routes page, click the RNAT tab.
  3. In the details pane, click Configure RNAT.
  4. In the Configure RNAT dialog box, do one of the following:
    - If you want to use the network address as a condition for creating an RNAT entry, click Network and set the following parameters:
      - Network
      - Netmask
    - If you want to use an extended ACL as a condition for creating an RNAT entry, click ACL and set the following parameters:
      - ACL Name
      - Redirect Port
  5. To set a MIP or SNIP address as a NAT IP address, skip to step 7.
  6. To set a unique IP address as a NAT IP, in the Available NAT IP (s) list, select the IP address that you want to set as the NAT IP, and then click Add. The NAT IP you selected appears in the Configured NAT IP(s) list.
  7. Click Create, and then click Close.

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named **nsmratsip-127.0.0.1-5061**. To bind the pair:

1. Navigate to Traffic Management > Load Balancing > Services and click the Internal Services tab.
2. Select nsmratsip-127.0.0.1-5061 and click **Edit**.
3. Click the **Certificates** section and bind a certificate key pair to the internal service.
7. If you want to append RPORT to the SIP messages that the SIP server initiates, configure the SIP parameters. Navigate to Traffic Management > Load Balancing and click Change SIP settings, set the various SIP parameters.

## SIP Expression and Policy Example: Compression Enabled in Client Requests

A NetScaler ADC cannot process compressed client SIP requests, so the client SIP request fails.

You can configure a responder policy that intercepts the SIP NEGOTIATE message from the client and looks for the compression header. If the message includes a compression header, the policy responds with "400 Bad Request," so that

the client resends the request without compressing it.

At the command prompt, type the following commands to create the responder policy:

```
> add responder action sipaction1 respondwith q{"SIP/2.0 400 Bad Request\r\n\r\n"}
```

Done.

```
> add responder policy sippol1
```

```
> add responder policy sippol1 "SIP.REQ.METHOD.EQ(\"NEGOTIATE\")&&SIP.REQ.HEADER(\"Compression\").EXISTS"
sipaction1
```

# Load Balancing RTSP Servers

Nov 12, 2013

The NetScaler appliance can balance load on RTSP servers to improve the performance of audio and video streams over networks. The following diagram describes the topology of an load balancing setup configured to load balance a group of RTSP servers.

Figure 1. Load Balancing Topology for RTSP

In the example, the services Service-RTSP-1, Service-RTSP-2, and Service-RTSP-3 are bound to the virtual server Vserver-LB-1. The following table lists the names and values of the example entities.

| Entity type    | Name           | IP address    | Port | Protocol |
|----------------|----------------|---------------|------|----------|
| Virtual Server | Vserver-LB-1   | 10.102.29.100 | 554  | RTSP     |
| Services       | Service-RTSP-1 | 10.102.29.101 | 554  | RTSP     |
|                | Service-RTSP-2 | 10.102.29.102 | 554  | RTSP     |
|                | Service-RTSP-3 | 10.102.29.103 | 554  | RTSP     |
| Monitors       | Monitor-RTSP-1 | None          | 554  | RTSP     |

The following diagram shows the load balancing entities used in RTSP configuration.

Figure 2. Load Balancing RTSP Servers Entity Model

To configure a basic load balancing setup for RTSP servers, see [Setting Up Basic Load Balancing](#). Create services and virtual servers of type RTSP. When you configure a basic load balancing setup, the default TCP-default monitor is bound to the services. To bind an RTSP monitor to these services, see [Binding Monitors to Services](#). The following procedure describes how create a monitor that checks RTSP servers.

To configure RTSP monitors by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> <type>
```

**Example**

```
add lb monitor Monitor-RTSP-1 RTSP
```

To configure RTSP monitors by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type RTSP.

# Load Balancing of Remote Desktop Protocol (RDP) Servers

Jun 28, 2017

Remote Desktop Protocol (RDP) is a multichannel-capable protocol that allows for separate virtual channels for carrying presentation data, serial device communication, licensing information, highly encrypted data (keyboard and mouse activity), and so on.

RDP is used for providing a graphical user interface to another computer on the network. RDP is used with Windows terminal servers for providing fast access with almost real-time transmission of mouse movements and key presses even over low-bandwidth connections.

When multiple terminal servers are deployed to provide remote desktop services, the NetScaler appliance provides load balancing of the terminal servers (Windows 2003 and 2008 Server Enterprise Editions). In some cases, a user who is accessing an application remotely may want to leave the application running on the remote machine but shut down the local machine. The user therefore closes the local application without logging out of the remote application. After reconnecting to the remote machine, the user should be able to continue with the remote application. To provide this functionality, the NetScaler RDP implementation honors the routing token (cookie) set by the Terminal Services Session Directory or Broker so that the client can reconnect to the same terminal server to which it was connected previously. The Session Directory, implemented on Windows 2003 Terminal Server, is referred to as Broker on Windows 2008 Terminal Server.

When a TCP connection is established between the client and the load balancing virtual server, the NetScaler applies the specified load balancing method and forwards the request to one of the terminal servers. The terminal server checks the session directory to determine whether the client has a session running on any other terminal server in the domain.

If there is no active session on any other terminal server, the terminal server responds by serving the client request, and the NetScaler forwards the response to the client.

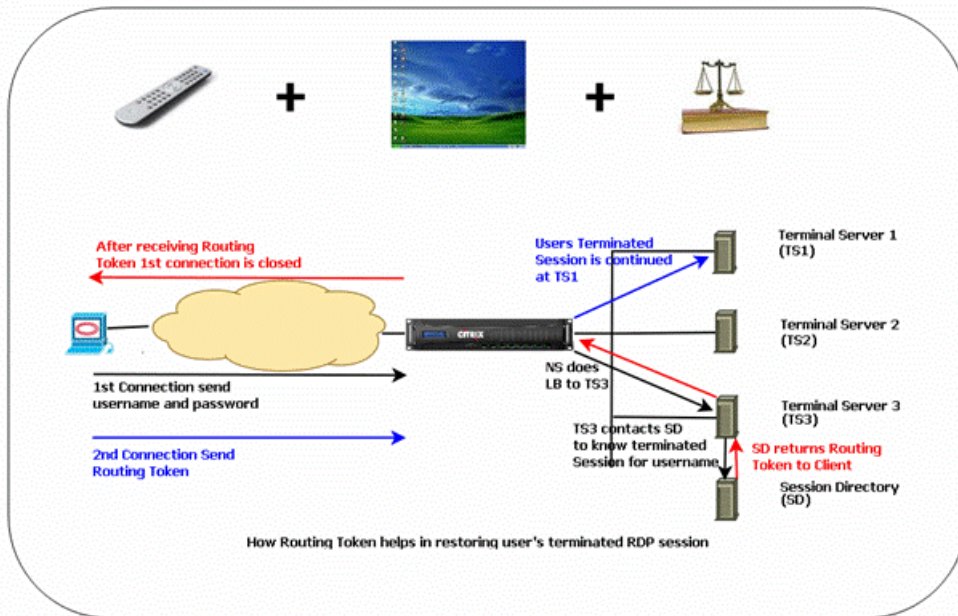

If there is an active session on any other terminal server, the terminal server that receives the request inserts a cookie (referred to as routing token) with the details of the active session and returns the packets to the NetScaler, which returns the packet to the client. The server closes the connection with the client. When the client retries to connect, the NetScaler reads the cookie information and forwards the packet to the terminal server on which the client has an active session.

The user on the client machine experiences a continuation of the service and does not have to take any specific action.

Note: The Windows Session Directory feature requires the Remote Desktop client that was first released with Windows XP. If a session with a Windows 2000 or Windows NT 4.0 Terminal Server client is disconnected and the client reconnects, the server with which the connection is established is selected by the load balancing algorithm.

The following diagram describes RDP load balancing.

Figure 1. Load Balancing Topology for RDP

## Note

- When an RDP service is configured, persistence is automatically maintained by using a routing token. You need not enable persistence explicitly.
- The NetScaler appliance supports only IP-based cookies.

Ensure that the disconnected RDP sessions are cleared on the terminal servers at the backend to avoid flapping between two terminal servers when an RDP session is disconnected without logging out. For more information, see [http://technet.microsoft.com/en-us/library/cc758177\(WS.10\).aspx#BKMK\\_2](http://technet.microsoft.com/en-us/library/cc758177(WS.10).aspx#BKMK_2)

When you add an RDP service, by default, NetScaler adds a monitor of the type TCP and binds it to the service. The default monitor is a simple TCP monitor that checks whether or not a listening process exists at the 3389 port on the server specified for the RDP service. If there is a listening process at 3389, NetScaler marks this service as UP and if there is no listening process, it marks the service as DOWN.

For more efficient monitoring of an RDP service, in addition to the default monitor, you can configure a script monitor that is meant for the RDP protocol. When you configure the scripting monitor, the NetScaler opens a TCP connection to the specified server and sends an RDP packet. The monitor marks the service as UP only if it receives a confirmation of the connection from the physical server. Therefore, from the scripting monitor, the NetScaler can know whether the RDP service is ready to service a request.

The monitor is a user-type monitor and the script is located on the NetScaler at `/nsconfig/monitors/nsrdp.pl`. When you configure the user monitor, the NetScaler runs the script automatically. To configure the scripting monitor, add the monitor and bind it to the RDP service.

To configure RDP load balancing, create services of type RDP and bind them to an RDP virtual server.

To configure RDP load balancing services by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing setup and verify the configuration:

```
add service <name>@ <serverName> <serviceType> <port>
```

Note: Repeat the above command to add more services.

Example

```
> add service ser1 10.102.27.182 RDP 3389
```

```
Done
```

```
> add service ser2 10.102.27.183 RDP 3389
```

```
Done
```

```
>show service ser1
```

```
ser1 (10.102. 27.182:3389) - RDP
```

```
State: UP
```

```
...
```

```
Server Name: 10.102.27.182
```

```
Server ID : 0 Monitor Threshold : 0
```

```
Down state flush: ENABLED
```

```
...
```

```
1) Monitor Name: tcp-default
```

```
State: UP Weight: 1
```

```
...
```

```
Response Time: 4.152 millisec
```

```
Done
```

To configure RDP load balancing services by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create services of type RDP.

To configure an RDP load balancing virtual server by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing virtual server and verify the configuration:

- add lb vserver <name>@ <serviceType> <ipAddress> <port>

- bind lb vserver <name>@ <serviceName>

Bind all the RDP services to be load balanced to the virtual server.

### Example

This example has two RDP services bound to the RDP virtual server.

```
> add lb vs v1 rdP 10.102.27.186 3389
```

```
Done
```

```
> bind lb vs v1 ser1
```

```
service "ser1" bound
> bind lb vs v1 ser2
service "ser2" bound
Done
```

```
>sh lb vs v1
v1 (10.102.27.186:3389) - RDP Type: ADDRESS
State: UP
...
No. of Bound Services : 2 (Total) 2 (Active)
Configured Method: LEASTCONNECTION
Current Method: Round Robin, Reason: A new service is bound
Mode: IP
Persistence: NONE
L2Conn: OFF
```

```
1) ser1 (10.102.27.182: 3389) - RDPState: UP Weight: 1
2) ser2 (10.102.27.183: 3389) - RDPState: UP Weight: 1
Done
```

To configure an RDP load balancing virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, create a virtual server of type RDP, and bind RDP services to this virtual server.

To configure a scripting monitor for RDP services by using the command line interface

At the command prompt, type the following commands:

- add lb monitor <monitorName> USER -scriptName nsrdp.pl
- bind lb monitor <monitorName> <rdpServiceName>

## Example

```
add service ser1 10.102.27.182 RDP 3389
add lb monitor RDP_MON USER -scriptName nsrdp.pl
bind lb monitor RDP_MON ser1
```

To configure a scripting monitor for RDP services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type USER.
2. In Special Parameters, in the Script Name list, select nsrdp.pl, and then bind this monitor to an RDP service.

# Use Case 1: SMPP Load Balancing

Feb 17, 2016

Note: This feature is available in NetScaler release 10.5.e.

Millions of short messages are exchanged daily between individuals and value-added service providers, such as banks, advertisers, and directory services, by using the short message peer to peer (SMPP) protocol. Often, message delivery is delayed because servers are overloaded and traffic is not optimally distributed among the servers. The NetScaler ADC supports SMPP load balancing and provides optimal distribution of messages across your servers, preventing poor performance and outages.

The NetScaler ADC performs load balancing on the server side when messages are received from clients and on the client side when messages are received from servers.

Load balancing of SMPP messages by the NetScaler ADC provides the following benefits:

- Better load distribution on servers, which translates to faster response time to end users
- Server health monitoring and better failover capabilities
- Quick and easy addition of new servers (message centers) without changing the client configuration
- High availability

## Introduction to SMPP

SMPP is an application layer protocol for transfer of short messages between External Short Message Entities (ESME), Routing Entities (RE) and Message Centers (MC) over long-lived TCP connections. It is used for sending short message service (SMS) messages between friends, contacts, and third parties such as banks (mobile banking), advertisers (mobile commerce), and directory services. Messages from an ESME (non-mobile entity) arrive at the MC, which distributes them to short message entities (SMEs) such as mobile phones. SMPP is also used by SMEs to send short messages to third parties (for example, for purchase of products, bill payment, and funds transfer). These messages arrive at the MC and are forwarded to the destination MC or ESME.

The following diagram shows the different SMPP entities: ESMEs, REs, and MCs, in a mobile network.

## Architecture Overview of the Different SMPP Entities in a Mobile Network

Note: The terms client and ESME are used interchangeably throughout the document.

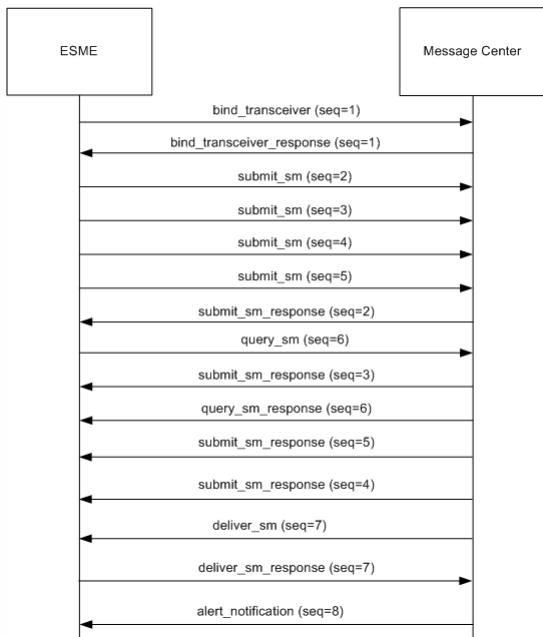

An ESME (client) opens a connection to the MC in one of the three modes: as a transmitter, a receiver, or a transceiver. As a transmitter, it can only submit messages for delivery. As a receiver, it can only receive messages. As a transceiver, the ESME can both submit and receives messages. The ESME sends the MC one of the three messages (also known as PDUs): bind\_transmitter, bind\_receiver, or bind\_transceiver. The MC responds with a bind\_transmitter\_resp, bind\_receiver\_resp, or bind\_transceiver\_resp, as appropriate for the request.

After the connection is established, the ESME can, depending on the mode in which it is bound to the MC, send a submit\_sm or data\_sm message, receive a deliver\_sm or data\_sm message, or send and receive any of these types of messages. The ESME can also send ancillary messages, such as query\_sm, replace\_sm, and cancel\_sm, to query the status of an earlier message delivery, replace an earlier message with a new message, or cancel an undelivered message.

If a message is not delivered because an ESME is not available or a mobile subscriber is not online, the message is queued. Later, when the MC detects that the mobile subscriber is now reachable, it sends an alert\_notification PDU to the ESME over a receiver or transceiver session, requesting delivery of any queued messages.

Each request PDU has a unique sequence number. The response PDU has the same sequence number as the original request. Because message exchange over SMPP can be in asynchronous mode, an ESME or an MC can send multiple requests at a time. The sequence number plays a crucial role in returning the response in the same SMPP session. In other words, the sequence number makes request and response matching possible.

The following diagram shows how the traffic flow uses the various PDUs when the ESME binds as a transceiver.

**Limitation**

The NetScaler appliance does not support outbind operations. That is, a message center cannot initiate an SMPP session with an ESME through the NetScaler appliance.

**How SMPP Load Balancing Works on the NetScaler ADC**

An ESME (client) sends a bind message to open a connection to the NetScaler ADC. The ADC authenticates each ESME and, if successful, responds with an appropriate message. The NetScaler ADC establishes a connection with each message center and load balances all the messages among these message centers. When the ADC receives a message from a client, it reuses an open connection to the message center or sends a bind request to a message center if an open connection is not available.

The ADC can load balance messages originating from the clients and from the servers. It can monitor the health of the message centers and handle concatenated messages. It also provides content switching support for the message centers.

**Messages Originating from the ESMEs**

Each ESME must be added as a user on the NetScaler ADC for authentication. The client establishes a TCP connection with an SMPP virtual server configured on the ADC by sending a bind request. The ADC authenticates the client and, if successful, parses the bind message. The ADC then sends the request to the message center selected by the configured load balancing method. If a connection to the message center is not available for reuse, the ADC opens a TCP connection with the message center by sending a new bind request to the message center. Before forwarding the response (submit\_sm\_resp or data\_sm\_resp) from the message center to the client, the ADC adds a custom server ID to the message ID to identify the message center for ancillary operations, such as query, replace, or cancel requests for a message, by the client. Requests from other clients are load balanced in the same way.

In the original bind request, a client specifies the address range that it can serve. This range is used for forwarding deliver\_sm or data\_sm messages from the message centers to the clients.

**Messages Originating from a Message Center**

ESMEs that can handle a specific address range are grouped into a cluster. All the nodes in a cluster provide the same credentials. Within a cluster, only the round robin method is used for load balancing. To deliver mobile originated (MO) messages, the message center sends a deliver\_sm message to the NetScaler ADC. If a cluster that can serve the destination address range (for example, numbers starting with 998) is bound to the ADC, it selects that cluster, and then load balances the message among the ESME nodes in that cluster.

If an ESME that can serve deliver\_sm messages for the address range is not bound to the ADC, and message queuing is enabled, the message is queued until such a client binds to the ADC in a receiver or transceiver mode. You can specify the size of the queue.

The following diagram illustrates the internal flow of PDUs between ESMEs, NetScaler ADC, and the message centers. For simplicity, only two ESMEs and two message centers are shown.

Flow of messages (PDUs):

1. ESME1 sends bind request to NetScaler
2. NetScaler sends bind request to MC1
3. MC1 sends bind response to NetScaler
4. NetScaler sends bind response to ESME1
5. ESME1 sends submit\_sm(1) to NetScaler
6. ESME1 sends submit\_sm(2) to NetScaler
7. NetScaler forwards submit\_sm(1) to MC1
8. NetScaler sends bind request to MC2
9. MC2 sends bind response to NetScaler
10. NetScaler forwards submit\_sm(2) to MC2
11. MC1 sends submit\_sm\_resp(1) to NetScaler
12. MC2 sends submit\_sm\_resp(2) to NetScaler
13. NetScaler forwards submit\_sm\_resp(1) to ESME1
14. NetScaler forwards submit\_sm\_resp(2) to ESME1
15. ESME2 sends bind request to NetScaler
16. NetScaler sends bind response to ESME2
17. ESME2 sends submit\_sm(3) to NetScaler
18. NetScaler forwards submit\_sm(3) to MC1
19. MC2 sends deliver\_sm to NetScaler (ESME2 serves the address range specified in the message)
20. MC1 sends submit\_sm\_resp(3) to NetScaler
21. NetScaler forwards submit\_sm\_resp(3) to ESME2
22. NetScaler forwards deliver\_sm to ESME2
23. ESME2 sends deliver\_sm\_resp to NetScaler
24. MC1 sends alert\_notification to NetScaler (ESME1 serves the address range specified in the message)
25. NetScaler forwards deliver\_sm\_resp to MC2
26. NetScaler forwards the alert\_notification to ESME1

#### Health Monitoring of Message Centers

By default, a TCP\_default monitor is bound to an SMPP service, but you can bind a custom monitor of type SMPP. The custom monitor opens a TCP connection to the message center and sends an enquire\_link packet. Depending on the success or failure of the probe, the service is marked UP or DOWN.

#### Content Switching on Message Centers

Message centers can accept multiple connections (or bind requests) from ESMEs. You can configure the NetScaler ADC to content switch these requests on the basis of the SMPP bind parameters. Following are some common expressions for configuring methods to select a message center:

- Based on the address range: In the following sample expression, the ADC selects a specific message center if the address range starts at 988.

##### Example

```
SMPP.BINDINFO.ADDRESS_RANGE.CONTAINS("^988")
```

- Based on the ESME ID: In the following sample expression, the ADC selects a specific message center if the ESME ID equals ESME1.

##### Example

```
SMPP.BINDINFO.SYSTEM_ID.EQ("ESME1")
```

- Based on the ESME type: In the following sample expression, the ADC selects a specific message center if the ESME type is VMS. VMS stands for voice mail system.

##### Example

```
SMPP.BINDINFO.SYSTEM_TYPE.EQ("VMS")
```

- Based on the type of number (TON) of the ESME: In the following sample expression, the ADC selects a specific message center if TON equals 1 (1 stands for an international number.)

##### Example

```
SMPP.BINDINFO.ADDR_TON.EQ(1)
```

- Based on the number plan indicator (NPI) of the ESME: In the following sample expression, the ADC selects a specific message center if NPI equals 0 (0 stands for an unknown connection.)

### Example

```
SMPP.BINDINFO.ADDR_NPI.EQ(0)
```

- Based on the bind type: In the following sample expression, the ADC selects a specific message center if the bind type is TRANSCEIVER. (A transceiver can send and receive messages.)

### Example

```
SMPP.BINDINFO.TYPE.EQ(TRANSCEIVER)
```

### Concatenated Message Handling

An SMS can hold a maximum of 140 bytes. Longer messages must be broken down into smaller parts. If the destination mobile is capable, the messages are combined and delivered as one long SMS. The NetScaler ADC forwards the fragments of a message to the same message center. Each message contains a reference number, a sequence number, and the total number of fragments. The reference number is the same for each fragment of a long message. The sequence number specifies that position of the particular fragment in the complete message. After all the fragments are received, the ESME combines the fragments into one long message and delivers the message to the mobile subscriber.

If a client disconnects from an active connection, the connection to the message center is not closed. It is reused for requests from other clients.

### Limitation

Message IDs, from the message center, longer than 59 bytes are not supported. If the message ID length returned by the message center is more than 59 bytes, ancillary operations fail and the NetScaler ADC responds with an error message.

### Configuring SMPP Load Balancing on the NetScaler ADC

Perform the following tasks to configure SMPP load balancing on the ADC:

1. Add an SMPP user. The ADC authenticates the user before it accepts a bind request from the user. The user is typically an ESME.
2. Add a load balancing virtual server, specifying the protocol as SMPP.
3. Add a service, specifying the protocol as SMPP, and a custom server ID that is unique for each server. Bind the service to the load balancing virtual server created earlier.
4. Optionally, create a service group and add services to the service group.
5. Optionally, add a monitor of type SMPP-ECV and bind it to the service. A TCP-default monitor is bound by default.
6. Set the SMPP parameters, such as client mode and message queue.

### To configure SMPP load balancing by using the command line

At the command prompt, type:

- `add smpp user <username> -password <password>`
- `add service <name> <IP> SMPP <port> -customserverID <customserverID>`
- `add lb vserver <name> <IP> SMPP <port>`
- `bind lb vserver <name> <service name>`
- `set smpp param`

### Example

```
add smpp user smppclient1 -password c03ebb540695b6110eb31172f32245a1 -encrypted -encryptmethod ENCMTHD_2
add smpp user smppclient2 -password c03ebb540695b6110eb31172f32245a1 -encrypted -encryptmethod ENCMTHD_2
add service smmpsvc 10.102.84.140 SMPP 2775 -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED -usip NO -useproxyport YES -sp ON -clTimeout 180 -svrTimeout 360 -CustomServerID ab -CKA N
add service smmpsvc2 10.102.81.175 SMPP 2775 -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED -usip NO -useproxyport YES -sp ON -clTimeout 180 -svrTimeout 360 -CustomServerID xy -CKA N
add lb vserver smppvs SMPP 10.102.239.179 2775 -persistenceType NONE -clTimeout 180
bind lb vserver smppvs smmpsvc2
bind lb vserver smppvs smmpsvc
set smpp param -addrange "\d"
```

### To configure SMPP load balancing by using the configuration utility

1. Navigate to System > User Administration > SMPP Users, and add an SMPP user.
2. Navigate to Traffic Management > Load Balancing > Configure SMPP Parameters, and set the parameters as required by your deployment.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a virtual server of type SMPP.
4. Click in the Service section, add a service of type SMPP, and specify a Server ID.

# Use Case 2: Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream

Jun 08, 2015

Some protocols transmit name-value pairs in a TCP byte stream. The protocol in the TCP byte stream in this example is the Financial Information eXchange (FIX) protocol. In its traditional, non-XML implementation, the FIX protocol enables two hosts communicating over a network to exchange business or trade-related information as a list of name-value pairs (called "FIX fields"). The field format is <tag>=<value><delimiter>. This traditional tag-value format makes the FIX protocol ideal for the use case.

The tag in a FIX field is a numeric identifier that indicates the meaning of the field. For example, the tag 35 indicates the message type. The value after the equal sign holds a specific meaning for the given tag and is associated with a data type. For example, a value of A for the tag 35 indicates that the message is a logon message. The delimiter is the nonprinting "Start of Header" (SOH) ASCII character (0x01), which is the caret symbol (^). Each field is also assigned a name. For example, the field with tag 35 is the msgType field. Following is an example of a logon message.

```
8=FIX.4.1 9=61 35=A 49=INVMGR 56=BRKR 34=1 52=20000426-12:05:06 98=0 108=30 10=157
```

Your choice of persistence type for a tag-value list such as the one shown above is determined by the options that are available to you for extracting a particular string from the list. Token-based persistence methods require you to specify the offset and length of the token that you want to extract from the payload. The FIX protocol does not allow you to do that, because the offset of a given field and the length of its value can vary from one message to another (depending on the message type, the preceding fields, and the lengths of the preceding values) and from one implementation to another (depending on whether custom fields have been defined). Such variations make it impossible to predict the exact offset of a given field or to specify the length of the value that is to be extracted as the token. In this case, therefore, rule based persistence is the preferred persistence type.

Assume that a virtual server fixlb1 is load balancing TCP connections to a farm of servers hosting instances of a FIX-enabled application, and that you want to configure persistence for connections on the basis of the value of the SenderCompID field, which identifies the firm sending the message. The tag for this FIX field is 49 (shown in the earlier logon message example).

To configure rule based persistence for the load balancing virtual server, set the persistence type for the load balancing virtual server to **RULE** and configure the rule parameter with an expression. The expression must be one that extracts the portion of the TCP payload in which you expect to find the SenderCompID field, typecasts the resulting string to a name-value list based on the delimiters, and then extracts the value of the SenderCompID field (tag 49), as follows:

```
set lb vserver fixlb1 -persistenceType RULE -rule
"CLIENT.TCP.PAYLOAD(300).TYPECAST_NVLIST_T('=', '^').VALUE("49")"
```

Note: Backslash characters have been used in the expression because this is a CLI command. If you are using the configuration utility, do not enter the backslash characters.

If the client sends a FIX message that contains the name-value list in the earlier logon message example, the expression extracts the value INVMGR, and the NetScaler appliance creates a persistence session based on this value.

The argument to the PAYLOAD() function can be as large as you deem is necessary to include the SenderCompID field in the string extracted by the function. Optionally, you can use the SET\_TEXT\_MODE(IGNORECASE) function if you want

the appliance to ignore case when extracting the value of the field, and the HASH function to create a persistence session based on a hash of the extracted value. The following expression uses the SET\_TEXT\_MODE(IGNORECASE) and HASH functions:

```
CLIENT.TCP.PAYLOAD(500).TYPECAST_NVLIST_T('=', '^').SET_TEXT_MODE(IGNORECASE).VALUE("49").HASH
```

Following are more examples of rules that you can use to configure persistence for FIX connections (replace <tag> with the tag of the field whose value you want to extract):

- To extract the value of any FIX field in the first 300 bytes of the TCP payload, you can use the expression  
CLIENT.TCP.PAYLOAD(300).BEFORE\_STR("^").AFTER\_STR("<tag>=").
- To extract a string that is 20 bytes long at offset 80, cast the string to a name-value list, and then extract the value of the field that you want, use the expression  
CLIENT.TCP.PAYLOAD(100).SUBSTR(80,20).TYPECAST\_NVLIST\_T('=', '^').VALUE("<tag>").
- To extract the first 100 bytes of the TCP payload, cast the string to a name-value list, and extract the value of the third occurrence of the field that you want, use the expression  
CLIENT.TCP.PAYLOAD(100).TYPECAST\_NVLIST\_T('=', '^').VALUE("<tag>",2).

Note: If the second argument that is passed to the VALUE() function is n, the appliance extracts the value of the (n+1)<sup>th</sup> instance of the field because the count starts from zero (0).

Following are more examples of rules that you can use to configure persistence. Only the payload-based expressions can evaluate data being transmitted through the FIX protocol. The other expressions are more general expressions for configuring persistence based on lower networking protocols.

- CLIENT.TCP.PAYLOAD(100)
- CLIENT.TCP.PAYLOAD(100).HASH
- CLIENT.TCP.PAYLOAD(100).SUBSTR(5,10)
- CLIENT.TCP.SRCPORT
- CLIENT.TCP.DSTPORT
- CLIENT.IP.SRC
- CLIENT.IP.DST
- CLIENT.IP.SRC.GET4
- CLIENT.IP.DST.GET4
- CLIENT.ETHER.SRCMAC.GET6
- CLIENT.ETHER.DSTMAC.GET5
- CLIENT.VLAN.ID

# Use Case 3: Configuring Load Balancing in Direct Server Return Mode

Jun 20, 2017

Load balancing in direct server return (DSR) mode allows the server to respond to clients directly by using a return path that does not flow through the NetScaler appliance. In DSR mode, however, the appliance can continue to perform health checks on services. In a high-data volume environment, sending server traffic directly to the client in DSR mode increases the overall packet handling capacity of the appliance because the packets do not flow through the appliance.

DSR mode has the following features and limitations:

- It supports one-arm mode and inline mode.
- The appliance ages out sessions based on idle timeout.
- Because the appliance does not proxy TCP connections (that is it does not send SYN-ACK to the client), it does not completely shut out SYN attacks. By using the SYN packet rate filter, you can control the rate of SYNs to the server. To control the rate of SYNs, set a threshold for the rate of SYNs. To get protection from SYN attacks, you must configure the appliance to proxy TCP connections. However, that requires the reverse traffic to flow through the appliance.
- In a DSR configuration, the NetScaler appliance does not replace the load balancing virtual server's IP address with the destination server's IP address. Instead, it forwards packets to a service by using the server's MAC address. The VIP must be configured on the server and ARP must be disabled for the VIP which is configured on the server to prevent the client request from bypassing the appliance when it is configured in one-arm mode. For example, a user needs to configure VIP in the loopback interface and disable the ARP for the same VIP.
- The appliance obtains the server's MAC address from the monitor bound to the service. However, custom user monitors (monitors of type USER), which use scripts stored on the NetScaler appliance, do not learn a server's MAC address. If you use only custom monitors in a DSR configuration, for each request the virtual server receives, the appliance attempts to resolve the destination IP address to a MAC address (by sending ARP requests). Because the destination IP address is a virtual IP address owned by the NetScaler appliance, the ARP requests always resolve to the MAC address of the NetScaler interface. Consequently, all traffic received by the virtual server is looped back to the appliance. If you use user monitors in a DSR configuration, you must also configure another monitor of a different type (for example, a PING monitor) for the services, ideally with a longer interval between probes, so that the MAC address of the servers can be learned.

In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service, and the service responds to clients directly, bypassing the NetScaler. The following table lists the names and values of the entities configured on the NetScaler in DSR mode.

| Entity type    | Name          | IP address   | Protocol |
|----------------|---------------|--------------|----------|
| Virtual server | Vserver-LB-1  | 10.102.29.94 | ANY      |
| Services       | Service-ANY-1 | 10.102.29.91 | ANY      |
|                | Service-ANY-2 | 10.102.29.92 | ANY      |

| Entity type | Name          | IP address   | Protocol |
|-------------|---------------|--------------|----------|
|             | Service-ANY-3 | 10.102.29.93 | ANY      |
| Monitors    | TCP           | None         | None     |

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 1. Entity Model for Load Balancing in DSR Model

For the appliance to function correctly in DSR mode, the destination IP in the client request must be unchanged. Instead, the appliance changes the destination MAC to that of the selected server. This setting enables the server to determine the client MAC address for forwarding requests to the client while bypassing the server. To enable the appliance to do this, you must enable MAC-based forwarding.

### To enable MAC-based forwarding by using the command line interface

At the command prompt, type:

```
enable ns mode MACbasedforwarding
```

### To enable MAC-based forwarding by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. On the Settings pane, under Modes and Features, click Configure modes.
3. In the Configure Modes dialog box, select the MAC Based Forwarding check box, and then click OK.
4. In the Enable/Disable Mode(s)? dialog box, click Yes.

Next, you configure a basic load balancing setup as described in [Setting Up Basic Load Balancing](#), naming the entities and setting the parameters using the values described in the previous table.

After you configure the basic load balancing setup, you must customize it for DSR mode. To do this, you configure a supported load balancing method, such as the Source IP Hash method with a sessionless virtual server. You also need to set

the redirection mode to allow the server to determine the client MAC address for forwarding responses and bypass the appliance.

After you configure the load balancing method and redirection mode, you need to enable the USIP mode on each service. The service then uses the source IP address when forwarding responses.

### **To configure the load balancing method and redirection mode for a sessionless virtual server by using the command line interface**

At the command prompt, type:

```
set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <RedirectionMode> -sessionless <Value>
```

#### **Example**

```
set lb vserver Vserver-LB-1 -lbMethod SourceIPHash -m MAC -sessionless enabled
```

#### **Note**

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

### **To configure the load balancing method and redirection mode for a sessionless virtual server by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, select Redirection Mode as MAC Based, and method as SOURCEIPHASH.
3. In Traffic Settings, select Sessionless Load Balancing.

### **To configure a service to use source IP address by using the command line interface**

At the command prompt, type:

```
set service <ServiceName> -usip <Value>
```

#### **Example**

```
set service Service-ANY-1 -usip yes
```

### **To configure a service to use source IP address by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service, and in Traffic Settings, select Use Source IP Address.

Some additional steps are required in certain situations, which are described in the succeeding sections.

# Use Case 4: Configuring LINUX Servers in DSR Mode

Jun 08, 2015

The LINUX operating system requires that you set up a loopback interface with the NetScaler appliance virtual IP address (VIP) on each load balanced server in the DSR cluster.

To configure LINUX server in DSR mode

To create a loop back interface with the NetScaler appliance's VIP on each load balanced server, at the Linux OS prompt type the following commands:

```
ifconfig dummy0 up
```

```
ifconfig dummy0:0 inet <netscaler vip> netmask 255.255.255.255 up
```

```
echo 1 > /proc/sys/net/ipv4/conf/dummy0/arp_ignore
```

```
echo 2 > /proc/sys/net/ipv4/conf/dummy0/arp_announce
```

Then, run the software that re-maps the TOS id to VIP.

Note: Add the correct mappings to the software before running it. In the preceding commands, the LINUX server uses dummy0 to connect to the network. When you use this command, type the name of the interface that your LINUX server uses to connect to the network.

# Use Case 5: Configuring DSR Mode When Using TOS

Jun 08, 2015

Differentiated services (DS), also known as TOS (Type of Service), is a field that is part of the TCP packet header. TOS is used by upper layer protocols for optimizing the path for a packet. The TOS information encodes the NetScaler appliance virtual IP address (VIP), and the load balanced servers extract the VIP from it.

In the following scenario, the appliance adds the VIP to the TOS field in the packet and then forwards the packet to the load balanced server. The load balanced server then responds directly to the client, bypassing the appliance, as illustrated in the following diagram.

Figure 1. The NetScaler Appliance in DSR mode with TOS

The TOS feature is specifically customized for a controlled environment, as described below:

- The environment must not have any stateful devices, such as stateful firewall and TCP gateways, in the path between the appliance and the load balanced servers.
- Routers at all the entry points to the network must remove the TOS field from all incoming packets to make sure that the load balanced server does not confuse another TOS field with that added by the appliance.
- Each server can have only 63 VIPs.
- The intermediate router must not send out ICMP error messages regarding fragmentation. The client will not understand the message, as the source IP address will be the IP address of the load balanced server and not the NetScaler VIP.
- TOS is valid only for IP-based services. You cannot use domain name based services with TOS.

In the example, Service-ANY-1 is created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to the service, and the service responds to clients directly, bypassing the appliance. The following table lists the names and values of the entities configured on the appliance in DSR mode.

| Entity Type | Name | IP Address | Protocol |
|-------------|------|------------|----------|
|             |      |            |          |

| Virtual server<br>Entity Type | Vserver-LB-1<br>Name | 10.102.33.91<br>IP Address | ANY<br>Protocol |
|-------------------------------|----------------------|----------------------------|-----------------|
| Services                      | Service-ANY-1        | 10.102.100.44              | ANY             |
| Monitors                      | PING                 | None                       | None            |

DSR with TOS requires that load balancing be set up on layer 3. To configure a basic load balancing setup for Layer 3, see [Setting Up Basic Load Balancing](#). Name the entities and set the parameters using the values described in the previous table.

After you configure the load balancing setup, you must customize the load balancing setup for DSR mode by configuring the redirection mode to allow the server to decapsulate the data packet and then respond directly to the client and bypass the appliance.

After specifying the redirection mode, you can optionally enable the appliance to transparently monitor the server. This enables the appliance to transparently monitor the load balanced servers.

To configure the redirection mode for the virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -m <Value> -tosld <Value>
```

**Example**

```
set lb vserver Vserver-LB-1 -m TOS -tosld 3
```

To configure the redirection mode for the virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, and in Redirect Mode, select TOS ID.

To configure the transparent monitor for TOS by using the command line interface

At the command prompt, type:

```
add monitor <MonitorName> <Type> -destip <DestinationIP> -tos <Value> -tosld <Value>
```

**Example**

```
add monitor mon1 PING -destip 10.102.33.91 -tos Yes -tosld 3
```

To create the transparent monitor for TOS by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor, select TOS, and type the TOS ID that you specified for the virtual server.

# Use Case 6: Configuring Load Balancing in DSR Mode for IPv6 Networks by Using the TOS Field

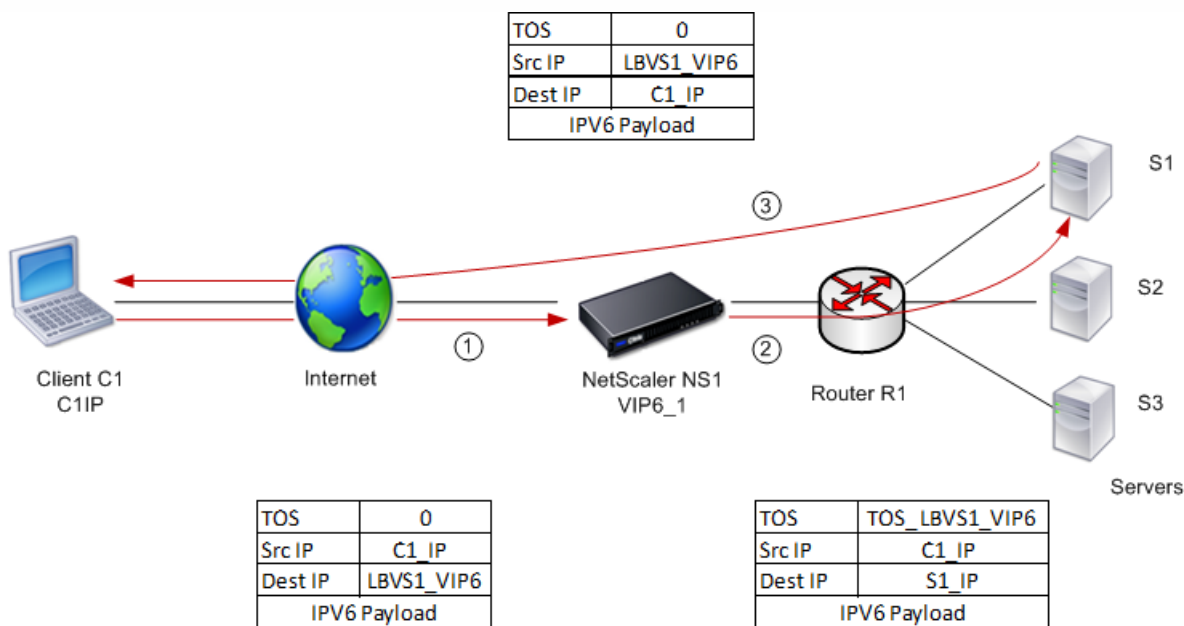

Jun 08, 2015

You can configure load balancing in Direct Server Return (DSR) mode for IPv6 networks by using the Type of Service (TOS) field when the NetScaler appliance and the servers are in different networks.

Note: The TOS field is also called the Traffic Class field.

In DSR mode, when a client sends a request to a VIP6 address on a NetScaler appliance, the appliance forwards this request to the server by changing the destination IPv6 address of the packet to the IPv6 address of the server and sets an encoded value of the VIP6 address in the TOS (also called traffic class) field of the IPv6 header. You can configure the server to use the information in the TOS field to derive the VIP6 address from the encoded value, which is then used as source IP address in response packets. Response traffic directly goes to the client, bypassing the NetScaler.

Consider an example where a load balancing virtual server LBVS1, configured on a NetScaler appliance NS1, is used to load balance traffic across servers S1, S2, and S3. The NetScaler appliance NS1 and the servers S1, S2, and S3 are in different networks so router R1 is deployed between NS1 and the servers.

The following table lists the settings used in this example.

| Entities                             | Name                                     |
|--------------------------------------|------------------------------------------|
| IPv6 address of client C1            | C1_IP (for reference purposes only)      |
| Load balancing virtual server on NS1 | LBVS1                                    |
| IPv6 address of LBVS1                | LBVS1_VIP6 (for references purpose only) |

| TOS value<br>Entities        | TOS_LBVS1_VIP6 (for references purpose only)<br>Name |
|------------------------------|------------------------------------------------------|
| Service for server S1 on NS1 | SVC_S1                                               |
| IPv6 address for server S1   | S1_IP (for references purpose only)                  |
| Service for server S2 on NS1 | SVC_S2                                               |
| IPv6 address for server S1   | S2_IP (for references purpose only)                  |
| Service for server S3 on NS1 | SVC_S3                                               |
| IPv6 address for server S1   | S3_IP (for references purpose only)                  |

Following is the traffic flow in the example scenario:

1. Client C1 sends a request to virtual server LBVS1.
2. LBVS1's load balancing algorithm selects server S1 and the appliance opens a connection to S1. NS1 sends the request to S1 with:
  - TOS field set to TOS\_LBVS1\_VIP6.
  - Source IP address as C1\_IP.
3. The server S1, on receiving the request, uses the information in the TOS field to derive the LBVS1\_VIP6 address, which is the IP address of the virtual server LBVS1 on NS1. The server directly sends the response to C1, bypassing the NetScaler, with:
  - Source IP address set to the derivedLBVS1\_VIP6 address so that the client communicates to the virtual server LBVS1 on NS1 and not to server S1.

To configure load balancing in DSR Mode using TOS, perform the following steps on the appliance:

1. Enable USIP mode globally.
2. Add the servers as services.
3. Configure a load balancing virtual server with a TOS value.
4. Bind the services to the virtual server.

To configure load balancing in DSR Mode using TOS by using the command line interface

At the command prompt, type:

- enable ns mode USIP
- add service <serviceName> <IP> <serviceType> <port>  
Repeat the above command as many times as necessary to add each server as a service on the NetScaler appliance.
- add lb vserver <name> <serviceType> <ip> <port> -m <redirectionMode> -tosId <positive\_integer>
- bind lb vserver <vserverName> <serviceName>

To enable USIP mode by using the configuration utility

Navigate to System > Settings > Configure Modes, and select Use Source IP Address.

To create services by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create a load balancing virtual server and bind services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server.
2. Click in the Service section to bind a service to this virtual server.

# Use Case 7: Configuring Load Balancing in DSR Mode by Using IP Over IP

Jul 18, 2017

You can configure your NetScaler appliance to use direct server return (DSR) mode across Layer 3 networks by using IP tunneling, also called *IP over IP* configuration. As with standard load balancing configurations for DSR mode, this allows servers to respond to clients directly instead of using a return path through the NetScaler appliance, improving response times and throughput. As with standard DSR mode, the NetScaler appliance monitors the servers and performs health checks on the application ports.

With IP over IP configuration, the NetScaler appliance and the servers do not need to be on the same Layer 2 subnet. Instead, the NetScaler appliance encapsulates the packets before sending them to the destination server. After the destination server receives the packets, it decapsulates the packets, and then sends its responses directly to the client.

To configure IP over IP DSR mode on your NetScaler appliance, you must do the following:

- **Create a load balancing virtual server.** Set the protocol to ANY and set the mode to IPTUNNEL.
- **Create services.** Create a service for each of your back-end applications. Bind the services that you created to the virtual server.
- **Configure for decapsulation:** You can configure either a NetScaler appliance or a backend server to act as a decapsulator.

## Configuring a Load Balancing Virtual Server

Updated: 2013-11-29

Configure a virtual server to handle requests to your applications. Assign a service type of ANY and set the forwarding method to IPTUNNEL. Optionally, configure the virtual server to operate in sessionless mode. You can configure any load balancing method that you want to use.

## To create and configure a load balancing virtual server for IP over IP DSR by using the command line interface

At the command prompt type the following command to configure a load balancing virtual server for IP over IP DSR and verify the configuration:

- `add lb vserver <name> serviceType <serviceType> IPAddress <ip> Port <port> -lbMethod <method> -m <ipTunnelTag> -sessionless <sessionless>`
- `show lb vserver <name>`

### Example

In the following example, we have selected the load balancing method as sourceIPHash and configured sessionless load balancing.

```
add lb vserver Vserver-LB-1 ANY 10.102.29.60 * -lbMethod SourceIPHash -m IPTUNNEL -sessionless enabled
```

## To create and configure a load balancing virtual server for IP over IP DSR by using

## the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Create a virtual server, and specify Redirection Mode as IP Tunnel Based.

### Configuring Services for IP over IP DSR

Updated: 2013-11-29

After creating your load-balanced server, You must configure one service for each of your applications. The service handles traffic from the NetScaler appliance to those applications, and allows the NetScaler appliance to monitor the health of each application.

You assign a service type of ANY and configure it for USIP mode. Optionally, you can also bind a monitor of type IPTUNNEL to the service for tunnel-based monitoring.

## To create and configure a service for IP over IP DSR by using the command line interface

At the command prompt, type the following commands to create a service and optionally, create a monitor and bind it to the service:

- add service <serviceName> <serverName> <serviceType> <port> -usip <usip>
- add monitor <monitorName> <monitorType> -dest ip <ip> -iptunnel <iptunnel>
- bind service <serviceName> -monitorName <monitorName>

### Example

In the following example, we are creating a monitor of type IPTUNNEL:

```
add monitor mon-1 PING -destip 10.102.29.60 -iptunnel yes
add service Service-DSR-1 10.102.30.5 ANY * -usip yes
bind service Service-DSR-1 -monitorName mon-1
```

## To configure a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor, and select IP Tunnel.

## To create and configure a service for IP over IP DSR by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Create a service and, in Settings, select Use Source IP Address.

## To bind a service to a load balancing virtual server by using the command line interface

At the command prompt type the following command:

```
bind lb vserver <name> <serviceName>
```

## Example

```
bind lb vserver Vserver-LB-1 Service-DSR-1
```

To bind a service to a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, and click in the Services section to bind a service to the virtual server.

## Decapsulator configuration

- When a NetScaler appliance is used as a decapsulator, an IP tunnel must be created in the NetScaler appliance. For details, see [Configuring IP Tunnels](#).

### Example configuration:

NetScaler as encapsulator

COPY

```
add lb vserver v1 any 1.1.1.1 *-m IPTUNNEL
```

```
add service s1 2.2.2.2 ANY *
```

```
bind lb vserver v1 s1
```

NetScaler as decapsulator

COPY

```
add iptunnel tun1 <snip_in_encap> netmask *

add ns ip 1.1.1.1 255.255.255.255 -type vip -arp disabled

add lb vserver v1 any 1.1.1.1 *

add service s1 <actualserverip> ANY *

bind lb vserver v1 s1
```

- When a backend server is used as a decapsulator, the backend configuration varies depending on the server type. The steps involved in configuring a backend server as a decapsulator are;
  1. Configure a loop back interface.
  2. Add a route through tunnel interface.

**Note:** Make sure that the tunnel modules are installed in the system.

**Example configuration:**

In this example, 1.1.1.1 is the NetScaler virtual IP (VIP) address and 2.2.2.2 is the backend server IP address.

The VIP address is configured in the loopback interface and a route is added through the tunnel interface. The modprobe ipip command is used for enabling the tunnel interface.

NetScaler as encapsulator

COPY

```
add lb vserver v1 ANY 1.1.1.1 80 -m IPTUNNEL
```

```
add service svc1 2.2.2.2 ANY 80 -usip YES -useproxyport NO
```

```
bind lb vserver v1 svc1
```

Backend server as decapsulator

COPY

```
ifconfig lo inet 1.1.1.1 netmask 255.255.255.255
```

```
modprobe ipip
```

```
echo 1 > /proc/sys/net/ipv4/conf/tunl0/arp_ignore
```

```
echo 2 > /proc/sys/net/ipv4/conf/tunl0/arp_announce
```

```
ifconfig tunl0 1.1.1.1 netmask 255.255.255.255 up
```

```
route add -host 1.1.1.1 dev tunl0
```

# Use Case 8: Configuring Load Balancing in One-arm Mode

Feb 19, 2016

In a one-arm setup, you connect the NetScaler appliance to the network through a single VLAN. The appliance receives the request from the client on a single VLAN and it sends the request to the server on the same VLAN. This is one of the simplest deployment scenarios, where the router, the servers and the appliance are all connected to the same switch. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service, as is shown in the following diagram.

Figure: Load Balancing in One-Arm Mode

In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service. The following table lists the names and values of the entities configured on the appliance in one-arm mode.

| Entity type    | Name          | IP address   | Protocol |
|----------------|---------------|--------------|----------|
| Virtual server | Vserver-LB-1  | 10.102.29.94 | ANY      |
| Services       | Service-ANY-1 | 10.102.29.91 | ANY      |
|                | Service-ANY-2 | 10.102.29.92 | ANY      |

| Entity type | Name          | IP address   | Protocol |
|-------------|---------------|--------------|----------|
|             | Service-ANY-3 | 10.102.29.93 | ANY      |
| Monitors    | TCP           | None         | None     |

To configure a load balancing setup in one-arm mode, see "[Setting Up Basic Load Balancing](#)."

# Use Case 9: Configuring Load Balancing in the Inline Mode

Feb 19, 2016

In an inline mode (also called two-arm mode) setup, you connect the NetScaler appliance to the network through multiple VLANs. The appliance receives the request from the client on one VLAN and it sends the request to the server on another VLAN. In the two-arm setup, the appliance is connected between the servers and the client. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service. This is shown in the following diagram.

Figure: Load Balancing in Inline Mode

The configuration and the entity diagram for inline mode are the same as described in "[Configuring Load Balancing in One-arm Mode.](#)"

# Use Case 10: Load Balancing of Intrusion Detection System Servers

Jun 08, 2015

To enable the NetScaler appliance to support load balancing of intrusion detection system (IDS) servers, the IDS servers and clients must be connected through a switch that has port mirroring enabled. The client sends a request to the server. Because port mirroring is enabled on the switch, the request packets are copied or sent to the NetScaler appliance virtual server port. The appliance then uses the configured load balancing method to select an IDS server, as shown in the following diagram.

Figure 1. Topology of Load Balanced IDS Servers

Note: Currently, the appliance supports load balancing of passive IDS devices only.

As illustrated in the preceding diagram, the IDS load balancing setup functions as follows:

1. The client request is sent to the IDS server, and a switch with a mirroring port enabled forwards these packets to the IDS server. The source IP address is the IP address of the client, and the destination IP address is the IP address of the server. The source MAC address is the MAC address of the router, and the destination MAC address is the MAC address of the server.
2. The traffic that flows through the switch is mirrored to the appliance. The appliance uses the layer 3 information (source IP address and destination IP address) to forward the packet to the selected IDS server without changing the source IP address or destination IP address. It modifies the source MAC address and the destination MAC address to the MAC address of the selected IDS server.

Note: When load balancing IDS servers, you can configure the SRCIPHASH, DESTIPHASH, or SRCIPDESTIPHASH load balancing methods. The SRCIPDESTIPHASH method is recommended because packets flowing from the client to a service on the appliance must be sent to a single IDS server.

Suppose Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to Vserver-LB-1. The virtual server balances the load on the services. The following table lists the names and values of the entities configured on the appliance.

| Entity type    | Name          | IP address    | Port | Protocol |
|----------------|---------------|---------------|------|----------|
| Virtual server | Vserver-LB-1  | *             | *    | ANY      |
| Services       | Service-ANY-1 | 10.102.29.101 | *    | ANY      |
|                | Service-ANY-2 | 10.102.29.102 | *    | ANY      |
|                | Service-ANY-3 | 10.102.29.103 | *    | ANY      |
| Monitors       | Ping          | None          | None | None     |

Note: You can use inline mode or one-arm mode for an IDS load balancing setup.

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 2. Entity Model for Load Balancing IDS Servers

To configure an IDS load balancing setup, you must first enable MAC-based forwarding. You must also disable layer 2 and layer 3 modes on the appliance.

### To enable MAC-based forwarding by using the command line interface

At the command prompt, type:

```
enable ns mode <ConfigureMode>
```

### Example

```
enable ns mode MAC
```

## To enable MAC-based forwarding by using the configuration utility

Navigate to System > Settings > Configure Modes, and select MAC Based Forwarding.

Next, see "[Setting Up Basic Load Balancing](#)", to configure a basic load balancing setup.

After you configure the basic load balancing setup, you must customize it for IDS by configuring a supported load balancing method (such as the SRCIPDESTIP Hash method on a sessionless virtual server) and enabling MAC mode. The appliance does not maintain the state of the connection and only forwards the packets to the IDS servers without processing them. The destination IP address and port remains unchanged because the virtual server is in the MAC mode.

## To configure LB method and redirection mode for a sessionless virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <RedirectionMode> -sessionless <Value>
```

### Example

```
set lb vserver Vserver-LB-1 -lbMethod SourceIPDestIPHash -m MAC -sessionless enabled
```

### Note

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

## To configure LB method and redirection mode for a sessionless virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server and, in Redirection Mode, select MAC Based.
3. In Advanced Settings, click Methods, and select SRCIPDESTIPHASH. Click Traffic Settings, and select Sessionless Load Balancing.

## To set a service to use source IP address by using the command line interface

At the command prompt, type:

```
set service <ServiceName> -usip <Value>
```

### Example

```
set service Service-ANY-1 -usip yes
```

## To set a service to use source IP address by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service, and in Settings select Use Source IP Address.

For USIP to function correctly, you must set it globally. For more information about configuring USIP globally, see "[IP Addressing](#)."

# Use Case 11: Isolating Network Traffic using Listen Policies

Jun 08, 2015

A very common security requirement in a data center is to maintain network path isolation between the traffic of various applications or tenants. One application or tenant's traffic must be isolated from the traffic of other applications or tenants. For example, a financial services company would want to keep the traffic of its insurance department's applications separate from that of its financial services applications. In the past, this was easily achieved through physical separation of network service devices such as firewalls, load balancers, and IDP, and network monitoring and logical separation in the switching fabric.

As data center architectures evolve toward multi-tenant virtualized data centers, networking services in the aggregation layer of a data center are getting consolidated. This development has made network path isolation a critical component for network service devices and is driving the requirement for ADCs to be able to isolate traffic at the L4 to L7 levels. Furthermore, all the traffic of a particular tenant must go through a firewall before reaching the service layer.

To address the requirement of isolating the network paths, a NetScaler appliance identifies network domains and controls the traffic across the domains. The NetScaler solution has two main components: listen policies and shadow virtual servers.

Each network path to be isolated is assigned a virtual server on which a listen policy is defined so that the virtual server listens to traffic only from a specified network domain.

To isolate the traffic, listen policies can be based on a number of client parameters or their combinations, and the policies can be assigned priorities. The following table lists the parameters that can be used in listen policies for identifying the traffic.

**Table 1. Client Parameters Used to Define Listen Policies**

| Category          | Parameters                                                                      |
|-------------------|---------------------------------------------------------------------------------|
| Ethernet protocol | Source MAC address, destination MAC address                                     |
| Network interface | Network ID, receiving throughput, sending throughput, transmission throughput   |
| IP protocol       | Source IP address, destination IP address                                       |
| IPv6 protocol     | Source IPv6 address, destination IPv6 address                                   |
| TCP protocol      | Source port, destination port, maximum segment size, payload, and other options |
| UDP protocol      | Source port, destination port                                                   |
| VLAN              | ID                                                                              |

On the NetScaler appliance, a virtual server is configured for each domain, with a listen policy specifying that the virtual server is to listen only to traffic for that domain. Also configured for each domain is a shadow load balancing virtual server, which listens to traffic destined for any domain. Each of the shadow load balancing virtual servers has a wildcard (\*) IP address and port, and its service type is set to ANY.

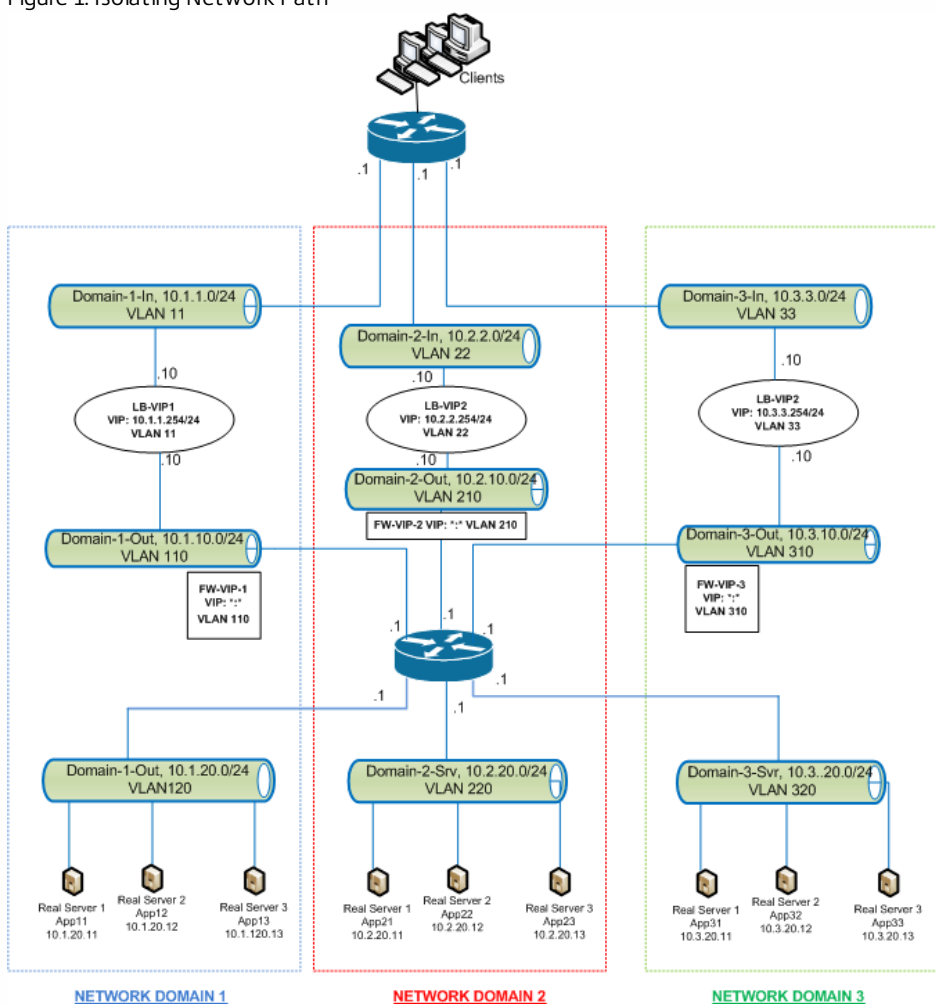

In each domain, a firewall for the domain is bound as a service to the shadow load balancing virtual server, which forwards all traffic through the firewall. Local traffic is forwarded to its destination, and traffic destined for another domain is forwarded to the firewall for that domain. The shadow load balancing virtual servers are configured for MAC mode redirection.

## How Network Paths Are Isolated

The following figure shows a typical traffic flow across domains. Consider the traffic flow within Network Domain 1, and between Network

Domain 1 and Network Domain 2.

Figure 1. Isolating Network Path

## Traffic within Network Domain 1

Network Domain 1 has three VLANs: VLAN 11, VLAN110, and VLAN120. The following steps describe the traffic flow.

- A client from VLAN 11 sends a request for a service available from the service pool in VLAN 120.
- The load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110. The virtual server in VLAN 110 forwards the request to shadow load balancing virtual server FW-VIP-1.
- FW-VIP-1, which is configured to listen to traffic from VLAN 110, receives the request and forwards it to VLAN 120.
- The load balancing virtual server in VLAN 120 load balances the request to one of the physical servers, App11, App12, or App13.
- The response sent by the physical server returns by the same path to the client in VLAN 11.

This configuration ensures that traffic is always segregated inside the NetScaler for all the traffic that originates from a client.

## Traffic between Network Domain 1 and Network Domain 2

Network Domain 1 has three VLANs: VLAN 11, VLAN 110, and VLAN 120. Network Domain 2 also has three VLANs: VLAN 22, VLAN 210, and VLAN 220. The following steps describe the traffic flow from VALN 11 to VLAN 22.

- A client from VLAN 11, which belongs to Network Domain 1, sends a request for a service available from the service pool in VLAN 220, which belongs to the Network Domain 2.
- In Network Domain 1, the load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110.
- Shadow load balancing virtual server FW-VIP-1, which is configured to listen to VLAN 110 traffic destined to any other domain, receives the request and forwards it to firewall virtual server FW-VIP-2 because the request is destined to a physical server in Network Domain 2.

- In Network Domain 2, FW-VIP-2 forwards the request to VLAN 220.
- The load balancing virtual server in VLAN 220 load balances the request to one of the physical servers, App21, App22, or App23.
- The response sent by the physical server returns by the same path through the firewall in Network Domain 2 and then to Network Domain 1 to reach the client in VLAN 11.

## Configuration Steps

To configure network path isolation by using listen policies, do the following:

- Add listen policy expressions. Each expression specifies a domain to which traffic is destined. You can use the VLAN ID or other parameters to identify the traffic. For more details, see "[Client Parameters Used to Define Listen Policies](#)."
- For each network domain, configure two virtual servers as follows:
  - Create a load balancing virtual server for which you specify a listen policy that identifies the traffic destined for this domain. You can specify the name of an expression created earlier, or you can create a new expression while creating the virtual server.
  - Create another load balancing virtual server, referred to as shadow virtual server, for which you specify a listen policy expression that applies to traffic destined for any domain. On this virtual server, set the service type to ANY and the IP address and port to an asterisk (\*). Enable MAC-based forwarding on this virtual server.
- Enable the L2 Connection option on both the virtual servers.
 

Generally, to identify a connection, the NetScaler uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.
- Add services representing the server pools in the domain, and bind them to the virtual server.
- Configure the firewall for each domain as a service, and bind all of the firewall services to the shadow virtual server.

## To isolate network traffic by using the command line interface

At the command prompt, type the following commands:

- `add policy expression <expressionName> <listenPolicyExpression>`
- `add lb vserver <name> <serviceType> <ip> <port> -l2conn ON -listenPolicy <expressionName>`  
Add a load balancing virtual server for each domain. This virtual server is for traffic of the same domain.
- `add lb vserver <name> ANY * * -l2conn ON -m MAC -listenPolicy <expressionName>`  
Add a shadow load balancing virtual server for each domain. This virtual server is for traffic of other domains.

### Example

```
add policy expression e110 client.vlan.id==110
add policy expression e210 client.vlan.id==210
add policy expression e310 client.vlan.id==310
add policy expression e11 client.vlan.id==11
add policy expression e22 client.vlan.id==22
add policy expression e33 client.vlan.id==33
```

```
add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -persistenceType NONE -listenPolicy e11
-cltTimeout 180 -l2Conn ON
```

```
add lb vserver LB-VIP2 HTTP 10.2.2.254 80 -persistenceType NONE -listenPolicy e22
-cltTimeout 180 -l2Conn ON
```

```
add lb vserver LB-VIP3 HTTP 10.3.3.254 80 -persistenceType NONE -listenPolicy e33
-cltTimeout 180 -l2Conn ON
```

```
add lb vserver FW-VIP-1 ANY * * -persistenceType NONE -lbMethod ROUNDROBIN -listenPolicy e110 -Listenpriority 1 -m MAC -cltTimeout 120
```

```
add lb vserver FW-VIP-2 ANY * * -persistenceType NONE -lbMethod ROUNDROBIN -listenPolicy e210 -Listenpriority 2 -m MAC -cltTimeout 120
```

```
add lb vserver FW-VIP-3 ANY * * -persistenceType NONE -lbMethod ROUNDROBIN -listenPolicy e310 -Listenpriority 3 -m MAC -cltTimeout 120
```

```
add service RD-1 10.1.1.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED
-usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA NO -TCPB NO -CMP NO
```

```
add service RD-2 10.2.2.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED
-usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA NO -TCPB NO -CMP NO
```

```
add service RD-3 10.3.3.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED
-usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA NO -TCPB NO -CMP NO
```

```
bind lb vserver FW-VIP-1 RD-1
```

```
bind lb vserver FW-VIP-2 RD-2
```

```
bind lb vserver FW-VIP-3 RD-3
```

## To isolate network traffic by using the configuration utility

1. Add services representing the servers, as described in "[Creating a Service.](#)"
2. Add each firewall as a service:
  1. Navigate to Traffic Management > Load Balancing > Services
  2. Create a service, specifying protocol as ANY, server as firewall's IP address, and port as 80.
3. Configure a load balancing virtual server.
4. Configure the shadow load balancing virtual server.
5. For each network domain, repeat steps 3 and 4.
6. From the Load Balancing Virtual Servers pane, open the virtual servers that you created and verify the settings.

# Use Case 12: Configuring XenDesktop for Load Balancing

Jun 08, 2015

For an improved performance in the delivery of virtual desktop applications, you can integrate the NetScaler appliance with Citrix XenDesktop and use the NetScaler load balancing feature to distribute the load across the Web Interface servers and the Desktop Delivery Controller (DDC) servers.

Generally, you use XenDesktop in situations where applications are not compatible with running on a terminal server or XenApp, or if each virtual desktop has unique requirements. In such cases, you need one desktop host for each user that connects. However, the hosts can be pooled so that you need only one host for each currently connected user.

The core application service deployed for XenDesktop is the Desktop Delivery Controller (DDC). The DDC is installed on a server, and its main function is to register desktop hosts and broker client connections to them.

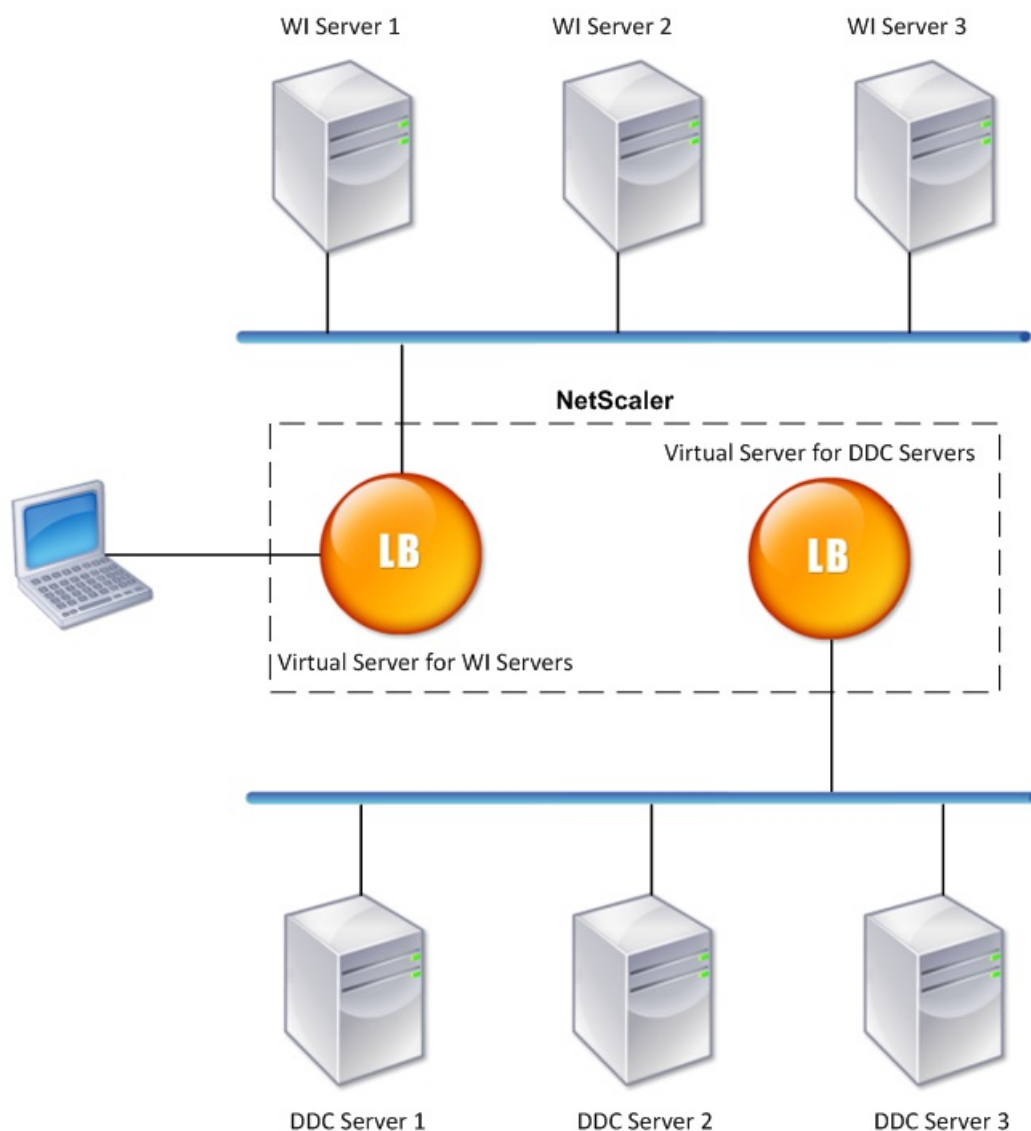

The DDC also authenticates users and manages the assembly of the users' virtual desktop environments by controlling the state of the desktops, and starting and stopping the desktops.

Generally, multiple DDCs are installed to enhance availability.

The Web Interface servers provide secure access to virtual desktops. The Web Interface is the initial connection portal to the Desktop Delivery Controller (DDC). The Web browser on the user's device sends information to the Web server, which communicates with the server farm to provide the user with access to the virtual desktop.

The following figure shows the topology of a NetScaler appliance working with XenDesktop.

Figure 1. **Load Balancing of XenDesktop**

Note: Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the NetScaler. You can use the HTTP protocol for communication between the NetScaler and the DDC servers even though you use the SSL protocol for communication with the client.

A wizard is available for configuring basic load balancing in a XenDesktop deployment. You can use the wizard to configure Web interface servers and a virtual server for them, and DDC servers and a virtual server for them. The virtual servers that you configure are bound to services specified as Web Interface services and DDC services. Each virtual server is configured with the default load balancing method, and the default features are enabled. A monitor is created and bound to each virtual server.

The wizard creates a basic setup, with default values for options such as the load balancing method, policies, persistence, and advanced settings. You can change any of the values if necessary.

To configure load balancing for XenDesktop by using the configuration utility

Click XenApp and XenDesktop, and follow the instructions in the wizard.

# Use Case 13: Configuring XenApp for Load Balancing

Jun 08, 2015

For efficient delivery of applications, you can integrate the NetScaler appliance with Citrix XenApp and use the NetScaler load balancing feature to distribute the load across the XenApp server farms. The following figure is a topology diagram of such a setup.

Figure 1. Load Balancing of XenApp

The Web Interface servers provide secure access to XenApp application resources through the user's Web browser. The Web Interface client presents to the users all the resources, such as applications, content, and desktops that are made available in the XenApp server farms. Users can access the published resources through a standard Web browser or through the Citrix online plug-in.

The Web browser on the user's device sends information to the Web server, which communicates with the servers on the server farm to provide the user with access to the resources.

The Web Interface and the XML Broker are complementary services. The Web Interface provides users with access to applications, and the XML Broker evaluates the user's permissions to determine which applications appear in the Web

Interface.

The XML service is installed on all the servers in the server farm. The XML service specified in the Web Interface functions as an XML broker. On the basis of the user credentials passed by the Web Interface server, the XML Broker server sends a list of applications accessible to the user.

In large enterprises where multiple Web Interface servers and XML Broker servers are deployed, Citrix recommends load balancing these servers by using NetScaler. Configure one virtual server to load balance all of the Web Interface servers and another for all of the XML Broker servers. The load balancing method and other features can be configured on the virtual server as required.

Note: Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the NetScaler. You can use the HTTP protocol for communication between the NetScaler and the WI servers even though you use the SSL protocol for communication with the client.

The configuration utility provides a wizard for setting up basic load balancing for XenApp.

Through this wizard, you can configure Web Interface servers and a virtual server for them, and XML Broker servers and a virtual server for them. You can also specify the site through which the status of Web Interface servers can be monitored and the software application used to monitor the status of the XML Broker servers.

When you complete the wizard, a basic load balancing setup is configured on the NetScaler. The specified virtual servers are created and bound to the services specified as Web Interface services and XML Broker services. Each virtual server is configured with the default load balancing method, and the default features are enabled. A monitor is created and bound to each virtual server.

The wizard creates a basic setup with default values for options such as the load balancing method, policies, persistence, and advanced settings. You can change any of the values if necessary.

To configure load balancing for XenApp by using the configuration utility

Click XenApp and XenDesktop, and follow the instructions in the wizard.

# Use Case 14: ShareFile Wizard for Load Balancing Citrix ShareFile

Jun 08, 2015

You can configure load balancing for Citrix ShareFile using the wizard. The Citrix ShareFile wizard helps in setting up load balancing configuration for ShareFile site based on the type of content requested. The content switching server directs the request based on whether it is a StorageZone, CIFS or a SharePoint request. The content switching is based on policies. The wizard auto generates the policies to identify whether the request is for StorageZone, CIFS or SharePoint. The content switching virtual server uses these policies to direct the request to the correct load balancing server.

A typical data flow can be depicted as shown in the diagram below.

Figure 1. ShareFile Data Load Balancing

You can view the load balancing virtual servers that the ShareFile wizard creates by navigating to Traffic Management >Virtual Servers and Services > Virtual Servers. You cannot manually remove the virtual servers created using the ShareFile

wizard. Use the wizard to remove the virtual servers.

NetScaler uses the LDAP authentication for SharePoint or CIFS request. Hash authentication is used for authenticating requests for StorageZones.

To configure a NetScaler appliance for load balancing Citrix ShareFile

Updated: 2015-06-04

1. In the navigation pane, click Load Balancing.
2. Navigate to Traffic Management > Load Balancing.
3. Under Citrix ShareFile, click Setup NetScaler for ShareFile.
4. On the Setup Load Balancing for ShareFile page, provide the following information:
  - Name: Name of the content switching virtual server.
  - IP Address: IP address of the content switching virtual server.
  - If you want to setup load balancing for CIFS or SharePoint, click the StorageZone Connector for Network File Shares/SharePoint checkbox and then click Continue. By default ShareFile Data checkbox is selected.

## To remove load balancing configuration for ShareFile

1. Click on Configuration > Traffic Management > Load Balancing.

2. On the Load Balancing page, under Citrix ShareFile click on Remove ShareFile Configuration.

# Troubleshooting

Aug 01, 2013

If the load balancing does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

## Resources for Troubleshooting Load Balancing

Updated: 2013-08-01

For best results, use the following resources to troubleshoot a content switching issue on a NetScaler appliance:

- Latest ns.conf file
- Relevant newnslog files
- Ethereal packet traces recorded on the appliance and relevant client, if possible
- The ns.log file

In addition to the above resources, the following tools expedite troubleshooting:

- A browser add-on tool that can display HTTP headers. This can be used to troubleshoot persistency related issues.
- The Wireshark application customized for the NetScaler trace files.

## Troubleshooting Load Balancing Issues

Updated: 2015-06-11

- **Issue**

CPU usage reaches 100% when a user monitor is bound to a service that is bound to a virtual server on which -m MAC option is enabled.

- **Resolution**

Bind a non-user monitor to the service.

- **Issue**

I created a user script for monitoring, but it is not working.

**Resolution**

Check the number of arguments in the script. The limit is 512. A script with more than 512 arguments might not work properly. Use the nsumon-debug.pl script from the NetScaler command line to debug the script.

- **Issue**

I see a lot of monitor probes, and they seem to be increasing the network traffic unnecessarily. Is there a way to turn off the monitor probes?

**Resolution**

You can turn off the monitor probe connections, by disabling the monitor or setting the value of the healthMonitor parameter in the set service command to NO. With the NO option, the appliance shows the service as UP at all times.

- **Issue**

I have set up monitors for services, but connections are still directed to servers that are DOWN.

## Resolution

You probably need to decrease the monitor probe intervals. The NetScaler appliance does not detect the DOWN state until the monitor sends a probe.

- **Issue**

A metric bound to the monitor is present in the local and custom metric tables.

## Resolution

Add the local prefix to the metric name if the metric is chosen from the local metric table. However, if the metric is chosen from the custom table, you don't need to add any prefix.

- **Issue**

The monitor probes to a service are not reaching the service.

## Resolution

Check whether you have set a limit on the number of connections for a service. If yes, exempt monitor-probe connections from this limit by setting the `monitorSkipMaxClient` parameter to `ENABLED`.

- **Issue**

I am able to ping the servers, but the state of the services is always shown as DOWN.

## Resolution

Check the type of monitors configured. For example, if a server is not configured for SSL and you use an HTTPS monitor, the state of the service is marked as DOWN. In this case using a TCP monitor should change the state of the service to UP.

- **Issue**

Setting a weight for load monitors does not help in deciding the state of the service.

## Resolution

Load monitors cannot decide the state of the service. Therefore, setting a weight on the load monitors is inappropriate.

- **Issue**

A service is not stable.

## Resolution

Consider troubleshooting the following components:

- Verify that a correct server is bound to the service.
- Verify the type of monitor bound to the service.
- Verify the reasons for the monitor failures. You can open service from the Services page and verify the details for the number of probes, failures, and last response status for the monitor in the Monitors tab of the Configure service dialog box. To display the details, click the monitor configured.
- If it is a custom monitor, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.
- You can record packet traces on the NetScaler appliance and verify the monitor probes and server response for

further investigation.

- **Issue**

The virtual IP (VIP) address is not stable or its status is displayed as DOWN.

**Resolution**

Consider troubleshooting the following components:

- Verify that the load balancing feature is licensed.
- Verify that the feature is enabled.
- Verify that an appropriate service is bound to the virtual server.
- If the status of the VIP address is displayed as DOWN, verify that an administrator has enabled the service. If it is not, the status of the service should be Out-Of-Service. In such as case, you must enable the service and verify if the issue is resolved.
- Verify the service(s) bound to the virtual server and complete the troubleshooting steps mentioned for service not stable issue.
- If the VIP address is not stable, all the services bound to the virtual server should fail. Therefore, verify if all the services are failing at the same time. If it is so, there is a network issue between the NetScaler appliance and the servers.

- **Issue**

The site is experiencing uneven load balancing.

**Resolution**

Consider troubleshooting the following components:

- Verify the load balancing method configured on the appliance.
- Verify weights associated with the services are as expected.
- If the load balancing method is other than round robin, verify the number of connections to the server logged in the newnslog file. You can run the following command to verify the number on the newnslog file:

```
nsconmsg -K <newnslog_file> -s ConLb=2 -d oldconmsg
```

Verify the services for the specific virtual server and check for the Response time, Open Established connections (OE), Hits, Persistent Hits and persistent rate (P) to troubleshoot the issue further.

- If the load balancing method is round robin, verify the persistent Hits as mentioned in the preceding step. Additionally, verify if the service is not stable. If it is not, complete the troubleshooting steps mentioned for service not stable issue
- Verify if persistency is configured on the appliance.
- Verify if any service is not stable. If yes, complete the troubleshooting steps mentioned for service not stable issue.

- **Issue**

The service status is displayed as DOWN.

**Resolution**

Consider troubleshooting the following components:

- Verify whether a SNIP or MIP address is configured.
- Verify that appropriate monitors are bound to the service.
- If custom monitors are bound to the service, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.

- Verify if the status of service is displayed as DOWN for the server that is in another subnet. If yes, verify if Use Subnet IP (USNIP) resolves the issue because this could be due to the MIP address being unable to communicate to the server.

- **Issue**

There is an issue with the response time.

#### **Resolution**

Consider troubleshooting the following components:

- Verify the server response time from the service stats either by running the following command:  
`# nscommsg -K <newslog_file> -s ConLb=2 -d oldcommsg`
- Check for service not stable and service status being displayed as DOWN issues.

- **Issue**

One of the servers is serving more requests than the other load balanced servers.

#### **Resolution**

Consider troubleshooting the following components:

- Verify the load balancing method. Use the round robin method to distribute the client request equally regardless of the load on the servers.
- Determine whether persistence is enabled for the load balancing configuration. If persistence is enabled, a given servers might be carrying a heavier load to maintain its session, especially If the persistence sessions are long.
- Verify whether weights are assigned to each service. Assigning proper weights helps in proper load distribution.

- **Issue**

Connections to a specific load balanced server are stalled. For example, all connections to one Outlook server might be stalled.

#### **Resolution**

Consider troubleshooting the following components:

- Verify the load balance method. If it is round robin, consider changing the method to least connections.
- Consider reducing the monitor time-out period. A shorter timeout period helps in marking a service as DOWN sooner, which would help in directing the traffic to server which is functional.
- If the connections are stalled for a long period, surge-queue might build. Consider flushing the surge-queue to avoid a sudden spike in load on the server.
- If the servers are working at their maximum level, consider adding a new server for better performance.

- **Issue**

A majority of the connections are directed to a particular server, even when the least connections method for load balancing is configured.

#### **Resolution**

Determine whether persistence is configured and is of type source IP. If source IP persistence is configured even with the least connections method, the requests go to a specific server. The server's IP address is required for maintaining the session information. Consider using HTTP Cookies based persistence.

- **Troubleshooting Tips**

For other issues, consider following tips to troubleshoot an issue not listed above:

- If multiple load monitors are bound to a service, the load on the service is the sum of all the values on the load monitors bound to it. For load balancing to work properly, you must bind the same set of monitors to all the services.
- If you disable a load monitor bound to the service and the service is bound to a virtual server, the virtual server uses the round robin method for load balancing.
- When you bind a service to a virtual server where the load balancing method is CUSTOMLOAD and the service status is UP, the virtual server uses the initial round robin method for load balancing. It continues to be in round robin if the service has no custom load monitors, or if status of at least one of the custom load monitors is not UP.
- All the services that are bound to a virtual server where the load balancing method is CUSTOMLOAD, the services must have load monitors bound to them.
- The CUSTOMLOAD load balancing method also follows startup round robin.
- If you disable a metric-based binding and this is the last active metric, the specific virtual server uses the round robin method for load balancing. A metric is disabled by setting the metric threshold to zero.
- When a metric bound to a monitor crosses the threshold value, that particular service is not considered for load balancing. If all the services have reached the threshold, the virtual server uses the round robin method for load balancing and an error message “5xx - server busy error” is displayed.
- A maximum of 10 metrics from a custom table can be bound to the monitor.
- The OIDs must be scalar variables.
- For successful load balancing, the interval must be as low as possible. If the interval is high, the time period for retrieving the load value increases. As a result, load balancing takes place using improper values.
- A user cannot modify the local table.

# SSL Offload and Acceleration

Dec 08, 2014

A Citrix® NetScaler® appliance configured for SSL acceleration transparently accelerates SSL transactions by offloading SSL processing from the server. To configure SSL offloading, you configure a virtual server to intercept and process SSL transactions, and send the decrypted traffic to the server (unless you configure end-to-end encryption, in which case the traffic is re-encrypted). Upon receiving the response from the server, the appliance completes the secure transaction with the client. From the client's perspective, the transaction seems to be directly with the server. A NetScaler configured for SSL acceleration also performs other configured functions, such as load balancing.

Configuring SSL offloading requires an SSL certificate and key pair, which you must obtain if you do not already have an SSL certificate. Other SSL-related tasks that you might need to perform include managing certificates, managing certificate revocation lists, configuring client authentication, and managing SSL actions and policies.

A non-FIPS NetScaler appliance stores the server's private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as a hardware security module (HSM). Only the MPX 9700/10500/12500/15500 appliances support a FIPS card, so other NetScaler models cannot be equipped with an HSM.

Beginning with release 10.5, build 52.1115.e, all NetScaler appliances that do not support a FIPS card (including virtual appliances) support the Thales nShield® Connect external HSM. (MPX 9700/10500/12500/15500 appliances do not support an external HSM.)

Note: FIPS-related options for some of the SSL configuration procedures described in this document are specific to a FIPS-enabled NetScaler.

# Configuring SSL Offloading

Jun 03, 2015

To configure SSL offloading, you must enable SSL processing on the NetScaler appliance and configure an SSL based virtual server that will intercept SSL traffic, decrypt the traffic, and forward it to a service that is bound to the virtual server. To secure time-sensitive traffic, such as media streaming, you can configure a DTLS virtual server. To enable SSL offloading, you must import a valid certificate and key and bind the pair to the virtual server.

To configure SSL offloading, see the following sections:

- [Enabling SSL Processing](#)
- [Configuring Services](#)
- [Configuring an SSL-Based Virtual Server](#)
- [Binding Services to the SSL-Based Virtual Server](#)
- [Adding or Updating a Certificate-Key Pair](#)
- [Binding the Certificate-Key Pair to the SSL-Based Virtual Server](#)
- [SSL Profiles](#)
- [Configuring an SSL Virtual Server for Secure Hosting of Multiple Sites](#)
- [Configuring a DTLS Virtual Server](#)
- [DTLS Profile](#)
- [Importing SSL Files from Remote Hosts](#)
- [SSL Profiles](#)
- [Enabling Stricter Control on Client Certificate Validation](#)
- [Graceful Cleanup of SSL Sessions](#)

# Enabling SSL Processing

Nov 11, 2013

To process SSL traffic, you must enable SSL processing. You can configure SSL based entities, such as virtual servers and services, without enabling SSL processing, but they will not work until SSL processing is enabled.

To enable SSL processing by using the command line interface

At the command prompt, type:

- enable ns feature ssl
- show ns feature

## Example

```
> enable ns feature SSL
```

```
Done
```

```
> show ns feature
```

|           | Feature               | Acronym    | Status    |
|-----------|-----------------------|------------|-----------|
|           | -----                 | -----      | -----     |
| 1)        | Web Logging           | WL         | OFF       |
| 2)        | Surge Protection      | SP         | ON        |
| 3)        | Load Balancing        | LB         | ON        |
| .         |                       |            |           |
| .         |                       |            |           |
| .         |                       |            |           |
| <b>9)</b> | <b>SSL Offloading</b> | <b>SSL</b> | <b>ON</b> |
| .         |                       |            |           |
| .         |                       |            |           |
| .         |                       |            |           |
| 24)       | NetScaler Push        | push       | OFF       |

```
Done
```

To enable SSL processing by using the configuration utility

Navigate to System > Settings and, in the Modes and Features group, select Configure Basic Features, and select SSL Offloading.

# Configuring Services

Oct 12, 2016

On the NetScaler appliance, a service represents a physical server or an application on a physical server. Once configured, services are in the disabled state until the appliance can reach the physical server on the network and monitor its status.

To add a service by using the command line interface

At the command prompt, type the following commands to add a service and verify the configuration:

- **add service** <name> (<IP> | <serverName>) <serviceType> <port>
- **show service** <serviceName>

EXAMPLE

COPY

```
> add service SSL1 192.168.0.12 SSL 443
```

```
Done
```

```
> sh service SSL1
```

```
SSL1 (192.168.0.12:443) - SSL
```

```
State: DOWN
```

```
Last state change was at Thu Oct 6 17:15:41 2016
```

```
Time since last state change: 0 days, 00:00:07.990
```

```
Server Name: 192.168.0.12
```

```
Server ID : None Monitor Threshold : 0
```

```
Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
```

```
Use Source IP: NO
```

```
Client Keepalive(CKA): NO
```

```
Access Down Service: NO
```

```
TCP Buffering(TCPB): NO
```

TCP Batching(TCPB): NO

HTTP Compression(CMP): NO

Idle timeout: Client: 180 sec Server: 360 sec

Client IP: DISABLED

Cacheable: NO

SC: OFF

SP: ON

Down state flush: ENABLED

Monitor Connection Close : NONE

Appflow logging: ENABLED

Process Local: DISABLED

Traffic Domain: 0

1) Monitor Name: tcp-default

State: DOWN Weight: 1 Passive: 0

Probes: 2 Failed [Total: 1 Current: 1]

Last response: Failure - Time out during TCP connection establishment stage

Response Time: 0.0 millsec

Done

To modify or remove a service by using the command line interface

To modify a service, use the `set service` command, which is just like using the `add service` command, except that you enter the name of an existing service. To remove a service, use the `rm service` command, which accepts only the `<name>` argument.

To configure a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, create a service, and specify the protocol as SSL.

# Configuring an SSL-Based Virtual Server

Sep 04, 2014

Secure sessions require establishing a connection between the client and an SSL-based virtual server on the NetScaler appliance. The SSL virtual server intercepts SSL traffic, decrypts it and processes it before sending it to services that are bound to the virtual server.

Note: The SSL virtual server is marked as down on the NetScaler appliance until a valid certificate / key pair and at least one service are bound to it. An SSL based virtual server is a load balancing virtual server of protocol type SSL or SSL\_TCP. The load balancing feature must be enabled on the NetScaler.

To add an SSL-based virtual server by using the command line interface

At the command prompt, type the following commands to create an SSL-based virtual server and verify the configuration:

- add lb vserver <name> (serviceType) <IPAddress> <port>
- show lb vserver <name>

## Example

```
> add lb vserver vssl SSL 10.102.29.133 443
```

```
Done
```

```
> show ssl vserver vssl
```

```
Advanced SSL configuration for VServer vssl:
```

```
DH: DISABLED
```

```
Ephemeral RSA: ENABLED Refresh Count: 0
```

```
Session Reuse: ENABLED Timeout: 120 seconds
```

```
Cipher Redirect: DISABLED
```

```
SSLv2 Redirect: DISABLED
```

```
ClearText Port: 0
```

```
Client Auth: DISABLED
```

```
SSL Redirect: DISABLED
```

```
Non FIPS Ciphers: DISABLED
```

```
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
```

```
1) Cipher Name: DEFAULT
```

```
Description: Predefined Cipher Alias
```

```
Done
```

To modify or remove an SSL-based virtual server by using the command line interface

To modify the load balancing properties of an SSL virtual server, use the set lb vserver command, which is just like using the add lb vserver command, except that you enter the name of an existing vserver. To modify the SSL properties of an SSL-based virtual server, use the set ssl vserver command. For more information, see [Customizing the SSL Configuration](#).

To remove an SSL virtual server, use the rm lb vserver command, which accepts only the <name> argument.

To configure an SSL-based virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, create a virtual server, and specify the protocol as SSL.

# Binding Services to the SSL-Based Virtual Server

Aug 20, 2013

For the NetScaler appliance to forward decrypted SSL data to servers in the network, services representing these physical servers must be bound to the virtual server that receives the SSL data.

Because the link between the NetScaler and the physical server is typically secure, data transfer between the appliance and the physical server does not have to be encrypted. However, you can provide end-to-end-encryption by encrypting data transfer between the NetScaler and the server. For details, see [Configuring SSL Offloading with End-to-End Encryption](#).

Note: The Load Balancing feature should be enabled on the NetScaler appliance before you bind services to the SSL based virtual server.

To bind a service to a virtual server by using the command line interface

At the command prompt, type the following commands to bind the service to the virtual server and verify the configuration:

- bind lb vserver <name> <serviceName>
- show lb vserver <name>

## Example

```
> bind lb vserver vssl ssl1
Done
> show lb vserver vssl
vssl (10.102.29.133:443) - SSL Type: ADDRESS
State: DOWN[Certkey not bound]
Last state change was at Thu Nov 12 05:31:17 2009 (+485 ms)
Time since last state change: 0 days, 00:08:52.130
Effective State: DOWN
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
No. of Bound Services : 1 (Total) 1 (Active)
Configured Method: LEASTCONNECTION
Mode: IP
Persistence: NONE
Vserver IP and Port insertion: OFF
Push: DISABLED Push VServer:
Push Multi Clients: NO
Push Label Rule: none
```

```
1) ssl1 (10.102.29.252: 80) - HTTP State: UP Weight: 1
Done
```

To unbind a service from a virtual server by using the command line interface

At the command prompt, type the following command:

```
unbind lb vserver <name> <serviceName>
```

## Example

```
unbind lb vserver vssl ssl1
```

To bind a service to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, and click in the Services section to bind a service to the virtual server.

# Adding or Updating a Certificate-Key Pair

Aug 08, 2016

For any SSL transaction, the server needs a valid certificate and the corresponding private and public key pair. The SSL data is encrypted with the server's public key, which is available through the server's certificate. Decryption requires the corresponding private key.

Because the NetScaler appliance offloads SSL transactions from the server, the server's certificate and private key must be present on the appliance, and the certificate must be paired with its corresponding private key. This certificate-key pair must then be bound to the virtual server that processes the SSL transactions.

Both the certificate and the key must be in local storage on the NetScaler appliance before they can be added to the appliance. If your certificate or key file is not on the appliance, upload it to the appliance before you create the pair.

**Important:** Certificates and keys are stored in the `/nsconfig/ssl` directory by default. If your certificates or keys are stored in any other location, you must provide the absolute path to the files on the NetScaler appliance. The NetScaler FIPS appliances do not support external keys (non-FIPS keys). On a FIPS appliance, you cannot load keys from a local storage device such as a hard disk or flash memory. The FIPS keys must be present in the Hardware Security Module (HSM) of the appliance.

On a NetScaler MPX appliance and a NetScaler FIPS appliance, only RSA private keys are supported. On a VPX virtual appliance, both RSA and DSA private keys are supported. On an SDX appliance if SSL chips are assigned to an instance, then only RSA private keys are supported. However, if SSL chips are not assigned to an instance, then both RSA and DSA private keys are supported. In all the cases, you can bind a CA certificate with either RSA or DSA keys.

Set the notification period and enable the expiry monitor to be prompted before the certificate expires.

Note: A certificate must be signed by using one of the following hash algorithms:

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384 (supported only on the front end)
- SHA-512 (supported only on the front end)

An MPX appliance supports certificates of 512 or more bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back-end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

A VPX virtual appliance supports certificates of 512 or more bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 2048-bit certificate on the back-end server
- 2048-bit client certificate (if client authentication is enabled on the virtual server)

## Note

A NetScaler SDX appliance supports certificates of 512 or more bits. Each NetScaler VPX instance hosted on the appliance supports the certificate sizes listed above for a VPX virtual appliance. However, if an SSL chip is assigned to an instance, that instance supports the

To add a certificate-key pair by using the command line interface

At the command prompt, type the following commands to add a certificate-key pair and verify the configuration:

- add ssl certKey <certkeyName> -cert <string>[(-key <string> [-password]) | -fipsKey <string>] [-inform ( DER | PEM )] [<passplain>] [-expiryMonitor ( ENABLED | DISABLED )] [-notificationPeriod <positive\_integer>]]
- show ssl certKey [<certkeyName>]

### Example

```
> add ssl certKey sslkey -cert server_cert.pem -key server_key.pem -password ssl -expiryMonitor ENABLED -notificationPeriod 30
Done
```

Note: For FIPS appliances, replace -key with -fipskey

```
> show ssl certKey sslkey
```

```
 Name: sslkey Status: Valid, Days to expiration:8418
 Version: 3
 Serial Number: 01
 Signature Algorithm: md5WithRSAEncryption
 Issuer: C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.root.com
 Validity
 Not Before: Jul 15 02:25:01 2005 GMT
 Not After : Nov 30 02:25:01 2032 GMT
 Subject: C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.server.com
 Public Key Algorithm: rsaEncryption
 Public Key size: 2048
```

Done

To update or remove a certificate-key pair by using the command line interface

To modify the expiry monitor or notification period in a certificate-key pair, use the set ssl certkey command. To replace the certificate or key in a certificate-key pair, use the update ssl certkey command. The update ssl certkey command has an additional parameter for overriding the domain check. For both commands, enter the name of an existing certificate-key pair. To remove an SSL certificate-key pair, use the rm ssl certkey command, which accepts only the <certkeyName> argument.

To add or update a certificate-key pair by using the configuration utility

Navigate to Traffic Management > SSL > Certificates, and configure a certificate-key pair.

# Binding the Certificate-Key Pair to the SSL-Based Virtual Server

Aug 20, 2013

An SSL certificate is an integral element of the SSL encryption and decryption process. The certificate is used during an SSL handshake to establish the identity of the SSL server.

The certificate being used for processing SSL transactions must be bound to the virtual server that receives the SSL data. If you have multiple virtual servers receiving SSL data, a valid certificate-key pair must be bound to each of them.

You can use a valid, existing SSL certificate that you have uploaded to the NetScaler appliance. As an alternative for testing purposes, you can create your own SSL certificate on the appliance. Intermediate certificates created by using a FIPS key on the NetScaler cannot be bound to an SSL virtual server.

As a part of the SSL handshake, in the certificate request message during client authentication, the server lists the distinguished names (DNs) of all the certificate authorities (CAs) bound to the server from which it will accept a client certificate. If you do not want the DN name of a specific CA certificate to be sent to the SSL client, set the skipCA flag. This setting indicates that the particular CA certificate's distinguished name should not be sent to the SSL client.

For details on how to create your own certificate, see [Managing Certificates](#).

Note: Citrix recommends that you use only valid SSL certificates that have been issued by a trusted certificate authority. To bind an SSL certificate-key pair to a virtual server by using the command line interface

At the command prompt, type the following commands to bind an SSL certificate-key pair to a virtual server and verify the configuration:

- bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -CA -skipCAName
- show ssl vserver <vServerName>

## Example

```
> bind ssl vs vs1 -certkeyName cert2 -CA -skipCAName
Done
> sh ssl vs vs1
Advanced SSL configuration for VServer vs1:
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
```

Push Encryption Trigger: Always

Send Close-Notify: YES

1) CertKey Name: cert1 CA Certificate OCSPCheck: Optional CA\_Name Sent

2) CertKey Name: cert2 CA Certificate OCSPCheck: Optional CA\_Name Skipped

1) Cipher Name: DEFAULT

Description: Predefined Cipher Alias

Done

To unbind an SSL certificate-key pair from a virtual server by using the command line interface

If you try to unbind a certificate-key pair from a virtual server by using the `unbind ssl certKey <certkeyName>` command, an error message appears because the syntax of the command has changed. At the command prompt, type the following command:

```
unbind ssl vserver <vServerName> -certkeyName <string>
```

#### **Example**

```
unbind ssl vserver vssl -certkeyName sslckey
```

To bind an SSL certificate-key pair to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open an SSL virtual server and, in Advanced Settings, click SSL Certificate.
3. Bind a server certificate or CA certificate to the virtual server. To add a server certificate as an SNI certificate, select Server Certificate for SNI.

# Configuring an SSL Virtual Server for Secure Hosting of Multiple Sites

May 13, 2015

Virtual hosting is used by Web servers to host more than one domain name with the same IP address. The NetScaler supports hosting of multiple secure domains by offloading SSL processing from the Web servers using transparent SSL services or virtual server-based SSL offloading. However, when multiple Web sites are hosted on the same virtual server, the SSL handshake is completed before the expected host name is sent to the virtual server. As a result, the NetScaler cannot determine which certificate to present to the client after a connection is established. This problem is resolved by enabling Server Name Indication (SNI) on the virtual server. SNI is a Transport Layer Security (TLS) extension used by the client to provide the host name during handshake initiation. Based on the information provided by the client in the SNI extension, the NetScaler presents the corresponding certificate to the client.

A wildcard SSL Certificate helps enable SSL encryption on multiple subdomains if the domains are controlled by the same organization and share the same second-level domain name. For example, a wildcard certificate issued to a sports network using the common name "\*.sports.net" can be used to secure domains, such as "login.sports.net" and "help.sports.net" but not "login.ftp.sports.net."

Note: On a NetScaler appliance, SNI is not supported with a Subject Alternative Name (SAN) extension certificate. You can bind multiple server certificates to a single SSL virtual server or transparent service using the `-SNI Cert` option. These certificates are issued by the virtual server or service if SNI is enabled on the virtual server or service. You can enable SNI at any time.

To bind multiple server certificates to a single SSL virtual server by using the command line interface

At the command prompt, type the following commands to configure SNI and verify the configuration:

- `set ssl vserver <vServerName>@ [-SNIEnable ( ENABLED | DISABLED )]`
- `bind ssl vserver <vServerName>@ -certkeyName <string> -SNI Cert`
- `show ssl vserver <vServerName>`

To bind multiple server certificates to a transparent service by using the NetScaler command line, replace `vserver` with `service` and `vservername` with `servicename` in the above commands.

Note: The SSL service should be created with `-clearTextPort 80` option.

## Example

```
set ssl vserver v1 -sni ENABLED
bind ssl vserver v1 -certkeyName serverabc -SNI Cert
sh ssl vserver v1
Advanced SSL configuration for VServer v1:
...
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: ENABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
```

- 1) CertKey Name: servercert Server Certificate
- 1) CertKey Name: abccert Server Certificate for SNI
- 2) CertKey Name: xyzcert Server Certificate for SNI
- 3) CertKey Name: startcert Server Certificate for SNI
- 1) Cipher Name: DEFAULT

Description: Predefined Cipher Alias

Done

To bind multiple server certificates to a single SSL virtual server or transparent SSL service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open an SSL virtual server and, in Certificates, click Server Certificate.
3. Add a new certificate or select a certificate from the list, and select Server Certificate for SNI.
4. In Advanced Settings, click SSL Parameters.
5. Select SNI Enable.

# Configuring a DTLS Virtual Server

May 11, 2015

The SSL and TLS protocols have traditionally been used to secure streaming traffic. Both of these protocols are based on TCP, which is very slow. In addition, TLS cannot handle lost or reordered packets.

UDP is the preferred protocol for audio and video applications, such as Lync, Skype, iTunes, YouTube, training videos, and flash. However, UDP is not secure or reliable. The DTLS protocol is designed to secure data over UDP and is used for applications such as media streaming, VOIP, and online gaming for communication. In DTLS, each handshake message is assigned a specific sequence number within that handshake. When a peer receives a handshake message, it can quickly determine whether that message is the next one expected. If it is, the peer processes the message. If not, the message is queued for handling after all the previous messages have been received.

You must create a DTLS virtual server and a service of type UDP. By default, a DTLS profile (`nsdtls_default_profile`) is bound to the virtual server. Optionally, you can create and bind a user-defined DTLS profile to the virtual server.

Note: RC4, EDH, DHE, ADH, EXP, and ECDHE ciphers are not supported on a DTLS virtual server.

To create a DTLS configuration by using the command line

At the command prompt, type:

```
add lb vserver <vserver_name> DTLS <IPAddress> <port>
add service <service_name> <IPAddress> UDP 443
bind lb vserver <vserver_name> <udp_service_name>
```

The following steps are optional:

```
add dtlsProfile dtls1 -maxretryTime <positive_integer>
set ssl vserver <vserver_name> -dtlsProfileName <dtls_profile_name>
```

To create a DTLS configuration by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Create a virtual server of type DTLS, and bind a UDP service to the virtual server.
3. A default DTLS profile is bound to the DTLS virtual server. To bind a different profile, in SSL Parameters, select a different DTLS profile. To create a new profile, click the plus (+) next to DTLS Profile.

## Example

The following example is for an end-to-end DTLS configuration:

```
> enable ns feature SSL LB
> add server s1 10.102.59.190
> add service svc1 s1 UDP 32000
> add lb vserver lb1 DTLS 10.102.59.244 443
> add ssl certKey servercert -cert server_cert.pem -key server_key.pem
> bind ssl vserver lb1 -certkeyname servercert
> bind lb vserver lb1 svc1

> sh lb vserver lb1
lb1 (10.102.59.244:443) - DTLS Type: ADDRESS
State: UP
Last state change was at Tue May 20 16:41:27 2014
```

Time since last state change: 0 days, 00:01:39.120  
Effective State: UP  
Client Idle Timeout: 120 sec

TD: 0  
Mac mode Retain Vlan: DISABLED  
DBS\_LB: DISABLED  
Process Local: DISABLED

1 bound service:

1) svc1 (10.102.59.190: 32000) - UDP State: UP Weight: 1  
Done

>

> sh ssl vserver lb1

Advanced SSL configuration for VServer lb1:

DH: DISABLED  
Ephemeral RSA: ENABLED Refresh Count: 0  
Session Reuse: ENABLED Timeout: 1800 seconds  
Cipher Redirect: DISABLED

ClearText Port: 0  
Client Auth: DISABLED  
SSL Redirect: DISABLED  
Non FIPS Ciphers: DISABLED  
SNI: DISABLED  
DTLSv1: ENABLED  
Send Close-Notify: YES

DTLS profile name: nsdtls\_default\_profile

1 bound certificate:

1) CertKey Name: servercert Server Certificate

1 configured cipher:

1) Cipher Name: DEFAULT  
Description: Predefined Cipher Alias  
Done

> sh dtlsProfile nsdtls\_default\_profile

1) Name: nsdtls\_default\_profile  
PMTU Discovery: DISABLED  
Max Record Size: 1460 bytes  
Max Retry Time: 3 sec  
Hello Verify Request: DISABLED  
Terminate Session: DISABLED  
Max Packet Count: 120 bytes  
Done

Features not supported by a DTLS virtual server

The following options cannot be enabled on a DTLS virtual server:

- SSLv2
- SSLv3
- TLSv1
- TLSv1.1
- TLSv1.2
- Push encrypt trigger
- SSLv2Redirect
- SSLv2URL
- SNI
- Secure renegotiation

Parameters not used by a DTLS virtual server

The following SSL parameters, even if set, are ignored by a DTLS virtual server:

- Encryption trigger packet count
- PUSH encryption trigger timeout
- SSL quantum size
- Encryption trigger timeout
- Subject/Issuer Name Insertion Format

# DTLS Profile

Feb 03, 2015

A DTLS profile with the default settings is automatically bound to a DTLS virtual server. However, you can create a new DTLS profile with specific settings to suit your requirement.

To create a DTLS profile by using the command line

- add ssl dtlsProfile <name>
- show ssl dtlsProfile<name>

## Example

```
> add dtlsProfile dtls1 -helloVerifyRequest ENABLED -maxretryTime 4
```

Done

```
> show dtlsProfile dtls1
```

```
1) Name: dtls1
```

```
 PMTU Discovery: DISABLED
```

```
 Max Record Size: 1460 bytes
```

```
 Max Retry Time: 4 sec
```

```
 Hello Verify Request: ENABLED
```

```
 Terminate Session: DISABLED
```

```
 Max Packet Count: 120 bytes
```

Done

To create a DTLS profile by using the configuration utility

Navigate to System > Profiles > DTLS Profiles and configure a new profile.

# Importing SSL Files from Remote Hosts

May 20, 2014

You can now import SSL resources, such as certificates, private keys, CRLs, and DH keys, from remote hosts even if FTP access to these hosts is not available. This is especially helpful in environments where shell access to the remote host is restricted. Default folders are created in /nsconfig/ssl as follows:

- For certificate files: /nsconfig/ssl/certfile
- For private keys: the /nsconfig/ssl/keyfile
- For CRLs: /var/netscaler/ssl/crlfile
- For DH keys: /nsconfig/ssl/dhfile

Imports from both HTTP and HTTPS servers are supported. However, the import fails if the file is on an HTTPS server that requires client certificate authentication for access.

Note: The import command is not stored in the configuration (ns.conf) file, because reimporting the file after a restart might cause an error.

To import a certificate file from a remote host by using the command line

At the command prompt, type:

```
import ssl certFile [<name>] [<src>]
```

## Example

```
import ssl certfile my-certfile http://www.example.com/file_1
```

```
> show ssl certfile
```

```
 Name : my-certfile
```

```
 URL : http://www.example.com/file_1
```

To remove a certificate file, use the `rm ssl certFile` command, which accepts only the <name> argument.

To import a key file from a remote host by using the command line

At the command prompt, type:

```
import ssl keyFile [<name>] [<src>]
```

## Example

```
import ssl keyfile my-keyfile http://www.example.com/key_file
```

```
> show ssl keyfile
```

```
 Name : my-keyfile
```

```
 URL : http://www.example.com/key_file
```

To remove a key file, use the `rm ssl keyFile` command, which accepts only the <name> argument.

To import a CRL file from a remote host by using the command line

At the command prompt, type:

```
import ssl crlFile [<name>] [<src>]
```

## Example

```
import ssl crlfile my-crlfile http://www.example.com/crl_file
```

```
> show ssl crlfile
```

```
 Name : my-crlfile
```

```
 URL : http://www.example.com/crl_file
```

To remove a CRL file, use the `rm ssl crlFile` command, which accepts only the `<name>` argument.

To import a DH file from a remote host by using the command line

At the command prompt, type:

```
import ssl dhFile [<name>] [<src>]
```

## Example

```
import ssl dhfile my-dhfile http://www.example.com/dh_file
```

```
> show ssl dhfile
```

```
 Name : my-dhfile
```

```
 URL : http://www.example.com/dh_file
```

To remove a DH file, use the `rm ssl dhFile` command, which accepts only the `<name>` argument.

To import an SSL resource by using the configuration utility

Navigate to Traffic Management > SSL > Imports, and then select the appropriate tab.

# SSL Profiles

May 20, 2015

You can use an SSL profile to specify how a NetScaler ADC processes SSL traffic. The profile is a collection of SSL parameter settings for SSL entities, such as virtual servers, services, and service groups, and offers ease of configuration and flexibility. You are not limited to configuring only one set of global parameters. You can create multiple sets (profiles) of global parameters and assign different sets to different SSL entities. SSL profiles are classified into two categories:

- Front end profiles, containing parameters applicable to the front-end entity. That is, they apply to the entity that receives requests from a client.
- Backend profiles, containing parameters applicable to the back-end entity. That is, they apply to the entity that sends client requests to a server.

Unlike a TCP or HTTP profile, an SSL profile is optional. Therefore, there is no default SSL profile. The same profile can be reused across multiple entities. If an entity does not have a profile attached, the values set at the global level apply. For dynamically learned services, current global values apply.

The following table lists the parameters that are part of each profile.

| Front end profile         | Backend profile        |
|---------------------------|------------------------|

| sslTriggerTimeout      |                   |
| strictCAChecks         |                   |
| tls1, tls11, tls12     |                   |

\* The clearTextPort parameter applies only to an SSL virtual server.

An error message appears if you try to set a parameter that is not part of the profile (for example, if you try to set the clientAuth parameter in a backend profile).

Some SSL parameters, such as CRL memory size, OCSP cache size, Undefined Action Control, and Undefined Action Data, are not part of any of the above profiles, because these parameters are independent of entities.

An SSL profile supports the following operations:

- Add—Creates an SSL profile on the NetScaler ADC. Specify whether the profile is front end or backend. Front end is the default.
- Set—Modifies the settings of an existing profile.
- Unset—Sets the specified parameters to their default values. If you do not specify any parameters, an error message appears. If you unset a profile on an entity, the profile is unbound from the entity.
- Remove—Deletes a profile. A profile that is being used by any entity cannot be deleted. Clearing the configuration deletes all the entities. As a result, the profiles are also deleted.
- Show—Displays all the profiles that are available on the NetScaler ADC. If a profile name is specified, the details of that profile are displayed. If an entity is specified, the profiles associated with that entity are displayed.

To create an SSL profile by using the command line

- To add an SSL profile, type: add ssl profile <name> [-sslProfileType ( BackEnd | FrontEnd )]
- To modify an existing profile, type: set ssl profile <name>
- To unset an existing profile, type: unset ssl profile <name> [-dh] [-dhFile] [-dhCount] [-eRSA]....
- To unset an existing profile from an entity, type: unset ssl vserver <vServerName> -sslProfile
- To remove an existing profile, type: rm ssl profile <name>
- To display an existing profile, type: sh ssl profile <name>

## Examples

1. Adding a front end (default) profile:

```
> add sslprofile p1
Done
```

2. Adding a backend profile:

```
> add sslprofile p2 -sslprofileType backend -tls1 disabled
Done
```

3. Enabling settings on a backend profile:

```
> set sslprofile p2 -serverAuth eENABLED
Done
```

4. Enabling settings on a frontend profile:

```
> set sslprofile p1 -clientauth eENABLED -clientcert optional
Done
```

```
sh ssl profile p1
```

- 1) Configuration for Front-End SSL profile

```
Name: p1
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
Session Reuse: ENABLED Timeout: 120 seconds
Non FIPS Ciphers: DISABLED
Cipher Redirect: DISABLED
Client Auth: ENABLED Client Cert Required: Optional
SSL Redirect: DISABLED
SNI: DISABLED
SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: DISABLED TLSv1.2: DISABLED
Push Encryption Trigger: Always
PUSH encryption trigger timeout: 1 ms
Send Close-Notify: YES
Push flag: 0x0 (Auto)
Deny SSL Renegotiation NO
SSL quantum size: 8 kB
Strict CA checks: NO
Encryption trigger timeout 100 mS
Encryption trigger packet count: 45
Subject/Issuer Name Insertion Format: Unicode
Strict Host Header check for SNI enabled SSL sessions: NO
```

```
Done
```

5. Settings parameters to their default values:

```
> unset sslprofile p1 -clientauth -clientcert
```

Done

```
> sh ssl profile p1
```

1) Configuration for Front-End SSL profile

Name: p1

DH: DISABLED

Ephemeral RSA: ENABLED Refresh Count: 0

Session Reuse: ENABLED Timeout: 120 seconds

Non FIPS Ciphers: DISABLED

Cipher Redirect: DISABLED

Client Auth: DISABLED

SSL Redirect: DISABLED

SNI: DISABLED

SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: DISABLED TLSv1.2: DISABLED

Push Encryption Trigger: Always

PUSH encryption trigger timeout: 1 ms

Send Close-Notify: YES

Push flag: 0x0 (Auto)

Deny SSL Renegotiation NO

SSL quantum size: 8 kB

Strict CA checks: NO

Encryption trigger timeout 100 mS

Encryption trigger packet count: 45

Subject/Issuer Name Insertion Format: Unicode

Strict Host Header check for SNI enabled SSL sessions: NO

Done

6. Deleting a profile:

```
> rm sslprofile p1
```

Done

7. Binding a profile to a virtual server:

```
> set ssl vserver v1 -sslprofile p3
```

Done

8. Unbinding a profile from a virtual server:

```
> unset ssl vserver v1 -sslprofile
```

Done

To create an SSL profile by using the configuration utility

Navigate to System > Profiles, select the SSL Profiles tab, and create an SSL profile.

### Enabling Stricter Control on Client Certificate Validation

Note: This feature is supported from release 10.5 build 57.7 and later.

The NetScaler appliance accepts valid Intermediate-CA certificates if they are issued by a single Root-CA. That is, if only the Root-CA certificate is bound to the virtual server, and any intermediate certificate sent with the client certificate is validated by that Root-CA, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, none of the intermediate certificates can be validated by using a CRL or OCSP responder unless that certificate is bound to the SSL virtual server. Therefore, even if one of the

intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that is signed by one of the CA certificates bound to that virtual server. To do so, you must enable the `ClientAuthUseBoundCAChain` setting in the SSL profile bound to the virtual server. The handshake fails if the client certificate is not signed by one of the CA certificates bound to the virtual server.

For example, say two client certificates, `clientcert1` and `clientcert2`, are signed by the intermediate certificates `Int-CA-A` and `Int-CA-B`, respectively. The intermediate certificates are signed by the root certificate `Root-CA`. `Int-CA-A` and `Root-CA` are bound to the SSL virtual server. In the default case (`ClientAuthUseBoundCAChain` disabled), both `clientcert1` and `clientcert2` are accepted. However, if `ClientAuthUseBoundCAChain` is enabled, only `clientcert1` is accepted by the NetScaler appliance.

### **To enable stricter control on client certificate validation by using the command line**

At the NetScaler command prompt, type: `set ssl profile <name> -ClientAuthUseBoundCAChain Enabled`

### **To enable stricter control on client certificate validation by using the configuration utility**

1. Navigate to `System > Profiles`, select the `SSL Profiles` tab, and create an SSL profile, or select an existing profile.
2. Select `Enable Client Authentication using bound CA Chain`.

# Enabling Stricter Control on Client Certificate Validation

May 14, 2015

The NetScaler appliance accepts valid Intermediate-CA certificates if they are issued by a single Root-CA. That is, if only the Root-CA certificate is bound to the virtual server, and any intermediate certificate sent with the client certificate is validated by that Root-CA, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, none of the intermediate certificates can be validated by using a CRL or OCSP responder unless that certificate is bound to the SSL virtual server. Therefore, even if one of the intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that is signed by one of the CA certificates bound to that virtual server. To do so, you must enable the `ClientAuthUseBoundCAChain` setting in the SSL profile bound to the virtual server. The handshake fails if the client certificate is not signed by one of the CA certificates bound to the virtual server.

For example, say two client certificates, `clientcert1` and `clientcert2`, are signed by the intermediate certificates `Int-CA-A` and `Int-CA-B`, respectively. The intermediate certificates are signed by the root certificate `Root-CA`. `Int-CA-A` and `Root-CA` are bound to the SSL virtual server. In the default case (`ClientAuthUseBoundCAChain` disabled), both `clientcert1` and `clientcert2` are accepted. However, if `ClientAuthUseBoundCAChain` is enabled, only `clientcert1` is accepted by the NetScaler appliance.

## To enable stricter control on client certificate validation by using the command line

At the NetScaler command prompt, type: `set ssl profile <name> -ClientAuthUseBoundCAChain Enabled`

## To enable stricter control on client certificate validation by using the configuration utility

1. Navigate to `System > Profiles`, select the `SSL Profiles` tab, and create an SSL profile, or select an existing profile.
2. Select `Enable Client Authentication using bound CA Chain`.

# Managing Certificates

Jun 03, 2015

An SSL certificate, which is an integral part of any SSL transaction, is a digital data form (X509) that identifies a company (domain) or an individual. The certificate has a public key component that is visible to any client that wants to initiate a secure transaction with the server. The corresponding private key, which resides securely on the NetScaler appliance, is used to complete asymmetric key (or public key) encryption and decryption.

You can obtain an SSL certificate and key in either of the following ways:

- From an authorized certificate authority (CA), such as VeriSign
- By generating a new SSL certificate and key on the NetScaler appliance

Alternately, you can use an existing SSL certificate on the appliance.

Caution: Citrix recommends that you use certificates obtained from authorized CAs, such as VeriSign, for all your SSL transactions. Certificates generated on the NetScaler appliance should be used for testing purposes only, not in any live deployment.

To manage certificates, see the following sections:

- [Obtaining a Certificate from a Certificate Authority](#)
- [Importing Existing Certificates and Keys](#)
- [Generating a Self-Signed Certificate](#)
- [Adding a Group of SSL Certificates](#)
- [Displaying a Certificate Chain](#)
- [Generating a Server Test Certificate](#)
- [Modifying and Monitoring Certificates and Keys](#)
- [Using Global Site Certificates](#)
- [Converting the Format of SSL Certificates for Import or Export](#)

# Obtaining a Certificate from a Certificate Authority

Mar 30, 2015

A certificate authority (CA) is an entity that issues digital certificates for use in public key cryptography. Certificates issued or signed by a CA are automatically trusted by applications, such as web browsers, that conduct SSL transactions. These applications maintain a list of the CAs that they trust. If the certificate being used for the secure transaction is signed by any of the trusted CAs, the application proceeds with the transaction.

To obtain an SSL certificate from an authorized CA, you must create a private key, use that key to create a certificate signing request (CSR), and submit the CSR to the CA. The only special characters allowed in the file names are underscore and dot.

## Creating a Private Key

The private key is the most important part of a digital certificate. By definition, this key is not to be shared with anyone and should be kept securely on the NetScaler appliance. Any data encrypted with the public key can be decrypted only by using the private key.

The appliance supports two encryption algorithms, RSA and DSA, for creating private keys. You can submit either type of private key to the CA. The certificate that you receive from the CA is valid only with the private key that was used to create the CSR, and the key is required for adding the certificate to the NetScaler.

Caution: Be sure to limit access to your private key. Anyone who has access to your private key can decrypt your SSL data.

All SSL certificates and keys are stored in the `/nsconfig/ssl` folder on the appliance. For added security, you can use the Data Encryption Standard (DES) or triple DES (3DES) algorithm to encrypt the private key stored on the appliance.

Note: The length of the SSL key name allowed includes the length of the absolute path name if the path is included in the key name.

## To create an RSA private key by using the command line interface

At the command prompt, type the following command:

```
create ssl rsakey <keyFile> <bits> [-exponent (3 | F4)] [-keyform (DER | PEM)]
```

### Example

```
> create ssl rsakey Key-RSA-1 2048 -exponent F4 -keyform PEM
```

## To create a DSA private key by using the command line interface

At the command prompt, type the following command:

```
create ssl dsakey <keyfile> <bits> [-keyform (DER | PEM)]
```

### Example

```
> create ssl dsakey Key-DSA-1 2048 -keyform PEM
```

## To create an RSA private key by using the configuration utility

Navigate to Traffic Management > SSL and, in the SSL Keys group, select Create RSA Key, and create an RSA key.

## To create a DSA private key by using the configuration utility

Navigate to Traffic Management > SSL and, in the SSL Keys group, select Create DSA Key, and create a DSA key.

## Creating a Certificate Signing Request

The certificate signing request (CSR) is a collection of information, including the domain name, other important company details, and the private key to be used to create the certificate. To avoid generating an invalid certificate, make sure that the details you provide are accurate.

## To create a certificate signing request by using the command line interface

At the command prompt, type the following command:

```
create ssl certreq <reqFile> -keyFile <input_filename> | -fipsKeyName <string> [-keyForm (DER | PEM) {-PEMPassPhrase }] -countryName <string> -stateName <string> -organizationName <string> [-organizationUnitName <string>] [-localityName <string>] [-commonName <string>] [-emailAddress <string>] [-challengePassword] [-companyName <string>]
```

### Example

```
create ssl certreq csreq1 -keyfile ramp -keyform PEM -countryName US -stateName Florida -localityName FortLauderdale -organizationName Citrix -organizationUnitName DNPG
```

## To create a certificate signing request by using the configuration utility

Navigate to Traffic Management > SSL and, in the SSL Certificates group, select Create Certificate Signing Request (CSR), and create a CSR.

## Submitting the CSR to the CA

Most CAs accept certificate submissions by email. The CA will return a valid certificate to the email address from which you submit the CSR.

# Importing Existing Certificates and Keys

Nov 11, 2013

If you want to use certificates and keys that you already have on other secure servers or applications in your network, you can export them, and then import them to the NetScaler appliance. You might have to convert exported certificates and keys before you can import them to the NetScaler appliance.

For the details of how to export certificates from secure servers or applications in your network, see the documentation of the server or application from which you want to export.

Note: For installation on the NetScaler appliance, key and certificate names cannot contain spaces or special characters other than those supported by the UNIX file system. Follow the appropriate naming convention when you save the exported key and certificate.

A certificate and private key pair is commonly sent in the PKCS#12 format. The NetScaler supports PEM and DER formats for certificates and keys. To convert PKCS#12 to PEM or DER, or PEM or DER to PKCS#12, see [Converting the Format of SSL Certificates for Import or Export](#).

The NetScaler appliance does not support PEM keys in PKCS#8 format. However, you can convert these keys to a supported format by using the OpenSSL interface, which you can access from the NetScaler command line or the configuration utility. Before you convert the key, you need to verify that the private key is in PKCS#8 format. Keys in PKCS#8 format typically start with the following text:

```
-----BEGIN ENCRYPTED PRIVATE KEY-----
```

```
leuSSZQZKgrgUQ==
```

```
-----END ENCRYPTED PRIVATE KEY-----
```

To open the OpenSSL interface from the command line interface

1. Open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on to the appliance by using the administrator credentials.
3. At the command prompt, type shell.
4. At the shell prompt type openssl.

To open the ssl interface from the configuration utility

Navigate to Traffic Management > SSL and, in the Tools group, select OpenSSL interface.

To convert a non-supported PKCS#8 key format to an encrypted supported key format by using the OpenSSL interface

At the OpenSSL prompt, type one of the following commands, depending on whether the non-supported key format is of type rsa or dsa:

- `rsa -in <PKCS#8 Key Filename> -des3 -out <encrypted Key Filename>`
- `dsa -in <PKCS#8 Key Filename> -des3 -out <encrypted Key Filename>`

To convert a non-supported PKCS#8 key format to an unencrypted key format by using the OpenSSL interface

At the OpenSSL prompt, type the following commands, depending on whether the non-supported key format is of type rsa

or dsa:

- `rsa -in <PKCS#8 Key Filename> -out <unencrypted Key Filename>`
- `dsa -in <PKCS#8 Key Filename> -out <unencrypted Key Filename>`

## Parameters for converting an unsupported key format to a supported key format

### **<PKCS#8 Key Filename>**

The input file name of the incompatible PKCS#8 private key.

### **<encrypted Key Filename>**

The output file name of the compatible encrypted private key in PEM format.

### **<unencrypted Key Filename>**

The output file name of the compatible unencrypted private key in PEM format.

# Generating a Self-Signed Certificate

Jun 15, 2015

The NetScaler appliance has a built in CA tools suite that you can use to create self-signed certificates for testing purposes.

Caution: Because these certificates are signed by the NetScaler itself, not by an actual CA, you should not use them in a production environment. If you attempt to use a self-signed certificate in a production environment, users will receive a "certificate invalid" warning each time the virtual server is accessed.

The NetScaler supports creation of the following types of certificates

- Root-CA certificates
- Intermediate-CA certificates
- End-user certificates
  - server certificates
  - client certificates

Before generating a certificate, create a private key and use that to create a certificate signing request (CSR) on the appliance. Then, instead of sending the CSR out to a CA, use the NetScaler CA Tools to generate a certificate.

For details on how to create a private key and a CSR, see [Obtaining a Certificate from a Certificate Authority](#).

To create a certificate by using a wizard

1. Navigate to Traffic Management > SSL.
2. In the details pane, under Getting Started, select the wizard for the type of certificate that you want to create.
3. Follow the instructions on the screen.

To create a Root-CA certificate by using the command line interface

At the command prompt, type the following command:

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform (DER | PEM)] [-days <positive_integer>]
```

## Example

```
> create ssl cert certi1 csreq1 ROOT_CERT -keyFile
rsa1 -keyForm PEM -days 365
Done
```

To create an Intermediate-CA certificate or end-user certificate by using the command line interface

At the command prompt, type the following command:

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform (DER | PEM)] [-days <positive_integer>] [-certForm (DER | PEM)] [-CAcert <input_filename>] [-CAcertForm (DER | PEM)] [-CAkey <input_filename>] [-CAkeyForm (DER | PEM)] [-CAserial <output_filename>]
```

## Example

```
> create ssl cert certsy csr1 INTM_CERT -CAcert certi1
```

```
-CAkey rsakey1 -CAserial 23
```

Done

To create a Root-CA certificate by using the configuration utility

Navigate to Traffic Management > SSL and, in the Getting Started group, select Root-CA Certificate Wizard, and configure a root CA certificate.

To create an Intermediate-CA certificate or end-user certificate by using the configuration utility

Navigate to Traffic Management > SSL and, in the Getting Started group, select Intermediate-CA Certificate Wizard, and configure an intermediate CA certificate.

### Generating a Diffie-Hellman (DH) Key

The Diffie-Hellman (DH) key exchange is a way for two parties involved in an SSL transaction that have no prior knowledge of each other to agree upon a shared secret over an insecure channel. This secret can then be converted into cryptographic keying material for mainly symmetric key cipher algorithms that require such a key exchange.

This feature is disabled by default and should be specifically configured to support ciphers that use DH as the key exchange algorithm.

Note: Generating a 2048-bit DH key may take a long time (up to 30 minutes).

### To generate a DH key by using the command line interface

At the command prompt, type the following command:

```
create ssl dhparam <dhFile> [<bits>] [-gen (2 | 5)]
```

#### **Example**

```
create ssl dhparam Key-DH-1 512 -gen 2
```

### To generate a DH key by using the configuration utility

Navigate to Traffic Management > SSL and, in the Tools group, select Create Diffie-Hellman (DH) key, and generate a DH key.

# Adding a Group of SSL Certificates

Feb 17, 2017

If the server certificate is issued by an intermediate CA that is not recognized by standard web browsers as a trusted CA, the CA certificate(s) must be sent to the client with the server's own certificate. Otherwise, the browser terminates the SSL session because it fails to authenticate the server certificate.

There are two ways to add the server and intermediate certificates:

- Create a certificate set that contains the chain of certificates.
- Create a chain of certificates manually by adding and linking the certificates individually.

## Adding and Linking a Certificate Set

Note: This feature is not supported on the NetScaler FIPS platform and in a cluster setup.

Instead of adding and linking individual certificates, you can now group a server certificate and up to nine intermediate certificates in a single file, and then specify the file's name when adding a certificate-key pair. Before you do so, make sure that the following prerequisites are met.

- The certificates in the file are in the following order:
  - Server certificate (should be the first certificate in the file)
  - Optionally, a server key
  - Intermediate certificate 1 (ic1)
  - Intermediate certificate 2 (ic2)
  - Intermediate certificate 3 (ic3), and so on

Note: Intermediate certificate files are created for each intermediate certificate with the name "`<certificatebundlename>.pem_ic<n>`" where n is between 1 and 9. For example, `bundle.pem_ic1`, where `bundle` is the name of the certificate set and `ic1` is the first intermediate certificate in the set.

- Bundle option is selected.
- No more than nine intermediate certificates are present in the file.

The file is parsed and the server certificate, intermediate certificates, and server key (if present) are identified. First, the server certificate and key are added. Then, the intermediate certificates are added, in the order in which they were added to the file, and linked accordingly.

An error is reported if any of the following conditions exist:

- A certificate file for one of the intermediate certificates already exists on the appliance.
- The key is placed before the server certificate in the file.
- An intermediate certificate is placed before the server certificate.
- Intermediate certificates are not in placed in the file in the same order as they are created.
- No certificates are present in the file.
- A certificate is not in the proper PEM format.
- The number of intermediate certificates in the file exceeds nine.

## To add a certificate set by using the command line interface

At the command prompt, type the following commands to create a certificate set and verify the configuration:

1. add ssl certKey <certkeyName> -cert <string> -key <string> -bundle (YES | NO)
2. show ssl certKey
3. show ssl certlink

#### Example

In the following example, the certificate set (bundle.pem) contains the following files:

- server certificate (bundle) linked to bundle\_ic1
- First intermediate certificate (bundle\_ic1) linked to bundle\_ic2
- Second intermediate certificate (bundle\_ic2) linked to bundle\_ic3
- Third intermediate certificate (bundle\_ic3)

```
> add ssl certKey bundle -cert bundle.pem -key bundle.pem -bundle yes
```

```
> show ssl certkey
```

```
1) Name: bundle
```

```
Cert Path: /nsconfig/ssl/bundle.pem
```

```
Format: PEM
```

```
Status: Valid, Days to expiration:10415
```

```
Certificate Expiry Monitor: DISABLED
```

```
2) Name: bundle_ic1
```

```
Cert Path: /nsconfig/ssl/bundle.pem_ic1
```

```
Format: PEM
```

```
Status: Valid, Days to expiration:10415
```

```
Certificate Expiry Monitor: DISABLED
```

```
3) Name: bundle_ic2
```

```
Cert Path: /nsconfig/ssl/bundle.pem_ic2
```

```
Format: PEM
```

```
Status: Valid, Days to expiration:10415
```

```
Certificate Expiry Monitor: DISABLED
```

```
4) Name: bundle_ic3
```

```
Cert Path: /nsconfig/ssl/bundle.pem_ic3
```

```
Format: PEM
```

```
Status: Valid, Days to expiration:10415
```

```
Certificate Expiry Monitor: DISABLED
```

```
Done
```

```
> show ssl certlink
```

```
1) Cert Name: bundle CA Cert Name: bundle_ic1
```

```
2) Cert Name: bundle_ic1 CA Cert Name: bundle_ic2
```

```
3) Cert Name: bundle_ic2 CA Cert Name: bundle_ic3
```

```
Done
```

## To add a certificate set by using the configuration utility

1. Navigate to Traffic Management > SSL > Certificates.
2. In the SSL Certificates pane, click Install.
3. In the Install Certificate dialog box, type the details, such as the certificate and key file name, and then select Certificate Bundle.
4. Click Install, and then click Close.

## Creating a Chain of Certificates

Updated: 2013-08-20

Instead of using a set of certificates (a single file), you can create a chain of certificates. The chain links the server certificate to its issuer (the intermediate CA). For this approach to work, the intermediate CA certificate file must already be installed on the NetScaler appliance, and one of the certificates in the chain must be trusted by the client application. For example, link Cert-Intermediate-A to Cert-Intermediate-B, where Cert-Intermediate-B is linked to Cert-Intermediate-C, which is a certificate trusted by the client application.

Note: The NetScaler supports sending a maximum of 10 certificates in the chain of certificates sent to the client (one server certificate and nine CA certificates).

## To create a certificate chain by using the command line interface

At the command prompt, type the following commands to create a certificate chain and verify the configuration. (Repeat the first command for each new link in the chain.)

- link ssl certkey <certKeyName> <linkCertKeyName>
- show ssl certlink

### Example

```
> link ssl certkey siteAcertkey CAcertkey
Done
```

```
> show ssl certlink
```

linked certificate:

```
1) Cert Name: siteAcertkey CA Cert Name: CAcertkey
Done
```

## To create a certificate chain by using the configuration utility

1. Navigate to Traffic Management > SSL > Certificates.
2. Select a server certificate, and in the Action list, select Link, and specify a CA certificate name.

# Displaying a Certificate Chain

Jun 18, 2014

A certificate contains the name of the issuing authority and the subject to whom the certificate is issued. To validate a certificate, you must look at the issuer of that certificate and confirm if you trust the issuer. If you do not trust the issuer, you must see who issued the issuer certificate. Go up the chain till you reach the root CA certificate or an issuer that you trust.

As part of the SSL handshake, when a client requests a certificate, the NetScaler appliance presents a certificate and the chain of issuer certificates that are present on the appliance. An administrator can view the certificate chain for the certificates present on the appliance and install any missing certificates.

To view the certificate chain for the certificates present on the appliance by using the command line

At the command prompt, type:

```
show ssl certchain <cert_name>
```

## Examples

There are 3 certificates: c1, c2, and c3. Certificate c1 is signed by c2, c2 is signed by c3, and c3 is the root CA certificate. The following examples illustrate the output of the `show ssl certchain c1` command in different scenarios.

### 1. Scenario 1:

- Certificate c2 is linked to c1, and c3 is linked to c2.
- Certificate c3 is a root CA certificate.

If you run the following command, the certificate links up to the root CA certificate are displayed.

```
> show ssl certchain c1
```

Certificate chain details of certificate name c1 are:

- 1) Certificate name: c2           linked; not a root certificate
- 2) Certificate name: c3           linked; root certificate

Done

### 2. Scenario 2:

- Certificate c2 is linked to c1.
- Certificate c2 is not a root CA certificate.

If you run the following command, information that certificate c3 is a root CA certificate but is not linked to c2 is displayed.

```
> show ssl certchain c1
```

Certificate chain details of certificate name c1 are:

- 1) Certificate Name: c2           linked; not a root certificate
- 2) Certificate Name: c3           not linked; root certificate

Done

### 3. Scenario 3:

- Certificate c1, c2, and c3 are not linked but are present on the appliance.

If you run the following command, information about all the certificates starting with the issuer of certificate c1 is displayed and it is specified that the certificates are not linked.

```
> show ssl certchain c1
```

Certificate chain details of certificate name c1 are:

- 1) Certificate Name: c2           not linked; not a root certificate

2) Certificate Name: c3           not linked; root certificate

Done

4. Scenario 4:

- Certificate c2 is linked to c1.
- Certificate c3 is not present on the appliance.

If you run the following command, information about the certificate linked to c1 is displayed and you are prompted to add a certificate with the subject name specified in c2. In this case, the user is asked to add the root CA certificate c3.

```
> show ssl certchain c1
```

Certificate chain details of certificate name c1 are:

1) Certificate Name: c2           linked; not a root certificate

2) Certificate Name: /C=IN/ST=ka/O=netScaler/CN=test

Action: Add a certificate with this subject name.

Done

5. Scenario 5:

- A certificate is not linked to certificate c1 and the issuer certificate of c1 is not present on the appliance.

If you run the following command, you are prompted to add a certificate with the subject name in certificate c1.

```
> sh ssl certchain c1
```

Certificate chain details of certificate name c1 are:

1) Certificate Name: /ST=KA/C=IN

Action: Add a certificate with this subject name.

# Generating a Server Test Certificate

Aug 20, 2013

The NetScaler appliance allows you to create a test certificate for server authentication by using a GUI wizard in the configuration utility. A server certificate is used to authenticate and identify a server in an SSL handshake. A server certificate is generally issued by a trusted CA and is sent out by the server to a client who uses it to authenticate the server.

For issuing a server test certificate, the appliance operates as a CA. This certificate can be bound to an SSL virtual server for authentication in an SSL handshake with a client. This certificate is for testing purposes only. It should not be used in a production environment.

You can install the server test certificate on any virtual server that uses the SSL or the SSL\_TCP protocol.

To generate a server test certificate by using the configuration utility

Navigate to Traffic Management > SSL and, in the SSL Certificates group, select Create and Install a Server Test Certificate.

# Modifying and Monitoring Certificates and Keys

Apr 28, 2016

To avoid downtime when replacing a certificate-key pair, you can update an existing certificate. If you want to replace a certificate with a certificate that was issued to a different domain, you must disable domain checks before updating the certificate.

To receive notifications about certificates due to expire, you can enable the expiry monitor.

## Updating an Existing Server Certificate

When you remove or unbind a certificate from a configured SSL virtual server, or an SSL service, the virtual server or service becomes inactive until a new valid certificate is bound to it. To avoid downtime, you can use the update feature to replace a certificate-key pair that is bound to an SSL virtual server or an SSL service, without first unbinding the existing certificate.

## To update an existing certificate-key pair by using the command line interface

At the command prompt, type the following commands to update an existing certificate-key pair and verify the configuration:

- `update ssl certkey <certkeyName> -cert <string> -key <string>`
- `show ssl certKey <certkeyName>`

### Example

```
> update ssl certkey siteAcertkey -cert /nsconfig/ssl/cert.pem
-key /nsconfig/ssl/pkey.pem
Done
```

```
> show ssl certkey siteAcertkey
Name: siteAcertkey Status: Valid
 Version: 3
 Serial Number: 02
 Signature Algorithm: md5WithRSAEncryption
 Issuer: /C=US/ST=CA/L=Santa Clara/O=siteA/OU=Tech
 Validity
 Not Before: Nov 11 14:58:18 2001 GMT
 Not After: Aug 7 14:58:18 2004 GMT
 Subject: /C=US/ST=CA/L=San Jose/O=CA/OU=Security
 Public Key Algorithm: rsaEncryption
 Public Key size: 2048
Done
```

## To update an existing certificate-key pair by using the configuration utility

Navigate to Traffic Management > SSL > Certificates, select a certificate, and click Update.

### Disabling Domain Checks

When an SSL certificate is replaced on the NetScaler, the domain name mentioned on the new certificate should match the domain name of the certificate being replaced. For example, if you have a certificate issued to abc.com, and you are updating it with a certificate issued to def.com, the certificate update fails.

However, if you want the server that has been hosting a particular domain to now host a new domain, you can disable the domain check before updating its certificate.

## To disable the domain check for a certificate by using the command line interface

At the command prompt, type the following commands to disable the domain check and verify the configuration:

- `update ssl certKey <certkeyName> -noDomainCheck`
- `show ssl certKey <certkeyName>`

### Example

```
> update ssl certKey sv -noDomainCheck
Done
> show ssl certkey sv
Name: sv
Cert Path: /nsconfig/ssl/complete/server/server_rsa_512.pem
Key Path: /nsconfig/ssl/complete/server/server_rsa_512.ky
Format: PEM
Status: Valid, Days to expiration:9349
Certificate Expiry Monitor: DISABLED
Done
```

## To disable the domain check for a certificate by using the configuration utility

1. Navigate to Traffic Management > SSL > Certificates, select a certificate, and click Update.
2. Select No Domain Check.

### Enabling the Expiry Monitor

An SSL certificate is valid for a specific period of time. A typical deployment includes multiple virtual servers that process SSL transactions, and the certificates bound to them can expire at different times. An expiry monitor configured on the NetScaler appliance creates entries in the appliance's syslog and nsaudit logs when a certificate configured on the appliance is due to expire.

If you want to create SNMP alerts for certificate expiration, you must configure them separately.

## To enable an expiry monitor for a certificate by using the command line interface

At the command prompt, type the following commands to enable an expiry monitor for a certificate and verify the configuration:

- `set ssl certKey <certkeyName> [-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <positive_integer>]]`
- `show ssl certKey <certkeyName>`

### Example

```
> set ssl certKey sv -expiryMonitor ENABLED --notificationPeriod 60
Done
```

```
> show ssl certkey sv
```

```
Name: sv
```

```
Cert Path: /nsconfig/ssl/complete/server/server_rsa_512.pem
```

```
Key Path: /nsconfig/ssl/complete/server/server_rsa_512.ky
```

```
Format: PEM
```

```
Status: Valid, Days to expiration:9349
```

```
Certificate Expiry Monitor: ENABLED
```

```
Expiry Notification period: 60 days
```

```
Done
```

## To enable an expiry monitor for a certificate by using the configuration utility

1. Navigate to Traffic Management > SSL > Certificates, select a certificate, and click Update.
2. Select Notify When Expires, and optionally specify a notification period.

# Using Global Site Certificates

Nov 11, 2013

A global site certificate is a special-purpose server certificate whose key length is greater than 128 bits. A global site certificate consists of a server certificate and an accompanying intermediate-CA certificate. You must import the global site certificate and its key from the server to the NetScaler appliance.

## How Global Site Certificates Work

Export versions of browsers use 40-bit encryption to initiate connections to SSL Web-servers. The server responds to connection requests by sending its certificate. The client and server then decide on an encryption strength based on the server certificate type:

- If the server certificate is a normal certificate and not a global site certificate, the export client and server complete the SSL handshake and uses 40-bit encryption for data transfer.
- If the server certificate is a global site certificate (and if the export client feature is supported by the browser), the export client automatically upgrades to 128-bit encryption for data transfer.

If the server certificate is a global site certificate, the server sends its certificate, along with the accompanying intermediate-CA certificate. The browser first validates the intermediate-CA certificate by using one of the Root-CA certificates that are normally included in web browsers. Upon successful validation of the intermediate-CA certificate, the browser uses the intermediate-CA certificate to validate the server certificate. Once the server is successfully validated, the browser renegotiates (upgrades) the SSL connection to 128-bit encryption.

With Microsoft's Server Gated Cryptography (SGC), if the Microsoft IIS server is configured with an SGC certificate, export clients that receive the certificate renegotiate to use 128-bit encryption.

## Importing a Global Site Certificate

To import a global site certificate, first export the certificate and server key from the Web server. Global site certificates are generally exported in some binary format, therefore, before importing the global site certificate, convert the certificate and key to the PEM format.

## To import a global site certificate

1. Using a text editor, copy the server certificate and the accompanying intermediate-CA certificate into two separate files.

The individual PEM encoded certificate will begin with the header -----BEGIN CERTIFICATE----- and end with the trailer -----END CERTIFICATE-----.

2. Use an SFTP client to transfer the server certificate, intermediate-CA certificate, and server-key to the NetScaler.
3. Use the following OpenSSL command to identify the server certificate and intermediate-CA certificate from the two separate files.

Note: You can launch the OpenSSL interface from the configuration utility. In the navigation pane, click SSL. In the details pane, under Tools, click Open SSL interface.

```
> openssl x509 -in >path of the CA cert file< text
```

X509v3 Basic Constraints:

**CA:TRUE**

X509v3 Key Usage:

Certificate Sign, CRL Sign

Netscape Cert Type:

**SSL CA, S/MIME CA**

```
> openssl x509 -in >path of the server certificate file< -text
```

X509v3 Basic Constraints:

**CA:FALSE**

Netscape Cert Type:

**SSL Server**

4. At the FreeBSD shell prompt, enter the following command:

```
openssl x509 -in cert.pem -text | more
```

Where **cert.pem** is one of the two certificate files.

Read the **Subject** field in the command output. For example,

```
Subject: C=US, ST=Oregon, L=Portland,
O=mycompany, Inc., OU=IT, CN=www.mycompany.com
```

If the CN field in the Subject matches the domain-name of your Web site, then this is the server certificate and the other certificate is the accompanying intermediate-CA certificate.

5. Use the server certificate and its private key) to create a certificate key pair on the NetScaler. For details on creating a certificate-key pair on the NetScaler, see [Adding a Certificate Key Pair](#).
6. Add the intermediate-CA certificate on the NetScaler. Use the server certificate you created in step 4 to sign this intermediate certificate. For details on creating an Intermediate-CA certificate on the NetScaler, see [Generating a Self-Signed Certificate](#).

# Converting the Format of SSL Certificates for Import or Export

Aug 20, 2013

A NetScaler appliance supports the PEM and DER formats for SSL certificates. Other applications, such as client browsers and some external secure servers, require various public key cryptography standard (PKCS) formats. The NetScaler can convert the PKCS#12 format (the personal information exchange syntax standard) to PEM or DER format for importing a certificate to the appliance, and can convert PEM or DER to PKCS#12 for exporting a certificate. For additional security, conversion of a file for import can include encryption of the private key with the DES or DES3 algorithm.

Note: If you use the configuration utility to import a PKCS#12 certificate, and the password contains a dollar sign (\$), backquote (`), or escape (\) character, the import may fail. If it does, the ERROR: Invalid password message appears. If you must use a special character in the password, be sure to prefix it with an escape character (\) unless all imports are performed by using the NetScaler command line.

To convert the format of a certificate by using the command line interface

At the command prompt, type the following command:

```
Convert ssl pkcs12 <outfile> [-import [-pkcs12File <inputFilename>] [-des | -des3] [-export [-certFile <inputFilename>] [-keyFile <inputFilename>]]
```

During the operation, you are prompted to enter an import password or an export password. For an encrypted file, you are also prompted to enter a passphrase.

## Example

```
convert ssl pkcs12 Cert-Import-1.pem -import -pkcs12File Cert-Import-1.pfx -des
```

```
convert ssl pkcs12 Cert-Client-1.pfx -export -certFile Cert-Client-1 -keyFile Key-Client-1
```

To convert the format of a certificate by using the configuration utility

Navigate to Traffic Management > SSL and, in the Tools group, select Import PKCS#12 or Export PKCS#12.

# Managing Certificate Revocation Lists

Jun 03, 2015

A certificate issued by a CA typically remains valid until its expiration date. However, in some circumstances, the CA may revoke the issued certificate before the expiration date (for example, when an owner's private key is compromised, a company's or individual's name changes, or the association between the subject and the CA changes).

A Certificate Revocation List (CRL) identifies invalid certificates by serial number and issuer.

Certificate authorities issue CRLs on a regular basis. You can configure the NetScaler appliance to use a CRL to block client requests that present invalid certificates.

If you already have a CRL file from a CA, add that to the NetScaler. You can configure refresh options. You can also configure the NetScaler to sync the CRL file automatically at a specified interval, from either a web location or an LDAP location. The NetScaler supports CRLs in either the PEM or the DER file format. Be sure to specify the file format of the CRL file being added to the NetScaler.

If you have used the NetScaler as a CA to create certificates that are used in SSL deployments, you can also create a CRL to revoke a particular certificate. This feature can be used, for example, to ensure that self-signed certificates that are created on the NetScaler are not used either in a production environment or beyond a particular date.

Note:

By default, CRLs are stored in the `/var/netscaler/ssl` directory on the NetScaler appliance.

To manage certificate revocation lists, see the following sections:

- [Creating a CRL on the NetScaler](#)
- [Adding an Existing CRL to the NetScaler](#)
- [Configuring CRL Refresh Parameters](#)
- [Synchronizing CRLs](#)
- [Performing Client Authentication by using a Certificate Revocation List](#)

## Creating a CRL on the NetScaler

Updated: 2013-09-04

Since you can use the NetScaler appliance to act as a certificate authority and create self-signed certificates, you can also revoke certificates that you have created and certificates whose CA certificate you own.

The appliance must revoke invalid certificates before creating a CRL for those certificates. The appliance stores the serial numbers of revoked certificates in an index file and updates the file each time it revokes a certificate. The index file is automatically created the first time a certificate is revoked.

## To revoke a certificate or create a CRL by using the command line interface

At the command prompt, type the following command:

```
create ssl crl <CAcertFile> <CAkeyFile> <indexFile> (-revoke <input_filename> | -genCRL <output_filename>)
```

### Example

```
create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -revoke Invalid-1
```

```
create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -genCRL CRL-1
```

## To revoke a certificate or create a CRL by using the configuration utility

1. Navigate to Traffic Management > SSL and, in the Getting Started group, select CRL Management.
2. Enter the certificate details and, in the Choose Operation list, select Revoke Certificate or Generate CRL.

## Adding an Existing CRL to the NetScaler

Updated: 2013-09-05

Before you configure the CRL on the NetScaler appliance, make sure that the CRL file is stored locally on the NetScaler. In the case of an HA setup, the CRL file must be present on both NetScaler appliances, and the directory path to the file must be the same on both appliances.

## To add a CRL on the NetScaler by using the command line

At the command prompt, type the following commands to add a CRL on the NetScaler and verify the configuration:

- `add ssl crl <crlName> <crlPath> [-inform (DER | PEM)]`
- `show ssl crl [<crlName>]`

### Example

```
> add ssl crl crl-one /var/netscaler/ssl/CRL-one -inform PEM
```

```
Done
```

```
> show ssl crl crl-one
```

```
Name: crl-one Status: Valid, Days to expiration: 29
```

```
CRL Path: /var/netscaler/ssl/CRL-one
```

```
Format: PEM CAcert: samplecertkey
Refresh: DISABLED
Version: 1
Signature Algorithm: sha1WithRSAEncryption
Issuer: C=US,ST=California,L=Santa Clara,O=NetScaler Inc.,OU=SSL Acceleration,CN=www.ns.com/emailAddress=support@netscaler.com
Last_update:Jun 15 10:53:53 2010 GMT
Next_update:Jul 15 10:53:53 2010 GMT
```

```
1) Serial Number: 00
Revocation Date:Jun 15 10:51:16 2010 GMT
Done
```

## To add a CRL on the NetScaler by using the configuration utility

Navigate to Traffic Management > SSL > CRL, and add a CRL.

### Configuring CRL Refresh Parameters

Updated: 2014-09-29

A CRL is generated and published by a Certificate Authority periodically or, in some cases, immediately after a particular certificate is revoked. Citrix recommends that you update CRLs on the NetScaler appliance regularly, for protection against clients trying to connect with certificates that are not valid.

The NetScaler can refresh CRLs from a web location or an LDAP directory. When you specify refresh parameters and a web location or an LDAP server, the CRL does not have to be present on the local hard disk drive at the time you execute the command. The first refresh stores a copy on the local hard disk drive, in the path specified by the CRL File parameter. The default path for storing the CRL is `/var/netscaler/ssl`.

Note: In release 10.0 and later, the method for refreshing a CRL is not included by default. You must explicitly specify an HTTP or LDAP method. If you are upgrading from an earlier release to release 10.0 or later, you must add a method and run the command again.

## To configure CRL autorefresh by using the command line

At the command prompt, type the following commands to configure CRL auto refresh and verify the configuration the following commands to configure CRL auto refresh and verify the configuration:

- `set ssl crl <crlName> [-refresh ( ENABLED | DISABLED )] [-CAcert <string>] [-url <URL | -server <ip_addr | ipv6_addr>] [-method HTTP | (LDAP [-baseDN <string>]) [-bindDN <string>] [-scope ( Base | One )] [-password <string>] [-binary ( YES | NO )]] [-port <port>] [-interval <interval>]`
- `show ssl crl [<crlName>]`

### Example

```
Set CRL crl1 -refresh enabled -method ldap -inform DER -CAcert ca1 -server 10.102.192.192 -port 389 -scope base -baseDN "cn=clnt_rsa4_multicert_der,ou=eng,o=ns,c=in" -time 00:01
```

```
set ssl crl crl1 -refresh enabled -method http -cacert ca1 -port 80 -time 00:10 -url http://10.102.192.192/crl/ca1.crl
```

```
> sh crl
```

```
1) Name: crl1 Status: Valid, Days to expiration: 355
CRL Path: /var/netscaler/ssl/crl1
Format: PEM CAcert: ca1
Refresh: ENABLED Method: HTTP
URL: http://10.102.192.192/crl/ca1.crl Port:80
Refresh Time: 00:10
Last Update: Successful, Date:Tue Jul 6 14:38:13 2010
```

```
Done
```

## To configure CRL autorefresh using LDAP or HTTP by using the configuration utility

1. Navigate to Traffic Management > SSL > CRL.
2. Open a CRL, and select Enable CRL Auto Refresh.

Note: If the new CRL has been refreshed in the external repository before its actual update time as specified by the Last Update time field of the CRL, you should immediately refresh the CRL on the NetScaler.

To view the last update time, select the CRL, and click Details.

### Synchronizing CRLs

Updated: 2013-09-03

The NetScaler appliance uses the most recently distributed CRL to prevent clients with revoked certificates from accessing secure resources.

If CRLs are updated often, the NetScaler needs an automated mechanism to fetch the latest CRLs from the repository. You can configure the NetScaler to update CRLs automatically at a specified refresh interval.

The NetScaler maintains an internal list of CRLs that need to be updated at regular intervals. At these specified intervals, the appliance scans the list for CRLs that need to be updated, connects to the remote LDAP server or HTTP server, retrieves the latest CRLs, and then updates the local CRL list with the new CRLs.

Note: If CRL check is set to mandatory when the CA certificate is bound to the virtual server, and the initial CRL refresh fails, all client-authentication connections with the same issuer

as the CRL are rejected as REVOKED until the CRL is successfully refreshed.  
 You can specify the interval at which the CRL refresh should be carried out. You can also specify the exact time.

## To synchronize CRL autorefresh by using the command line interface

At the command prompt, type the following command:

```
set ssl crl <crlName> [-interval <interval>] [-day <integer>] [-time <HH:MM>]
```

### Example

```
set ssl crl CRL-1 -refresh ENABLE -interval
MONTHLY -days 10 -time 12:00
```

## To synchronize CRL refresh by using the configuration utility

1. Navigate to Traffic Management > SSL > CRL.
2. Open a CRL, select enable CRL Auto Refresh, and specify the interval.

### Performing Client Authentication by using a Certificate Revocation List

Updated: 2013-09-03

If a certificate revocation list (CRL) is present on a NetScaler appliance, a CRL check is performed regardless of whether performing the CRL check is set to mandatory or optional. The success or failure of a handshake depends on a combination of the following factors:

- Rule for CRL check
- Rule for client certificate check
- State of the CRL configured for the CA certificate

The following table lists the results of the possible combinations for a handshake involving a revoked certificate.

**Table 1. Result of a Handshake with a Client Using a Revoked Certificate**

| Rule for CRL Check | Rule for Client Certificate Check | State of the CRL Configured for the CA certificate | Result of a Handshake with a Revoked Certificate |
|--------------------|-----------------------------------|----------------------------------------------------|--------------------------------------------------|
| Optional           | Optional                          | Missing                                            | Success                                          |
| Optional           | Mandatory                         | Missing                                            | Success                                          |
| Optional           | Mandatory                         | Present                                            | Failure                                          |
| Mandatory          | Optional                          | Missing                                            | Success                                          |
| Mandatory          | Mandatory                         | Missing                                            | Failure                                          |
| Mandatory          | Optional                          | Present                                            | Success                                          |
| Mandatory          | Mandatory                         | Present                                            | Failure                                          |
| Optional/Mandatory | Optional                          | Expired                                            | Success                                          |
| Optional/Mandatory | Mandatory                         | Expired                                            | Failure                                          |

### Note:

- The CRL check is optional by default. To change from optional to mandatory or vice-versa, you must first unbind the certificate from the SSL virtual server, and then bind it again after changing the option.
- In the output of the `sh ssl vsver` command, OCSP check: optional implies that a CRL check is also optional. The CRL check settings are displayed in the output of the `sh ssl vsver` command only if CRL check is set to mandatory. If CRL check is set to optional, the CRL check details do not appear.

## To configure CRL check by using the command line interface

At the command prompt, type the following command:

```
bind ssl vsver <vServerName> -certkeyName <string> [(-CA -crlCheck (Mandatory | Optional))]
```

### Example

```
bind ssl vs v1 -certkeyName ca -CA -crlCheck mandatory
sh ssl vsver
> sh ssl vs v1
```

Advanced SSL configuration for VServer v1:

DH: DISABLED  
Ephemeral RSA: ENABLED Refresh Count: 0  
Session Reuse: ENABLED Timeout: 120 seconds  
Cipher Redirect: DISABLED  
SSLv2 Redirect: DISABLED  
ClearText Port: 0  
Client Auth: ENABLED Client Cert Required: Mandatory  
SSL Redirect: DISABLED  
Non FIPS Ciphers: DISABLED  
SNI: DISABLED  
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED  
Push Encryption Trigger: Always  
Send Close-Notify: YES

1) CertKey Name: ca CA Certificate CRLCheck: Mandatory CA\_Name Sent

1) Cipher Name: DEFAULT  
Description: Predefined Cipher Alias  
Done

To configure CRL check by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open an SSL virtual server.
2. Click in the Certificates section.
3. Select a certificate and, in the OCSP and CRL Check list, select CRL Mandatory.

# Monitoring Certificate Status with OCSP

Jul 07, 2016  
Online Certificate Status Protocol (OCSP) is an Internet protocol that is used to determine the status of a client SSL certificate. NetScaler appliances support OCSP as defined in RFC 2560. OCSP offers significant advantages over certificate revocation lists (CRLs) in terms of timely information. Up-to-date revocation status of a client certificate is especially useful in transactions involving large sums of money and high-value stock trades. It also uses fewer system and network resources. NetScaler implementation of OCSP includes request batching and response caching.

To monitor certificate status with OCSP, see the following sections:

- [NetScaler Implementation of OCSP](#)
- [OCSP Request Batching](#)
- [OCSP Response Caching](#)
- [Configuring an OCSP Responder](#)

## NetScaler Implementation of OCSP

OCSP validation on a NetScaler appliance begins when the appliance receives a client certificate during an SSL handshake. To validate the certificate, the NetScaler creates an OCSP request and forwards it to the OCSP responder. To do so, the NetScaler uses a locally configured URL. The transaction is in a suspended state until the NetScaler evaluates the response from the server and determines whether to allow the transaction or reject it. If the response from the server is delayed beyond the configured time and no other responders are configured, the NetScaler will allow the transaction or display an error, depending on whether the OCSP check was set to optional or mandatory, respectively.

The NetScaler supports batching of OCSP requests and caching of OCSP responses to reduce the load on the OCSP responder and provide faster responses.

### OCSP Request Batching

Each time the NetScaler receives a client certificate, it sends a request to the OCSP responder. To help avoid overloading the OCSP responder, the NetScaler can query the status of more than one client certificate in the same request. For this to work efficiently, a timeout needs to be defined so that processing of a single certificate is not inordinately delayed while waiting to form a batch.

### OCSP Response Caching

Caching of responses received from the OCSP responder enables faster responses to the clients and reduces the load on the OCSP responder. Upon receiving the revocation status of a client certificate from the OCSP responder, the NetScaler caches the response locally for a predefined length of time. When a client certificate is received during an SSL handshake, the NetScaler first checks its local cache for an entry for this certificate. If an entry is found that is still valid (within the cache timeout limit), it is evaluated and the client certificate is accepted or rejected. If a certificate is not found, the NetScaler sends a request to the OCSP responder and stores the response in its local cache for a configured length of time.

### Configuring an OCSP Responder

Configuring OCSP involves adding an OCSP responder, binding the OCSP responder to a certification authority (CA) certificate, and binding the certificate to an SSL virtual server. If you need to bind a different certificate to an OCSP responder that has already been configured, you need to first unbind the responder and then bind the responder to a different certificate.

## To add an OCSP responder by using the command line interface

At the command prompt, type the following commands to configure OCSP and verify the configuration:

- `add ssl ocsppResponder <name> -url <URL> [-cache ( ENABLED | DISABLED )][-cacheTimeout <positive_integer>] [-batchingDepth <positive_integer>][-batchingDelay <positive_integer>] [-resptimeout <positive_integer>][-responderCert <string> | -trustResponder] [-producedAtTimeSkew <positive_integer>][-signingCert <string>][-useNonce ( YES | NO )][-insertClientCert ( YES | NO )]`
- `bind ssl certKey [<certKeyName>] [-ocsppResponder <string>] [-priority <positive_integer>]`
- `bind ssl vserver <vServerName>@ (<certKeyName <string> ( CA [-ocspCheck ( Mandatory | Optional )]))`
- `show ssl ocsppResponder [<name>]`

### Example

```
add ssl ocsppResponder ocspp_responder1 -url "http://www.myCA.org:80/ocsp/" -cache ENABLED -cacheTimeout 30 -batchingDepth 8 -batchingDelay 100 -resptimeout 100 -responderCert responder_cert
bind ssl certKey ca_cert -ocsppResponder ocspp_responder1 -priority 1
bind ssl vserver vs1 -certKeyName ca_cert -CA -ocspCheck Mandatory
```

```
sh ocsppResponder ocspp_responder1
1)Name: ocspp_responder1
URL: http://www.myCA.org:80/ocsp/, IP: 192.128.22.22
Caching: Enabled Timeout: 30 minutes
Batching: 8 Timeout: 100 mS
HTTP Request Timeout: 100mS
Request Signing Certificate: sign_cert
Response Verification: Full, Certificate: responder_cert
ProducedAt Time Skew: 300 s
Nonce Extension: Enabled
Client Cert Insertion: Enabled
Done
```

```
show certkey ca_cert
Name: ca_cert Status: Valid, Days to expiration:8907
Version: 3
...
1) VServer name: vs1 CA Certificate
1) OCSP Responder name: ocspp_responder1 Priority: 1
Done
```

```
sh ssl vs vs1
Advanced SSL configuration for VServer vs1:
```

DH: DISABLED

...

1) CertKey Name: ca\_cert CA Certificate OCSPCheck: Mandatory

1) Cipher Name: DEFAULT

Description: Predefined Cipher Alias

Done

## To modify an OCSP responder by using the command line interface

You cannot modify the responder name. All other parameters can be changed using the `set ssl ocspResponder` command.

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `set ssl ocspResponder <name> [-url <URL>] [-cache ( ENABLED | DISABLED)] [-cacheTimeout <positive_integer>] [-batchingDepth <positive_integer>] [-batchingDelay <positive_integer>] [-resptimeout <positive_integer>] [-responderCert <string>] [-trustResponder] [-producedAtTimeSkew <positive_integer>] [-signingCert <string>] [-useNonce ( YES | NO )]`
- `unbind ssl certKey [<certkeyName>] [-ocspResponder <string>]`
- `bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <positive_integer>]`
- `show ssl ocspResponder [<name>]`

## To configure an OCSP responder by using the configuration utility

1. Navigate to Traffic Management > SSL > OCSP Responder, and configure an OCSP responder.
2. Navigate to Traffic Management > SSL > Certificates, select a certificate, and in the Action list, select OCSP Bindings. Bind an OCSP responder.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, open a virtual server, and click in the Certificates section to bind a CA certificate.
4. Optionally, select select OCSP Mandatory.

# Configuring Client Authentication

Sep 12, 2016

In a typical SSL transaction, the client that is connecting to a server over a secure connection checks the validity of the server by checking the server's certificate before initiating the SSL transaction. In some cases, however, you might want to configure the server to authenticate the client that is connecting to it.

With client authentication enabled on an SSL virtual server, the NetScaler appliance asks for the client certificate during the SSL handshake. The appliance checks the certificate presented by the client for normal constraints, such as the issuer signature and expiration date.

Note: For the NetScaler to verify issuer signatures, the certificate of the CA that issued the client certificate must be installed on the NetScaler and bound to the virtual server that the client is transacting with.

If the certificate is valid, the NetScaler allows the client to access all secure resources. But if the certificate is invalid, the NetScaler drops the client request during the SSL handshake.

The NetScaler verifies the client certificate by first forming a chain of certificates, starting with the client certificate and ending with the root CA certificate for the client (for example, VeriSign). The root CA certificate may contain one or more intermediate CA certificates (if the client certificate is not directly issued by the root CA).

Before you enable client authentication on the NetScaler, make sure that a valid client certificate is installed on the client. Then, enable client authentication for the virtual server that will handle the transactions. Finally, bind the certificate of the CA that issued the client certificate to the virtual server on the NetScaler.

Note: A NetScaler MPX appliance supports a certificate-key pair size from 512 to 4096 bits. The certificate must be signed by using one of the following hash algorithms:

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384
- SHA-512

On an SDX appliance, if an SSL chip is assigned to a VPX instance, the certificate-key pair size support of an MPX appliance applies. Otherwise, the normal certificate-key pair size support of a VPX instance applies.

A NetScaler virtual appliance (VPX instance) supports certificates of at least 512 bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate
- 2048-bit certificate on the physical server
- 2048-bit client certificate (if client authentication is enabled on the virtual server)

To configure client authentication, see the following sections:

- [Providing the Client Certificate](#)
- [Enabling Client-Certificate-Based Authentication](#)
- [Binding CA Certificates to the Virtual Server](#)

## Providing the Client Certificate

Before you configure client authentication, a valid client certificate must be installed on the client. A client certificate includes details about the specific client system that will create secure sessions with the NetScaler appliance. Each client certificate is unique and should be used by only one client system.

Whether you obtain the client certificate from a CA, use an existing client certificate, or generate a client certificate on the NetScaler appliance, you must convert the certificate to the correct format. On the NetScaler, certificates are stored in either the PEM or DER format and must be converted to PKCS#12 format before they are installed on the client system. After converting the certificate and transferring it to the client system, make sure that it is installed on that system and configured for the client application that will be part of the SSL transactions (for example, the web browser).

For instructions on how to convert a certificate from PEM or DER format to PKCS#12 format, see [Converting SSL Certificates for Import or Export](#).

For instructions on how to generate a client certificate, see [Generating Self-Signed Certificates](#).

## Enabling Client-Certificate-Based Authentication

Updated: 2013-08-20

By default, client authentication is disabled on the NetScaler appliance, and all SSL transactions proceed without authenticating the client. You can configure client authentication to be either optional or mandatory as part of the SSL handshake.

If client authentication is optional, the NetScaler requests the client certificate but proceeds with the SSL transaction even if the client presents an invalid certificate. If client authentication is mandatory, the NetScaler terminates the SSL handshake if the SSL client does not provide a valid certificate.

**Caution:** Citrix recommends that you define proper access control policies before changing client-certificate-based authentication check to optional.

**Note:** Client authentication is configured for individual SSL virtual servers, not globally.

## To enable client-certificate-based authentication by using the command line interface

At the command prompt, type the following commands to enable the client-certificate-based authentication and verify the configuration:

- `set ssl vserver <vServerName> [-clientAuth (ENABLED | DISABLED)] [-clientCert (MANDATORY | OPTIONAL)]`
- `show ssl vserver <vServerName>`

### Example

```
> set ssl vserver vssl -clientAuth ENABLED -clientCert Mandatory
Done
> show ssl vserver vssl
```

```
Advanced SSL configuration for VServer vssl:
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
```

Session Reuse: ENABLED      Timeout: 120 seconds  
Cipher Redirect: DISABLED  
SSLv2 Redirect: DISABLED  
ClearText Port: 0  
Client Auth: ENABLED    Client Cert Required: Mandatory  
SSL Redirect: DISABLED  
Non FIPS Ciphers: DISABLED  
SSLv2: DISABLED SSLv3: ENABLED    TLSv1: ENABLED

1) CertKey Name: sslckey    Server Certificate

1) Policy Name: client\_cert\_policy    Priority: 0

1) Cipher Name: DEFAULT  
Description: Predefined Cipher Alias

Done

## To enable client-certificate-based authentication by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Client Authentication, and in the Client Certificate list, select Mandatory.

### Binding CA Certificates to the Virtual Server

A CA whose certificate is present on the NetScaler appliance must issue the client certificate used for client authentication. You must bind this certificate to the NetScaler virtual server that will carry out client authentication.

You must bind the CA certificate to the SSL virtual server in such a way that the NetScaler can form a complete certificate chain when it verifies the client certificate. Otherwise, certificate chain formation fails and the client is denied access even if its certificate is valid.

You can bind CA certificates to the SSL virtual server in any order. The NetScaler forms the proper order during client certificate verification.

For example, if the client presents a certificate issued by **CA\_A**, where **CA\_A** is an intermediate CA whose certificate is issued by **CA\_B**, whose certificate is in turn issued by a trusted root CA, **Root\_CA**, a chain of certificates that contain all three of these certificates must be bound to the virtual server on the NetScaler.

For instructions on binding one or more certificates to the virtual server, see [Binding the Certificate-key Pair to the SSL Based Virtual Server](#).

For instructions on creating a chain of certificates, see [Creating a Chain of Certificates](#).

# Customizing the SSL Configuration

Jun 03, 2015

Once your basic SSL configuration is operational, you can customize some of the parameters that are specific to the certificates being used in SSL transactions. You can also enable and disable session reuse and client authentication, and you can configure redirect responses for cipher and SSLv2 protocol mismatches.

You can also customize SSL settings for two NetScaler appliances in a High Availability configuration, and you can synchronize settings, certificates and keys across those appliances.

These settings will depend on your network deployment and the type of clients you expect will connect to your servers.

To customize the SSL configuration, see the following sections:

- [Configuring Diffie-Hellman \(DH\) Parameters](#)
- [Configuring Ephemeral RSA](#)
- [Configuring Session Reuse](#)
- [Configuring Cipher Redirection](#)
- [Configuring SSLv2 Redirection](#)
- [Configuring SSL Protocol Settings](#)
- [Configuring Close-Notify](#)
- [Configuring ECDHE Ciphers](#)
- [Configuring a Common Name on an SSL Service or Service Group for Server Certificate Authentication](#)
- [Configuring Advanced SSL Settings](#)
- [Synchronizing Configuration Files in a High Availability Setup](#)
- [Managing Server Authentication](#)
- [Configuring User-Defined Cipher Groups on the NetScaler Appliance](#)

# Configuring Diffie-Hellman (DH) Parameters

Dec 22, 2014

If you are using ciphers on the NetScaler that require a DH key exchange to set up the SSL transaction, enable DH key exchange on the NetScaler and configure other settings based on your network.

To list the ciphers for which DH parameters must be set by using the NetScaler command line, type: `sh cipher DH`.

To list the ciphers for which DH parameters must be set by using the configuration utility, navigate to Traffic Management > SSL > Cipher Groups, and double-click DH.

For details on how to enable DH key exchange, see [Generating a Diffie-Hellman \(DH\) Key](#).

To configure DH Parameters by using the command line interface

At the command prompt, type the following commands to configure DH parameters and verify the configuration:

- `set ssl vserver <vserverName> -dh <Option> -dhCount <RefreshCountValue> -filepath <string>`
- `show ssl vserver <vServerName>`

## Example

```
> set ssl vserver vs-server -dh ENABLED -dhFile /nsconfig/ssl/ns-server.cert -dhCount 1000
```

```
Done
```

```
> show ssl vserver vs-server
```

```
Advanced SSL configuration for VServer vs-server:
```

```
DH: ENABLED
```

```
Ephemeral RSA: ENABLED Refresh Count: 1000
```

```
Session Reuse: ENABLED Timeout: 120 seconds
```

```
Cipher Redirect: DISABLED
```

```
SSLv2 Redirect: DISABLED
```

```
ClearText Port: 0
```

```
Client Auth: DISABLED
```

```
SSL Redirect: DISABLED
```

```
Non FIPS Ciphers: DISABLED
```

```
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
```

```
1) Cipher Name: DEFAULT
```

```
Description: Predefined Cipher Alias
```

```
Done
```

To configure DH Parameters by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Enable DH Param, and specify a refresh count and file path.

# Configuring Ephemeral RSA

Aug 20, 2013

Ephemeral RSA allows export clients to communicate with the secure server even if the server certificate does not support export clients (1024-bit certificate). If you want to prevent export clients from accessing the secure web object and/or resource, you need to disable ephemeral RSA key exchange.

By default, this feature is enabled on the NetScaler appliance, with the refresh count set to zero (infinite use).

Note:

The ephemeral RSA key is automatically generated when you bind an export cipher to an SSL or TCP-based SSL virtual server or service. When you remove the export cipher, the eRSA key is not deleted but reused at a later date when another export cipher is bound to an SSL or TCP-based SSL virtual server or service. The eRSA key is deleted when the system restarts.

To configure Ephemeral RSA by using the command line interface

At the command prompt, type the following commands to configure ephemeral RSA and verify the configuration:

- set ssl vserver <vServerName> -eRSA (enabled | disabled) -eRSACount <positive\_integer>
- show ssl vserver <vServerName>

## Example

```
> set ssl vserver vs-server -eRSA ENABLED -eRSACount 1000
Done
> show ssl vserver vs-server
```

Advanced SSL configuration for VServer vs-server:

```
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 1000
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
```

- 1) Cipher Name: DEFAULT  
Description: Predefined Cipher Alias

Done

To configure Ephemeral RSA by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Enable Ephemereal RSA, and specify a refresh count.

# Configuring Session Reuse

Aug 20, 2013

For SSL transactions, establishing the initial SSL handshake requires CPU-intensive public key encryption operations. Most handshake operations are associated with the exchange of the SSL session key (client key exchange message). When a client session is idle for some time and is then resumed, the SSL handshake is typically conducted all over again. With session reuse enabled, session key exchange is avoided for session resumption requests received from the client.

Session reuse is enabled on the NetScaler appliance by default. Enabling this feature reduces server load, improves response time, and increases the number of SSL transactions per second (TPS) that can be supported by the server.

To configure session reuse by using the command line interface

At the command prompt, type the following commands to configure session reuse and verify the configuration:

- set ssl vserver <vServerName> -sessReuse ( ENABLED | DISABLED ) -sessTimeout <positive\_integer>
- show ssl vserver <vServerName>

## Example

```
> set ssl vserver vs-ssl -sessreuse enabled -sesstimeout 600
```

```
Done
```

```
> show ssl vserver vs-ssl
```

```
Advanced SSL configuration for VServer vs-ssl:
```

```
DH: DISABLED
```

```
Ephemeral RSA: ENABLED Refresh Count: 1000
```

```
Session Reuse: ENABLED Timeout: 600 seconds
```

```
Cipher Redirect: DISABLED
```

```
SSLv2 Redirect: DISABLED
```

```
ClearText Port: 0
```

```
Client Auth: DISABLED
```

```
SSL Redirect: DISABLED
```

```
Non FIPS Ciphers: DISABLED
```

```
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
```

```
1) CertKey Name: Auth-Cert-1 Server Certificate
```

```
1) Cipher Name: DEFAULT
```

```
Description: Predefined Cipher Alias
```

```
Done
```

To configure session reuse by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Enable Session Reuse, and specify a time for which to keep the session active.

# Configuring Cipher Redirection

Aug 20, 2013

During the SSL handshake, the SSL client (usually a web browser) announces the suite of ciphers that it supports, in the configured order of cipher preference. From that list, the SSL server then selects a cipher that matches its own list of configured ciphers.

If the ciphers announced by the client do not match those configured on the SSL server, the SSL handshake fails, and the failure is announced by a cryptic error message displayed in the browser. These messages rarely mention the exact cause of the error.

With cipher redirection, you can configure an SSL virtual server to deliver accurate, meaningful error messages when an SSL handshake fails. When SSL handshake fails, the NetScaler appliance redirects the user to a previously configured URL or, if no URL is configured, displays an internally generated error page.

To configure cipher redirection by using the command line interface

At the command prompt, type the following commands to configure cipher redirection and verify the configuration:

- `set ssl vserver <vServerName> -cipherRedirect < ENABLED | DISABLED> -cipherURL < URL>`
- `show ssl vserver <vServerName>`

## Example

```
> set ssl vserver vs-ssl -cipherRedirect ENABLED -cipherURL http://redirectURI
Done
> show ssl vserver vs-ssl
```

```
Advanced SSL configuration for VServer vs-ssl:
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 1000
Session Reuse: ENABLED Timeout: 600 seconds
Cipher Redirect: ENABLED Redirect URL: http://redirectURI
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
```

```
1) CertKey Name: Auth-Cert-1 Server Certificate
```

```
1) Cipher Name: DEFAULT
 Description: Predefined Cipher Alias
```

```
Done
```

To configure cipher redirection by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.

2. In the SSL Parameters section, select Enable Cipher Redirect, and specify a redirect URL.

# Configuring SSLv2 Redirection

Aug 20, 2013

For an SSL transaction to be initiated, and for successful completion of the SSL handshake, the server and the client should agree on an SSL protocol that both of them support. If the SSL protocol version supported by the client is not acceptable to the server, the server does not go ahead with the transaction, and an error message is displayed.

You can configure the server to display a precise error message (user-configured or internally generated) advising the client on the next action to be taken. Configuring the server to display this message requires that you set up SSLv2 redirection.

To configure SSLv2 redirection by using the command line interface

At the command prompt, type the following commands to configure SSLv2 redirection and verify the configuration:

- set ssl vsserver <vServerName> [-ssl2Redirect ( ENABLED | DISABLED ) [-ssl2URL <URL>]]
- show ssl vsserver <vServerName>

## Example

```
> set ssl vsserver vs-ssl -ssl2Redirect ENABLED -ssl2URL http://ssl2URL
Done
> show ssl vsserver vs-ssl
```

Advanced SSL configuration for VServer vs-ssl:

DH: DISABLED

Ephemeral RSA: ENABLED Refresh Count: 1000

Session Reuse: ENABLED Timeout: 600 seconds

Cipher Redirect: DISABLED

SSLv2 Redirect: ENABLED Redirect URL: http://ssl2URL

ClearText Port: 0

Client Auth: DISABLED

SSL Redirect: DISABLED

Non FIPS Ciphers: DISABLED

SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: Auth-Cert-1 Server Certificate

1) Cipher Name: DEFAULT

Description: Predefined Cipher Alias

Done

To configure SSLv2 redirection by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select SSLv2 Redirect, and specify a URL.

# Configuring SSL Protocol Settings

May 20, 2015

The NetScaler appliance supports the SSLv2, SSLv3, TLSv1, TLSv1.1, and TLSv1.2 protocols. Each of these can be set on the appliance as required by your deployment and the type of clients that will connect to the appliance.

Note: Support for TLS protocol versions 1.1 and 1.2 is not available on a FIPS appliance or on a NetScaler virtual appliance. TLS protocol versions 1.0, 1.1, and 1.2 are more secure than older versions of the TLS/SSL protocol. However, to support legacy systems, many TLS implementations maintain backward compatibility with the SSLv3 protocol. In an SSL handshake, the highest protocol version common to the client and the SSL virtual server configured on the NetScaler appliance is used.

In the first handshake attempt, a TLS client offers the highest protocol version that it supports. If the handshake fails, the client offers a lower protocol version. For example, if a handshake with TLS version 1.1 is not successful, the client attempts to renegotiate by offering the TLSv1.0 protocol. If that attempt is unsuccessful, the client reattempts with the SSLv3 protocol. A “man in the middle” (MITM) attacker can break the initial handshake and trigger renegotiation with the SSLv3 protocol, and then exploit a vulnerability in SSLv3. To mitigate such attacks, you can disable SSLv3 or not allow renegotiation using a downgraded protocol. However, this might not be practical if your deployment includes legacy systems. An alternative is to recognize a signaling cipher suite value (TLS\_FALLBACK\_SCSV) in the client request.

Note: TLS\_FALLBACK\_SCSV is supported from release 10.5 build 57.7 and later.

A TLS\_FALLBACK\_SCSV value in a client hello message indicates to the virtual server that the client has previously attempted to connect with a higher protocol version and that the current request is a fallback. If the virtual server detects this value, and it supports a version higher than the one indicated by the client, it rejects the connection with a fatal alert. If a TLS\_FALLBACK\_SCSV is not included in the client hello message, or if the protocol version in the client hello is the highest protocol version supported by the virtual server, the handshake succeeds.

To configure SSL protocol support by using the command line interface

At the command prompt, type the following commands to configure SSL protocol support and verify the configuration:

- `set ssl vserver <vServerName> -ssl2 ( ENABLED | DISABLED ) -ssl3 ( ENABLED | DISABLED ) -tls1 ( ENABLED | DISABLED ) -tls11 ( ENABLED | DISABLED ) -tls12 ( ENABLED | DISABLED )`
- `show ssl vserver <vServerName>`

## Example

```
> set ssl vserver vs-ssl -tls11 ENABLED -tls12 ENABLED
```

```
Done
```

```
> sh ssl vs vs-ssl
```

```
Advanced SSL configuration for VServer vs-ssl:
```

```
DH: DISABLED
```

```
Ephemeral RSA: ENABLED
```

```
Session Reuse: ENABLED
```

```
Cipher Redirect: DISABLED
```

```
SSLv2 Redirect: DISABLED
```

```
ClearText Port: 0
```

```
Client Auth: DISABLED
```

```
SSL Redirect: DISABLED
```

```
Non FIPS Ciphers: DISABLED
```

```
Refresh Count: 0
```

```
Timeout: 120 seconds
```

SNI: DISABLED

SSLv2: DISABLED    SSLv3: ENABLED    TLSv1.0: ENABLED    TLSv1.1: ENABLED    TLSv1.2: ENABLED

Push Encryption Trigger: Always

Send Close-Notify: YES

1 bound certificate:

- 1) CertKey Name: mycert Server Certificate

1 configured cipher:

- 1) Cipher Name: DEFAULT

Description: Predefined Cipher Alias

Done

To configure SSL protocol support by using the configuration Utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select a protocol to enable.

# Configuring Close-Notify

Aug 20, 2013
