The name of the file containing the private key.

password

The password to the private key. If you are entering this at the NetScaler command line, you simply include the -password parameter, and then, after entering the command, enter the actual password when prompted. If you are using the configuration utility, you type the password in the appropriate text box.

inform

The format of the certificate-key pair. Possible values: DER, PEM. Default: PEM.

expiryMonitor

Whether to monitor the certificate-key pair for expiration. Possible values: ENABLED, DISABLED. Default: ENABLED.

notificationPeriod

The period, in days before the certificate-key pair expires, during which the NetScaler appliance should notify the administrator of the impending expiration.

vservername

The name of the authentication virtual server to which to bind the root certificate.

To configure the AAA client certificate parameters by using the configuration utility

1. Navigate to Security > AAA - Application Traffic > Virtual Servers.
2. In the details pane, select the virtual server that you want to configure to handle client certificate authentication, and then click Open.
3. In the Configure Virtual Server (Authentication) dialog box, in the Certificates tab, click Install.
4. In the Install Certificate dialog box, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for authentication with client certificates" as follows (asterisk indicates a required parameter):
   - Certificate-Key Pair Name*—certkeyName
   - Certificate File Name—certFile
   - Private Key File Name—keyFile
   - Password—password
   - Certificate Format—inform
   - Notify When Expires—expiryMonitor
   - Notification Period—notificationPeriod
5. Click Install, and then click Close.
6. In the Configure Virtual Server (Authentication) dialog box, in the Available list, select the root certificate.
7. Click Add as CA.
8. Click OK.
9. In the navigation pane, expand Policies, and then click Authentication.
10. In the details pane, select the policy you want to configure to handle client certificate authentication, and then click Open.
11. In the Authentication Type drop-down list, select CERT.
12. In the Server drop-down list, select the virtual server you just configured to handle client certificate authentication.
13. Click OK. A message appears in the status bar, stating that the configuration completed successfully.

Configuring AAA with Commonly Used Protocols

Configuring the NetScaler for Authentication, Authorization, and Auditing (AAA) needs a specific setup on the NetScaler and clients' browsers. The configuration varies with the protocol used for AAA.

For more information about configuring the NetScaler for Kerberos authentication, see Handling Authentication, Authorization and Auditing with Kerberos/NTLM.

Handling Authentication, Authorization and Auditing with Kerberos/NTLM

Kerberos, a computer network authentication protocol, provides secure communication over the Internet. Designed primarily for client-server applications, it provides for mutual authentication by which the client and server can each ensure the other's authenticity. Kerberos uses a trusted third party, referred to as Key Distribution Center (KDC). A KDC consists of an Authentication Server (AS), which authenticates a user, and a Ticket Granting Server (TGS).

Each entity on the network (client or server) has a secret key that is known only to itself and the KDC. The knowledge of this key implies authenticity of the entity. For communication between two entities on the network, the KDC generates a session key, referred to as the *Kerberos ticket* or *service ticket*. The client makes a request to the AS for credentials for a specific server. The client then receives a ticket, referred to as *Ticket Granting Ticket (TGT)*. The client then contacts the TGS, using the TGT it received from the AS to prove its identity, and asks for a service. If the client is eligible for the service, the TGS issues a Kerberos ticket to the client. The client then contacts the server hosting the service (referred to as the *service server*), using the Kerberos ticket to prove that it is authorized to receive the service. The Kerberos ticket has a configurable lifetime. The client authenticates itself with the AS only once. If it contacts the physical server multiple times, it reuses the AS ticket.

The following figure shows the basic functioning of the Kerberos protocol.

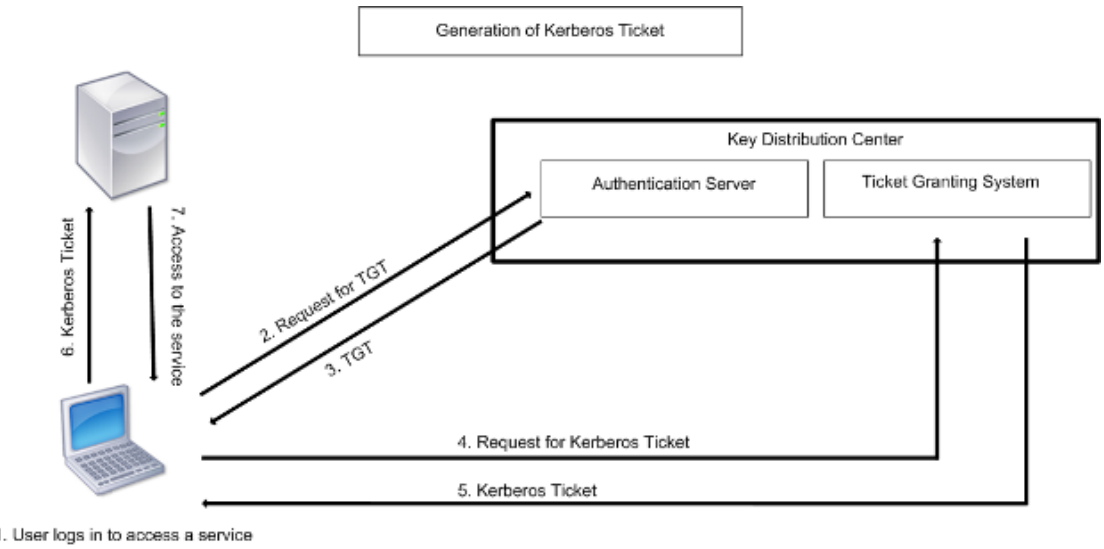

Figure 1. **Functioning of Kerberos**

Kerberos authentication has the following advantages:

- Faster authentication. When a physical server gets a Kerberos ticket from a client, the server has enough information to authenticate the client directly. It does not have to contact a domain controller for client authentication, and therefore the authentication process is faster.

- Mutual authentication. When the KDC issues a Kerberos ticket to a client and the client uses the ticket to access a service, only authenticated servers can decrypt the Kerberos ticket. If the virtual server on the NetScaler is able to decrypt the Kerberos ticket, you can conclude that both the virtual server and client are authenticated. Thus, the authentication of the server happens along with the authentication of the client.

- Single sign-on between Windows and other operating systems that support Kerberos.

Kerberos authentication may have the following disadvantages:

- Kerberos has strict time requirements; the clocks of the involved hosts must be synchronized with the Kerberos server clock to ensure that the authentication does not fail. You can mitigate this disadvantage by using the Network Time Protocol daemons to keep the host clocks synchronized. Kerberos tickets have an availability period, which you can configure.

- Kerberos needs the central server to be available continuously. When the Kerberos server is down, no one can log on. You can mitigate this risk by using multiple Kerberos servers and fallback authentication mechanisms.

- Because all the authentication is controlled by a centralized KDC, any compromise in this infrastructure, such as the user's password for a local workstation being stolen, can allow an attacker to impersonate any user. You can mitigate this risk to some extent by using only a desktop machine or laptop that you trust, or by enforcing preauthentication by means of a hardware-token.

To use Kerberos authentication, you must configure it on the NetScaler appliance and on each client.

How NetScaler Implements Kerberos Authentication

Note: Kerberos/NTLM authentication is supported only in the NetScaler 9.3 nCore release or later, and it can be used only for AAA traffic management (AAA-TM) virtual servers.

NetScaler handles the components involved in Kerberos authentication in the following way:

Key Distribution Center (KDC)

In the Windows 2000 Server or later versions, the Domain Controller and KDC are part of the Windows Server. If the Windows Server is UP and running, it indicates that the Domain Controller and KDC are configured. The KDC is also the Active Directory server.

Note: All Kerberos interactions are validated with the Windows Kerberos Domain Controller.

Authentication Service and Protocol Negotiation

A NetScaler appliance supports Kerberos authentication on the AAA-TM authentication virtual servers. If the Kerberos authentication fails, the NetScaler uses the NTLM authentication.

By default, Windows 2000 Server and later Windows Server versions use Kerberos for AAA. If you create an authentication policy with NEGOTIATE as the authentication type, the NetScaler attempts to use the Kerberos protocol for AAA and if the client's browser fails to receive a Kerberos ticket, the NetScaler uses the NTLM authentication. This process is referred to as *negotiation*.

The client may fail to receive a Kerberos ticket in any of the following cases:

- Kerberos is not supported on the client.
- Kerberos is not enabled on the client.
- The client is in a domain other than that of the KDC.
- The Access Directory on the KDC is not accessible to the client.

For Kerberos/NTLM authentication, the NetScaler does not use the data that is present locally on the NetScaler appliance.

Authorization

The traffic management virtual server can be a load balancing virtual server or a content switching virtual server.

Auditing

The NetScaler appliance supports auditing of Kerberos authentication with the following audit logging:

- Complete audit trail of the traffic management end-user activity
- SYSLOG and high performance TCP logging
- Complete audit trail of system administrators
- All system events
- Scriptable log format

Supported Environment

Kerberos authentication does not need any specific environment on the NetScaler. The client (browser) must provide support for Kerberos authentication.

High Availability

In a high availability setup, only the active NetScaler joins the domain. In case of a failover, the NetScaler lwagent daemon joins the secondary NetScaler appliance to the domain. No specific configuration is required for this functionality.

Kerberos Authentication Process

The following figure shows a typical process for Kerberos authentication in the NetScaler environment.

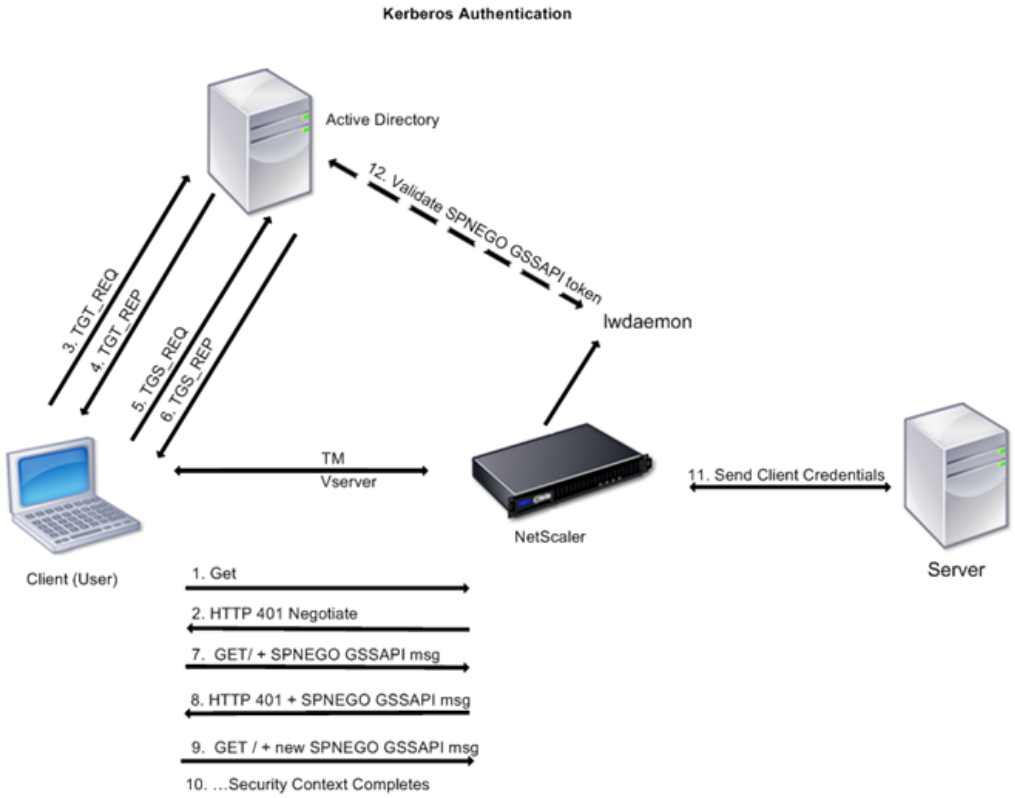

Figure 1. Kerberos Authentication Process on NetScaler

The Kerberos authentication occurs in the following stages:

Client authenticates itself to the KDC.

1. The NetScaler appliance receives a request from a client.
2. The traffic management (load balancing or content switching) virtual server on the NetScaler sends a challenge to the client.
3. To respond to the challenge, the client gets a Kerberos ticket.
    - The client sends the Authentication Server of the KDC a request for a ticket-granting ticket (TGT) and receives the TGT. (See 3, 4 in the figure, Kerberos Authentication Process.)
    - The client sends the TGT to the Ticket Granting Server of the KDC and receives a Kerberos ticket. (See 5, 6 in the figure, Kerberos Authentication Process.)

Note: The above authentication process is not necessary if the client already has a Kerberos ticket whose lifetime has not expired. In addition, clients such as Web Services, .NET, or J2EE, which support SPNEGO, get a Kerberos ticket for the target server, create an SPNEGO token, and insert the token in the HTTP header when they send an HTTP request. They do not go through the client authentication process.

Client requests a service.

1. The client sends the Kerberos ticket containing the SPNEGO token and the HTTP request to the traffic management virtual server on the NetScaler. The SPNEGO token has the necessary GSSAPI data.
2. The NetScaler establishes a security context between the client and the NetScaler. If the NetScaler cannot accept the data provided in the Kerberos ticket, the client is asked to get a different ticket. This cycle repeats till the GSSAPI data is acceptable and the security context is established. The traffic management virtual server on the NetScaler acts as an HTTP proxy between the client and the physical server.

NetScaler completes the authentication.

1. After the security context is complete, the traffic management virtual server validates the SPNEGO token.
2. From the valid SPNEGO token, the virtual server extracts the user ID and GSS credentials, and passes them to the authentication daemon.
3. A successful authentication completes the Kerberos authentication.

Kerberos Authentication - Configuration on the NetScaler Appliance

To configure Kerberos authentication on the NetScaler appliance, perform the following tasks:

1. Enable the Authentication, Authorization, and Auditing (AAA) feature on the NetScaler appliance.

2. On the Active Directory, add a user for Kerberos authentication, map the HTTP service to this user, and generate a keytab file and import it to the NetScaler appliance. You can map more than one service if the Kerberos authentication is required for more than one service. The keytab file should contain entries for every service that is bound to the traffic management virtual server on the NetScaler. The keytab file is necessary for decrypting the secret received from the client during Kerberos authentication. The authentication details of all the services are stored in a single keytab file on the NetScaler.

3. Add a DNS server.

   Note: The NetScaler must obtain the IP address of the domain controller from the fully qualified domain name (FQDN). Therefore, Citrix recommends configuring the NetScaler with a DNS server. A less preferred alternative is to create a static DNS entry.

4. Create an authentication negotiation policy with a negotiation action.

5. Configure an authentication server and bind the authentication policy to the authentication virtual server.

6. Configure an authentication service and a traffic management virtual server, and bind the service to the virtual server. You can use either a load balancing or a content switching virtual server.

7. Verify the configuration.

Enabling AAA on the NetScaler

Enable authentication of the traffic on the NetScaler appliance.

To enable Authentication, Authorization, and Auditing (AAA) by using the command line interface

At the command prompt, type the following commands to enable AAA and verify the configuration:

- enable ns feature AAA
- show ns feature

Example

```
> enable feature aaa
 Done
> show ns feature
 Feature Acronym Status
 ------- ------- ------
1) Web Logging WL ON
 …
3) Load Balancing LB ON
4) Content Switching CS ON
5) Cache Redirection CR ON
 …
14) SSL VPN SSLVPN ON
15) AAA AAA ON
 …
26) CloudBridge CloudBridge OFF
 Done
```

To enable Authentication, Authorization, and Auditing (AAA) on NetScaler by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure basic features.
3. In the Configure Basic Features dialog box, select the Authentication, Authorization and Auditing check box.
4. Click OK.
5. In the confirmation dialog box, click Yes. A message appears in the status bar to indicate that the feature is enabled.

Adding a Keytab file

The keytab file contains information about services necessary for Kerberos authentication. The keytab file is necessary for decrypting the secret received from the client during Kerberos authentication. You can map more than one service if the Kerberos authentication is required for more than one service. The keytab file should contain entries for every service that is bound to the traffic management virtual server on the NetScaler. The authentication details of all the services are stored in a single keytab file on the NetScaler.

To generate a keytab file and import it to the NetScaler appliance, follow the procedure described below:

Note: You can generate the keytab file and import it onto the NetScaler only from the command line.

1. Log onto the Active Directory server and create a user for Kerberos authentication.

   For example, type the following command:

   net user Kerb-SVC-Account freebsd!@#456 /add

2. In the User Properties section, ensure the following settings:

   - The Change password at next logon option is not selected.
   - The Password does not expire option is selected.

3. Map the HTTP service to the above user and export the keytab file. For example, run the following command on the Active Directory server:

   ktpass /out keytabfile /princ HTTP/owa.newacp.com@NEWACP.COM /pass freebsd!@#456 /mapuser newacp\dummy /ptype KRB5_NT_PRINCIPAL

   Note: If you want to map more services, repeat the above command for every service. You can give the same name or different names for the output file.

4. Transfer the keytab file to the NetScaler by using the unix ftp command or any other file transfer utility of your choice.

5. Log onto the NetScaler appliance, and run the ktutil utility to verify the keytab file. The keytab file has an entry for the HTTP service after it is imported.

Example

```
root@ns# ktutil
ktutil: rkt /var/keytabfile
ktutil: list
slot KVNO Principal
----------------------------------------------------------------------
```

```
ktutil: wkt /etc/ krb5.keytab
ktutil: list
slot KVNO Principal
---- ---- ---------------------------------------------------------------------
1 2 HTTP/owa.newacp.com@NEWACP.COM
ktutil: quit
```

Adding a DNS Server

The NetScaler appliance should obtain the IP address of the domain controller from the fully qualified domain name (FQDN). Therefore, Citrix recommends configuring the NetScaler with a DNS server. A less preferred alternative is to create a static DNS entry.

To add a DNS server by using the command line interface

At the command prompt, type the following command:

add dns nameserver <IP>

Note: Alternatively, you can add static host entries or use any other means so that the NetScaler can resolve the FQDN name of the domain controller to an IP address.

Example

add dns nameserver 1.2.3.4

Parameters for configuring the DNS server

dnsIpAddress

The IP address of the name server that is used to resolve domain names to IP addresses.

To add a DNS server by using the NetScaler configuration utility

1. In the navigation pane, expand DNS, and then click Name Servers.
2. In the details pane, click Add.
3. In the IP Address box, type the IP address.
4. Click Create, and then Close.
5. Verify that the details pane shows the newly added DNS server.

Creating an Authentication Negotiation Policy

Create a negotiation policy with a negotiation action for Kerberos authentication of services.

To create an authentication negotiation policy by using the command line interface

At the command prompt, type the following commands:

- add authentication negotiateAction <name> -domain <domainName> -domainUser <domainUsername> -domainUserPasswd <domainUserPassword> -encrypted
- add authentication negotiatePolicy <negotiatePolicyName> <negotiatePolicyExpression> <negotiateActionName>

Example

```
add authentication negotiateAction negact -domain newacp.com -domainUser Administrator -domainUserPas
add authentication negotiatePolicy negopol ns_true negact
```

Parameters for creating an authentication negotiation policy

negotiateActionName

The name of the negotiate action associated with the negotiate policy.

domainName

The fully qualified domain name in which the client and KDC are present.

domainUsername

The user name of the user who can access the domain.

domainUserPassword

The password of the user who can access the domain.

negotiatePolicyName

A name for the policy you are creating. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. (Cannot be changed for existing policies.)

negotiatePolicyExpression

A policy expression that defines the requests to be authenticated.

To create an authentication negotiation policy by using the NetScaler configuration utility

1. In the navigation pane, expand AAA-Application Traffic, expand Policies, and then click Authentication.
2. In the details pane, on the Policies tab, click Add.
3. In the Create Authentication Policy dialog box, set the following parameters:
   - Name
   - Authentication Type - Select NEGOTIATE.
   - Server - Select an existing server from the dropdown list. To add a new authentication server, click New…, and in the Create Authentication Server dialog box, set the following parameters:
     - Domain Name
     - User Name
     - Password
     - Confirm Password - Retype the password.
   - Expression - In the Named Expression list, select General and select True Value from the dropdown list, and then click Add Expression.
4. Click Create, and then click Close.
5. Verify that the policy you created appears in the Authentication Policies and Servers pane.

Creating an Authentication Virtual Server

Configure an authentication virtual server and bind the authentication negotiation policy to the authentication virtual server.

To create an authentication virtual server and bind the negotiation policy by using the command line interface

At the command prompt, type the following commands:

- add authentication vserver <name> SSL <ipAuthVserver> 443 -authenticationDomain <domainName>
- bind authentication vserver <name> -policy <negotiatePolicyName>

Example

```
add authentication vserver authen1 SSL 10.102.113.166 443 -authenticationDomain newacp.com
add ssl certKey cert1 -cert "/nsconfig/ssl/complete/server/server_rsa_2048.pem" -key "/nsconfig/ssl/compl
bind ssl vserver authen1 -certkeyName cert1
bind authentication vserver authen1 -policy negopol
```

Parameters for configuring an authentication virtual server and binding the negotiation policy

authVserverName

A name for the new authentication virtual server. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. (Cannot be changed after the virtual server is created.)

ipAuthVserver

The IP address of the authentication virtual server.

domainName

The fully qualified domain name in which the client and KDC are present. This domain is assigned to the authentication virtual server.

negotiatePolicyName

A name for the policy you are creating. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. (Cannot be changed for existing policies.)

To create an authentication virtual server and bind the negotiation policy by using the NetScaler configuration utility

1. In the navigation pane, expand AAA - Application Traffic and click Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Authentication) dialog box, set the following parameters:
   - Name
   - IP Address
   - Protocol - Select SSL
   - Domain - Type the fully qualified domain name added while creating the keytab file.

   Note: For AAA, the protocol must be SSL protocol and port must be 443. Therefore, these options are not provided.
4. On the Authentication tab, click Insert Policy. In the Authentication Policies group, from the Policy Name dropdown list, select the negotiate authentication policy you added for Kerberos authentication.
5. On the Certificates tab, select an SSL certificate from the list of available certificates, and then click Add. If the certificate you want to bind is not displayed in the Available Certificates list, click Install..., and then select the certificate file.
6. Click Create, and then click Close. The new authentication virtual server appears in the Authentication Virtual Servers pane.

Configuring a Traffic Management Virtual Server

Configure an authentication service and a traffic management virtual server, and bind the service to the virtual server. You can use either a load balancing or a content switching virtual server.

To create a traffic management virtual server and service, and bind the service by using the command line interface

At the command prompt, type the following commands:

- add service <name>@ <ipBackendWebserver> HTTP 80
- add lb vserver <name>@ SSL <ipAddressLbVserver> 443 -authn401 ON -authnVsName <authVserverName>
- bind lb vserver <name>@ <serviceName>

Note: Use a similar procedure for using a content switching virtual server as the traffic management virtual server.

Example

```
add service svc1 10.217.28.92 HTTP 80
 add lb vserver v2 HTTP 10.102.113.164 80 -persistenceType NONE -cltTimeout 180 -authn401 ON -authnVsNa
bind lb vserver v2 svc1
```

Parameters for configuring the traffic management virtual server

serviceName

Name of the service. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

ipBackendWebServer

IP address of the Web server used in backend communication.

lbVserverName

Name of the load balancing virtual server used as the traffic management virtual server.

csVserverName

Name of the content switching virtual server used as the traffic management virtual server.

ipAddressLbVserver

IP address of the load balancing virtual server.

ipAddressCsVserver

IP address of the content switching virtual server.

authVserverName

Name of the authentication virtual server associated with the traffic management virtual server.

To create a traffic management virtual server and service, and bind the service by using the NetScaler configuration utility

1. In the navigation pane, expand Load Balancing and click Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, set the following parameters:
   - Service Name
   - Server
   - Protocol - Select HTTP.
   - Port - Select 80.
4. In the navigation pane, expand Load Balancing and click Virtual Servers.
5. In the details pane, click Add.
6. In the Create Virtual Server (Load balancing) dialog box, set values for the following parameters:
   - Name
   - IP Address

- Protocol
- Port

7. In the Create Virtual Server (Load balancing) dialog box, on the Services tab, select the service you created in Step 3 to Step 5.
8. In the Create Virtual Server (Load balancing) dialog box, on the Advanced tab, expand Authentication Settings, and then select the 401 Based Authentication check box.
9. Click Create, and then click Close. The new load balancing virtual server appears in the Load Balancing Virtual Servers pane.
10. In the details pane, verify the settings of the virtual server.

Note: Use a similar procedure to create a content switching virtual server.

Note: For more information, see Setting up basic load balancing.

Verifying the configuration for Kerberos Authentication

Ensure that you completed the following tasks and verify whether the configuration is complete and correct.

- Enable the AAA feature
- Import the keytab file
- Configure the DNS server
- Configure negotiation policies and actions
- Configure authentication virtual server
- Configure traffic management virtual server

To verify the configuration:

1. Access the load balancing virtual server, using the FQDN. For example, http://owa.newacp.com.
2. View the AAA session on the NetScaler. show aaa session

Example

```
ClientIp (ClientPort) ->ServerIp(ServerPort)
 ---------------------------------------------
 PE id : 4
 User name: john.smith@NEWACP.COM Session Type: TM
Done
```

Configuration of Kerberos Authentication on a Client

Kerberos support must be configured on the browser to use Kerberos for authentication. You can use any Kerberos-compliant browser. Instructions for configuring Kerberos support on Internet Explorer and Mozilla Firefox follow. For other browsers, see the documentation of the browser.

To configure Internet Explorer for Kerberos authentication

1. In the Tools menu select Internet Options.
2. On the Security tab, click Local Intranet, and then click Sites.
3. In the Local Intranet dialog box, make sure that the Automatically detect intranet network option is selected, and then click Advanced.
4. In the Local Intranet dialog box, add the web sites of the domains of the traffic management virtual server on the NetScaler. The specified sites become local intranet sites.
5. Click Close or OK to close the dialog boxes.

To configure Mozilla Firefox for Kerberos authentication

1. Make sure that you have Kerberos properly configured on your computer.
2. Type `about:config` in the URL bar.
3. In the filter text box, type `network.negotiate`.
4. Change network.negotiate-auth.delegation-uris to the domain that you want to add.
5. Change network.negotiate-auth.trusted-uris to the domain that you want to add.

   Note: If you are running Windows, you also need to enter `sspi` in the filter text box and change the network.auth.use-sspi option to `False`.

Offloading Kerberos Authentication from Physical Servers

The NetScaler appliance can offload authentication tasks from servers. Instead of the physical servers authenticating the requests from clients, the Netscaler authenticates all the client requests before it forwards them to any of the physical servers bound to it. The user authentication is based on Active Directory tokens.

There is no authentication between the NetScaler and the physical server, and the authentication offload is transparent to the end users. After the initial logon to a Windows computer, the end user does not have to enter any additional authentication information in a pop-up or on a logon page.

In the current NetScaler release, Kerberos authentication is available only for Authentication, Authorization, and Auditing (AAA) Traffic Management Virtual Servers. Kerberos authentication is not supported for SSL VPN in the Access Gateway Enterprise Edition appliance or for NetScaler appliance management.

Kerberos authentication requires configuration on the NetScaler appliance and on client browsers.

To configure Kerberos authentication on the NetScaler appliance

1. Create a user account on Active Directory. When creating a user account, verify the following options in the User Properties section:

   - Make sure that you do not select the Change password at next logon option.

   - Be sure to select the Password does not expire option.
2. On the NetScaler appliance, at the CLI command prompt, type:

   - ktpass -princ HTTP/kerberos.crete.lab.net@crete.lab.net -ptype KRB5_NT_PRINCIPAL -mapuser kerbuser@crete.lab.net -mapop set -pass Citrix1 -out C:\kerbtabfile.txt

   Note: Be sure to type the above command on a single line. The output of the above command is written into the `C:\kerbatabfile.txt` file.

3. Upload the `kerbatabfile.txt` file to the */etc* directory of the NetScaler appliance by using a Secure Copy (SCP) client.

4. Run the following command to add a DNS server to the NetScaler appliance.

   - add dns nameserver `1.2.3.4`

   The NetScaler appliance cannot process Kerberos requests without the DNS server. Be sure to use the same DNS server that is used in the Microsoft Windows domain.

5. Switch to the shell prompt and run the following commands from the shell prompt:

   - ktutil # rkt /etc/kerbtabfile.txt

   - # wkt /etc/krb5.keytab

   - # list

     The list command displays the user account details that you created in the Active Directory. A sample screen of the output of the list command is shown below.

```
> shell

   1    3 HTTP/kerberos.crete.example.com@crete.example.com
ktutil:  quit
root@ns#
```

Figure 1. Sample Output of the list Command

6. Switch to the command line interface of NetScaler.

7. Run the following command to create a Kerberos authentication server:

   - add authentication negotiateAction KerberosServer -domain "crete.lab.net" -domainUser kerbuser -domainUserPasswd Citrix1

8. Run the following command to create a negotiation policy:

   - add authentication negotiatePolicy Kerberos-Policy "REQ.IP.DESTIP == 192.168.17.200" KerberosServer

9. Run the following command to create an authentication virtual server.

   - add authentication vserver Kerb-Auth SSL 192.168.17.201 443 -AuthenticationDomain crete.example.com

10. Run the following command to bind the Kerberos policy to the authentication virtual server:

    - bind authentication vserver Kerb-Auth -policy Kerberos-Policy -priority 100

11. Run the following command to bind an SSL certificate to the authentication virtual server. You can use one of the test certificates, which you can install from the GUI NetScaler appliance. Run the following command to use the ServerTestCert sample certificate.

    - bind ssl vserver Kerb-Auth -certkeyName ServerTestCert

12. Create an HTTP load balancing virtual server with the IP address, 192.168.17.200.

    Ensure that you create a virtual server from the command line interface for NetScaler 9.3 releases if they are older than 9.3.47.8.

13. Run the following command to configure an authentication virtual server:

    - set lb vserver LB-Vserver-Name -authn401 ON -authnVsName Kerb-Auth

14. Enter the host name `http://www.crete.example.com` in the address bar of the Web browser.

    The Web browser displays an authentication dialog box because the Kerberos authentication is not set up in the browser.

Note: Kerberos authentication requires a specific configuration on the client. Ensure that the client can resolve the hostname, which results in the Web browser connecting to an HTTP virtual server.

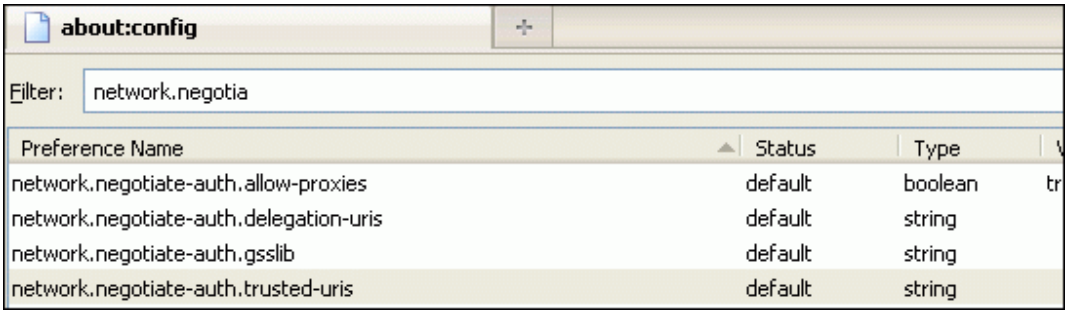
15. Configure Kerberos on the Web browser of the client computer.
    - For configuring on Internet Explorer, see "Configuring Internet Explorer for Kerberos authentication."
    - For configuring on Mozilla Firefox, see "Configuring Mozilla Firefox for Kerberos authentication."
16. Verify whether you can access the backend physical server without authentication.

To configure Internet Explorer for Kerberos authentication

1. Select Internet Options from the Tools menu.
2. Activate the Security tab.
3. Select Local Intranet from the Select a zone to view change security settings section.
4. Click Sites.
5. Click Advanced.
6. Specify the URL, `http://www.crete.example.com` and click Add.
7. Restart Internet Explorer.

To configure Mozilla Firefox for Kerberos authentication

1. Enter `about:config` in the address bar of the browser.
2. Click the warning disclaimer.
3. Type `Network.Negotiate-auth.trusted-uris` in the Filter box.
4. Double click `Network.Negotiate-auth.trusted-uris`. A sample screen is shown below.



5. In the Enter String Value dialog box, specify `www.crete.example.com`.
6. Restart Firefox.

NetScaler Kerberos Single Sign-On

NetScaler appliances now support single sign-on (SSO) using the Kerberos 5 protocol. Users log on to a proxy, the Application Delivery Controller (ADC), which then provides access to protected resources.

The NetScaler Kerberos SSO implementation requires the user's password for SSO methods that rely on basic, NTLM, or forms-based authentication. The user's password is not required for Kerberos SSO, although if Kerberos SSO fails and the NetScaler appliance has the user's password, it uses the password to attempt NTLM SSO.

If the user's password is available, the KCD account is configured with a realm, and no delegated user information is present, the NetScaler Kerberos SSO engine impersonates the user to obtain access to authorized resources. Impersonation is also called *unconstrained delegation*.

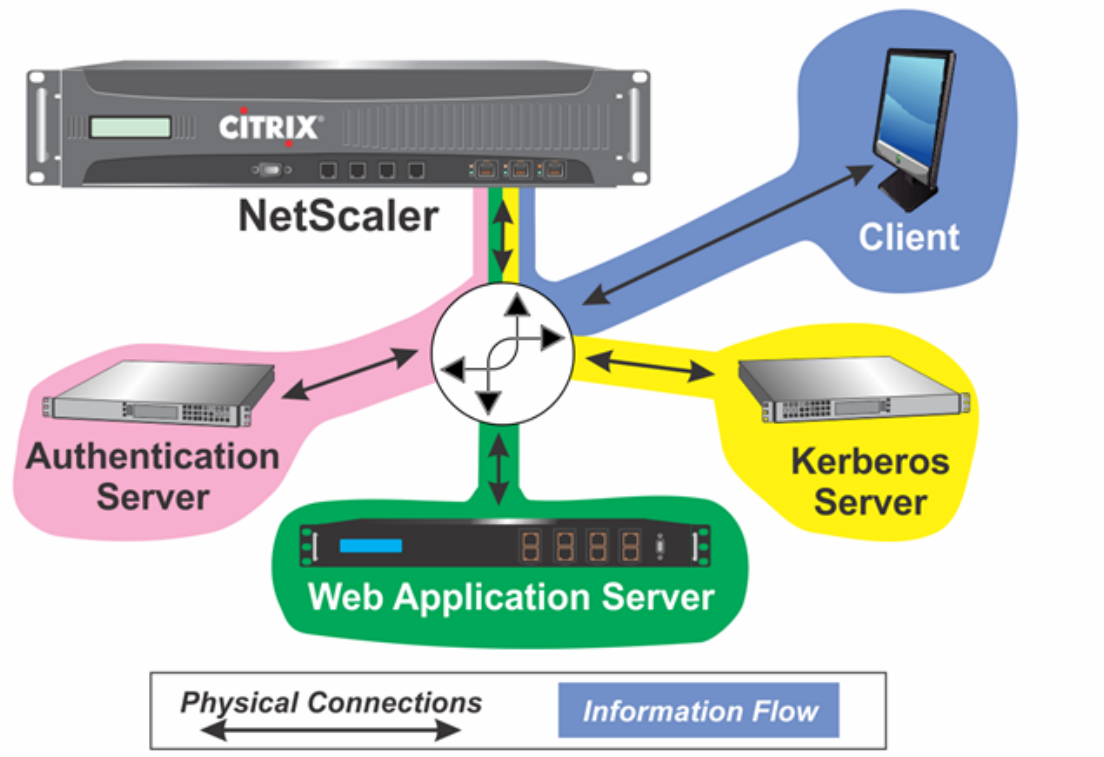
The NetScaler Kerberos SSO engine can also be configured to use a delegated account to obtain access to protected resources on the user's behalf. This configuration requires delegated user credentials, a keytab, or a delegated user certificate and matching CA certificate. Configuration that uses a delegated account is called *constrained delegation*.

An Overview of NetScaler Kerberos SSO

To use the NetScaler Kerberos SSO feature does, users first authenticate with Kerberos or a supported third-party authentication server. Once authenticated, the user requests access to a protected web application. The web server responds with a request for proof that the user is authorized to access that web application. The user's browser contacts the Kerberos server, which verifies that the user is authorized to access that resource, and then provides the user's browser with a service ticket that provides proof. The browser resends the user's request to the web application server with the service ticket attached. The web application server verifies the service ticket, and then allows the user to access the application.

AAA-TM implements this process as shown in the following diagram. The diagram illustrates the flow of information through the NetScaler appliance and AAA-TM, on a secure network with LDAP authentication and Kerberos authorization. AAA-TM environments that use other types of authentication have essentially the same information flow, although they might differ in some details.

Figure 1. A Secure Network with LDAP and Kerberos



NetScaler AAA-TM authentication and authorization in a Kerberos environment requires that the following actions take place.

1. The client sends a request for a resource to the traffic management virtual server on the NetScaler appliance.

2. The traffic management virtual server passes the request to the authentication virtual server, which authenticates the client and then passes the request back to the traffic

management virtual server.

3. The traffic management virtual server sends the client's request to the web application server.
4. The web application server responds to the traffic management virtual server with a 401 Unauthorized message that requests Kerberos authentication, with fallback to NTLM authentication if the client does not support Kerberos.
5. The traffic management virtual server contacts the Kerberos SSO daemon.
6. The Kerberos SSO daemon contacts the Kerberos server and obtains a ticket-granting ticket (TGT) allowing it to request service tickets authorizing access to protected applications.
7. The Kerberos SSO daemon obtains a service ticket for the user and sends that ticket to the traffic management virtual server.
8. The traffic management virtual server attaches the ticket to the user's initial request and sends the modified request back to the web application server.
9. The web application server responds with a 200 OK message.

These steps are transparent to the client, which just sends a request and receives the requested resource.

Integration of NetScaler Kerberos SSO with Authentication Methods

All AAA-TM authentication mechanisms support NetScaler Kerberos SSO. AAA-TM supports the Kerberos SSO mechanism with the Kerberos, CAC (Smart Card) and SAML authentication mechanisms with any form of client authentication to the NetScaler appliance. It also supports the HTTP-Basic, HTTP-Digest, Forms-based, and NTLM (versions 1 and 2) SSO mechanisms if the client uses either HTTP-Basic or Forms-Based authentication to log on to the NetScaler appliance.

The following table shows each supported client-side authentication method, and the supported server-side authentication method for that client-side method.

Table 1. Supported Authentication Methods

	Basic/Digest/ NTLM	Kerberos Constrained Delegation	User Impersonation
CAC (Smart Card): at SSL/TLS Layer		X	X
Forms-Based (LDAP/RADIUS/TACACS)	X	X	X

HTTP Basic (LDAP/RADIUS/TACACS)	X	X	X
Kerberos		X	
NTLM v1/v2		X	X
SAML		X	
SAML Two-Factor	X	X	X
Certificate Two-Factor	X	X	X

Setting up NetScaler SSO

You can configure NetScaler SSO to work in one of two ways: by impersonation or by delegation. SSO by impersonation is a simpler configuration than SSO by delegation, and is therefore usually preferable when your configuration allows it. To configure NetScaler SSO by impersonation, you must have the user's user name and password.

To configure NetScaler SSO by delegation, you must have the delegated user's credentials in one of the following formats: the user's user name and password, the keytab configuration that includes the user name and an encrypted password, or the delegated user certificate and the matching CA certificate.

Prerequisites

Before you configure NetScaler SSO, you need to have your NetScaler appliance fully configured to manage traffic to and authentication for your web application servers. Therefore, you must configure either load balancing or content switching, and then AAA, for these web application servers. You should also verify routing between the appliance, your LDAP server, and your Kerberos server.

If your network is not already configured in this manner, perform the following configuration tasks:

- Configure a server and service for each web application server.
- Configure a traffic management virtual server to handle traffic to and from your web application server.

Following are brief instructions and examples for performing each of these tasks from the NetScaler command line. For further assistance, see ns-lb-setup-wrapper-con.html and Setting up AAA Virtual Servers and DNS.

To create a server and service by using the NetScaler command line

For NetScaler SSO to obtain a TGS (service ticket) for a service, either the FQDN assigned to the server entity on the NetScaler appliance must match the FQDN of the web application server, or the server entity name must match the NetBios name of the web application server. You can take either of the following approaches:

- Configure the NetScaler server entity by specifying the FQDN of the web application server.
- Configure the NetScaler server entity by specifying the IP address of the web application server, and assign the server entity the same name as the NetBios name of the web application server.

At the command prompt, type the following commands:

- add server <serverName> <serverFQDN>
- add service <serviceName> <serverName> <type> <port>

For the variables, substitute the following values:

- **serverName**—A name for the NetScaler appliance to use to refer to this server.
- **serverFQDN**—The FQDN of the server. If the server has no domain assigned to it, use the server's IP address and make sure that the server entity name matches the NetBios name of the web application server.

- **serviceName**—A name for the NetScaler appliance to use to refer to this service.
- **type**—The protocol used by the service, either HTTP or MSSQLSVC.
- **port**—The port on which the service listens. HTTP services normally listen on port 80. Secure HTTPS services normally listen on port 443.

Example

The following examples add server and service entries on the NetScaler appliance for the web application server `was1.example.com`. The first example uses the FQDN of the web application server; the second uses the IP address.

To add the server and service using the web application server FQDN, `was1.example.com`, you would type the following commands:

```
add server was1 was1.example.com
add service was1service was1 HTTP 80
```

To add the server and service using the web application server IP and NetBios name, where the web application server IP is `10.237.64.87` and its NetBios name is `WAS1`, you would type the following commands:

```
add server WAS1 10.237.64.87
add service was1service WAS1 HTTP 8
```

To create a traffic management virtual server by using the NetScaler command line

The traffic management virtual server manages traffic between the client and the web application server. You can use either a load balancing or a content switching virtual server as the traffic management server. The SSO configuration is the same for either type.

To create a load balancing virtual server, at the command prompt, type the following command:

add lb vserver <vserverName> <type> <IP> <port>

For the variables, substitute the following values:

- **vserverName**—A name for the NetScaler appliance to use to refer to this virtual server.
- **type**—The protocol used by the service, either HTTP or MSSQLSVC.
- **IP**—The IP address assigned to the virtual server. This would normally be an IANA-reserved, non-public IP address on your LAN.
- **port**—The port on which the service listens. HTTP services normally listen on port 80. Secure HTTPS services normally listen on port 443.

Example

To add a load balancing virtual server called `tmvserver1` to a configuration that manages HTTP traffic on port 80, assigning it a LAN IP address of `10.217.28.20` and then binding the load balancing virtual server to the `wasservice1` service, you would type the following commands:

```
add lb vserver tmvserver1 HTTP 10.217.28.20 80
bind lb vserver tmvserv1 wasservice1
```

To create an authentication virtual server by using the NetScaler command line

The authentication virtual server manages authentication traffic between the client and the authentication (LDAP) server. To create an authentication virtual server, at the command prompt type the following commands:

- add authentication vserver <authvserverName> SSL <IP> 443
- set authentication vserver <authvserverName> –authenticationdomain <domain>

For the variables, substitute the following values:

- **authvserverName** —A name for the NetScaler appliance to use to refer to this authentication virtual server.
- **IP**—The IP address assigned to the authentication virtual server. As with the traffic management virtual server, this address would normally be an IANA-reserved, non-public IP on your LAN.
- **domain**—The domain assigned to the virtual server. This would usually be the domain of your network. It is customary, though not required, to enter the domain in all capitals when configuring the authentication virtual server.

Example

To add an authentication virtual server called `authverver1` to your configuration and assign it the LAN IP `10.217.28.21` and the domain `EXAMPLE.COM`, you would type the following commands:

```
add authentication vserver authvserver1 SSL 10.217.28.21 443
set authentication vserver authvserver1 –authenticationdomain EXAMPLE.COM
```

To configure a traffic management virtual server to use an authentication profile

The authentication virtual server can be configured to handle authentication for a single domain or for multiple domains. If it is configured to support authentication for multiple domains, you must also specify the domain for NetScaler SSO by creating an authentication profile, and then configuring the traffic management virtual server to use that authentication profile.

Note: The traffic management virtual server can be either a load balancing (`lb`) or content switching (`cs`) virtual server. The following instructions assume that you are using a load balancing virtual server. To configure a content switching virtual server, simply substitute `set cs vserver` for `set lb vserver`. The procedure is otherwise the same.

To create the authentication profile, and then configure the authentication profile on a traffic management virtual server, type the following commands:

- add authentication authnProfile <authnProfileName> {-authvserverName <string>} {-authenticationHost <string>} {-authenticationDomain <string>}
- set lb vserver <vserverName> -authnProfile <authnprofileName>

For the variables, substitute the following values:

- **authnprofileName**—A name for the authentication profile. Must begin with a letter, number, or the underscore character (_), and must consist of from one to thirty-one alphanumeric or hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters.
- **authvserverName**—The name of the authentication virtual server that this profile uses for authentication.
- **authenticationHost**—Host name of the authentication virtual server.
- **authenticationDomain**—Domain for which NetScaler SSO handles authentication. Required if the authentication virtual server performs authentication for more than one domain, so that the correct domain is included when the NetScaler appliance sets the traffic management virtual server cookie.

Example

To create an authentication profile named `authnProfile1` for authentication of the `example.com` domain, and to configure the load balancing virtual server `vserver1` to use the authentication profile `authnProfile1`, you would type the following commands:

```
add authentication authnProfile authnProfile1 -authnvsName authvsesrver1
    -authenticationHost authvsesrver1 -authenticationDomain example.com
set lb vserver vserver1 -authnProfile authnProfile1
```

Configuring SSO

Configuring NetScaler SSO to authenticate by impersonation is simpler than configuring than SSO to authenticate by delegation, and is therefore usually preferable when your configuration allows it. You just create a KCD account. You can use the user's password.

If you do not have the user's password, you can configure NetScaler SSO to authenticate by delegation. Although somewhat more complex than configuring SSO to authenticate by impersonation, the delegation method provides flexibility in that a user's credentials might not be available to the NetScaler appliance in all circumstances.

For either impersonation or delegation, you must also enable integrated authentication on the web application server.

Enabling Integrated Authentication on the Web Application Server

To set up NetScaler Kerberos SSO on each web application server that Kerberos SSO will manage, use the configuration interface on that server to configure the server to require authentication. Select Kerberos (negotiate) authentication by preference, with fallback to NTLM for clients that do not support Kerberos.

Following are instructions for configuring Microsoft Internet Information Server (IIS) to require authentication. If your web application server uses software other than IIS, consult the documentation for that web server software for instructions.

To configure Microsoft IIS to use integrated authentication

1. Log on to the IIS server and open Internet Information Services Manager.
2. Select the web site for which you want to enable integrated authentication. To enable integrated authentication for all IIS web servers managed by IISM, configure authentication settings for the Default Web Site. To enable integrated authentication for individual services (such as Exchange, Exadmin, ExchWeb, and Public), configure these authentication settings for each service individually.
3. Open the Properties dialog box for the default web site or for the individual service, and click the Directory Security tab.
4. Beside Authentication and Access Control, select Edit.
5. Disable anonymous access.
6. Enable Integrated Windows authentication (only). Enabling integrated Windows authentication should automatically set protocol negotiation for the web server to `Negotiate, NTLM`, which specifies Kerberos authentication with fallback to NTLM for non-Kerberos capable devices. If this option is not automatically selected, manually set protocol negotiation to `Negotiate, NTLM`.

Setting Up SSO by Impersonation

You can configure the KCD account for NetScaler SSO by impersonation. In this configuration, the NetScaler appliance obtains the user's username and passwordwhen the user authenticates to the authentication server and uses those credentials to impersonate the user to obtain a ticket-granting ticket (TGT). If the user's name is in UPN format, the appliance obtains the user's realm from UPN. Otherwise, it obtains the user's name and realm by extracting it from the SSO domain used during initial authentication, or from the session profile.

When configuring the KCD account, you must set the realm parameter to the realm of the service that the user is accessing. The same realm is also used as the user's realm if the user's realm cannot be obtained from authentication with the Netscaler appliance or from the session profile.

To create the KCD account for SSO by impersonation with a password

At the command prompt, type the following command:

add aaa kcdaccount <accountname> -realmStr <realm>

For the variables, substitute the following values:

- **accountname**—The KCD account name.
- **realm**—The domain assigned to NetScaler SSO.

Example:

To add a KCD account named `kcdccount1`, and use the keytab named `kcdvserver.keytab`, you would type the following command:

add aaa kcdAccount kcdaccount1 –realmStr EXAMPLE.COM

Configuring SSO by Delegation

To configure SSO by Delegation, you need to perform the following tasks:

- If you are configuring delegation by delegated user certificate, install the matching CA certificates on the NetScaler appliance and add them to the NetScaler configuration.
- Create the KCD account on the appliance. The appliance uses this account to obtain service tickets for your protected applications.
- Configure the Active Directory server.

Installing the Client CA Certificate on the NetScaler appliance

If you are configuring NetScaler SSO with a client certificate, you must copy the matching CA certificate for the client certificate domain (the *client CA certificate*) to the NetScaler appliance, and then install the CA certificate. To copy the client CA certificate, use the file transfer program of your choice to transfer the certificate and private-key file to the NetScaler appliance, and store the files in `/nsconfig/ssl`.

To install the client CA certificate on the NetScaler appliance

At the command prompt, type the following command:

add ssl certKey <certkeyName> -cert <cert> [(-key <key> [-password]) | -fipsKey <fipsKey>] [-inform (DER | PEM)] [-expiryMonitor (ENABLED | DISABLED | UNSET) [-notificationPeriod <positive_integer>]] [-bundle (YES | NO)]

For the variables, substitute the following values:

- **certkeyName**—A name for the client CA certificate. Must begin with an ASCII alphanumeric or underscore (_) character, and must consist of from one to thirty-one characters. Allowed characters include the ASCII alphanumerics, underscore, hash (#), period(.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the certificate-key pair is created. If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my cert" or 'my cert').
- **cert**—Full path name and file name of the X509 certificate file used to form the certificate-key pair. The certificate file must be stored on the NetScaler appliance, in the /nsconfig/ssl/ directory.
- **key**—Full path name and file name of the file that contains the private key to the X509 certificate file. The key file must be stored on the NetScaler appliance in the /nsconfig/ssl/ directory.

- **password**—If a private key is specified, the passphrase used to encrypt the private key. Use this option to load encrypted private keys in PEM format.
- **fipsKey**—Name of the FIPS key that was created inside the Hardware Security Module (HSM) of a FIPS appliance, or a key that was imported into the HSM.

  Note: You can specify either a `key` or a `fipsKey`, but not both.
- **inform**—Format of the certificate and private-key files, either PEM or DER.
- **passplain**—Pass phrase used to encrypt the private key. Required when adding an encrypted private-key in PEM format.
- **expiryMonitor**—Configure the NetScaler appliance to issue an alert when the certificate is about to expire. Possible values: ENABLED, DISABLED, UNSET.
- **notificationPeriod**—If expiryMonitor is ENABLED, number of days before the certificate expires to issue an alert.
- **bundle**—Parse the certificate chain as a single file after linking the server certificate to its issuer's certificate within the file. Possible values: YES, NO.

Example

The following example adds the specified delegated user certificate `customer-cert.pem` to the NetScaler configuration along with the key `customer-key.pem`, and sets the password, certificate format, expiration monitor, and notification period.

To add the delegated user certificate, you would type the following commands:

```
add ssl certKey customer -cert "/nsconfig/ssl/customer-cert.pem"
      -key "/nsconfig/ssl/customer-key.pem" -password "dontUseDefaultPWs!"
      -inform PEM -expiryMonitor ENABLED [-notificationPeriod 14
```

Creating the KCD Account

If you are configuring NetScaler SSO by delegation, you can configure the KCD account to use the user's log-on name and password, to use the user's log-on name and keytab, or to use the user's client certificate. If you configure SSO with user name and password, the NetScaler appliance uses the delegated user account to obtain a Ticket Granting Ticket (TGT), and then uses the TGT to obtain service tickets for the specific services that each user requests. If you configure SSO with keytab file, the NetScaler appliance uses the delegated user account and keytab information. If you configure SSO with a delegated user certificate, the NetScaler appliance uses the delegated user certificate.

To create the KCD account for SSO by delegation with a password

At the command prompt, type the following commands:

add aaa kcdaccount <accountname> -delegatedUser root -kcdPassword <password> -realmStr <realm>

For the variables, substitute the following values:

- **accountname**—A name for the KCD account.
- **password**—A password for the KCD account.
- **realm**—The realm of the KCD account, usually the domain for which SSO is active.

Example (UPN Format)

To add a KCD account named `kcdaccount1` to the NetScaler appliance configuration with a password of `password1` and a realm of `EXAMPLE.COM`, specifying the delegated user account in UPN format (as root), you would type the following commands:

```
add aaa kcdaccount kcdaccount1 –delegatedUser root
-kcdPassword password1 -realmStr EXAMPLE.COM
```

Example (SPN Format)

To add a KCD account named `kcdaccount1` to the NetScaler appliance configuration with a password of `password1` and a realm of `EXAMPLE.COM`, specifying the delegated user account in SPN format, you would type the following commands:

```
add aaa kcdAccount kcdaccount1 -realmStr EXAMPLE.COM
-delegatedUser "host/kcdvserver.example.com" -kcdPassword password1
```

Creating the KCD account for SSO by delegation with a keytab

If you plan to use a keytab file for authentication, first create the keytab. You can create the keytab file manually by logging onto the AD server and using the ktpass utility, or you can use the NetScaler configuration utility to create a batch script, and then run that script on the AD server to generate the keytab file. Next, use FTP or another file transfer program to transfer the keytab file to the NetScaler appliance and place it in the /nsconfig/krb directory. Finally, configure the KCD account for NetScaler SSO by delegation and provide the path and file name of the keytab file to the NetScaler appliance.

To create the keytab file manually

Log on to the AD server command line and, at the command prompt, type the following command:

ktpass /princ <SPN> /ptype KRB5_NT_PRINCIPAL /mapuser <DOMAIN>\<username> /pass <password> -out <File_Path>

For the variables, substitute the following values:

- **SPN**—The service principal name for the KCD service account.

- **DOMAIN**—The domain of the Active Directory server.
- **username**—The KSA account username.
- **password**—The KSA account password.
- **path**— The full path name of the directory in which to store the keytab file after it is generated.

To use the NetScaler configuration utility to create a script to generate the keytab file.

1. Navigate to Security > AAA - Application Traffic
2. In the data pane, under Kerberos Constrained Delegation, click Batch file to generate Keytab.
3. In the Generate KCD (Kerberos Constrained Delegation) Keytab Script dialog box, set the following parameters:
   - **Domain User Name**—The KSA account username.
   - **Domain Password**—The KSA account password.
   - **Service Principal**—The service principal name for the KSA.
   - **Output File Name**—The full path and file name to which to save the keytab file on the AD server.
4. Clear the Create Domain User Account check box.
5. Click Generate Script.
6. Log on to the Active Directory server and open a command line window.
7. Copy the script from the Generated Script window and paste it directly into the Active Directory server command-line window. The keytab is generated and stored in the directory under the file name that you specified as **Output File Name**.
8. Use the file transfer utility of your choice to copy the keytab file from the Active Directory server to the NetScaler appliance and place it in the `/nsconfig/krb` directory.

To create the KCD account

At the command prompt, type the following command:

add aaa kcdaccount <accountname> –keytab <keytab>

Example:

To add a KCD account named `kcdccount1`, and use the keytab named `kcdvserver.keytab`, you would type the following commands:

add aaa kcdaccount kcdaccount1 –keytab kcdvserver.keytab

To create the KCD account for SSO by delegation with a delegated user cert

At the command prompt, type the following command:

add aaa kcdaccount <accountname> -realmStr <realm> -delegatedUser <user_name/SPN> -usercert <cert> -cacert <cacert>

For the variables, substitute the following values:

- **accountname**—A name for the KCD account.
- **realmStr**—The realm for the KCD account, usually the domain for which SSO is configured.
- **delegatedUser**—The delegated user name, in SPN format.
- **usercert**—The full path and name of the delegated user certificate file on the NetScaler appliance. The delegated user certificate must contain both the client certificate and the private key, and must be in PEM format. If you use smart card authentication, you might need to create a smart card certificate template to allow certificates to be imported with the private key.
- **cacert**—The full path to and name of the CA certificate file on the NetScaler appliance.

Example:

To add a KCD account named `kcdccount1`, and use the keytab named `kcdvserver.keytab`, you would type the following command:

```
add aaa kcdaccount kcdaccount1 -realmStr EXAMPLE.COM
    -delegatedUser "host/kcdvserver.example.com" -usercert /certs/usercert
    -cacert /cacerts/cacert
```

Setting up Active Directory for NetScaler SSO

When you configure SSO by delegation, in addition to creating the KCDAccount on the NetScaler appliance, you must also create a matching Kerberos Service Account (KSA) on your LDAP active directory server, and configure the server for SSO. To create the KSA, use the account creation process on the active directory server. To configure SSO on the active directory server, open the properties window for the KSA. In the Delegation tab, enable the following options: Trust this user for delegation to specified services only and Use any Authentication protocol. (The Kerberos only option does not work, because it does not enable protocol transition or constrained delegation.) Finally, add the services that NetScaler SSO will manage.

Note: If the Delegation tab is not visible in the KSA account properties dialog box, before you can configure the KSA as described, you must use the Microsoft `setspn` command-line tool to configure the active directory server so that the tab is visible.

To configure delegation for the Kerberos service account

1. In the LDAP account configuration dialog box for the Kerberos service account that you created, click the Delegation tab.

2. Choose "Trust this user for delegation to the specified services only".

3. Under "Trust this user for delegation to the specified services only," choose "Use any authentication protocol".

4. Under “Services to which this account can present delegated credentials,” click Add.

5. In the Add Services dialog box, click Users or Computers, choose the server that hosts the resources to be assigned to the service account, and then click OK.

   Note: Constrained delegation does not support services hosted in domains other than the domain assigned to the account, even though Kerberos might have a trust relationship with other domains

6. Back in the Add Services dialog box, in the Available Services list, choose the services assigned to the service account. NetScaler SSO supports the HTTP and MSSQLSVC services.

7. Click OK.

Application Firewall

The following topics cover installation and configuration of the Citrix Application Firewall feature.

Introduction	An overview of web application security and how the application firewall works.
Configuration	How to configure the application firewall to protect a web site, a web service, or a web 2.0 site.
Signatures	A detailed description of the signatures feature and how to configure the signatures, add signatures from a supported vulnerability scanning tool, and define your own signatures, with examples.
Advanced Protections	A detailed description of all of the application firewall security checks, with configuration information and examples.
Profiles	A description of how profiles are configured and used in the application firewall.
Policies	A description of how policies are used when configuring the application firewall, with examples of useful policies.
Imports	A description of how the application firewall uses different types of imported files, and how to import and export files.
Global Configuration	A description of application firewall features that apply to all profiles, and how to configure them.
Use Cases	Extended examples that demonstrate how to set up the application firewall to best protect specific types of more complex web sites and web services.
Logs, Statistics, and Reports	How to access and use the application firewall logs, the statistics, and the reports to assist in configuring the application firewall.

Introduction

The Citrix® Application Firewall™ prevents security breaches, data loss, and possible unauthorized modifications to web sites that access sensitive business or customer information. It does so by filtering both requests and responses, examining them for evidence of malicious activity, and blocking those that exhibit such activity. Your site is protected not only from common types of attacks, but also from new, as yet unknown attacks. In addition to protecting web servers and web sites from unauthorized access and misuse by hackers and malicious programs, the application firewall provides protection against security vulnerabilities in legacy CGI code or scripts, other web frameworks, web server software, and the underlying operating systems.

The Application Firewall is available as a stand-alone appliance, or as a feature on a Citrix NetScaler appliance or Citrix NetScaler virtual appliance. In the application firewall documentation, the term *application firewall appliance* refers to the platform on which the application firewall is running, regardless of whether that platform is a dedicated firewall appliance, a NetScaler appliance on which other features have also been configured, or a NetScaler virtual appliance,

To use the application firewall, you must create at least one security configuration to block connections that violate the rules that you set for your protected web sites. The number of security configurations that you might want to create depends on the complexity of your web site. In many cases, one is sufficient. You can probably use the defaults for the global settings, which affect all security configurations, but you can change the global settings if necessary.

Web Application Security

Web application security is that part of network security that covers computers and programs that communicate by using the HTTP and HTTPS protocols. This is an extremely broad area in which security flaws and weaknesses abound. Operating systems on both servers and clients have security issues and are vulnerable to attack. Web server software and web site enabling technologies such as CGI, Java, JavaScript, PERL and PHP have underlying vulnerabilities. Browsers and other client applications that communicate with web-enabled applications also have vulnerabilities. Web sites that use any technology but the simplest of HTML, including any site that allows interaction with visitors, often have vulnerabilities of their own.

In the past, a breach in security was often just an annoyance, but today that is seldom the case. For example, attacks in which a hacker gained access to a web server and made unauthorized modifications to (*defaced*) a web site used to be common. They were usually launched by hackers who had no motivation beyond demonstrating their skills to fellow hackers or embarrassing the targeted person or company. Most current security breaches, however, are motivated by a desire for money. The majority attempt to accomplish one or both of the following goals: to obtain sensitive and potentially valuable private information, or to obtain unauthorized access to and control of a web site or web server.

Certain forms of web attacks focus on obtaining private information. These attacks are often possible even against web sites that are secure enough to prevent an attacker from taking full control. The information that an attacker can obtain from a web site can include customer names, addresses, phone numbers, social security numbers, credit card numbers, medical records, and other private information. The attacker can then use this information or sell it to others. Much of the information obtained by such attacks is protected by law, and all of it by custom and expectation. A breach of this type can have extremely serious consequences for customers whose private information is compromised. At best, these customers will have to exercise vigilance to prevent others from abusing their credit cards, opening unauthorized credit accounts in their name, or appropriating their identities outright (identity theft). At worst, the customers may face ruined credit ratings or even be blamed for criminal activities in which they had no part.

Other web attacks are aimed at obtaining control of (or *compromising*) a web site or the server on which it operates, or both. A hacker who gains control of a web site or server can use it to host unauthorized content, act as a proxy for content hosted on another web server, provide SMTP services to send unsolicited bulk email, or provide DNS services to support such activities on other compromised web servers. Most web sites that are hosted on compromised web servers promote questionable or outright fraudulent businesses. For example, the majority of phishing web sites and child pornography web sites are hosted on compromised web servers.

Protecting your web sites and web services against these attacks requires a multilayered defense capable of both blocking known attacks with identifiable characteristics and protecting against unknown attacks, which can often be detected because they look different from the normal traffic to your web sites and web services.

Known Web Attacks

The first line of defense for your web sites is protection against the large number of attacks that are known to exist and have been observed and analyzed by web security experts. Common types of attacks against HTML-based web sites include:

- **Buffer overflow attacks.** Sending an extremely long URL, extremely long cookie, or other extremely long bit of information to a web server in hopes of causing it or the underlying operating system to hang, crash, or provide the attacker with access to the underlying operating system. A buffer overflow attack can be used to gain access to unauthorized information, to compromise a web server, or both.

- **Cookie security attacks.** Sending a modified cookie to a web server, usually in hopes of obtaining access to unauthorized content by using falsified credentials.

- **Forceful browsing.** Accessing URLs on a web site directly, without navigating to the URLs by means of hyperlinks on the home page or other common start URLs on the web site. Individual instances of forceful browsing may simply indicate a user who bookmarked a page on your web site, but repeated attempts to access nonexistent content, or content that users should never access directly, often represent an attack on web site security. Forceful browsing is normally used to gain access to unauthorized information, but can also be combined with a buffer overflow attack in an attempt to compromise your server.

- **Web form security attacks.** Sending inappropriate content to your web site in a web form. Inappropriate content can include modified hidden fields, HTML or code in a field intended for alphanumeric data only, an overly long string in a field that accepts only a short string, an alphanumeric string in a field that accepts only an integer, and a wide variety of other data that your web site does not expect to receive in that web form. A web form security attack can be used either to obtain unauthorized information from your web site or to compromise the web site outright, usually when combined with a buffer overflow attack.

Two specialized types of attacks on web form security deserve special mention:

- **SQL injection attacks.** Sending an active SQL command or commands in a web form or as part of a URL, with the goal of causing an SQL database to execute the command or commands. SQL injection attacks are normally used to obtain unauthorized information.

- **Cross-site scripting attacks.** Using a URL or a script on a web page to violate the same-origin policy, which forbids any script from obtaining properties from or modifying any content on a different web site. Since scripts can obtain information and modify files on your web site, allowing a script access to content on a different web site can provide an attacker the means to obtain unauthorized information, to compromise a web server, or both.

Attacks against XML-based web services normally fall into at least one of the following two categories: attempts to send inappropriate content to a web service, or attempts to breach security on a web service. Common types of attacks against XML-based web services include:

- **Malicious code or objects.** XML requests that contain code or objects that can either directly obtain sensitive information or can give an attacker control of the web service or underlying server.

- **Badly-formed XML requests.** XML requests that do not conform to the W3C XML specification, and that can therefore breach security on an insecure web service.

- **Denial of service (DoS) attacks.** XML requests that are sent repeatedly and in high volume, with the intent of overwhelming the targeted web service and denying legitimate users access to it.

In addition to standard XML-based attacks, XML web services and Web 2.0 sites are also vulnerable to SQL injection and cross-site scripting attacks, as described below:

- **SQL injection attacks.** Sending an active SQL command or commands in an XML-based request, with the goal of causing an SQL database to execute that command or commands. As with HTML SQL injection attacks, XML SQL injection attacks are normally used to obtain unauthorized information.

- **Cross-site scripting attacks.** Using a script included in an XML based application to violate the same-origin policy, which does not allow any script to obtain properties from or modify any content on a different application. Since scripts can obtain information and modify files by using your XML application, allowing a script access to content belonging to a different application can give an attacker the means to obtain unauthorized information, to compromise the application, or both.

Known web attacks can usually be stopped by filtering web site traffic for specific characteristics (*signatures*) that always appear for a specific attack and should never appear in legitimate traffic. This approach has the advantages of requiring relatively few resources and posing relatively little risk of false positives. It is therefore a valuable tool in fighting attacks on web sites and web services, and configuring basic signature protections that intercept most known web attacks is easy to do.

Unknown Web Attacks

The greatest threat against web sites and applications does not come from known attacks, but from unknown attacks. Most unknown attacks fall into one of two categories: newly-launched attacks for which security firms have not yet developed an effective defense (*zero-day* attacks), and carefully-targeted attacks on a specific web site or web service rather than many web sites or web services (*spear* attacks). These attacks, like known attacks, are usually intended to obtain sensitive private information, compromise the web site or web service and allow it to be used for further attacks, or both of those goals.

Zero-day attacks are a major threat to all users. These attacks are usually of the same types as known attacks; zero-day attacks often involve injected SQL, a cross-site script, a cross-site request forgery, or another type of attack similar to known attacks. In most cases, they target vulnerabilities that the developers of the targeted software, web site, or web service either are unaware of or have just learned about. Security firms have therefore usually not developed defenses against these attacks, and even if they have, users have usually not obtained and installed the patches or performed the workarounds necessary to protect against these attacks. The time between discovery of a zero-day attack and availability of a defense (the *vulnerability window*) is shrinking, but perpetrators can still count on hours or even days in which many web sites and web services lack any specific protection against the attack.

Spear attacks are a major threat, but to a more select group of users. A common type of spear attack, a spear phish, is usually targeted at customers of a specific bank or financial institution, or (less commonly) at employees of a specific company or organization. Unlike other phishes, which are often crudely written forgeries that a user with any familiarity with the actual communications of that bank or financial institution can recognize, spear phishes are letter perfect and extremely convincing. They can contain information specific to the individual that, at first look, no stranger should know or be able to obtain. The spear phisher is therefore able to convince his or her target to provide the requested information, which the phisher can then use to loot accounts, to process illegitimately obtained money from other sources, or to gain access to other, even more sensitive information.

Both of these types of attack have certain characteristics that can usually be detected, although not by using static patterns that look for specific characteristics, as do standard signatures. Detecting these types of attacks requires more sophisticated and more resource-intensive approaches, such as heuristic filtering and positive security model systems. Heuristic filtering looks, not for specific patterns, but for patterns of behaviors. Positive security model systems model the normal behavior of the web site or web service that they are protecting, and then block connections that do not fit within that model of normal use. URL based and web-form based security checks profile normal use of your web sites, and then control how users interact with your web sites, using both heuristics and positive security to block anomalous or unexpected traffic. Both heuristic and positive security, properly designed and deployed, can catch most attacks that signatures miss. However, they require considerably more resources than do signatures, and you must spend some time configuring them properly to avoid false positives. They are therefore usually used, not as the primary line of defense, but as backups to signatures or other less resource-intensive approaches.

By configuring these advanced protections in addition to signatures, you create a hybrid security model, which enables the application firewall to provide comprehensive protection against both known and unknown attacks.

How The Application Firewall Works

When you install the application firewall, you create an initial *security configuration*, which consists of a *policy*, a *profile*, and a *signatures object*. The policy is a rule that identifies the traffic to be filtered, and the profile identifies the patterns and types of behavior to allow or block when the traffic is filtered. The simplest patterns, which are called *signatures*, are not specified within the profile, but in a signatures object that is associated with the profile.

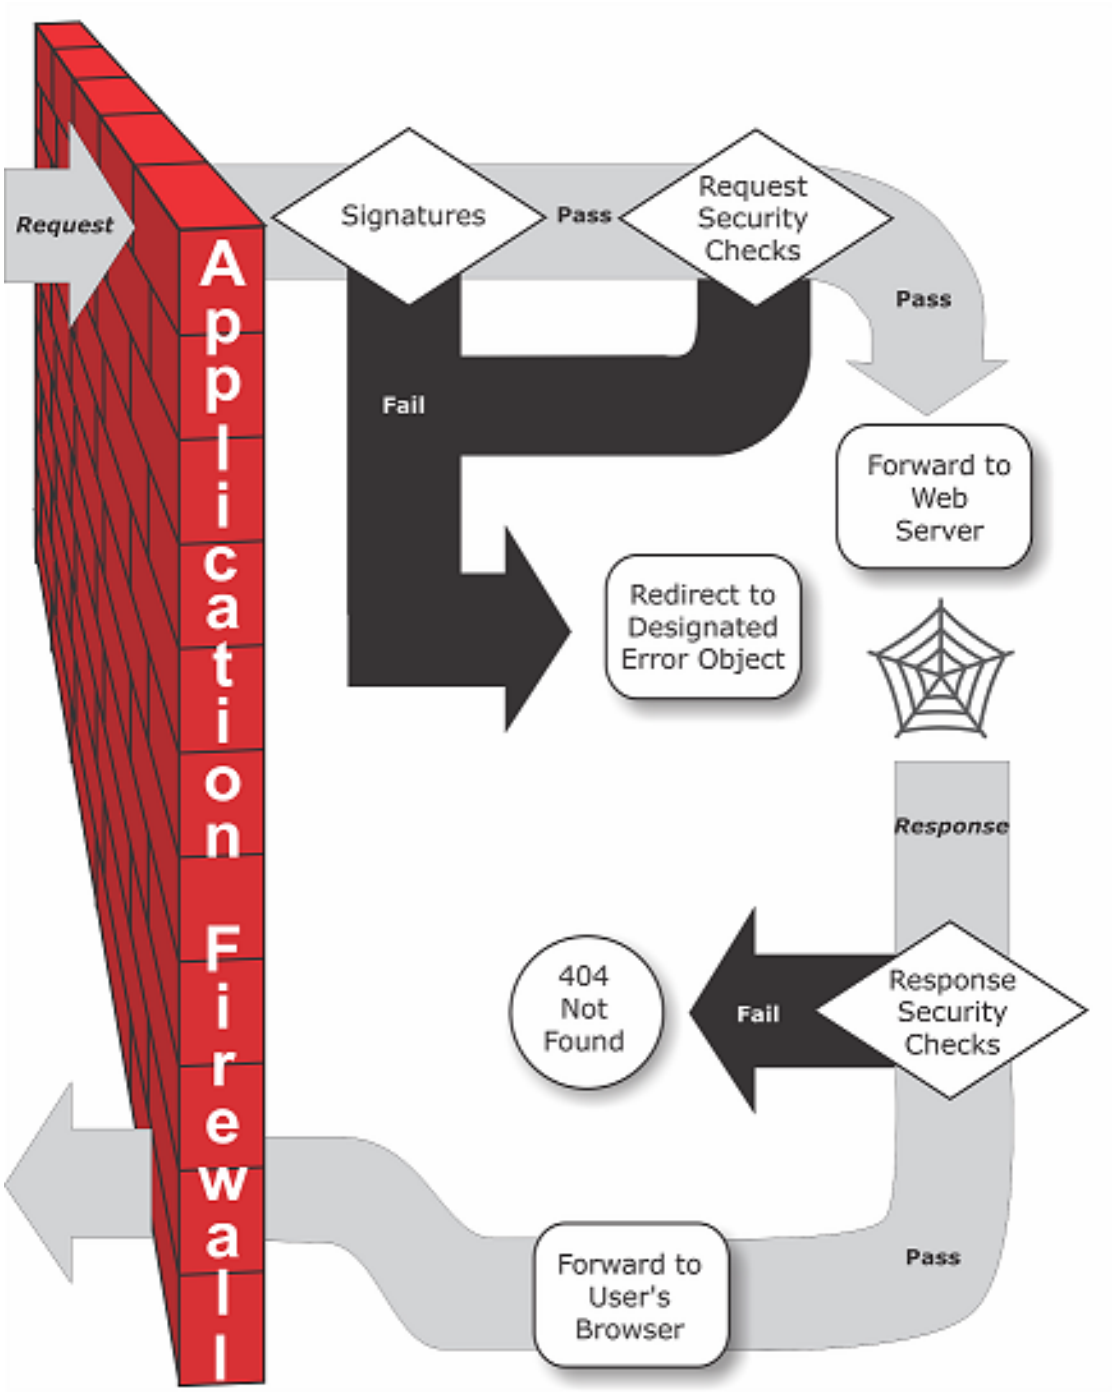
A signature is a string or pattern that matches a known type of attack. The application firewall contains over a thousand signatures in seven categories, each directed at attacks on specific types of web servers and web content. Citrix updates the list with new signatures as new threats are identified. During configuration, you specify the signature categories that are appropriate for the web servers and content that you need to protect. Signatures provide good basic protection with low processing overhead. If your applications have special vulnerabilities or you detect an attack against them for which no signature exists, you can add your own signatures.

The more advanced protections are called *security checks*. A security check is a more rigorous, algorithmic inspection of a request for specific patterns or types of behavior that might indicate an attack or constitute a threat to your protected web sites and web services. It can, for example, identify a request that attempts to perform a certain type of operation that might breach security, or a response that includes sensitive private information such as a social security number or credit card number. During configuration, you specify the security checks that are appropriate for the web servers and content that you need to protect. The security checks are restrictive. Many of them can block legitimate requests and responses if you do not add the appropriate exceptions (*relaxations*) when configuring them. Identifying the needed exceptions is not difficult if you use the adaptive learning feature, which observes normal use of your web site and creates recommended exceptions.

The application firewall can be installed as either a Layer 3 network device or a Layer 2 network bridge between your servers and your users, usually behind your company's router or firewall. It must be installed in a location where it can intercept traffic between the web servers that you want to protect and the hub or switch through which users access those web servers. You then configure the network to send requests to the application firewall instead of directly to your web servers, and responses to the application firewall instead of directly to your users. The application firewall filters that traffic before forwarding it to its final destination, using both its internal rule set and your additions and modifications. It blocks or renders harmless any activity that it detects as harmful, and then forwards the remaining traffic to the web server. The following figure provides an overview of the filtering process.

Note: The figure omits the application of a policy to incoming traffic. It illustrates a security configuration in which the policy is to process all requests. Also, in this configuration, a signatures object has been configured and associated with the profile, and security checks have been configured in the profile.

Figure 1. A Flowchart of Application Firewall Filtering



As the figure shows, when a user requests a URL on a protected web site, the application firewall first examines the request to ensure that it does not match a signature. If the request matches a signature, the application firewall either displays the *error object* (a web page that is located on the application firewall appliance and which you can configure by using the imports feature) or forwards the request to the designated error URL (the *error page*). Signatures do not require as many resources as do security checks, so detecting and stopping attacks that are detected by a signature before running any of the security checks reduces the load on the server.

If a request passes signature inspection, the application firewall applies the request security checks that have been enabled. The request security checks verify that the request is appropriate for your web site or web service and does not contain material that might

pose a threat. For example, security checks examine the request for signs indicating that it might be of an unexpected type, request unexpected content, or contain unexpected and possibly malicious web form data, SQL commands, or scripts. If the request fails a security check, the application firewall either sanitizes the request and then sends it back to the NetScaler appliance (or NetScaler virtual appliance), or displays the error object. If the request passes the security checks, it is sent back to the NetScaler appliance, which completes any other processing and forwards the request to the protected web server.

When the web site or web service sends a response to the user, the application firewall applies the response security checks that have been enabled. The response security checks examine the response for leaks of sensitive private information, signs of web site defacement, or other content that should not be present. If the response fails a security check, the application firewall either removes the content that should not be present or blocks the response. If the response passes the security checks, it is sent back to the NetScaler appliance, which forwards it to the user.

Application Firewall Features

The basic application firewall features are policies, profiles, and signatures, which provide a hybrid security model as described in "Known Web Attacks," "Unknown Web Attacks," and "How the Application Firewall Works." Of special note is the learning feature, which observes traffic to your protected applications and recommends appropriate configuration settings for certain security checks.

The imports feature manages files that you upload to the application firewall. These files are then used by the application firewall in various security checks, or when responding to a connection that matches a security check.

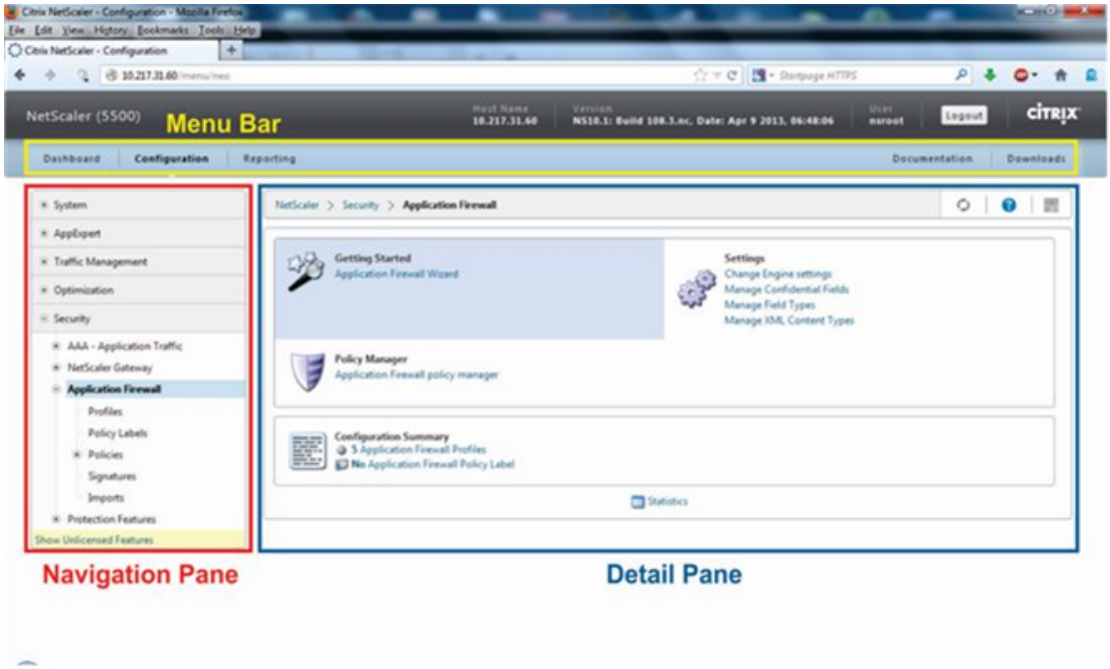
You can use the logs, statistics, and reports features to evaluate the performance of the application firewall and identify possible needs for additional protections.

The Application Firewall User Interfaces

All models in the Citrix NetScaler Application Delivery product line can be configured and managed from the Citrix NetScaler command line interface or the web-based configuration utility. However, the configuration utility provides a more complete interface. Not all application firewall configuration tasks can be performed at the command line. Also, the configuration utility provides access to a wizard that reduces the complexity of configuring the application firewall. Unlike most wizards, the application firewall wizard can serve as your primary interface to the application firewall.

The command line interface is a modified UNIX shell based on the FreeBSD `bash` shell. To configure the application firewall from the command line interface, you type commands at the prompt and press the Enter key, just as you do with any other Unix shell. For instructions for using the command line interface, see "Command Reference."

Figure 1 shows the navigation pane expanded to display the application firewall screens, and in the detail pane the main application firewall screen.



The configuration utility has two main areas on all screens. The panel on the left, called the *Navigation Pane*, contains a navigation tree, with which you navigate to the screens on which you configure the features that are installed on your appliance. The screens to which you navigate appear to the right of the Navigation Pane, in the *details pane*.

When you access the configuration utility, the details pane displays the System Overview screen, as shown in Figure 1. If, in the navigation pane, you click plus sign next to the application firewall folder, the Application Firewall node *expands* to include the main application firewall elements that you can configure. If you click the first element, Profiles, the details pane displays the configured profiles, if any profiles have been configured. At the bottom of the details pane, you can click Add to configure a new profile. Other buttons at the bottom of the details pane are grayed out until you select an existing profile.

Screens for the other elements work in the same way.

If, instead of expanding the application firewall node, you click the node itself, the details pane displays different options, one of which is the application firewall wizard. Citrix recommends that you use the wizard for initial configuration, and many users use it almost exclusively. It includes most of the functionality that is available elsewhere in the configuration utility.

For information and instructions on accessing the configuration utility, see "Citrix NetScaler Getting Started Guide."

Configuring the Application Firewall

You can configure the Citrix Application Firewall using any of the following methods:

- **Application Firewall Wizard.** A dialog box consisting of a series of screens that step you through the configuration process.
- **Citrix Web Interface AppExpert Template.** A NetScaler AppExpert template (a set of configuration settings) that are designed to provide appropriate protection for web sites. This AppExpert template contains appropriate Application Firewall configuration settings for protecting many web sites.
- **Citrix NetScaler Configuration Utility.** The NetScaler web-based configuration interface.
- **Citrix NetScaler Command Line Interface.** The NetScaler command line configuration interface.

Citrix recommends that you use the Application Firewall Wizard. Most users will find it the easiest method to configure the application firewall, and it is designed to prevent mistakes. If you have a new Citrix NetScaler appliance that you will use primarily to protect web sites, you may find the Web Interface AppExpert template a better option because it provides a good default configuration, not just for the Application Firewall, but for the entire appliance. Both the configuration utility and the command line interface are intended for experienced users, primarily to modify an existing configuration or use advanced options.

The Application Firewall Wizard

The application firewall wizard is a dialog box that consists of several screens that prompt you to configure each part of a simple configuration. The application firewall then creates the appropriate configuration elements from the information that you give it. This is the simplest and, for most purposes, the best way to configure the application firewall.

To use the wizard, connect to the configuration utility with the browser of your choice. When the connection is established, verify that the application firewall is enabled, and then run the application firewall wizard, which prompts you for configuration information. You do not have to provide all of the requested information the first time you use the wizard. Instead, you can accept default settings, perform a few relatively straightforward configuration tasks to enable important features, and then allow the application firewall to collect important information to help you complete the configuration.

For example, when the wizard prompts you to specify a rule for selecting the traffic to be processed, you can accept the default, which selects all traffic. When it presents you with a list of signatures, you can enable the appropriate categories of signatures and turn on the collection of statistics for those signatures. For this initial configuration, you can skip the advanced protections (*security checks*). The wizard automatically creates the appropriate policy, signatures object, and profile (collectively, the *security configuration*) , and binds the policy to global. The application firewall then begins filtering connections to your protected web sites, logging any connections that match one or more of the signatures that

you enabled, and collecting statistics about the connections that each signature matches. After the application firewall processes some traffic, you can run the wizard again and examine the logs and statistics to see if any of the signatures that you have enabled are matching legitimate traffic. After determining which signatures are identifying the traffic that you want to block, you can enable blocking for those signatures. If your web site or web service is not complex, does not use SQL, and does not have access to sensitive private information, this basic security configuration will probably provide adequate protection.

You may need additional protection if, for example, your web site is dynamic. Content that uses scripts may need protection against cross-site scripting attacks. Web content that uses SQL—such as shopping carts, many blogs, and most content management systems—may need protection against SQL injection attacks. Web sites and web services that collect sensitive private information such as social security numbers or credit card numbers may require protection against unintentional exposure of that information. Certain types of web-server or XML-server software may require protection from types of attacks tailored to that software. Another consideration is that specific elements of your web sites or web services may require different protection than do other elements. Examining the application firewall logs and statistics can help you identify the additional protections that you might need.

After deciding which advanced protections are needed for your web sites and web services, you can run the wizard again to configure those protections. Certain security checks require that you enter exceptions (*relaxations*) to prevent the check from blocking legitimate traffic. You can do so manually, but it is usually easier to enable the adaptive learning feature and allow it to recommend the necessary relaxations. You can use the wizard as many times as necessary to enhance your basic security configuration and/or create additional security configurations.

The wizard automates some tasks that you would have to perform manually if you did not use the wizard. It automatically creates a policy, a signatures object, and a profile, and assigns them the name that you provided when you were prompted for the name of your configuration. The wizard also adds your advanced-protection settings to the profile, binds the signatures object to the profile, associates the profile with the policy, and puts the policy into effect by binding it to Global.

A few tasks cannot be performed in the wizard. You cannot use the wizard to bind a policy to a bind point other than Global. If you want the profile to apply to only a specific part of your configuration, you must manually configure the binding. You cannot configure the engine settings or certain other global configuration options in the wizard. While you can configure any of the advanced protection settings in the wizard, if you want to modify a specific setting in a single security check, it may be easier to do so on the manual configuration screens in the configuration utility.

For more information on using the Application Firewall Wizard, see "The Application Firewall Wizard."

The Citrix Web Interface AppExpert Template

AppExpert Templates are a different and simpler approach to configuring and managing complex enterprise applications. The AppExpert display in the configuration utility consists of a table. Applications are listed in the left-most column, with the NetScaler features that are applicable to that application appearing each in its own column to the right. (In the AppExpert interface, those features that are associated with an application are called *application units*.) In the AppExpert interface, you configure the interesting traffic for each application, and turn on rules for compression, caching, rewrite, filtering, responder and the application firewall, instead of having to configure each feature individually.

The Web Interface AppExpert Template contains rules for the following application firewall signatures and security checks:

- "**Deny URL check.**" Detects connections to content that is known to pose a security risk, or to any other URLs that you designate.
- "**Buffer Overflow check.**" Detects attempts to cause a buffer overflow on a protected web server.
- "**Cookie Consistency check.**" Detects malicious modifications to cookies set by a protected web site.
- "**Form Field Consistency check.**" Detects modifications to the structure of a web form on a protected web site.
- "**CSRF Form Tagging check.**" Detects cross-site request forgery attacks.
- "**Field Formats check.**" Detects inappropriate information uploaded in web forms on a protected web site.
- "**HTML SQL Injection check.**" Detects attempts to inject unauthorized SQL code.
- "**HTML Cross-Site Scripting check.**" Detects cross-site scripting attacks.

For information on installing and using an AppExpert Template, see "AppExpert Applications and Templates."

The Citrix NetScaler Configuration Utility

The NetScaler configuration utility is a web-based interface that provides access to all configuration options for the application firewall feature, including advanced configuration and management options that are not available from any other configuration tool or interface. Specifically, many advanced Signatures options can be configured only in the configuration utility. You can review recommendations generated by the learning feature only in the configuration utility. You can bind policies to a bind point other than Global only in the configuration utility.

For a description of the configuration utility, see "The Application Firewall User Interfaces." For more information on using the configuration utility to configure the application firewall, see "Manual Configuration By Using the Configuration Utility."

For instructions on configuring the application firewall by using the configuration utility, see "Manual Configuration By Using the Configuration Utility." For information on the Citrix NetScaler Configuration Utility, see "The Application Firewall User Interfaces."

The Citrix NetScaler Command Line Interface

The Citrix NetScaler command line interface is a modified UNIX shell based on the FreeBSD `bash` shell. To configure the Application Firewall from the command line interface, you type commands at the prompt and press the Enter key, just as you do with any other Unix shell. You can configure most parameters and options for the application firewall by using the NetScaler command line. Exceptions are the signatures feature, many of whose options can be configured only by using the configuration utility or the Application Firewall wizard, and the learning feature, whose recommendations can only be reviewed in the configuration utility.

For instructions on configuring the application firewall by using the NetScaler command line, see "Manual Configuration By Using the Command Line Interface."

Enabling the Application Firewall

Before you can create an application firewall security configuration, you must make sure that the application firewall feature is enabled.

- If you are configuring a dedicated Citrix Application Firewall appliance, the feature is already enabled. You do not have to perform either of the procedures described here.
- If you have a Citrix NetScaler appliance but have not previously configured the application firewall, you need to enable the application firewall feature before you configure it.
- If you are upgrading a NetScaler appliance from a previous version of the NetScaler operating system to the current version, you may need to enable the application firewall feature before you configure it.
- If you are installing a new application firewall appliance or NetScaler appliance, you do not need to perform this procedure.

Note: If you are upgrading a NetScaler appliance or NetScaler virtual appliance from a previous version, you may need to update the licenses on your appliance before you can enable this feature.

You can enable the application firewall by using the NetScaler command line or the configuration utility.

To enable the application firewall by using the command line interface

At the command prompt, type:

enable ns feature **AppFW**

To enable the application firewall by using the configuration utility

1. In the navigation pane, expand System and click Settings.
2. In the Settings pane, under Modes & Features, click basic features.
3. In the Configure Basic Features dialog box, select the Application Firewall check box.
4. Click OK.

The Application Firewall Wizard

Unlike most wizards, the Application Firewall wizard is designed not just to simplify the initial configuration process, but also to modify previously created configurations and to maintain your Application Firewall setup. A typical user runs the wizard multiple times, skipping some of the screens each time.

Opening the Wizard

To run the Application Firewall wizard, first open the configuration utility. Next, in the navigation pane, expand Application Firewall, and then in the details pane click Application Firewall Wizard. (For more information about the configuration utility, see "The Application Firewall User Interfaces.") Then:

1. In the navigation pane, click Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard. The first screen of the wizard appears.
3. To advance to the next screen, click Next.

The Wizard Screens

The Application Firewall wizard displays the following screens, in the following order:

1. **Introduction screen.** Provides an introduction to the Application Firewall wizard. There is nothing that you can configure on this screen.
2. **Specify Name screen.** On this screen, when creating a new security configuration, you specify the name that the wizard is to assign to the configuration. The name can begin with a letter, number, or the underscore symbol, and can consist of from 1 to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols. Choose a name that makes it easy for others to tell what content your new security configuration protects.

   Note: Because the wizard uses this name for both the policy and the profile, it is limited to 31 characters. Manually created policies can have names up to 127 characters in length.

   When creating an existing configuration, you select Modify Existing Configuration and then, in the Name drop-down list, select the name of the existing configuration that you want to modify.

   Note: Only policies that are bound to global or to a bind point appear in this list; you cannot modify an unbound policy by using the Application Firewall wizard. You must either manually bind it to Global or a bind point, or modify it manually. (For manual modification, in the configuration utility's Application Firewall --> Policies --> Firewall pane, select the policy and click Open).

You also select a profile type on this screen. The profile type determines the types of advanced protection (*security checks*) that can be configured. Because certain kinds of content are not vulnerable to certain types of security threats, restricting the list of available checks saves time during configuration. The types of Application Firewall profiles are:

- **Web Application (HTML).** Any HTML-based Web site that does not use XML or Web 2.0 technologies.
- **XML Application (XML, SOAP).** Any XML-based Web service.
- **Web 2.0 Application (HTML, XML, REST).** Any Web 2.0 site that combines HTML and XML-based content, such as an ATOM-based site, a blog, an RSS feed, or a wiki.

Note: If you are unsure which type of content is used on your Web site, you can choose Web 2.0 Application to ensure that you protect all types of Web application content.

3. **Specify Rule screen.** On this screen, you specify the policy rule (*expression*) that defines the traffic to be examined by this security configuration. If you are creating an initial configuration to protect your Web sites and Web services, you can simply accept the default value, `true`, which selects all web traffic .

   If you want this security configuration to examine, not all HTTP traffic that is routed through the appliance, but specific traffic, you can write a policy rule specifying the traffic that you want it to examine. Rules are written in Citrix NetScaler expressions language, which is a fully functional object-oriented programming language.

   - For a simple description of using the NetScaler expressions syntax to create Application Firewall rules, and a list of useful rules, see "Firewall Policies."
   - For a detailed explanation of how to create policy rules in NetScaler expressions syntax, see "Policies and Expressions."

   Note: In addition to the default expressions syntax, for backward compatibility the NetScaler operating system supports the NetScaler classic expressions syntax on NetScaler Classic and nCore appliances and virtual appliances. Classic expressions are not supported on NetScaler Cluster appliances and virtual appliances. Current users who want to migrate their existing configurations to the NetScaler cluster must migrate any policies that contain classic expressions to the default expressions syntax.

4. **Select Signature Protections screen.** On this screen, you select the categories of signatures that you want to use to protect your web sites and web services. The default categories are:

   - **CGI.** Protection against attacks on web sites that use CGI scripts in any language, including PERL scripts, Unix shell scripts, and Python scripts.
   - **Cold Fusion.** Protection against attacks on web sites that use the Adobe Systems® ColdFusion® Web development platform.
   - **FrontPage.** Protection against attacks on web sites that use the Microsoft® FrontPage® Web development platform.

- **PHP.** Protection against attacks on web sites that use the PHP open-source Web development scripting language.
- **Client side.** Protection against attacks on client-side tools used to access your protected web sites, such as Microsoft Internet Explorer, Mozilla Firefox, the Opera browser, and the Adobe Acrobat Reader.
- **Microsoft IIS.** Protection against attacks on Web sites that run the Microsoft Internet Information Server (IIS).
- **Miscellaneous.** Protection against attacks on other server-side tools, such as Web servers and database servers.

If you are creating a new security configuration, the signature categories that you select are enabled, and by default they are recorded in a new signatures object. The new signatures object is assigned the same name that you entered on the Specify name screen as the name of the security configuration.

If you have previously configured signatures objects and want to use one of them as the signatures object associated with the security configuration that you are creating, click Select Existing Signature and select a signatures object from the Signatures list.

If you are modifying an existing security configuration, you can click Select Existing Signature and assign a different signatures object to the security configuration.

5. **Select Signature Actions screen.** On this screen, you select the actions associated with the signature categories that you selected on the Select signature protections screen. If you are creating an initial configuration, you might want to accept the defaults, which enable the Log and Stats actions but not the Block action. You can decide later, after reviewing the collected logs and statistics, which signatures you should use to block traffic, and then enable the Block action for those signatures. Signatures are designed to catch specific known attacks on your web sites, and therefore they have extremely low false positive rates. However, with any new configuration, you should probably observe how the settings you chose are working before you use them to block traffic.

   If you select More for one of the signature categories, the Configure Actions for Signatures dialog box appears. Its contents are the same as the contents of the Modify Signatures Object dialog box, as described in "To Configure a Signatures Object."

   If the signatures object has already logged connections, you can click Logs to display the Syslog Viewer with the logs, as described in "Logs, Statistics, and Reports." If a signature is blocking legitimate access to your protected web site or web service, you can create and implement a relaxation for that signature by selecting a log that shows the unwanted blocking, and then clicking Deploy.

6. **Select Advanced Protections screen.** On this screen, you choose the advanced protections (also called *security checks* or simply *checks*) that you want to use to protect your web sites and web services. The checks are divided into categories. Which categories are available (and which checks are available within a category) depends on the profile type that you chose on the Specify Name screen. All checks are available for Web 2.0 Application profiles. If you chose that profile type, the Select advanced protections screen displays the following categories of security checks:

   - Top--level protections (Some checks appear at the top level, not in any category.)
   - Data Leak Prevention Protections

- Advanced Form Protections
- URL Protections
- XML Protections

To display the individual checks in a category, click the icon to the left of the category. To apply a security check to your filtered data, select the check box next to the name of the security check. For descriptions of the security checks see "Advanced Protections" and its subtopics.

7. **Select Advanced Actions screen.** On this screen, you configure the actions for the advanced protections that you have enabled.

   Note: If no advanced protections are enabled, the Wizard skips the Advanced Actions screen and goes directly to the Summary screen.

   The actions that you can configure are:

   - **Block.** Block connections that match the signature. Disabled by default.
   - **Log.** Log connections that match the signature for later analysis. Enabled by default.
   - **Stats.** Maintain statistics, for each signature, that show how many connections it matched and provide certain other information about the types of connections that were blocked. Disabled by default.
   - **Learn.** Observe traffic to this Web site or Web service, and use connections that repeatedly violate this check to generate recommended exceptions to the check, or new rules for the check. Available only for some checks.

   To enable or disable an action for a check, in the list, select or clear the check box for that action to the right of that check.

   To configure other parameters for those checks that have them, in the list, click the blue chevron to the far right of that check. In the dialog box that appears, configure the parameters. These vary from check to check. You can also select a check and, at the bottom of the dialog box, click Open to display a dialog box for modifying any of the options for that check. These dialog boxes also vary from check to check. Most of them include a Checks tab and a General tab. If the check supports relaxations, the Checks tab includes an Add button, which opens yet another dialog box, in which you can specify a relaxation for the check. A relaxation is a rule for exempting specified traffic from the check.

   For information about the settings available for a check, see the detailed description of that check.

   To review the recommendations generated by the learning engine for a specific check, select that check and then click Learned Violations to open the Manage Learned Rules dialog box for that check. For more information on how learning works and how to configure exceptions (relaxations) or deploy learned rules for a check, see "Manual Configuration By Using the Configuration Utility" under To configure and use the learning feature

   To view all logs for a specific check, select that check, and then click Logs to display the Syslog Viewer, as described in "Logs, Statistics, and Reports." If a security check is

blocking legitimate access to your protected web site or web service, you can create and implement a relaxation for that security check by selecting a log that shows the unwanted blocking, and then clicking Deploy.

8. **Summary screen.** On this screen, you review your configuration choices to verify that they are what you want. If you want to make changes, you click Back until you have returned to the appropriate screen, and make your changes. If the configuration is as you want it, you click Finish to save it , and then click Exit to close the Application Firewall wizard.

Following are four procedures that show how to perform specific types of configuration by using the Application Firewall wizard.

To configure the Application Firewall: Initial Configuration

1. In the navigation pane, click Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard.
3. On the Application Firewall wizard, Introduction screen, in the lower right-hand corner, click Next.
4. On the Specify Name screen, in the Name text box, type a name for your new security configuration, and from the Type drop-down list, select the type of security configuration. Then, click Next.
5. On the Specify Rule screen, click Next again.

   Note: The default rule, `true`, protects all Web traffic that is sent via your NetScaler appliance or virtual appliances. You can create specific security configurations to protect specific parts of your Web sites or Web applications later.
6. On the Select Signature Protections screen, select check boxes to specify the groups of signatures that are appropriate for protecting the content on your protected web sites, and then click Next.

   For more information about signatures, see "Signatures."
7. On the Select Signature Actions screen, select or clear the associated check boxes to choose the signature actions that you want for each signature category that you selected in the previous step, and then click Next.
8. On the Select Advanced Protections screen, click Next again.

   You typically do not need to configure the security checks during initial configuration.
9. On the Summary screen, review your choices to verify that they are what you want. Then, click Finish, or click Back to return to a previous screen and make changes. When you are finished, click Exit to close the Application Firewall wizard.

To configure the Application Firewall: Enabling Blocking for Signatures

1. In the navigation pane, click Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard.
3. On the Application Firewall wizard, Introduction screen, in the lower right-hand corner, click Next.
4. On the Specify Name screen, select Modify Existing Configuration and, in the Name drop-down list, choose the security configuration that you created during simple configuration, and then click Next.
5. In the Specify Rule screen, click Next again.
6. In the Select Signature Protections screen, click Next again.
7. In the Select Signature Actions screen, enable blocking for your chosen signatures by selecting the Block check box to the left of each of those signature.

   For more information about which signatures to consider for blocking and how to determine when you can safely enable blocking for a signature, see "Signatures."
8. In the Select advanced protections screen, click Next.
9. On the Summary screen, review your choices to verify that they appear correct. Then, click Finish, or click Back to return to the Select Signature Actions screen and make changes. When you are finished, click Exit to close the Application Firewall wizard.

To configure the Application Firewall: Enabling and Configuring advanced protection

1. In the navigation pane, click Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard.
3. On the Application Firewall wizard, Introduction screen, in the lower right-hand corner, click Next.
4. On the Specify Name screen, select Modify Existing Configuration and, in the Name drop-down list, choose the security configuration that you created during simple configuration. Then, click Next.
5. On the Specify Rule screen, click Next again.
6. On the Select Signature Protections screen, click Next.
7. On the Select Signature Actions screen, click Next again.
8. On the Select advanced protections screen, select the check box beside each security check that you want to enable, and then click Next.

   For information about the security checks, see "Advanced Protections" and its subtopics.
9. On the Select Deep Actions screen, select check boxes to specify the actions that you want the Application Firewall to perform for each security check, and then click Next.

   For general information about the actions, see "Advanced Protections" and its subtopics. For information about the learning feature, which is available for some security checks, see "To configure and use the Learning feature."
10. On the Summary screen, review your choices to verify that they appear correct. Then, click Finish, or click Back to return to the Select Signature Actions screen and make changes. When you are finished, click Exit to close the Application Firewall wizard.

To configure the Application Firewall: Creating A Policy

The following procedure describes how to use the Application Firewall wizard to create a specialized security configuration to protect only specific content. In this case, you create a new security configuration instead of modifying the initial configuration. This type of security configuration requires a custom rule, so that the policy applies the configuration to only the selected Web traffic.

1. In the navigation pane, click Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard.
3. On the Application Firewall wizard, Introduction screen, in the lower right-hand corner, click Next.

4. On the Specify Name screen, type a name for your new security configuration in the Name text box, select the type of security configuration from the Type drop-down list, and then click Next.

5. On the Specify Rule screen, enter a rule that matches only that content that you want this Web application to protect, and then click Next.

   For a description of policies and policy rules, see "Policies."

6. On the Select Signature Protections screen, choose the appropriate groups of signatures to protect the content on your protected web sites by selecting the check box beside each group of signatures, and then click Next.

   For detailed information about signatures, see "Signatures."

7. On the Select Signature Actions screen, select or clear the associated check boxes to choose the signature actions that you want for each signature category that you selected in the previous step, and then click Next. For a detailed description of actions, see "Signatures."

8. In the Select Advanced Protections screen, select the check box beside each security check that you want to enable, and then click Next.

   For detailed information about the security checks, see "Advanced Protections" and its subtopics.

9. In the Select Advanced Actions screen, select check boxes to specify the actions that you want the Application Firewall to perform for each security check. Then, click Next.

   For information about each security check to help you determine which actions to enable, see the Advanced Protections section.

10. On the Summary screen, review your choices to verify that they appear correct. Then, click Finish, or click Back to return to the Select Signature Actions screen and make changes. When you are finished, click Exit to close the wizard.

Manual Configuration

If you want to bind a profile to a bind point other than Global, you must manually configure the binding. Also, certain security checks require that you either manually enter the necessary exceptions or enable the learning feature to generate the exceptions that your Web sites and Web services need. Some of these tasks cannot be performed by using the application firewall wizard.

If you are familiar with how the application firewall works and prefer manual configuration, you can manually configure a signatures object and a profile, associate the signatures object with the profile, create a policy with a rule that matches the web traffic that you want to configure, and associate the policy with the profile. You then bind the policy to Global, or to a bind point, to put it into effect, and you have created a complete security configuration.

For manual configuration, you can use the configuration utility (a graphical interface) or the command line. Citrix recommends that you use the configuration utility. Not all configuration tasks can be performed at the command line. Certain tasks, such as enabling signatures and reviewing learned data, must be done in the configuration utility. Most other tasks are easier to perform in the configuration utility.

Manual Configuration By Using the Configuration Utility

If you need to configure the Application Firewall feature manually, Citrix recommends that you use the configuration utility. For a description of the configuration utility, see "The Application Firewall User Interfaces."

To create and configure a signatures object

Before you can configure the signatures, you must create a new signatures object from the appropriate default signatures object template. Assign the copy a new name, and then configure the copy. You cannot configure or modify the default signatures objects directly. The following procedure provides basic instructions for configuring a signatures object. For more detailed instructions, see "Manually Configuring the Signatures Feature." If you need to create your own, user defined signatures, see "The Signatures Editor."

1. In the navigation pane, expand Application Firewall, and then select Signatures.
2. In the details pane, select the signatures object that you want to use as a template, and then click Add.

   Your choices are:

   - *** Default Signatures.** Contains the signatures rules, the SQL injection rules, and the cross-site scripting rules.
   - *** XPath Injection.** Contains all of the items in the * Default Signatures, and in addition contains the XPath injection rules.
3. In the Add Signatures Object dialog box, type a name for your new signatures object, click OK, and then click Close. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), and underscore (_) symbols.
4. Select the signatures object that you created, and then click Open.
5. In the Modify Signatures Object dialog box, set the Display Filter Criteria options at the left to display the filter items that you want to configure.

   As you modify these options, the results that you specify are displayed in the Filtered Results window at the right. For more information about the categories of signatures, see "Signatures."
6. In the Filtered Results area, configure the settings for a signature by selecting and clearing the appropriate check boxes.
7. When finished, finished, click Close.

To create an application firewall profile by using the configuration utility

Creating an application firewall profile requires that you specify only a few configuration details.

1. In the navigation pane, expand Application Firewall, and then select Profiles.
2. In the details pane, click Add.
3. In the Create Application Firewall Profile dialog box, type a name for your profile.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.
4. Choose the profile type from the drop-down list.

   The profile types are HTML (for HTML-based Web sites), XML (for XML-based Web services) and Web 2.0 (for blogs, RSS feeds, wikis, and other sites that contain both HTML and XML).

   Note: If you are unsure what types of content your profile will protect, you can choose Web 2.0 to make the full range of Application Firewall security checks available to protect your Web site.
5. If you plan to use the learning feature or to enable and configure a large number of advanced protections, select Advanced. Otherwise, select Basic.

   You probably should use the learning feature if you plan to configure either of the SQL injection checks, either of the cross-site scripting checks, any check that provides protection against Web form attacks, or the cookie consistency check. Unless you include the proper exceptions for your protected Web sites when configuring these checks, they can block legitimate traffic. Anticipating all of the necessary exceptions without creating any that are too broad is difficult. The learning feature makes this task much easier.
6. Click Create, and then click Close.

To configure an application firewall profile by using the configuration utility

1. Navigate to Application Firewall > Profiles.
2. In the details pane, select the profile that you want to configure, and then click Open.
3. In the Configure Application Firewall Profile dialog box, on the Security Checks tab, configure the security checks.
   - To enable or disable an action for a check, in the list, select or clear the check box for that action.
   - To configure other parameters for those checks that have them, in the list, click the blue chevron to the far right of that check. In the dialog box that appears, configure the parameters. These vary from check to check.

     You can also select a check and, at the bottom of the dialog box, click Open to display the Configure Relaxation dialog box or Configure Rule dialog box for that check. These dialog boxes also vary from check to check. Most of them include a Checks tab and a General tab. If the check supports relaxations or user-defined rules, the Checks tab includes an Add button, which opens yet another dialog box, in which you can specify a relaxation or rule for the check. (A relaxation is a rule for exempting specified traffic from the check.) If relaxations have already been configured, you can select one and click Open to modify it.

     For more information about the Configure Relaxation or Configure Rule dialog boxes, see "Configuring an Application Firewall Rule or Relaxation."
   - To review learned exceptions or rules for a check, select the check, and then click Learned Violations. In the Manage Learned Rules dialog box, select each learned exception or rule in turn.
     - To edit the exception or rule, and then add it to the list, click Edit & Deploy.
     - To accept the exception or rule without modification, click Deploy.
     - To remove the exception or rule from the list, click Skip.
   - To refresh the list of exceptions or rules to be reviewed, click Refresh.
   - To open the Learning Visualizer and use it to review learned rules, click Visualizer.
   - To review the log entries for connections that matched a check, select the check, and then click Logs. You can use this information to determine which checks are matching attacks, so that you can enable blocking for those checks. You can also use this information to determine which checks are matching legitimate traffic, so that you can configure an appropriate exemption to allow those legitimate connections. For more information about the logs, see "Logs, Statistics, and Reports."
   - To completely disable a check, in the list, clear all of the check boxes to the right of that check.
4. On the Settings tab, configure the profile settings.

- To associate the profile with the set of signatures that you previously created and configured, under Common Settings, choose that set of signatures in the Signatures drop-down list.

  Note: You may need to use the scroll bar on the right of the dialog box to scroll down to display the Common Settings section.

- To configure an HTML or XML Error Object, select the object from the appropriate drop-down list.

  Note: You must first upload the error object that you want to use in the Imports pane. For more information about importing error objects, see "Imports."

- To configure the default XML Content Type, type the content type string directly into the Default Request and Default Response text boxes, or click Manage Allowed Content Types to manage the list of allowed content types. ">>More...."

5. If you want to use the learning feature, click Learning, and configure the learning settings for the profile, as described in "Configuring and Using the Learning Feature".

6. Click OK to save your changes and return to the Profiles pane.

Configuring an Application Firewall Rule or Relaxation

You configure two different types of information in this dialog box, depending upon which security check you are configuring. In the majority of cases, you configure an exception (or *relaxation*) to the security check. If you are configuring the Deny URL check or the Field Formats check, you configure an addition (or *rule*). The process for either of these is the same.

To configure a relaxation or rule by using the configuration utility

1. Navigate to Application Firewall > Profiles.

2. In the Profiles pane, select the profile you want to configure, and then click Open.

3. In the Configure Application Firewall Profile dialog box, click the Security Checks tab. The Security Checks tab contains the list of application firewall security checks.

4. In the Security Checks window, click the check that you want to configure, and then click Open. The Modify Check dialog box for the check that you chose is displayed, with the Checks tab selected. The Checks tab contains a list of existing relaxations or rules for this check. The list might be empty if you have not either manually added any relaxations or approved any relaxations that were recommended by the learning engine. Beneath the list is a row of buttons that allow you to add, modify, delete, enable, or disable the relaxations on the list.

5. To add or modify a relaxation or a rule, do one of the following:

   - To add a new relaxation, click Add.

   - To modify an existing relaxation, select the relaxation that you want to modify, and then click Open.

   The Add Check Relaxation or Modify Check Relaxation dialog box for the selected check is displayed. Except for the title, these dialog boxes are identical.

6. Fill in the dialog box as described below. The dialog boxes for each check are different; the list below covers all elements that might appear in any dialog box.

   - **Enabled check box**—Select to place this relaxation or rule in active use; clear to deactivate it.

   - **Attachment Content Type**—The Content-Type attribute of an XML attachment. In the text area, enter a regular expression that matches the Content-Type attribute of the XML attachments to allow.

   - **Action URL**—In the text area, enter a PCRE-format regular expression that defines the URL to which data entered into the web form is delivered.

   - **Cookie**—In the text area, enter a PCRE-format regular expression that defines the cookie.

   - **Field Name**—A web form field name element may be labeled Field Name, Form Field, or another similar name. In the text area, enter a PCRE-format regular expression that defines the name of the form field.

   - **Form Origin URL**—In the text area, enter a PCRE-format regular expression that defines the URL that hosts the web form.

   - **Form Action URL**—In the text area, enter a PCRE-format regular expression that defines the URL to which data entered into the web form is delivered.

   - **Name**—An XML element or attribute name. In the text area, enter a PCRE-format regular expression that defines the name of the element or attribute.

- **URL**—A URL element may be labeled Action URL, Deny URL, Form Action URL, Form Origin URL, Start URL, or simply URL. In the text area, enter a PCRE-format regular expression that defines the URL.
- **Format**—The format section contains multiple settings that include list boxes and text boxes. Any of the following can appear:
  - **Type**—Select a field type in the Type drop-down list. To add a new field type definition, click Manage—
  - **Minimum Length**—Type a positive integer that represents the minimum length in characters if you want to force users to fill in this field. Default: 0 (Allows field to be left blank.)
  - **Maximum length**—To limit the length of data in this field, type a positive integer that represents the maximum length in characters. Default: 65535
- **Location**—Choose the element of the request that your relaxation will apply to from the drop-down list. For HTML security checks, the choices are:
  - `FORMFIELD`—Form fields in web forms.
  - `HEADER`—Request headers.
  - `COOKIE`—Set-Cookie headers.

  For XML security checks, the choices are:
  - `ELEMENT`—XML element.
  - `ATTRIBUE`—XML attribute.
- **Maximum Attachment Size**—The maximum size in bytes allowed for an XML attachment.
- **Comments**—In the text area, type a comment. Optional.

Note: For any element that requires a regular expression, you can type the regular expression, use the Regex Tokens menu to insert regular expression elements and symbols directly into the text box, or click Regex Editor to open the Add Regular Expression dialog box, and use it to construct the expression.

7. To remove a relaxation or rule, select it, and then click Remove.
8. To enable a relaxation or rule, select it, and then click Enable.
9. To disable a relaxation or rule, select it, and then click Disable.
10. To configure the settings and relationships of all existing relaxations in an integrated interactive graphic display, click Visualizer, and use the display tools.

    Note: The Visualizer button does not appear on all check relaxation dialog boxes.
11. To review learned rules for this check, click Learning and perform the steps in "To configure and use the Learning feature."
12. Click OK.

To configure the Learning feature by using the configuration utility

1. In the navigation pane, expand Application Firewall, and then select Profiles.
2. In the Profiles pane, select the profile, and then click Open.
3. Click the Learning tab. At the top of the Learning tab is list of the security checks that are available in the current profile and that support the learning feature.
4. To configure the learning thresholds, select a security check, and then type the appropriate values in the following text boxes:
   - **Minimum number threshold.** Depending on which security check's learning settings you are configuring, the minimum number threshold might refer to the minimum number of total user sessions that must be observed, the minimum number of requests that must be observed, or the minimum number of times a specific form field must be observed, before a learned relaxation is generated. Default: 1
   - **Percentage of times threshold.** Depending on which security check's learning settings you are configuring, the percentage of times threshold might refer to the percentage of total observed user sessions that violated the security check, the percentage of requests, or the percentage of times a form field matched a particular field type, before a learned relaxation is generated. Default: 0
5. To remove all learned data and reset the learning feature, so that it must start its observations again from the beginning, click Remove All Learned Data.

   Note: This button removes only learned recommendations that have not been reviewed and either approved or skipped. It does not remove learned relaxations that have been accepted and deployed.
6. Click Close to return to the Configure Application Firewall Profile dialog box.
7. Click Close to close the Configure Application Firewall Profile dialog box, and return to the Application Firewall Profile screen.

To create and configure a policy by using the configuration utility

1. Navigate to Application Firewall > Policies.
2. In the details pane, do one of the following:
   - To create a new firewall policy, click Add. The Create Application Firewall Policy is displayed.
   - To edit an existing firewall policy, select the policy, and then click Open. The Configure Application Firewall Policy is displayed.
3. If you are creating a new firewall policy, in the Create Application Firewall Policy dialog box, Policy Name text box, type a name for your new policy.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 128 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.

   If you are configuring an existing firewall policy, this field is read-only. You cannot modify it.
4. Select the profile that you want to associate with this policy from the Profile drop-down list. You can create a new profile to associate with your policy by clicking New, and you can modify an existing profile by clicking Modify.
5. In the Expression text area, create a rule for your policy.
   - You can type a rule directly into the text area.
   - You can click Prefix to select the first term for your rule, and follow the prompts. See "To Create an Application Firewall Rule (Expression)" for a complete description of this process.
   - You can click Add to open the Add Expression dialog box, and use it to construct the rule. See "The Add Expression Dialog Box" for a complete description of this process.
6. Click Create or OK, and then click Close.

To create or configure an Application Firewall rule (expression)

The policy rule, also called the *expression*, defines the web traffic that the application firewall filters by using the profile associated with the policy. Like other NetScaler policy rules (or *expressions*), application firewall rules use NetScaler expressions syntax. This syntax is powerful, flexible, and extensible. It is too complex to describe completely in this set of instructions. You can use the following procedure to create a simple firewall policy rule, or you can read it as an overview of the policy creation process.

1. If you have not already done so, navigate to the appropriate location in the Application Firewall wizard or the NetScaler configuration utility to create your policy rule:

- If you are configuring a policy in the Application Firewall wizard, in the navigation pane, click Application Firewall, then in the details pane click Application Firewall Wizard, and then navigate to the Specify Rule screen.

- If you are configuring a policy manually, in the navigation pane, expand Application Firewall, then Policies, and then Firewall. In the details pane, to create a new policy, click Add. To modify an existing policy, select the policy, and then click Open.

2. On the Specify Rule screen, the Create Application Firewall Profile dialog box, or the Configure Application Firewall Profile dialog box, click Prefix, and then choose the prefix for your expression from the drop-down list. Your choices are:

   - **HTTP.** The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.

   - **SYS.** The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

   - **CLIENT.** The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

   - **SERVER.** The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

   After you choose a prefix, the application firewall displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom.

3. Choose your next term.

   If you chose HTTP as your prefix, your only choice is REQ, which specifies the Request/Response pair. (The application firewall operates on the request and response as a unit instead of on each separately.) If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

   When you have decided which term you want, double-click it to insert it into the Expression window.

4. Type a period after the term you just chose. You are then prompted to choose your next term, as described in the previous step. When a term requires that you type a value, fill in the appropriate value. For example, if you choose `HTTP.REQ.HEADER("")`, type the header name between the quotation marks.

5. Continue choosing terms from the prompts and filling in any values that are needed, until your expression is finished.

   Following are some examples of expressions for specific purposes.

   - **Specific web host.** To match traffic from a particular web host:

     HTTP.REQ.HEADER("Host").EQ("shopping.example.com")

     For `shopping.example.com`, substitute the name of the web host that you want to match.

- **Specific web folder or directory.** To match traffic from a particular folder or directory on a Web host:

  HTTP.REQ.URL.STARTSWITH("https//www.example.com/folder")

  For `www.example.com`, substitute the name of the web host. For `folder`, substitute the folder or path to the content that you want to match. For example, if your shopping cart is in a folder called `/solutions/orders`, you substitute that string for folder.

- **Specific type of content: GIF images.** To match GIF format images:

  HTTP.REQ.URL.ENDSWITH(".gif")

  To match other format images, substitute another string in place of `.gif`.

- **Specific type of content: scripts.** To match all CGI scripts located in the `CGI-BIN` directory:

  HTTP.REQ.URL.STARTSWITH("https//www.example.com/CGI-BIN")

  To match all JavaScripts with `.js` extensions:

  HTTP.REQ.URL.ENDSWITH(".js")

  For more information about creating policy expressions, see "Policies and Expressions."

Note: If you use the command line to configure a policy, remember to escape any double quotation marks within NetScaler expressions. For example, the following expression is correct if entered in the configuration utility:

HTTP.REQ.HEADER("Host").EQ("shopping.example.com")

If entered at the command line, however, you must type this instead:

HTTP.REQ.HEADER(\"Host\").EQ(\"shopping.example.com\")

To add a firewall rule (expression) by using the Add Expression dialog box

The Add Expression dialog box (also referred to as the *Expression Editor*) helps users who are not familiar with the NetScaler expressions language to construct a policy that matches the traffic that they want to filter.

1. If you have not already done so, navigate to the appropriate location in the Application Firewall wizard or the NetScaler configuration utility:

- If you are configuring a policy in the Application Firewall wizard, in the navigation pane, click Application Firewall, then in the details pane click Application Firewall Wizard, and then navigate to the Specify Rule screen.

- If you are configuring a policy manually, in the navigation pane, expand Application Firewall, then Policies, and then Firewall. In the details pane, to create a new policy, click Add. To modify an existing policy, select the policy, and then click Open.

2. On the Specify Rule screen, in the Create Application Firewall Profile dialog box, or in the Configure Application Firewall Profile dialog box, click Add.

3. In the Add Expression dialog box, in the Construct Expression area, in the first list box, choose one of the following prefixes:

   - **HTTP.** The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol. The default choice.

   - **SYS.** The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

   - **CLIENT.** The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

   - **SERVER.** The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

4. In the second list box, choose your next term. The available terms differ depending on the choice you made in the previous step, because the dialog box automatically adjusts the list to contain only those terms that are valid for the context. For example, if you selected HTTP in the previous list box, the only choice is REQ, for requests. Because the application firewall treats requests and associated responses as a single unit and filters both, you do not need to specific responses separately. After you choose your second term, a third list box appears to the right of the second. The Help window displays a description of the second term, and the Preview Expression window displays your expression.

5. In the third list box, choose the next term. A new list box appears to the right, and the Help window changes to display a description of the new term. The Preview Expression window updates to display the expression as you have specified it to that point.

6. Continue choosing terms, and when prompted filling in arguments, until your expression is complete. If you make a mistake or want to change your expression after you have already selected a term, you can simply choose another term. The expression is modified, and any arguments or additional terms that you added after the term that you modified are cleared.

7. When you have finished constructing your expression, click OK to close the Add Expression dialog box. Your expression is inserted into the Expression text area.

To bind an application firewall policy by using the configuration utility

1. In the navigation pane, expand Application Firewall, then Policies, and then select Firewall Policies.

2. In the details pane, click Policy Manager.

3. In the Application Firewall Policy Manager dialog box, choose the bind point to which you want to bind the policy. The choices are:

   - **Override Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance, and are applied before any other policies.

   - **LB Virtual Server.** Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.

   - **CS Virtual Server.** Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.

   - **Default Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance.

   - **Policy Label.** Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.
4. Select Insert Policy to insert a new row and display a drop-down list with all available, unbound application firewall policies.

5. Select the policy you want to bind, or select New Policy to create a new policy. The policy that you selected or created is inserted into the list of globally bound application firewall policies.

6. Make any additional adjustments to the binding.

   - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.

   - To modify the policy expression, double click that field to open the Configure Application Firewall Policy dialog box, where you can edit the policy expression.

   - To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.

   - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression
7. Repeat steps 3 through 6 to add any additional application firewall policies you want to globally bind.

8. Click OK. A message appears in the status bar, stating that the policy has been successfully bound.

Manual Configuration By Using the Command Line Interface

You can configure many application firewall features from the NetScaler command line. There are important exceptions, however. You cannot enable signatures from the command line. There are over 1,000 default signatures in seven categories; the task is simply too complex for the command line interface. You can configure the check actions and parameters for security checks from the command line, but cannot enter manual relaxations. While you can configure the adaptive learning feature and enable learning from the command line, you cannot review learned relaxations or learned rules and approve or skip them. The command line interface is intended for advanced users who are thoroughly familiar with the NetScaler appliance and the application firewall feature.

To manually configure the Application Firewall by using the NetScaler command line, use a telnet or secure shell client of your choice to log on to the NetScaler command line.

To create a profile by using the command line interface

At the command prompt, type the following commands:

- add appfw profile <name> [-defaults (**basic** | **advanced**)]
- set appfw profile <name> -type (**HTML** | **XML** | **HTML XML**)
- save ns config

Example

The following example adds a profile named `pr-basic`, with basic defaults, and assigns a profile type of `HTML`. This is the appropriate initial configuration for a profile to protect an HTML Web site.

```
add appfw profile pr-basic -defaults basic
set appfw profile pr-basic -type HTML
save ns config
```

Parameters for Creating a Profile

name (Profile Name)

A name for the profile. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.

defaults (Defaults)

You can choose one of two default configurations when you create a profile: Basic or Advanced. A profile created with basic defaults should protect most Web sites while requiring little additional configuration. A profile created with advanced defaults is intended to protect more complex Web sites requiring additional configuration. You can modify either type of default configuration.

type (Profile Type)

The type of content that the profile will protect. There are three types of profile: **HTML** (`HTML`), **XML** (`XML`), or **Web 2.0** (`HTML XML`). If you are unsure what types of content your profile will protect, you can specify Web 2.0 to make the full range of Application Firewall security checks available to protect your Web site.

To configure a profile by using the command line interface

At the command prompt, type the following commands:

- set appfw profile <name> <arg1> [<arg2> ...] where <arg1> represents a parameter and <arg2> represents either another parameter or the value to assign to the parameter represented by <arg1>. For descriptions of the parameters to use when configuring specific security checks, see Advanced Protections and its subtopics. For descriptions of the other parameters, see "Parameters for Creating a Profile."
- save ns config

Example

The following example shows how to configure an HTML profile created with basic defaults to begin protecting a simple HTML-based Web site. This example turns on logging and maintenance of statistics for most security checks, but enables blocking only for those checks that have extremely low false positive rates and require no special configuration. It also turns on transformation of unsafe HTML and unsafe SQL, which prevents attacks but does not block requests to your Web sites. With logging and statistics enabled, you can later review the logs to determine whether to enable blocking for a specific security check.

```
set appfw profile -startURLAction log stats
set appfw profile -denyURLAction block log stats
set appfw profile -cookieConsistencyAction log stats
set appfw profile -crossSiteScriptingAction log stats
set appfw profile -crossSiteScriptingTransformUnsafeHTML ON
set appfw profile -fieldConsistencyAction log stats
set appfw profile -SQLInjectionAction log stats
set appfw profile -SQLInjectionTransformSpecialChars ON
set appfw profile -SQLInjectionOnlyCheckFieldsWithSQLChars ON
set appfw profile -SQLInjectionParseComments checkall
set appfw profile -fieldFormatAction log stats
set appfw profile -bufferOverflowAction block log stats
set appfw profile -CSRFtagAction log stats
```

save ns config

To create and configure a policy

At the command prompt, type the following commands:

- add appfw policy <name> <rule> <profile>
- save ns config

Example

The following example adds a policy named `pl-blog`, with a rule that intercepts all traffic to or from the host `blog.example.com`, and associates that policy with the profile `pr-blog`. This is an appropriate policy to protect a blog hosted on a specific hostname.

```
add appfw policy pl-blog "HTTP.REQ.HOSTNAME.DOMAIN.EQ("blog.example.com")" pr-blog
```

Parameters for creating and configuring a policy

name

A name for your policy. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 128 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols.

rule

A policy rule, or expression, in NetScaler expressions language. For a short description and some useful examples of Application Firewall rules, see "Manually Configuring Firewall Policies." For a complete description of the NetScaler expressions language, see "Introduction to Policies and Expressions."

profile

The name of the profile that you previously created.

To bind an Application Firewall policy

At the command prompt, type the following commands:

- bind appfw global <policyName> <priority>
- save ns config

Example

The following example binds the policy named `pl-blog` and assigns it a priority of `10`.

```
bind appfw global pl-blog 10
save ns config
```

Signatures

The application firewall signatures function provides specific, configurable rules that protect your web sites against known attacks. A signature represents a pattern that is a component of a known attack on an operating system, a web server, a web site, an XML-based web service, or any other server that is connected to a web site or web service. A signature can be used to check either requests or responses. A signature can consist of a literal string or a PCRE-compliant regular expression.

To specify how the application firewall is to use signatures, you configure a signatures object, which specifies the signatures to apply to your traffic and the actions to be taken when the signatures match the traffic. A signatures object also contains the SQL injection and cross-site scripting patterns, and may also contain XPath injection patterns. These patterns are not actually signatures but are used by some of the advanced protection checks. The SQL Injection and Cross-Site Scripting patterns contain the SQL special symbols and keywords, the cross-site scripting allowed tags and attributes, and the denied patterns for the HTML and XML SQL Injection and Cross-Site Scripting checks. The XPath injection patterns contain the XPath (*XML Path Language*) denied patterns.

Note: If you use the wizard to configure signatures, the signatures object is created automatically.

The application firewall examines requests to your protected web sites and web services to determine whether a request matches a signature. Matching requests are handled as you specify when configuring the Signatures actions. By default, matching requests are logged so that you can examine them later. If you enabled blocking, the application firewall displays an error page or error object. If you enabled statistics, the application firewall also includes the request in the statistics that it maintains about requests that match an application firewall signature or security check.

If you want to configure signatures manually, you must create a signatures object from a template or import a signatures object file. There are two default templates that you can use: the *Default Signatures template and the *Xpath Injection template. The *Default Signatures template contains over 1,000 signatures, in addition to the complete list of SQL injection and cross-site scripting allowed and denied patterns. The *Xpath Injection template contains all of those, and in addition contains 57 Xpath keywords and special strings.

In addition to using its native signatures format, the application firewall can create a signatures object by using a built-in template for any supported external signatures format, or by importing an external signatures file in a supported format. The supported formats are as follows:

- **Cenzic**—Signatures files, produced by Cenzic products, that use Cenzic Hailstorm technology.
- **IBM AppScan**—Signatures files produced by IBM AppScan Enterprise and IBM AppScan Standard.
- **Qualys**—Qualys WAS signatures files produced by QualysGuard products. Only Qualys WAS 1.0 files are supported for importing as signatures. WAS 2.0 is not supported.

Note: Qualys classifies a single SQL special character in a URL as a security threat, even when no SQL keywords are present. The SQL injection check does not consider the presence of a single SQL special character a threat unless an SQL keyword is present. For that reason, a Qualys scanner continues to report such requests as containing SQL injection vulnerabilities, but the application firewall does not detect or block these requests because they pose no actual threat to your protected web sites and web services.

- **Trend Micro**—Signatures files produced by the Trend Micro Vulnerability Scanner (TMVS).

- **Whitehat**—WASC 1.0, WASC 2.0, and best practices signatures produced by Whitehat Sentinel products.

  WASC signatures include information about many vulnerabilities. The application firewall generates blocking signatures from all WASC vulnerabilities. However, only certain vulnerabilities are appropriate for the web application firewall environment. For a list of appropriate Whitehat signatures, see Whitehat WASC Signature Types for WAF Use.

Once you have created a signatures object, you can configure all parts of it, including the signatures rules, the XML SQL Injection and Cross-Site Scripting rules, and the Xpath injection rules. You can manually create and modify your own custom signatures in the signatures editor. You can also add new SQL injection, cross-site scripting, and XPath injection patterns, modify existing patterns, and remove patterns.

Regardless of whether you use the wizard for initial configuration or configure your signatures object manually, you should regularly apply the Citrix updates to keep your signatures current. Citrix regularly updates the default application firewall signatures. You can apply those updates manually, or you can enable automatic signature updates so that the application firewall can update the signatures from the Cloud-based application firewall updates service. You can obtain the correct URL for either type of updates from your Citrix service representative or reseller.

Manually Configuring the Signatures Feature

To use signatures to protect your web sites, you must review the rules, and enable and configure the ones that you want to apply. The rules are disabled by default. Citrix recommends that you enable all rules that are applicable to the type of content that your web site uses.

To manually configure the signatures feature, use a browser to connect to the configuration utility. Then, create a signatures object from a built-in template, an existing signatures object, or by importing a file. Next, configure the new signatures object.

Note: The following procedures do not address adding user-defined signatures to a signatures object. To create your own signatures, see "The Signatures Editor."

Adding a New Signatures Object

You can add a new signatures object to the application firewall by:

- Copying either a built-in template or an existing signatures object.
- Importing a signatures object from an external file.

To create a signatures object from a template

1. Navigate to Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to use as a template.

   Your choices are:

   - *** Default Signatures.** Contains the signatures rules, the SQL injection rules, and the cross-site scripting rules.
   - *** XPath Injection.** Contains everything that is in the *** Default Signatures** template, and also contains the XPath injection rules.
   - **Any existing signatures object.**
3. Click Add.
4. In the Add Signatures Object dialog box, type a name for your new signatures object, and then click OK. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), and underscore (_) symbols.
5. Click Close.

To create a signatures object by importing a file

1. Navigate to Application Firewall > Signatures.
2. In the details pane, click Add.
3. In the Add Signatures Object dialog box, select the External Format tab.
4. Choose the external format file that you want to use to create your new signatures object.
   - To import a native NetScaler format signatures object file, in the Import section select either Import from Local File or Import from URL, then type or browse to the path or URL to the file.
   - To import a Cenzic, IBM AppScan, Qualys, or Whitehat format file, in the XSLT section select Use Built-in XSLT File, Use Local File, or Reference from URL. Next, if you chose Use Built-in XSLT File, select the appropriate file format from the drop-down list. If you chose Use Local File or Reference from URL, then type or browse to the path or URL to the file.
5. Click Add, and then click Close.

Configuring or Modifying a Signatures Object

You configure a signatures object after creating it, or modify an existing signatures object, to enable or disable signature categories or specific signatures, and configure how the application firewall responds when a signature matches a connection.

To configure or modify a signatures object

1. Navigate to Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to configure, and then click Open.
3. In the Modify Signatures Object dialog box, set the Display Filter Criteria options at the left to display the filter items that you want to configure.

   As you modify these options, the results that you requested are displayed in the Filtered Results window at the right.

   - To display only selected categories of signatures, check or clear the appropriate signature-category check boxes. The signature categories are:

Name	Type of Attack that this Signature Protects Against
cgi	CGI scripts. Includes Perl and UNIX shell scripts.
client	Browsers and other clients.
coldfusion	Web sites that use the Adobe Systems ColdFusion application server.
frontpage	Web sites that use Microsoft's FrontPage server.
iis	Web sites that use the Microsoft Internet Information Server (IIS).
misc	Miscellaneous attacks.
php	Web sites that use PHP

   - To display only signatures that have specific check actions enabled, select the ON check box for each of those actions, clear the ON check boxes for the other actions, and clear all of the OFF check boxes. To display only signatures that have a specific check action disabled, select their respective OFF check boxes and clear all of the ON check boxes. To display signatures regardless of whether they have a check action enabled or disabled, select or clear both the ON and the OFF check boxes for that action. The check actions are:

Criterion	Description
Enabled	The signature is enabled. The application firewall checks only for signatures that are enabled when it processes traffic.
Block	Connections that match this signature are blocked.
Log	A log entry is produced for any connection that matches this signature.
Stats	The application firewall includes any connection that matches this signature in the statistics that it generates for that check.

   - To display only signatures that contain a specific string, type the string into the text box under the filter criteria, and then click Search.
   - To reset all display filter criteria to the default settings and display all signatures, click Show All.

4. For information about a specific signature, select the signature, and then click the blue double arrow to the left of the Category field. The Signature Rule Vulnerability Detail message box appears. It contains information about the purpose of the signature and provides links to external web-based information about the vulnerability or vulnerabilities that this signature addresses. To access an external link, click the blue double arrow to the left of the description of that link.

5. Configure the settings for a signature by selecting the appropriate check boxes.

6. If you want to add a local signature rule to the signatures object, or modify an existing local signature rule, see "The Signatures Editor."

7. If you have no need for SQL injection, cross-site scripting, or Xpath injection patterns, click OK, and then click Close. Otherwise, in the lower left-hand corner of the details pane, click Manage SQL/XSS Patterns.

8. In the Manage SQL/XSS Patterns dialog box, Filtered Results window, navigate to the pattern category and pattern that you want to configure. For information about the SQL injection patterns, see "HTML SQL Injection Check." For information about the cross-site scripting patterns, see "HTML Cross-Site Scripting Check."

9. To add a new pattern:

    a. Select the branch to which you want to add the new pattern.

    b. Click the Add button directly below the lower section of the Filtered Results window.

    c. In the Create Signature Item dialog box, fill in the Element text box with the pattern that you want to add. If you are adding a transformation pattern to the transform rules branch, under Elements, fill in the From text box with the pattern that you want to change and the To text box with the pattern to which you want to change the previous pattern.

    d. Click OK.

10. To modify an existing pattern:

    a. In the Filtered Results window, select the branch that contains the pattern that you want to modify.

    b. In the detail window beneath the Filtered Results window, select the pattern that you want to modify.

    c. Click Modify.

    d. In the Modify Signature Item dialog box, Element text box, modify the pattern. If you are modifying a transformation pattern, you can modify either or both patterns under Elements, in the From and the To text boxes.

    e. Click OK.

11. To remove a pattern, select the pattern that you want to remove, then click the Remove button below the details pane beneath the Filtered Results window. When prompted, confirm your choice by clicking Close.

12. To add the patterns category to the XSS branch:

a. Select the branch to which you want to add the patterns category.

b. Click the Add button directly below the Filtered Results window.

Note: Currently you can add only one category, named patterns, to the XSS branch, so after you click Add, you must accept the default choice, which is `patterns`.

c. Click OK.

13. To remove a branch, select that branch, and then click the Remove button directly below the Filtered Results window. When prompted, confirm your choice by clicking OK.

Note: If you remove a default branch, you remove all of the patterns in that branch. Doing so can disable the security checks that use that information.

14. When you are finished modifying the SQL injection, cross-site scripting, and XPath injection patterns, click OK, and then click Close to return to the Modify Signatures Object dialog box.

15. Click OK at any point to save your changes, and when you are finished configuring the signatures object, click Close.

Updating a Signatures Object

You should update your signatures objects frequently to ensure that your application firewall is providing protection against current threats. You should regularly update both the default application firewall signatures and any signatures that you import from a supported vulnerability scanning tool.

Citrix regularly updates the default signatures for the application firewall. You can update the default signatures manually or automatically. In either case, ask your Citrix representative or Citrix reseller for the URL to access the updates. You can enable automatic updates of the Citrix native format signatures in the "Engine Settings" and "Signature Auto Update Settings" dialog box.

Most makers of vulnerability scanning tools regularly update the tools. Most web sites also change frequently. You should update your tool and rescan your web sites regularly, exporting the resulting signatures to a file and importing them into your application firewall configuration.

Note: When you update the application firewall signatures from the NetScaler command line, you must first update the deafult signatures, and then issue additional update commands to update each custom signatures file that is based on the default signatures. If you do not update the default signatures first, a version mismatch error prevents updating of the custom signatures files.

To update a signatures object from a Citrix format file by using the configuration utility

1. Navigate to Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to update.
3. In the Action drop-down list, select Merge.
4. In the Update Signatures Object dialog box, choose one of the following options.
   - **Import from URL**—Choose this option if you download signature updates from a web URL.
   - **Import from Local File**—Choose this option if you import signature updates from a file on your local hard drive, network hard drive, or other storage device.
5. In the text area, type the URL, or type or browse to the local file.
6. Click Update. The update file is imported, and the Update Signatures dialog box changes to a format nearly identical to that of the Modify Signatures Object dialog box, which is described in "Configuring or Modifying a Signatures Object" and "To configure or modify a signatures object." The Update Signatures Object dialog box displays all branches with new or modified signature rules, SQL injection or cross-site scripting patterns, and XPath injection patterns if there are any.
7. Review and configure the new and modified signatures.
8. When you are finished, click OK, and then click Close.

To import and update signatures from a vulnerability scanning tool

1. Navigate to Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to update, and then click Update.
3. In the Update Signatures Object dialog box, on the External Format tab, Import section, choose one of the following options.
   - **Import from URL**—Choose this option if you download signature updates from a Web URL.
   - **Import from Local File**—Choose this option if you import signature updates from a file on your local or a network hard drive or other storage device.
4. In the text area, type the URL, or browse or type the path to the local file.
5. In the XSLT section, choose one of the following options.
   - **Use Built-in XSLT File**—Choose this option if you want to use a built-in XSLT files.
   - **Use Local File**—Choose this option to use an XSLT file on your local computer.
   - **Reference from URL**—Choose this option to import an XSLT file from a web URL.
6. If you chose Use Built-in XSLT File, in the Built-In XSLT drop-down list choose the built-in XSLT file that you want to use.
   - To use the Cenzic XSLT file, select Cenzic.
   - To use the IBM AppScan Standard XSLT file, select IBM AppScan Standard.
   - To use the IBM AppScan Enterprise XSLT file, select IBM AppScan Enterprise.
   - To use the Qualys XSLT file, select Qualys.
   - To use the Trend Microsystems XSLT file, select Trend Micro.
   - To use the Whitehat XSLT file, select Whitehat.
7. Click Update. The update file is imported, and the Update Signatures dialog box changes to a format nearly identical to that of the Modify Signatures Object dialog box, which is described in "Configuring or Modifying a Signatures Object." The Update Signatures Object dialog box displays all branches with new or modified signature rules, SQL injection or cross-site scripting patterns, and XPath injection patterns if there are any.
8. Review and configure the new and modified signatures.
9. When you are finished, click OK, and then click Close.

Updating a Signatures Object from a Citrix Format File

Citrix regularly updates the signatures for the Application Firewall. You should regularly update the signatures on your Application Firewall to ensure that your Application Firewall is using the most current list. Ask your Citrix representative or Citrix reseller for the URL to access the updates.

To update a signatures object from a Citrix format file by using the command line

At the command prompt, type the following commands:

- update appfw signatures <name> [-mergeDefault]
- save ns config

To update a signatures object from a Citrix format file by using the configuration utility

1. Navigate to Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to update.
3. In the Action drop-down list, select Merge.
4. In the Update Signatures Object dialog box, choose one of the following options.
   - **Import from URL**—Choose this option if you download signature updates from a web URL.
   - **Import from Local File**—Choose this option if you import signature updates from a file on your local hard drive, network hard drive, or other storage device.
5. In the text area, type the URL, or type or browse to the local file.
6. Click Update. The update file is imported, and the Update Signatures dialog box changes to a format nearly identical to that of the Modify Signatures Object dialog box, which is described in "Configuring or Modifying a Signatures Object" and "To configure or modify a signatures object." The Update Signatures Object dialog box displays all branches with new or modified signature rules, SQL injection or cross-site scripting patterns, and XPath injection patterns if there are any.
7. Review and configure the new and modified signatures.
8. When you are finished, click OK, and then click Close.

Updating a Signatures Object from a Supported Vulnerability Scanning Tool

Note: Before you update a signatures object from a file, you must create the file by exporting signatures from the vulnerability scanning tool.

To import and update signatures from a vulnerability scanning tool

1. Navigate to Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to update, and then click Update.
3. In the Update Signatures Object dialog box, on the External Format tab, Import section, choose one of the following options.
   - **Import from URL**—Choose this option if you download signature updates from a Web URL.
   - **Import from Local File**—Choose this option if you import signature updates from a file on your local or a network hard drive or other storage device.
4. In the text area, type the URL, or browse or type the path to the local file.
5. In the XSLT section, choose one of the following options.
   - **Use Built-in XSLT File**—Choose this option if you want to use a built-in XSLT files.
   - **Use Local File**—Choose this option to use an XSLT file on your local computer.
   - **Reference from URL**—Choose this option to import an XSLT file from a web URL.
6. If you chose Use Built-in XSLT File, in the Built-In XSLT drop-down list choose the built-in XSLT file that you want to use.
   - To use the Cenzic XSLT file, select Cenzic.
   - To use the IBM AppScan Standard XSLT file, select IBM AppScan Standard.
   - To use the IBM AppScan Enterprise XSLT file, select IBM AppScan Enterprise.
   - To use the Qualys XSLT file, select Qualys.
   - To use the Trend Microsystems XSLT file, select Trend Micro.
   - To use the Whitehat XSLT file, select Whitehat.
7. Click Update. The update file is imported, and the Update Signatures dialog box changes to a format nearly identical to that of the Modify Signatures Object dialog box, which is described in "Configuring or Modifying a Signatures Object." The Update Signatures Object dialog box displays all branches with new or modified signature rules, SQL injection or cross-site scripting patterns, and XPath injection patterns if there are any.
8. Review and configure the new and modified signatures.
9. When you are finished, click OK, and then click Close.

Exporting a Signatures Object to a File

You export a signatures object to a file so that you can import it to another application firewall.

To export a signatures object to a file

1. Navigate to Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to configure.
3. In the Actions drop-down list, select Export.
4. In the Export Signatures Object dialog box, Local File text box, type the path and name of the file to which you want to export the signatures object, or use the Browse dialog to designate a path and name.
5. Click OK.

The Signatures Editor

You can use the signatures editor, which is available in the configuration utility, to add a new user-defined (*local*) signature rule to an existing signatures object, or to modify a previously configured local signature rule. Except that it is defined by the user (you), a local signature rule has the same attributes as a default signature rule from Citrix, and it functions in the same way. You enable or disable it, and configure the signature actions for it, just as you do for a default signature.

Add a local rule if you need to protect your web sites and services from a known attack that the existing signatures do not match. For example, you might discover a new type of attack and determine its characteristics by examining the logs on your web server, or you might obtain third-party information about a new type of attack.

At the heart of a signature rule are the rule *patterns*, which collectively describe the characteristics of the attack that the rule is designed to match. Each pattern can consist of a simple string, a PCRE-format regular expression, or the built-in SQL injection or cross-site scripting patterns.

You might want to modify a signature rule by adding a new pattern or modifying an existing pattern to match an attack. For example, you might find out about changes to an attack, or you might determine a better pattern by examining the logs on your web server, or from third-party information.

Parameters for the Signature Editor

Actions

The Enabled, Block, Log, and Stats check boxes. Select or clear the check boxes as appropriate to configure what the Application Firewall does when the signature rule is matched.

- To enable the signature rule, select Enabled.
- To enable blocking for the signature rule, select Block.
- To enable logging for the signature rule, select Log.
- To enable maintaining of statistics for the signature rule, select Stats.

Category

The category in which the signature rule is included. Assigning a signature to a category enables you to configure it and other signatures in that category as a group, which can significantly speed up the configuration process when you want to configure many signature rules in the same way.

LogString

A brief string (a few words or a short sentence) that describes the attack that this signature rule matches. This string is used when logging a match to the NetScaler log.

Comment

A longer description of the attack and the signature rule, with information that another user who is configuring this signature object would need to know. Optional.

Patterns

The patterns that describe the characteristics of the attack that this signature rule should match. Patterns can be fixed strings, PCRE-format regular expressions, or the built-in SQL injection or cross-site scripting patterns. See "Signature Rule Patterns" for more information.

Note: If a signature rule has more than one pattern, a match does not occur unless all of the patterns match the data to which the rule is compared. If either of two patterns can define an attack, but both would not necessarily be present, you should create two signature rules.

To add or modify a local signature rule by using the Signatures Editor

1. Navigate to Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to edit, and then click Open.
3. In the Modify Signatures Object dialog box, in the middle of the screen beneath the Filtered Results window, do one of the following:.
   - To add a new local signature rule, click Add.
   - To modify an existing local signature rule, select that rule, and then click Open.
4. In the Add Local Signature Rule or the Modify Local Signature Rule dialog box, configure the actions for a signature by selecting the appropriate check boxes.
   - **Enabled.** Enables the new signature rule. If you do not select this, this new signature rule is added to your configuration, but is inactive.
   - **Block.** Blocks connections that violate this signature rule.
   - **Log.** Logs violations of this signature rule to the NetScaler log.
   - **Stats.** Includes violations of this signature rule in the statistics.
   - **Strip.** Removes comments from the request or response before applying the signature rule.
   - **Remove.** Strips information that matches the signature rule from the response. (Applies only to response rules.)
   - **X-Out.** Masks information that matches the signature rule with the letter X. (Applies only to response rules.)
   - **Allow Duplicates.** Allows duplicates of this signature rule in this signatures object.
5. Choose a category for the new signature rule from the Category drop-down list.

   You can also create a new category by clicking the icon to the right of the list and using the Add Signature Rule Category dialog box to add a new category to the list, The rule you are modifying is automatically added to the new category. For instructions, see "To add a signature rule category."
6. In the **LogString** text box, type a brief description of the signature rule to be used in the logs.
7. In the **Comment** text box, type a comment. (Optional)
8. Click More..., and modify the advanced options.
   a. To strip HTML comments before applying this signature rule, in the Strip Comments drop-down list choose All or Exclude Script Tag.

b. To set CSRF Referer Header checking, in the CSRF Referer Header checking radio button array, select either the If Present or Always radio button.

c. To manually modify the Rule ID assigned to this local signature rule, modify the number in the Rule ID text box. The ID must be a positive integer between 1000000 and 1999999 that has not already been assigned to a local signature rule.

d. To assign a version number to the new signature rule, modify the number in the Version Number text box.

e. To assign a Source ID, modify the string in the Source ID text box.

f. To specify the source, choose Local or Snort from the Source drop-down list, or click the Add icon to the right of the list and add a new source.

g. To assign a harm score to violations of this local signature rule, type a number between 1 and 10 in the Harm Score text box.

h. To assign a severity rating to this local signature rule, in the Severity drop-down list choose High, Medium, or Low, or click the Add icon to the right of the list and add a new severity rating.

i. To assign a violation type to this local signature rule, in the Type drop-down list choose Vulnerable or Warning, or click the Add icon to the right of the list and add a new violation type.

9. In the **Patterns** list, add or edit a pattern.

   · To add a pattern, click Add. In the Create New Signature Rule Pattern dialog box, add one or more patterns for your signature rule, and then click OK.

   · To edit a pattern, select the pattern, and then click Open. In the Edit Signature Rule Pattern dialog box, modify the pattern, and then click OK.

   For more information about adding or editing patterns, see "Signature Rule Patterns."

10. Click OK.

To add a signature rule category

Putting signature rules into a category enables you to configure the actions for a group of signatures instead of for each individual signature. You might want to do so for the following reasons:

- **Ease of selection.** For example, assume that all of signature rules in a particular group protect against attacks on a specific type of web server software or technology. If your protected web sites use that software or technology, you want to enable them all. If they do not, you do not want to enable any of them.
- **Ease of initial configuration.** It is easiest to set defaults for a group of signatures as a category, instead of one-by-one. You can then make any changes to individual signatures as needed.
- **Ease of ongoing configuration.** It is easier to configure signatures if you can display only those that meet specific criteria, such as belonging to a specific category.

1. Navigate to Application Firewall > Signatures.
2. In the details pane, select that signatures object that you want to configure, and then click Open.
3. In the Modify Signatures Object dialog box, in the middle of the screen, beneath the Filtered Results window, click Add.
4. In the Add Local Signature Rule dialog box, click the icon to the right of the Category drop-down list.
5. In the Add Signature Rule Category dialog box, New Category text box, type a name for your new signature category. The name can consist of from one to 64 characters.
6. Click **OK**.

Signature Rule Patterns

You can add a new pattern to a signature rule or modify an existing pattern of a signature rule to specify a string or expression that characterizes an aspect of the attack that the signature matches. To determine which patterns an attack exhibits, you can examine the logs on your web server, use a tool to observe connection data in real time, or obtain the string or expression from a third-party report about the attack.

Caution: Any new pattern that you add to a signature rule is in an AND relationship with the existing patterns. Do not add a new pattern to an existing signature rule if you do not want a potential attack to have to match all of the patterns in order to match the signature.

Each pattern can consist of a simple string, a PCRE-format regular expression, or the built-in SQL injection or cross-site scripting pattern. Before you attempt to add a pattern that is based on a regular expression, you should make sure that you understand PCRE-format regular expressions. PCRE expressions are complex and powerful; if you do not understand how they work, you can unintentionally create a pattern that matches something that you did not want (a *false positive*) or that fails to match something that you did want (a *false negative*).

If you are not already familiar with PCRE-format regular expressions, you can use the following resources to learn the basics, or for help with some specific issue:

- *"Mastering Regular Expressions"*, Third Edition. Copyright (c) 2006 by Jeffrey Friedl. O'Reilly Media, ISBN: 9780596528126
- *"Regular Expressions Cookbook"*. Copyright (c) 2009 by Jan Goyvaerts and Steven Levithan. O'Reilly Media, ISBN: 9780596520687
- **PCRE Man page/Specification** (text/official): "http://www.pcre.org/pcre.txt"
- **PCRE Man Page/Specification** (html/gammon.edu.au): "http://www.gammon.com.au/pcre/index.html"
- **Wikipedia PCRE entry**: "http://en.wikipedia.org/wiki/PCRE"
- **PCRE Mailing List** (run by exim.org): "http://lists.exim.org/mailman/listinfo/pcre-dev"

If you need to encode non-ASCII characters in a PCRE-format regular expression, the NetScaler platform supports encoding of hexadecimal UTF-8 codes. For more information, see "PCRE Character Encoding Format."

To configure a signature rule pattern

1. Navigate to Application Firewall > Signatures.
2. In the details pane, select that signatures object that you want to configure, and then click **Open**.
3. In the Modify Signatures Object dialog box, in the middle of the screen beneath the Filtered Results window, either click Add to create a signature rule, or select an existing signature rule and click Open.

   Note: You can modify only signature rules that you added. You cannot modify the default signature rules.

   Depending on your action, either the Add Local Signature Rule or the Modify Local Signature Rule dialog box appears. Both dialog boxes have the same contents.
4. Under the Patterns window in the dialog box that you opened, either click Add to add a new pattern, or select an existing pattern from the list beneath the Add button and click Open. Depending on your action, either the Create New Signature Rule Pattern or the Edit Signature Rule Pattern dialog box appears. Both dialog boxes have the same contents.
5. In the Pattern Type drop-down list, choose the type of connection that the pattern is intended to match.

   - If the pattern is intended to match request elements or features, such as injected SQL code, attacks on web forms, cross-site scripts, or inappropriate URLs, choose **Request**.
   - If the pattern is intended to match response elements or features, such as credit card numbers or safe objects, choose **Response**.
6. In the Location area, define the elements to examine with this pattern.

   The Location area describes what elements of the HTTP request or response to examine for this pattern. The choices that appear in the Location area depend upon the chosen pattern type. If you chose `Request` as the pattern type, items relevant to HTTP requests appear; if you chose `Response`, items relevant to HTTP responses appear.

   In addition, as you choose a value from the Area drop-down list, the remaining parts of the Location area change interactively. Following are all configuration items that might appear in this section.

   Area

   Drop-down list of elements that describe a particular portion of the HTTP connection. The choices are as follows:

   - **HTTP_ANY**. All parts of the HTTP connection.
   - **HTTP_COOKIE**. All cookies in the HTTP request headers after any cookie transformations are performed.

     Note: Does not search HTTP response "Set-Cookie:" headers.

- **HTTP_FORM_FIELD**. Form fields and their contents, after URL decoding, percent decoding, and removal of excess whitespace. You can use the `<Location>` tag to further restrict the list of form field names to be searched.
- **HTTP_HEADER**. The value portions of the HTTP header after any cross-site scripting or URL decoding transformations.
- **HTTP_METHOD**. The HTTP request method.
- **HTTP_ORIGIN_URL**. The origin URL of a web form.
- **HTTP_POST_BODY**. The HTTP post body and the web form data that it contains.
- **HTTP_RAW_COOKIE**. All HTTP request cookie, including the "Cookie:" name portion.

  Note: Does not search HTTP response "Set-Cookie:" headers.
- **HTTP_RAW_HEADER**. The entire HTTP header, with individual headers separated by linefeed characters (`\n`) or carriage return/line-feed strings (`\r\n`).
- **HTTP_RAW_RESP_HEADER**. The entire response header, including the name and value parts of the response header after URL transformation has been done, and the complete response status. As with HTTP_RAW_HEADER, individual headers are separated by linefeed characters (`\n`) or carriage return/line-feed strings (`\r\n`).
- **HTTP_RAW_SET_COOKIE**. The entire Set-Cookie header after any URL transformations have been performed.

  Note: URL transformation can change both the domain and path parts of the Set-Cookie header.
- **HTTP_RAW_URL**. The entire request URL before any URL transformations are performed, including any query or fragment parts.
- **HTTP_RESP_HEADER**. The value part of the complete response headers after any URL transformations have been performed.
- **HTTP_RESP_BODY**. The HTTP response body.
- **HTTP_SET_COOKIE**. All "Set-Cookie" headers in the HTTP response headers.
- **HTTP_STATUS_CODE**. The HTTP status code.
- **HTTP_STATUS_MESSAGE**. The HTTP status message.
- **HTTP_URL**. The value portion of the URL in the HTTP headers, excluding any query or fragment ports, after conversion to the UTF-* character set, URL decoding, stripping of whitespace, and conversion of relative URLs to absolute. Does not include HTML entity decoding.

URL

Examines any URLs found in the elements specified by the Area setting.

- To enable, select the Enabled check box.
- To search for a literal string in a URL, type the string in the text area.
- To search for a pattern defined by a regular expression, select the Is Regular Expression check box, and then type the regular expression in the text area. Use the **Regex Tokens** to insert common regular expression elements at the cursor, or the Regex Editor for more assistance in constructing the regular expression that you want.

Field Name

Examines any form field names found in the elements specified by the Area selection.

- To enable, select the Enabled check box.
- To search for a literal string in a form field, type the string in the text area.
- To search for a pattern defined by a regular expression, select the **Is Regular Expression** check box, and then type the regular expression in the text area. Use the **Regex Tokens** to insert common regular expression elements at the cursor, or the Regex Editor for more assistance in constructing the regular expression that you want.

7. In the Pattern area, define the pattern. A pattern is a literal string or PCRE-format regular expression that defines the pattern that you want to match. The Pattern area contains the following elements:

Match

A drop-down list of search methods that you can use for the signature. This list differs depending on whether the pattern type is Request or Response.

Request Match Types

- **Literal**. A literal string.
- **PCRE**. A PCRE-format regular expression.

  NOTE: When you choose PCRE, the regular expression tools beneath the Pattern window are enabled. These tools are not useful for most other types of patterns.
- **Injection**. Directs the application firewall to look for injected SQL in the specified location. The Pattern window disappears, because the application firewall already has the patterns for SQL injection.
- **CrossSiteScripting**. Directs the application firewall to look for cross-site scripts in the specified location. The Pattern window disappears, because the application firewall already has the patterns for cross-site scripts.
- **Expression**. An expression in the NetScaler default expressions language. This is the same expressions language that is used to create application firewall policies and other policies on the NetScaler appliance. Although the NetScaler expressions language was originally developed for policy rules, it is a highly flexible general purpose language that can also be used to define a signature pattern.

When you choose Expression, the NetScaler Expression Editor appears beneath Pattern window. For more information about the Expression Editor and instructions on how to use it, see "To add a firewall rule (expression) by using the Add Expression dialog box." For more information about NetScaler expressions, see "Policies and Expressions."

Response Match Types

- **Literal**. A literal string.
- **PCRE**. A PCRE-format regular expression.

  NOTE: When you choose PCRE, the regular expression tools beneath the Pattern window are enabled. These tools are not useful for most other types of patterns.
- **Credit Card**. A built-in pattern to match one of the six supported types of credit card number.

Note: The Expression match type is not available for Response-side signatures.

Pattern Window (unlabeled)

In this window, type the pattern that you want to match, and fill in any additional data.

- **Literal.** Type the string you want to search for in the text area.
- **PCRE.** Type the regular expression in the text area. Use the **Regex Editor** for more assistance in constructing the regular expression that you want, or the Regex Tokens to insert common regular expression elements at the cursor. To enable UTF-8 characters, click UTF-8.
- **Expression.** Type the NetScaler advanced expression in the text area. Use Prefix to choose the first term in your expression, or Operator to insert common operators at the cursor. Click **Add** to open the Add Expression dialog box for more assistance in constructing the regular expression that you want. Click Evaluate to open the Advanced Expression Evaluator to help determine what effect your expression has.
- **Offset.** The number of characters to skip over before starting to match on this pattern. You use this field to start examining a string at some point other than the first character.
- **Depth.** How many characters from the starting point to examine for matches. You use this field to limit searches of a large string to a specific number of characters.
- **Min-Length.** The string to be searched must be at least the specified number of bytes in length. Shorter strings are not matched.
- **Max-Length.** The string to be searched must be no longer than the specified number of bytes in length. Longer strings are not matched.
- **Search method.** A check box labeled fastmatch. You can enable fastmatch only for a literal pattern, to improve performance.

8. Click OK.

9. Repeat the previous four steps to add or modify additional patterns.

10. When finished adding or modifying patterns, click OK to save your changes and return to the Signatures pane.

Caution: Until you click **OK** in the **Add Local Signature Rule** or **Modify Local Signature Rule** dialog box, your changes are not saved. Do not close either of these dialog boxes without clicking **OK** unless you want to discard your changes.

Advanced Protections

The application firewall advanced protections (*security checks*) are a set of filters designed to catch complex or unknown attacks on your protected web sites and web services. The security checks use heuristics, positive security, and other techniques to detect attacks that may not be detected by signatures alone. You configure the security checks by creating and configuring an application firewall *profile*, which is a collection of user-defined settings that tell the application firewall which security checks to use and how to handle a request or response that fails a security check. A profile is associated with a *signatures object* and with a *policy* to create a security configuration.

The application firewall provides twenty security checks, which differ widely in the types of attacks that they target and how complex they are to configure. The security checks are organized into the following categories:

- **Common security checks.** Checks that apply to any aspect of web security that either does not involve content or is equally applicable to all types of content.
- **HTML security checks.** Checks that examine HTML requests and responses. These checks apply to HTML-based web sites and to the HTML portions of Web 2.0 sites, which contain mixed HTML and XML content.
- **XML security checks.** Checks that examine XML requests and responses. These checks apply to XML-based web services and to the XML portions of Web 2.0 sites.

The security checks protect against a wide range of types of attack, including attacks on operation system and web server software vulnerabilities, SQL database vulnerabilities, errors in the design and coding of web sites and web services, and failures to secure sites that host or can access sensitive information.

All security checks have a set of configuration options, the check actions, which control how the application firewall handles a connection that matches a check. Three check actions are available for all security checks. They are:

- **Block.** Block connections that match the signature. Disabled by default.
- **Log.** Log connections that match the signature, for later analysis. Enabled by default.
- **Stats.** Maintain statistics, for each signature, that show how many connections it matched and provide certain other information about the types of connections that were blocked. Disabled by default.

A fourth check action, **Learn**, is available for more than half of the check actions. It observes traffic to a protected Web site or web service and uses connections that repeatedly violate the security check to generate recommended exceptions (*relaxations*) to the check, or new rules for the check. In addition to the check actions, certain security checks have parameters that control the rules that the check uses to determine which connections violate that check, or that configure the application firewall's response to connections that violate the check. These parameters are different for each check, and they are described in the documentation for each check.

To configure security checks, you can use the application firewall wizard, as described in "The Application Firewall Wizard," or you can configure the security checks manually, as described in "Manual Configuration By Using the Configuration Utility." Some tasks, such as manually entering relaxations or rules or reviewing learned data, can be done only by using the configuration utility, not the command line. Using the wizard is usually best configuration method, but in some cases manual configuration might be easier if you are thoroughly familiar with it and simply want to adjust the configuration for a single security check.

Regardless of which method you use to configure the security checks, each security check requires that certain tasks be performed. Many checks require that you specify exceptions (*relaxations*) to prevent blocking of legitimate traffic before you enable blocking for that security check. You can do this manually, by observing the log entries after a certain amount of traffic has been filtered and then creating the necessary exceptions. However, it is usually much easier to enable the learning feature and let it observe the traffic and recommend the necessary exceptions.

Top-Level Advanced Protections

Four of the advanced protections are especially effective against common types of Web attacks, and are therefore more commonly used than any of the others. They are:

- **HTML Cross-Site Scripting.** Examines requests and responses for scripts that attempt to access or modify content on a different Web site than the one on which the script is located. When this check finds such a script, it either renders the script harmless before forwarding the request or response to its destination, or it blocks the connection.

- **HTML SQL Injection.** Examines requests that contain form field data for attempts to inject SQL commands into an SQL database. When this check detects injected SQL code, it either blocks the request or renders the injected SQL code harmless before forwarding the request to the Web server.

  Note: If both of the following conditions apply to your configuration, you should make certain that your Application Firewall is correctly configured:

  - If you enable the HTML Cross-Site Scripting check or the HTML SQL Injection check (or both), and

  - Your protected Web sites accept file uploads or contain Web forms that can contain large POST body data.

  For more information about configuring the Application Firewall to handle this case, see "Configuring the Application Firewall."

- **Buffer Overflow.** Examines requests to detect attempts to cause a buffer overflow on the Web server.

- **Cookie Consistency.** Examines cookies returned with user requests to verify that they match the cookies your Web server set for that user. If a modified cookie is found, it is stripped from the request before the request is forwarded to the Web server.

The Buffer Overflow check is simple; you can usually enable blocking for it immediately. The other three top-level checks are considerably more complex and require configuration before you can safely use them to block traffic. Citrix strongly recommends that, rather than attempting to configure these checks manually, you enable the learning feature and allow it to generate the necessary exceptions.

HTML Cross-Site Scripting Check

HTML Cross-Site Scripting Check

The HTML Cross-Site Scripting check examines both the headers and the POST bodies of user requests for possible cross-site scripting attacks. If it finds a cross-site script, it either modifies (*transforms*) the request to render the attack harmless, or blocks the request.

To prevent misuse of the scripts on your protected web sites to breach security on your web sites, the HTML Cross-Site Scripting check blocks scripts that violate the *same origin rule*, which states that scripts should not access or modify content on any server but the server on which they are located. Any script that violates the same origin rule is called a cross-site script, and the practice of using scripts to access or modify content on another server is called cross-site scripting. The reason cross-site scripting is a security issue is that a web server that allows cross-site scripting can be attacked with a script that is not on that web server, but on a different web server, such as one owned and controlled by the attacker.

Unfortunately, many companies have a large installed base of JavaScript-enhanced web content that violates the same origin rule. If you enable the HTML Cross-Site Scripting check on such a site, you have to generate the appropriate exceptions so that the check does not block legitimate activity.

If you use the wizard or the configuration utility, in the Modify HTML Cross-Site Scripting Check dialog box, on the General tab you can enable or disable the Block, Log, Learn, and Statistics actions, and in addition the following parameters:

- **Transform.** If enabled, the application firewall makes the following changes to requests that match the HTML Cross-Site Scripting check:
  - Left angle bracket (<) to HTML character entity equivalent (<)
  - Right angle bracket (>) to HTML character entity equivalent (>)

  This ensures that browsers do not interpret unsafe html tags, such as `<script>`, and thereby execute malicious code. If you enable both request-header checking and transformation, any special characters found in request headers are also modified as described above. If scripts on your protected web site contain cross-site scripting features, but your web site does not rely upon those scripts to operate correctly, you can safely disable blocking and enable transformation. This configuration ensures that no legitimate web traffic is blocked, while stopping any potential cross-site scripting attacks.

- **Check complete URLs.** If checking of complete URLs is enabled, the application firewall examines entire URLs for HTML cross-site scripting attacks instead of checking just the query portions of URLs.

- **Check Request headers.** If Request header checking is enabled, the application firewall examines the headers of requests for HTML cross-site scripting attacks, instead of just URLs.

If you use the command-line interface, you can enter the following commands to configure the HTML Cross-Site Scripting Check:

- set appfw profile <name> -crossSiteScriptingAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -crossSiteScriptingTransformUnsafeHTML ([**ON**] | [**OFF**])
- set appfw profile <name> -crossSiteScriptingCheckCompleteURLs ([**ON**] | [**OFF**])

To specify relaxations for the HTML Cross-Site Scripting check, you must use the configuration utility. On the Checks tab of the Modify HTML Cross-Site Scripting Check dialog box, click Add to open the Add HTML Cross-Site Scripting Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify HTML Cross-Site Scripting Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation, as described in "Manual Configuration By Using the Configuration Utility."

Following are examples of HTML Cross-Site Scripting check relaxations:

Web Form Field Expressions

- **Logon Fields.** The following expression exempts all fields beginning with the string `logon_` followed by a string of upper- and lower-case letters or numbers that is at least two characters long and no more than fifteen characters long:

  ^logon_[0-9A-Za-z]{2,15}$

- **Name Fields.** The following expression exempts form fields with names beginning with `Name_` followed by a string beginning with a letter or number and consisting of from one to twenty letters, numbers, or the apostrophe or hyphen symbol:

  ^Name_[0-9A-Za-z][0-9A-Za-z'-]{0,20}$

- **Name Fields (Special Characters).** If your web site has Turkish-speaking customers whose first names may contain special characters, you might have a form field that begins with the string Turkish-Name_ on their logon page. In addition, the customers may use the same special characters in their names. The special characters in both of these strings must be represented as encoded UTF-8 strings. The following expression exempts form fields beginning with Turkish-Name_ and containing Turkish special characters:

  ^T\xC3\xBCrk\xC3\xA7e-Name_([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])+$

  Note: See "PCRE Character Encoding Format" for a complete description of supported special characters and how to encode them properly.

- **Session-ID Fields.** The following expression exempts all fields beginning with the string `sessionid-` followed by a ten-digit number:

  ^sessionid-[0-9]{10,10}$

URL Expressions

- **URLs using JavaScript.** You can use a single expression to exempt all URLs that end with a filename that follows a specified pattern. The following expression exempts all URLs that end with the string `query_` followed by a string of upper- and lower-case letters or numbers that is at least two characters long and no more than forty characters long, and ending with the string `.js`:

query_[0-9A-Za-z]{2,40}[.]js$

- **URLs containing a Specified String.** You can use an expression to exempt all URLs that contain a specific string. The following expression exempts all URLs that contain the string `prodinfo`:

  ^https?://(([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])([0-9A-Za-z_-]|\\x[0-9A-Fa-f][0-9A-Fa-f]+[.])+[a-z]{2,6}/[^<>?]*\?prodinfo[^<>?]*$

  In the above expression , each character class has been grouped with the string `\\x[0-9A-Fa-f][0-9A-Fa-f]`, which matches all properly constructed character encoding strings but does not allow stray backslash characters that are not associated with a UTF-8 character encoding string. The double backslash (\\) is an escaped backslash, which tells the application firewall to interpret it as a literal backslash. If you included only one backslash, the application firewall would interpret the following left square bracket ([) as a literal character instead of as the opening of a character class, which would break the expression.

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (`.*`) metacharacter/wildcard combination, can have results you do not want or expect, such as blocking access to web content that you did not intend to block or allowing an attack that the HTML Cross-Site Scripting check would otherwise have blocked.

HTML SQL Injection Check

The HTML SQL Injection check provides special defenses against injection of unauthorized SQL code that might break security. It examines both the headers and the POST bodies of requests for injected SQL code. If the application firewall detects unauthorized SQL code in a user request, it either transforms the request, to render the SQL code inactive, or blocks the request.

Many web applications have web forms that use SQL to communicate with relational database servers. Often, the scripts that pass web form information to the database do not validate the information provided by the user before sending it to the database. Malicious code or a hacker can use the insecure web form to send SQL commands to the web server.

Note: To prevent blocking of legitimate requests, this check ignores cookies that were set by the server, even if they contain elements that the Cookie Consistency Check would otherwise block.

If you use the wizard or the configuration utility, in the Modify Cookie Consistency Check dialog box, on the General tab you can enable or disable the Block, Log, Statistics, and Learn actions, and the following actions:

- **Transform.** Make the following changes to requests that match the HTML SQL Injection check:
  - Single straight quote (') to double straight quote (")
  - Backslash (\) to double backslash (\\).
  - Semicolon (;) is dropped completely.

  These three characters (*special strings*) are necessary to issue commands to an SQL server. Unless an SQL command is prefaced with a special string, most SQL servers ignore that command. For this reason, the changes that the application firewall performs when transformation is enabled prevent an attacker from injecting active SQL. After these changes are made, it is safe to forward the request to your protected web site. When web forms on your protected web site may legitimately contain SQL special strings, but the web form does not rely upon the special strings to operate correctly, you can disable blocking and enable transformation to prevent blocking of legitimate web form data without reducing the protection that the application firewall provides to your protected web sites.

  Note: You normally enable either transformation or blocking, but not both. If you have blocking enabled, enabling transformation is redundant because the application firewall already blocks access to requests that contain injected SQL.

- **Restrict checks to fields containing SQL special characters.** If you configure the application firewall to check only fields that contain SQL special strings, the application firewall skips web form fields that do not contain special characters. Since most SQL servers do not process SQL commands that are not preceded by a special character, enabling this parameter can significantly reduce the load on the application firewall and speed up processing without placing your protected web sites at risk.

- **SQL comments handling.** By default, the application firewall checks all SQL comments for injected SQL commands. Many SQL servers ignore anything in a comment, however, even if it is preceded by an SQL special character. For faster processing, if your SQL server ignores comments, you can configure the application firewall to skip comments when examining requests for injected SQL. The SQL comments handling options are:
  - **ANSI.** Skip ANSI-format SQL comments, which are normally used by UNIX-based SQL databases.
  - **Nested.** Skip nested SQL comments, which are normally used by Microsoft SQL Server.
  - **ANSI/Nested.** Skip comments that adhere to both the ANSI and nested SQL comment standards. Comments that match only the ANSI standard, or only the nested standard, are still checked for injected SQL.

    Caution: In most cases, you should not choose the Nested or the ANSI/Nested option unless your back-end database runs on Microsoft SQL Server. Most other types of SQL server software do not recognize nested comments. If nested comments appear in a request directed to another type of SQL server, they may indicate an attempt to breach security on that server.
  - **Check all Comments.** Check the entire request for injected SQL, without skipping anything. The default setting.
- **Check Request headers.** Examine the headers of requests for HTML SQL Injection attacks, instead of just URLs.

  Caution: If you enable both request header checking and transformation, any SQL special characters found in headers are also transformed. The Accept, Accept-Charset, Accept-Encoding, Accept-Language, Expect, and User-Agent headers normally contain semicolons (;), so enabling both Request header checking and transformation simultaneously may cause errors.

If you use the command-line interface, you can enter the following commands to configure the HTML SQL Injection Check:

- set appfw profile <name> -SQLInjectionAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -SQLInjectionTransformSpecialChars ([**ON**] | [**OFF**])
- set appfw profile <name> -SQLInjectionOnlyCheckFieldsWithSQLChars ([**ON**]|[**OFF**])
- set appfw profile <name> -SQLInjectionParseComments ([**checkall**] | [**ansi**|**nested**] | [**ansinested**])

To specify relaxations for the HTML SQL Injection check, you must use the configuration utility. On the Checks tab of the Modify HTML SQL Injection Check dialog box, click Add to open the Add HTML SQL Injection Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify HTML SQL Injection Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation, as described in "Manual Configuration By Using the Configuration Utility."

Following are examples of HTML SQL Injection check relaxations:

Web Form Field Name Expressions

- **Logon Fields.** The following expression exempts all fields beginning with the string `logon_` followed by a string of letters or numbers that is at least two characters long and no more than fifteen characters long:

  ^logon_[0-9A-Za-z]{2,15}$

- **Name Fields.** The following expression exempts form fields with names beginning with `Name_` followed by a string beginning with a letter or number and consisting of from one to twenty letters, numbers, or the apostrophe or hyphen symbol:

  ^Name_[0-9A-Za-z][0-9A-Za-z'-]{0,20}$

- **Name Fields (Special Characters).** If your web site has Turkish-speaking customers whose first names may contain special characters, you might have a form field that begins with the string Turkish-Name_ on their logon page. In addition, the customers may use the same special characters in their names. The special characters in both of these strings must be represented as encoded UTF-8 strings. The following expression exempts form fields beginning with Turkish-Name_ and containing Turkish special characters:

  ^T\xC3\xBCrk\xC3\xA7e-Name_([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])+$

  Note: See "PCRE Character Encoding Format" for a complete description of supported special characters and how to encode them properly.

- **Session-ID Fields.** The following expression exempts all fields beginning with the string `sessionid-` followed by a ten-digit number:

  ^sessionid-[0-9]{10,10}$

Action URL Expressions

- **URLs using JavaScript.** You can use a single expression to exempt all URLs that end with a filename that follows a specified pattern. The following expression exempts all URLs that end with the string `query_` followed by a string of upper- and lower-case letters or numbers that is at least two characters long and no more than forty characters long, and that end with the string `.js`:

  query_[0-9A-Za-z]{2,40}[.]js$

- **URLs containing a Specified String.** You can use an expression to exempt all URLs that contain a specific string. The following expression exempts all URLs that contain the string `prodinfo`:

  ^https?://(([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])([0-9A-Za-z_-]|\\x[0-9A-Fa-f][0-9A-Fa-f]+[.])+[a-z]{2,6}/[^<>?]*\?prodinfo[^<>?]*$

  In the expression above, each character class has been grouped with the string `\\x[0-9A-Fa-f][0-9A-Fa-f]`, which matches all properly constructed character

encoding strings but does not allow stray backslash characters that are not associated with a UTF-8 character encoding string. The double backslash (\\) is an escaped backslash, which tells the application firewall to interpret it as a literal backslash. If you included only one backslash, the application firewall would interpret the following left square bracket ([) as a literal character instead of as the opening of a character class, which would break the expression.

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (`.*`) metacharacter/wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the HTML SQL Injection check would otherwise have blocked.

Buffer Overflow Check

The Buffer Overflow check detects attempts to cause a buffer overflow on the web server. If the application firewall detects a URL, cookie or header longer than the specified maximum length in a request, it blocks that request because it might be an attempt to cause a buffer overflow.

The Buffer Overflow check prevents attacks against insecure operating-system or web-server software that can crash or behave unpredictably when it receives a data string that is larger than it can handle. Proper programming techniques prevent buffer overflows by checking incoming data and either rejecting or truncating overlong strings. Many programs, however, do not check all incoming data and are therefore vulnerable to buffer overflows. This issue especially affects older versions of web-server software and operating systems, many of which are still in use.

If you use the wizard or the configuration utility, in the Modify Buffer Overflow Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions. On the Checks tab, you can set the following parameters:

- **Maximum URL Length.** The maximum length the application firewall allows in a requested URL. Requests with longer URLs are blocked. Possible Values: 0-65536. Default: 1024
- **Maximum Cookie Length.** The maximum length the application firewall allows for an individual cookie in a request. Longer cookies are stripped from requests before those requests are forwarded to your protected web server. Possible Values: 0-65536. Default: 4096
- **Maximum Header Length.** The maximum length the application firewall allows for HTTP headers. Requests with longer headers are blocked. Possible Values: 0-65536. Default: 4096

If you use the command-line interface, you can add the following Buffer Overflow Check arguments to the set appfwl profile <profileName> command:

- -bufferOverflowAction [**block**] [**log**| [**stats**]
- -bufferOverflowMaxURLLength <positiveInteger>
- -bufferOverflowMaxCookieLength <positiveInteger>
- -bufferOverflowMaxHeaderLength <positiveInteger>

Cookie Consistency Check

The Cookie Consistency check examines cookies returned by users, to verify that they match the cookies that your web site set for that user. If a modified cookie is found, it is stripped from the request before the request is forwarded to the web server. You can also configure the Cookie Consistency check to transform all of the server cookies that it processes, by encrypting the cookies, proxying the cookies, or adding flags to the cookies. This check applies to requests and responses.

An attacker would normally modify a cookie to gain access to sensitive private information by posing as a previously authenticated user, or to cause a buffer overflow. The Buffer Overflow check protects against attempts to cause a buffer overflow by using a very long cookie. The Cookie Consistency check focuses on the first scenario.

If you use the wizard or the configuration utility, in the Modify Cookie Consistency Check dialog box, on the General tab you can enable or disable the following actions:

- Block
- Log
- Learn
- Statistics
- Transform. If enabled, the Transform action modifies all cookies as specified in the following settings:
    - **Encrypt Server Cookies.** Encrypt cookies set by your web server, except for any listed in the Cookie Consistency check relaxation list, before forwarding the response to the client. Encrypted cookies are decrypted when the client sends a subsequent request, and the decrypted cookies are reinserted into the request before it is forwarded to the protected web server. Specify one of the following types of encryption:
        - **None.** Do not encrypt or decrypt cookies. The default.
        - **Decrypt only.** Decrypt encrypted cookies only. Do not encrypt cookies.
        - **Encrypt session only.** Encrypt session cookies only. Do not encrypt persistent cookies. Decrypt any encrypted cookies.
        - **Encrypt all.** Encrypt both session and persistent cookies. Decrypt any encrypted cookies.

          Note: When encrypting cookies, the application firewall adds the **HttpOnly** flag to the cookie. This flag prevents scripts from accessing and parsing the cookie. The flag therefore prevents a script-based virus or trojan from accessing a decrypted cookie and using that information to breach security. This is done regardless of the Flags to Add in Cookies parameter settings, which are handled independently of the Encrypt Server Cookies parameter

settings.

- **Proxy Server Cookies.** Proxy all non-persistent (*session*) cookies set by your web server, except for any listed in the Cookie Consistency check relaxation list. Cookies are proxied by using the existing application firewall session cookie. The application firewall strips session cookies set by the protected web server and saves them locally before forwarding the response to the client. When the client sends a subsequent request, the application firewall reinserts the session cookies into the request before forwarding it to the protected web server. Specify one of the following settings:
  - **None.** Do not proxy cookies. The default.
  - **Session only.** Proxy session cookies only. Do not proxy persistent cookies.

    Note: If you disable cookie proxying after having enabled it (set this value to None after it was set to Session only), cookie proxying is maintained for sessions that were established before you disabled it. You can therefore safely disable this feature while the application firewall is processing user sessions.
- **Flags to Add in Cookies**. Add flags to cookies during transformation. Specify one of the following settings:
  - **None.** Do not add flags to cookies. The default.
  - **HTTP only.** Add the HttpOnly flag to all cookies. Browsers that support the HttpOnly flag do not allow scripts to access cookies that have this flag set.
  - **Secure**. Add the Secure flag to cookies that are to be sent only over an SSL connection. Browsers that support the Secure flag do not send the flagged cookies over an insecure connection.
  - **All.** Add the HttpOnly flag to all cookies, and the Secure flag to cookies that are to be sent only over an SSL connection.

If you use the command-line interface, you can enter the following commands to configure the Cookie Consistency Check:

- set appfw profile <name> -cookieConsistencyAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -cookieTransforms ([**ON**] | [**OFF**])
- set appfw profile <name> -cookieEncryption ([**none**] | [**decryptOnly**] | [**encryptSession**] | [**encryptAll**])
- set appfw profile <name> -cookieProxying ([**none**] | [**sessionOnly**])
- set appfw profile <name> -addCookieFlags ([**none**] | [**httpOnly**] | [**secure**] | [**all**])

To specify relaxations for the Cookie Consistency check, you must use the configuration utility. On the Checks tab of the Modify Cookie Consistency Check dialog box, click Add to open the Add Cookie Consistency Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Cookie Consistency Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation, as described in "Manual Configuration By Using the Configuration Utility."

Following are examples of Cookie Consistency check relaxations:

- **Logon Fields.** The following expression exempts all form fields beginning with the string `logon_` followed by a string of letters or numbers that is at least two characters long and no more than fifteen characters long:

  ```
  ^logon_[0-9A-Za-z]{2,15}$
  ```

- **Logon Fields (special characters).** The following expression exempts all form fields beginning with the string `türkçe-logon_` followed by a string of letters or numbers that is at least two characters long and no more than fifteen characters long:

  ```
  ^t\xC3\xBCrk\xC3\xA7e-logon_[0-9A-Za-z]{2,15}$
  ```

  Note: The special characters in that string must be represented as encoded UTF-8 strings. See "PCRE Character Encoding Format" for a complete description of supported special characters and how to encode them properly.

- **Arbitrary strings.** Allow cookies that contain the string `sc-item_`, followed by the ID of an item that the user has added to his shopping cart ([0-9A-Za-z]+), a second underscore (_), and finally the number of these items he wants ([1-9][0-9]?), to be user-modifiable:

  ```
  ^sc-item_[0-9A-Za-z]+_[1-9][0-9]?$
  ```

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (`.*`) metacharacter/wildcard combination, can have results you do not want or expect, such as blocking access to web content that you did not intend to block or allowing an attack that the Cookie Consistency check would otherwise have blocked.

Data Leak Prevention Checks

The data-leak-prevention checks filter responses to prevent leaks of sensitive information, such as credit card numbers and social security numbers, to unauthorized recipients.

Credit Card Check

The Credit Card check provides special handling for credit card numbers. A web application does not usually send a credit card number in a response to a user request, even when the user supplies a credit card number in the request. The application firewall examines web server responses, including headers, for credit card numbers. If it finds a credit card number in the response, and the administrator has not configured it to allow credit card numbers to be sent, it responds in one of two ways:

- It blocks the response.
- It replaces all but the final group of digits in the credit card with x's. For example, a credit card number of 9876-5432-1234-5678 would be rendered xxxx-xxxx-xxxx-5678.

The Credit Card check prevents attackers from exploiting a security flaw in your web server software or on your web site to obtain credit card numbers of your customers. If your web sites do not have access to credit card information, you do not need to configure this check. If you have a shopping cart or other application that can access credit card numbers, or your web sites have access to database servers that contain credit card numbers, you should configure protection for each type of credit card that you accept.

Note: A web site that does not access an SQL database usually does not have access to sensitive private information such as credit card numbers.

If you use the wizard or the configuration utility, in the Credit Card Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions, and the following actions:

- **X-Out.** Mask any credit card number detected in a response by replacing each digit, except the digits in the final group, with the letter "X."
- **Maximum credit cards allowed per page.** Allow up to the specified number of credit card numbers per page in responses without masking the credit card numbers or blocking the response. The Maximum is set to zero (0) by default. Web pages do not usually contain unmasked credit card numbers, but occasionally a web page might legitimately contain a credit card number or even a list of credit card numbers. To allow one or more credit card numbers to appear in a web page before masking the numbers or blocking the response, change the value in the "Maximum credit cards allowed per page" text box to the number of credit cards that you want to allow.

To configure the types of credit cards to be protected, in the Modify Credit Card Check dialog box, select each credit card type that you want to protect, and then click Protect. If you want to cancel protection for a credit card type, select that credit card type and then click Unprotect. You can hold down your Shift or Ctrl key while choosing credit card types, and then enable or disable several credit card types at once by clicking the Protect or Unprotect button while multiple credit card types are selected.

If you use the command-line interface, you can enter the following commands to configure the Credit Card Check:

- set appfw profile <name> -creditCardAction [**block**] [**log**] [**stats**] [**none**]

- set appfw profile <name> -creditCard (**VISA** | **MASTERCARD** | **DISCOVER** | **AMEX** | **JCB** | **DINERSCLUB**)
- set appfw profile <name> -creditCardMaxAllowed <integer>
- set appfw profile <name> -creditCardXOut ([**ON**] | [**OFF**])

Safe Object Check

The Safe Object check provides user-configurable protection for sensitive business information, such as customer numbers, order numbers, and country-specific or region-specific telephone numbers or postal codes. A user-defined regular expression or custom plug-in tells the application firewall the format of this information and defines the rules to be used to protect it. If a string in a user request matches a safe object definition, the application firewall either blocks the response, masks the protected information, or removes the protected information from the response before sending it to the user, depending on how you configured that particular safe object rule.

The Safe Object check prevents attackers from exploiting a security flaw in your web server software or on your web site to obtain sensitive private information, such as company credit card numbers or social security numbers. If your web sites do not have access to these types of information, you do not need to configure this check. If you have a shopping cart or other application that can access such information, or your web sites have access to database servers that contain such information, you should configure protection for each type of sensitive private information that you handle and store.

Note: A web site that does not access an SQL database usually does not have access to sensitive private information.

The Safe Object Check dialog box is unlike that for any other check. Each safe object expression that you create is the equivalent of a separate security check, similar to the Credit Card check, for that type of information. If you use the wizard or the configuration utility, you add a new expression by clicking Add and configuring the expression in the Add Safe Object dialog box. You modify an existing expression by selecting it, then clicking Open, and then configuring the expression in the Modify Safe Object dialog box.

In the Safe Object dialog box for each safe object expression, you can configure the following:

- **Safe Object Name.** A name for your new safe object. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 255 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols.

- **Actions.** Enable or disable the Block, Log, and Statistics actions, and the following actions:

    - **X-Out.** Mask any information that matches the safe object expression with the letter “X”.

    - **Remove.** Remove any information that matches the safe object expression.
- **Regular Expression.** Enter a PCRE-compatible regular expression that defines the safe object. You can create the regular expression in one of three ways: by typing the regular expression directly into the text box, by using the **Regex Tokens** menu to enter regular expression elements and symbols directly into the text box, or by opening the Regular Expressions Editor and using it to construct the expression. The regular expression must consist of ASCII characters only. Do not cut and paste characters that are not part of the basic 128-character ASCII set. If you want to include non-ASCII characters, you must manually type those characters in PCRE hexadecimal character

encoding format.

Note: Do not use start anchors (^) at the beginning of Safe Object expressions, or end anchors ($) at the end of Safe Object expressions. These PCRE entities are not supported in Safe Object expressions, and if used, will cause your expression not to match what it was intended to match.

- **Maximum Match Length.** Enter a positive integer that represents the maximum length of the string that you want to match. For example, if you want to match U.S. social security numbers, enter the number eleven (11) in this field. That allows your regular expression to match a string with nine numerals and two hyphens. If you want to match California driver's license numbers, enter the number eight (8).

Caution: If you do not enter a maximum match length in this field, the application firewall uses a default value of one (1) when filtering for strings that match your safe object expressions. As a result, most safe object expressions fail to match their target strings.

You cannot use the command-line interface to configure the Safe Object check. You must configure it by using either the application firewall wizard or the configuration utility.

Following are examples of Safe Object check regular expressions:

- Look for strings that appear to be U.S. social security numbers, which consist of three numerals (the first of which must not be zero), followed by a hyphen, followed by two more numerals, followed by a second hyphen, and ending with a string of four more numerals:

  [1-9][0-9]{2,2}-[0-9]{2,2}-[0-9]{4,4}

- Look for strings that appear to be California driver's license IDs, which start with a letter and are followed by a string of exactly seven numerals:

  [A-Za-z][0-9]{7,7}

- Look for strings that appear to be Example Manufacturing customer IDs which, consist of a string of five hexadecimal characters (all the numerals and the letters A through F), followed by a hyphen, followed by a three-letter code, followed by a second hyphen, and ending with a string of ten numerals:

  [0-9A-Fa-f]{5,5}-[A-Za-z]{3,3}-[0-9]{10,10}

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write to ensure that they define exactly the type of string you want to add as a safe object definition, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.*) metacharacter/wildcard combination, can have results you did not want or expect, such as blocking access to web content that you did not intend to block.

Advanced Form Protection Checks

The advanced Form Protection checks examine web form data to prevent attackers from compromising your system by modifying the web forms on your web sites or sending unexpected types and quantities of data to your web site in a form.

Field Formats Check

The Field Formats check verifies the data that users send to your web sites in a web form. It examines both the length and type of data to ensure that it is appropriate for the form field in which it appears. If the application firewall detects inappropriate web form data in a user request, it blocks the request. This check applies to HTML requests only. It does not apply to XML requests.

By preventing an attacker from sending inappropriate web form data to your web site, the Field Formats check prevents certain types of attacks on your web site and database servers. For example, if a particular field expects the user to enter a phone number, the Field Formats check examines the user's response to ensure that the data matches the format for a phone number. If a particular field expects a first name, the Field Formats check ensures that the data in that field is of a type and length appropriate for a first name. It does the same thing for each form field that you configure it to protect.

The Field Formats check provides a different type of protection than does the Form Field Consistency check. The Form Field Consistency check verifies that the structure of the web forms returned by users is intact, that data format restrictions configured in the HTML are respected, and that data in hidden fields has not been modified. It can do this without any specific knowledge about your web forms other than what it derives from the web form itself. The Field Formats check verifies that the data in each form field matches the specific formatting restrictions that you configured manually, or that the learning feature generated and you approved. In other words, the Form Field Consistency check enforces general web form security, while the Field Formats check enforces the specific rules that you set for your web forms.

Before it can protect your web forms, the Field Formats check requires that you configure the application firewall to recognize the type and length of data expected in each form field on each web form that you want to protect.

If you use the wizard or the configuration utility, in the Modify Field Formats Check dialog box, on the General tab you can enable or disable the Block, Log, Learn, and Statistics actions and the following parameters:

- **Field Type.** Assign a default field type to form fields in web forms that do not have a field type. This parameter is not set by default. You can assign any field type that is defined on your application firewall as the default field type.

  Caution: If you set a restrictive default field type and do not disable blocking until you are certain that the field types assigned to your form fields are correct, users may be unable to use your web forms.

- **Minimum Length.** The default minimum data length assigned to form fields in web forms that do not have an explicit setting. This parameter is set to 0 by default, which allows the user to leave the field blank. Any higher setting forces users to fill in the field.

- **Maximum Length.** The default maximum data length assigned to form fields in web forms that do not have an explicit setting. This parameter is set to 65535 by default.

If you use the command-line interface, you can enter the following commands to configure the Field Formats Check:

- set appfw profile <name> -fieldFormatAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -defaultFieldFormatType <string>
- set appfw profile <name> -defaultFieldFormatMinLength <integer>
- set appfw profile <name> -defaultFieldFormatMaxLength <integer>

To specify relaxations for the Field Formats check, you must use the configuration utility. On the Checks tab of the Modify Field Formats Check dialog box, click Add to open the Add Field Formats Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Field Formats Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation, as described in "Manual Configuration By Using the Configuration Utility."

Following are examples of Field Formats check relaxations:

- Choose form fields with the name FirstName:

  ^FirstName$

- Choose form fields with names that begin with Name_ and are followed by a string beginning with a letter or number and consisting of from one to twenty letters, numbers, or the apostrophe or hyphen symbol:

  ^Name_[0-9A-Za-z][0-9A-Za-z'-]{0,20}$

- Choose form fields with names that begin with Turkish-FirstName_ and are otherwise the same as the previous expression, except that they can contain Turkish special characters throughout:

  ^T\xC3\xBCrk\xC3\xA7e-FirstName_([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])+$

  Note: See "PCRE Character Encoding Format" for a complete description of supported special characters and how to encode them properly.

- Choose form field names that begin with a letter or number, consist of a combination of letters and/or numbers only, and that contain the string Num anywhere in the string:

  ^[0-9A-Za-z]*Num[0-9A-Za-z]*$

Form Field Consistency Check

The Form Field Consistency check examines the web forms returned by users of your web site, and verifies that web forms were not modified inappropriately by the client. This check applies only to HTML requests that contain a web form, with or without data. It does not apply to XML requests.

The Form Field Consistency check prevents clients from making unauthorized changes to the structure of the web forms on your web site when they are filling out a web form and submitting data by using that form. It also ensures that the data a user submits meets the HTML restrictions for length and type, and that data in hidden fields is not modified. This prevents an attacker from tampering with a web form and using the modified form to gain unauthorized access to web site, redirect the output of a contact form that uses an insecure script and thereby send unsolicited bulk email, or exploit a vulnerability in your web server software to gain control of the web server or the underlying operating system. Web forms are a weak link on many web sites and attract a wide range of attacks.

The Form Field Consistency check verifies all of the following:

- If a field is sent to the user, the check ensures that it is returned by the user.
- The check enforces HTML field lengths and types.

  Note: The Form Field Consistency check enforces HTML restrictions on data type and length but does not otherwise validate the data in web forms. You can use the Field Formats check to set up rules that validate data returned in specific form fields on your web forms.
- If your web server does not send a field to the user, the check does not allow the user to add that field and return data in it.
- If a field is a read-only or hidden field, the check verifies that the data has not changed.
- If a field is a list box or radio button field, the check verifies that the data in the response corresponds to one of the values in that field.

If a web form returned by a user violates one or more of the Form Field consistency checks, and you have not configured the application firewall to allow that web form to violate the Form Field Consistency checks, the request is blocked.

If you use the wizard or the configuration utility, in the Modify Form Field Consistency Check dialog box, on the General tab you can enable or disable the Block, Log, Learn, and Statistics actions.

You also configure Sessionless Field Consistency in the General tab. If Sessionless Field Consistency is enabled, the application firewall checks only the web form structure, dispensing with those parts of the Form Field Consistency check that depend upon maintaining session information. This can speed the Form Field Consistency check with little security penalty for web sites that use many forms. To use Sessionless Field Consistency on all web forms, select On. To use it only for forms submitted with the HTTP POST method, select postOnly

If you use the command-line interface, you can enter the following command to configure the Form Field Consistency Check:

- set appfw profile <name> -fieldConsistencyAction [**block**] [**learn**] [**log**] [**stats**] [**none**]

To specify relaxations for the Form Field Consistency check, you must use the configuration utility. On the Checks tab of the Modify Form Field Consistency Check dialog box, click Add to open the Add Form Field Consistency Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Form Field Consistency Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation, as described in "Manual Configuration By Using the Configuration Utility."

Following are examples of Form Field Consistency check relaxations:

Form Field Names

- Choose form fields with the name UserType:

  ^UserType$

- Choose form fields with names that begin with UserType_ and are followed by a string that begins with a letter or number and consists of from one to twenty-one letters, numbers, or the apostrophe or hyphen symbol:

  ^UserType_[0-9A-Za-z][0-9A-Za-z'-]{0,20}$

- Choose form fields with names that begin with Turkish-UserType_ and are otherwise the same as the previous expression, except that they can contain Turkish special characters throughout:

  ^T\xC3\xBCrk\xC3\xA7e-UserType_([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])+$

  Note: See "PCRE Character Encoding Format" for a complete description of supported special characters and how to encode them properly.

- Choose form field names that begin with a letter or number, consist of a combination of letters and/or numbers only, and that contain the string Num anywhere in the string:

  ^[0-9A-Za-z]*Num[0-9A-Za-z]*$

Form Field Action URLs

- Choose URLs beginning with http://www.example.com/search.pl? and containing any string after the query except for a new query:

  ^http://www[.]example[.]com/search[.]pl\?[^?]*$

- Choose URLs that begin with http://www.example-español.com and have paths and filenames that consist of upper-case and lower-case letters, numbers, non-ASCII special characters, and selected symbols in the path. The ñ character and any other special characters are represented as encoded UTF-8 strings containing the hexadecimal code assigned to each special character in the UTF-8 charset:

  ^http://www[.]example-espa\xC3\xB1ol[.]com/(([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])([0-9A-Za-z_-]|\\x[0-9A-Fa-f][0-9A-Fa-f])*/)*([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])

```
([0-9A-Za-z_-]|\\x[0-9A-Fa-f][0-9A-Fa-f])*[.](asp|htp|php|s?html?)$
```

Note: See "PCRE Character Encoding Format" for a complete description of supported special characters and how to encode them properly.

- Choose all URLs that contain the string /search.cgi?:

```
^[^?<>]*/search[.]cgi\?[^?<>]*$
```

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (`.*`) metacharacter/wildcard combination, can have results you do not want or expect, such as blocking access to web content that you did not intend to block or allowing an attack that the Cookie Consistency check would otherwise have blocked.

CSRF Form Tagging Check

The CSRF Form Tagging check tags each web form sent by a protected web site to users with a unique and unpredictable FormID, and then examines the web forms returned by users to ensure that the supplied FormID is correct. This check protects against Cross Site Request Forgery (CSRF) attacks. This check applies only to HTML requests that contain a web form, with or without data. It does not apply to XML requests.

The CSRF Form Tagging check prevents attackers from using their own web forms to send high volume form responses with data to your protected web sites. This check requires relatively little CPU processing capacity compared to certain other security checks that analyze web forms in depth. It is therefore able to handle high volume attacks without seriously degrading the performance of the protected web site or the application firewall itself.

Before you enable the CSRF Form Tagging check, you should be aware of the following:

- You need to enable form tagging. The CSRF check depends on form tagging and does not work without it.
- You should disable the Citrix NetScaler Integrated Caching feature for all web pages containing forms that are protected by that profile. The Integrated Caching feature and CSRF form tagging are not compatible.
- You should consider enabling Referer checking. Referer checking is part of the Start URL check, but it prevents cross-site request forgeries, not Start URL violations. Referer checking also puts less load on the CPU than does the CSRF Form Tagging check. If a request violates Referer checking, it is immediately blocked, so the CSRF Form Tagging check is not invoked.
- The CSRF Form Tagging check does not work with web forms that use different domains in the form-origin URL and form-action URL. For example, CSRF Form Tagging cannot protect a web form with a form-origin URL of `http://www.example.com/` and a form action URL of `http://www.example.org/form.pl`, because `example.com` and `example.org` are different domains.

If you use the wizard or the configuration utility, in the Modify CSRF Form Tagging Check dialog box, on the General tab you can enable or disable the Block, Log, Learn and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the CSRF Form Tagging Check:

- set appfw profile <name> -fieldConsistencyAction [**block**] [**log**] [**learn**] [**stats**] [**none**]

To specify relaxations for the CSRF Form Tagging check, you must use the configuration utility. On the Checks tab of the Modify CSRF Form Tagging Check dialog box, click Add to open the Add CSRF Form Tagging Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify CSRF Form Tagging Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation, as described in "Manual Configuration By Using the Configuration Utility."

Following are examples of CSRF Form Tagging check relaxations:

Note: The following expressions are URL expressions that can be used in both the Form Origin URL and Form Action URL roles.

- Choose URLs beginning with http://www.example.com/search.pl? and containing any string after the query, except for a new query:

  ^http://www[.]example[.]com/search[.]pl\?[^?]*$

- Choose URLs that begin with http://www.example-español.com and have paths and filenames that consist of upper-case and lower-case letters, numbers, non-ASCII special characters, and selected symbols in the path. The ñ character and any other special characters are represented as encoded UTF-8 strings containing the hexadecimal code assigned to each special character in the UTF-8 charset:

  ^http://www[.]example-espa\xC3\xB1ol[.]com/(([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])([0-9A-Za-z_-]|\\x[0-9A-Fa-f][0-9A-Fa-f])*/)*([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])([0-9A-Za-z_-]|\\x[0-9A-Fa-f][0-9A-Fa-f])*[.](asp|htp|php|s?html?)$

  Note: See "PCRE Character Encoding Format" for a complete description of supported special characters and how to encode them properly.

- Choose all URLs that contain the string /search.cgi?:

  ^[^?<>]*/search[.]cgi\?[^?<>]*$

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.*) metacharacter/wildcard combination, can have results you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the check would otherwise have blocked.

Deny URL Check

The Deny URL check examines and blocks connections to URLs that are commonly accessed by hackers and malicious code. This check contains a list of URLs that are common targets of hackers or malicious code and that rarely if ever appear in legitimate requests. You can also add URLs or URL patterns to the list. The Deny URL check prevents attacks against various security weaknesses known to exist in web server software or on many web sites.

The Deny URL check takes priority over the Start URL check, and thus denies malicious connection attempts even when a Start URL relaxation would normally allow a request to proceed.

If you use the wizard or the configuration utility, in the Modify Deny URL Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the Deny URL Check:

- set appfw profile <name> -denyURLAction [**block**] [**log**] [**stats**] [**none**]

To create and configure your own deny URLs, you must use the configuration utility. On the Checks tab of the Modify Deny URL Check dialog box, click Add to open the Add Deny URL dialog box, or select an existing user-defined deny URL and click Open to open the Modify Deny URLdialog box. Either dialog box provides the same options for creating and configuring a deny URL, as described in "Manual Configuration By Using the Configuration Utility."

Following are examples of Deny URL expressions:

- Do not allow users to access the image server at `images.example.com` directly:

  ^http://images[.]example[.]com$

- Do not allow users to access CGI (`.cgi`) or PERL (`.pl`) scripts directly:

  ^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*/)*
  [0-9A-Za-z][0-9A-Za-z_.-]*[.](cgi|pl)$

- Here is the same deny URL, modified to support non-ASCII characters:

  ^http://www[.]example[.]com/(([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])
  ([0-9A-Za-z_-]|\\x[0-9A-Fa-f][0-9A-Fa-f])*/)*([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])
  ([0-9A-Za-z_-]|\\x[0-9A-Fa-f][0-9A-Fa-f])*[.](cgi|pl)$

  Note: See "PCRE Character Encoding Format" for a complete description of supported special characters and how to encode them properly.

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL or pattern that you want to block, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (`.*`) metacharacter/wildcard combination, can have results that you do not want, such as

blocking access to web content that you did not intend to block.

URL Protection Checks

The URL Protection checks examine request URLs to prevent attackers from aggressively attempting to access multiple URLs (*forceful browsing*) or using a URL to trigger a known security vulnerability in web server software or web site scripts.

Start URL Check

The Start URL check examines the URLs in incoming requests and blocks the connection attempt if the URL does not meet the specified criteria. To meet the criteria, the URL must match an entry in the Start URL list, unless the Enforce URL Closure parameter is enabled. If you enable this parameter, a user who clicks a link on your Web site is connected to the target of that link.

The primary purpose of the Start URL check is to prevent repeated attempts to access random URLs on a Web site, (*forceful browsing*). Forceful browsing can be used to trigger a buffer overflow, find content that users were not intended to access directly, or find a back door into secure areas of your Web server.

If you use the wizard or the configuration utility, in the Modify Start URL Check dialog box, on the General tab you can enable or disable Block, Log, Statistics, Learn actions, and the following parameters:

- **Enforce URL Closure.** Allow users to access any web page on your web site by clicking a hyperlink on any other page on your web site. Users can navigate to any page on your web site that can be reached from the home page or any designated start page by clicking hyperlinks.

  Note: The URL closure feature allows any query string to be appended to and sent with the action URL of a web form submitted by using the HTTP GET method. If your protected web sites use forms to access an SQL database, make sure that you have the SQL injection check enabled and properly configured.

- **Sessionless URL Closure.** From the client's point of view, this type of URL closure functions in exactly the same way as standard, session-aware URL Closure, but uses a token embedded in the URL instead of a cookie to track the user's activity, which consumes considerably fewer resources.

  Note: When enabling sessionless (Sessionless URL Closure), you must also enable regular URL closure (Enforce URL Closure) or sessionless URL closure does not work.

- **Validate Referer Header.** Verify that the Referer header in a request that contains web form data from your protected web site instead of another web site. This action verifies that your web site, not an outside attacker, is the source of the web form. Doing so protects against cross-site request forgeries (CSRF) without requiring form tagging, which is more CPU-intensive than header checks. The application firewall can handle the HTTP Referer header in one of the following three ways, depending on which option you select in the drop-down list:

  - **Off.** Do not validate the Referer header.

  - **If-Present.** Validate the Referer header if a Referer header exists. If an invalid Referer header is found, the request generates a referer-header violation. If no Referer header exists, the request does not generate a referer-header violation. This option enables the application firewall to perform Referer header validation on requests that contain a Referer header, but not block requests from users whose browsers do not set the Referer header or who use web proxies or filters that remove that header.

- **Always.** Always validate the Referer header. If there is no Referer header, or if the Referer header is invalid, the request generates a referer-header violation.

Note: Although the referer header check and Start URL security check share the same action settings, it is possible to violate the referer header check without violating the Start URL check. The difference is visible in the logs, which log referer header check violations separately from Start URL check violations.

One Start URL setting, Exempt Closure URLs from Security Checks, is not configured in the Modify Start URL Check dialog box, but in the Settings tab of the Configure Application Firewall Profile dialog box. If enabled, this setting directs the application firewall not to run further security checks on URLs that meet the URL Closure criteria.

If you use the command-line interface, you can enter the following commands to configure the Start URL Check:

- set appfw profile <name> -startURLAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -startURLClosure ([**ON**] | [**OFF**])
- set appfw profile <name> -sessionlessURLClosure ([**ON**] | [**OFF**])
- set appfw profile <name> -exemptClosureURLsFromSecurityChecks ([**ON**] | [**OFF**])
- set appfw profile <name> -RefererHeaderCheck ([**none**] | [**if-present**] | [**always**])

To specify relaxations for the Start URL check, you must use the configuration utility. On the Checks tab of the Modify Start URL Check dialog box, click Add to open the Add Start URL Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Start URL Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation, as described in "Manual Configuration By Using the Configuration Utility."

Following are examples of Start URL check relaxations:

- Allow users to access the home page at `www.example.com`:

  ^http://www[.]example[.]com$

- Allow users to access all static HTML (`.htm` and `.html`), server-parsed HTML (`.htp` and `.shtml`), PHP (`.php`), and Microsoft ASP (`.asp`) format web pages at `www.example.com`:

  ^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*/)*
  [0-9A-Za-z][0-9A-Za-z_.-]*[.](asp|htp|php|s?html?)$

- Allow users to access web pages with pathnames or file names that contain non-ASCII characters at `www.example-español.com`:

  ^http://www[.]example-espa\xC3\xB1ol[.]com/(([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])([0-9A-Za-z_-]|\\x
  ([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])([0-9A-Za-z_-]|\\x[0-9A-Fa-f][0-9A-Fa-f])*[.](asp|htp|php|s?html?)

Note: In the above expression, each character class has been grouped with the string `\\x[0-9A-Fa-f][0-9A-Fa-f]`, which matches all properly-constructed character encoding strings but does not allow stray backslash characters that are not associated with a UTF-8 character encoding string. The double backslash (\\) is an escaped backslash, which tells the application firewall to interpret it as a literal backslash. If you included only one backslash, the application firewall would instead interpret the following left square bracket ([) as a literal character instead of the opening of a character class, which would break the expression. See "PCRE Character Encoding Format" for a complete description of supported special characters and how to encode them properly.

- Allow users to access all GIF (`.gif`), JPEG (`.jpg` and `.jpeg`), and PNG (`.png`) format graphics at `www.example.com`:

  ^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*/)*
  [0-9A-Za-z][0-9A-Za-z_.-]*[.](gif|jpe?g|png)$

- Allow users to access CGI (`.cgi`) and PERL (`.pl`) scripts, but only in the CGI-BIN directory:

  ^http://www[.]example[.]com/CGI-BIN/[0-9A-Za-z][0-9A-Za-z_.-]*[.](cgi|pl)$

- Allow users to access Microsoft Office and other document files in the `docsarchive` directory:

  ^http://www[.]example[.]com/docsarchive/[0-9A-Za-z][0-9A-Za-z_-.]*[.](doc|xls|pdf|ppt)$

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions that you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (`.*`) metacharacter/wildcard combination, can have results you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the Start URL check would otherwise have blocked.

Deny URL Check

The Deny URL check examines and blocks connections to URLs that are commonly accessed by hackers and malicious code. This check contains a list of URLs that are common targets of hackers or malicious code and that rarely if ever appear in legitimate requests. You can also add URLs or URL patterns to the list. The Deny URL check prevents attacks against various security weaknesses known to exist in web server software or on many web sites.

The Deny URL check takes priority over the Start URL check, and thus denies malicious connection attempts even when a Start URL relaxation would normally allow a request to proceed.

If you use the wizard or the configuration utility, in the Modify Deny URL Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the Deny URL Check:

- set appfw profile <name> -denyURLAction [**block**] [**log**] [**stats**] [**none**]

To create and configure your own deny URLs, you must use the configuration utility. On the Checks tab of the Modify Deny URL Check dialog box, click Add to open the Add Deny URL dialog box, or select an existing user-defined deny URL and click Open to open the Modify Deny URLdialog box. Either dialog box provides the same options for creating and configuring a deny URL, as described in "Manual Configuration By Using the Configuration Utility."

Following are examples of Deny URL expressions:

- Do not allow users to access the image server at `images.example.com` directly:

  ^http://images[.]example[.]com$

- Do not allow users to access CGI (`.cgi`) or PERL (`.pl`) scripts directly:

  ^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*/)*
  [0-9A-Za-z][0-9A-Za-z_.-]*[.](cgi|pl)$

- Here is the same deny URL, modified to support non-ASCII characters:

  ^http://www[.]example[.]com/(([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])
  ([0-9A-Za-z_-]|\\x[0-9A-Fa-f][0-9A-Fa-f])*/)*([0-9A-Za-z]|\\x[0-9A-Fa-f][0-9A-Fa-f])
  ([0-9A-Za-z_-]|\\x[0-9A-Fa-f][0-9A-Fa-f])*[.](cgi|pl)$

  Note: See "PCRE Character Encoding Format" for a complete description of supported special characters and how to encode them properly.

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL or pattern that you want to block, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (`.*`) metacharacter/wildcard combination, can have results that you do not want, such as

blocking access to web content that you did not intend to block.

XML Protection Checks

The XML Protection checks examine requests for XML-based attacks of all types.

Caution: The XML security checks apply only to content that is sent with an HTTP content-type header of text/xml. If the content-type header is missing, or is set to a different value, all XML security checks are bypassed. If you plan to protect XML or Web 2.0 web applications, the webmasters of each web server that hosts those applications should ensure that the proper HTTP content-type header is sent.

XML Format Check

The XML Format check examines the XML format of incoming requests and blocks those requests that are not well formed or that do not meet the criteria in the XML specification for properly-formed XML documents. Some of those criteria are:

- An XML document must contain only properly-encoded Unicode characters that match the Unicode specification.
- No special XML syntax characters—such as < , > and &—can be included in the document except when used in XML markup.
- All begin, end, and empty-element tags must be correctly nested, with none missing or overlapping.
- XML element tags are case-sensitive. All beginning and end tags must match exactly.
- A single root element must contain all the other elements in the XML document.

A document that does not meet the criteria for well-formed XML does not meet the definition of an XML document. Strictly speaking, it is not XML. However, not all XML applications and web services enforce the XML well-formed standard, and not all handle poorly-formed or invalid XML correctly. Inappropriate handling of a poorly-formed XML document can cause security breaches. The purpose of the XML Format check is to prevent a malicious user from using a poorly-formed XML request to breach security on your XML application or web service.

If you use the wizard or the configuration utility, in the Modify XML Format Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the XML Format Check:

- set appfw profile <name> -xmlFormatAction [**block**] [**log**] [**stats**] [**none**]

You cannot configure exceptions to the XML Format check. You can only enable or disable it.

XML Denial-of-Service Check

The XML Denial of Service (*XML DoS* or *XDoS*) check examines incoming XML requests to determine whether they match the characteristics of a denial-of-service (DoS) attack, and blocks those requests that do. The purpose of the XML DoS check is to prevent an attacker from using XML requests to launch a denial-of-service attack on your web server or web site.

If you use the wizard or the configuration utility, in the Modify XML Denial-of-Service Check dialog box, on the General tab you can enable or disable the Block, Log, Statistics, and Learn actions:

If you use the command-line interface, you can enter the following command to configure the XML Denial-of-Service check:

- set appfw profile <profileName> -xmlDoSAction [**block**] [**log**] [**learn**] [**stats**] [**none**]

To configure individual XML Denial-of-Service rules, you must use the configuration utility. On the Checks tab of the Modify XML Denial-of-Service Check dialog box, select a rule and click Open to open the Modify XML Denial-of-Service dialog box for that rule. The individual dialog boxes differ for the different rules but are extremely simple. Some only allow you to enable or disable the rule; others allow you to modify a number by typing a new value in a text box.

The individual XML Denial-of-Service rules are:

Maximum Element Depth

Restrict the maximum number of nested levels in each individual element to 256. If this rule is enabled, and the application firewall detects an XML request with an element that has more than the maximum number of allowed levels, it blocks the request. You can modify the maximum number of levels to any value from one (1) to 65,535.

Maximum Element Name Length

Restrict the maximum length of each element name to 128 characters. This includes the name within the expanded namespace, which includes the XML path and element name in the following format:

{http://prefix.example.com/path/}target_page.xml

The user can modify the maximum name length to any value between one (1) character and 65,535.

Maximum # Elements

Restrict the maximum number of any one type of element per XML document to 65,535. You can modify the maximum number of elements to any value between one (1) and 65,535.

Maximum # Element Children

Restrict the maximum number of children (including other elements, character information, and comments) each individual element is allowed to have to 65,535. You can modify the maximum number of element children to any value between one (1) and 65,535.

Maximum # Attributes

Restrict the maximum number of attributes each individual element is allowed to have to 256. You can modify the maximum number of attributes to any value between one (1) and 256.

Maximum Attribute Name Length

Restrict the maximum length of each attribute name to 128 characters. You can modify the maximum attribute name length to any value between one (1) and 2,048.

Maximum Attribute Value Length

Restrict the maximum length of each attribute value to 2048 characters. You can modify the maximum attribute name length to any value between one (1) and 2,048.

Maximum Character Data Length

Restrict the maximum character data length for each element to 65,535. You can modify the length to any value between one (1) and 65,535.

Maximum File Size

Restrict the size of each file to 20 MB. You can modify the maximum file size to any value.

Minimum File Size

Require that each file be at least 9 bytes in length. You can modify the minimum file size to any positive integer representing a number of bytes.

Maximum # Entity Expansions

Limit the number of entity expansions allowed to the specified number. Default: 1024.

Maximum Entity Expansion Depth

Restrict the maximum number of nested entity expansions to no more than the specified number. Default: 32.

Maximum # Namespaces

Limit the number of namespace declarations in an XML document to no more than the specified number. Default: 16.

Maximum Namespace URI Length

Limit the URL length of each namespace declaration to no more than the specified number of characters. Default: 256.

Block Processing Instructions

Block any special processing instructions included in the request. This rule has no user-modifiable values.

Block DTD

Block any document type definitions (*DTD*) included with the request. This rule has no user-modifiable values.

Block External Entities

Block all references to external entities in the request. This rule has no user-modifiable values.

SOAP Array Check

Enable or disable the following SOAP array checks:

- **Maximum SOAP Array Size.** The maximum total size of all SOAP arrays in an XML request before the connection is blocked. You can modify this value. Default: 20000000.
- **Maximum SOAP Array Rank.** The maximum rank or dimensions of any single SOAP array in an XML request before the connection is blocked. You can modify this value. Default: 16.

XML Cross-Site Scripting Check

The XML Cross-Site Scripting check examines both the headers and the bodies of user requests for possible cross-site scripting attacks. If it finds a possible cross-site scripting attack, it blocks the request.

To prevent misuse of the scripts on your protected web services to breach security on your web services, the XML Cross-Site Scripting check blocks scripts that violate the *same origin rule*, which states that scripts should not access or modify content on any server but the server on which they are located. Any script that violates the same origin rule is called a cross-site script, and the practice of using scripts to access or modify content on another server is called cross-site scripting. The reason cross-site scripting is a security issue is that a web server that allows cross-site scripting can be attacked with a script that is not on that web server, but on a different web server, such as one owned and controlled by the attacker.

Unfortunately, many companies have a large installed base of JavaScript-enhanced web content that violates the same origin rule. If you enable the XML Cross-Site Scripting check on such a site, you have to generate the appropriate exceptions so that the check does not block legitimate activity. In addition, to prevent blocking of legitimate requests, this check ignores cookies that were set by the server, even if they contain elements that the Cookie Consistency check would otherwise block. You should keep that in mind when configuring this check.

If you use the wizard or the configuration utility, in the Modify Cookie Consistency Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions, and the following parameters:

- **Transform.** Make the following changes to requests that match the XML Cross-Site Scripting check:
  - Left angle bracket (<) to HTML character entity equivalent (<)
  - Right angle bracket (>) to HTML character entity equivalent (>)

  These changes prevent browsers from interpreting unsafe html tags, such as `<script>`, and thereby executing malicious code. If you enable both request-header checking and transformation, any special characters found in request headers are also modified as described above. If scripts on your protected web site contain cross-site scripting features, but your web site does not rely upon those scripts to operate correctly, you can safely disable blocking and enable transformation. This configuration ensures that no legitimate web traffic is blocked, while stopping any potential cross-site scripting attacks.

- **Check complete URLs.** If checking of complete URLs is enabled, the application firewall examines entire URLs for XML Cross-Site Scripting attacks instead of checking just the query portions of URLs.

- **Check Request headers.** If Request header checking is enabled, the application firewall examines request headers for XML Cross-Site Scripting attacks, instead of examining just URLs.

If you use the command-line interface, you can enter the following commands to configure the XML Cross-Site Scripting Check:

- set appfw profile <name> -crossSiteScriptingAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -crossSiteScriptingTransformUnsafeHTML ([**ON**] | [**OFF**])
- set appfw profile <name> -crossSiteScriptingCheckCompleteURLs ([**ON**] | [**OFF**])

To specify relaxations for the XML Cross-Site Scripting check, you must use the configuration utility. On the Checks tab of the Modify XML Cross-Site Scripting Check dialog box, click Add to open the Add XML Cross-Site Scripting Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify XML Cross-Site Scripting Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation, as described in "Manual Configuration By Using the Configuration Utility."

Following are examples of XML Cross-Site Scripting check relaxations:

- **Name element or attribute.** The following expression exempts all elements beginning with the string `name_` followed by a string of upper- and lower-case letters or numbers that is at least two characters long and no more than fifteen characters long:

  ^name_[0-9A-Za-z]{2,15}$

- **URL element or attribute.** The following expression exempts URLs with hostnames of `web.example.com`, with a path up to four levels deep followed by an optional filename and extension, but no HTML or query symbols :

  ^https?://web[.]example[.]com(/[^<>?]{1,30}){0,4}(/[^<>?]{1,30})*$

- **URL element or attribute (special characters).** The following expression exempts URLs with hostnames of `web.türkçe-example.com`, with the same path and file restrictions as above:

  ^https?://web[.]t\xC3\xBCrk\xC3\xA7e-example[.]com(/[^<>?]{1,30}){0,4}(/[^<>?]{1,30})*$

  Note: See "PCRE Character Encoding Format" for a complete description of supported special characters and how to encode them properly.

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (`.*`) metacharacter/wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the XML Cross-Site Scripting check would otherwise have blocked.

XML SQL Injection Check

The XML SQL Injection check examines both the headers and the bodies of user requests for possible XML SQL Injection attacks. If it finds injected SQL, it blocks the request.

To prevent misusing the scripts on your protected web services to breach security on your web services, the XML SQL Injection check blocks scripts that violate the *same origin rule*, which states that scripts should not access or modify content on any server but the server on which they are located. Any script that violates the same origin rule is called a cross-site script, and the practice of using scripts to access or modify content on another server is called XML SQL Injection. The reason XML SQL Injection is a security issue is that a web server that allows XML SQL Injection can be attacked with a script that is not on that web server, but on a different web server, such as one owned and controlled by the attacker.

Unfortunately, many companies have a large installed base of JavaScript-enhanced web content that violates the same origin rule. If you enable the XML SQL Injection check on such a site, you have to generate the appropriate exceptions so that the check does not block legitimate activity. In addition, to prevent blocking of legitimate requests, this check ignores cookies that were set by the server, even if they contain elements that the Cookie Consistency check would otherwise block. You should keep this in mind when configuring this check.

Note: To prevent blocking of legitimate requests, this check ignores cookies that were set by the server, even if they contain elements that the Cookie Consistency check would otherwise block.

If you use the wizard or the configuration utility, in the Modify XML SQL Injection Check dialog box, on the General tab you can enable or disable Block, Log, and Statistics actions, and the following parameters:

- **Restrict checks to fields containing SQL special characters.** If you configure the application firewall to check only fields that contain SQL special strings, the application firewall skips web form fields that do not contain special characters. Since most SQL servers do not process SQL commands that are not preceded by a special character, enabling this parameter can significantly reduce the load on the application firewall and speed up processing without placing your protected web sites at risk.

- **SQL comments handling.** By default, the application firewall checks all SQL comments for injected SQL commands. Many SQL servers ignore anything in a comment, however, even if it is preceded by an SQL special character. For faster processing, if your SQL server ignores comments, you can configure the application firewall to skip comments when examining requests for injected SQL. The SQL comments handling options are:

    - **ANSI.** Skip ANSI-format SQL comments, which are normally used by UNIX-based SQL databases.

    - **Nested.** Skip nested SQL comments, which are normally used by Microsoft SQL Server.

    - **ANSI/Nested.** Skip comments that adhere to both the ANSI and nested SQL comment standards. Comments that match only the ANSI standard, or only the nested standard, are checked for injected SQL.

Caution: In most cases, you should not choose the Nested or the ANSI/Nested option unless your database runs on Microsoft SQL Server. Most other types of SQL server software do not recognize nested comments. If nested comments appear in a request directed to another type of SQL server, they may indicate an attempt to breach security on that server.

- **Check all Comments.** Check the entire request for injected SQL, without skipping anything. The default setting.

- **Check Request headers.** If Request header checking is enabled, the application firewall examines the headers of requests for XML SQL Injection attacks, instead of just URLs.

  Caution: If you enable both request header checking and transformation, any SQL special characters found in headers are also transformed. The Accept, Accept-Charset, Accept-Encoding, Accept-Language, Expect, and User-Agent headers normally contain semicolons (;), so enabling both Request header checking and transformation simultaneously may cause errors.

If you use the command-line interface, you can enter the following commands to configure the XML SQL Injection Check:

- set appfw profile <name> -XMLSQLInjectionAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -XMLSQLInjectionOnlyCheckFieldsWithSQLChars (**ON** | **OFF**)]
- set appfw profile <name> -XMLSQLInjectionParseComments ([**checkall**] | [**ansi** | **nested**] | [**ansinested**])

You configure the exceptions to the XML SQL Injection check by opening the Modify XML SQL Injection Check dialog box, Checks tab. An exception can consist of either a literal string or a PCRE-format regular expression. For information about adding, modifying, removing, enabling, or disabling exceptions, see "Manual Configuration By Using the Configuration Utility."

Following are examples of XML SQL Injection check relaxations:

- **Name element or attribute.** The following expression exempts all elements beginning with the string `name_` followed by a string of upper- and lower-case letters or numbers that is at least two characters long and no more than fifteen characters long:

  ```
  ^name_[0-9A-Za-z]{2,15}$
  ```

- **URL element or attribute.** The following expression exempts URLs with hostnames of `web.example.com`, with a path up to four levels deep followed by an optional file name and extension, but no HTML or query symbols :

  ```
  ^https?://web[.]example[.]com(/[^<>?]{1,30}){0,4}(/[^<>?]{1,30})*$
  ```

- **URL element or attribute (special characters).** The following expression exempts URLs with hostnames of `web.türkçe-example.com`, with the same path and file restrictions as above:

^https?://web[.]t\xC3\xBCrk\xC3\xA7e-example[.]com(/[^<>?]{1,30}){0,4}(/[^<>?]{1,30})*$

Note: See "PCRE Character Encoding Format" for a complete description of supported special characters and how to encode them properly.

XML Attachment Check

The XML Attachment check examines incoming requests for malicious attachments, and it blocks those requests that contain attachments that might breach applications security. The purpose of the XML Attachment check is to prevent an attacker from using an XML attachment to breach security on your server.

If you use the wizard or the configuration utility, in the Modify XML Attachment Check dialog box, on the General tab you can enable or disable the Block, Learn, Log, Statistics, and Learn actions:

If you use the command-line interface, you can enter the following command to configure the XML Attachment Check:

- set appfw profile <name> -xmlAttachmentAction [**block**] [**learn**] [**log**] [**stats**] [**none**]

You must configure the other XML Attachment check settings in the configuration utility. In the Modify XML Attachment Check dialog box, on the Checks tab, you can configure the following settings:

- **Maximum Attachment Size.** Allow attachments that are no larger than the maximum attachment size you specify. To enable this option, first select the Enabled check box, and then type the maximum attachment size in bytes in the Size text box.
- **Attachment Content Type.** Allow attachments of the specified content type. To enable this option, first select the Enabled check box, and then enter a regular expression that matches the Content-Type attribute of the attachments that you want to allow.
    - You can type the URL expression directly in the text window. If you do so, you can use the Regex Tokens menu to enter a number of useful regular expressions at the cursor instead of typing them manually.
    - You can click Regex Editor to open the Add Regular Expression dialog box and use it to construct the URL expression.

Web Services Interoperability Check

The Web Services Interoperability (WS-I) check examines both requests and responses for adherence to the WS-I standard, and blocks those requests and responses that do not adhere to this standard. The purpose of the WS-I check is to block requests that might not interact with other XML appropriately. An attacker can use inconsistencies in interoperability to launch an attack on your XML application.

If you use the wizard or the configuration utility, in the Modify Web Services Interoperability Check dialog box, on the General tab you can enable or disable the Block, Log, Statistics, and Learn actions.

If you use the command-line interface, you can enter the following command to configure the Web Services Interoperability check:

- set appfw profile <name> -xmlWSIAction [**block**] [**log**] [**learn**] [**stats**] [**none**]

To configure individual Web Services Interoperability rules, you must use the configuration utility. On the Checks tab of the Modify Web Services Interoperability Check dialog box, select a rule and click Enable or Disable to enable or disable the rule. You can also click Open to open the Web Services Interoperability Detail message box for that rule. The message box displays read-only information about the rule. You cannot modify or make other configuration changes to any of these rules.

XML Message Validation Check

The XML Message Validation check examines requests that contain XML messages to ensure that they are valid. If a request contains an invalid XML message, the application firewall blocks the request. The purpose of the XML Validation check is to prevent an attacker from using specially constructed invalid XML messages to breach the security of your application.

If you use the wizard or the configuration utility, in the Modify XML Message Validation Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the XML Message Validation Check:

- set appfw profile <name> -xmlValidationAction [**block**] [**log**] [**stats**] [**none**]

You must use the configuration utility to configure the other XML Validation check settings. In the Modify XML Message Validation Check dialog box, on the Checks tab, you can configure the following settings:

- **XML Message Validation.** Use one of the following options to validate the XML message:
  - **SOAP Envelope.** Validate only the SOAP envelope of XML messages.
  - **WSDL.** Validate XML messages by using an XML SOAP WSDL. If you choose WSDL validation, in the WSDL Object drop-down list you must choose a WSDL. If you want to validate against a WSDL that has not already been imported to the application firewall, you can click the Import button to open the Manage WSDL Imports dialog box and import your WSDL. See "WSDL" for more information.
    - If you want to validate the entire URL, leave the Absolute radio button in the End Point Check button array selected. If you want to validate only the portion of the URL after the host, select the Relative radio button.
    - If you want the application firewall to enforce the WSDL strictly, and not allow any additional XML headers not defined in the WSDL, you must clear the Allow additional headers not defined in the WSDL check box.

      Caution: If you uncheck the Allow Additional Headers not defined in the WSDL check box, and your WSDL does not define all XML headers that your protected XML application or Web 2.0 application expects or that a client sends, you may block legitimate access to your protected service.
  - **XML Schema.** Validate XML messages by using an XML schema. If you choose XML schema validation, in the XML Schema Object drop-down list you must choose an XML schema. If you want to validate against an XML schema that has not already been imported to the application firewall, you can click the Import button to open the Manage XML Schema Imports dialog box and import your WSDL. See "WSDL" for more information.
- **Response Validation.** By default, the application firewall does not attempt to validate responses. If you want to validate responses from your protected application or Web 2.0 site, select the Validate Response check box. When you do, the Reuse the XML Schema

specified in request validation check box and the XML Schema Object drop-down list are activated.

- Check the Reuse XML Schema check box to use the schema you specified for request validation to do response validation as well.

  Note: If you check this check box, the XML Schema Object drop-down list is grayed out.

- If you want to use a different XML schema for response validation, use the XML Schema Object drop-down list to select or upload that XML schema .

XML SOAP Fault Filtering Check

The XML SOAP Fault Filtering check examines responses from your protected web services and filters out XML SOAP faults. This prevents leaking of sensitive information to attackers.

If you use the wizard or the configuration utility, in the Modify XML SOAP Fault Filtering Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions, and the Remove action, which removes SOAP faults before forwarding the response to the user.

If you use the command-line interface, you can enter the following command to configure the XML SOAP Fault Filtering Check:

set appfw profile <name> -XMLSOAPFaultAction [**block**] [**log**] [**stats**] [**none**]

You cannot configure exceptions to the XML SOAP Fault Filtering check. You can only enable or disable it.

Profiles

A profile is a collection of security settings that are used to protect specific types of web content or specific parts of your web site. In a profile, you determine how the application firewall applies each of its filters (or checks) to requests to your web sites, and responses from them. There are three types of profile:

- **HTML.** Protects HTML-based web pages.
- **XML.** Protects XML-based web services and web sites.
- **Web 2.0.** Protects Web 2.0 content that combines HTML and XML content, such as ATOM feeds, blogs, and RSS feeds.

The application firewall has a number of security checks, all of which can be enabled or disabled, and configured in a number of ways in each profile. Each profile also has a number of settings that control how it handles different types of content. Finally, rather than manually configuring all of the security checks, you can enable and configure the learning feature. This feature observes normal traffic to your protected web sites for a period of time, and uses those observations to provide you with a tailored list of recommended exceptions (*relaxations*) to some security checks, and additional rules for other security checks.

During initial configuration, whether by using the Application Firewall Wizard or manually, you create one general purpose profile to protect all content on your web sites that is not covered by a more specific profile. After that, you can create as many specific profiles as you want to protect more specialized content.

The Profiles pane contains the following elements:

Name. Displays all the application firewall profiles configured in the appliance.

Type. Displays the profile type: HTML, XML, or Web 2.0.

Add. "Add a new profile."

Open. "Configure the selected profile's" security checks, settings, and learning.

Remove. Remove the selected profile.

Change Profile Type. "Change the profile type" of the selected profile.

Statistics. View the statistics for the selected profile.

Creating Application Firewall Profiles

Creating an application firewall profile is simple, and requires that you specify only two options. You specify basic or advanced *defaults*, the default configuration for the various security checks and settings that are part of a profile, and choose the profile *type* to match the type of content that the profile is intended to protect.

There are three profile types:

- **HTML.** Protects standard HTML-based web sites.
- **XML.** Protects XML-based web services and web sites.
- **Web 2.0 (HTML XML).** Protects sites that contain both HTML and XML elements, such as ATOM feeds, blogs, and RSS feeds.

An application firewall profile name cannot be the same as the name assigned to any other profile or action in any feature on the NetScaler appliance. Certain action or profile names are assigned to built-in actions or profiles, and can never be used for user profiles. (A complete list of disallowed names can be found in the Application Firewall ProfileSupplemental Information.) If you attempt to create a profile with a name that has already been used for an action or a profile, an error message is displayed and the profile is not created.

To create an application firewall profile by using the command line interface

At the command prompt, type the following commands:

- add appfw profile <name> [-defaults (**basic** | **advanced**)]
- set appfw profile <name> -type (**HTML** | **XML** | **HTML XML**)
- save ns config

Example

The following example adds a profile named `pr-basic`, with basic defaults, and assigns a profile type of `HTML`. This is the appropriate initial configuration for a profile to protect an HTML Web site.

```
add appfw profile pr-basic -defaults basic
set appfw profile pr-basic -type HTML
save ns config
```

Parameters for Creating Application Firewall Profiles

name (Profile Name)

A name for the profile. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.

defaults (Defaults)

You can choose one of two default configurations when you create a profile: Basic or Advanced. A profile created with basic defaults should protect most Web sites while requiring little additional configuration. A profile created with advanced defaults is intended to protect more complex Web sites requiring additional configuration. You can modify either type of default configuration.

type (Profile Type)

The type of content that the profile will protect. There are three types of profile: **HTML** (HTML), **XML** (XML), or **Web 2.0** (HTML XML). If you are unsure what types of content your profile will protect, you can specify Web 2.0 to make the full range of Application Firewall security checks available to protect your Web site.

To create an application firewall profile by using the configuration utility

Creating an application firewall profile requires that you specify only a few configuration details.

1. In the navigation pane, expand Application Firewall, and then select Profiles.
2. In the details pane, click Add.
3. In the Create Application Firewall Profile dialog box, type a name for your profile.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.
4. Choose the profile type from the drop-down list.

   The profile types are HTML (for HTML-based Web sites), XML (for XML-based Web services) and Web 2.0 (for blogs, RSS feeds, wikis, and other sites that contain both HTML and XML).

   Note: If you are unsure what types of content your profile will protect, you can choose Web 2.0 to make the full range of Application Firewall security checks available to protect your Web site.
5. If you plan to use the learning feature or to enable and configure a large number of advanced protections, select Advanced. Otherwise, select Basic.

You probably should use the learning feature if you plan to configure either of the SQL injection checks, either of the cross-site scripting checks, any check that provides protection against Web form attacks, or the cookie consistency check. Unless you include the proper exceptions for your protected Web sites when configuring these checks, they can block legitimate traffic. Anticipating all of the necessary exceptions without creating any that are too broad is difficult. The learning feature makes this task much easier.

6. Click Create, and then click Close.

Configuring Application Firewall Profiles

The primary tasks in configuring an application firewall profile are configuring the security checks, which are called *deep protections* or *advanced protections* in the application firewall wizard. In addition, you can configure a number of other settings that control the behavior, not of a single security check, but the application firewall feature.

For more information about the application firewall security checks, see "Advanced Protections."

To configure an application firewall profile by using the command line

At the command prompt, type the following commands:

- set appfw profile <name> <arg1> [<arg2> ...]

  where:

  - <arg1> = a parameter and any associated options.
  - <arg2> = a second parameter and any associated options.
  - ... = additional parameters and options.

  For descriptions of the parameters to use when configuring specific security checks, see "Advanced Protections."

- save ns config

Example

The following example shows how to configure an HTML profile created with basic defaults to begin protecting a simple HTML-based Web site. This example turns on logging and maintenance of statistics for most security checks, but enables blocking only for those checks that have extremely low false positive rates and require no special configuration. It also turns on transformation of unsafe HTML and unsafe SQL, which prevents attacks but does not block requests to your Web sites. With logging and statistics enabled, you can later review the logs to determine whether to enable blocking for a specific security check.

```
set appfw profile -startURLAction log stats
set appfw profile -denyURLAction block log stats
set appfw profile -cookieConsistencyAction log stats
set appfw profile -crossSiteScriptingAction log stats
set appfw profile -crossSiteScriptingTransformUnsafeHTML ON
set appfw profile -fieldConsistencyAction log stats
set appfw profile -SQLInjectionAction log stats
set appfw profile -SQLInjectionTransformSpecialChars ON
```

```
set appfw profile -SQLInjectionOnlyCheckFieldsWithSQLChars ON
set appfw profile -SQLInjectionParseComments checkall
set appfw profile -fieldFormatAction log stats
set appfw profile -bufferOverflowAction block log stats
set appfw profile -CSRFtagAction log stats
save ns config
```

To configure an application firewall profile by using the configuration utility

1. Navigate to Application Firewall > Profiles.
2. In the details pane, select the profile that you want to configure, and then click Open.
3. In the Configure Application Firewall Profile dialog box, on the Security Checks tab, configure the security checks.
   - To enable or disable an action for a check, in the list, select or clear the check box for that action.
   - To configure other parameters for those checks that have them, in the list, click the blue chevron to the far right of that check. In the dialog box that appears, configure the parameters. These vary from check to check.

     You can also select a check and, at the bottom of the dialog box, click Open to display the Configure Relaxation dialog box or Configure Rule dialog box for that check. These dialog boxes also vary from check to check. Most of them include a Checks tab and a General tab. If the check supports relaxations or user-defined rules, the Checks tab includes an Add button, which opens yet another dialog box, in which you can specify a relaxation or rule for the check. (A relaxation is a rule for exempting specified traffic from the check.) If relaxations have already been configured, you can select one and click Open to modify it.

     For more information about the Configure Relaxation or Configure Rule dialog boxes, see "Configuring an Application Firewall Rule or Relaxation."
   - To review learned exceptions or rules for a check, select the check, and then click Learned Violations. In the Manage Learned Rules dialog box, select each learned exception or rule in turn.
     - To edit the exception or rule, and then add it to the list, click Edit & Deploy.
     - To accept the exception or rule without modification, click Deploy.
     - To remove the exception or rule from the list, click Skip.
   - To refresh the list of exceptions or rules to be reviewed, click Refresh.
   - To open the Learning Visualizer and use it to review learned rules, click Visualizer.
   - To review the log entries for connections that matched a check, select the check, and then click Logs. You can use this information to determine which checks are matching attacks, so that you can enable blocking for those checks. You can also use this information to determine which checks are matching legitimate traffic, so that you can configure an appropriate exemption to allow those legitimate connections. For more information about the logs, see "Logs, Statistics, and Reports."
   - To completely disable a check, in the list, clear all of the check boxes to the right of that check.
4. On the Settings tab, configure the profile settings.

- To associate the profile with the set of signatures that you previously created and configured, under Common Settings, choose that set of signatures in the Signatures drop-down list.

  Note: You may need to use the scroll bar on the right of the dialog box to scroll down to display the Common Settings section.

- To configure an HTML or XML Error Object, select the object from the appropriate drop-down list.

  Note: You must first upload the error object that you want to use in the Imports pane. For more information about importing error objects, see "Imports."

- To configure the default XML Content Type, type the content type string directly into the Default Request and Default Response text boxes, or click Manage Allowed Content Types to manage the list of allowed content types. ">>More...."

5. If you want to use the learning feature, click Learning, and configure the learning settings for the profile, as described in "Configuring and Using the Learning Feature".

6. Click OK to save your changes and return to the Profiles pane.

Managing Content Types

Web servers usually add a Content-Type header that contains a MIME/type definition for the type of content in each file that the web server serves to users. Web servers serve many different types of content. For example, standard HTML is assigned the "text/html" MIME type. JPG images are assigned the "image/jpeg" or "image/jpg" content type. A normal web server can serve dozens or hundreds of different types of content, all defined in the Content Type header by an assigned MIME/type.

Many application firewall filtering rules are designed to filter specific types of content. Because filtering rules that apply to one type of content (such as HTML) are often inappropriate when filtering a different type of content (such as images), the application firewall attempts to determine the content type of requests and responses before it filters them. When a web server or browser does not add a Content-Type header to a request or response, the application firewall applies a default content type to the connection and filters the content accordingly.

The default content type is normally "application/octet-stream", the most generic MIME/type definition.This MIME/type is appropriate for any type of content that a web server is likely to serve, but also does not provide much information to the application firewall to allow it to choose appropriate filtering. If a protected web server on your network is configure to add accurate content type headers to the content it serves, or serves only one type of content, you can create a profile for that web server and assign a different default content type to it to improve both the speed and the accuracy of filtering.

You can also configure a list of allowed response content types for a specific profile. When this feature is configured, if the application firewall filters a response that does not match one of the allowed content types, it blocks the response.

Requests must always be of either the "application/x-www-form-urlencoded" or "multipart/form-data" types. The application firewall bypasses any request that has any other content type designated.

Note: You cannot include the "application/x-www-form-urlencoded" or "multipart/form-data" content types on the allowed response content types list.

To set the default request content type by using the command line interface

At the command prompt, type the following commands:

- set appfw profile <name> -requestContentType <type>
- save ns config

Example

The following example sets the "text/html" content type as the default for the specified profile:

```
set appfw profile profile1 -requestContentType "text/html"
save ns config
```

To remove the user-defined default request content type by using the command line interface

At the command prompt, type the following commands:

- unset appfw profile <name> -requestContentType <type>
- save ns config

Example

The following example unsets the default content type of "text/html" for the specified profile, allowing the type to revert to "application/octet-stream":

```
unset appfw profile profile1 -requestContentType "text/html"
save ns config
```

To set the default response content type by using the command line interface

At the command prompt, type the following commands:

- set appfw profile <name> -responseContentType <type>
- save ns config

Example

The following example sets the "text/html" content type as the default for the specified profile:

```
set appfw profile profile1 -responseContentType "text/html"
save ns config
```

To remove the user-defined default response content type by using the command line interface

At the command prompt, type the following commands:

- unset appfw profile <name> -responseContentType <type>
- save ns config

Example

The following example unsets the default content type of "text/html" for the specified profile, allowing the type to revert to "application/octet-stream":

```
unset appfw profile profile1 -responseContentType "text/html"
save ns config
```

To add a content type to the allowed content types list by using the command line interface

At the command prompt, type the following commands:

- bind appfw profile <name> -ContentType <contentTypeName>
- save ns config

Example

The following example adds the "text/shtml" content type to the allowed content types list for the specified profile:

```
bind appfw profile profile1 -contentType "text/shtml"
save ns config
```

To remove a content type from the allowed content types list by using the command line interface

At the command prompt, type the following commands:

- unbind appfw profile <name> -ContentType <contentTypeName>
- save ns config

Example

The following example removes the "text/shtml" content type from the allowed content types list for the specified profile:

```
unbind appfw profile profile1 -contentType "text/shtml"
save ns config
```

To manage the default and allowed content types by using the configuration utility

1. Navigate to Application Firewall > Profiles.
2. In the details pane, select the profile that you want to configure, and then click Open. The Configure Application Firewall Profile dialog box is displayed.
3. In the Configure Application Firewall Profile dialog box, click the Settings tab
4. On the Settings tab, scroll down about halfway to the Content Type area.
5. In the Content Type area, configure the default request or response content type:
   - To configure the default request content type, type the MIME/type definition of the content type you want to use in the Default Request text box.
   - To configure the default response content type, type the MIME/type definition of the content type you want to use in the Default Response text box.
   - To create a new allowed content type, click Add. The Add Allowed Content Type dialog box is displayed.
   - To edit an existing allowed content type, select that content type, and then click Open. The Modify Allowed Content Type dialog box is displayed.
6. To manage the allowed content types, click Manage Allowed Content Types.
7. To add a new content type or modify an existing content type, click Add or Open, and in the Add Allowed Content Type or Modify Allowed Content Type dialog box, do the following steps.
   a. Select/clear the Enabled check box to include the content type in, or exclude it from, the list of allowed content types.
   b. In the Content Type text box, type a regular expression that describes the content type that you want ot add, or change the existing content type regular expression.

      Content types are formatted exactly as MIME type descriptions are.

      Note: You can include any valid MIME type on the allowed contents type list. Since many types of document can contain active content and therefore could potentially contain malicious content, you should exercise caution when adding MIME types to this list.
   c. In the Comments text box, add an optional comment that describes the reason for adding this particular MIME type to the allowed contents type list.
   d. Click Create or OK to save your changes.
8. Click Close to close the Manage Allowed Content Types dialog box and return to the Settings tab.
9. To manage the content types for Safe Commerce, click Manage Content Types for Safe Commerce, fill out the Exclude Content Types from Inspection for Safe Commerce dialog box as described in the previous step and substeps, and then click Close. (The

dialog boxes are nearly identical.)

10. Click OK to save your changes.

Changing an Application Firewall Profile Type

If you chose the wrong profile type for an application firewall profile, or the type of content on the protected web site has changed, you can change the profile type.

Note: When you change the profile type, you lose all configuration settings and learned relaxations or rules for the features that the new profile type does not support. For example, if you change the profile type from Web 2.0 to XML, you lose any configuration options for Start URL, Form Field Consistency Check, and the other HTML-specific security checks. The configuration for any options that is supported by both the old and the new profile types remains unchanged.

To change an application firewall profile type by using the command line interface

At the command prompt, type the following commands:

- set appfw profile <name> -type (**HTML** | **XML** | **HTML XML**)
- save ns config

Example

The following example changes the type of a profile named `pr-basic`, from `HTML` to `HTML XML`, which is equivalent to the Web 2.0 type in the configuration utility.

```
set appfw profile pr-basic -type HTML XML
save ns config
```

To change an application firewall profile type by using the configuration utility.

1. In the navigation pane, expand Application Firewall, and then select Profiles.
2. In the details pane, click Change Profile Type.
3. In the Change Application Firewall Profile Type dialog box, Profile Type drop-down list, select a new profile type.
4. Click OK to save your changes and return to the Profiles pane.

Exporting and Importing an Application Firewall Profile

You can export application firewall profiles to your local computer as files, and import previously exported profile files. You might want to configure a single application firewall in a test bed configuration and then export the profile or profiles so that you can import the profile configuration to your production NetScaler appliances. You might also want to export a profile to back up your configuration before making changes so that you can easily roll the configuration back to a know state if necessary.

To export an application firewall profile by using the command line interface

At the command prompt, type the following command:

archive appfw profile <name> <archivename>

Example

Assuming that your local computer uses the Windows 7 operating system, and you are logged onto your local computer as "administrator", the following example exports a profile named `pr-basic` to the home directory.

```
archive appfw profile pr-basic "c:\users\administrator\pr-basic.tgz"
```

To export an application firewall profile by using the configuration utility

1. Navigate to Application Firewall > Profiles.
2. In the details pane, select a profile to export, and then click Export.
3. Choose the local path and filename for the exported file.
   - You can accept the default choice, which consists of the path to your home directory or folder and a filename of the profile name plus the extension `.tgz`, which indicates a Unix-style `tar` archive that is compressed by `gzip`.
   - You can type a new path and/or file name. The path must exist, and the filename must be a valid filename in your local computer's operating system. If you do not specify the `.tgz` extension, it is added automatically.
   - You can use the Browse dialog to locate the path and save the file under the default filename. (Recommended)
4. Click Export. The profile is exported and saved to your computer under the path and file name that you designated.

To import an application firewall profile by using the command line interface

At the command prompt, type the following command:

restore appfw profile <archivename>

Example

Assuming that your local computer uses the Windows 7 operating system, and you are logged onto your local computer as "administrator", the following example imports a profile named `pr-basic.tgz`, located in the home directory, to the application firewall and installs it as a profile named pr-basic.

restore appfw profile "c:\users\administrator\pr-basic.tgz"

To import an application firewall profile by using the configuration utility

1. Navigate to Application Firewall > Profiles.
2. In the details pane, click Import.
3. Choose the import type.
    - To import from a URL, accept the default selection, Import from URL.
    - To import a local file, select Import from Local File.
4. Specify the location of the profile to be imported.
    - You can type a URL, or a path and/or file name for the profile to be imported. The URL or path and filename must exist.
    - If you are importing a local file, you can use the Browse dialog to locate the path and filename of the profile to be imported. (Recommended)
5. Click Import. The profile is imported and appears in the Profiles pane.

Configuring and Using the Learning Feature

The learning feature is a repetitive pattern filter that observes activity on a web site or application protected by the application firewall, to determine what constitutes normal activity on that web site or application. It then generates a list of suggested rules or exceptions (*relaxations*) for those security checks that include support for the learning feature. Users normally find it easier to configure relaxations by using the learning feature than by entering the necessary relaxations manually.

You perform two different types of activities when using the learning feature. First, you enable and configure the feature to use it. Second, after the feature has been enabled and has processed a certain amount of traffic to your protected web sites, you review the list of suggested rules and relaxations (*learned rules*) and mark each with one of the following designations:

- **Edit & Deploy.** The rule is pulled into the Edit dialog box so that you can modify it, and the modified form is deployed.
- **Deploy.** The unmodified learned rule is placed on the list of rules or relaxations for this security check.
- **Skip.** The learned rule is placed on a list of rules or relaxations that are not deployed, and that should not be learned again.

Although you can use the command line interface for basic configuration of the learning feature, the feature is designed primarily for configuration through the Application Firewall wizard or the configuration utility. You can perform only limited configuration of the learning feature by using the command line.

The wizard integrates configuration of learning features with configuration of the application firewall as a whole, and is therefore the easiest method for configuring this feature on a new NetScaler appliance or when managing a simple application firewall configuration. The configuration utility visualizer and manual interface both provide direct access to all learned rules for all security checks, and are therefore often preferable when you must review learned rules for a large number of security checks.

The learning database is limited to 20 MB in size, which is reached after approximately 2,000 learned rules or relaxations are generated per security check for which learning is enabled. If you do not regularly review and either approve or ignore learned rules and this limit is reached, an error is logged to the NetScaler log and no more learned rules are generated until you review the existing learned rules and relaxations.

If learning stops because the database has reached its size limit, you can restart learning either by reviewing the existing learned rules and relaxations or by resetting the learning data. After learned rules or relaxations are approved or ignored, they are removed from the database. After you reset the learning data, all existing learning data is removed from the database and it is reset to its minimum size. When the database falls below 20 MB in size, learning restarts automatically.

To configure the learning settings by using the command line interface

Specify the application firewall profile to be configured and, for each security check that you want to include in that profile, specify the minimum threshold or the percent threshold. The minimum threshold is an integer representing the minimum number of user sessions that the application firewall must process before it learns a rule or relaxation (default: 1). The percent threshold is an integer representing the percentage of user sessions in which the application firewall must observe a particular pattern (URL, cookie, field, attachment, or rule violation) before it learns a rule or relaxation (default: 0). Use the following commands:

- set appfw learningsettings <profileName> [-startURLMinThreshold <positive_integer>] [-startURLPercentThreshold <positive_integer>] [-cookieConsistencyMinThreshold <positive_integer>] [-cookieConsistencyPercentThreshold <positive_integer>] [-CSRFtagMinThreshold <positive_integer>] [-CSRFtagPercentThreshold <positive_integer>] [-fieldConsistencyMinThreshold <positive_integer>] [-fieldConsistencyPercentThreshold <positive_integer>] [-crossSiteScriptingMinThreshold <positive_integer>] [-crossSiteScriptingPercentThreshold <positive_integer>] [-SQLInjectionMinThreshold <positive_integer>] [-SQLInjectionPercentThreshold <positive_integer>] [-fieldFormatMinThreshold <positive_integer>] [-fieldFormatPercentThreshold <positive_integer>] [-XMLWSIMinThreshold <positive_integer>] [-XMLWSIPercentThreshold <positive_integer>] [-XMLAttachmentMinThreshold <positive_integer>] [-XMLAttachmentPercentThreshold <positive_integer>]

- save ns config

Example

The following example enables and configures the learning settings in the profile pr-basic for the HTML SQL Injection security check. This is an appropriate initial test bed learning configuration, where you have complete control over the traffic that is sent to the application firewall.

```
set appfw learningsettings pr-basic -SQLInjectionMinThreshold 10
set appfw learningsettings pr-basic -SQLInjectionPercentThreshold 70
save ns config
```

To reset learning settings to their defaults by using the command line interface

To remove any custom configuration of the learning settings for the specified profile and security check, and return the learning settings to their defaults, at the command prompt type the following commands:

- unset appfw learningsettings <profileName> [-startURLMinThreshold] [-startURLPercentThreshold] [-cookieConsistencyMinThreshold] [-cookieConsistencyPercentThreshold] [-CSRFtagMinThreshold]

[-CSRFtagPercentThreshold] [-fieldConsistencyMinThreshold]
[-fieldConsistencyPercentThreshold] [-crossSiteScriptingMinThreshold]
[-crossSiteScriptingPercentThreshold] [-SQLInjectionMinThreshold]
[-SQLInjectionPercentThreshold] [-fieldFormatMinThreshold]
[-fieldFormatPercentThreshold] [-XMLWSIMinThreshold] [-XMLWSIPercentThreshold]
[-XMLAttachmentMinThreshold] [-XMLAttachmentPercentThreshold]

- save ns config

To display the learning settings for a profile by using the command line interface

At the command prompt, type the following command:

show appfw learningsettings <profileName>

To display unreviewed learned rules or relaxations for a profile by using the command line interface

At the command prompt, type the following command:

show appfw learningdata <profileName> <securityCheck>

To remove specific unreviewed learned rules or relaxations from the learning database by using the command line interface

At the command prompt, type the following command:

rm appfw learningdata <profileName> (-startURL <expression> | -cookieConsistency <string> | (-fieldConsistency <string> <formActionURL>) | (-crossSiteScripting <string> <formActionURL>) | (-SQLInjection <string> <formActionURL>) | (-fieldFormat <string> <formActionURL>) | (-CSRFTag <expression> <CSRFFormOriginURL>) | -XMLDoSCheck <expression> | -XMLWSICheck <expression> | -XMLAttachmentCheck <expression>) [-TotalXMLRequests]

Example

The following example removes all unreviewed learned relaxations for the pr-basic profile, HTML SQL Injection security check, that apply to the LastName form field.

rm appfw learningdata pr-basic -SQLInjection LastName

To remove all unreviewed learned data by using the command line interface

At the command prompt, type the following command:

reset appfw learningdata

To export learning data by using the command line interface

At the command prompt, type the following command:

export appfw learningdata <profileName> <securitycheck> [-target <string>]

Example

The following example exports learned relaxations for the `pr-basic` profile and the HTML SQL Injection security check to a comma-separated values (CSV) format file in the `/var/learnt_data/` directory under the filename specified in the `-target` parameter.

export appfw learningdata pr-basic SQLInjection -target sqli_ld

To configure the Learning feature by using the configuration utility

1. In the navigation pane, expand Application Firewall, and then select Profiles.
2. In the Profiles pane, select the profile, and then click Open.
3. Click the Learning tab. At the top of the Learning tab is list of the security checks that are available in the current profile and that support the learning feature.
4. To configure the learning thresholds, select a security check, and then type the appropriate values in the following text boxes:
   - **Minimum number threshold.** Depending on which security check's learning settings you are configuring, the minimum number threshold might refer to the minimum number of total user sessions that must be observed, the minimum number of requests that must be observed, or the minimum number of times a specific form field must be observed, before a learned relaxation is generated. Default: 1
   - **Percentage of times threshold.** Depending on which security check's learning settings you are configuring, the percentage of times threshold might refer to the percentage of total observed user sessions that violated the security check, the percentage of requests, or the percentage of times a form field matched a particular field type, before a learned relaxation is generated. Default: 0
5. To remove all learned data and reset the learning feature, so that it must start its observations again from the beginning, click Remove All Learned Data.

   Note: This button removes only learned recommendations that have not been reviewed and either approved or skipped. It does not remove learned relaxations that have been accepted and deployed.
6. Click Close to return to the Configure Application Firewall Profile dialog box.
7. Click Close to close the Configure Application Firewall Profile dialog box, and return to the Application Firewall Profile screen.

To review learned rules or relaxations by using the configuration utility

1. In the navigation pane, expand Application Firewall, and then select Profiles.
2. Select the security check for which you want to review learned rules or relaxations, and then click Manage Rules.
3. In the Manage Learned Rules dialog box, choose how you want to review the learned rules.
   - To review the actual learned patterns as displayed in the window, do nothing and proceed to the next step.
   - To review the learned data hierarchically as a branching tree, enabling you to choose general patterns that match many of the learned patterns, click Visualizer.
4. If you have chosen to review actual learned patterns, perform the following steps.
   a. Select the first learned relaxation and choose how to handle it.
      - To modify and then accept the relaxation, click Edit & Deploy, edit the relaxation regular expression, and then click OK.
      - To accept the relaxation without modifications, click Deploy.
      - To remove the relaxation from the list without deploying it, click Skip.
   b. Repeat the previous step to review each additional learned relaxation.
5. If you have chosen to use the Learning Visualizer, perform the following steps.
   a. In the branching hierarchical display, select a node that contains a learned pattern, and choose how to handle it.

      The screen area beneath the tree structure, under Regex of Selected Node, displays a generalized expression that matches all of the patterns in that node. If you want to display an expression that matches just one of the branches or just one of the leaves, select that branch or leaf.

      - To modify and then accept the learned relaxation, click Edit & Deploy, edit the relaxation regular expression, and then click OK.
      - To accept the relaxation without modifications, click Deploy.
      - To remove the modification from the list without deploying it, click Skip.
   b. Repeat the previous step to review other portions of the display.
   c. Click Close to return to the Manage Learned Rules dialog box.
6. Click Close to return to the Configure Application Firewall Profile dialog box.
7. Click Close to close the Configure Application Firewall Profile dialog box, and return to the Application Firewall Profile screen.

Supplemental Information about Profiles

Following is supplemental information about particular aspects of application firewall profiles. This information explains how to include special characters in a security check rule or relaxation, and how to use variables when configuring profiles.

Configuration Variable Support

Instead of using static values, to configure the application firewall's security checks and settings, you can now use standard NetScaler named variables. By creating variables, you can more easily export and then import configurations to new NetScaler appliances, or update existing NetScaler appliances from a single set of configuration files. This simplifies updates when you use a test bed setup to develop a complex application firewall configuration that is tuned for your local network and servers and then transfer that configuration to your production NetScaler appliances.

You create application firewall configuration variables in the same manner as you do any other NetScaler named variables, following standard NetScaler conventions. To create a named expression variable by using the configuration utility, you use the "Add Expression dialog box." To create a named expression variable by using the NetScaler command line, you use the `add expression` command followed by the appropriate parameter.

The following URLs and expressions can be configured with variables instead of static values:

- **Start URL** (-starturl)
- **Deny URL** (-denyurl)
- **Form Action URL** for *Form Field Consistency Check* (-fieldconsistency)
- **Action URL** for *XML SQL Injection Check* (-xmlSQLInjection)
- **Action URL** for *XML Cross-Site Scripting Check* (-xmlXSS)
- **Form Action URL** for *HTML SQL Injection Check* (-sqlInjection)
- **Form Action URL** for *Field Format Check* (-fieldFormat)
- **Form Origin URL** and **Form Action URL** for *Cross-Site Request Forgery (CSRF) Check* (-csrfTag)
- **Form Action URL** for *HTML Cross-Site Scripting Check* (-crossSiteScripting)
- **Safe Object** (-safeObject)
- **Action URL** for *XML Denial-of-Service (XDoS) check* (-XMLDoS)
- **URL** for *Web Services Interoperability check* (-XMLWSIURL)

- **URL** for *XML Validation check* (-XMLValidationURL)
- **URL** for *XML Attachment check* (-XMLAttachmentURL)

For more information, see "Policies and Expressions."

To use a variable in the configuration, you enclose the variable name between two at (@) symbols and then use it exactly as you would the static value that it replaces. For example, if you are configuring the Deny URL check by using the configuration utility and want to add the named expression variable myDenyURL to the configuration, you would type `@myDenyURL@` into the Add Deny URL dialog box, Deny URL text area. To do the same task by using the NetScaler command line, you would type `add appfw profile <name> -denyURLAction @myDenyURL@`.

PCRE Character Encoding Format

The NetScaler operating system supports direct entry of characters in the printable ASCII character set only—characters with hexadecimal codes between HEX 20 (ASCII 32) and HEX 7E (ASCII 127). To include a character with a code outside that range in your application firewall configuration, you must enter its UTF-8 hexadecimal code as a PCRE regular expression.

A number of character types require encoding using a PCRE regular expression if you include them in your application firewall configuration as a URL, form field name, or Safe Object expression. They include:

- **Upper-ASCII characters.** Characters with encodings from HEX 7F (ASCII 128) to HEX FF (ASCII 255). Depending on the character map used, these encodings can refer to control codes, ASCII characters with accents or other modifications, non-Latin alphabet characters, and symbols not included in the basic ASCII set. These characters can appear in URLs, form field names, and safe object expressions.
- **Double-Byte characters.** Characters with encodings that use two 8-byte words. Double-byte characters are used primarily for representing Chinese, Japanese, and Korean text in electronic format. These characters can appear in URLs, form field names, and safe object expressions.
- **ASCII control characters.** Non-printable characters used to send commands to a printer. All ASCII characters with hexadecimal codes less than HEX 20 (ASCII 32) fall into this category. These characters should never appear in a URL or form field name, however, and would rarely if ever appear in a safe object expression.

The NetScaler appliance does not support the entire UTF-8 character set, but only the characters found in the following eight charsets:

- **English US (ISO-8859-1).** Although the label reads, “English US,” the application firewall supports all characters in the ISO-8859-1 character set, also called the Latin-1 character set. This character set fully represents most modern western European languages and represents all but a few uncommon characters in the rest.
- **Chinese Traditional (Big5).** The application firewall supports all characters in the BIG5 character set, which includes all of the Traditional Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in Hong Kong, Macau, Taiwan, and by many people of Chinese ethnic heritage who live outside of mainland China.

- **Chinese Simplified (GB2312).** The application firewall supports all characters in the GB2312 character set, which includes all of the Simplified Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in mainland China.

- **Japanese (SJIS).** The application firewall supports all characters in the Shift-JIS (SJIS) character set, which includes most characters (ideographs) commonly used in modern Japanese.

- **Japanese (EUC-JP).** The application firewall supports all characters in the EUC-JP character set, which includes all characters (ideographs) commonly used in modern Japanese.

- **Korean (EUC-KR).** The application firewall supports all characters in the EUC-KR character set, which includes all characters (ideographs) commonly used in modern Korean.

- **Turkish (ISO-8859-9).** The application firewall supports all characters in the ISO-8859-9 character set, which includes all letters used in modern Turkish.

- **Unicode (UTF-8).** The application firewall supports certain additional characters in the UTF-8 character set, including those used in modern Russian.

When configuring the application firewall, you enter all non-ASCII characters as PCRE-format regular expressions using the hexadecimal code assigned to that character in the UTF-8 specification. Symbols and characters within the normal ASCII character set, which are assigned single, two-digit codes in that character set, are assigned the same codes in the UTF-8 character set. For example, the exclamation point (!), which is assigned hex code 21 in the ASCII character set, is also hex 21 in the UTF-8 character set. Symbols and characters from another supported character set have a paired set of hexadecimal codes assigned to them in the UTF-8 character set. For example, the letter a with an acute accent (á) is assigned UTF-8 code C3 A1.

The syntax you use to represent these UTF-8 codes in the application firewall configuration is “\xNN” for ASCII characters; “\xNN\xNN” for non-ASCII characters used in English, Russian, and Turkish; and “\xNN\xNN\xNN” for characters used in Chinese, Japanese, and Korean. For example, if you want to represent a ! in an application firewall regular expression as a UTF-8 character, you would type \x21. If you want to include an á, you would type \xC3\xA1.

Note: Normally you do not need to represent ASCII characters in UTF-8 format, but when those characters might confuse a web browser or an underlying operating system, you can use the character’s UTF-8 representation to avoid this confusion. For example, if a URL contains a space, you might want to encode the space as \x20 to avoid confusing certain browsers and web server software.

Below are examples of URLs, form field names, and safe object expressions that contain non-ASCII characters that must be entered as PCRE-format regular expressions to be included in the application firewall configuration. Each example shows the actual URL, field name, or expression string first, followed by a PCRE-format regular expression for it.

- A URL containing extended ASCII characters.

  Actual URL: `http://www.josénuñez.com`

  Encoded URL: `^http://www[.]jos\xC3\xA9nu\xC3\xB1ez[.]com$`

- Another URL containing extended ASCII characters.

  Actual URL: `http://www.example.de/trömso.html`

  Encoded URL: `^http://www[.]example[.]de/tr\xC3\xB6mso[.]html$`

- A form field name containing extended ASCII characters.

  Actual Name: `nome_do_usuário`

  Encoded Name: `^nome_do_usu\xC3\xA1rio$`

- A safe object expression containing extended ASCII characters.

  Unencoded Expression `[A-Z]{3,6}¥[1-9][0-9]{6,6}`

  Encoded Expression: `[A-Z]{3,6}\xC2\xA5[1-9][0-9]{6,6}`

You can find a number of tables that include the entire Unicode character set and matching UTF-8 encodings on the Internet. A useful web site that contains this information is located at the following URL:

http://www.utf8-chartable.de/unicode-utf8-table.pl

For the characters in the table on this web site to display correctly, you must have an appropriate Unicode font installed on your computer. If you do not, the visual display of the character may be in error. Even if you do not have an appropriate font installed to display a character, however, the description and the UTF-8 and UTF-16 codes on this set of web pages will be correct.

Inverted PCRE Expressions

In addition to matching content that contains a pattern, you can match content that does not contain a pattern by using an inverted PCRE expression. To invert an expression, you simply include an exclamation point (!) followed by white space as the first character in the expression.

Note: If an expression consists only of an exclamation point with nothing following, the exclamation point is treated as a literal character, not syntax indicating an inverted expression.

The following application firewall commands support inverted PCRE expressions:

- Start URL (URL)
- Deny URL (URL)
- Form Field Consistency (form action URL)
- Cookie Consistency (form action URL)
- Cross Site Request Forgery (CSRF) (form action URL)
- HTML Cross-site Scripting (form action URL)

- Field Format (form action URL)
- Field Type (type)
- Confidential Field (URL)

Note: If the security check contains an isRegex flag or check box, it must be set to YES or checked to enable regular expressions in the field. Otherwise the contents of that field are treated as literal and no regular expressions (inverted or not) are parsed.

Disallowed Names for Application Firewall Profiles

The following names are assigned to built-in actions and profiles on the NetScaler appliance, and cannot be used as names for a user-created application firewall profile.

- AGRESSIVE
- ALLOW
- BASIC
- CLIENTAUTH
- COMPRESS
- CSSMINIFY
- DEFLATE
- DENY
- DNS-NOP
- DROP
- GZIP
- HTMLMINIFY
- IMGOPTIMIZE
- JSMINIFY
- MODERATE
- NOCLIENTAUTH
- NOCOMPRESS
- NONE
- NOOP
- NOREWRITE

- RESET
- SETASLEARNNSLOG_ACT
- SETNSLOGPARAMS_ACT
- SETSYSLOGPARAMS_ACT
- SETTMSESSPARAMS_ACT
- SETVPNPARAMS_ACT
- SET_PREAUTHPARAMS_ACT
- default_DNS64_action
- dns_default_act_Cachebypass
- dns_default_act_Drop
- nshttp_default_profile
- nshttp_default_strict_validation
- nstcp_default_Mobile_profile
- nstcp_default_XA_XD_profile
- nstcp_default_profile
- nstcp_default_tcp_interactive_stream
- nstcp_default_tcp_lan
- nstcp_default_tcp_lan_thin_stream
- nstcp_default_tcp_lfp
- nstcp_default_tcp_lfp_thin_stream
- nstcp_default_tcp_lnp
- nstcp_default_tcp_lnp_thin_stream
- nstcp_internal_apps

Policies

The application firewall uses two types of policies: firewall policies and auditing policies. Firewall policies control which traffic is sent to the application firewall. Auditing policies control the log server to which application firewall logs are sent.

Firewall policies can be complex because the policy rule can consist of multiple expressions in the NetScaler expressions language, which is a full-fledged object oriented programming language capable of defining with extreme precision exactly which connections to filter. Because firewall policies operate within the context of the application firewall, they must meet certain criteria that are connected to how the application firewall functions and what traffic is appropriately filtered by it. As long as you keep these criteria in mind, however, firewall policies are similar to policies for other NetScaler features. The instructions here do not attempt to cover all aspects of writing firewall policies, but only provide an introduction to policies and cover those criteria that are unique to the application firewall.

Auditing policies are simple because the policy rule is always `ns_true`. You need only specify the log server that you want to send logs to, the logging levels that you want to use, and a few other criteria that are explained in detail.

Firewall Policies

A firewall policy is a rule associated with a profile. The rule is an expression or group of expressions that defines the types of request/response pairs that the application firewall is to filter by applying the profile. Firewall policy expressions are written in the NetScaler expressions language, an object-oriented programming language with special features to support specific NetScaler functions. The profile is the set of actions that the application firewall is to use to filter request/response pairs that match the rule.

Firewall policies enable you to assign different filtering rules to different types of web content. Not all web content is alike. A simple web site that uses no complex scripting and accesses and handles no private data might require only the level of protection provided by a profile created with basic defaults. Web content that contains JavaScript-enhanced web forms or accesses an SQL database probably requires more tailored protection. You can create a different profile to filter that content, and create a separate firewall policy that can determine which requests are attempting to access that content. You then associate the policy expression with a profile you created and globally bind the policy to put it into effect.

The application firewall processes only HTTP connections, and therefore uses a subset of the overall NetScaler expressions language. The information here is limited to topics and examples that are likely to be useful when configuring the application firewall. Following are links to additional information and procedures for firewall policies:

- For procedures that explain how to create and configure a policy, see "Creating and Configuring Application Firewall Policies."
- For a procedure that explains in detail how to create a policy rule (expression), see "To create or configure an Application Firewall rule (expression)."
- For a procedure that explains how to use the Add Expression dialog box to create a policy rule, see "To add a firewall rule (expression) by using the Add Expression dialog box."
- For a procedure that explains how to view the current bindings for a policy, see "Viewing a Firewall Policy's Bindings."
- For procedures that explain how to bind an application firewall policy, see "Binding Application Firewall Policies."
- For detailed information about the NetScaler expressions language, see "Policies and Expressions."

Creating and Configuring Application Firewall Policies

A firewall policy consists of two elements: a *rule*, and an associated *profile*. The rule selects the HTTP traffic that matches the criteria that you set, and sends that traffic to the application firewall for filtering. The profile contains the filtering criteria that the application firewall uses.

The policy rule consists of one or more expressions in the NetScaler expressions language. The NetScaler expressions syntax is a powerful, object-oriented programming language that enables you to precisely designate the traffic that you want to process with a specific profile. For users who are not completely familiar with the NetScaler expressions language syntax, or who prefer to configure their NetScaler appliance by using a web-based interface, the configuration utility provides two tools: the Prefix menu and the Add Expression dialog box. Both help you to write expressions that select exactly the traffic that you want to process. Experienced users who are thoroughly familiar with the syntax may prefer to use the NetScaler command line to configure their NetScaler appliances.

Note: In addition to the default expressions syntax, for backward compatibility the NetScaler operating system supports the NetScaler classic expressions syntax on NetScaler Classic and nCore appliances and virtual appliances. Classic expressions are not supported on NetScaler Cluster appliances and virtual appliances. Current NetScaler users who want to migrate existing configurations to the NetScaler Cluster must migrate any policies that contain classic expressions to the default expressions syntax.

For detailed information about the NetScaler expressions languages, see "Policies and Expressions."

You can create a firewall policy by using the configuration utility or the NetScaler command line.

To create and configure a policy by using the command line interface

At the command prompt, type the following commands:

- add appfw policy <name> <rule> <profileName>
- save ns config

Example

The following example adds a policy named `pl-blog`, with a rule that intercepts all traffic to or from the host `blog.example.com`, and associates that policy with the profile `pr-blog`. This is an appropriate policy to protect a blog hosted on a specific hostname.

```
add appfw policy pl-blog "HTTP.REQ.HOSTNAME.DOMAIN.EQ("blog.example.com")" pr-blog
```

Parameters for Creating and Configuring Firewall Policies

name

A name for your policy. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 128 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols.

rule

A policy rule, or expression, in NetScaler expressions language. For a short description and some useful examples of Application Firewall rules. For a complete description of the NetScaler expressions language, see "Introduction to Policies and Expressions."

profile

The name of the profile that you previously created.

To create and configure a policy by using the configuration utility

1. Navigate to Application Firewall > Policies.
2. In the details pane, do one of the following:
   - To create a new firewall policy, click Add. The Create Application Firewall Policy is displayed.
   - To edit an existing firewall policy, select the policy, and then click Open. The Configure Application Firewall Policy is displayed.
3. If you are creating a new firewall policy, in the Create Application Firewall Policy dialog box, Policy Name text box, type a name for your new policy.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 128 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.

   If you are configuring an existing firewall policy, this field is read-only. You cannot modify it.
4. Select the profile that you want to associate with this policy from the Profile drop-down list. You can create a new profile to associate with your policy by clicking New, and you can modify an existing profile by clicking Modify.
5. In the Expression text area, create a rule for your policy.
   - You can type a rule directly into the text area.
   - You can click Prefix to select the first term for your rule, and follow the prompts. See "To Create an Application Firewall Rule (Expression)" for a complete description of this process.
   - You can click Add to open the Add Expression dialog box, and use it to construct the rule. See "The Add Expression Dialog Box" for a complete description of this process.
6. Click Create or OK, and then click Close.

To create or configure an Application Firewall rule (expression)

The policy rule, also called the *expression*, defines the web traffic that the application firewall filters by using the profile associated with the policy. Like other NetScaler policy rules (or *expressions*), application firewall rules use NetScaler expressions syntax. This syntax is powerful, flexible, and extensible. It is too complex to describe completely in this set of instructions. You can use the following procedure to create a simple firewall policy rule, or you can read it as an overview of the policy creation process.

1. If you have not already done so, navigate to the appropriate location in the Application Firewall wizard or the NetScaler configuration utility to create your policy rule:

- If you are configuring a policy in the Application Firewall wizard, in the navigation pane, click Application Firewall, then in the details pane click Application Firewall Wizard, and then navigate to the Specify Rule screen.

- If you are configuring a policy manually, in the navigation pane, expand Application Firewall, then Policies, and then Firewall. In the details pane, to create a new policy, click Add. To modify an existing policy, select the policy, and then click Open.

2. On the Specify Rule screen, the Create Application Firewall Profile dialog box, or the Configure Application Firewall Profile dialog box, click Prefix, and then choose the prefix for your expression from the drop-down list. Your choices are:

   - **HTTP.** The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.

   - **SYS.** The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

   - **CLIENT.** The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

   - **SERVER.** The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

   After you choose a prefix, the application firewall displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom.

3. Choose your next term.

   If you chose HTTP as your prefix, your only choice is REQ, which specifies the Request/Response pair. (The application firewall operates on the request and response as a unit instead of on each separately.) If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

   When you have decided which term you want, double-click it to insert it into the Expression window.

4. Type a period after the term you just chose. You are then prompted to choose your next term, as described in the previous step. When a term requires that you type a value, fill in the appropriate value. For example, if you choose `HTTP.REQ.HEADER("")`, type the header name between the quotation marks.

5. Continue choosing terms from the prompts and filling in any values that are needed, until your expression is finished.

   Following are some examples of expressions for specific purposes.

   - **Specific web host.** To match traffic from a particular web host:

     ```
     HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
     ```

     For `shopping.example.com`, substitute the name of the web host that you want to match.

- **Specific web folder or directory.** To match traffic from a particular folder or directory on a Web host:

  HTTP.REQ.URL.STARTSWITH("https//www.example.com/folder")

  For `www.example.com`, substitute the name of the web host. For `folder`, substitute the folder or path to the content that you want to match. For example, if your shopping cart is in a folder called `/solutions/orders`, you substitute that string for folder.

- **Specific type of content: GIF images.** To match GIF format images:

  HTTP.REQ.URL.ENDSWITH(".gif")

  To match other format images, substitute another string in place of `.gif`.

- **Specific type of content: scripts.** To match all CGI scripts located in the `CGI-BIN` directory:

  HTTP.REQ.URL.STARTSWITH("https//www.example.com/CGI-BIN")

  To match all JavaScripts with `.js` extensions:

  HTTP.REQ.URL.ENDSWITH(".js")

  For more information about creating policy expressions, see "Policies and Expressions."

Note: If you use the command line to configure a policy, remember to escape any double quotation marks within NetScaler expressions. For example, the following expression is correct if entered in the configuration utility:

HTTP.REQ.HEADER("Host").EQ("shopping.example.com")

If entered at the command line, however, you must type this instead:

HTTP.REQ.HEADER(\"Host\").EQ(\"shopping.example.com\")

To add a firewall rule (expression) by using the Add Expression dialog box

The Add Expression dialog box (also referred to as the *Expression Editor*) helps users who are not familiar with the NetScaler expressions language to construct a policy that matches the traffic that they want to filter.

1. If you have not already done so, navigate to the appropriate location in the Application Firewall wizard or the NetScaler configuration utility:

- If you are configuring a policy in the Application Firewall wizard, in the navigation pane, click Application Firewall, then in the details pane click Application Firewall Wizard, and then navigate to the Specify Rule screen.

- If you are configuring a policy manually, in the navigation pane, expand Application Firewall, then Policies, and then Firewall. In the details pane, to create a new policy, click Add. To modify an existing policy, select the policy, and then click Open.

2. On the Specify Rule screen, in the Create Application Firewall Profile dialog box, or in the Configure Application Firewall Profile dialog box, click Add.

3. In the Add Expression dialog box, in the Construct Expression area, in the first list box, choose one of the following prefixes:

   - **HTTP.** The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol. The default choice.

   - **SYS.** The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

   - **CLIENT.** The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

   - **SERVER.** The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

4. In the second list box, choose your next term. The available terms differ depending on the choice you made in the previous step, because the dialog box automatically adjusts the list to contain only those terms that are valid for the context. For example, if you selected HTTP in the previous list box, the only choice is REQ, for requests. Because the application firewall treats requests and associated responses as a single unit and filters both, you do not need to specific responses separately. After you choose your second term, a third list box appears to the right of the second. The Help window displays a description of the second term, and the Preview Expression window displays your expression.

5. In the third list box, choose the next term. A new list box appears to the right, and the Help window changes to display a description of the new term. The Preview Expression window updates to display the expression as you have specified it to that point.

6. Continue choosing terms, and when prompted filling in arguments, until your expression is complete. If you make a mistake or want to change your expression after you have already selected a term, you can simply choose another term. The expression is modified, and any arguments or additional terms that you added after the term that you modified are cleared.

7. When you have finished constructing your expression, click OK to close the Add Expression dialog box. Your expression is inserted into the Expression text area.

Binding Application Firewall Policies

After you have configured your application firewall policies, you bind them to Global or a bind point to put them into effect. After binding, any request or response that matches an application firewall policy is transformed by the profile associated with that policy.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the NetScaler OS, policy priorities work in reverse order - the higher the number, the lower the priority.

Because the application firewall feature implements only the first policy that a request matches, not any additional policies that it might also match, policy priority is important for achieving the results that you intend. If you give your first policy a low priority (such as 1000), you configure the application firewall to perform it only if other policies with a higher priority do not match a request. If you give your first policy a high priority (such as 1), you configure the application firewall to perform it first, and skip any other policies that might also match. You can leave yourself plenty of room to add other policies in any order, without having to reassign priorities, by setting priorities with intervals of 50 or 100 between each policy when you bind your policies.

For more information about binding policies on the NetScaler appliance, see "Policies and Expressions."

To bind an application firewall policy by using the command line interface

At the command prompt, type the following commands:

- bind appfw global <policyName> <priority>
- save ns config

Example

The following example binds the policy named `pl-blog` and assigns it a priority of `10`.

```
bind appfw global pl-blog 10
save ns config
```

Parameters for Binding Application Firewall Policies

policyName

The name of the application firewall policy you want to bind.

priority

The priority assigned to this application firewall policy. The priority determines the order in which policies are evaluated, allowing the NetScaler to evaluate the most specific policy first, and more general policies in descending order, finishing with the most general policy.

To bind an application firewall policy by using the configuration utility

1. In the navigation pane, expand Application Firewall, then Policies, and then select Firewall Policies.

2. In the details pane, click Policy Manager.

3. In the Application Firewall Policy Manager dialog box, choose the bind point to which you want to bind the policy. The choices are:

   - **Override Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance, and are applied before any other policies.

   - **LB Virtual Server.** Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.

   - **CS Virtual Server.** Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.

   - **Default Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance.

   - **Policy Label.** Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.
4. Select Insert Policy to insert a new row and display a drop-down list with all available, unbound application firewall policies.

5. Select the policy you want to bind, or select New Policy to create a new policy. The policy that you selected or created is inserted into the list of globally bound application firewall policies.

6. Make any additional adjustments to the binding.

   - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.

   - To modify the policy expression, double click that field to open the Configure Application Firewall Policy dialog box, where you can edit the policy expression.

   - To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.

   - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression
7. Repeat steps 3 through 6 to add any additional application firewall policies you want to globally bind.

8. Click OK. A message appears in the status bar, stating that the policy has been successfully bound.

Viewing a Firewall Policy's Bindings

You can quickly check to determine what bindings are in place for any firewall policy by viewing the bindings in the configuration utility.

To view bindings for an application firewall policy

1. In the navigation pane, expand Application Firewall, then Policies, and then select Firewall Policies.
2. In the details pane, select the policy that you want to check, and then click Show Bindings. The Binding Details for Policy: Policy message box is displayed, with a list of bindings for the selected policy.
3. Click Close.

Auditing Policies

Auditing policies determine the messages that are generated and logged during an Application Firewall session. These messages are logged in SYSLOG format to the local NSLOG server or to an external logging server. Different types of messages are logged on the basis of the level of logging selected.

To create an auditing policy, you must first create either an NSLOG server or a SYSLOG server. After specifying the server, you create the policy and specify the type of log and the server to which logs are sent.

To create an auditing server by using the command line interface

You can create two different types of auditing server: an NSLOG server or a SYSLOG server. The command names are different, but the parameters for the commands are the same.

To create an auditing server, at the NetScaler command prompt, type the following commands:

- add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> ... [-dateFormat (**MMDDYYYY** | **DDMMYYYY**)] [-logFacility <logFacility>] [-tcp (**NONE** | **ALL**)] [-acl (**ENABLED** | **DISABLED**)] [-timeZone (**GMT_TIME** | **LOCAL_TIME**)] [-userDefinedAuditlog (**YES** | **NO**)] [-appflowExport (**ENABLED** | **DISABLED**)]
- save ns config

Example

The following example creates a syslog server named syslog1 at IP 10.124.67.91, with loglevels of emergency, critical, and warning, log facility set to LOCAL1, that logs all TCP connections:

```
add audit syslogAction syslog1 10.124.67.91 -logLevel emergency critical warning -logFacility LOCAL1 -tcp ALL
save ns config
```

To modify or remove an auditing server by using the command line interface

- To modify an auditing server, type the set audit <type> command, the name of the auditing server, and the parameters to be changed, with their new values.
- To remove an auditing server, type the rm audit <type> command and the name of the auditing server.

Example

The following example modifies the syslog server named syslog1 to add errors and alerts to the log level:

```
set audit syslogAction syslog1 10.124.67.91 -logLevel emergency critical warning alert error
-logFacility LOCAL1 -tcp ALL
save ns config
```

Parameters for configuring an auditing server

type (Auditing Type)

The type of logging server you are configuring. Possible values: nslogAction (NSLOG), syslogAction (SYSLOG).

name (Name)

A name for the syslog server. The name can consist of from one to 31 upper-case and lower-case letters, numbers, and the period (.), underscore (_) and hyphen (-) symbols.

serverIP (IP Address)

The IP address of the server, in IPV4 or IPV6 format.

serverPort (Port)

The port number on which the server listens for connections.

logLevel (Log Levels)

The types of information to be logged to the server. The choices are:

- ALERT
- CRITICAL
- DEBUG
- EMERGENCY

- ERROR
- INFORMATIONAL
- NOTICE
- WARNING

dateFormat (Date format)

The format used for dates in the logs. The choices are MMDDYYYY (U.S. style) or DDMMYYYY (International style).

logFacility (Log Facility)

The log facility on the NetScaler appliance. Possible values: LOCAL0, LOCAL1, LOCAL2.

tcp (TCP Logging)

Enable logging of TCP connections. Possible values: NONE, ALL.

acl (ACL Logging)

Enable logging of ACL connections. Possible values: ENABLED, DISABLED.

timeZone (Time Zone)

The Unix time zone to use in the logs.

userDefinedAuditLog (User Configurable Log Messages)

Enable user configurable log messages. Possible values: YES, NO.

appflowExport (AppFlow Logging)

Enable export of logs to the NetScaler AppFlow feature. Possible values: ENABLED, DISABLED.

Example

The following example creates a syslog server named syslog1 at IP 10.124.67.91, with loglevels of emergency, critical, and warning, log facility set to LOCAL1, that logs all TCP connections:

```
add audit syslogAction syslog1 10.124.67.91 -logLevel emergency critical warning
-logFacility LOCAL1 -tcp ALL
save ns config
```

To create or configure an auditing server by using the configuration utility

1. Navigate to Application Firewall > Policies > Auditing.
2. In the details pane, click the Server tab.
3. Do one of the following:
   - To add a new auditing server, click Add.
   - To modify an existing auditing server, select the server, and then click Open.
4. In the Create Auditing Server or Configure Auditing Server dialog box, set the following parameters:
   - Name
   - Auditing Type
   - IP Address
   - Port
   - Log Levels
   - Log Facility
   - TCP Logging
   - ACL Logging
   - User-Configurable Log Messages
   - AppFlow Logging
   - Date Format
   - Time Zone
5. Click Create or OK.

To create an auditing policy by using the command line interface

You can create an NSLOG policy or a SYSLOG policy. The type of policy must match the type of server. The command names for the two types of policy are different, but the parameters for the commands are the same.

At the command prompt, type the following commands:

- add audit syslogPolicy <name> [-rule <expression>] [-action <string>]
- save ns config

Example

The following example creates a policy named syslogP1 that logs application firewall traffic to a syslog server named syslog1.

```
add audit syslogPolicy syslogP1 -rule "ns_true" -action syslog1
save ns config
```

To configure an auditing policy by using the command line interface

At the command prompt, type the following commands:

- set audit syslogPolicy <name> [-rule <expression>] [-action <string>]
- save ns config

Example

The following example modifies the policy named syslogP1 to log application firewall traffic to a syslog server named syslog2.

```
set audit syslogPolicy syslogP1 -rule "ns_true" -action syslog2
save ns config
```

Parameters for an auditing policy

type (Auditing Type)

The type of syslog server that you are using. The choices are nslogPolicy (NSLOG) and syslogPolicy (SYSLOG).

name (Name)

A name for the syslog server. The name can consist of from one to 31 upper-case and lower-case letters, numbers, and the period (.), underscore (_) and hyphen (-) symbols.

rule (no configuration utility equivalent)

The rule that defines the policy. Always `ns_true` for application firewall policies. Must be included when configuring an auditing policy at the NetScaler command line. Is included automatically when configuring by using the configuration utility.

action (Server)

The name of the auditing server.

To configure an auditing policy by using the configuration utility

1. Navigate to Application Firewall > Policies > Auditing.
2. In the details pane, do one of the following:
   - To add a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.
3. In the Create Auditing Policy or Configure Auditing Policy dialog box, set the following parameters:
   - Name
   - Auditing Type
   - Server
4. Click Create or OK.

Imports

Several application firewall features make use of external files that you upload to the application firewall when configuring it. Using the configuration utility, you manage those files in the Imports pane, which has four tabs corresponding to the four types of files you can import: HTML error objects, XML error objects, XML schemas, and Web Services Description Language (WSDL) files. Using the NetScaler command line, you can import these types of files, but you cannot export them.

HTML Error Object

When a user's connection to an HTML or Web 2.0 page is blocked, or a user asks for a non-existent HTML or Web 2.0 page, the application firewall sends an HTML-based error response to the user's browser. When configuring which error response the application firewall should use, you have two choices:

- You can configure a *redirect URL*, which can be hosted on any Web server to which users also have access. For example, if you have a custom error page on your Web server, `404.html`, you can configure the application firewall to redirect users to that page when a connection is blocked.
- You can configure an *HTML error object*, which is an HTML-based Web page that is hosted on the application firewall itself. If you choose this option, you must upload the HTML error object to the application firewall. You do that in the Imports pane, on the HTML Error Object tab.

The error object must be a standard HTML file that contains no non-HTML syntax except for application firewall error object customization variables. It cannot contain any CGI scripts, server-parsed code, or PHP code. The customization variables enable you to embed troubleshooting information in the error object that the user receives when a request is blocked. While most requests that the application firewall blocks are illegitimate, even a properly configured application firewall can occasionally block legitimate requests, especially when you first deploy it or after you make significant changes to your protected Web sites. By embedding information in the error page, you provide the user with the information that he or she needs to give to the technical support person so that any issues can be fixed.

The application firewall error page customization variables are:

- `${NS_TRANSACTION_ID}`. The transaction ID that the application firewall assigned to this transaction.
- `${NS_APPFW_SESSION_ID}`. The application firewall session ID.
- `${NS_APPFW_VIOLATION_CATEGORY}`. The specific application firewall security check or rule that was violated.
- `${NS_APPFW_VIOLATION_LOG}`. The detailed error message associated with the violation.

- `${COOKIE("<CookieName>")}`. The contents of the specified cookie. For <CookieName>, substitute the name of the specific cookie that you want to display on the error page. If you have multiple cookies whose contents you want to display for troubleshooting, you can use multiple instances of this customization variable, each with the appropriate cookie name.

  Note: If you have blocking enabled for the Cookie Consistency Check, any blocked cookies are not displayed on the error page because the application firewall blocks them.

To use these variables, you embed them in the HTML or XML of the error page object as if they were an ordinary text string. When the error object is displayed to the user, for each customization variable the application firewall substitutes the information to which the variable refers. An example HTML error page that uses custom variables is shown below.

```
<!doctype html public "-//w3c//dtd html 4.0//en">
<html>
<head>
<title>Page Not Accessible</title>
</head>
<body>
<h1>Page Not Accessible</h1>
<p>The page that you accessed is not available. You can:</p>
<ul>
<li>return to the <b><a href="[homePage]">home page</a></b>, re-establish your session, and try again, or,
<li>report this incident to the help desk via <b><a href="mailto:[helpDeskEmailAddress]">email</a></b> or b
</ul>
<p>If you contact the help desk, please provide the following information:</p>
<table cellpadding=8 width=80%>
<tr><th align="right" width=30%>Transaction ID:</th><td align="left" valign="top" width=70%>${NS_TRANSACT
<tr><th align="right" width=30%>Session ID:</th><td align="left" valign="top" width=70%>${NS_APPFW_SESSIO
<tr><th align="right" width=30%>Violation Category:</th><td align="left" valign="top" width=70%>${NS_APPFW
<tr><th align="right" width=30%>Violation Log:</th><td align="left" valign="top" width=70%>${NS_APPFW_VIO
<tr><th align="right" width=30%>Cookie Name:</th><td align="left" valign="top" width=70%>${COOKIE("[cooki
</table>
<body>
<html>
```

To use this error page, copy it into a text or HTML editor. Substitute the appropriate local information for the following variables, which are enclosed in square brackets to distinguish them from the NetScaler variables. (Leave those unchanged.):

- **[homePage]**. The URL for your web site's home page.
- **[helpDeskEmailAddress]**. The email address that you want users to use to report blocking incidents.
- **[helpDeskPhoneNumber]**. The phone number that you want users to call to report blocking incidents.
- **[cookieName]**. The name of the cookie whose contents you want to display on the error page.

XML Error Object

When a user's connection to an XML page is blocked, or a user asks for a nonexistent XML application, the application firewall sends an XML-based error response to the user's browser. You configure the error response by uploading an XML-based error page to the application firewall in the Imports Pane, on the XML Error Object tab. All XML error responses are hosted on the application firewall. You cannot configure a redirect URL for XML applications.

Note: You can use the same customization variables in an XML error object as in an HTML error object.

XML Schema

When the application firewall performs a validation check on a user's request for an XML or Web 2.0 application, it can validate the request against the XML schema or design type document (DTD) for that application and reject any request that does not follow the schema or DTD. Both an XML schema and a DTD are standard XML configuration files that describe the structure of a specific type of XML document.

WSDL

When the application firewall performs a validation check on a user's request for an XML SOAP-based web service, it can validate the request against the web services type definition (*WSDL*) file for that web service. A WSDL file is a standard XML SOAP configuration file that defines the elements of a specific XML SOAP web service.

Importing and Exporting Files

You can import HTML or XML error objects, XML schemas, DTDs, and WSDLs to the application firewall by using the configuration utility or the NetScaler command line. To export any of these files or objects, or to edit a file or object directly on the application firewall, you must use the configuration utility.

To import a file or object by using the command line interface

At the command prompt, type the following commands:

- import appfw htmlerrorpage <src> <name>
- save ns config

Example

The following example imports an HTML error object from a file named `error.html` and assigns it the name `HTMLError`.

```
import htmlerrorpage error.html HTMLError
save ns config
```

Parameters for Importing a File or Object

type (Type)

The type of file or object that you are uploading. Possible Values: `HTMLErrorPage`, `xmlerrorpage`, `xmlschema`, `wsdl`.

src (Source File)

The full URL or path and filename of the object or file that you want to upload.

- If you are uploading the object from a web site or intranet location, you should type a URL in standard browser format.
- If you are importing the object from your local computer, you should type the path and file name of the object in the appropriate format for your local computer, or use the browse dialog to locate the file.

name (Name)

The name to be assigned to the file or object on the application firewall. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31

letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.

To import a file or object by using the configuration utility

Before you attempt to import an XML schema, DTD, or WSDL file, or an HTML or XML error object from a network location, verify that the NetScaler appliance can connect to the Internet or LAN computer where the file is located. Otherwise, you cannot import the file or object.

1. In the Application Firewall Imports pane, select the tab for the type of file you want to import, and then click Add.

   The upload process is identical on all four tabs from the user point of view.

2. In the Import New dialog box, Name text box, type a name for the object you are importing.

3. Choose the type of upload.

   - If the object is on a web site or other location on a LAN, WAN, or the Internet, select Import from URL.

   - If the object is on your local computer or a file server mounted on your local computer, select Import from Local File.

4. In the URL or Local File text box, type the full URL or path and filename to the resource.

5. Click Import.

   - If the application firewall finds the specified resource, the Import Console message box notifies you that the import succeeded. Click Close.

   - If the application firewall is unable to locate the resource, and you are uploading from an Internet or Intranet site, and you have verified that the URL and file you requested exists, click Close to close the Import Console message box. Next, check the NetScaler log file (`ns.log`) to verify that the URL or path and file that you used is accessible from your application firewall. If it is not, fix the access issue or move the file or object to a location that is accessible, and then repeat steps 4 and 5 to import the object.

6. To delete an object, select the object, and then click Remove. When the Proceed dialog box appears, click OK.

To export a file or object

Before you attempt to export an XML schema, DTD, or WSDL file, or an HTML or XML error object from a network location, verify that the application firewall appliance can connect to the Internet or LAN computer where the file is located. Otherwise, you cannot export the file or object.

1. In the Application Firewall Imports pane, select the tab for the type of file you want to export.

   The export process is identical on all four tabs from the user point of view.

2. Select the file that you want to export, and then click Export.

3. In the Export dialog box, click Browse, navigate to a local file system and directory in which to save the file or object that you are exporting, and click Select.

4. Click Export.

To edit a file or object

In the configuration utility, you can modify the properties of configuration files that you previously uploaded to the application firewall. You can also edit the text of HTML and XML error objects directly in the configuration utility.

1. Select the file that you want to modify, and then click Open.

   - If the object is an HTML or XML error object, the text of the object is displayed in a window. You can modify the text by using the standard browser-based editing tools and methods for your browser.

     Note: The edit window is designed to allow you to make minor changes to your HTML or XML error object. To make extensive changes, you may prefer to export the error object to your local computer and use standard HTML or XML web page editing tools.

   - If the object is an XML schema, DTD, or WSDL file, the name and URL of the object are displayed in a dialog box. The name is read-only. You can modify the URL.

2. Click OK (for HTML or XML error objects) or Import (for XML schemas, DTDs, or WSDLs) to save your changes, and then click Close.

Global Configuration

The application firewall global configuration affects all profiles and policies. The Global Configuration items are:

- **Engine Settings.** A collection of global settings—session cookie name, session time-out, maximum session lifetime, logging header name, undefined profile, default profile, and import size limit—that pertain to all connections that the application firewall processes, rather than to a specific subset of connections.

- **Confidential Fields.** A set of form fields in web forms that contain sensitive information that should not be logged to the application firewall logs. Form fields such as password fields on a logon page or credit card information on a shopping cart checkout form are normally designated as confidential fields.

- **Field Types.** The list of web form field types used by the Field Formats security check. Each of these field types is defined by a PCRE-compliant regular expression that defines the type of data and the minimum/maximum length of data that should be allowed in that type of form field.

- **XML Content Types.** The list of content types recognized as XML and subjected to XML-specific security checks. Each of these content types is defined by a PCRE-compliant regular expression that defines the exact MIME type assigned to that content.

- **JSON Content Types.** The list of content types recognized as JSON and subjected to JSON-specific security checks. Each of these content types is defined by a PCRE-compliant regular expression that defines the exact MIME type assigned to that content.

Engine Settings

The engine settings affect all requests and responses that the application firewall processes. They include the following items:

- **Cookie name**—The name of the cookie that stores the NetScaler session ID.
- **Session timeout**—The maximum inactive period allowed. If a user session shows no activity for this length of time, the session is terminated and the user is required to reestablish it by visiting a designated start page.
- **Cookie post-encrypt prefix**—The string that precedes the encrypted portion of any encrypted cookies.
- **Maximum session lifetime**—The maximum amount of time, in seconds, that a session is allowed to remain live. After this period is reached, the session is terminated and the user is required to reestablish it by visiting a designated start page.
- **Logging header name**—The name of the HTTP header that holds the Client IP, for logging.
- **Undefined profile**—The profile applied when the corresponding policy action evaluates as undefined.
- **Default profile**—The profile applied to connections that do not match a policy.
- **Import size limit**—The maximum size in bytes of files imported to the NetScaler appliance.
- **Learn message rate limit**—The maximum number of requests and responses per second that the learning engine is to process. Any additional requests or responses over this limit are not sent to the learning engine.
- **CEF logging**—Use the CEF format instead of the NetScaler format when logging application firewall entries to the NetScaler log.
- **Entity decoding**—Decode HTML entities when running application firewall checks.
- **Log malformed request**—Enable logging of malformed HTTP requests.
- **Use configurable secret key**—Use a configurable secret key for application firewall operations.
- **Manage learned data**—Remove all learned data from the application firewall. Restarts the learning process by collecting fresh data.

Normally, the default values for these settings are correct. If the default settings cause a conflict with other servers or cause premature disconnection of your users, however, you may need to modify them.

To configure engine settings by using the command line interface

At the command prompt, type the following commands:

- set appfw settings [-sessionCookieName <name>] [-sessionTimeout <positiveInteger>] [-cookiePostEncryptPrefix <string>] [-sessionLifetime <positiveInteger>] [-clientIPLoggingHeader <headerName>] [-undefaction <profileName>] [-defaultProfile <profileName>] [-importSizeLimit <positiveInteger>] [-cookiePostEncryptPrefix <string>] [-logMalformedReq (ON | OFF)] [-CEFLogging (ON | OFF)] [-entityDecoding (ON | OFF)] [-useConfigurableSecretKey (ON | OFF)] [-learnRateLimit <positiveInteger>]
- save ns config

Example

```
set appfw settings -sessionCookieName citrix-appfw-id -sessionTimeout 3600
-sessionLifetime 14400 -clientIPLoggingHeader NS-AppFW-Client-IP -undefaction APPFW_RESET
-defaultProfile APPFW_RESET -importSizeLimit 4096
save ns config
```

Parameters for configuring engine settings

sessionCookieName (Cookie Name)

Name of the session cookie, which is a cookie that the application firewall uses to track user sessions. You do not normally need to modify the name of this cookie, but if it conflicts in any way with a cookie set by your protected web servers, you can change it. The cookie name must begin with a letter or number, and can consist of from 1 to 31 letters, numbers, and the hyphen (-) and underscore (_) symbols. Default: `citrix_ns_id`.

sessionTimeout (Session Timeout)

Length of time, in seconds, that the application firewall waits before timing out user sessions. After the application firewall times out the session, the user must reestablish a session by visiting the home page or a designated start URL. Possible values: 1 to 600 seconds. Default: 900 seconds (15 minutes).

cookiePostEncryptPrefix (Cookie Post Encrypt Prefix)

String that is prepended to all encrypted cookie values. Default: ENC

sessionLifetime (Maximum Session Lifetime)

Maximum amount of time, in seconds, that the application firewall allows a user session to remain active, regardless of user activity. When the limit is reached, the application firewall terminates the session. To regain access, the user must establish a new session by visiting a designated start page. Possible values: Disabled, or any value from 1 through 14,400 seconds. Default: 900 seconds (15 minutes).

clientIPLoggingHeader (Logging Header Name)

Name of an HTTP header containing the IP address that the client used to connect to your protected web site or service. Possible values: Any value that the HTTP server supports. Default: Null value (do not add a logging header).

undefAction (Undefined Profile)

Profile to use when an application firewall policy evaluates as undefined. An undefined evaluation indicates an internal error condition. If such an error occurs when evaluating a classic policy, the application firewall aborts processing of the associated connections and passes them back to the NetScaler appliance without attempting to filter them. This behavior can constitute a security hazard in some circumstances, so the default setting specifies the APPFW_BLOCK built-in profile. You can specify a different built-in or user-created profile as the undefined profile.

defaultProfile (Default Profile)

Profile to use when a connection does not match any of the policies that you have defined on the application firewall. Normally the default profile is set to APPFW_BYPASS, which configures the application firewall to send connections that fail to match any policy back to the NetScaler appliance without attempting to filter them further.

importSizeLimit (Import Size Limit)

Cumulative total maximum number of bytes allowed for importing files to the application firewall. If the total size of uploaded files in a web form is larger than the configured limit, the application firewall blocks the request. Possible value: Any number. Default: 0 (disabled).

learnRateLimit (Learn Message Rate Limit)

Total number of requests and responses per second that the application firewall learning feature is to examine and use to learn new rules and relaxations. The learning feature ignores any requests or responses in excess of this number. Possible value: Any positive integer. Default: 0 (disabled).

CEFLogging (CEF Logging)

Enable or disable CEF-format logging. For more information about CEF logging, see "Logs, Statistics, and Reports." Possible values: Yes, No. Default: No.

entityDecoding (Entity Decoding)

Decode HTML entities before performing security checks. Possible values: Yes, No. Default: No

logMalformedReq (Log Malformed Request)

Log requests that are so malformed that the application firewall does not attempt to parse them. Possible values: Yes, No. Default: No

useConfigurableSecretKey (Use Configurable Secret Key)

Use a configurable secret key for application firewall operations. Possible values: Yes, No. Default: No

(Manage Learned Data)

Click Remove Learned Data to remove all learned data that you have not yet reviewed and deployed from the learning feature, and starts over from the beginning. Does not remove learned data that has been deployed (implemented) as rules or relaxations for security checks. This button is only available when using the configuration utility, and is identical to the Remove Learned Data button on the Configure Application Firewall Profile dialog box, Learning tab.

To configure engine settings by using the configuration utility

1. In the navigation pane, click Application Firewall.
2. In the details pane, click Change Engine Settings.
3. In the Application Firewall Engine Settings dialog box, set the following parameters:
   - Cookie Name
   - Session Timeout
   - Cookie Post Encrypt Prefix
   - Maximum Session Lifetime
   - Logging Header Name
   - Undefined Profile
   - Default Profile
   - Import Size Limit
   - Learn Messages Rate Limit
   - CEF Logging
   - Entity Decoding
   - Log Malformed Request
   - Use Configurable Secret Key
   - Manage Learned Data
   - Signatures Auto Update
   - Signatures Update URL
4. Click OK.

Confidential Fields

You can designate web-form fields as confidential to protect the information users type into them. Normally, any information a user types into a web form on one of your protected web servers is logged in the NetScaler logs. The information typed into a web-form field designated as confidential, however, is not logged. That information is saved only where the web site is configured to save such data, normally in a secure database.

Common types of information that you may want to protect with a confidential field designation include:

- Passwords
- Credit card numbers, validation codes, and expiration dates
- Social security numbers
- Tax ID numbers
- Home addresses
- Private telephone numbers

In addition to being good practice, proper use of confidential field designations may be necessary for PCI-DSS compliance on ecommerce servers, HIPAA compliance on servers that manage medical information in the United States, and compliance with other data protection standards.

Important: In the following two cases, the Confidential Field designation does not function as expected:

- If a Web form has either a confidential field or an action URL longer than 256 characters, the field or action URL is truncated in the NetScaler logs.
- With certain SSL transactions, the logs are truncated if either the confidential field or the action URL is longer than 127 characters.

In either of these cases, the application firewall masks a fifteen-character string with the letter "x," instead of the normal eight character string. To ensure that any confidential information is removed, the user must use form field name and action URL expressions that match the first 256, or (in cases where SSL is used) the first 127 characters.

To configure your application firewall to treat a web-form field on a protected web site as confidential, you add that field to the Confidential Fields list. You can enter the field name as a string, or you can enter a PCRE-compatible regular expression specifying one or more fields. You can enable the confidential-field designation when you add the field, or you can modify the designation later.

To add a confidential field by using the command line interface

At the command prompt, type the following commands:

- add appfw confidField <fieldName> <url> [-isRegex (REGEX | NOTREGEX)] [-comment "<string>"] [-state (ENABLED | DISABLED)]
- save ns config

Example

The following example adds all web form fields whose names begin with Password to the confidential fields list.

```
add appfw confidField Password "https?://www[.]example[.]com/[^<>]*[^a-z]password[0-9a-z._-]*[.](asp|cg
save ns config
```

To modify a confidential field by using the command line interface

At the command prompt, type the following commands:

- set appfw confidField <fieldName> <url> [-isRegex (REGEX | NOTREGEX)] [-comment "<string>"] [-state (ENABLED | DISABLED)]
- save ns config

Example

The following example modifies the confidential field designation to add a comment.

```
set appfw confidField Password "https?://www[.]example[.]com/[^<>]*[^a-z]password[0-9a-z._-]*[.](asp|cgi
save ns config
```

To remove a confidential field by using the command line interface

At the command prompt, type the following commands:

- rm appfw confidField <fieldName> <url>
- save ns config

Parameters for configuring a confidential field

state (Enable)

Enable the field's designation as a confidential field.

name (Field Name)

The name of the web form field that you are designating as confidential.

isRegex (Is form field name a regular expression)

Is the string that you used to define the form field name a regular expression or not?

url (Action URL)

The URL of the web page that contains that web form.

comment (Comments)

A comment. Optional.

To configure a confidential field by using the configuration utility

1. In the navigation pane, click Application Firewall.
2. In the details pane, under Settings, click Manage Confidential Fields.
3. In the Manage Confidential Fields dialog box, do one of the following:
   - To add a new form field to the list, click Add.
   - To change an existing confidential field designation, select the field, and then click Open.

   The Create Confidential Form Field dialog box or the Configure Confidential Form Field dialog box appears.

   Note: If you select an existing confidential field designation and then click Add, the Create Confidential Form Field dialog box displays the information for that confidential field. You can modify that information to create your new confidential field.
4. In the dialog box, fill out the elements. They are:
   - **Enabled check box.** Select or clear to enable/disable this confidential field designation.
   - **Is form field name a regular expression check box.** Select or clear to enable PCRE-format regular expressions in the form field name.
   - **Field Name.** Enter a literal string or PCRE-format regular expression that either represents a specific field name or that matches multiple fields with names that follow a pattern.
   - **Action URL.** Enter a literal URL or a regular expression that defines one or more URLs of the web page(s) on which the web form(s) that contains the confidential field are located.
   - **Comments.** Enter a comment. Optional.
5. Click Create or OK.
6. To remove a confidential field designation from the confidential fields list, select the confidential field listing you want to remove, then click Remove to remove it, and then click OK to confirm your choice.
7. When you have finished adding, modifying, and removing confidential field designations, click Close.

Examples

Following are some regular expressions that define form field names that you might find useful:

- `^passwd_` (Applies confidential-field status to all field names that begin with the "passwd_" string.)

- `^(([0-9a-zA-Z._-]*||\\x[0-9A-Fa-f][0-9A-Fa-f])+-)?passwd_` (Applies confidential-field status to all field names that begin with the string passwd_, or that contain the string -passwd_ after another string that might contain non-ASCII special characters.)

Following are some regular expressions that define specific URL types that you might find useful. Substitute your own web host(s) and domain(s) for those in the examples.

- If the web form appears on multiple web pages on the web host `www.example.com`, but all of those web pages are named `logon.pl?`, you could use the following regular expression:

  https?://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_.-]*/)*logon[.]pl\?

- If the web form appears on multiple web pages on the web host `www.example-español.com`, which contains the n-tilde (ñ) special character, you could use the following regular expression, which represents the n-tilde special character as an encoded UTF-8 string containing C3 B1, the hexadecimal code assigned to that character in the UTF-8 charset:

  https?://www[.]example-espa\xC3\xB1ol[.]com/([0-9A-Za-z][0-9A-Za-z_.-]*/)* logon[.]pl\?

- If the web form containing `query.pl` appears on multiple web pages on different hosts within the `example.com` domain, you could use the following regular expression:

  https?://([0-9A-Za-z][0-9A-Za-z_-.]*[.])*example[.]com/([0-9A-Za-z][0-9A-Za-z_-.]*/)*logon[.]pl\?

- If the web form containing `query.pl` appears on multiple web pages on different hosts in different domains, you could use the following regular expression:

  https?://([0-9A-Za-z][0-9A-Za-z_-.]*[.])*[0-9A-Za-z][0-9A-Za-z_-.]+[.][a-z]{2,6}/([0-9A-Za-z][0-9A-Za-z_-.

- If the web form appears on multiple web pages on the web host `www.example.com`, but all of those web pages are named `logon.pl?`, you could use the following regular expression:

  https?://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-.]*/)*logon[.]pl\?

Field Types

A field type is a PCRE-format regular expression that defines a particular data format and minimum/maximum data lengths for a form field in a web form. Field types are used in the Field Formats check.

The application firewall comes with several default field types, which are:

- `integer`. A string of any length consisting of numbers only, without a decimal point, and with an optional preceding minus sign (-).
- `alpha`. A string of any length consisting of letters only.
- `alphanum`. A string of any length consisting of letters and/or numbers.
- `nohtml`. A string of any length consisting of characters, including punctuation and spaces, that does not contain HTML symbols or queries.
- `any`. Anything at all.

  Important: Assigning the `any` field type as the default field type, or to a field, allows active scripts, SQL commands, and other possibly dangerous content to be sent to your protected web sites and applications in that form field. You should use the any type sparingly, if you use it at all.

You can also add your own field types to the Field Types list. For example, you might want to add a field type for a social security number, postal code, or phone number in your country. You might also want to add a field type for a customer identification number or store credit card number.

To add a field type to the Field Types list, you enter the field name as a literal string or PCRE-format regular expression.

To add a field type by using the command line interface

At the command prompt, type the following commands:

- add appfw fieldType <name> <regex> <priority> [-comment "<string>"]
- save ns config

Example

The following example adds a field type named `SSN` that matches US Social Security numbers to the Field Types list, and sets its priority to 1.

```
add appfw fieldType SSN "^[1-9][0-9]{2,2}-[0-9}{2,2}-[0-9]{4,4}$" 1
save ns config
```

To modify a field type by using the command line interface

At the command prompt, type the following commands:

- set appfw fieldType <name> <regex> <priority> [-comment "<string>"]
- save ns config

Example

The following example modifies the field type to add a comment.

```
set appfw fieldType SSN "^[1-9][0-9]{2,2}-[0-9}{2,2}-[0-9]{4,4}$" 1 -comment "US Social Security Number"
save ns config
```

To remove a field type by using the command line interface

At the command prompt, type the following commands:

- rm appfw fieldType <name>
- save ns config

Parameters for configuring a field type

name (Field Name)

The name of the field type. If you are adding a new field type, this can be a string of from one to 31 letters, numbers, and the underscore and hyphen symbols.

rule (Regular Expression)

The PCRE-format regular expression that defines the character format and length allowed in this field type.

url (URL)

A literal string or PCRE-format regular expression that describes the URL or URLs that host the web form(s) where the form field(s) are located.

priority (Priority)

A positive integer that designates the order in which this field type is checked for a match. A field type with a lower priority (such as 1) is checked before a field type with a higher priority (such as 2)

comment (Comments)

A comment. Optional.

To configure a field type by using the configuration utility

1. In the navigation pane, click Application Firewall.
2. In the details pane, under Settings, click Manage Field Types.
3. In the Manage Field Types dialog box, do one of the following:
   - To add a new field type to the list, click Add.
   - To change an existing field type, select the field type, and then click Open.

   The Create Field Type dialog box or the Configure Field Type dialog box appears.

   Note: If you select an existing field type designation and then click Add, the Create Field Type dialog box displays the information for that field type. You can modify that information to create your new field type.
4. In the dialog box, fill out the elements. They are:
   - Name
   - Regular Expression
   - Priority
   - Comment
5. Click Create or OK.
6. To remove a field type from the Field Types list, select the field type listing you want to remove, then click Remove to remove it, and then click OK to confirm your choice.
7. When you have finished adding, modifying, and removing field types, click Close.

Examples

Following are some regular expressions for field types that you might find useful:

- `^[1-9][0-9]{2,2}-[0-9}{2,2}-[0-9]{4,4}$` U.S. Social Security numbers
- `^[A-C][0-9]{7,7}$` California driver's license numbers.

- `^+[0-9]{1,3} [0-9() -]{1,40}$` International phone numbers with country codes.
- `^[0-9]{5,5}-[0-9]{4,4}$` U.S. ZIP code numbers.
- `^[0-9A-Za-z][0-9A-Za-z.+_-]{0,25}@([0-9A-Za-z][0-9A-Za-z_-]*[.]){1,4}[A-Za-z]{2,6}$` Email addresses.

XML Content Types

By default, the application firewall treats files that follow certain naming conventions as XML. You can configure the application firewall to examine web content for additional strings or patterns that indicate that those files are XML files. This can ensure that the application firewall recognizes all XML content on your site, even if certain XML content does not follow normal XML naming conventions, ensuring that XML content is subjected to XML security checks.

To configure the XML content types, you add the appropriate patterns to the XML Content Types list. You can enter a content type as a string, or you can enter a PCRE-compatible regular expression specifying one or more strings. You can also modify the existing XML content types patterns.

To add an XML content type pattern by using the command line interface

At the command prompt, type the following commands:

- add appfw XMLContentType <XMLContenttypevalue> [-isRegex (REGEX | NOTREGEX)]
- save ns config

Example

The following example adds the pattern `.*/xml` to the XML Content Types list and designates it as a regular expression.

```
add appfw XMLContentType ".*/xml" -isRegex REGEX
```

To remove an XML content type pattern by using the command line interface

At the command prompt, type the following commands:

- rm appfw XMLContentType <XMLContenttypevalue>
- save ns config

Parameters for configuring an XML content type pattern

XMLContenttypevalue (XML Content Type)

The string or regular expression that identifies the XML content type.

isRegex (Is XML content type a regular expression)

Is the string that you used to define the XML content type a regular expression or not?

To configure the XML content type list by using the configuration utility

1. In the navigation pane, click Application Firewall.
2. In the details pane, under Settings, click Manage XML Content Types.
3. In the Manage XML Content Types dialog box, click Add. The Create XML Content Type dialog box appears.

   Note: If you select an existing XML content type pattern and then click Add, the Create XML Content Type dialog box displays the information for that XML content type pattern. You can modify that information to create your new XML content type pattern.
4. In the dialog box, fill out the elements. They are:
   - **Is XML content type a regular expression check box.** Select or clear to enable PCRE-format regular expressions in the form field name.
   - **XML Content Type** Enter a literal string or PCRE-format regular expression that matches the XML content type pattern that you want to add.
5. Click Create.
6. To remove an XML content type pattern from the list, select it, then click Remove to remove it, and then click OK to confirm your choice.
7. When you have finished adding and removing XML content type patterns, click Close.

JSON Content Types

By default, the application firewall treats files with the content type "appliction/json" as JSON files. You can configure the application firewall to examine web content for additional strings or patterns that indicate that those files are JSON files. This can ensure that the application firewall recognizes all JSON content on your site, even if certain JSON content does not follow normal JSON naming conventions, ensuring that JSON content is subjected to JSON security checks.

To configure the JSON content types, you add the appropriate patterns to the JSON Content Types list. You can enter a content type as a string, or you can enter a PCRE-compatible regular expression specifying one or more strings. You can also modify the existing JSON content types patterns.

To add a JSON content type pattern by using the command line interface

At the command prompt, type the following commands:

- add appfw JSONContentType <JSONContenttypevalue> [-isRegex (REGEX | NOTREGEX)]
- save ns config

Example

The following example adds the pattern `.*/json` to the JSON Content Types list and designates it as a regular expression.

```
add appfw JSONContentType ".*/json" -isRegex REGEX
```

To configure the JSON content type list by using the configuration utility

1. In the navigation pane, click Application Firewall.
2. In the details pane, under Settings, click Manage JSON Content Types.
3. In the Manage JSON Content Types dialog box, click Add. The Create JSON Content Type dialog box appears.

   Note: If you select an existing JSON content type pattern and then click Add, the Create JSON Content Type dialog box displays the information for that JSON content type pattern. You can modify that information to create your new JSON content type pattern.

4. In the dialog box, fill out the elements. They are:

   - **Is JSON content type a regular expression check box.** Select or clear to enable PCRE-format regular expressions in the form field name.
   - **JSON Content Type** Enter a literal string or PCRE-format regular expression that matches the JSON content type pattern that you want to add.

5. Click Create.
6. To remove a JSON content type pattern from the list, select it, then click Remove to remove it, and then click OK to confirm your choice.
7. When you have finished adding and removing XML content type patterns, click Close.

Logs, Statistics, and Reports

The information maintained in the logs and statistics, and displayed in the reports, provides important guidance for configuring and maintaining the application firewall.

The Application Firewall Logs

The logs provide information about the requests and responses that the application firewall has observed while protecting your web sites and applications. Most important, it logs each connection that matches a signature or a security check. You can observe the logs to determine which connections are matching a signature or security check. You can then use this information, along with your own knowledge about your protected web sites and applications, to determine whether the connections that each signature or check is matching are valid (*false positives*). If they are, you can either remove the signature or check from your configuration, or take appropriate measures to mitigate the false positives before you enable blocking for that signature or security check.

NetScaler Format Logs

When configured to use NetScaler format logs, the application firewall produces logs that follow the same format as other NetScaler features. Each log contains the following fields:

- **Timestamp.** The date and time when the connection occurred.
- **Severity.** The severity level of the log.
- **Module.** The NetScaler module that generated the log entry.
- **Event Type.** The type of event, such as signature violation or security check violation.
- **Event ID.** The ID assigned to the event.
- **Client IP.** The IP address of the user whose connection was logged.
- **Transaction ID**. The ID assigned to the transaction that caused the log.
- **Session ID.** The ID assigned to the user session that caused the log.
- **Message.** The log message. Contains information identifying the signature or security check that triggered the log entry.

You can search on any of these fields, or any combination of information from different fields, to select logs to display, limited only by the capabilities of the tools you use to view the logs. You can observe the signatures by using the application firewall wizard to access the NetScaler syslog viewer, or manually by logging onto the NetScaler appliance or NetScaler virtual appliance.

Viewing the Application Firewall Logs

You can view the logs by using the syslog viewer, or by logging onto the NetScaler appliance, opening a Unix shell, and using the Unix text editor of your choice.

- **Viewing by using the syslog viewer.** You invoke the syslog viewer from one of two locations: the Select Signature Actions page or the Select Advanced Actions page in the Application Firewall Wizard. To invoke the syslog viewer for a signature, in the Select Signature Actions pane click the logs link to the right of that signature. To invoke the syslog viewer for a security check, in the Select Advanced Actions page, security checks list, select that security check, and then beneath the list click the Logs button. Either procedure causes the configuration utility to download the current `ns.log` file and then display the entries that are relevant to that signature or security check.

  The syslog viewer contains the following elements:

  - *Module list box*. The NetScaler module whose logs you want to view. Always set to APPFW for application firewall logs.
  - *Event Type list box*. The type of event. For signatures, this is always APPFW_SIGNATURE_MATCH. For security checks, this is the specific security check that you selected.
  - *Severity*. It lets you specify only logs of a specific severity level. Leave blank to see all logs.
  - *Find Now button*. Search the `nslog.file`, using the current criteria, and display the logs that match.
  - *Clear button*. Resets your settings to the defaults.
  - *Logs display window*. Displays the logs that meet the current criteria. Log information is displayed in several columns that correspond to the log fields for the log format that the application firewall is currently configured to maintain, with an additional column, Deploy, to the extreme left. You can sort the display by clicking a column heading. You can create and implement a relaxation for a signature or security check that is blocking legitimate use of a protected web site or web service by selecting a log that shows the unwanted blocking, and then clicking Deploy.
  - *Log directory*. The directory where the logs are stored. If you have archived logs stored in a different directory and want to view those, you can click Browse and browse to that directory to display those logs in the Log files list.
  - *Log files list*. A list of the log files in the Log directory. To download and uncompress an archived log file, select the file, and then click Download. To refresh the display, click Refresh.
  - *Search in list box*. Searches in a particular section of logs when selecting logs to display in the Logs display window. To search something other than the log message, select a different choice.
  - *Search string*. Search for the specified string or regular expression to choose the logs to display in the Logs display window. This field is filled out by the application firewall wizard for you with the appropriate value to display the logs relevant to the signature or security check that you selected. You can modify the string to choose logs based on different criteria.

- *Case Sensitive check box*. Select if the Search string is case sensitive.
- *Regular Expression check box*. Select if the Search string is a regular expression.
- *Clear button*. Resets the syslog viewer to its default settings.
- *Go button*. Uses the new search criteria to search the `ns.log` file and displays the results in the Logs display window.

For more information about the Application Firewall Wizard, see "The Application Firewall Wizard."

- **Viewing from the command line.** Log onto the application firewall appliance, and then type the following command at the NetScaler command prompt:

  ```
  shell
  ```

  After the Unix shell is displayed, type the following command to navigate to the directory where the logs are stored:

  ```
  cd /var/log
  ```

  You can use the vi editor, or any Unix text editor or text search tool of your choice to view and filter the logs for specific entries.

  Note: If the text editor or text search tool is not installed by default on the NetScaler appliance, you must first install it before you can use it to view and filter the logs.

The Application Firewall Statistics

When you enable the statistics action for application firewall signatures or security checks, the application firewall maintains information about connections that match that signature or security check. You can view the accumulated statistics information on the Monitoring tab of the main logon page of your application firewall appliance by selecting one of the following choices in the Select Group list box:

- **Application Firewall.** A summary of all statistics information gathered by your application firewall appliance for all profiles.
- **Application Firewall (per profile).** The same information, but displayed per-profile rather than summarized.

You can use this information to monitor how your application firewall is operating and determine whether there is any abnormal activity or abnormal amounts of hits on a signature or security check. If you see such a pattern of abnormal activity, you can check the logs for that signature or security check, to diagnose the issue, and then take corrective action.

The Application Firewall Reports

The application firewall reports provide information about your application firewall configuration and how it is handling traffic for your protected web sites.

The PCI DSS Report

The Payment Card Industry (PCI) Data Security Standard (DSS), version 1.2, consists of twelve security criteria that most credit card companies require businesses who accept online payments via credit and debit cards to meet. These criteria are designed to prevent identity theft, hacking, and other types of fraud. If an internet service provider or online merchant does not meet the PCI DSS criteria, that ISP or merchant risks losing authorization to accept credit card payments through its web site.

ISPs and online merchants prove that they are in compliance with PCI DSS by having an audit conducted by a PCI DSS Qualified Security Assessor (QSA) Company. The PCI DSS report is designed to assist them both before and during the audit. Before the audit, it shows which application firewall settings are relevant to PCI DSS, how they should be configured, and (most important) whether your current application firewall configuration meets the standard. During the audit, the report can be used to demonstrate compliance with relevant PCI DSS criteria.

The PCI DSS report consists of a list of those criteria that are relevant to your application firewall configuration. Under each criterion, it lists your current configuration options, indicates whether your current configuration complies with the PCI DSS criterion, and explains how to configure the application firewall so that your protected web site(s) will be in compliance with that criterion.

The PCI DSS report is located under System > Reports. To generate the report as an Adobe PDF file, click Generate PCI DSS Report. Depending on your browser settings, the report is displayed in the pop-up window or you are prompted to save it to your hard disk.

Note: To view this and other reports, you must have the Adobe Reader program installed on your computer.

The PCI DSS report consists of the following sections:

- **Description.** A description of the PCI DSS Compliance Summary report.
- **Firewall License and Feature Status.** Tells you whether the application firewall is licensed and enabled on your NetScaler appliance.
- **Executive Summary.** A table that lists the PCI DSS criteria and tells you which of those criteria are relevant to the application firewall.
- **Detailed PCI DSS Criteria Information.** For each PCI DSS criterion that is relevant to your application firewall configuration, the PCI DSS report provides a section that contains information about whether your configuration is currently in compliance and, if it is not, how to bring it into compliance.
- **Configuration.** Data for individual profiles, which you access either by clicking Application Firewall Configuration at the top of the report, or directly from the Reports pane. The Application Firewall Configuration report is the same as the PCI DSS report, with the PCI DSS-specific summary omitted, and is described below.

The Application Firewall Configuration Report

The Application Firewall Configuration report is located under System > Reports. To display it, click Generate Application Firewall Configuration Report. Depending on your browser settings, the report is displayed in the pop-up window or you are prompted to save it to your hard disk.

The Application Firewall Configuration report starts with a Summary page, which consists of the following sections:

- **Application Firewall Policies.** A table that lists your current application firewall policies, showing the policy name, the content of the policy, the action (or profile) it is associated with, and global binding information.

- **Application Firewall Profiles.** A table that lists your current application firewall profiles and indicates which policy each profile is associated with. If a profile is not associated with a policy, the table displays INACTIVE in that location.

To download all report pages for all policies, at the top of the Profiles Summary page click Download All Profiles. You display the report page for each individual profile by selecting that profile in the table at the bottom of the screen. The Profile page for an individual profile shows whether each check action is enabled or disabled for each check, and the other configuration settings for the check.

To download a PDF file containing the PCI DSS report page for the current profile, click Download Current Profile at the top of the page. To return to the Profiles Summary page, click Application Firewall Profiles. To go back to the main page, click Home. You can refresh the PCI DSS report at any time by clicking Refresh in the upper right corner of the browser. You should refresh the report if you make changes to your configuration.

Appendices

The following supplemental material provides additional detail about complex or peripheral application firewall tasks.

PCRE Character Encoding Format

The NetScaler operating system supports direct entry of characters in the printable ASCII character set only—characters with hexadecimal codes between HEX 20 (ASCII 32) and HEX 7E (ASCII 127). To include a character with a code outside that range in your application firewall configuration, you must enter its UTF-8 hexadecimal code as a PCRE regular expression.

A number of character types require encoding using a PCRE regular expression if you include them in your application firewall configuration as a URL, form field name, or Safe Object expression. They include:

- **Upper-ASCII characters.** Characters with encodings from HEX 7F (ASCII 128) to HEX FF (ASCII 255). Depending on the character map used, these encodings can refer to control codes, ASCII characters with accents or other modifications, non-Latin alphabet characters, and symbols not included in the basic ASCII set. These characters can appear in URLs, form field names, and safe object expressions.

- **Double-Byte characters.** Characters with encodings that use two 8-byte words. Double-byte characters are used primarily for representing Chinese, Japanese, and Korean text in electronic format. These characters can appear in URLs, form field names, and safe object expressions.

- **ASCII control characters.** Non-printable characters used to send commands to a printer. All ASCII characters with hexadecimal codes less than HEX 20 (ASCII 32) fall into this category. These characters should never appear in a URL or form field name, however, and would rarely if ever appear in a safe object expression.

The NetScaler appliance does not support the entire UTF-8 character set, but only the characters found in the following eight charsets:

- **English US (ISO-8859-1).** Although the label reads, “English US,” the application firewall supports all characters in the ISO-8859-1 character set, also called the Latin-1 character set. This character set fully represents most modern western European languages and represents all but a few uncommon characters in the rest.

- **Chinese Traditional (Big5).** The application firewall supports all characters in the BIG5 character set, which includes all of the Traditional Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in Hong Kong, Macau, Taiwan, and by many people of Chinese ethnic heritage who live outside of mainland China.

- **Chinese Simplified (GB2312).** The application firewall supports all characters in the GB2312 character set, which includes all of the Simplified Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in mainland China.

- **Japanese (SJIS).** The application firewall supports all characters in the Shift-JIS (SJIS) character set, which includes most characters (ideographs) commonly used in modern Japanese.

- **Japanese (EUC-JP).** The application firewall supports all characters in the EUC-JP character set, which includes all characters (ideographs) commonly used in modern Japanese.

- **Korean (EUC-KR).** The application firewall supports all characters in the EUC-KR character set, which includes all characters (ideographs) commonly used in modern Korean.

- **Turkish (ISO-8859-9).** The application firewall supports all characters in the ISO-8859-9 character set, which includes all letters used in modern Turkish.

- **Unicode (UTF-8).** The application firewall supports certain additional characters in the UTF-8 character set, including those used in modern Russian.

When configuring the application firewall, you enter all non-ASCII characters as PCRE-format regular expressions using the hexadecimal code assigned to that character in the UTF-8 specification. Symbols and characters within the normal ASCII character set, which are assigned single, two-digit codes in that character set, are assigned the same codes in the UTF-8 character set. For example, the exclamation point (!), which is assigned hex code 21 in the ASCII character set, is also hex 21 in the UTF-8 character set. Symbols and characters from another supported character set have a paired set of hexadecimal codes assigned to them in the UTF-8 character set. For example, the letter a with an acute accent (á) is assigned UTF-8 code C3 A1.

The syntax you use to represent these UTF-8 codes in the application firewall configuration is “\xNN” for ASCII characters; “\xNN\xNN” for non-ASCII characters used in English, Russian, and Turkish; and “\xNN\xNN\xNN” for characters used in Chinese, Japanese, and Korean. For example, if you want to represent a ! in an application firewall regular expression as a UTF-8 character, you would type \x21. If you want to include an á, you would type \xC3\xA1.

Note: Normally you do not need to represent ASCII characters in UTF-8 format, but when those characters might confuse a web browser or an underlying operating system, you can use the character’s UTF-8 representation to avoid this confusion. For example, if a URL contains a space, you might want to encode the space as \x20 to avoid confusing certain browsers and web server software.

Below are examples of URLs, form field names, and safe object expressions that contain non-ASCII characters that must be entered as PCRE-format regular expressions to be included in the application firewall configuration. Each example shows the actual URL, field name, or expression string first, followed by a PCRE-format regular expression for it.

- A URL containing extended ASCII characters.

  Actual URL: `http://www.josénuñez.com`

  Encoded URL: `^http://www[.]jos\xC3\xA9nu\xC3\xB1ez[.]com$`

- Another URL containing extended ASCII characters.

  Actual URL: `http://www.example.de/trömso.html`

  Encoded URL: `^http://www[.]example[.]de/tr\xC3\xB6mso[.]html$`

- A form field name containing extended ASCII characters.

Actual Name: `nome_do_usuário`

Encoded Name: `^nome_do_usu\xC3\xA1rio$`

- A safe object expression containing extended ASCII characters.

  Unencoded Expression `[A-Z]{3,6}¥[1-9][0-9]{6,6}`

  Encoded Expression: `[A-Z]{3,6}\xC2\xA5[1-9][0-9]{6,6}`

You can find a number of tables that include the entire Unicode character set and matching UTF-8 encodings on the Internet. A useful web site that contains this information is located at the following URL:

http://www.utf8-chartable.de/unicode-utf8-table.pl

For the characters in the table on this web site to display correctly, you must have an appropriate Unicode font installed on your computer. If you do not, the visual display of the character may be in error. Even if you do not have an appropriate font installed to display a character, however, the description and the UTF-8 and UTF-16 codes on this set of web pages will be correct.

Whitehat WASC Signature Types for WAF Use

The Citrix NetScaler Application Firewall accepts and generates blocking rules for all vulnerability types that the Whitehat scanners generate. However, certain vulnerabilities are most applicable to a web application firewall. Following are lists of those vulnerabilities, categorized by whether they are addressed by WASC 1.0, WASC 2.0, or best practices signature types.

WASC 1.0 Signature Types

- HTTP Request Smuggling
- HTTP Response Splitting
- HTTP Response Smuggling
- Null Byte Injection
- Remote File Inclusion
- URL Redirector Abuse

WASC 2.0 Signature Types

- Abuse of Functionality
- Brute Force
- Content Spoofing
- Denial of Service
- Directory Indexing
- Information Leakage
- Insufficient Anti-automation
- Insufficient Authentication
- Insufficient Authorization
- Insufficient Session Expiration
- LDAP Injection
- Session Fixation

Best Practices

- Autocomplete Attribute
- Insufficient Cookie Access Control
- Insufficient Password Strength
- Invalid HTTP Method Usage
- Non-HttpOnly Session Cookie
- Persistent Session Cookie
- Personally Identifiable Information
- Secured Cachable HTTP Messages
- Unsecured Session Cookie

Content Filtering

Content filtering can do some of the same tasks as the Citrix® Application Firewall™, and is a less CPU-intensive tool. It is limited, however, to examining the header portion of the HTTP request or response and to performing a few simple actions on connections that match. If you have a complex Web site that makes extensive use of scripts and accesses back-end databases, the Application Firewall may be the better tool for protecting that Web site. For more information about the Citrix® Application Firewall™, see the *Citrix Application Firewall Guide* at http://support.citrix.com/article/CTX132360.

Content filtering is based on regular expressions that you can apply to either HTTP requests or HTTP responses. To block requests from a particular site, for example, you could use an expression that compares each request's URL to the URL specified in the expression. The expression is part of a policy, which also specifies an action to be performed on requests or responses that match the expression. For example, an action might drop a request or reset the connection.

Following are some examples of things you can do with content filtering policies:

- Prevent users from accessing certain parts of your Web sites unless they are connecting from authorized locations.
- Prevent inappropriate HTTP headers from being sent to your Web server, possibly breaching security.
- Redirect specified requests to a different server or service.

To configure content filtering, once you have made sure that the feature is enabled, you configure filtering actions for your servers to perform on selected connections (unless the predefined actions are adequate for your purposes). Then you can configure policies to apply the actions to selected connections. Your policies can use predefined expressions, or you can create your own. To activate the policies you configured, you bind them either globally or to specific virtual servers.

Enabling Content Filtering

By default, content filtering is enabled on NetScaler appliances running the NetScaler operating system 8.0 or above. If you are upgrading an existing appliance from an operating system version earlier than 8.0, you must update the licenses before you can use content filtering, and you may need to enable the content filtering feature itself manually.

To enable content filtering by using the command line interface

At the command prompt, type the following commands to enable content filtering and verify the configuration:

- enable ns feature `ContentFiltering`
- show ns feature

Example

```
> enable ns feature ContentFiltering
 Done
> show ns feature

      Feature                 Acronym          Status
      -------                 -------          ------
1)    Web Logging               WL               ON
2)    Surge Protection          SP               OFF
.
.
.
.
11)   Http DoS Protection       HDOSP            OFF
12)   Content Filtering         CF               ON
.
.
23)   HTML Injection            HTMLInjection    ON
24)   NetScaler Push            push             OFF
Done
```

To enable content by filtering by using the configuration utility

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Change basic features.
3. In the Configure Basic Features dialog box, select the Content Filtering check box, and then click OK.
4. In the Enable/Disable feature(s) dialog box, click Yes. A message appears in the status bar, stating that the selected feature is enabled.

Configuring a Content Filtering Action

After you enable the content filtering feature, you create one or more actions to tell your NetScaler appliance how to handle the connections it receives.

Content filtering supports the following actions for HTTP requests:

Add

Adds the specified HTTP header before sending the request to the Web server.

Reset

Terminates the connection, sending the appropriate termination notice to the user's browser.

Forward

Redirects the request to the designated service.

Drop

Silently deletes the request, without sending a response to the user's browser.

Corrupt

Modifies the designated HTTP header in a manner that prevents it from performing the function it was intended to perform, then sends the request to the server.

Content filtering supports the following actions for HTTP responses:

Add

Adds the specified HTTP header before sending the response to the user's browser.

ErrorCode

Returns the designated HTTP error code to the user's browser.

Corrupt

Modifies the designated HTTP header in a manner that prevents it from performing the function it was intended to perform, then sends the response to the user's browser.

To configure a content filtering action by using the command line interface

At the command prompt, type the following commands to configure a Content Filtering action and verify the configuration:

- add filter action <name> <qualifier> [<serviceName>] [<value>] [<respCode>] [<page>]
- show filter action <name>

Example

```
> add filter action act_drop Drop
 Done
> show filter action act_drop
1)      Name: act_drop    Filter Type: drop
 Done
```

Parameters for configuring a content filtering action

name

A name for the filtering action. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should choose a name that helps identify the type of action. (Cannot be changed after the action has been created.)

qualifier

The action that you want your content filtering Action to perform. (Cannot be changed after the action has been created.)

servicename

If the Qualifier is Forward, the name of the service to which you want to forward requests. If the Qualifier is Forward, you must configure either a servicename or a page, but not both. Otherwise, you should not set this value.

value

If the Qualifier is Add, the header that you want added. This argument is optional.

respcode

If the Qualifier is ErrorCode, the numeric code you want returned to the user (such as 404, the standard HTTP code for a non-existent Web page). This argument is optional.

page

If the Qualifier is Forward, you must configure either a servicename or a page, but not both. Otherwise, you should not set this value.

To configure a content filtering action by using the configuration utility

1. Navigate to Protection Features > Filter.
2. In the details pane, do one of the following:
   - To create a new action, click Add.
   - To modify an existing action, select the action, and then click Open.
3. In the Add Filter Action or Configure Filter Action dialog box, specify values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring a content filtering action" as follows (asterisk indicates a required parameter):
   - Action Name*—name
   - Qualifier*—qualifier (Determines which of the following parameters you can configure)
   - Service Name—servicename
   - HeaderName:Value—value
   - Response Code—respcode
   - Response Page—page
4. Fill in any other required information. For example, if you are configuring an action to send an HTTP error code, you must choose the appropriate error code from a drop-down list. If necessary, you can then modify the text of the error message, which is displayed beneath the drop-down list.
5. Click Create or OK, and then click Close. The Actions list displays the action you configured, and a message in the status bar indicates that your action has been created.

Configuring a Content Filtering Policy

To implement content filtering, you must configure at least one policy to tell your NetScaler appliance how to distinguish the connections you want to filter. You must first have configured at least one filtering action, because when you configure a policy, you associate it with an action.

Content filtering policies examine a combination of one or more of the following elements to select requests or responses for filtering:

URL

The URL in the HTTP request.

URL query

Only the query portion of the URL, which is the portion after the query (?) symbol.

URL token

Only the tokens in the URL, if any, which are the parts that begin with an ampersand (&) and consist of the token name, followed by an equals sign (=), followed by the token value.

HTTP method

The HTTP method used in the request, which is usually GET or POST, but can be any of the eight defined HTTP methods.

HTTP version

The HTTP version in the request, which is usually HTTP 1.1.

Standard HTTP header

Any of the standard HTTP headers defined in the HTTP 1.1 specification.

Standard HTTP header value

The value portion of the HTTP header, which is the portion after the colon and space (:).

Custom HTTP header

A non-standard HTTP header issued by your Web site or that appears in a user request.

Custom header value

The value portion of the custom HTTP header, which (as with the standard HTTP header) is the portion after the colon and space (:).

Client Source IP

The IP from which the client request was sent.

Content filtering policies use the simpler of two NetScaler expressions languages, called classic expressions. For a complete description of classic expressions, how they work, and how to configure them manually, see "Policies and Expressions."

Note: Users who are not experienced in configuring policies at the NetScaler command line will usually find using the configuration utility considerably easier.

To configure a content filtering policy by using the command line interface

At the command prompt, type the following commands to configure a content filtering policy and verify the configuration:

- add filter policy <name> -rule <expression> (-reqAction <action> | -resAction <string>
- show filter policy <name>

Example

```
> add filter policy cf-pol -rule "REQ.HTTP.URL CONTAINS http://abc.com" -reqaction DROP
 Done
> show filter policy cf-pol
1)     Name: cf-pol    Rule: REQ.HTTP.URL CONTAINS http://abc.com
       Request action: DROP
       Response action:
       Hits: 0
 Done
```

Parameters for configuring a content filtering policy

name

A name for the filtering action. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should chose a name that helps identify the type of action. (Cannot be changed after the action has been created.)

rule

A NetScaler classic expression that describes the connections you want to select using this policy.

reqaction or resaction

Type -reqaction if your policy applies to requests, or -resaction if your policy applies to responses. You must choose one or the other, but not both.

action

The name of the content filtering action you want to perform on connections that match this policy.

To configure a content filtering policy by using the configuration utility

1. In the details pane, to create a new policy, click Add.

2. If you are creating a new policy, in the Create Filter Policy dialog box, in the Filter Name text box, type a name for your new policy.

3. Select either Request Action or Response Action to activate the drop-down list to the right of that item.

4. Click the down arrow to the right of the drop-down list and select the action to be performed on the request or response. The default choices are RESET and DROP. Any other actions you have created will also appear in this list.

   Note: You can also click New to create a new Content Filtering action, or Modify to modify an existing Content Filtering action. You can only modify actions you created; the default actions are read-only.

5. If you want to use a predefined expression (or named expression) to define your policy, choose one from the Named Expressions list.

   a. Click the down arrow to the right of the first Named Expressions drop-down list, and choose the category of named expressions that contains the named expression you want to use.

   b. Click the down arrow to the right of the second Named Expressions drop-down list, and choose the named expression you want. As you choose a named expression, the regular expression definition of that named expression appears in the Preview Expression pane beneath the Named Expression list boxes.

   c. Click Add Expression to add that named expression to the Expression list.

   Note: You should perform either this step or step 7, but not both.

6. If you want to create a new expression to define your policy, use the Expression Editor.

   a. Click the Add button. The Add Expression dialog box appears.

   b. In the Add Expression dialog box, choose the type of connection you want to filter. The Flow Type is set to REQ by default, which tells the NetScaler appliance to look at incoming connections, or requests. If you want to filter outgoing connections (responses), you click the right arrow beside the drop-down list and choose RES.

   c. If the Protocol is not already set to HTTP, click the down arrow to the right of the Protocol drop-down list and choose HTTP.

      Note: In the NetScaler classic expressions language, “HTTP” includes HTTPS requests, as well.

   d. Click the down arrow to the right of the Qualifier drop-down list, and then choose a qualifier for your expression. Your choices are:

      METHOD

The HTTP method used in the request.

URL

The contents of the URL header.

URLTOKENS

The URL tokens in the HTTP header.

VERSION

The HTTP version of the connection.

HEADER

The header portion of the HTTP request.

URLLEN

The length of the contents of the URL header.

URLQUERY

The query portion of the contents of the URL header.

URLQUERYLEN

The length of the query portion of the URL header.

The contents of the remaining list boxes change to the choices appropriate to the Qualifier you pick. For example, if you choose HEADER, a text field labeled Header Name* appears below the Flow Type list box.

e. Click the down arrow to the right of the Operator drop-down list, and choose an operator for your expression. Your choices will vary depending on the Protocol you chose in the preceding step. The following list includes all of the operators:

==

Matches the following text string exactly.

!=

Does not exactly match the following text string.

>

Is greater than the following integer.

CONTAINS

Contains the following text string.

CONTENTS

The contents of the designated header, URL, or URL query.

EXISTS

The specified header or query exists.

NOTCONTAINS

Does not contain the following text string.

NOTEXISTS

The specified header or query does not exist.

f. If the Value text box is visible, type the appropriate string or number. If you are testing a string in any way, type the string into the Value text box. If you are testing an integer in any way, type the integer into the Value text box.

g. If you chose HEADER as the Protocol, type the header you want in the Header Name* text box.

h. Click OK to add your expression to the Expressions list.

i. Repeat steps B through H to create any additional expressions you want for your profile.

j. Click Close to close the Expressions Editor.

7. If you created a new expression, in the Expression frame select an option from the Match Any Expression drop-down list. Your choices are:

- Match Any Expression. If a request matches any expression in the Expressions list, the request matches this policy.

- Match All Expressions If a request matches all expressions in the Expressions list, the request matches this policy. If it does not matchall of them, it does not match this policy.

- Tabular Expression Switches the Expressions list to a tabular format with three columns. In the first column you can place a BEGIN [(] operator. The second column contains the expressions you have selected or created. In the third column, you can place any of the other operators in the following list, to create complex policy groups in which each group can be configured for match any expression or match all expressions.
- The AND [&&] operator tells the appliance to require that are quest match both the current expression and the following expression.

- The OR [||] operator tells the appliance to require that arequest match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.

- The END [)] operator tells the appliance that this is the last expression in this expression group or policy.

Note: The Tabular format allows you to create a complex policy that contains both “Match Any Expression” and “Match All Expressions” on a per-expression

basis. You are not limited to just one or the other.

- Advanced Free-Form Switches off the Expressions Editor entirely and modifies the Expressions list into a text area. In the text area, you can type the PCRE-format regular expression of your choice to define this policy. This is both the most powerful and the most difficult method of creating a policy, and is recommended only for those thoroughly familiar with the NetScaler appliance and PCRE-formatregular expressions.

  Caution: If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression editing mode unless you are sure that is what you want.

8. Repeat steps 6 through 8 to add any additional expressions you want to the Expressions list. You can mix named expressions and expressions created in the Expressions Editor. To the NetScaler appliance, they are all the same.

9. Click Create to create your new policy. Your new policy appears in the Policies pane list.

10. Click Close. To create additional Content Filtering policies, repeat the previous procedure. To remove a Content Filtering policy, select the policy in the Policies tab and click Remove.

Binding a Content Filtering Policy

You must bind each content filtering policy to put it into effect. You can bind policies globally or to a particular virtual server. Globally bound policies are evaluated each time traffic directed to any virtual server matches the policy. Policies bound to a specific vserver are evaluated only when that vserver receives traffic that matches the policy.

To bind a policy to a virtual server by using the command line interface

At the command prompt, type the following commands to bind a policy to a virtual server and verify the configuration:

- bind lb vserver <name>@ -policyName <string> -priority <positive_integer>
- show lb vserver <name>

Example

```
> bind lb vserver vs-loadbal -policyName policyTwo -priority 100
 Done
> show lb vserver vs-loadbal
1)      vs-loadbal (10.102.29.20:80) - HTTP      Type: ADDRESS
        State: OUT OF SERVICE
        Last state change was at Wed Aug 19 09:05:47 2009 (+211 ms)
        Time since last state change: 2 days, 00:58:03.260
        Effective State: DOWN
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        No. of Bound Services :  0 (Total)       0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE
        Vserver IP and Port insertion: OFF
        Push: DISABLED  Push VServer:
        Push Multi Clients: NO
        Push Label Rule: none

 Done
```

To globally bind a policy by using the command line interface

At the command prompt, type the following commands to globally bind a policy and verify the configuration:

- bind filter global (<policyName> [-priority <positive_integer>]) [-state (ENABLED | DISABLED)]
- show filter global

Example

```
bind filter global cf-pol -priority 1
Done show filter global
1)      Policy Name: cf-pol     Priority: 1
Done
```

To bind a policy to a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing and click Virtual Servers.
2. In the details pane, select the virtual server to which you want to bind the content filtering policy from the list, and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab, and then select the check box in the Active column of the filter policy that you want to bind to the virtual server.
4. Click OK. The policies you have bound display a check mark and the word Yes in the Policies Bound column of the Policies tab.

To globally bind a policy by using the configuration utility

1. In the navigation pane, expand Protection Features, and then select Filter.
2. In the details pane, in the Policies tab, select the policy that you want to bind, and then click Global Bindings.
3. In the Bind/Unbind Filter Policies dialog box, in the Policy Name drop-down list, select a policy, and then click Add. The policy is added to the Configured list.

   Note: To select multiple policies from the list, press and hold the Ctrl key, then click each policy you want.
4. Click OK, and then click Close. The policies you have bound display a check mark and the word Yes in the Globally Bound column of the Policies tab.

Configuring Content Filtering for a Commonly Used Deployment Scenario

This example provides instructions for using the configuration utility to implement a content filtering policy in which, if a requested URL contains root.exe or cmd.exe, the content filtering policy filter-CF-nimda is evaluated and the connection is reset.

To configure this content filtering policy, you must do the following:

- Enable content filtering
- Configure content filtering policy
- Bind content filtering policy globally or to a virtual server
- Verify the configuration

Note: Since this example uses a default content filtering action, you do not need to create a separate content filtering action.

To enable content filtering

1. In the navigation pane, expand System, and click Settings.
2. In the details pane, under Modes & Features, click Change Basic Features.
3. In the Configure Basic Features dialog box, select the Content Filtering check box, and then click OK.
4. In the Enable/Disable feature(s) dialog box, click Yes. A message appears in the status bar, stating that the selected feature is enabled.

To configure the content filtering policy filter-CF-nimda

1. In the navigation pane, expand Protection Features, and click Filter.
2. In the details pane, click Add. The Create Filter Policy dialog box appears.
3. In the Create Filter Policy dialog box, in the Filter Name text box, type the name `filter-CF-nimda`.
4. Select the Request Action option, and in the drop-down list, select RESET.
5. In the Expression frame, select Match Any Expression from the drop-down list, and then click Add.
6. In the Add Expression dialog box, Expression Type drop-down list, select General.
7. In the Flow Type drop-down list, select REQ.
8. In the Protocol drop-down list, select HTTP.
9. In the Qualifier drop-down list, select URL.
10. In the Operator drop-down list, select CONTAINS.
11. In the Value text box, type `cmd.exe`, and then click OK. The expression is added in the Expression text box.
12. To create another expression, repeat Steps 7 through 11, but in the Value text box, type `root.exe`. Then click OK, and finally click Close.
13. Click Create on the Create Filter Policy dialog box. The filter policy filter-CF-nimda appears in the Filter list.
14. Click Close.

To globally bind the content filtering policy

1. In the navigation pane, expand Protection Features, and click Filter. The Filter page appears in the right pane.
2. In the details pane, Policies tab, select the policy that you want to bind and click Global Bindings. The Bind/Unbind Filter Policies dialog box appears.
3. In the Bind/Unbind Filter Policies dialog box, in the Policy Name drop-down list, select the policy filter-CF-nimda, and click Add. The policy is added to the Configured list.
4. Click OK, and then click Close. The policy you have bound displays a check mark and Yes in the Globally Bound column of the Policies tab.

To bind the content filtering policy to a virtual server

1. In the navigation pane, expand the Load Balancing node and click Virtual Servers.
2. In the details pane virtual servers list, select vserver-CF-1 to which you want to bind the content filtering policy and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab.
4. In the Active column, select the check box for the policy filter-CF-nimda, and then click OK. Your content filtering policy is now active, and should be filtering requests. If it is functioning correctly, the Hits counter is incremented every time there is a request for a URL containing either root.exe or cmd.exe. This allows you to confirm that your content filtering policy is working. The content filtering policy is bound to the virtual server.

To verify the content filtering configuration by using the command line interface

At the command prompt, type the following command to verify the content filtering configuration:

show filter policy filter-CF-nimda

Example

```
sh filter policy filter-CF-nimda
      Name: filter-CF-nimda   Rule: REQ.HTTP.URL CONTAINS cmd.exe || REQ.HTTP.URL CONTAINS root.exe
      Request action: RESET
      Response action:
      Hits: 0
Done
```

Note: The Hits counter displays an integer that denotes the number of times the `filter-CF-nimda` policy is evaluated. In the preceding steps, the Hits counter is set to zero because no requests for a URL containing either cmd.exe or root.exe have been made yet. If you want to see the counter increment in real time, you can simply request a URL that contains either of these strings.

To verify the content filtering configuration by using the configuration utility

1. In the navigation pane, expand Protection Features, and click Filter.
2. In the details pane, select the filter policy filter-CF-nimda. The bottom of the pane should display the following:

   Request Action:

   RESET

   Rule:

   REQ.HTTP.URL CONTAINS cmd.exe || REQ.HTTP.URL CONTAINS root.exe

   Hits:

   0

HTTP Denial-of-Service Protection

Internet hackers can bring down a site by sending a surge of GET requests or other HTTP-level requests. HTTP Denial-of-Service (HTTP Dos) Protection provides an effective way to prevent such attacks from being relayed to your protected Web servers. The HTTP DoS feature also ensures that a NetScaler appliance located between the internet cloud and your Web servers is not brought down by an HTTP DoS attack.

Most attackers on the Internet use applications that discard responses to reduce computation costs, and minimize their size to avoid detection. The attackers focus on speed, devising ways to send attack packets, establish connections or send HTTP requests as rapidly as possible.

Real HTTP clients such as Internet Explorer, Firefox, or NetScape browsers can understand HTML Refresh meta tags, Java scripts, and cookies. In standard HTTP the clients have most of these features enabled. However, the dummy clients used in DoS attacks cannot parse the response from the server. If malicious clients attempt to parse and send requests intelligently, it becomes difficult for them to launch the attack aggressively.

When the NetScaler appliance detects an attack, it responds to a percentage of incoming requests with a Java or HTML script containing a simple refresh and cookie. (You configure that percentage by setting the Client Detect Rate parameter.) Real Web browsers and other Web-based client programs can parse this response and then resend a POST request with the cookie. DoS clients drop the NetScaler appliance's response instead of parsing it, and their requests are therefore dropped as well.

Even when a legitimate client responds correctly to the NetScaler appliance's refresh response, the cookie in the client's POST request may become invalid in the following conditions:

- If the original request was made before the NetScaler appliance detected the DoS attack, but the resent request was made after the appliance had come under attack.
- When the client's think time exceeds four minutes, after which the cookie becomes invalid.

Both of these scenarios are rare, but not impossible. In addition, the HTTP DoS protection feature has the following limitations:

- Under an attack, all POST requests are dropped, and an error page with a cookie is sent.
- Under an attack, all embedded objects without a cookie are dropped, and an error page with a cookie is sent.

The HTTP DoS protection feature may affect other NetScaler features. Using DoS protection for a particular content switching policy, however, creates additional overhead because the policy engine must find the policy to be matched. There is some overhead for SSL requests due to SSL decryption of the encrypted data. Because most attacks are not on a secure network, though, the attack is less aggressive.

If you have implemented priority queuing, while it is under attack a NetScaler appliance places requests without proper cookies in a low-priority queue. Although this creates overhead, it protects your Web servers from false clients. HTTP DoS protection typically has minimal effect on throughput, since the test JavaScript is sent for a small percentage of requests only. The latency of requests is increased, because the client must re-issue the request after it receives the JavaScript. These requests are also queued

To implement HTTP DoS protection, you enable the feature and define a policy for applying this feature. Then you configure your services with the settings required for HTTP DoS. You also bind a TCP monitor to each service and bind your policy to each service to put it into effect.

Layer 3-4 SYN Denial-of-Service Protection

Any NetScaler appliance with system software version 8.1 or later automatically provides protection against SYN DoS attacks.

To mount such an attack, a hacker initiates a large number of TCP connections but does not respond to the SYN-ACK messages sent by the victimized server. The source IP addresses in the SYN messages received by the server are typically spoofed. Because new SYN messages arrive before the half-open connections initiated by previous SYN messages time out, the number of such connections increases until the server no longer has enough memory available to accept new connections. In extreme cases, the system memory stack can overflow.

A NetScaler appliance defends against SYN flood attacks by using SYN cookies instead of maintaining half-open connections on the system memory stack. The appliance sends a cookie to each client that requests a TCP connection, but it does not maintain the states of half-open connections. Instead, the appliance allocates system memory for a connection only upon receiving the final ACK packet, or, for HTTP traffic, upon receiving an HTTP request. This prevents SYN attacks and allows normal TCP communications with legitimate clients to continue uninterrupted.

SYN DoS protection on the NetScaler appliance ensures the following:

- The memory of the NetScaler is not wasted on false SYN packets. Instead, memory is used to serve legitimate clients.
- Normal TCP communications with legitimate clients continue uninterrupted, even when the Web site is under SYN flood attack.

In addition, because the NetScaler appliance allocates memory for HTTP connection state only after it receives an HTTP request, it protects Web sites from idle connection attacks.

SYN DoS protection on your NetScaler appliance requires no external configuration. It is enabled by default.

Enabling HTTP DoS Protection

To configure HTTP DoS protection, you must first enable the feature.

To enable HTTP DoS protection by using the command line interface

At the command prompt, type the following commands to enable HTTP DoS protection and verify the configuration:

- enable ns feature HttpDoSProtection
- show ns feature

Example

```
> enable ns feature HttpDoSProtection
 Done
> show ns feature

      Feature                 Acronym          Status
      -------                 -------          ------
 1)   Web Logging               WL               ON
 2)   Surge Protection          SP               OFF
 .
 .
 .
 10)  Global Server Load Balancing  GSLB            ON
 11)  Http DoS Protection        HDOSP            ON
 12)  Content Filtering          CF               ON
 .
 .
 23)  HTML Injection             HTMLInjection    ON
 24)  NetScaler Push             push             OFF
 Done
>
```

To enable HTTP DoS protection by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, click Configure Advanced Features.
3. In the Configure Advanced Features dialog box, select the HTTP DoS Protection check box.
4. Click OK.

Defining an HTTP DoS Policy

After you enable HTTP DoS protection, you next create a policy.

Note: Before changing the default setting for Client Detect Rate, see "Tuning the Client Detection/JavaScript Challenge Response Rate."

To configure a HTTP DoS policy by using the command line interface

At the command prompt, type one of the following commands to configure an HTTP DoS policy and verify the configuration:

- add dos policy <name> -qDepth <positive_integer> [-cltDetectRate <positive_integer>]
- set dos policy <name> -qDepth <positive_integer> [-cltDetectRate <positive_integer>]

Example

```
> add dos policy pol-HTTP-DoS  -qDepth 30
 Done
> set dos policy pol-HTTP-DoS  -qDepth 40
 Done
> show dos policy
1)      Policy: pol-HTTP-DoS    QDepth: 40
 Done
>
```

Parameters for defining an HTTP DoS policy

name

A name for your HTTP DoS policy. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should chose a name that helps identify the type of action.

qdepth

An integer that represents the maximum number of connections that can be placed in the queue at one time.

cltDetectRate

An integer that represents the percentage of traffic to which the HTTP DoS policy should be applied.

To configure an HTTP DoS policy by using the configuration utility

1. Navigate to Protection Features > HTTP DoS.
2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.
3. In the Create HTTP DoS Policy or Configure HTTP DoS Policy dialog box, specify values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for defining an HTTP DoS policy" as follows (asterisk indicates a required parameter):
   - Name*—name (You cannot change the name of an existing policy.)
   - QDepth*—qdepth
   - Client Detect Rate—cltDetectRate (Before changing the default setting for cltDetectRate, see "Tuning the Client Detection/JavaScript Challenge Response Rate.")
4. Click OK to create your new policy. The policy that you created appears in the details pane, and the status bar displays a message indicating that the DoS policy is successfully configured.

Configuring an HTTP DoS Service

After you configure an HTTP DoS policy, you must configure a service for your policy. The service accepts HTTP traffic that is protected by the HTTP DoS policy.

To configure an HTTP DoS service by using the command line interface

At the command prompt, type one of the following commands to configure an HTTP DoS service and verify the configuration:

- add service <name>@ (<IP>@ | <serverName>@) HTTP <port> [-maxClient <positive_integer>] [-maxReq <positive_integer>] -state ENABLED
- set service <name>@ (<IP>@ | <serverName>@) HTTP <port> [-maxClient <positive_integer>] [-maxReq <positive_integer>] -state ENABLED

Example

```
> add service ser-HTTP-Dos1 10.102.29.40 HTTP 87
 Done
> set service ser-HTTP-Dos1 -maxReq 20
 Done
> show service
1)      srv-http-10 (10.102.29.30:80) - HTTP
        State: DOWN
        Last state change was at Wed Jul  8 07:49:52 2009
        Time since last state change: 34 days, 00:48:18.700
        Server Name: 10.102.29.30
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): NO
        HTTP Compression(CMP): NO
        Idle timeout: Client: 180 sec   Server: 360 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED
         .
         .
         .
5)      ser-HTTP-Dos1 (10.102.29.40:87) - HTTP
```

```
        State: DOWN
        Last state change was at Tue Aug 11 08:23:40 2009
        Time since last state change: 0 days, 00:14:30.300
        Server Name: 10.102.29.40
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 20     Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): NO
        HTTP Compression(CMP): YES
        Idle timeout: Client: 180 sec   Server: 360 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED
 Done
>
```

Parameters for configuring an HTTP DoS service

name

A name for your service. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should chose a name that helps identify the traffic this service will handle.

IP

The IP of the server that the service represents.

serverName

The FQDN of the server that the service represents.

port

The port on which your service will listen. This is normally port 80 (for HTTP) or port 443 (for HTTPS).

maxClient

The maximum number of clients.

maxReq

The maximum number of requests that can be sent on a persistent connection to the service.

state

The state of the service after it is added.

To configure an HTTP DoS service by using the configuration utility

1. Navigate to Load Balancing > Services.
2. In the details pane, do one of the following:
   - To create a new service, click Add.
   - To modify an existing service, select the service, and then click Open.
3. In the Create Server or Configure Server dialog box, specify values for the following parameters, which correspond to the descriptions in "Parameters for configuring an HTTP DoS service" as follows (asterisk indicates a required parameter):
   - Service Name*—name (You cannot change the name of an existing service.)
   - Server*—IP or serverName (Specify one or the other, not both.)
   - Port*—port
4. If the Enable Service check box is not selected, select it.
5. Select the Advanced tab, and select the Override Global check box to enable those choices.
6. Specify values for the following parameters.
   - Max Clients*—maxClient
   - Max Requests*—maxReq
7. Click Create or OK, and then click Close. The service appears in the list of services.

Binding an HTTP DoS Monitor and Policy

To put HTTP DoS protection into effect after you have configured an HTTP DoS service, you must bind the monitor, and then bind the service to the HTTP DoS policy.

To bind the monitor to the service by using the command line interface

At the command prompt, type the following commands to bind the monitor to the service and verify the configuration:

- bind lb monitor <monitorName> <serviceName>
- show lb monitor

Example

```
> bind lb monitor tcp ser-HTTP-DoS
 Done
> show lb monitor
1)  Name.......:  ping-default  Type......:    PING   State....ENABLED
2)  Name.......:   tcp-default  Type......:     TCP   State....ENABLED
3)  Name.......:        ping  Type......:    PING   State....ENABLED
4)  Name.......:         tcp  Type......:     TCP   State....ENABLED
5)  Name.......:        http  Type......:    HTTP   State....ENABLED
 .
 .
 .
17)  Name.......:     ldns-dns  Type......: LDNS-DNS   State....ENABLED
 Done
```

To bind the policy to the service by using the command line interface

At the command prompt, type the following commands to bind the policy to the service and verify the configuration:

bind service <serviceName> -policyName <policyname>

Example

```
> bind service ser-HTTP-DoS -policyName pol-HTTP-DoS
```

```
 Done
> show service
1)    srv-http-10 (10.102.29.30:80) - HTTP
      State: DOWN
      Last state change was at Wed Jul  8 07:49:52 2009
      Time since last state change: 34 days, 01:24:58.510
      Server Name: 10.102.29.30
      Server ID : 0   Monitor Threshold : 0
      Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
      Use Source IP: NO
      Client Keepalive(CKA): NO
      Access Down Service: NO
      TCP Buffering(TCPB): NO
      HTTP Compression(CMP): NO
      Idle timeout: Client: 180 sec   Server: 360 sec
      Client IP: DISABLED
      Cacheable: NO
      SC: OFF
      SP: ON
      Down state flush: ENABLED
      .
      .
      .
4)    ser-HTTP-Dos (10.102.29.18:88) - HTTP
      State: DOWN
      Last state change was at Tue Aug 11 08:19:45 2009
      Time since last state change: 0 days, 00:55:05.40
      Server Name: 10.102.29.18
      Server ID : 0   Monitor Threshold : 0
      Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
      Use Source IP: NO
      Client Keepalive(CKA): NO
      Access Down Service: NO
      TCP Buffering(TCPB): NO
      HTTP Compression(CMP): YES
      Idle timeout: Client: 180 sec   Server: 360 sec
      Client IP: DISABLED
      Cacheable: NO
      SC: OFF
      SP: ON
      Down state flush: ENABLED
5)    ser-HTTP-Dos1 (10.102.29.40:87) - HTTP
      State: DOWN
      Last state change was at Tue Aug 11 08:23:40 2009
      Time since last state change: 0 days, 00:51:10.110
      Server Name: 10.102.29.40
      Server ID : 0   Monitor Threshold : 0
      Max Conn: 0     Max Req: 20     Max Bandwidth: 0 kbits
      Use Source IP: NO
      Client Keepalive(CKA): NO
      Access Down Service: NO
      TCP Buffering(TCPB): NO
      HTTP Compression(CMP): YES
      Idle timeout: Client: 180 sec   Server: 360 sec
      Client IP: DISABLED
      Cacheable: NO
```

```
        SC: OFF
        SP: OFF
        Down state flush: ENABLED
 Done
>
```

To bind the monitor and policy to the service by using the configuration utility

1. Navigate to Load Balancing > Services.
2. In the details pane, select the service that you want to bind, and then click Open.
3. In the Configure Service dialog box, select the Monitor tab, click the name of the monitor you want in the Monitors list, and then click Add. The selected monitor is added to the Configured frame.
4. Select the Policies tab, then select the HTTP DoS tab.
5. Select a policy from the Available Policies list, and then click Add. The policy appears in the Configured Policies list.
6. Click OK, and then click Close. A message appears in the status bar, stating that the service has been configured.

Tuning the Client Detection/JavaScript Challenge Response Rate

After you have enabled and configured HTTP DoS protection, if more than the maximum specified number of clients are waiting in the NetScaler surge queue for the HTTP DoS service, the HTTP DoS protection function is triggered. The default rate of challenged JavaScript responses sent to the client is one percent of the server response rate. The default response rate is inadequate in many real attack scenarios, however, and may need to be tuned.

For example, assume that the Web server is capable of a maximum of 500 responses/sec, but is receiving 10,000 Gets/sec. If 1% of the server responses are sent as JavaScript challenges, responses are reduced to almost none: 5 client (500 *0.01) JavaScript responses, for 10000 waiting client requests. Only about 0.05% of the real clients receive JavaScript challenge responses. However, if the client detection/JavaScript challenge response rate is very high (for example, 10%, generating 1000 challenge JavaScript responses per second), it may saturate the upstream links or harm the upstream network devices. Exercise care when modifying the default **Client Detect Rate** value.

If the configured triggering surge queue depth is, for example, 200, and the surge queue size is toggling between 199 and 200, the NetScaler toggles between the “attack” and “no-attack” modes, which is not desirable. The HTTP DoS feature includes a window mechanism is provided. When the surge queue size reaches the designated queue depth value, triggering “attack” mode, the surge queue size must fall for the NetScaler to enter “no-attack” mode. In the scenario just described, if the value of WINDOW_SIZE is set to 20, the surge queue size must fall below 180 before the NetScaler enters “no-attack” mode. During configuration, you must specify a value more than the WINDOW_SIZE for the **QDepth** parameter when adding a DoS policy or setting a DoS policy.

The triggering surge queue depth should be configured on the basis of previous observations of traffic characteristics. For more information about setting up a correct configuration, see "Guidelines for HTTP DoS Protection Deployment."

Guidelines for HTTP DoS Protection Deployment

Citrix recommends you to deploy the HTTP DoS protection feature in a tested and planned manner and closely monitor its performance after the initial deployment. Use the following information to fine-tune the deployment of HTTP DoS Protection.

- The maximum number of concurrent connections supported by your servers.
- The average and normal values of the concurrent connections supported by your servers.
- The maximum output rate (responses/sec) that your server can generate.
- The average traffic that your server handles.
- The typical bandwidth of your network.
- The maximum bandwidth available upstream.
- The limits affecting bandwidth (such as external links, a particular router, or other critical devices on the path that may suffer from a traffic surge).
- Whether allowing a greater number of clients to connect is more important than protecting upstream network devices.

To determine the characteristics of a HTTP DoS attack, you should consider the following issues.

- What is the rate of incoming fake requests that you have experienced in the past?
- What types of requests have you received (complete posts, incomplete gets)?
- Did previous attacks saturate your downstream links? If not, what was the bandwidth?
- What types of source IP addresses and source ports did the HTTP requests have (e.g., IP addresses from one subnet, constant IP, ports increasing by one).
- What types of attacks do you expect in future? What type have you seen in the past?
- Any or all information that can help you tune DoS attack protection.

Priority Queuing

The priority queuing feature lets you filter incoming HTTP traffic on the basis of categories that you create and define, and prioritize those HTTP requests accordingly. Priority queuing directs high-priority requests to the server ahead of low-priority requests, so that users who need resources for important business uses receive expedited access to your protected Web servers.

Note: The priority queuing feature is not supported in NetScaler 9.2 nCore.

To implement priority queuing, you create priority queuing policies that specify a priority, weight, threshold, and implicit action. When an incoming request matches a priority queuing policy, the request is processed as the associated action indicates. For example, you can create a priority queuing policy that places all matching requests above a certain threshold in a surge queue, while giving priority treatment to other requests.

You can bind up to three priority queuing policies to a single load balancing virtual server. The priority levels are:

Level 1

A Level 1 policy processes priority requests.

Level 2

A Level 2 policy processes requests that should receive responses as soon as Level 1 requests have been cleared from the queue.

Level 3

A Level 3 policy processes non-priority requests that receive responses only after requests in the first two queues have been cleared.

You can use weighted queuing to adjust the relative priority of each of these queues. Weights can range from 0 to 101. A weight of 101 tells the NetScaler appliance to clear all requests in that queue before forwarding any requests in the lower-priority queues to the Web server. A weight of 0 tells the appliance to send requests in that queue to the Web server only when there are no requests waiting in any of the other queues.

You must assign a unique name to each priority queuing policy. Policy names can be up to 127 characters. Multiple policies bound to the same load balancing virtual server cannot have the same priority level. No two virtual servers that have one or more common underlying physical services can have priority queuing configured or enabled on both virtual servers simultaneously.

To configure priority queuing the NetScaler, you perform the following steps:

- Enable the load balancing feature
- Define a server and service
- Define a load balancing virtual server

- Bind the service to the load balancing virtual server
- Enable the priority queuing feature
- Create the priority queuing policies
- Bind the priority queuing policies to the load balancing virtual server
- Enable priority queuing on load balancing virtual server

For information about enabling load balancing, creating servers, creating virtual servers and services, and binding these servers and services, see the *Citrix NetScaler Traffic Management Guide* at http://support.citrix.com/article/CTX132359. For complete information about policies and expressions, see the *Citrix NetScaler Policy Configuration and Reference Guide* at http://support.citrix.com/article/CTX132362.

Enabling Priority Queuing

To use the priority queuing feature the NetScaler appliance, you must first enable it.

To enable priority queuing by using the command line interface

At the command prompt, type the following commands to enable priority queuing and verify the configuration:

- enable ns feature PriorityQueuing
- show ns feature

Example

```
> enable ns feature PriorityQueuing
 Done
> show ns feature

      Feature                 Acronym           Status
      -------                 -------           ------
1)    Web Logging               WL               ON
2)    Surge Protection          SP               OFF
3)    Load Balancing            LB               ON
.
.
.
8)    Priority Queuing          PQ               ON
.
23)   HTML Injection            HTMLInjection    ON
24)   NetScaler Push            push             OFF
Done
```

To enable priority queuing by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, click Configure advanced features.
3. In the Configure Advanced Features dialog box, select the Priority Queuing check box.
4. Click OK.

Configuring a Priority Queuing Policy

To configure a priority queuing policy, you can use either the configuration utility or the command line.

Note: For more information about using the command line, see "Command Reference."

To configure a priority queuing policy by using the command line interface

At the command prompt, type the following command to configure a priority queuing policy and verify the configuration:

add pq policy <policyName> -rule <expression> -priority <positive_integer> [-weight <positive_integer>] [-qDepth <positive_integer> | -polqDepth <positive_integer>]

Example

```
> add pq policy pol_cgibin -rule "URL == '/cgi-bin/'" -priority 1
 Done
> show pq policy pol_cgibin
1)      Policy: pol_cgibin      Rule: URL == '/cgi-bin/'        Priority: 1     Weight: 10
        Hits: 0
 Done
```

Parameters for configuring a priority queuing policy

policyName

A name for your priority queuing policy. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should chose a name that helps identify the type of action.

rule

An expression that tells the policy which connections it should handle. For complete information about policy expressions, "Policies and Expressions."

priority

An integer from 1 to 3 that represents the priority queue that connections matching this policy should be placed in.

weight

An integer from 1 to 101 that represents the weight assigned to this priority queuing policy. For detailed information about the meaning and uses of different policy weights, see "Setting Up Weighted Queuing."

qDepth

An integer that represents the maximum number of connections that can be placed in the queue at one time.

polqDepth

An integer that represents the total number of waiting clients or requests belonging to the policy.

To configure a priority queuing policy by using the configuration utility

1. Navigate to Protection Features > Priority Queuing.
2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.
3. If you are creating a new policy, in the Create PQ Policy dialog box, in the Name text box, type a name for your new policy.

   The name can consist of from one to 127 letters, numbers and the hyphen and underscore symbol.

   If you are modifying an existing policy, skip this step. You cannot change the name of an existing policy.

4. In the Rule text box, either enter the policy expression directly, or click New to create a policy expression. If you click New, perform the following steps:

   a. In the Create Expression dialog box, click Add.

   b. In the Add Expression dialog box, leave Expression Type set to `General`, and in the Flow Type drop-down list, select a Flow Type. Your choices are REQ (for requests) and RES (for responses).

   c. In the Protocol drop-down list, select a protocol. If you selected REQ in the previous step, your choices are HTTP (Web-based connections), SSL (secure Web connections), TCP and IP. If you selected RES in the previous step, your choices are HTTP, TCP and IP.

   d. In the Qualifier drop-down list, select a qualifier.

      Your choices depend upon your selections in the previous step. Common choices are HTTP VERSION (the version of the HTTP connection), HTTP HEADER (the specified HTTP header), TCP SOURCEPORT/ DESTPORT (the source or destination port of a TCP connection), and IP SOURCEIP/DESTIP (the source or destination IP of the connection).

      If you choose HTTP HEADER, the Header text box appears beneath the original row of text boxes. You fill in the name of the HTTP header you want.

      For a complete description of the available choices, see "Policies and Expressions."

   e. In the Operator drop-down list, select an operator.

      For a complete description of the available choices, see "Policies and Expressions."

   f. In the Value text box, type the value you want to test for.

      This may be a text string or a number, depending upon the context. For a complete description of values appropriate to the specific context, see "Policies and

Expressions."

g. Click OK. The expression is added in the Expression text box.

h. Click Create. The expression appears in the Rule text box.

5. In the Priority and Weight text boxes, type numeric values, for example, 1 and 30. For more information about Priority and Weight, see "Setting Up Weighted Queuing."

6. Enter a numeric value for either Queue Depth or Policy Queue Depth, for example 234, and click Create.

   - Queue Depth Defines the total number of waiting clients or requests on the virtual server to which the policy is bound.

   - Policy Queue Depth Defines the total number of waiting clients or requests belonging to the policy.

   The policy is created and appears in the Priority Queuing page.

   Note: To create additional priority queuing policies, repeat the procedure in the preceding section, and click Close after you finish.

Binding a Priority Queuing Policy

After you create a priority queuing policy, you must bind it to the appropriate virtual server to put it into effect.

To bind a priority queuing policy by using the command line interface

At the command prompt, type the following commands to bind a policy and verify the configuration:

- bind lb vserver <name> -policyName <policyname>
- show lb vserver <name>

Example

```
> bind lb vserver lbvip -policyname pol_cgibin
 Done
> show lb vserver lbvip
        lbvip (8.7.6.6:80) - HTTP       Type: ADDRESS
        State: DOWN
        Last state change was at Wed Jul 15 05:54:24 2009 (+782 ms)
        Time since last state change: 26 days, 05:44:37.370
        Effective State: DOWN
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        No. of Bound Services :  0 (Total)       0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE
        Vserver IP and Port insertion: OFF
        Push: DISABLED  Push VServer:
        Push Multi Clients: NO
        Push Label Rule: none

1)      Policy : ns_cmp_msapp Priority:0

1)      Priority Queuing Policy : pol_cgibin
 Done
>
```

To bind a priority queuing policy by using the configuration utility

1. In the navigation pane, locate and select the virtual server to which you want to bind the priority queuing policy.

   - To select a load balancing virtual server, expand Load Balancing > Virtual Servers, then select the load balancing virtual server that you want..

   - To select a content switching virtual server, expand Content Switching > Virtual Servers, then select the content switching virtual server that you want..
2. In the Configure Virtual Server dialog box, select the Policies tab.

3. Click the double right-arrow (») symbol to display the complete list of policy types, and then select Priority Queuing from the drop-down list.

4. Click Insert Policy.

5. In the Policy Name row, select the policy that you want to bind from the drop-down list.

6. ClickOK to save your changes.

Setting Up Weighted Queuing

When priority queuing is implemented, lower-priority requests are typically kept on hold while higher-priority requests are served. The lower-priority requests may therefore be delayed if there is a constant flow of higher-priority requests.

To prevent delays for low-priority requests across multiple priority levels, you can configure weighted queuing for serving requests. The default weights for the priorities are:

- Gold - Priority 1 - Weight 3
- Silver - Priority 2 - Weight 2
- Bronze - Priority 3 - Weight 1

You assign the minimum weight, zero (0), to requests that the NetScaler appliance should send to the server only if no requests are stored in any of the other queues. You assign the maximum weight, 101, to requests that the appliance should send to the server immediately, ahead of any requests stored in any of the other queues. Weights between these two set the relative priority of a particular queue in relation to the other queues. Queues with a higher weight are processed first; queues with a lower weight after the others have been processed. To assign the weights, see "Configuring a Priority Queuing Policy."

Note: The weight assigned to a higher-priority queue must be larger than the weight assigned to a lower-priority queue. For example, the weight assigned to The Gold (Priority 1) queue must be greater than the weight assigned to the Silver (Priority 2) queue.

SureConnect

You can use the SureConnect feature of the Citrix NetScaler appliance to service all incoming connections with either the requested content or a custom Web page that displays information about a delay in the request being serviced.

When servers are overloaded with the requests, the servers might either respond slowly or not at all. The SureConnect feature enables the NetScaler appliance to detect and compensate such conditions by ensuring that every client request gets serviced in some way, such as either a custom Web page or actual content is sent to the client.

SureConnect is activated when the response time or maximum server connections to a client request exceeds a limit that you have set. The SureConnect browser window displays one of the following:

- A progress bar with the amount of time remaining until the requested content will be available.
- Alternate Web content of your choice (alternate page).
- Both a progress bar and alternate page.
- Complete custom content of your choice.

You can configure whether the SureConnect progress bar alone is displayed or both the progress bar and the alternate page are displayed.

When the server becomes responsive again, the original request for content is served. If the user chooses, the alternate content window can remain in focus.

Subsequent requests from the same user within the same session are served immediately. This can be configured using the settings described later in this section.

SureConnect can be activated when a response is delayed, and when the number of user connections to a given URL exceeds a specified threshold.

SureConnect works with all standard browsers, including Microsoft Internet Explorer, Netscape Navigator, and Mozilla Firefox.

SureConnect is advantageous in the following situations:

- **Full server queue**

  The server can respond fast, but there are too many users. This results in the server's queue being full and unable to process additional client requests.

  SureConnect Solution: In this situation, the SureConnect window is displayed, showing the time left until the content will be available. The alternate page is displayed under the progress bar, if an alternate page has been configured.

- **Large response delay**

The server response is slow. Typically, if a Web server does not respond to a client request quickly, the user will leave the site.

SureConnect Solution: When the predicted delay reaches a configured time threshold, the SureConnect window displays the progress bar and the optional alternate page in the client browser.

- **Client time-out**

  When the client requests content from a very slow Web site, a time-out message displays in the client browser, and the content is not delivered. The user may leave the site.

  SureConnect Solution: The appliance stores the request until the server is no longer busy and delivers the requested content to the client.

- **Server experiencing a traffic surge**

  The server typically responds quickly, but the current load of open connections is greater than the server capacity to serve them. Therefore, the server response is delayed.

  SureConnect Solution: A SureConnect window is displayed in the client browser, showing the time left. The alternate page from the server is also displayed if it has been configured.

Installing SureConnect

SureConnect files must be installed on the alternate content server, which can be the same as the primary server.

On a Windows server, extract the sc_xx.exe file (where xx is the build number), or on a UNIX server, extract the sc_xx.tar file (where xx is the build number).

Note: You must install SureConnect in the default Web root directory.

If the alternate content server is the same as the primary server, place the SureConnect and alternate content files in any directory under the Web root directory. Specify this path when you add a policy to configure SureConnect. By default, SureConnect files are installed in the /Citrix NetScaler appliance directory under the default Web root directory.

If the alternate content server is different than the primary server, the SureConnect and alternate content files must be in a unique directory under the Web root directory. By default, this unique directory is the /Citrix NetScaler system directory. Specify this path when you add a policy to configure SureConnect.

The following files are extracted:

- Alternate content files (progressbar.htm, alternatepage.htm, and barandpage.htm)
- System-Logo.gif
- Customer-Logo.gif
- Sample.gif
- README.txt.

Installing on UNIX

This section describes how to install SureConnect alternate content on a UNIX server. The following are the prerequisites:

- The UNIX server is running the Apache server.
- The shell with the # prompt is in use.
- Apache is installed in the default location.
- The sc_xx.tar file is downloaded from the organization's Web site into the /var/ftp/incoming directory.

To install SureConnect

1. At the command prompt, navigate to the htdocs directory:

   cd /usr/local/apache/htdocs

2. Type the following command:

   tar xvpf/var/ftp/incoming/sc_xx.tar

The output from the .tar file is displayed. A /Citrix NetScaler system directory is created under the specified path and the SureConnect files are installed.

Installing on Windows

This section describes how to install SureConnect alternate content on a Windows server. The following are the prerequisites:

- The server is running the Microsoft Internet Information Server.
- The DOS prompt is being used.
- The SureConnect zip (self-extracting) file is downloaded from the organization Web site using FTP into the C:\inetpub\wwwroot directory.

To install SureConnect on Windows

Do one of the following:

- At the command prompt, navigate to the wwwroot directory:

  cd c:\inetpub\wwwroot

- Type the name of the executable file:

  sc_xx.exe

- Double-click the sc_xx.exe icon from the Microsoft Windows Explorer Web browser, extract from the compressed file into the default path (for example, the c:\inetpub\wwwroot directory).

Output from the zip file is displayed. A /Citrix NetScaler system directory is created under the specified path, and the SureConnect files are installed.

Configuring SureConnect

The following topics describe how to configure SureConnect for scenarios involving alternate server failure.

- "Configuring the Response for Alternate Server Failure"
- "Configuring the SureConnect Policies"
- "Customizing the Alternate Content File"
- "Configuring SureConnect for Citrix NetScaler Features"

Configuring the Response for Alternate Server Failure

If the alternate server fails, and the primary server cannot immediately deliver the requested content to the client, SureConnect does not display alternate content from the failed alternate server in the client Web browser.

The Citrix NetScaler appliance automatically sends a response to the client browser. You can customize the server response to display information suited to your needs.

The default response is:

```
Your Request is being processed… Estimated Time: ____ Secs
```

Customizing the Default Response

The NetScaler appliance automatically sends the response to the client if the alternate server fails, or if the appliance is configured to send the default response.

To customize the default response of the appliance, create a vsr.htm file (a sample is provided in this section) as follows:

- The file can contain any valid HTML statements other than embedded objects.
- The file size cannot exceed 800 bytes.
- The file must reside on the NetScaler appliance. If you have a high availability (HA) setup, the file must reside on the primary and secondary nodes. Any changes made to the file on the primary node must also be applied to the file on the secondary node.
- Put vsr.htm file in the /etc directory.

To customize the default response

Change any of the contents between the </HEAD> and </HTML> tags in the vsr.htm file. Following is the sample content from vsr.htm file. The sections that you can edit are in bold text.

HTTP/1.1 200 OK
Server: NS_WS3.0
Content-Type: text/html
Cache-control: no-cache
Pragma: no-cache
Set-Cookie: NSC_BPIP=@@SID@@; path=/
<HTML> <HEAD> <META HTTP-EQUIV="Refresh" CONTENT="0">
</HEAD> **Your request is being processed...**
**
Estimated Delay: @@DELAY@@ Sec ** </HTML>

Note: Include @@DELAY@@ to display the predicted delayed response time in seconds.

SureConnect with In-Memory response (NS action)

When defining the SureConnect policy by using the add sc policy command, you can configure the NetScaler Appliance to serve alternative content to the client.

To enable SureConnect and configure the in-memory response, perform the following tasks:

- Enable the SureConnect feature on the appliance by using the `enable feature SC` command
- Define the services by using the `add service <servicename> <IP address> <servicetype> <port>` command. This identifies the original server for which the SureConnect is configured and the types of services.
- Add a SureConnect policy by using the `add sc policy` command. You can configure a URL-based policy or a rule-based policy. The incoming requests are validated against the URL or rule you specify in the policy.

Note: You can configure the SureConnect feature on a load balancing virtual server. In that case, perform the following additional actions:

- Enable Load Balancing by using the `enable feature LB` command.
- Enable SureConnect feature on the virtual server by using the `set lb vserver <vservername> -sc ON` command.
- Bind services to the virtual server by using the `bind lb vserver <name> <serviceName>` command.
- Bind policies to the virtual server by using the `bind lb vserver <name> -policyname <name>` command.

The following example illustrates how to configure SureConnect for the load balancing feature so that SureConnect will display alternative content from the NetScaler appliance.

In this example, two physical servers, with IP addresses, 10.101.3.187 and 10.101.3.188 are load balanced by the NetScaler appliance. The appliance has one configured virtual server, vs-NSact, whose IP address is 10.101.3.201. The file that contains the alternative content is vsr.htm. It is copied from the file system into system memory. Services are loaded until the SureConnect policy triggers, and the appliance supplies the alternate content.

```
enable feature SC LB
add service psvc1 10.101.3.187 http 80
add service psvc2 10.101.3.188 http 80
add lb vserver vs-NSact HTTP 10.101.3.201 80
bind lb vserver vs-NSact psvc1
bind lb vserver vs-NSact psvc2
```

```
add sc policy policyNS -url /cgi-bin/*.cgi -delay 400000
-action NS
set sc parameter -vsr /nsconfig/ssl/vsr.htm
bind lb vserver vs-NSact -policyName policyNS
set lb vserver vs-NSact -sc ON
save config
```

Table 1. Parameter values used in this example

Service	
Name	psvc1, psvc2
Server	10.101.3.187, 10.101.3.188
Protocol	HTTP
Port	80
Load Balancing Virtual Server	
Name	vs-NSact
IP Address	10.101.3.201
Protocol	HTTP
Port	80
SureConnect Policy	
Name	policyNS
URL	/cgi-bin/*.cgi
Delay(microseconds)	400000
SC Parameter	
VSR File Name	vsr.htm

To configure this example by using the configuration utility

1. In the In the navigation pane, navigate to System > Settings. In the Modes and Features pane, perform the following actions:

   a. Click Configure Basic Features, select Load Balancing, and Click Go.

   b. Click Configure Advanced Features, select SureConnect, and Click Go.
2. In the navigation pane, navigate to Protection Features > SureConnect. In the details pane, click Parameters. In the Configure SureConnect Parameters window, browse and select the VSR filename.

3. Navigate to Load Balancing > Services. In the details pane, click Add. In the **Create Services** window, enter the paramter values as shown in Table 5-1, and click **OK**.

4. Navigate to Load Balancing > Virtual servers. In the details pane, click Add. In the Create Virtual Server (Load Balancing) dialog box, enter the values shown in Table 5.1 for the Load Balancing Virtual Server parameters and click OK.

5. In the navigation pane, navigate to Load Balancing > Virtual servers. Select the virtual server vs-NSact and click Open in the details pane. The Configure Virtual system (Load Balancing) dialog box, displays the list of configured services. Select services psvc1 and psvc2 and click OK.

6. In the navigation pane, expand Protection Features > SureConnect. In the details pane, click Add. Create the policy with the values as given in the parameters table.

7. In the navigation pane, navigate to Load Balancing > Virtual servers. Select the virtual server vs-NSact and click Open in the details pane. In the Configure Virtual system (Load Balancing) dialog box, click the Policies tab. Click >> to expand the features. Select **SureConnect**. When the list of SureConnect polices appear, select policyNS and click OK.

8. In the navigation pane, navigate to Load Balancing > Virtual servers. Select the virtual server vs-NSact and click Open in the details pane. In the Configure Virtual system (Load Balancing) dialog box, on the Advanced tab, select SC and click OK.

Configuring the SureConnect Policies

You can configure the following SureConnect policies. The NetScaler appliance matches incoming requests in the order the policies are configured:

- Exact URL-based policies
- Wildcard rule-based policies

Configuring Exact URL Based Policies

When you configure an exact URL based policy, the NetScaler appliance matches the incoming request against the URL that has been configured in the policy. URL based policies take precedence over rule based policies.

To configure an exact URL based policy by using the command line interface

At the command prompt, type:

add sc policy <name> [-url <*URL*> | -rule <*expression*>] [-delay <*usecs*>] [-maxConn <positive_integer>] [-action (ACS <altContentSvcName> <altContentPath>) | NS | NOACTION)]

Parameters for configuring an exact URL-based policy

name (Name)

The name of the SureConnect policy. Maximum length: 31 characters. Must begin with an ASCII alphabetic or underscore (_) character and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

url (URL)

The URL against which to match incoming client request. If the request does not match any SureConnect policy, SureConnect does not trigger. Maximum Length: 127 characters. Must begin with an ASCII alphabetic or underscore (_) character and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

rule (Expression)

The expression that the system matches against the incoming request. Expression logic requires names of predefined expressions separated by the logical operators || and &&, and possibly grouped by using parentheses. If the expression contains blanks (for example, between an expression name and a logical operator), the entire argument must be enclosed in double quotation marks ("This requirement does not apply to the configuration utility"). Following are examples of valid expression logic:

```
ns_ext_cgi||ns_ext_asp
```

```
ns_non_get && (ns_header_cookie||ns_header_pragma)
```

Maximum Length: 1499 characters.

delay (Delay)

The delay threshold, in microseconds, for the configured URL or the rule. If the delay statistics gathered for the request that matches the URL specified in the policy exceed the specified delay SureConnect is triggered for that request. Minimum value: 1 Maximum value: 599999999.

maxConn (Maximum Client Connections)

The maximum number of concurrent connections that can be open for the configured policy. Minimum value: 1 Maximum value: 4294967294

action (Action)

The action to be taken when the thresholds are reached. Possible values: ACS , NS, NOACTION.

ACS - Specifies that alternative content is to be served from altContSvcName, with the path altContPath.

NS - Specifies that alternate content is to be served from the NetScaler appliance.

NO ACTION - Specifies that no alternative content is to be served. However, delay statistics are still collected for the configured URLs, and, if the - maxconn parameter is set, the number of connections is limited to the value specified by that parameter. (However, alternative content is not served even if the -maxconn threshold is met).

altContentSvcName (Alternate Service Name)

The alternative content service name used in the ACS action. Maximum Length: 127 characters.

altContentPath (Alternate Content Path)

The alternative content path for the ACS action. Maximum Length: 127 characters.

To configure an exact URL based policy by using the configuration utility

1. In the navigation pane, expand Protection Features, and then click SureConnect.
2. In the details pane, click Add.
3. In the Create SureConnect Policy dialog box, set the following parameters:
   - Name*
   - URL (Make sure that the URL check box is selected)
   - Value*
   - Delay (microseconds)*
   - Maximum Client Connections
   - Action (Select from the Choose Action list.)
   - Alternate Service Name (if you select ACS as the Action)
   - Alternate Content Path (if you select ACS as the Action)

   *A required parameter
4. Click Create, and click Close. The URL based policy appears in the right pane, and a message displays in the status bar that the policy is successfully configured.

Configuring Wildcard Rule-Based Policies

SureConnect matches the incoming requests to a defined rule, if you configure a rule-based policy.

To configure a SureConnect policy based on a wildcard rule by using the command line interface

1. Create the expression(s).

   Use the add expression command to create each expression.

2. Create the rule(s).

   Use the add sc policy command with the -rule expression_logic argument to specify the rule(s). In the -rule expression_logic argument, refer to the expression(s) you created in step 1.

   Repeat this command to create and name each rule.

The following example creates a rule “rule = = /*.cgi”:

```
add vserver vs-lb http 1.1.1.1 80
add expression expr1 url == /cgi-bin/*.cgi
add expression expr2 url == /index.html
add sc policy surecpolicy1 -rule (expr1||expr2) -delay 1000000 -action NS
bind lb vserver vs-lb -policyName surecpolicy1
```

To complete the SureConnect configuration, you will need to enter additional commands, beyond those shown in the example.

To configure a wildcard rule-based policy by using the configuration utility

1. Navigate to Protection Features > SureConnect.
2. In the details pane, click Add.
3. In the Create SureConnect Policy dialog box, in the Name text box, type the name of the policy.
4. Under What to Monitor, click Expression, and then click Configure.
5. In the Create Expression dialog box, click Add.
6. In the Add Expression dialog box, enter an expression. For example, you can select an Expression Type of General, a Flow Type of REQ, a Protocol of HTTP, a Qualifier of URLQUERY, an Operator of CONTAINS, and in the Value text box, type AA. For more information about expressions, see "Policies and Expressions."
7. Click OK, and click Close.
8. In the Create Expression dialog box, click Create.

Examples of wildcard rules:

`"/sports/*"` matches all URLs under `/sports`

`"/sports*"` matches all URLs whose prefix matches `"/sports"`, starting at the beginning of the URL.

`"/*.jsp"` matches all URLs whose file extension is `"jsp"`

When configuring rule-based policies, first add the more specific rule-based policies, before adding more generic rules (for example, `add /cgi-bin/sports*.cgi before adding /cgi-bin/*.cgi`).

Displaying the Configured SureConnect Policy

To view the SureConnect policy that you have configured, at the NetScaler command prompt, enter the show sc policy command.

Customizing the Alternate Content File

When SureConnect activates, it can display alternate content from one of the following files that you have configured:

- **progressbar.htm.** Displays the progress information.
- **alternatepage.htm.** Displays an alternate page.
- **barandpage.htm.** Displays both the progress information and an alternate page.

The alternate content files are JavaScript files. During SureConnect installation, these files are copied onto the server that contains the alternate content. These files can contain alternate content (including an alternate page) or references to other files that contain the alternate content.

This section describes the changes you can make to the alternate content file provided by the appliance.

```
//**** DEFINE YOUR VALUES HERE ****
var alt_url = "/Citrix NetScaler system /sample.gif";
var alt_url = "http://www.DomainName.com";
var Citrix NetScaler system _logo = "netscaler_logo.gif";
var our_logo = "netscaler_logo.gif";
var height = 450;
var width = 550;
var top = 200;
var left = 200;
var popunder = "no"; //specify yes for pop-under & no for pop-up
var shift_focus = "yes" //if you want to send pop-up to background on getting primary content else specify no
//**** YOUR DEFINITIONS ENDS HERE ****
```

You can make these changes:

- **var alt_url.** Specify the URL for the alternate content if a file provides the alternate content. For example:

  var alt_url = “/Citrix NetScaler system/sports.htm”

  Note: The alternate content file must be present in the /Citrix NetScaler system directory under the documents root of the Web server.
- **var our_logo.** Specify the image file of your organization logo.
- **var height.** Specify the height of the SureConnect window.
- **var width.** Specify the width of the SureConnect window.
- **var top and var left.** Specify the position of the SureConnect window.

- **var popunder.** Specifies the position of the alternate content window. Specify the value as NO to place the alternate content window above the original window. Specify the value as YES to place the alternate content window beneath the original window.

- **var shift_focus.** Specify the focus of the alternate content window. YES places the pop-up window in the background when getting the primary content. NO always keeps the pop-up window in focus, even when getting the primary content.

Note: For more information, see the README.txt file provided by the appliance with other alternate content files.

Configuring SureConnect for Citrix NetScaler Features

This section describes how SureConnect works in combination with the load balancing, content switching, cache redirection, and high availability features of the NetScaler appliance.

Configuring SureConnect for Load Balancing

You can use SureConnect in environments where the primary servers use the load balancing feature, with or without alternate servers. If the load balancing virtual server configured for SureConnect fails, the backup virtual server (if there is one) handles the traffic. Backup virtual servers do not support SureConnect policies.

Note: For information about load balancing, see "Load Balancing."

Configuring SureConnect for Cache Redirection

You can use SureConnect in environments where cache redirection is configured. The primary server is a load balancing virtual server bound to the cache redirection virtual server. Regardless of any rules configured for the cache redirection feature:

- You can configure any URL for SureConnect.
- Once SureConnect is activated for a client, requests from the client are always sent to the origin server.

Configuring SureConnect for High Availability

SureConnect is compatible with NetScaler appliances operating in high availability mode.

Note: If the optional vsr.htm file is used, it must be present in both nodes (primary and secondary) and must use the same name and directory.

Activating SureConnect

You can set the Citrix NetScaler appliance to activate SureConnect if either of two criteria match. Both criteria are arguments to the add sc policy command, as described here:

- -delay <microseconds>

  The first time the client requests the URL, the appliance records how long the server takes to respond. The appliance will not activate SureConnect until the second time the URL is requested. The first and second requests may be from the same or different clients.

  If you set -delay argument, SureConnect will be activated the second time the delay reaches the threshold you set.

- -maxConn <positive_integer>

  When the appliance receives a request, it checks the number of connections to the server for the configured URL. SureConnect is activated if the number of connections is greater than or equal to the value that you set for the -maxConn argument.

  If you will be providing alternate content to be displayed in the client’s Web browser, you should configure the -action argument of the add sc policy command. This specifies for the NetScaler appliance whether the alternate content is coming from a dedicated alternate server (-action ACS) or the appliance (-action NS).

  When SureConnect is activated by the –maxConn argument, the SureConnect window and progress bar are displayed in the client's browser (with an alternate page, if configured).

SureConnect Environments

The following topics describe SureConnect environments.

- "Primary and Alternate Servers"
- "Configuration Checklist"
- "Example Configurations"

Primary and Alternate Servers

The SureConnect environment uses a dedicated server to provide alternate content when the requested content is not available. The alternate content may include an alternate page, plus optional components such as frame set, organization logo, and so on. The alternate and primary servers can be the same server.

You can configure SureConnect to display a progress bar when the requested content is not available (or the progress bar and an alternate page).

The following figure illustrates the SureConnect environment.

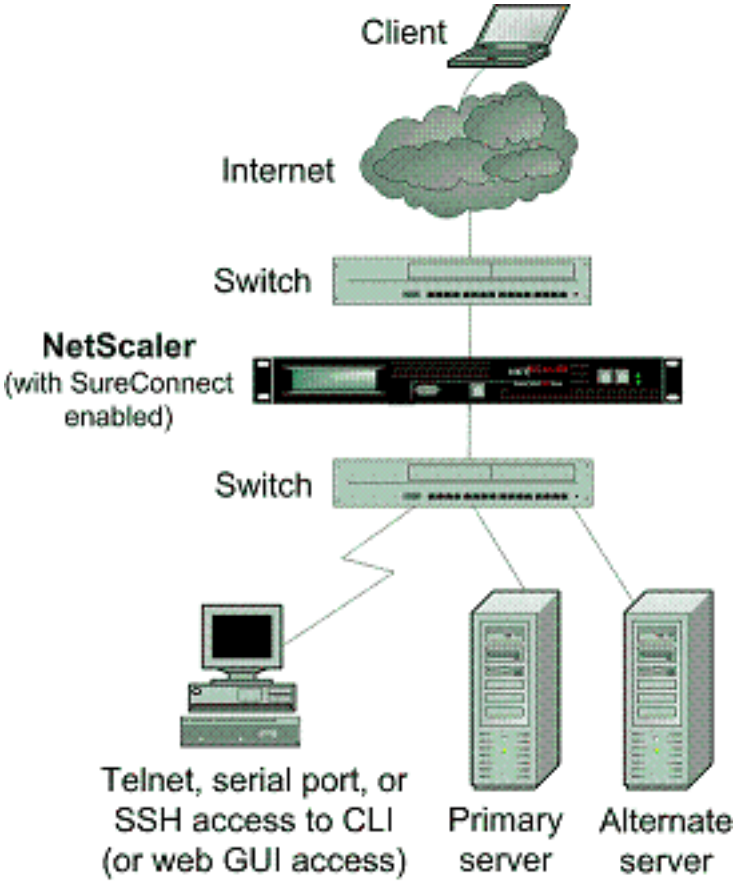


Figure 1. SureConnect - Primary and Alternate Servers

Configuration Checklist

Complete the following checklist before you start configuration:

Table 1. Configuration Checklist

☐	The same builds are running for the appliance and for the SureConnect files as suggested by appliance staff. Appliance Build Number: _____ SureConnect (sc_xx.exe) Build Number: _____
☐	The latest SureConnect files (style files) are extracted to: · All primary servers (required for NS action). · The alternate content server (required for ACS action).
☐	All customizations to the latest style and vsr.htm files are applied.
☐	The alternate content server is accessible from the Internet (required for ACS action).
☐	If the -redirectURL URL argument of the add vserver CLI command needs to be specified: · The URL is up and running. · This URL is not on the configured servers. · This URL does not match any content in the vserver (that is, do not redirect a missing URL to itself). Redirecting a missing URL to itself can send some browsers into an infinite loop.
☐	All URLs to be configured for SureConnect are top-level URLs only. (Only the URLs that occupy the whole window or frame can be configured, not the embedded objects).

Following are the steps to configure SureConnect in a setup with a primary server and a dedicated alternate server:

· Enable the SureConnect feature

· Add the SureConnect policy

· Bind the SureConnect policy

You can optionally configure the following:

· Redirect the client to another URL if the primary server fails, or send a customized response to the client if the alternate server fails.

· If the servers do not provide alternate content, send a default or customized response.

To redirect the client to another URL

1. Enable the SureConnect feature.

2. Define the primary server and its service.

   You must identify the original server for which SureConnect support is being configured. At the NetScaler command prompt, type the following command:

   add service <serviceName> <IP> HTTP <port>

   where <serviceName> assigns a name for the service; <IP> is the server's IP address; and <port> is the port number that the service will use.

   Repeat use of the add service CLI command for each service that is to be added.

   You can also configure SureConnect on a load balancing virtual server. At the NetScaler command prompt, type the following command:

   add vserver <name> HTTP <IP> <port>

3. Define and bind the SureConnect policy as follows. If you are configuring a rule-based policy, perform this step as described in "Configuring Wildcard Rule-Based Policies." To configure a URL-based policy, at the NetScaler command prompt, type the following command:

   add sc policy <name> [-url <URL>] [-delay <microsec>] [-maxConn <positiveInteger>]

   For a detailed description of the add sc policy command, see "Command Reference."

   To bind the SureConnect policy, at the NetScaler command prompt, type the following command:

   bind service <serviceName> -policyname <string>

   where <serviceName> is the name of the service defined in step 2, and <string> is the name of the SureConnect policy.

   Repeat the bind service command for each policy created.

   You must include the alternate content page in the altContSvcName argument, and in the altContPath argument of the add sc policy command.

   In the following example, the name of the alternate content file is /Citrix NetScaler system /barandpage.htm, and this file resides in svc2.

4. To save the configuration, at the NetScaler command prompt, type the following command:

   save config

Example Configurations

The following examples illustrate various SureConnect configurations.

The examples assume that monitoring of physical services is enabled. If the alternate system is down, SureConnect will deliver the alternate content from the system itself.

Example 1 - SureConnect Progress Bar and Alternate Page

You can configure SureConnect to display both the progress bar and an alternate page to the user.

To bind a SureConnect policy to a load balancing virtual server, at the command prompt, type the following commands:

bind lb vserver <virtualServerName> -policyName <string>

where <virutalServerName> is the name of the load balancing virtual server defined in step 2 of the configuration process, and <string> is the name of the SureConnect policy defined in step 3.

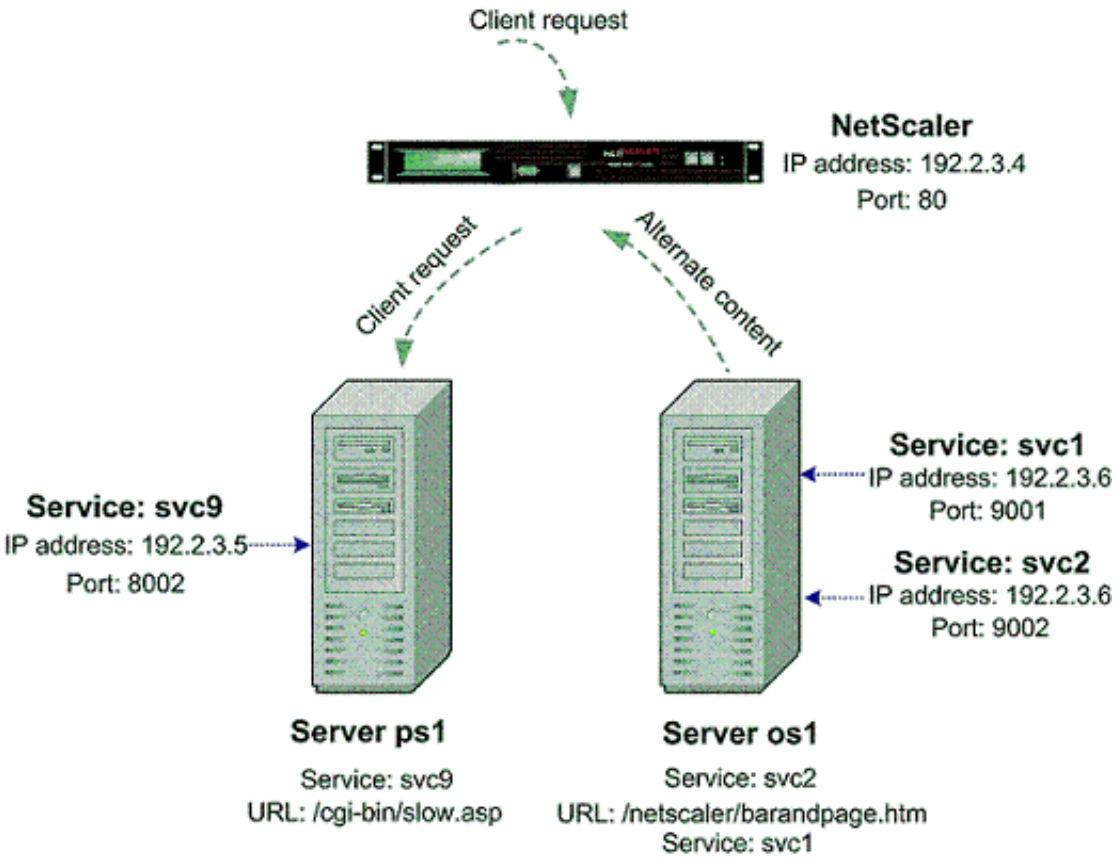

Figure 1. SureConnect Configuration - Example 1

At the NetScaler command prompt, type the following commands:

```
enable feature SC
show ns info
add service svc2 192.2.3.6 HTTP 9002
show server
show service svc2
add service svc9 192.2.3.5 HTTP 8002
add sc policy policy8 -url /cgi-bin/slow.asp
-delay 3000000 -action ACS svc2 /NetScaler 9000 system barandpage.htm
bind service svc9 -policyname policy8
set service svc9 -sc ON
save config
```

After you configure SureConnect, you can enter commands that show information to verify what you have configured.

Example 2 - SureConnect Progress Bar Only

In this example, SureConnect will display only the progress bar. The server orgsrvr with IP address 10.101.8.187 has service orgsvc. This server is connected to the appliance. The service is bound to the appliance. The progressbar.htm file specifies that only the progress bar will be displayed.

At the NetScaler command prompt, type the following commands:

```
enable feature SC
add service orgsvc 10.101.3.187 HTTP 80
add sc policy policy9 -url /cgi-bin/slow.asp
-delay 4000000 -action ACS orgsvc /NetScaler 9000 system / progressbar.htm
bind service orgsvc -policyname policy9
set service orgsvc -sc ON
save config
```

Example 3 - SureConnect with Load Balancing

This example illustrates how to configure the load balancing feature so that SureConnect will display alternate contents from the primary server. For information about load balancing, see "Load Balancing."

In this example, two physical servers with IP 10.101.3.187 and 10.101.3.188 are being load balanced by the appliance. The name and location of the alternate page file is specified in the file alternatepage.htm, which resides on both servers.

The appliance has one configured virtual server address: 10.101.3.201. At the NetScaler command prompt, type the following commands:

```
enable feature SC LB
add service psvc1 10.101.3.187 HTTP 80
add service psvc2 10.101.3.188 HTTP 80
add vserver vs-SureC HTTP 10.101.3.201 80
bind lb vserver vs-SureC psvc1
bind lb vserver vs-SureC psvc2
add sc policy policy9 -url /cgi-bin/slow.asp -delay 4000000
-action ACS vs-SureC /NetScaler system /alternatepage.htm
bind lb vserver vs-SureC -policyName policy9
set lb vserver vs-SureC -sc ON
save config
```

Example 4 - SureConnect with Load Balancing (ACS Action)

This example illustrates how to configure the NetScaler appliance load balancing feature so that SureConnect will display alternate content from the alternate server. For information about load balancing, see "Load Balancing."

In this case, there are two physical servers, IP 10.101.3.187 and 10.101.3.188. Both are being load balanced by the appliance.

The name and location of the alternate page file are specified in file barandpage.htm, which resides on a third server not being load balanced.

The third server's IP address is 10.101.3.189. Because barandpage.htm is specified, the progress bar and alternate page will both be displayed.

The appliance has one configured virtual server "vsvr" whose IP address (Virtual Server) is 10.101.3.200.

At the NetScaler command prompt, type the following commands:

```
enable feature SC LB
add service psvc1 10.101.3.187 HTTP 80
add service psvc2 10.101.3.188 HTTP 80
add service alt-cont-svc 10.101.3.189 HTTP 80
add vserver vsvr HTTP 10.101.3.200 80
bind lb vserver vsvr psvc1
bind lb vserver vsvr psvc2
add sc policy policy10 -url /cgi-bin/slow.asp
-delay 4000000 -action ACS alt-cont-svc
/NetScaler 9000 system /barandpage.htm
bind lb vserver vsvr -policyName policy10
set lb vserver vsvr -sc ON
save config
```

Example 5 - SureConnect with Content Switching

This example illustrates how to configure SureConnect where the NetScaler content switching and load balancing features are being used. SureConnect is configured on a load balancing virtual server bound to a content switching virtual server.

The alternate content is distributed under the content switching virtual server according to the content switching rules. For more information about load balancing and content switching, see "Load Balancing" and "Content Switching."

In this case, three physical services with IP addresses 10.100.100.104, 10.100.100.105, and 10.100.100.106 are bound to three load balancing virtual servers with IP addresses 10.100.100.101, 10.100.100.102, and 10.100.100.103. These three load balancing virtual servers are bound to a content switching virtual server with IP address 10.100.100.100.

In this setup, lbvip1 contains .cgi content, lbvip2 contains .gif content, and .lbvip3 contains .html content.

The name and location of the alternate page file is specified in the file alternatepage.htm, which resides on lbvip3. The embedded objects in this file must be distributed according to the content switching rules (any embedded gif will reside on lbvip2, any embedded htm will reside on lbvip3, and so on).

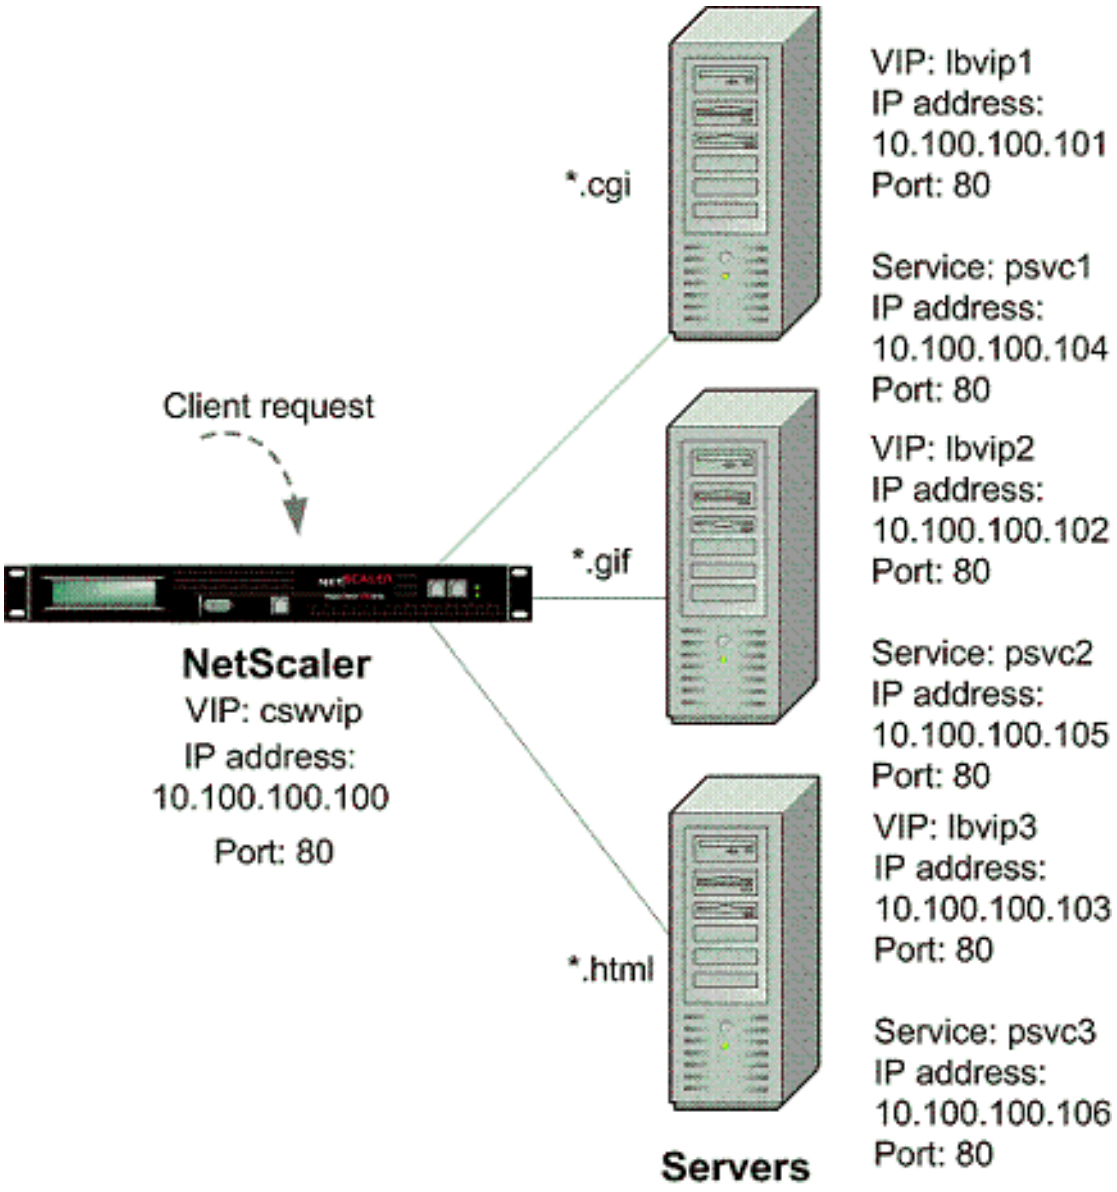

Figure 2. SureConnect Configuration - Example 5

At the NetScaler command prompt, type the following commands:

```
enable feature CS LB SC
add vserver cswvip HTTP 10.100.100.100 80 -type CONTENT
add vserver lbvip1 HTTP 10.100.100.101 80 -type ADDRESS
add vserver lbvip2 HTTP 10.100.100.102 80 -type ADDRESS
add vserver lbvip3 HTTP 10.100.100.103 80 -type ADDRESS
add service psvc1 10.100.100.104 HTTP 80
add service psvc2 10.100.100.105 HTTP 80
add service psvc3 10.100.100.106 HTTP 80
bind lb vserver lbvip1 psvc1
bind lb vserver lbvip2 psvc2
bind lb vserver lbvip3 psvc3
add cs policy CSWpolicy1 -url /*.cgi
```

```
bind cs vserver cswvip lbvip1 -policyName CSWpolicy1
add cs policy CSWpolicy2 -url /*.gif
bind cs vserver cswvip lbvip2 -policyName CSWpolicy2
add cs policy CSWpolicy3 -url /*.htm
bind cs vserver cswvip lbvip3 -policyName CSWpolicy3
add sc policy SCpol -url /cgi-bin/delay.cgi -delay 4000000 -action ACS cswvip /alternatepage.htm
bind lb vserver lbvip1 -policyName SCpol
set lb vserver lbvip1 -sc ON
save config
```

Surge Protection

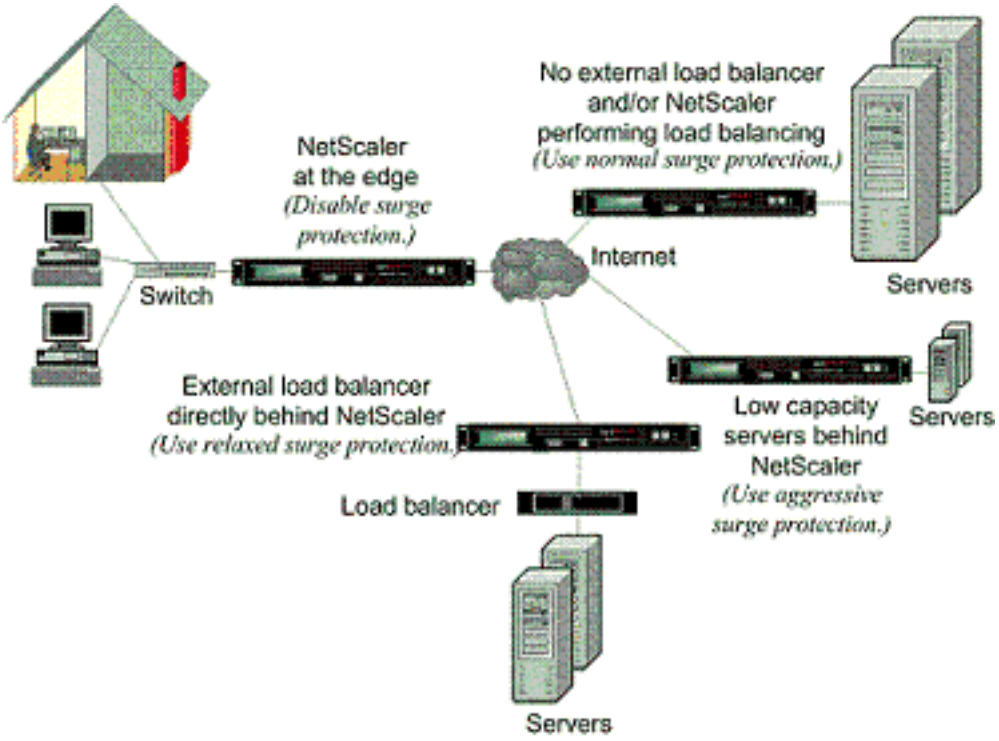
When a surge in client requests overloads a server, server response becomes slow, and the server is unable to respond to new requests. The Surge Protection feature ensures that connections to the server occur at a rate that the server can handle. The response rate depends on how surge protection is configured. The NetScaler appliance also tracks the number of connections to the server, and uses that information to adjust the rate at which it opens new server connections.

Surge protection is enabled by default. If you do not want to use surge protection, as will be the case with some special configurations, you must disable it.

The default surge protection settings are sufficient for most uses, but you can configure surge protection to tune it for your needs. First, you can set the throttle value to tell it how aggressively to manage connection attempts. Second you can set the base threshold value to control the maximum number of concurrent connections that the NetScaler appliance will allow before triggering surge protection. (The default base threshold value is set by the throttle value, but after setting the throttle value you can change it to any number you want.)

The following figure illustrates how surge protection is configured to handle traffic to a Web site.

Figure 1. A Functional Illustration of NetScaler Surge Protection



Note: If the NetScaler appliance is installed at the edge of the network, where it interacts with network devices on the client side of the Internet, the surge protection

feature must be disabled. Surge protection must also be disabled if you enable USIP (Using Source IP) mode on your appliance.

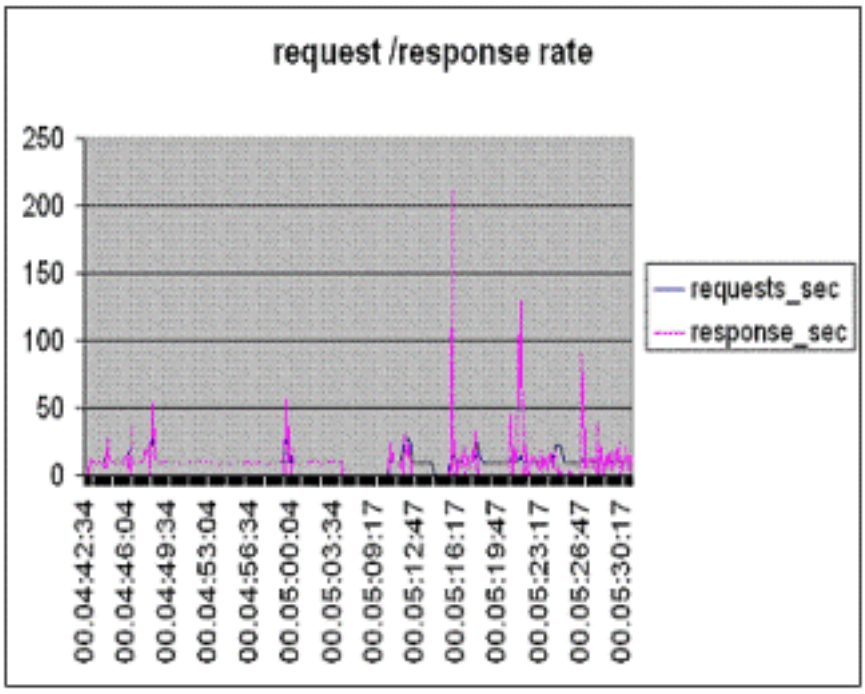
The following example and illustration show the request and response rates for two cases. In one case, surge protection is disabled, and in the other it is enabled.

When surge protection is disabled and a surge in requests occurs, the server accepts as many requests as it can process concurrently, and then begins to drop requests. As the server becomes more overloaded, it goes down and the response rate is reduced to zero. When the server recovers from the crash, usually several minutes later, it sends resets for all pending requests, which is abnormal behavior, and also responds to new requests with resets. The process repeats for each surge in requests. Therefore, a server that is under DDoS attack and receives multiple surges of requests can become unavailable to legitimate users.

When surge protection is enabled and a surge in requests occurs, surge protection manages the rate of requests to the server, sending requests to the server only as fast as the server can handle those requests. This enables the server to respond to each request correctly in the order it was received. When the surge is over, the backlogged requests are cleared as fast as the server can handle them, until the request rate matches the response rate.

The following figure compares the request and response scenarios when surge protection is enabled to that when it is disabled.

Figure 2. Request/Response Rate with and without Surge Protection



Disabling and Reenabling Surge Protection

The surge protection feature is enabled by default. When surge protection is enabled, it is active for any service that you add.

To disable or reenable surge protection by using the command line interface

At the command prompt, type one of the following sets of commands to disable or reenable surge protection and verify the configuration:

- disable ns feature SurgeProtection
- show ns feature
- enable ns feature SurgeProtection
- show ns feature

Example

```
disable ns feature SurgeProtection
 Done show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)   Web Logging              WL               ON
 2)   Surge Protection          SP               OFF
 .
 .
 .
 23)  HTML Injection           HTMLInjection     ON
 24)  NetScaler Push           push              OFF
 Done

 enable ns feature SurgeProtection
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)   Web Logging              WL               ON
 2)   Surge Protection          SP               ON
 .
 .
```

```
.

23)  HTML Injection          HTMLInjection     ON
24)  NetScaler Push          push              OFF
Done
>
```

To disable or reenable surge protection by using the configuration utility

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Change Advanced Features.
3. In the Configure Advanced Features dialog box, clear the selection from the Surge Protection check box to disable the surge protection feature, or select the check box to enable the feature.
4. Click OK.
5. In the Enable/Disable Feature(s) dialog box, click Yes. A message appears in the status bar, stating that the feature has been enabled or disabled.

To disable or reenable surge protection for a particular service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then select Services. The list of configured services is displayed in the details pane.
2. In the details pane, select the service for which you want to disable or reenable the surge protection feature, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab and scroll down.
4. In the Others frame, clear the selection from the Surge Protection check box to disable the surge protection feature, or select the check box to enable the feature.
5. Click OK. A message appears in the status bar, stating that the feature has been enabled or disabled.

   Note: Surge protection works only when both the feature and the service setting are enabled.

Setting Thresholds for Surge Protection

To set the rate at which the NetScaler appliance opens connections to the server, you must configure the threshold and throttle values for surge protection.

The following figure shows the surge protection curves that result from setting the throttle rate to relaxed, normal, or aggressive. Depending on the configuration of the server capacity, you can set base threshold values to generate appropriate surge protection curves.

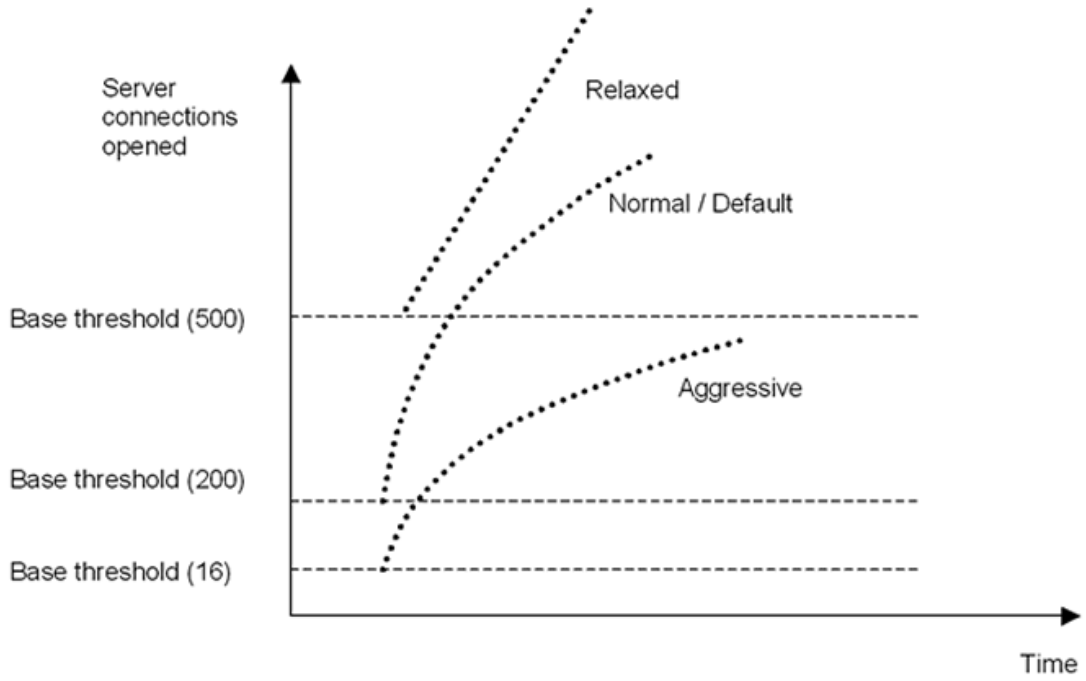


Figure 1. Surge Protection Curves

Your configuration settings affect the behavior of surge protection in the following manner:

- If you do not specify a throttle rate, it is set to normal (the default value), and the base threshold is set to 200, as shown in the preceding figure.
- If you specify a throttle rate (aggressive, normal, or relaxed) without specifying a base threshold, the curve reflects the default values of the base threshold for that throttle rate. For example, if you set the throttle rate to relaxed, the resulting curve will have the base threshold value of 500.
- If you specify only the base threshold, the entire surge protection curve shifts up or down, depending on the value you specify, as shown in the figure that follows.
- If you specify both a base threshold and a throttle rate, the resulting surge protection curve is based on the set throttle rate and adjusted according to the value set for the base threshold.

In the following figure, the lower curve (Aggressive 1) results when the throttle rate is set to aggressive but the base threshold is not set. The upper curve (Aggressive 2) results when the base threshold is set to 500, but the throttle rate is not set. The second upper curve (Aggressive 2) also results when the base threshold is set to 500, and the throttle rate is set to aggressive.

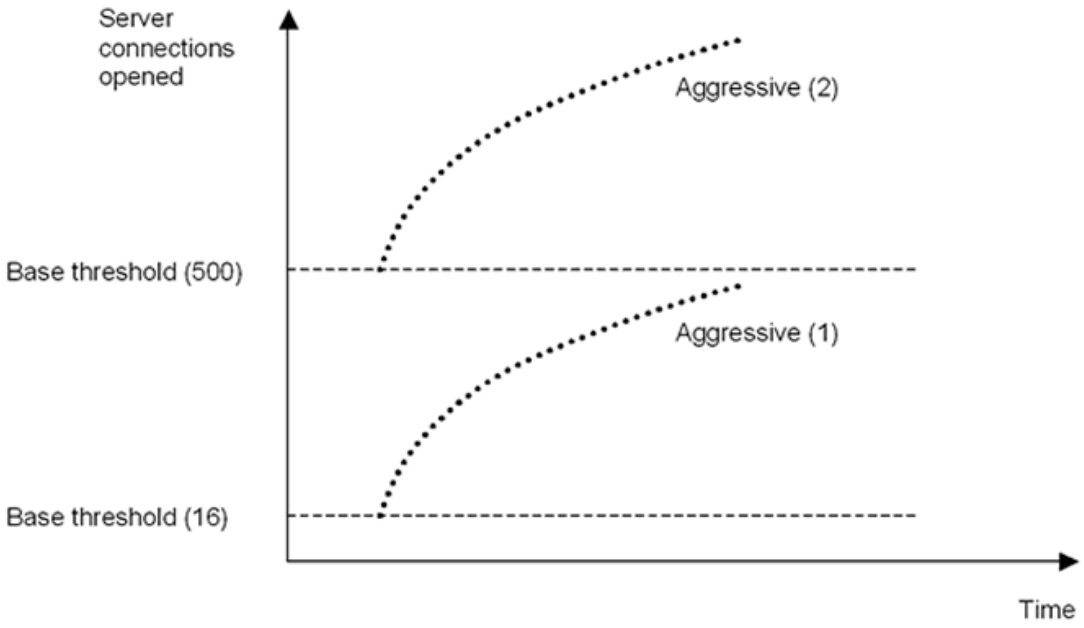

Figure 2. Aggressive Rate with the Default or a Set Base Threshold

To set the threshold for surge protection by using the configuration utility

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Global System Settings.
3. If you want to set a base threshold different from the default for the throttle rate, in the Configure Global Settings dialog box, Base Threshold text box, enter the maximum number of concurrent server connections allowed before surge protection is triggered. The base threshold is the maximum number of server connections that can be open before surge protection is activated. The maximum value for this setting is 32,767 server connections. The default setting for this value is controlled by the throttle rate you choose in the next step.

   Note: If you do not set an explicit value here, the default value will be used.
4. In the Throttle drop-down list, select a throttle rate. The throttle is the rate at which the NetScaler appliance allows connections to the server to be opened. The throttle can be set to the following values:

   Aggressive

   Choose this option when the connection-handling and surge-handling capacity of the server is low and the connection needs to be managed carefully. When you set the throttle to aggressive, the base threshold is set to a default value of 16, which means that surge protection is triggered whenever there are 17 or more concurrent

connections to the server.

Normal

Choose this option when there is no external load balancer behind the NetScaler appliance or downstream. The base threshold is set to a value of 200, which means that surge protection is triggered whenever there are 201 or more concurrent connections to the server. Normal is the default throttle option.

Relaxed

Choose this option when the NetScaler appliance is performing load balancing between a large number of Web servers, and can therefore handle a high number of concurrent connections. The base threshold is set to a value of 500, which means that surge protection is triggered only when there are 501 or more concurrent connections to the server.

5. Click OK. A message appears in the status bar, stating that the global settings are configured.

Flushing the Surge Queue

When a physical server receives a surge of requests, it becomes slow in responding to the currently connected clients and leaves many users dissatisfied and disgruntled. Often, the overloading also causes the clients to receive error pages. To avoid such overloading, the NetScaler appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.

Note: Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

To flush a surge queue by using the command line interface

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]

Examples

1.
flush ns surgeQ –name SVC1ANZGB –serverName 10.10.10.1 80
The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and h
2.
flush ns surgeQ
The above command flushes all the surge queues on the appliance.

Parameters for flushing a surge queue

name

Name of a virtual server, service or service group

serverName

Name of a service group member

To flush a surge queue by using the configuration utility

1. In the navigation pane, expand Load Balancing.
2. To select an entity, do one of the following:
   - To flush the surge queue of a virtual server, click Virtual Servers, and then select the virtual server.
   - To flush the surge queue of a service, click Services, and then select the service.
   - To flush the surge queue of all the members in a service group, click Service Groups, and then select the service group.
   - To flush the surge queue of a specific member in a service group, click Service Groups, and in the action pane, click Manage Members. In the Manage Members of a Service Group dialog box, select the service group member.

   Note: You can select multiple entities in any window.

   Note: To flush the surge queue of a content switching virtual server, in Steps 1 and 2, expand Content Switching, and then select a virtual server.
3. In the action pane, click Flush Surge Queue.
4. Click OK.

   Note: On the appliance, if there are other entities with the same name as you selected, you are alerted that the surge queues of those entities would also be flushed. Take an appropriate action.

Getting Started with Citrix NetScaler VPX

Contents

Getting Started with Citrix NetScaler VPX

Intended for system and network administrators who install and configure complex networking equipment, this section of the library describes initial setup and basic configuration of the Citrix® NetScaler® VPX™ product, including the following topics.

Citrix NetScaler VPX Overview	Defines NetScaler VPX and includes a description of the virtualization platforms on which NetScaler VPX can be hosted.
Understanding the NetScaler	What a NetScaler is and where it fits in a network, with descriptions of entities used in typical configurations and the order in which data is processed by the various features.
Installing NetScaler Virtual Appliances on XenServer	Prerequisites and tasks for installing NetScaler VPX on XenServer.
Installing NetScaler Virtual Appliances on VMware ESX	Prerequisites and tasks for installing NetScaler VPX on VMware ESX 4.0 and VMware ESX 3.5.
Installing NetScaler Virtual Appliances on Microsoft Server 2008 RT	Prerequisites and tasks for installing NetScaler VPX on Microsoft Server 2008 RT
Installing NetScaler VPX on AWS	Prerequisites and tasks for installing NetScaler VPX on AWS
Configuring the Basic System Settings	Tasks for setting up an initial configuration by using the NetScaler VPX Console in XenCenter and tasks for configuring a NetScaler VPX virtual appliance.
Understanding Common Network Topologies	Describes the four common deployment topologies: Two-Arm Multiple Subnet, Two-Arm Transparent, One-Arm Single Subnet, and One-Arm Multiple Subnet. Includes topology diagrams, sample values, and references.
Configuring System Management Settings	Procedures for configuring basic system management settings, such as VLANs, SNMP, and DNS.
Load Balancing Traffic on a NetScaler	Basic introduction to the load balancing feature. Includes procedures for configuring a basic load balancing setup to deliver a Web application, and procedures for configuring persistence, URL redirection, and backup vservers.
Accelerating Load Balanced Traffic by Using Compression	Basic introduction to the compression feature. Includes procedures for configuring a NetScaler to compress application traffic.

Securing Load Balanced Traffic by Using SSL	Basic introduction to the SSL offload feature. Includes procedures for configuring a NetScaler to secure application traffic by using SSL.
Features at a Glance	Brief description of all the features, with links to documentation for the features.

Citrix NetScaler Virtual Appliance Overview

The NetScaler virtual appliance product is a virtual NetScaler appliance that can be hosted on Citrix XenServer®, VMware ESX or ESXi, and Microsoft Hyper-V virtualization platforms.

A NetScaler virtual appliance supports all the features of a physical NetScaler, except virtual MAC (vMAC) addresses, Layer 2 (L2) mode, and link aggregation control protocol (LACP). VLAN tagging is supported on the NetScaler virtual appliances hosted on the XenServer and on VMware ESX platforms.

For the VLAN tagging feature to work, do one of the following:

- On the Citrix XenServer, configure tagged VLANs on a port on the switch but do NOT configure any VLANs on the XenServer interface attached to that port. The VLAN tags are passed through to the virtual appliance and you can use the tagged VLAN configuration on the virtual appliance.

- On the VMware ESX, set the port group's VLAN ID to 4095 on the VSwitch of VMware ESX server. For more information about setting a VLAN ID on the VSwitch of VMware ESX server, see http://www.vmware.com/pdf/esx3_vlan_wp.pdf.

This overview covers only aspects that are unique to NetScaler virtual appliance. For an overview of NetScaler virtual appliance functionality, see Understanding the NetScaler.

Note: The terms *NetScaler*, *NetScaler appliance*, and *appliance* are used interchangeably with *NetScaler virtual appliance* unless stated otherwise.

Citrix NetScaler Virtual Appliance Overview

The NetScaler virtual appliance product is a virtual NetScaler appliance that can be hosted on Citrix XenServer®, VMware ESX or ESXi, and Microsoft Hyper-V virtualization platforms.

A NetScaler virtual appliance supports all the features of a physical NetScaler, except virtual MAC (vMAC) addresses, Layer 2 (L2) mode, and link aggregation control protocol (LACP). VLAN tagging is supported on the NetScaler virtual appliances hosted on the XenServer and on VMware ESX platforms.

For the VLAN tagging feature to work, do one of the following:

- On the Citrix XenServer, configure tagged VLANs on a port on the switch but do NOT configure any VLANs on the XenServer interface attached to that port. The VLAN tags are passed through to the virtual appliance and you can use the tagged VLAN configuration on the virtual appliance.

- On the VMware ESX, set the port group's VLAN ID to 4095 on the VSwitch of VMware ESX server. For more information about setting a VLAN ID on the VSwitch of VMware ESX server, see http://www.vmware.com/pdf/esx3_vlan_wp.pdf.

This overview covers only aspects that are unique to NetScaler virtual appliance. For an overview of NetScaler virtual appliance functionality, see Understanding the NetScaler.

Note: The terms *NetScaler*, *NetScaler appliance*, and *appliance* are used interchangeably with *NetScaler virtual appliance* unless stated otherwise.

NetScaler Virtual Appliance Setup for the XenServer Platform

When you set up NetScaler virtual appliance on XenServer, you must use the XenCenter client to install the first NetScaler virtual appliance. Subsequent virtual appliances can be added by using either the XenCenter client or Citrix Command Center.

XenServer

The XenServer® product is a server virtualization platform that offers near bare-metal virtualization performance for virtualized server and client operating systems. XenServer uses the Xen® hypervisor to virtualize each server on which it is installed, enabling each server to host multiple virtual machines simultaneously.

The following figure shows the bare-metal solution architecture of NetScaler virtual appliance on XenServer.

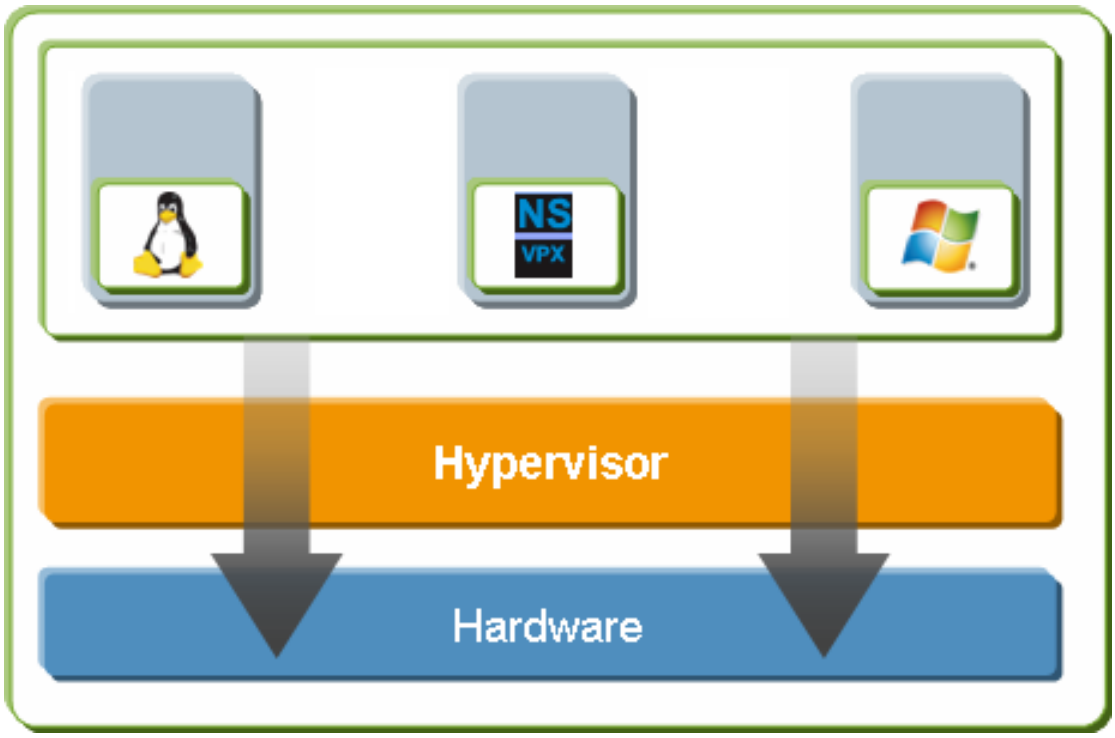

Figure 1. NetScaler Virtual Appliance on XenServer

The bare-metal solution architecture has the following components:

Hardware or physical layer:

Physical hardware components including memory, CPU, network cards, and disk drives.

Xen hypervisor:

Thin layer of software that runs on top of the hardware. The Xen hypervisor gives each virtual machine a dedicated view of the hardware.

Virtual machine:

Operating system hosted on the hypervisor and appearing to the user as a separate physical computer. However, the machine shares physical resources with other virtual machines, and it is portable because the virtual machine is abstracted from physical hardware.

A NetScaler virtual machine, or *virtual appliance*, is installed on the Xen hypervisor and uses paravirtualized drivers to access storage and network resources. It appears to the users as an independent NetScaler appliance with its own network identity, user authorization and authentication capabilities, configuration, applications, and data. The paravirtualization technique enables the virtual machines and the hypervisor to work together to achieve high performance for I/O and for CPU and memory virtualization.

For more information about XenServer, see the XenServer documentation at http://support.citrix.com/product/xens/.

XenCenter

XenCenter® is a graphical virtualization-management interface for XenServer®, enabling you to manage servers, resource pools, and shared storage, and to deploy, manage, and monitor virtual machines from your Windows desktop machine.

Use XenCenter to install NetScaler virtual appliance on XenServer.

For more information about XenCenter, see the XenServer documentation at http://support.citrix.com/product/xens/.

Command Center

Command Center is a management and monitoring solution for Citrix application networking products that include NetScaler, NetScaler virtual appliance, Access Gateway Enterprise Edition, Citrix® Branch Repeater™, Branch Repeater VPX™, and Citrix Repeater™. Command Center enables network administrators and operations teams to manage, monitor, and troubleshoot the entire global application delivery infrastructure from a single, unified console.

This centralized management solution simplifies operations by providing administrators with enterprise-wide visibility and automating management tasks that need to be executed across multiple devices.

Command Center is available with Citrix NetScaler Enterprise and Platinum editions.

You can use Command Center to provision NetScaler virtual appliance on XenServer, and then you can manage and monitor the virtual appliances from Command Center.

Note: You must use the XenCenter client to manage XenServer. You cannot manage XenServer from Command Center.

For more information about Command Center, see the Command Center documentation.

NetScaler Virtual Appliance Setup for the VMware ESX Platform

The NetScaler virtual appliance setup for the VMware ESX platform requires a VMware ESX or ESXi server and the vSphere client.

VMware ESX and ESXi are virtualization products based on bare-metal architecture, offered by VMware, Inc. Citrix NetScaler virtual appliance can be hosted on a VMware ESX or ESXi server.

For more information about VMware ESX, see http://www.vmware.com/.

The vSphere client is a graphical interface for managing virtual machines on VMware ESX servers. You use the vSphere client to allocate resources on the ESX server to virtual appliances installed on the server or to deallocate resources. For example, you can allocate virtual network ports to a virtual appliance.

For more information about VMware vSphere client, see http://www.vmware.com/.

NetScaler Virtual Appliance Setup for the Microsoft Hyper-V Platform

Note: This feature is only available in releases 9.3.e and 10.

The NetScaler virtual appliance setup for the Microsoft Hyper-V platform requires Windows Server 2008 R2 or 2012 with the Hyper-V role installed. Like all virtualization systems, Hyper-V enables you to create a virtualized computing environment that results in better utilization of your hardware resources.

Hyper-V is a type 1 hypervisor that comes preinstalled with Windows Server 2008 R2 or 2012. It needs to be enabled as a role on the Windows Server.

For more information about Hyper-V, see http://technet.microsoft.com/en-us/library/cc816638(WS.10).aspx.

NetScaler Virtual Appliance Setup for Linux-KVM Platform

The NetScaler® VPX™ is a virtual NetScaler appliance that can be hosted on a kernel based Virtualization Machine(KVM). The host Linux operating system must be installed on suitable hardware by using virtualization tools such as KVM Module and QEMU. NetScaler VPX runs as a virtual appliance on Linux-KVM server. Like all virtualization systems, KVM enables you to create a virtualized computing environment that results in better utilization of your hardware resources.

Hypervisors Supported on a NetScaler Virtual Appliance

The following table lists the details, such as system ID (sysID) and whether support is available for multiple packet engines (multi-PE), for the different hypervisors supported on a NetScaler virtual appliance.

Table 1. Hypervisors Supported on a NetScaler Virtual Appliance

	VPX on XenServer	VPX on VMware ESX	VPX on Microsoft Hyper-V	VPX on Amazon Web Services
Hypervisor Version	6.0, 6.1	4.1, 5.1	2008, 2012	N/A
SysID	450000	450010	450020	450040
Multi-PE Supported	Yes	Yes	No	No
Clustering Supported	Yes	Yes	Yes	No
Licenses	VPX-10, VPX-200, VPX-1000, VPX-3000, VPX-8000	VPX-10, VPX-200, VPX-1000, VPX-3000, VPX-8000	VPX-10, VPX-200, VPX-1000, VPX-3000, VPX-8000	VPX-10, VPX-200, VPX-1000, VPX-BYOL

Understanding the NetScaler

The Citrix NetScaler product is an application switch that performs application-specific traffic analysis to intelligently distribute, optimize, and secure Layer 4-Layer 7 (L4–L7) network traffic for web applications. For example, a NetScaler bases load balancing decisions on individual HTTP requests instead of on long-lived TCP connections, so that the failure or slowdown of a server is managed much more quickly and with less disruption to clients. The NetScaler feature set can be broadly categorized as consisting of switching features, security and protection features, and server-farm optimization features.

Switching Features

When deployed in front of application servers, a NetScaler ensures optimal distribution of traffic by the way in which it directs client requests. Administrators can segment application traffic according to information in the body of an HTTP or TCP request, and on the basis of L4–L7 header information such as URL, application data type, or cookie. Numerous load balancing algorithms and extensive server health checks improve application availability by ensuring that client requests are directed to the appropriate servers.

Security and Protection Features

NetScaler security and protection features protect web applications from Application Layer attacks. A NetScaler allows legitimate client requests and can block malicious requests. It provides built-in defenses against denial-of-service (DoS) attacks and supports features that protect against legitimate surges in application traffic that would otherwise overwhelm the servers. An available built-in firewall protects web applications from Application Layer attacks, including buffer overflow exploits, SQL injection attempts, cross-site scripting attacks, and more. In addition, the firewall provides identity theft protection by securing confidential corporate information and sensitive customer data.

Optimization Features

Optimization features offload resource-intensive operations, such as Secure Sockets Layer (SSL) processing, data compression, client keep-alive, TCP buffering, and the caching of static and dynamic content from servers. This improves the performance of the servers in the server farm and therefore speeds up applications. A NetScaler supports several transparent TCP optimizations, which mitigate problems caused by high latency and congested network links, accelerating the delivery of applications while requiring no configuration changes to clients or servers.

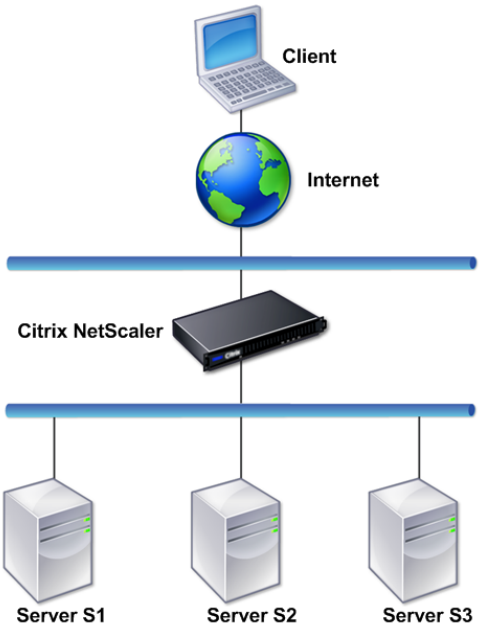
Where Does a NetScaler Appliance Fit in the Network?

A NetScaler appliance resides between the clients and the servers, so that client requests and server responses pass through it. In a typical installation, virtual servers configured on the appliance provide connection points that clients use to access the applications behind the appliance. In this case, the appliance owns public IP addresses that are associated with its virtual servers, while the real servers are isolated in a private network. It is also possible to operate the appliance in a transparent mode as an L2 bridge or L3 router, or even to combine aspects of these and other modes.

Physical Deployment Modes

A NetScaler appliance logically residing between clients and servers can be deployed in either of two physical modes: inline and one-arm. In inline mode, multiple network interfaces are connected to different Ethernet segments, and the appliance is placed between the clients and the servers. The appliance has a separate network interface to each client network and a separate network interface to each server network. The appliance and the servers can exist on different subnets in this configuration. It is possible for the servers to be in a public network and the clients to directly access the servers through the appliance, with the appliance transparently applying the L4-L7 features. Usually, virtual servers (described later) are configured to provide an abstraction of the real servers. The following figure shows a typical inline deployment.

Figure 1. Inline Deployment



In one-arm mode, only one network interface of the appliance is connected to an Ethernet segment. The appliance in this case does not isolate the client and server sides of the network, but provides access to applications through configured virtual servers. One-arm mode can simplify network changes needed for NetScaler installation in some environments.

For examples of inline (two-arm) and one-arm deployment, see "Understanding Common Network Topologies."

Citrix NetScaler as an L2 Device

A NetScaler functioning as an L2 device is said to operate in L2 mode. In L2 mode, the NetScaler forwards packets between network interfaces when all of the following conditions are met:

- The packets are destined to another device's media access control (MAC) address.
- The destination MAC address is on a different network interface.
- The network interface is a member of the same virtual LAN (VLAN).

By default, all network interfaces are members of a pre-defined VLAN, VLAN 1. Address Resolution Protocol (ARP) requests and responses are forwarded to all network interfaces that are members of the same VLAN. To avoid bridging loops, L2 mode must be disabled if another L2 device is working in parallel with the NetScaler.

For information about how the L2 and L3 modes interact, see "Configuring Modes of Packet Forwarding."

For information about configuring L2 mode, see "Enabling and Disabling Layer 2 Mode."

Citrix NetScaler as a Packet Forwarding Device

A NetScaler appliance can function as a packet forwarding device, and this mode of operation is called *L3 mode*. With L3 mode enabled, the appliance forwards any received unicast packets that are destined for an IP address that does not belong to the appliance, if there is a route to the destination. The appliance can also route packets between VLANs.

In both modes of operation, L2 and L3, the appliance generally drops packets that are in:

- Multicast frames
- Unknown protocol frames destined for an appliance's MAC address (non-IP and non-ARP)
- Spanning Tree protocol (unless BridgeBPDUs is ON)

For information about how the L2 and L3 modes interact, see "Configuring Modes of Packet Forwarding."

For information about configuring the L3 mode, see "Enabling and Disabling Layer 3 Mode."

How a NetScaler Communicates with Clients and Servers

A NetScaler appliance is usually deployed in front of a server farm and functions as a transparent TCP proxy between clients and servers, without requiring any client-side configuration. This basic mode of operation is called Request Switching technology and is the core of NetScaler functionality. Request Switching enables an appliance to multiplex and offload the TCP connections, maintain persistent connections, and manage traffic at the request (application layer) level. This is possible because the appliance can separate the HTTP request from the TCP connection on which the request is delivered.

Depending on the configuration, an appliance might process the traffic before forwarding the request to a server. For example, if the client attempts to access a secure application on the server, the appliance might perform the necessary SSL processing before sending traffic to the server.

To facilitate efficient and secure access to server resources, an appliance uses a set of IP addresses collectively known as *NetScaler-owned IP addresses*. To manage your network traffic, you assign NetScaler-owned IP addresses to virtual entities that become the building blocks of your configuration. For example, to configure load balancing, you create virtual servers to receive client requests and distribute them to services, which are entities representing the applications on your servers.

Understanding NetScaler-Owned IP Addresses

To function as a proxy, a NetScaler appliance uses a variety of IP addresses. The key NetScaler-owned IP addresses are:

NetScaler IP (NSIP) address

The NSIP address is the IP address for management and general system access to the appliance itself, and for communication between appliances in a high availability configuration.

Mapped IP (MIP) address

A MIP address is used for server-side connections. It is not the IP address of the appliance. In most cases, when the appliance receives a packet, it replaces the source IP address with a MIP address before sending the packet to the server. With the servers abstracted from the clients, the appliance manages connections more efficiently.

Virtual server IP (VIP) address

A VIP address is the IP address associated with a virtual server. It is the public IP address to which clients connect. An appliance managing a wide range of traffic may have many VIPs configured.

Subnet IP (SNIP) address

A SNIP address is used in connection management and server monitoring. You can specify multiple SNIP addresses for each subnet. SNIP addresses can be bound to a VLAN.

IP Set

An IP set is a set of IP addresses, which are configured on the appliance as SNIP . An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it.

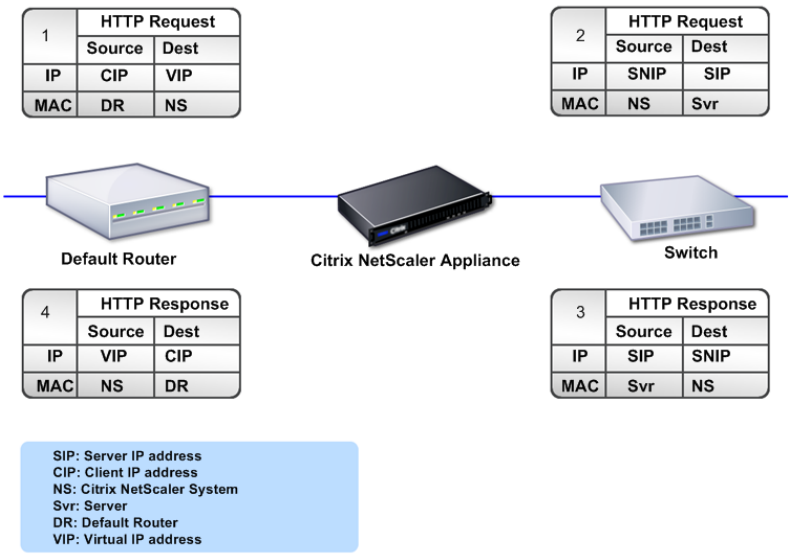
Net Profile

A net profile (or network profile) contains an IP address or an IP set. A net profile can be bound to load balancing or content switching virtual servers, services, service groups, or monitors. During communication with physical servers or peers, the appliance uses the addresses specified in the profile as source IP addresses.

How Traffic Flows Are Managed

Because a NetScaler appliance functions as a TCP proxy, it translates IP addresses before sending packets to a server. When you configure a virtual server, clients connect to a VIP address on the NetScaler instead of directly connecting to a server. As determined by the settings on the virtual server, the appliance selects an appropriate server and sends the client's request to that server. By default, the appliance uses a SNIP address to establish connections with the server, as shown in the following figure.

Figure 1. Virtual Server Based Connections



In the absence of a virtual server, when an appliance receives a request, it transparently forwards the request to the server. This is called the transparent mode of operation. When operating in transparent mode, an appliance translates the source IP addresses of incoming client requests to the SNIP address but does not change the destination IP address. For this mode to work, L2 or L3 mode has to be configured appropriately.

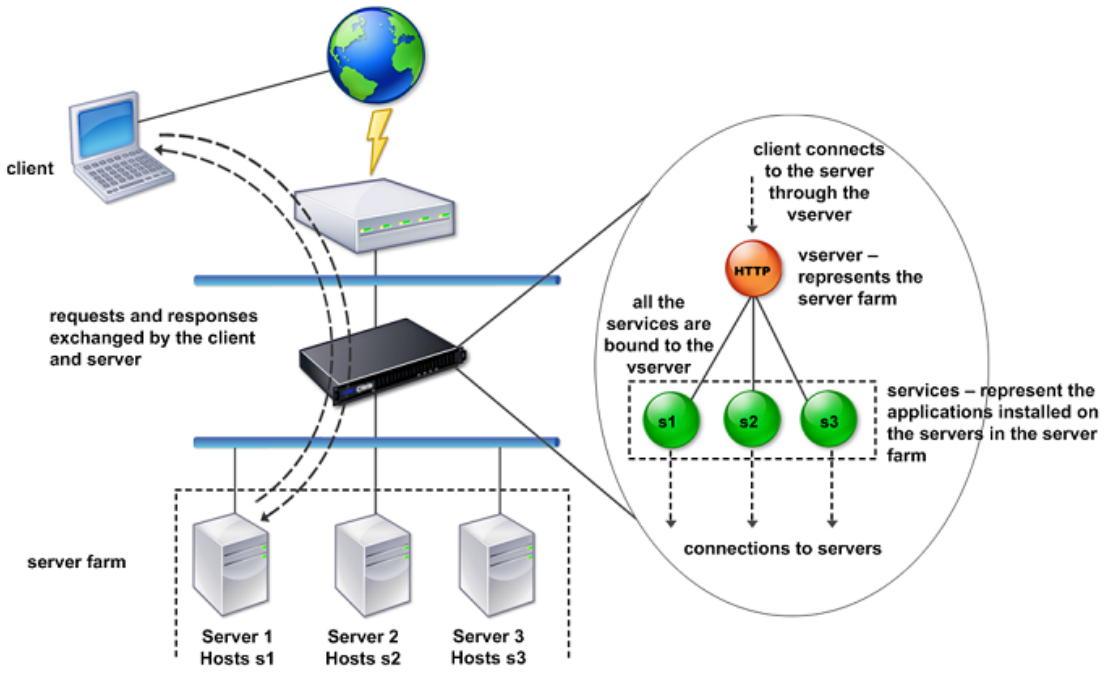
For cases in which the servers need the actual client IP address, the appliance can be configured to modify the HTTP header by inserting the client IP address as an additional field, or configured to use the client IP address instead of a SNIP address for connections to the servers.

Traffic Management Building Blocks

The configuration of a NetScaler appliance is typically built up with a series of virtual entities that serve as building blocks for traffic management. The building block approach helps separate traffic flows. Virtual entities are abstractions, typically representing IP addresses, ports, and protocol handlers for processing traffic. Clients access applications and resources through these virtual entities. The most commonly used entities are virtual servers and services. Virtual servers represent groups of servers in a server farm or remote network, and services represent specific applications on each server.

Most features and traffic settings are enabled through virtual entities. For example, you can configure an appliance to compress all server responses to a client that is connected to the server farm through a particular virtual server. To configure the appliance for a particular environment, you need to identify the appropriate features and then choose the right mix of virtual entities to deliver them. Most features are delivered through a cascade of virtual entities that are bound to each other. In this case, the virtual entities are like blocks being assembled into the final structure of a delivered application. You can add, remove, modify, bind, enable, and disable the virtual entities to configure the features. The following figure shows the concepts covered in this section.

Figure 1. How Traffic Management Building Blocks Work

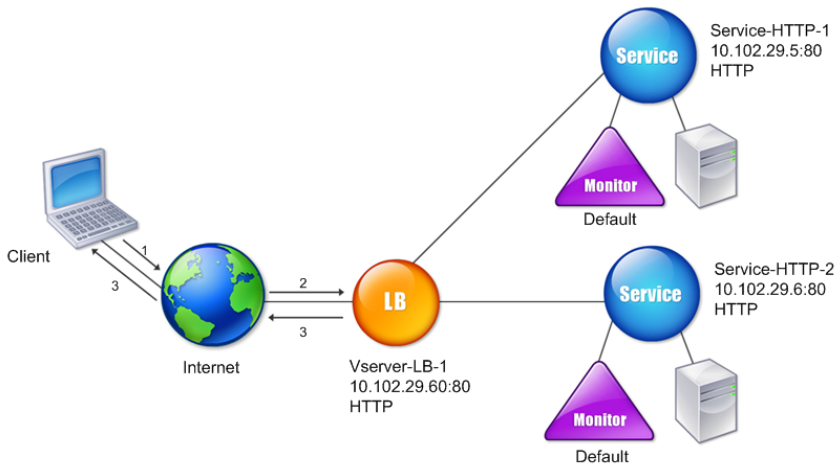


A Simple Load Balancing Configuration

In the example shown in the following figure, the NetScaler appliance is configured to function as a load balancer. For this configuration, you need to configure virtual entities specific to load balancing and bind them in a specific order. As a load balancer, an appliance distributes client requests across several servers and thus optimizes the utilization of resources.

The basic building blocks of a typical load balancing configuration are services and load balancing virtual servers. The services represent the applications on the servers. The virtual servers abstract the servers by providing a single IP address to which the clients connect. To ensure that client requests are sent to a server, you need to bind each service to a virtual server. That is, you must create services for every server and bind the services to a virtual server. Clients use the VIP address to connect to a NetScaler appliance. When the appliance receives client requests sent to the VIP address, it sends them to a server determined by the load balancing algorithm. Load balancing uses a virtual entity called a *monitor* to track whether a specific configured service (server plus application) is available to receive requests.

Figure 1. Load Balancing Virtual Server, Services, and Monitors



In addition to configuring the load balancing algorithm, you can configure several parameters that affect the behavior and performance of the load balancing configuration. For example, you can configure the virtual server to maintain persistence based on source IP address. The appliance then directs all requests from any specific IP address to the same server.

Understanding Virtual Servers

A virtual server is a named NetScaler entity that external clients can use to access applications hosted on the servers. It is represented by an alphanumeric name, virtual IP (VIP) address, port, and protocol. The name of the virtual server is of only local significance and is designed to make the virtual server easier to identify. When a client attempts to access applications on a server, it sends a request to the VIP instead of the IP address of the physical server. When the appliance receives a request at the VIP address, it terminates the connection at the virtual server and uses its own connection with the server on behalf of the client. The port and protocol settings of the virtual server determine the applications that the virtual server represents. For example, a web server can be represented by a virtual server and a service whose port and protocol are set to 80 and HTTP, respectively. Multiple virtual servers can use the same VIP address but different protocols and ports.

Virtual servers are points for delivering features. Most features, like compression, caching, and SSL offload, are normally enabled on a virtual server. When the appliance receives a request at a VIP address, it chooses the appropriate virtual server by the port on which the request was received and its protocol. The appliance then processes the request as appropriate for the features configured on the virtual server.

In most cases, virtual servers work in tandem with services. You can bind multiple services to a virtual server. These services represent the applications running on physical servers in a server farm. After the appliance processes requests received at a VIP address, it forwards them to the servers as determined by the load balancing algorithm configured on the virtual server. The following figure illustrates these concepts.

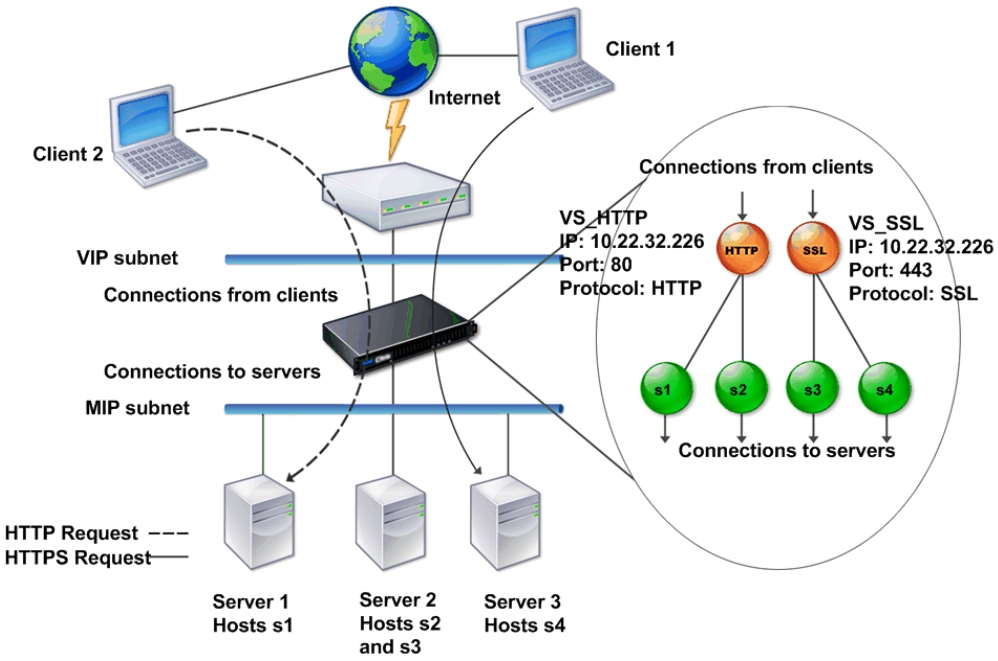


Figure 1. Multiple Virtual Servers with a Single VIP Address

The preceding figure shows a configuration consisting of two virtual servers with a common VIP address but different ports and protocols. Each of the virtual servers has two services bound to it. The services s1 and s2 are bound to VS_HTTP and represent the HTTP applications on Server 1 and Server 2. The services s3 and s4 are bound to VS_SSL and represent the SSL applications on Server 2 and Server 3 (Server 2 provides both HTTP and SSL applications). When the appliance receives an HTTP request at the VIP address, it processes the request as specified by the settings of VS_HTTP and sends it to either Server 1 or Server 2. Similarly, when the appliance receives an HTTPS request at the VIP address, it processes it as specified by the settings of VS_SSL and it sends it to either Server 2 or Server 3.

Virtual servers are not always represented by specific IP addresses, port numbers, or protocols. They can be represented by wildcards, in which case they are known as *wildcard* virtual servers. For example, when you configure a virtual server with a wildcard instead of a VIP, but with a specific port number, the appliance intercepts and processes all traffic conforming to that protocol and destined for the predefined port. For virtual servers with wildcards instead of VIPs and port numbers, the appliance intercepts and processes all traffic conforming to the protocol.

Virtual servers can be grouped into the following categories:

Load balancing virtual server

Receives and redirects requests to an appropriate server. Choice of the appropriate server is based on which of the various load balancing methods the user configures.

Cache redirection virtual server

Redirects client requests for dynamic content to origin servers, and requests for static content to cache servers. Cache redirection virtual servers often work in conjunction with load balancing virtual servers.

Content switching virtual server

Directs traffic to a server on the basis of the content that the client has requested. For example, you can create a content switching virtual server that directs all client requests for images to a server that serves images only. Content switching virtual servers often work in conjunction with load balancing virtual servers.

Virtual private network (VPN) virtual server

Decrypts tunneled traffic and sends it to intranet applications.

SSL virtual server

Receives and decrypts SSL traffic, and then redirects to an appropriate server. Choosing the appropriate server is similar to choosing a load balancing virtual server.

Understanding Services

Services represent applications on a server. While services are normally combined with virtual servers, in the absence of a virtual server, a service can still manage application-specific traffic. For example, you can create an HTTP service on a NetScaler appliance to represent a web server application. When the client attempts to access a web site hosted on the web server, the appliance intercepts the HTTP requests and creates a transparent connection with the web server.

In service-only mode, an appliance functions as a proxy. It terminates client connections, uses a SNIP address to establish a connection to the server, and translates the destination IP addresses of incoming client requests to a SNIP address. Although the clients send requests directly to the IP address of the server, the server sees them as coming from the SNIP address. The appliance translates the IP addresses, port numbers, and sequence numbers.

A service is also a point for applying features. Consider the example of SSL acceleration. To use this feature, you must create an SSL service and bind an SSL certificate to the service. When the appliance receives an HTTPS request, it decrypts the traffic and sends it, in clear text, to the server. Only a limited set of features can be configured in the service-only case.

Services use entities called monitors to track the health of applications. Every service has a default monitor, which is based on the service type, bound to it. As specified by the settings configured on the monitor, the appliance sends probes to the application at regular intervals to determine its state. If the probes fail, the appliance marks the service as down. In such cases, the appliance responds to client requests with an appropriate error message or re-routes the request as determined by the configured load balancing policies.

Understanding Policies and Expressions

A policy defines specific details of traffic filtering and management on a NetScaler. It consists of two parts: the expression and the action. The expression defines the types of requests that the policy matches. The action tells the NetScaler what to do when a request matches the expression. As an example, the expression might be to match a specific URL pattern to a type of security attack, with the action being to drop or reset the connection. Each policy has a priority, and the priorities determine the order in which the policies are evaluated.

When a NetScaler receives traffic, the appropriate policy list determines how to process the traffic. Each policy on the list contains one or more expressions, which together define the criteria that a connection must meet to match the policy.

For all policy types except Rewrite policies, a NetScaler implements only the first policy that a request matches, not any additional policies that it might also match. For Rewrite policies, the NetScaler evaluates the policies in order and, in the case of multiple matches, performs the associated actions in that order. Policy priority is important for getting the results you want.

Processing Order of Features

Depending on requirements, you can choose to configure multiple features. For example, you might choose to configure both compression and SSL offload. As a result, an outgoing packet might be compressed and then encrypted before being sent to the client.

The following figure shows the L7 packet flow in the NetScaler.

Figure 1. L7 Packet Flow Diagram

Installing NetScaler Virtual Appliances on XenServer

To install NetScaler virtual appliances on Citrix XenServer, you must first install XenServer on a machine with adequate system resources. To perform the NetScaler virtual appliance installation, you use Citrix XenCenter, which must be installed on a remote machine that can connect to the XenServer host through the network.

Note: After the initial configuration of the NetScaler appliance, if you want to upgrade the appliance to the latest software release, see Upgrading or Downgrading the System Software.

Prerequisites for Installing NetScaler Virtual Appliances on XenServer

Before you begin installing a virtual appliance, do the following:

- Install XenServer® version 5.6 or later on hardware that meets the minimum requirements.
- Install XenCenter® on a management workstation that meets the minimum system requirements.
- Obtain virtual appliance license files. For more information about virtual appliance licenses, see the *NetScaler VPX Licensing Guide* at http://support.citrix.com/article/ctx122426.

XenServer Hardware Requirements

The following table describes the minimum hardware requirements for a XenServer platform running NetScaler.

Table 1. Minimum System Requirements for XenServer Running NetScaler nCore virtual appliance

Component	Requirement
CPU	2 or more 64-bit x86 CPUs with virtualization assist (Intel-VT or AMD-V) enabled **Note:** To run NetScaler virtual appliance, hardware support for virtualization must be enabled on the XenServer host. Make sure that the BIOS option for virtualization support is not disabled. Consult your BIOS documentation for more details.
RAM	3 gigabytes (GB)
Disk space	Locally attached storage (PATA, SATA, SCSI) with 40 GB of disk space **Note:** XenServer installation creates a 4 GB partition for the XenServer host control domain; the remaining space is available for NetScaler virtual appliance and other virtual machines.
Network Interface Card (NIC)	One 1-Gbps NIC Recommended: Two 1-Gbps NICs

For information about installing XenServer, see the XenServer documentation at http://support.citrix.com/product/xens/.

The following table lists the virtual computing resources that XenServer must provide for each NetScaler nCore virtual appliance .

Table 2. Minimum Virtual Computing Resources Required for Running NetScaler ncore virtual appliance

Component	Requirement
Memory	2 GB
Virtual CPU (VCPU)	2
Virtual network interfaces	2

Note: For production use of NetScaler virtual appliance, Citrix recommends that CPU priority (in virtual machine properties) be set to the highest level, in order to improve scheduling behavior and network latency.

XenCenter System Requirements

XenCenter® is a Windows client application. It cannot run on the same machine as the XenServer® host. The following table describes the minimum system requirements.

Table 3. Minimum System Requirements for XenCenter Installation

Component	Requirement
Operating system	Windows 7, Windows XP, Windows Server 2003, or Windows Vista
.NET framework	Version 2.0 or later
CPU	750 megahertz (MHz) Recommended: 1 gigahertz (GHz) or faster
RAM	1 GB Recommended: 2 GB
Network Interface Card (NIC)	100 megabits per second (Mbps) or faster NIC

For information about installing XenCenter, see the XenServer documentation at http://support.citrix.com/product/xens/.

Installing NetScaler Virtual Appliances on XenServer by Using XenCenter

After you have installed and configured XenServer and XenCenter, you can use XenCenter to install virtual appliances on XenServer. The number of virtual appliances that you can install depends on the amount of memory available on the hardware that is running XenServer.

After you have used XenCenter to install the initial NetScaler virtual appliance (.xva image) on XenServer, you have the option to use Command Center to provision NetScaler virtual appliance. For more information, see the Command Center documentation.

To install NetScaler virtual appliances on XenServer by using XenCenter

1. Start XenCenter on your workstation.
2. On the Server menu, click Add.
3. In the Add New Server dialog box, in the Hostname text box, type the IP address or DNS name of the XenServer that you want to connect to.
4. In the User Name and Password text boxes, type the administrator credentials, and then click Connect. The XenServer name appears in the navigation pane with a green circle, which indicates that the XenServer is connected.
5. In the navigation pane, click the name of the XenServer on which you want to install NetScaler virtual appliance.
6. On the VM menu, click Import.
7. In the Import dialog box, in Import file name, browse to the location at which you saved the NetScaler virtual appliance .xva image file. Make sure that the Exported VM option is selected, and then click Next.
8. Select the XenServer on which you want to install the virtual appliance, and then click Next.
9. Select the local storage repository in which to store the virtual appliance, and then click Import to begin the import process.
10. You can add, modify, or delete virtual network interfaces as required. When finished, click Next.
11. Click Finish to complete the import process.

    Note: To view the status of the import process, click the **Log** tab.
12. If you want to install another virtual appliance, repeat steps 5 through 11.

Installing NetScaler Virtual Appliances on VMware ESX

Important: You cannot install standard VMware Tools or upgrade the VMware Tools version available on a NetScaler virtual appliance. VMware Tools for a NetScaler virtual appliance are delivered as part of the NetScaler software release.

Before installing NetScaler virtual appliances on VMware ESX, make sure that VMware ESX Server is installed on a machine with adequate system resources. To install NetScaler virtual appliances on VMware ESXi version 4.0 or later, you use VMware vSphere client. The client or tool must be installed on a remote machine that can connect to VMware ESX through the network.

After the installation, you can use vSphere client or vSphere Web Client to manage virtual appliances on VMware ESX 4.0 or later release.

Note:

The VMware vSphere client shows the guest operating system as "Sun Solaris 10" for NetScaler virtual machine. This is by design because VMware ESXi does not recognize FreeBSD.

After the initial configuration of the NetScaler appliance, if you want to upgrade the appliance to the latest software release, see "Upgrading or Downgrading the System Software."

Prerequisites for Installing NetScaler Virtual Appliances on VMware

Before you begin installing a virtual appliance, do the following:

- Install VMware ESX version 4.1 or later on hardware that meets the minimum requirements.
- Install VMware Client on a management workstation that meets the minimum system requirements.
- Download the NetScaler virtual appliance setup files.
- Label the physical network ports of VMware ESX.
- Obtain NetScaler license files. For more information about NetScaler virtual appliance licenses, see the *NetScaler VPX Licensing Guide* at http://support.citrix.com/article/ctx131110.

VMware ESX Hardware Requirements

The following table describes the minimum system requirements for VMware ESX servers running NetScaler ncore virtual appliance.

Table 1. Minimum System Requirements for VMware ESX Servers Running NetScaler nCore virtual appliance

Component	Requirement
CPU	2 or more 64-bit x86 CPUs with virtualization assist (Intel-VT or AMD-V) enabled **Note:** To run NetScaler virtual appliance, hardware support for virtualization must be enabled on the VMware ESX host. Make sure that the BIOS option for virtualization support is not disabled. For more information, see your BIOS documentation.
RAM	3 GB
Disk space	40 GB of disk space available
Network	One 1-Gbps NIC; Two 1-Gbps NICs recommended (The network interfaces must be Intel E1000.)

For information about installing VMware ESX, see http://www.vmware.com/.

The following table lists the virtual computing resources that the VMware ESX server must provide for each NetScaler ncore virtual appliance.

Table 2. Minimum Virtual Computing Resources Required for Running NetScaler ncore virtual appliance

Component	Requirement
Memory	2 GB
Virtual CPU (VCPU)	2 **Important:** Do not modify the system resources to create a virtual CPU (VCPU) in addition to the two CPUs already allotted to the virtual appliance.
Virtual network interfaces	1 **Note:** With ESX 4.0 or later, you can install a maximum of 10 virtual network interfaces if the VPX hardware is upgraded version to 7 or higher.
Disk space	20 GB **Note:** This is in addition to any disk requirements for the hypervisor.

Note: For production use of NetScaler virtual appliance, the full memory allocation must be reserved. CPU cycles (in MHz) equal to at least the speed of one CPU core of the ESX should also be reserved.

VMware vSphere Client System Requirements

VMware vSphere is a client application that can run on Windows and Linux operating systems. It cannot run on the same machine as the VMware ESX server. The following table describes the minimum system requirements.

Table 3. Minimum System Requirements for VMware vSphere Client Installation

Component	Requirement
Operating system	For detailed requirements from VMware, search for the "vSphere Compatibility Matrixes" PDF file at http://kb.vmware.com/.
CPU	750 megahertz (MHz); 1 gigahertz (GHz) or faster recommended
RAM	1 GB; 2 GB recommended
Network Interface Card (NIC)	100 Mbps or faster NIC

OVF Tool 1.0 System Requirements

OVF Tool is a client application that can run on Windows and Linux systems. It cannot run on the same machine as the VMware ESX server. The following table describes the minimum system requirements.

Table 4. Minimum System Requirements for OVF Tool Installation

Component	Requirement
Operating system	For detailed requirements from VMware, search for the "OVF Tool User Guide" PDF file at http://kb.vmware.com/.
CPU	750 MHz minimum, 1 GHz or faster recommended.
RAM	1 GB Minimum, 2 GB recommended.
Network Interface Card (NIC)	100 Mbps or faster NIC

For information about installing OVF, search for the "OVF Tool User Guide" PDF file at http://kb.vmware.com/.

Downloading the NetScaler virtual appliance Setup Files

The NetScaler virtual appliance setup package for VMware ESX follows the Open Virtual Machine (OVF) format standard. You can download the files from MyCitrix.com. You need a My Citrix account to log on. If you do not have a My Citrix account, access the home page at http://www.mycitrix.com, click the New Users link, and follow the instructions to create a new My Citrix account.

Once logged on, navigate the following path from the My Citrix home page:

MyCitrix.com > Downloads > NetScaler > Virtual Appliances.

Copy the following files to a workstation on the same network as the ESX server. Copy all three files into the same folder.

- NSVPX-ESX-<release number>-<build number>-disk1.vmdk (for example, NSVPX-ESX-9.3-39.8-disk1.vmdk)
- NSVPX-ESX-<release number>-<build number>.ovf (for example, NSVPX-ESX-9.3-39.8.ovf)
- NSVPX-ESX-<release number>-<build number>.mf (for example, NSVPX-ESX-9.3-39.8.mf)

Labeling the Physical Network Ports of VMware ESX

Before installing a NetScaler virtual appliance, label of all the interfaces that you plan to assign to virtual appliances, in a unique format. Citrix recommends the following format: NS_NIC_1_1, NS_NIC_1_2, and so on. In large deployments, labeling in a unique format helps in quickly identifying the interfaces that are allocated to the NetScaler virtual appliance among other interfaces used by other virtual machines, such as Windows and Linux. Such labeling is especially important when different types of virtual machines share the same interfaces.

To label the physical network ports of VMware ESX server

1. Log on to the VMware ESX server by using the vSphere client.
2. On the vSphere client, select the Configuration tab, and then click Networking.
3. At the top-right corner, click Add Networking.
4. In the Add Network Wizard, for **Connection Type**, select **Virtual Machine**, and then click Next.
5. Scroll through the list of vSwitch physical adapters, and choose the physical port that will map to interface 1/1 on the virtual appliances.
6. Enter NS_NIC_1_1 as the name of the vSwitch that will be associated with interface 1/1 of the virtual appliances.
7. Click Next to finish the vSwitch creation. Repeat the procedure, beginning with step 2, to add any additional interfaces to be used by your virtual appliances. Label the interfaces sequentially, in the correct format (for example, NS_NIC_1_2).

Installing NetScaler Virtual Appliances on VMware ESX 4.0 or Later

After you have installed and configured VMware ESX 4.0 or later, you can use the VMware vSphere client to install virtual appliances on the VMware ESX. The number of virtual appliances that you can install depends on the amount of memory available on the hardware that is running VMware ESX.

To install NetScaler virtual appliances on VMware ESX 4.0 or later by using VMware vSphere Client

1. Start the VMware vSphere client on your workstation.
2. In the IP address / Name text box, type the IP address of the VMware ESX server that you want to connect to.
3. In the User Name and Password text boxes, type the administrator credentials, and then click Login.
4. On the File menu, click Deploy OVF Template.
5. In the Deploy OVF Template dialog box, in Deploy from file, browse to the location at which you saved the NetScaler virtual appliance setup files, select the .ovf file, and click Next.
6. Map the networks shown in the virtual appliance OVF template to the networks that you configured on the ESX host. Click Next to start installing a virtual appliance on VMware ESX. When installation is complete, a pop-up window informs you of the successful installation.
7. You are now ready to start the NetScaler virtual appliance. In the navigation pane, select the NetScaler virtual appliance that you have just installed and, from the right-click menu, select Power On. Click the Console tab to emulate a console port.
8. If you want to install another virtual appliance, repeat steps 4 through 6.

Installing Citrix NetScaler Virtual Appliances on Microsoft Hyper-V Servers

To install Citrix NetScaler virtual appliances on Microsoft Windows Server, you must first install Windows Server, with the Hyper-V role enabled, on a machine with adequate system resources. While installing the Hyper-V role, be sure to specify the network interface cards (NICs) on the server that Hyper-V will use to create the virtual networks. You can reserve some NICs for the host. Use Hyper-V Manager to perform the NetScaler virtual appliance installation.

NetScaler virtual appliance for Hyper-V is delivered in virtual hard disk (VHD) format. It includes the default configuration for elements such as CPU, network interfaces, and hard-disk size and format. After you install NetScaler virtual appliance, you can configure the network adapters on virtual appliance, add virtual NICs, and then assign the NetScaler IP address, subnet mask, and gateway, and complete the basic configuration of the virtual appliance.

Note:

After the initial configuration of the NetScaler appliance, if you want to upgrade the appliance to the latest software release, see "Upgrading or Downgrading the System Software."

Prerequisites for Installing NetScaler Virtual Appliance on Microsoft Servers

Before you begin installing a virtual appliance, do the following:

- Enable the Hyper-V role on Windows Servers . For more information, see http://technet.microsoft.com/en-us/library/ee344837(WS.10).aspx.
- Download the virtual appliance setup files.
- Obtain NetScaler virtual appliance license files. For more information about NetScaler virtual appliance licenses, see the *NetScaler VPX Licensing Guide* at http://support.citrix.com/article/ctx131110.

Microsoft Server Hardware Requirements

The following table describes the minimum system requirements for Microsoft Servers .

Table 1. Minimum System Requirements for Microsoft Servers

Component	Requirement
CPU	1.4 GHz 64-bit processor
RAM	3 GB
Disk Space	32 GB or greater

The following table lists the virtual computing resources for each NetScaler virtual appliance.

Table 2. Minimum Virtual Computing Resources Required for Running NetScaler Virtual Appliance

Component	Requirement
RAM	2 GB
Virtual CPU	2
Disk Space	20 GB
Virtual Network Interfaces	1

Downloading the NetScaler Virtual Appliance Setup Files

NetScaler virtual appliance for Hyper-V is delivered in virtual hard disk (VHD) format. You can download the files from MyCitrix.com. You will need a My Citrix account to log on. If you do not have a My Citrix account, access the home page at http://www.mycitrix.com, click the New Users link, and follow the instructions to create a new My Citrix account.

To download the NetScaler virtual appliance setup files

1. In a Web browser, go to http://www.citrix.com/ and click My Citrix.
2. Type your user name and password.
3. Click Downloads.
4. In Search Downloads by Product, select NetScaler.
5. Under Virtual Appliances, click NetScaler VPX.
6. Copy the compressed file to your server.

Installing NetScaler Virtual Appliance on Microsoft Servers

After you have enabled the Hyper-V role on Microsoft Server and extracted the virtual appliance files, you can use Hyper-V Manager to install NetScaler virtual appliance. After you import the virtual machine, you need to configure the virtual NICs by associating them to the virtual networks created by Hyper-V.

You can configure a maximum of eight virtual NICs. Even if the physical NIC is DOWN, the virtual appliance assumes that the virtual NIC is UP, because it can still communicate with the other virtual appliances on the same host (server).

Note: You cannot change any settings while the virtual appliance is running. Shut down the virtual appliance and then make changes.

To install NetScaler Virtual Appliance on Microsoft Server by using Hyper-V Manager

1. To start Hyper-V Manager, click **Start**, point to **Administrative Tools**, and then click **Hyper-V Manager**.
2. In the navigation pane, under Hyper-V Manager, select the server on which you want to install NetScaler virtual appliance.
3. On the **Action** menu, click **Import Virtual Machine**.
4. In the **Import Virtual Machine** dialog box, in **Location**, specify the path of the folder that contains the NetScaler virtual appliance software files, and then select **Copy the virtual machine (create a new unique ID)**. This folder is the parent folder that contains the Snapshots, Virtual Hard Disks, and Virtual Machines folders.

   Note: If you received a compressed file, make sure that you extract the files into a folder before you specify the path to the folder.
5. Click **Import**.
6. Verify that the virtual appliance that you imported is listed under **Virtual Machines**.
7. To install another virtual appliance, repeat steps 2 through 6.

   Important: Make sure that you extract the files to a different folder in step 4.

To configure virtual NICs on the NetScaler Virtual Appliance

1. Select the virtual appliance that you imported, and then on the **Action** menu, select **Settings**.
2. In the **Settings for** <virtual appliance name> dialog box, click **Add Hardware** in the left pane.
3. In the right pane, from the list of devices, select **Network Adapter**.
4. Click **Add**.
5. Verify that **Network Adapter** (**not connected**) appears in the left pane.
6. Select the network adapter in the left pane.
7. In the right pane, from the **Network** drop-down list, select the virtual network to connect the adapter to.
8. To select the virtual network for additional network adapters that you want to use, repeat steps 6 and 7.
9. Click **Apply**, and then click **OK**.

To configure NetScaler Virtual Appliance

1. Right-click the virtual appliance that you previously installed, and then select **Start**.
2. Access the console by double-clicking the virtual appliance.
3. Type the NetScaler IP address, subnet mask, and gateway for your virtual appliance.

You have completed the basic configuration of your virtual appliance. Type the IP address in a Web browser to access the virtual appliance.

Configuring the Basic System Settings

After installing a Citrix NetScaler virtual appliance, you need to access it to configure the basic settings. Initially, you must access the NetScaler command line through the respective management application of the virtualization host (either Citrix XenCenter for Citrix XenServer or VMware vSphere client for VMware ESX) to specify a NetScaler IP (NSIP) address, subnet mask, and default gateway. The NSIP is the management address at which you can then access the NetScaler command line, through an SSH client, or access the configuration utility. You can use either of these access methods, or the console, to continue with basic configuration.

To access the configuration utility, type the NSIP into the address field of any browser (for example, `http://<NSIP_address>`). You need Java RunTime Environment (JRE) version 1.6 or later.

Setting Up the Initial Configuration by Using the NetScaler Virtual Appliance Console

Your first task after installing a NetScaler virtual appliance on a virtualization host is to use the NetScaler virtual appliance console in the XenCenter client or vSphere client to configure the following initial settings.

Note: If you have installed a virtual appliance on XenServer by using Command Center, you do not have to configure these settings. Command Center implicitly configures the settings during installation. For more information about provisioning virtual appliance from Command Center, see the "Command Center" documentation.

NetScaler IP address (NSIP):

The IP address at which you access a NetScaler or a NetScaler virtual appliance for management purposes. A physical NetScaler or virtual appliance can have only one NSIP. You must specify this IP address when you configure the virtual appliance for the first time. You cannot remove an NSIP address.

Netmask:

The subnet mask associated with the NSIP address.

Default Gateway:

You must add a default gateway on the virtual appliance if you want access it through SSH or the configuration utility from an administrative workstation or laptop that is on a different network.

To configure the initial settings on the virtual appliance through the virtual appliance Console by using the management application

1. Connect to the XenServer or VMware ESX server on which the virtual appliance is installed by using XenCenter or vSphere client, respectively.
2. In the details pane, on the Console tab, log on to the virtual appliance by using the administrator credentials.
3. At the prompts, enter the NSIP address, subnet mask, and default gateway, and then save the configuration.

After you have set up an initial configuration through the NetScaler virtual appliance Console in the management application, you can use either the NetScaler command-line

interface or the configuration utility to complete the configuration or to change the initial settings.

Configuring NetScaler Virtual Appliance by Using the Command Line Interface

You can use the command line interface to set up the NSIP, Mapped IP (MIP), Subnet IP (SNIP), and hostname. You can also configure advanced network settings and change the time zone.

For information about MIP, SNIP, other NetScaler-owned IP addresses, and network settings, see "Configuring NetScaler-Owned IP Addresses."

To complete initial configuration by using the command line interface

1. Use either the SSH client or the NetScaler virtual appliance Console in XenCenter to access the command line interface.
2. Log on to the virtual appliance, using the administrator credentials.
3. At the command prompt, type `config ns` to run the configuration script.
4. To complete the initial configuration, follow the prompts.

You have now completed the basic configuration of the virtual appliance. To continue the configuration process, choose one of the following options:

Citrix NetScaler Load Balancing Switch

If you are configuring the virtual appliance as a standard NetScaler load balancing switch with other licensed features, see "Traffic Management."

Citrix® Application Firewall™

If you are configuring the virtual appliance as a standalone application firewall, see "Application Firewall."

For more information about the various features supported on the NetScaler virtual appliance, see Features at a Glance.

Configuring NetScaler Virtual Appliance by Using the Configuration Utility

To use the Setup Wizard to set up the NetScaler virtual appliance, you must access the configuration utility from your Web browser. You can use the Setup Wizard to configure the NSIP, MIP, SNIP, hostname, and default gateway. You can also configure settings for a Web application by using an application template. You can also configure the appliance as a load balancer for Citrix XenDesktop or Citrix XenApp.

For information about MIP, SNIP, other NetScaler-owned IP addresses, and network settings, see "Configuring NetScaler-Owned IP Addresses."

For information about application templates, see "AppExpert."

For information about the load balancing feature of a virtual appliance, see "Traffic Management."

To configure initial settings by using the configuration utility

1. In the address field of a Web browser, type: `http://<NSIP address>`
2. In User Name and Password, type the administrator credentials.
3. In Start in, select Configuration, and then click Login.
4. In the Setup Wizard, click Next and follow the instructions.

You have now completed the basic configuration of the virtual appliance. To continue the configuration process, choose one of the following options:

Citrix NetScaler Load Balancing Switch

If you are configuring the virtual appliance as a standard NetScaler load balancing switch with other licensed features, see "Traffic Management."

Citrix® Application Firewall™

If you are configuring the virtual appliance as a standalone application firewall, see "Application Firewall."

For more information about the various features supported on the NetScaler virtual appliance, see Features at a Glance.

Understanding Common Network Topologies

As described in "Physical Deployment Modes," you can deploy the Citrix NetScaler appliance either inline between the clients and servers or in one-arm mode. Inline mode uses a two-arm topology, which is the most common type of deployment.

Setting Up Common Two-Arm Topologies

In a two-arm topology, one network interface is connected to the client network and another network interface is connected to the server network, ensuring that all traffic flows through the appliance. This topology might require you to reconnect your hardware and also might result in a momentary downtime. The basic variations of two-arm topology are multiple subnets, typically with the appliance on a public subnet and the servers on a private subnet, and transparent mode, with both the appliance and the servers on the public network.

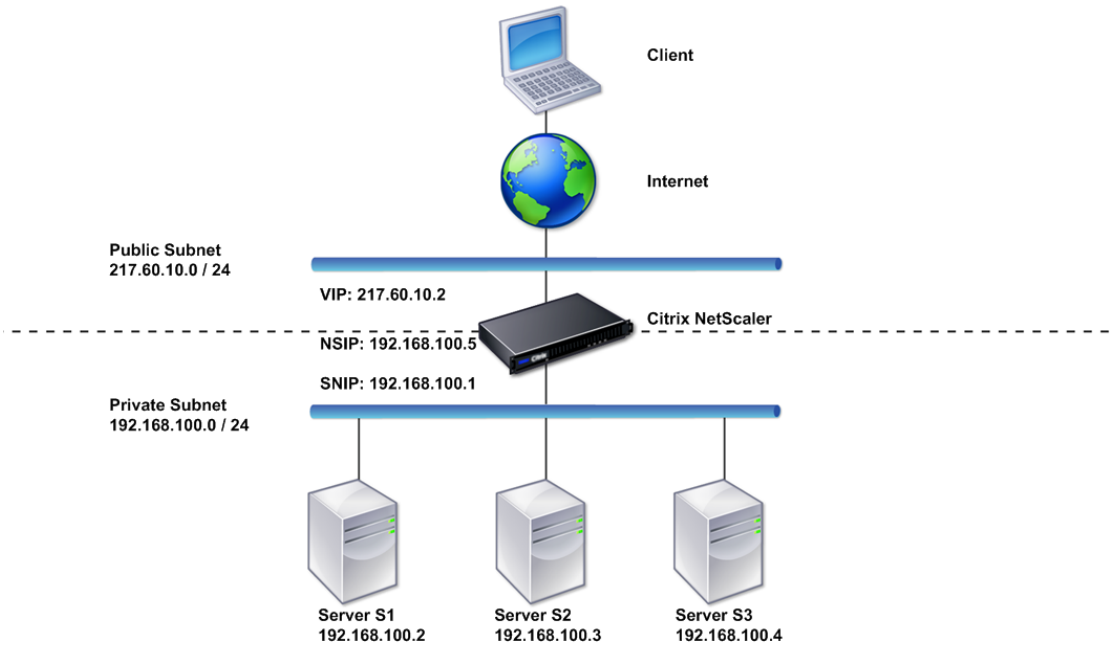
Setting Up a Simple Two-Arm Multiple Subnet Topology

One of the most commonly used topologies has the NetScaler appliance inline between the clients and the servers, with a virtual server configured to handle the client requests. This configuration is used when the clients and servers reside on different subnets. In most cases, the clients and servers reside on public and private subnets, respectively.

For example, consider an appliance deployed in two-arm mode for managing servers S1, S2, and S3, with a virtual server of type HTTP configured on the appliance, and with HTTP services running on the servers. The servers are on a private subnet and a SNIP is configured on the appliance to communicate with the servers. The Use SNIP (USNIP) option must be enabled on the appliance so that it uses the SNIP instead of the MIP.

As shown in the following figure, the VIP is on public subnet 217.60.10.0, and the NSIP, the servers, and the SNIP are on private subnet 192.168.100.0/24.

Figure 1. Topology Diagram for Two-Arm Mode, Multiple Subnets



Task overview: To deploy a NetScaler appliance in two-arm mode with multiple subnets

1. Configure the NSIP and default gateway, as described in "Configuring the NetScaler IP Address (NSIP)."

2. Configure the SNIP, as described in "Configuring Subnet IP Addresses."

3. Enable the USNIP option, as described in "To enable or disable USNIP mode."

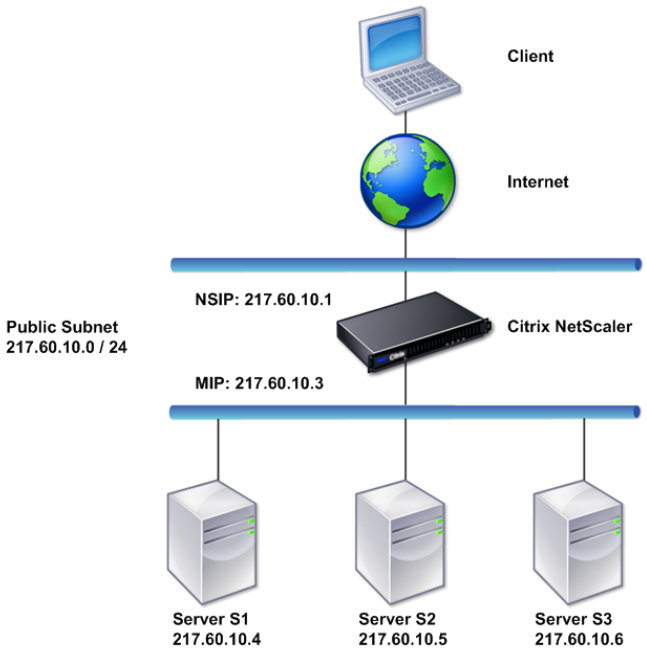
4. Configure the virtual server and the services, as described in "Creating a Virtual Server" and "Configuring Services."

5. Connect one of the network interfaces to a private subnet and the other interface to a public subnet.

Setting Up a Simple Two-Arm Transparent Topology

Use transparent mode if the clients need to access the servers directly, with no intervening virtual server. The server IP addresses must be public because the clients need to be able to access them. In the example shown in the following figure, a NetScaler appliance is placed between the client and the server, so the traffic must pass through the appliance. You must enable L2 mode for bridging the packets. The NSIP and MIP are on the same public subnet, 217.60.10.0/24.

Figure 1. Topology Diagram for Two-Arm, Transparent Mode



Task overview: To deploy a NetScaler in two-arm, transparent mode

1. Configure the NSIP, MIP, and default gateway, as described in "Configuring a NetScaler by Using the Command Line Interface."
2. Enable L2 mode, as described in "Enabling and Disabling Layer 2 Mode."
3. Configure the default gateway of the managed servers as the MIP.
4. Connect the network interfaces to the appropriate ports on the switch.

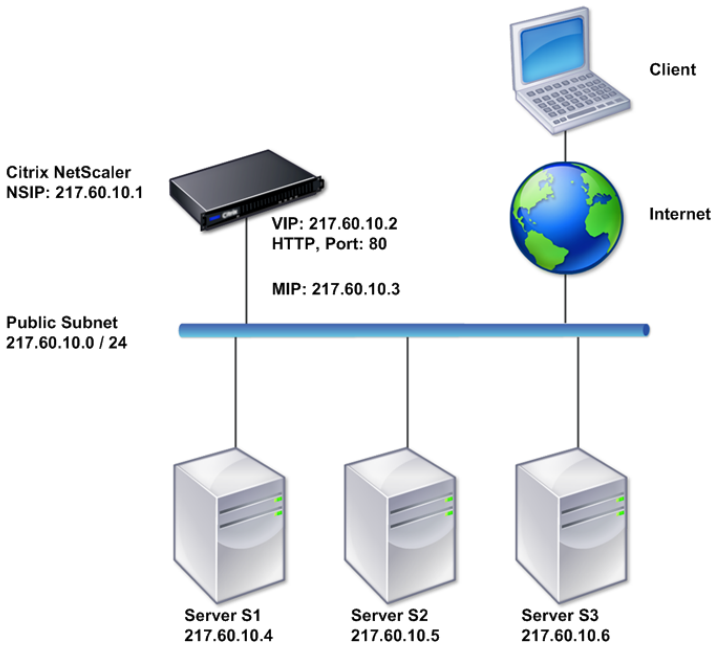
Setting Up Common One-Arm Topologies

The two basic variations of one-arm topology are with a single subnet and with multiple subnets.

Setting Up a Simple One-Arm Single Subnet Topology

You can use a one-arm topology with a single subnet when the clients and servers reside on the same subnet. For example, consider a NetScaler deployed in one-arm mode for managing servers S1, S2, and S3. A virtual server of type HTTP is configured on a NetScaler, and HTTP services are running on the servers. As shown in the following figure, the NetScaler IP address (NSIP), the Mapped IP address (MIP), and the server IP addresses are on the same public subnet, 217.60.10.0/24.

Figure 1. Topology Diagram for One-Arm Mode, Single Subnet



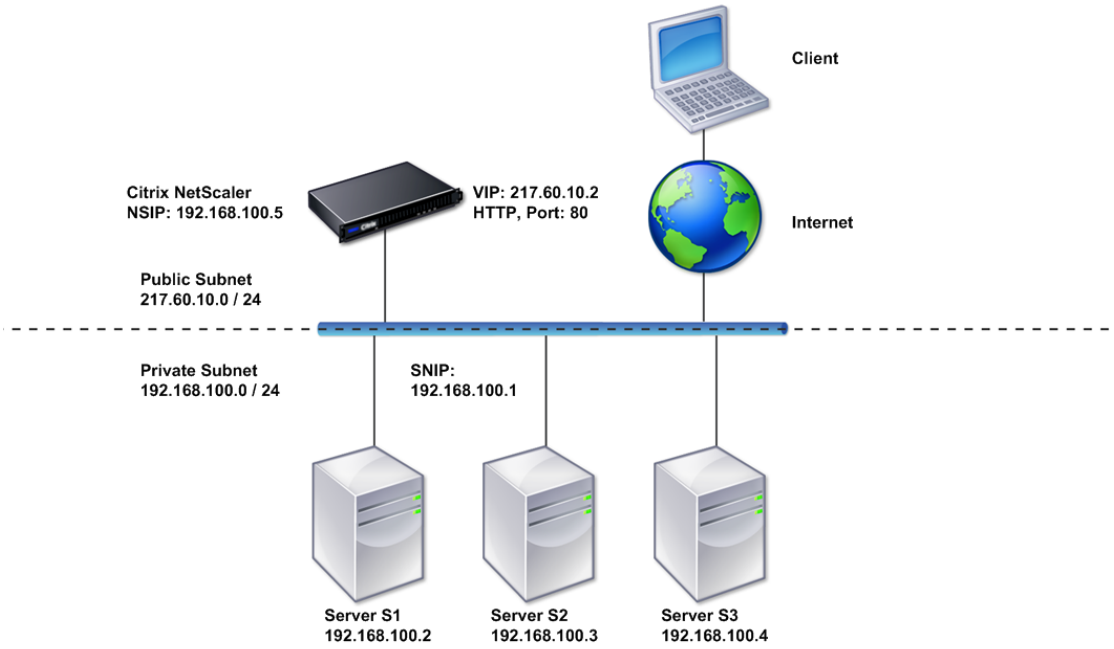
Task overview: To deploy a NetScaler in one-arm mode with a single subnet

1. Configure the NSIP, MIP, and the default gateway, as described in "Configuring the NetScaler IP Address (NSIP)".
2. Configure the virtual server and the services, as described in "Creating a Virtual Server" and "Configuring Services".
3. Connect one of the network interfaces to the switch.

Setting Up a Simple One-Arm Multiple Subnet Topology

You can use a one-arm topology with multiple subnets when the clients and servers reside on the different subnets. For example, consider a NetScaler appliance deployed in one-arm mode for managing servers S1, S2, and S3, with the servers connected to switch SW1 on the network. A virtual server of type HTTP is configured on the appliance, and HTTP services are running on the servers. These three servers are on the private subnet, so a subnet IP address (SNIP) is configured to communicate with them. The Use Subnet IP address (USNIP) option must be enabled so that the appliance uses the SNIP instead of a MIP. As shown in the following figure, the virtual IP address (VIP) is on public subnet 217.60.10.0/24; the NSIP, SNIP, and the server IP addresses are on private subnet 192.168.100.0/24.

Figure 1. Topology Diagram for One-Arm Mode, Multiple Subnets



Task overview: To deploy a NetScaler appliance in one-arm mode with multiple subnets

1. Configure the NSIP and the default gateway, as described in "Configuring the NetScaler IP Address (NSIP)".

2. Configure the SNIP and enable the USNIP option, as described in "Configuring Subnet IP Addresses".

3. Configure the virtual server and the services, as described in "Creating a Virtual Server" and "Configuring Services".

4. Connect one of the network interfaces to the switch.

Configuring System Management Settings

Once your initial configuration is in place, you can configure settings to define the behavior of the Citrix NetScaler appliance and facilitate connection management. You have a number of options for handling HTTP requests and responses. Routing, bridging, and MAC based forwarding modes are available for handling packets not addressed to the NetScaler. You can define the characteristics of your network interfaces and can aggregate the interfaces. To prevent timing problems, you can synchronize the NetScaler clock with a Network Time Protocol (NTP) server. The NetScaler can operate in various DNS modes, including as an authoritative domain name server (ADNS). You can set up SNMP for system management and customize syslog logging of system events. Before deployment, verify that your configuration is complete and correct.

Configuring System Settings

Configuration of system settings includes basic tasks such as configuring HTTP ports to enable connection keep-alive and server offload, setting the maximum number of connections for each server, and setting the maximum number of requests per connection. You can enable client IP address insertion for situations in which a proxy IP address is not suitable, and you can change the HTTP cookie version.

You can also configure a NetScaler appliance to open FTP connections on a controlled range of ports instead of ephemeral ports for data connections. This improves security, because opening all ports on the firewall is insecure. You can set the range anywhere from 1,024 to 64,000.

Before deployment, go through the verification checklists to verify your configuration. To configure HTTP parameters and the FTP port range, use the NetScaler configuration utility.

You can modify the types of HTTP parameters described in the following table.

Table 1. HTTP Parameters

Parameter Type	Specifies
HTTP Port Information	The web server HTTP ports used by your managed servers. If you specify the ports, the appliance performs request switching for any client request that has a destination port matching a specified port. **Note:** If an incoming client request is not destined for a service or a virtual server that is specifically configured on the appliance, the destination port in the request must match one of the globally configured HTTP ports. This allows the appliance to perform connection keep-alive and server off-load.

Limits	The maximum number of connections to each managed server, and the maximum number of requests sent over each connection. For example, if you set Max Connections to 500, and the appliance is managing three servers, it can open a maximum of 500 connections to each of the three servers. By default, the appliance can create an unlimited number of connections to any of the servers it manages. To specify an unlimited number of requests per connection, set Max Requests to 0. **Note:** If you are using the Apache HTTP server, you must set Max Connections equal to the value of the MaxClients parameter in the Apache httpd.conf file. Setting this parameter is optional for other web servers.
Client IP Insertion	Enable/disable insertion of the client's IP address into the HTTP request header. You can specify a name for the header field in the adjacent text box. When a web server managed by an appliance receives a mapped IP address or a subnet IP address, the server identifies it as the client's IP address. Some applications need the client's IP address for logging purposes or to dynamically determine the content to be served by the web server. You can enable insertion of the actual client IP address into the HTTP header request sent from the client to one, some, or all servers managed by the appliance. You can then access the inserted address through a minor modification to the server (using an Apache module, ISAPI interface, or NSAPI interface).
Cookie Version	The HTTP cookie version to use when COOKIEINSERT persistence is configured on a virtual server. The default, version 0, is the most common type on the Internet. Alternatively, you can specify version 1.
Requests/Responses	Options for handling certain types of requests, and enable/disable logging of HTTP error responses.
Server Header Insertion	Insert a server header in NetScaler-generated HTTP responses.

To configure HTTP parameters by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Settings, click Change HTTP parameters.
3. In the Configure HTTP parameters dialog box, specify values for some or all of the parameters that appear under the headings listed in the table above.
4. Click OK.

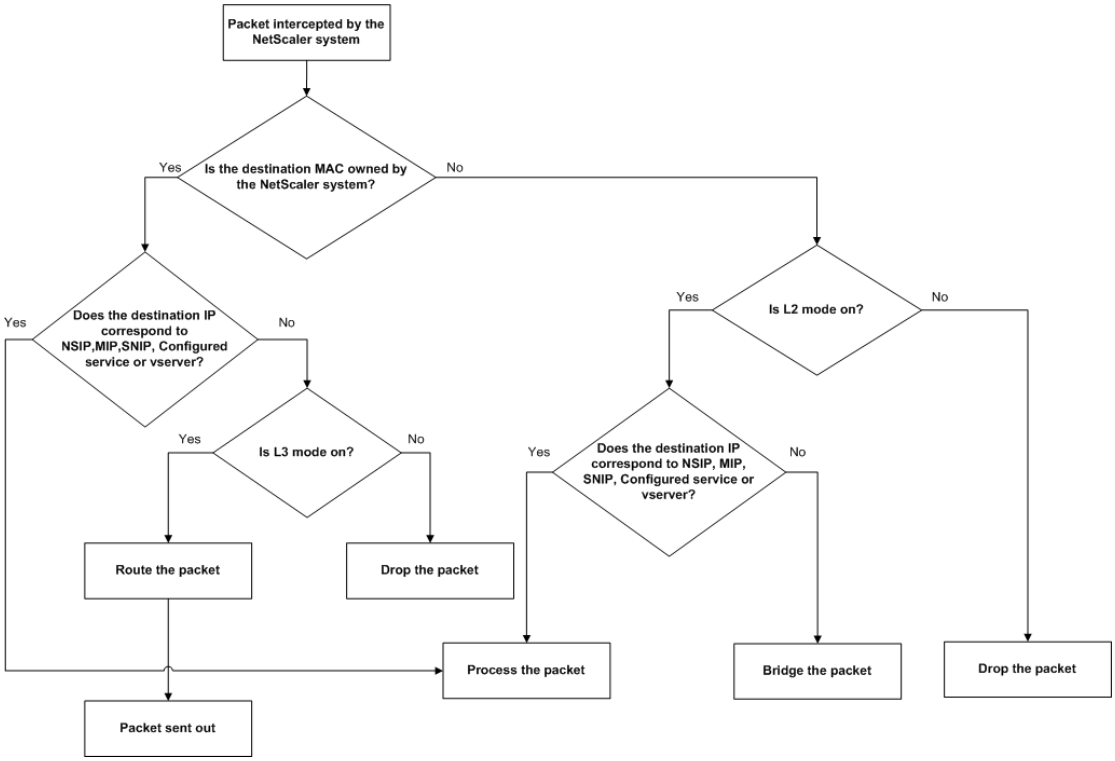
To set the FTP port range by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Settings, click Change global system settings.
3. Under FTP Port Range, in the Start Port and End Port text boxes, type the lowest and highest port numbers, respectively, for the range you want to specify (for example, 5000 and 6000).
4. Click OK.

Configuring Modes of Packet Forwarding

The NetScaler appliance can either route or bridge packets that are not destined for an IP address owned by the appliance (that is, the IP address is not the NSIP, a MIP, a SNIP, a configured service, or a configured virtual server). By default, L3 mode (routing) is enabled and L2 mode (bridging) is disabled, but you can change the configuration. The following flow chart shows how the appliance evaluates packets and either processes, routes, bridges, or drops them.

Figure 1. Interaction between Layer 2 and Layer 3 Modes



An appliance can use the following modes to forward the packets it receives:

- Layer 2 (L2) Mode
- Layer 3 (L3) Mode
- MAC-Based Forwarding Mode

Enabling and Disabling Layer 2 Mode

Layer 2 mode controls the Layer 2 forwarding (bridging) function. You can use this mode to configure a NetScaler appliance to behave as a Layer 2 device and bridge the packets that are not destined for it. When this mode is enabled, packets are not forwarded to any of the MAC addresses, because the packets can arrive on any interface of the appliance and each interface has its own MAC address.

With Layer 2 mode disabled (which is the default), the appliance drops packets that are not destined for one of its MAC address. If another Layer 2 device is installed in parallel with the appliance, Layer 2 mode must be disabled to prevent bridging (Layer 2) loops. You can use the configuration utility or the command line to enable Layer 2 mode.

Note: The appliance does not support spanning tree protocol. To avoid loops, if you enable L2 mode, do not connect two interfaces on the appliance to the same broadcast domain.

To enable or disable Layer 2 mode by using the command line interface

At the command prompt, type the following commands to enable/disable Layer 2 mode and verify that it has been enabled/disabled:

- `enable ns mode <Mode>`
- `disable ns mode <Mode>`
- `show ns mode`

Examples

```
> enable ns mode l2
 Done
> show ns mode

     Mode              Acronym        Status
     -------           -------        ------
 1)  Fast Ramp           FR            ON
 2)  Layer 2 mode         L2            ON
 .
 .
 .
 Done
>

> disable ns mode l2
 Done
> show ns mode
```

```
    Mode                Acronym        Status
    -------             -------        ------
1)  Fast Ramp             FR             ON
2)  Layer 2 mode          L2             OFF
.
.
.
Done
>
```

To enable or disable Layer 2 mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In the Configure Modes dialog box, to enable Layer 2 mode, select the Layer 2 Mode check box. To disable Layer 2 mode, clear the check box.
4. Click OK. The Enable/Disable Mode(s)? message appears in the details pane.
5. Click Yes.

Enabling and Disabling Layer 3 Mode

Layer 3 mode controls the Layer 3 forwarding function. You can use this mode to configure a NetScaler appliance to look at its routing table and forward packets that are not destined for it. With Layer 3 mode enabled (which is the default), the appliance performs route table lookups and forwards all packets that are not destined for any appliance-owned IP address. If you disable Layer 3 mode, the appliance drops these packets.

To enable or disable Layer 3 mode by using the command line interface

At the command prompt, type the following commands to enable/disable Layer 3 mode and verify that it has been enabled/disabled:

- `enable ns mode <Mode>`
- `disable ns mode <Mode>`
- `show ns mode`

Examples

```
> enable ns mode l3
 Done
> show ns mode

    Mode                    Acronym        Status
    -------                 -------        ------
 1)  Fast Ramp                FR            ON
 2)  Layer 2 mode             L2            OFF
 .
 .
 .
 9)  Layer 3 mode (ip forwarding)  L3            ON
 .
 .
 .
 Done
>

> disable ns mode l3
 Done
> show ns mode

    Mode                    Acronym        Status
    -------                 -------        ------
 1)  Fast Ramp                FR            ON
 2)  Layer 2 mode             L2            OFF
```

```
.
.
.
9)  Layer 3 mode (ip forwarding)  L3              OFF
.
.
.
Done
>
```

To enable or disable Layer 3 mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In the Configure Modes dialog box, to enable Layer 3 mode, select the Layer 3 Mode (IP Forwarding) check box. To disable Layer 3 mode, clear the check box.
4. Click OK. The Enable/Disable Mode(s)? message appears in the details pane.
5. Click Yes.

Enabling and Disabling MAC-Based Forwarding Mode

You can use MAC-based forwarding to process traffic more efficiently and avoid multiple-route or ARP lookups when forwarding packets, because the NetScaler appliance remembers the MAC address of the source. To avoid multiple lookups, the appliance caches the source MAC address of every connection for which it performs an ARP lookup, and it returns the data to the same MAC address.

MAC-based forwarding is useful when you use VPN devices because the appliance ensures that all traffic flowing through a particular VPN passes through the same VPN device.

The following figure shows the process of MAC-based forwarding.

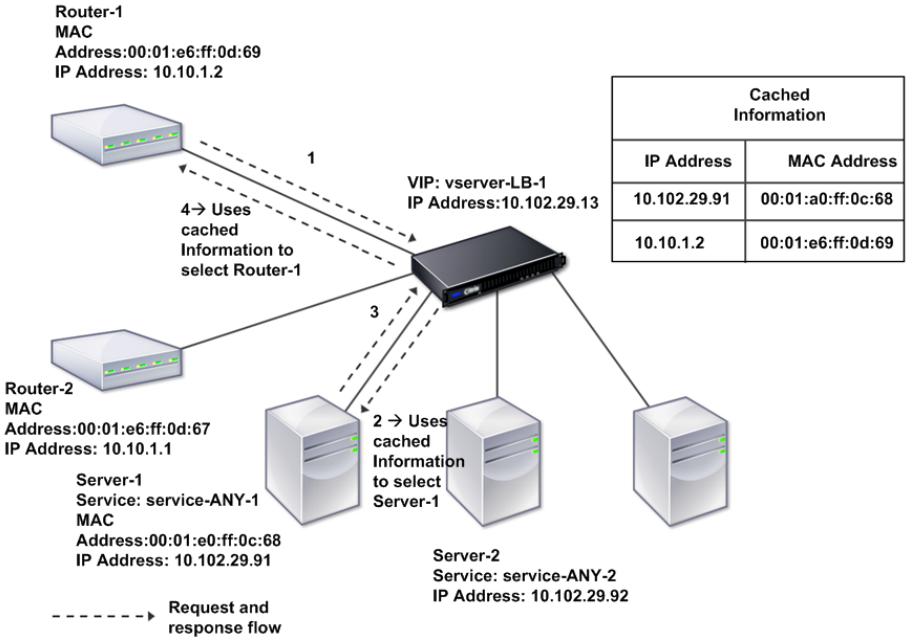


Figure 1. MAC-Based Forwarding Process

When MAC-based forwarding is enabled, the appliance caches the MAC address of:

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server responds through an appliance, the appliance sets the destination MAC address of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when an appliance initiates a connection, it uses the route and ARP tables for the lookup function. To enable MAC-based forwarding, use the configuration utility or the command line.

Some deployments require the incoming and outgoing paths to flow through different routers. In these situations, MAC-based forwarding breaks the topology design. For a global server load balancing (GSLB) site that requires the incoming and outgoing paths to flow through different routers, you must disable MAC-based forwarding and use the appliance's default router as the outgoing router.

With MAC-based forwarding disabled and Layer 2 or Layer 3 connectivity enabled, a route table can specify separate routers for outgoing and incoming connections. To disable MAC-based forwarding, use the configuration utility or the command line.

To enable or disable MAC-based forwarding by using the command line interface

At the command prompt, type the following commands to enable/disable MAC-based forwarding mode and verify that it has been enabled/disabled:

- `enable ns mode <Mode>`
- `disable ns mode <Mode>`
- `show ns mode`

Example

```
> enable ns mode mbf
 Done
> show ns mode

    Mode                  Acronym         Status
    -------               -------         ------
 1) Fast Ramp               FR              ON
 2) Layer 2 mode            L2              OFF
 .
 .
 .
 6) MAC-based forwarding    MBF             ON
 .
 .
 .
 Done
>

> disable ns mode mbf
 Done
> show ns mode
```

```
   Mode                  Acronym         Status
   -------               -------         ------
1) Fast Ramp               FR              ON
2) Layer 2 mode            L2              OFF
.
.
.
6) MAC-based forwarding    MBF             OFF
.
.
.
Done
>
```

To enable or disable MAC-based forwarding by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features group, click Configure modes.
3. In the Configure Modes dialog box, to enable MAC-based forwarding mode, select the MAC Based Forwarding check box. To disable MAC-based forwarding mode, clear the check box.
4. Click OK. The Enable/Disable Mode(s)? message appears in the details pane.
5. Click Yes.

Configuring Network Interfaces

NetScaler interfaces are numbered in slot/port notation. In addition to modifying the characteristics of individual interfaces, you can configure virtual LANs to restrict traffic to specific groups of hosts. You can also aggregate links into high-speed channels.

Virtual LANs

The NetScaler supports (Layer 2) port and IEEE802.1Q tagged virtual LANs (VLANs). VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface to belong to multiple VLANs by using IEEE 802.1q tagging.

You can bind your configured VLANs to IP subnets. The NetScaler (if it is configured as the default router for the hosts on the subnets) then performs IP forwarding between these VLANs. A NetScaler supports the following types of VLANs.

Default VLAN

By default, the network interfaces on a NetScaler are included in a single, port-based VLAN as untagged network interfaces. This default VLAN has a VID of 1 and exists permanently. It cannot be deleted, and its VID cannot be changed.

Port-Based VLANs

A set of network interfaces that share a common, exclusive, Layer 2 broadcast domain define the membership of a port-based VLAN. You can configure multiple port-based VLANs. When you add an interface to a new VLAN as an untagged member, it is automatically removed from the default VLAN.

Tagged VLAN

A network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of only one VLAN (its native VLAN). The untagged network interface forwards the frames for the native VLAN as untagged frames. A tagged network interface can be a part of more than one VLAN. When you configure tagging, be sure that both ends of the link have matching VLAN settings. You can use the configuration utility to define a tagged VLAN (nsvlan) that can have any ports bound as tagged members of the VLAN. Configuring this VLAN requires a reboot of the NetScaler and therefore must be done during initial network configuration.

Link Aggregate Channels

Link aggregation combines incoming data from multiple ports into a single high speed link. Configuring the link aggregate channel increases the capacity and availability of the communication channel between a NetScaler and other connected devices. An aggregated link is also referred to as a channel.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. A network interface can be bound to only one channel. Binding a network interface to a link aggregate channel changes the VLAN configuration. That is, binding network interfaces to a channel removes them from the VLANs that they originally belonged to and adds them to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you have bound network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then you bind them to link aggregate channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them to VLAN 2.

Note: You can also use Link Aggregation Control Protocol (LACP) to configure link aggregation. For more information, see "Configuring Link Aggregation by Using the Link Aggregation Control Protocol."

Configuring Clock Synchronization

You can configure your NetScaler appliance to synchronize its local clock with a Network Time Protocol (NTP) server. This ensures that its clock has the same date and time settings as the other servers on your network. NTP uses User Datagram Protocol (UDP) port 123 as its transport layer. You have to add NTP servers in the NTP configuration file so that the appliance periodically gets updates from these servers.

If you do not have a local NTP server, you can find a list of public, open access, NTP servers at the official NTP site at http://www.ntp.org.

To configure clock synchronization on your appliance

1. Log on to the command line and enter the `shell` command.

2. At the shell prompt, copy the ntp.conf file from the /etc directory to the /nsconfig directory. If the file already exists in the /nsconfig directory, make sure that you remove the following entries from the ntp.conf file:

   ```
   restrict localhost

   restrict 127.0.0.2
   ```

   These entries are required only if you want to run the device as a time server. However, this feature is not supported on the NetScaler.

3. Edit /nsconfig/ntp.conf by typing the IP address for the desired NTP server under the file's server and restrict entries.

4. Create a file named rc.netscaler in the /nsconfig directory, if the file does not already exist in the directory.

5. Edit /nsconfig/rc.netscaler by adding the following entry: `/usr/sbin/ntpd -c /nsconfig/ntp.conf -l /var/log/ntpd.log &`

   This entry starts the ntpd service, checks the ntp.conf file, and logs messages in the /var/log directory.

   Note: If the time difference between the NetScaler and the time server is more than 1000 sec, the ntpd service terminates with a message to the NetScaler log. To avoid this, you need to start ntpd with the -g option, which forcibly syncs the time. Add the following entry in /nsconfig/rc.netscaler:

   ```
   /usr/sbin/ntpd -g -c /nsconfig/ntp.conf -l /var/log/ntpd.log &
   ```

   If you do not want to forcibly sync the time when there is a large difference, you can set the date manually and then start ntpd again. You can check the time difference between the appliance and the time server by running the following command in the shell:

   ntpdate -q <IP address or domain name of the NTP server>

6. Reboot the appliance to enable clock synchronization.

   Note: If you want to start time synchronization before you restart the appliance, enter the following command (which you added to the rc.netscaler file in step 5) at the shell prompt:

   /usr/sbin/ntpd -c /nsconfig/ntp.conf -l /var/log/ ntpd.log &

Configuring DNS

You can configure a NetScaler appliance to function as an Authoritative Domain Name Server (ADNS), DNS proxy server, End Resolver, or Forwarder. You can add DNS resource records such as SRV Records, AAAA Records, A Records, MX Records, NS Records, CNAME Records, PTR Records, and SOA Records. Also, the appliance can balance the load on external DNS servers.

A common practice is to configure an appliance as a forwarder. For this configuration, you need to add external name servers. After you have added the external servers, you should verify that your configuration is correct.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

When adding name servers, you can specify IP addresses or virtual IP addresses (VIPs). If you use IP addresses, the appliance load balances requests to the configured name servers in a round robin manner. If you use VIPs, you can specify any load balancing method. For information about using a VIP, see "Load Balancing DNS Servers."

To add a name server by using the command line interface

At the command prompt, type the following commands to add a name server and verify the configuration:

- `add dns nameServer <IP>`
- `show dns nameServer <IP>`

Example

```
> add dns nameServer 10.102.29.10
 Done
> show dns nameServer 10.102.29.10
1)      10.102.29.10  -  State: DOWN
 Done
>
```

To add a name server by using the configuration utility

1. In the navigation pane, expand DNS, and then click Name Servers.
2. In the details pane, click Add.
3. In the Create Name Server dialog box, select IP Address.
4. In the IP Address text box, type the IP address of the name server (for example, `10.102.29.10`). If you are adding an external name server, clear the Local check box.
5. Click Create, and then click Close.
6. Verify that the name server you added appears in the Name Servers pane.

Configuring SNMP

The Simple Network Management Protocol (SNMP) network management application, running on an external computer, queries the SNMP agent on the NetScaler. The agent searches the management information base (MIB) for data requested by the network management application and sends the data to the application.

SNMP monitoring uses traps messages and alarms. SNMP traps messages are asynchronous events that the agent generates to signal abnormal conditions, which are indicated by alarms. For example, if you want to be informed when CPU utilization is above 90 percent, you can set up an alarm for that condition. The following figure shows a network with a NetScaler that has SNMP enabled and configured.

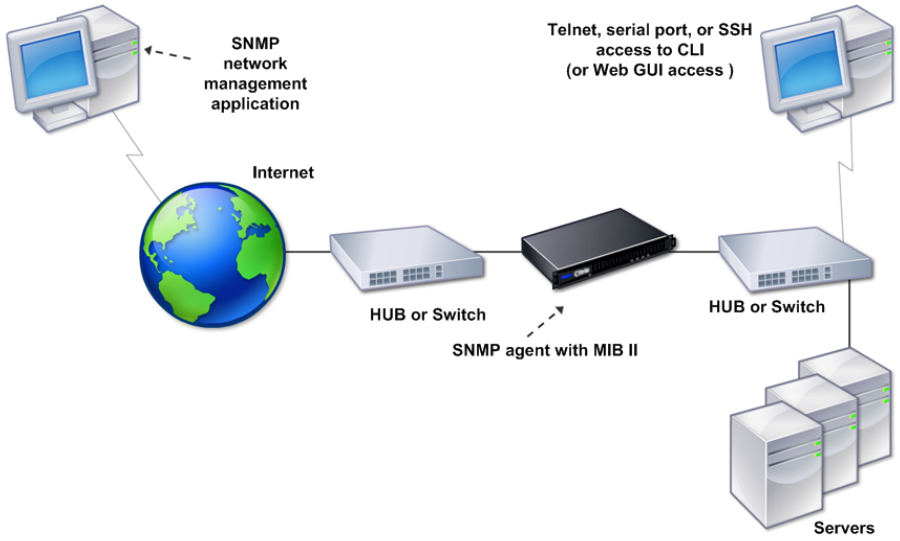

Figure 1. SNMP on the NetScaler

The SNMP agent on a NetScaler supports SNMP version 1 (SNMPv1), SNMP version 2 (SNMPv2), and SNMP version 3 (SNMPv3). Because it operates in bilingual mode, the agent can handle SNMPv2 queries, such as Get-Bulk, and SNMPv1 queries. The SNMP agent also sends traps compliant with SNMPv2 and supports SNMPv2 data types, such as counter64. SNMPv1 managers (programs on other servers that request SNMP information from the NetScaler) use the NS-MIB-smiv1.mib file when processing SNMP queries. SNMPv2 managers use the NS-MIB-smiv2.mib file.

The NetScaler supports the following enterprise-specific MIBs:

A subset of standard MIB-2 groups

Provides MIB-2 groups SYSTEM, IF, ICMP, UDP, and SNMP.

A system enterprise MIB

Provides system-specific configuration and statistics.

To configure SNMP, you specify which managers can query the SNMP agent, add SNMP trap listeners that will receive the SNMP trap messages, and configure SNMP Alarms.

Adding SNMP Managers

You can configure a workstation running a management application that complies with SNMP version 1, 2, or 3 to access an appliance. Such a workstation is called an SNMP manager. If you do not specify an SNMP manager on the appliance, the appliance accepts and responds to SNMP queries from all IP addresses on the network. If you configure one or more SNMP managers, the appliance accepts and responds to SNMP queries from only those specific IP addresses. When specifying the IP address of an SNMP manager, you can use the netmask parameter to grant access from entire subnets. You can add a maximum of 100 SNMP managers or networks.

To add an SNMP manager by using the command line interface

At the command prompt, type the following commands to add an SNMP manager and verify the configuration:

- `add snmp manager <IPAddress> ... [-netmask <netmask>]`
- `show snmp manager <IPAddress>`

Example

```
> add snmp manager 10.102.29.5 -netmask 255.255.255.255
 Done
> show snmp manager 10.102.29.5
1)     10.102.29.5        255.255.255.255
 Done
>
```

To add an SNMP manager by using the configuration utility

1. In the navigation pane, expand System, expand SNMP, and then click Managers.
2. In the details pane, click Add.
3. In the Add SNMP Manager dialog box, in the IP Address text box, type the IP address of the workstation running the management application (for example, `10.102.29.5`).
4. Click Create, and then click Close.
5. Verify that the SNMP manager you added appears in the Details section at the bottom of the pane.

Adding SNMP Traps Listeners

After configuring the alarms, you need to specify the trap listener to which the appliance will send the trap messages. Apart from specifying parameters like IP address and the destination port of the trap listener, you can specify the type of trap (either generic or specific) and the SNMP version.

You can configure a maximum of 20 trap listeners for receiving either generic or specific traps.

To add an SNMP trap listener by using the command line interface

At the command prompt, type the following command to add an SNMP trap and verify that it has been added:

- `add snmp trap specific <IP>`
- `show snmp trap`

Example

```
> add snmp trap specific 10.102.29.3
 Done
> show snmp trap
Type    DestinationIP   DestinationPort  Version  SourceIP     Min-Severity  Community
----    -------------   ---------------  -------  --------     ------------  ---------
generic  10.102.29.9    162           V2      NetScaler IP  N/A          public
generic  10.102.29.5    162           V2      NetScaler IP  N/A          public
generic  10.102.120.101  162           V2      NetScaler IP  N/A          public
.
.
.
specific 10.102.29.3    162           V2      NetScaler IP   -           public
 Done
>
```

To add an SNMP trap listener by using the configuration utility

1. In the navigation pane, expand System, expand SNMP, and then click Traps.
2. In the details pane, click Add.
3. In the Create SNMP Trap Destination dialog box, in the Destination IP Address text box, type the IP address (for example, `10.102.29.3`).
4. Click Create and then click Close.
5. Verify that the SNMP trap you added appears in the Details section at the bottom of the pane.

Configuring SNMP Alarms

You configure alarms so that the appliance generates a trap message when an event corresponding to one of the alarms occurs. Configuring an alarm consists of enabling the alarm and setting the severity level at which a trap is generated. There are five severity levels: Critical, Major, Minor, Warning, and Informational. A trap is sent only when the severity of the alarm matches the severity specified for the trap.

Some alarms are enabled by default. If you disable an SNMP alarm, the appliance will not generate trap messages when corresponding events occur. For example, if you disable the Login-Failure SNMP alarm, the appliance will not generate a trap message when a login failure occurs.

To enable or disable an alarm by using the command line interface

At the command prompt, type the following commands to enable or disable an alarm and verify that it has been enabled or disabled:

- `set snmp alarm <trapName> [-state ENABLED | DISABLED ]`
- `show snmp alarm <trapName>`

Example

```
> set snmp alarm LOGIN-FAILURE -state ENABLED
 Done
> show snmp alarm LOGIN-FAILURE
  Alarm          Alarm Threshold  Normal Threshold  Time  State    Severity   Logging
  -----          ---------------  ----------------  ----  --------  ---------  --------
 1) LOGIN-FAILURE  N/A           N/A           N/A   ENABLED   -       ENABLED
 Done
>
```

To set the severity of the alarm by using the command line interface

At the command prompt, type the following commands to set the severity of the alarm and verify that the severity has been set correctly:

- `set snmp alarm <trapName> [-severity <severity>]`
- `show snmp alarm <trapName>`

Example

```
> set snmp alarm LOGIN-FAILURE -severity Major
 Done
> show snmp alarm LOGIN-FAILURE
   Alarm          Alarm Threshold  Normal Threshold  Time  State     Severity   Logging
   -----          ---------------  ----------------  ----  --------  ---------  --------
 1) LOGIN-FAILURE  N/A             N/A               N/A   ENABLED   Major      ENABLED
 Done
>
```

To configure alarms by using the configuration utility

1. In the navigation pane, expand System, expand SNMP, and then click Alarms.
2. In the details pane, select an alarm (for example, LOGIN-FAILURE), and then click Open.
3. In the Configure SNMP Alarm dialog box, to enable the alarm, select the Enable check box. To disable the alarm, clear the Enable check box.
4. In the Severity drop-down list, select a severity option (for example, Major).
5. Click OK, and then click Close.
6. Verify that the parameters for the SNMP alarm you configured are correctly configured by viewing the Details section at the bottom of the pane.

Configuring Syslog

You can customize logging of NetScaler and Access Gateway Enterprise Edition access events for the needs of your site. You can direct these logs either to files on the NetScaler or to external log servers. The NetScaler uses the Audit Server Logging feature for logging the states and status information collected by different modules in the kernel and by user-level daemons.

Syslog is used to monitor a NetScaler and to log connections, statistics, and so on. You can customize the two logging functions for system events messaging and syslog. The NetScaler internal event message generator passes log entries to the syslog server. The syslog server accepts these log entries and logs them. For more information about the Audit Server Logging feature, see "Audit Logging."

Verifying the Configuration

After you finish configuring your system, complete the following checklists to verify your configuration.

Configuration Checklist

- The build running is:
- There are no incompatibility issues. (Incompatibility issues are documented in the build's release notes.)
- The port settings (speed, duplex, flow control, monitoring) are the same as the switch's port.
- Enough mapped IP addresses have been configured to support all server-side connections during peak times.
  - The number of configured mapped IP addresses is: ____
  - The expected number of simultaneous server connections is:

    [ ] 62,000 [ ] 124,000 [ ] Other____

Topology Configuration Checklist

- The routes have been used to resolve servers on other subnets.

  The routes entered are:

  _____
- If the NetScaler is in a public-private topology, reverse NAT has been configured.
- The failover (high availability) settings configured on the NetScaler resolve in a one arm or two-arm configuration. All unused network interfaces have been disabled:

  _____
- If the NetScaler is placed behind an external load balancer, then the load balancing policy on the external load balancer is not "least connection."

  The load balancing policy configured on the external load balancer is:

  _____
- If the NetScaler is placed in front of a firewall, the session time-out on the firewall is set to a value greater than or equal to 300 seconds.

  Note: The TCP idle connection timeout on a NetScaler appliance is 360 seconds. If the timeout on the firewall is also set to 300 seconds or more, then the appliance can

perform TCP connection multiplexing effectively because connections will not be closed earlier.

The value configured for the session time-out is: _____

Server Configuration Checklist

- "Keep-alive" has been enabled on all the servers.

  The value configured for the keep-alive time-out is: _____

- The default gateway has been set to the correct value. (The default gateway should either be a NetScaler or upstream router.) The default gateway is:

  _____

- The server port settings (speed, duplex, flow control, monitoring) are the same as the switch port settings.

  _____

- If the Microsoft® Internet Information Server is used, buffering is enabled on the server.

- If an Apache Server is used, the MaxConn (maximum number of connections) parameter is configured on the server and on the NetScaler.

  The MaxConn (maximum number of connections) value that has been set is:

  _____

- If a Netscape® Enterprise Server™ is used, the maximum requests per connection parameter is set on the NetScaler. The maximum requests per connection value that has been set is:

  _____

Software Features Configuration Checklist

- Does the Layer 2 mode feature need to be disabled? (Disable if another Layer 2 device is working in parallel with a NetScaler.)

  Reason for enabling or disabling:

  _____

- Does the MAC-based forwarding feature need to be disabled? (If the MAC address used by return traffic is different, it should be disabled.)

  Reason for enabling or disabling:

  _____

- Does host-based reuse need to be disabled? (Is there virtual hosting on the servers?)

Reason for enabling or disabling:

_____

- Do the default settings of the surge protection feature need to be changed?

Reason for changing or not changing:

_____

Access Checklist

- The system IPs can be pinged from the client-side network.
- The system IPs can be pinged from the server-side network.
- The managed server(s) can be pinged through the NetScaler.
- Internet hosts can be pinged from the managed servers.
- The managed server(s) can be accessed through the browser.
- The Internet can be accessed from managed server(s) using the browser.
- The system can be accessed using SSH.
- Admin access to all managed server(s) is working.

Note: When you are using the ping utility, ensure that the pinged server has ICMP ECHO enabled, or your ping will not succeed.

Firewall Checklist

The following firewall requirements have been met:

- UDP 161 (SNMP)
- UDP 162 (SNMP trap)
- TCP/UDP 3010 (GUI)
- HTTP 80 (GUI)
- TCP 22 (SSH)

Load Balancing Traffic on a NetScaler Appliance

The load balancing feature distributes client requests across multiple servers to optimize resource utilization. In a real-world scenario with a limited number of servers providing service to a large number of clients, a server can become overloaded and degrade the performance of the server farm. A Citrix NetScaler appliance uses load balancing criteria to prevent bottlenecks by forwarding each client request to the server best suited to handle the request when it arrives.

To configure load balancing, you define a virtual server to proxy multiple servers in a server farm and balance the load among them.

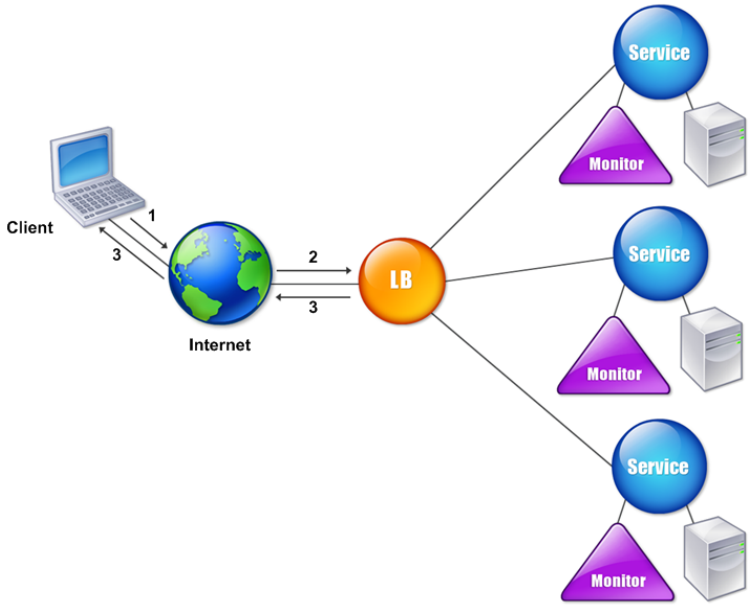
How Load Balancing Works

When a client initiates a connection to the server, a virtual server terminates the client connection and initiates a new connection with the selected server, or reuses an existing connection with the server, to perform load balancing. The load balancing feature provides traffic management from Layer 4 (TCP and UDP) through Layer 7 (FTP, HTTP, and HTTPS).

The NetScaler appliance uses a number of algorithms, called load balancing methods, to determine how to distribute the load among the servers. The default load balancing method is the Least Connections method.

A typical load balancing deployment consists of the entities described in the following figure.

Figure 1. Load Balancing Architecture



The entities function as follows:

- **Virtual server**. An entity that is represented by an IP address, a port, and a protocol. The virtual server IP address (VIP) is usually a public IP address. The client sends connection requests to this IP address. The virtual server represents a bank of servers.

- **Service**. A logical representation of a server or an application running on a server. Identifies the server's IP address, a port, and a protocol. The services are bound to the virtual servers.

- **Server object**. An entity that is represented by an IP address. The server object is created when you create a service. The IP address of the service is taken as the name of the server object. You can also create a server object and then create services by using the server object.

- **Monitor**. An entity that tracks the health of the services. The appliance periodically probes the servers using the monitor bound to each service. If a server does not respond within a specified response timeout, and the specified number of probes fails, the service is marked DOWN. The appliance then performs load balancing among the remaining services.

Configuring Load Balancing

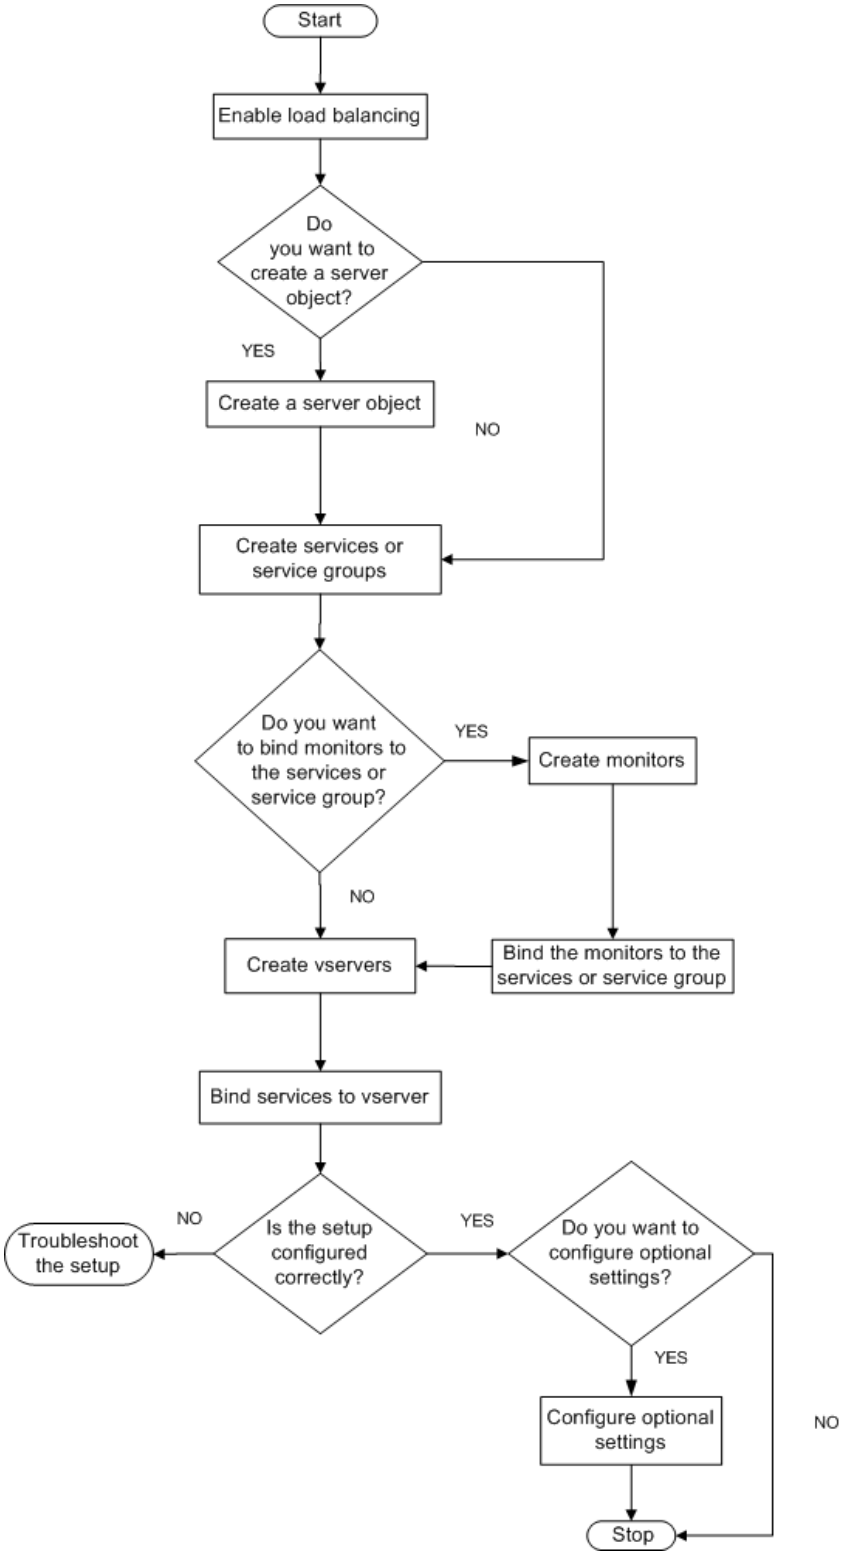
To configure load balancing, you must first create services. Then, you create virtual servers and bind the services to the virtual servers. By default, the NetScaler appliance binds a monitor to each service. After binding the services, verify your configuration by making sure that all of the settings are correct.

Note: After you deploy the configuration, you can display statistics that show how the entities in the configuration are performing. Use the statistical utility or the `stat lb vserver <vserverName>` command.

Optionally, you can assign weights to a service. The load balancing method then uses the assigned weight to select a service. For getting started, however, you can limit optional tasks to configuring some basic persistence settings, for sessions that must maintain a connection to a particular server, and some basic configuration-protection settings.

The following flow chart illustrates the sequence of the configuration tasks.

Figure 1. Sequence of Tasks to Configure Load Balancing



Start
Enable load balancing
Do you want to create a server object?
YES
Create a server object
NO
Create services or service groups
Do you want to bind monitors to the services or service group?
YES
Create monitors
NO
Create vservers
Bind the monitors to the services or service group
Bind services to vserver
Is the setup configured correctly?
NO
Troubleshoot the setup
YES
Do you want to configure optional settings?
YES
Configure optional settings
NO
Stop

Enabling Load Balancing

Before configuring load balancing, make sure that the load balancing feature is enabled.

To enable load balancing by using the command line interface

At the command prompt, type the following commands to enable load balancing and verify that it is enabled:

- `enable feature lb`
- `show feature`

Example

```
> enable feature lb
 Done
> show feature

    Feature              Acronym        Status
    -------             -------        ------
 1)  Web Logging          WL             OFF
 2)  Surge Protection      SP             OFF
 3)  Load Balancing        LB             ON
 .
 .
 .
 9)  SSL Offloading        SSL            ON
 .
 .
 .
Done
```

To enable load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click OK.
4. In the Enable/Disable Feature(s)? message, click Yes.

Configuring Services and a Virtual Server

When you have identified the services you want to load balance, you can implement your initial load balancing configuration by creating the service objects, creating a load balancing virtual server, and binding the service objects to the virtual server.

To implement the initial load balancing configuration by using the command line interface

At the command prompt, type the following commands to implement and verify the initial configuration:

- add service <name> <IPaddress> <serviceType> <port>
- add lb vserver <vServerName> <serviceType> [<IPaddress> <port>]
- bind lb vserver <name> <serviceName>
- show service bindings <serviceName>

  Example

```
> add service service-HTTP-1 10.102.29.5 HTTP 80
 Done
> add lb vserver vserver-LB-1 HTTP 10.102.29.60 80
 Done
> bind lb vserver vserver-LB-1 service-HTTP-1
 Done
> show service bindings service-HTTP-1
   service-HTTP-1 (10.102.29.5:80) - State : DOWN

     1)      vserver-LB-1 (10.102.29.60:80) - State : DOWN
 Done
```

To implement the initial load balancing configuration by using the configuration utility

1. In the navigation pane, click Load Balancing.
2. In the details pane, under Getting Started, click Load Balancing wizard, and follow the instructions to create a basic load balancing setup.
3. Return to the navigation pane, expand Load Balancing, and then click Virtual Servers.
4. Select the virtual server that you configured and verify that the parameters displayed at the bottom of the page are correctly configured.
5. Click Open.
6. Verify that each service is bound to the virtual server by confirming that the Active check box is selected for each service on the Services tab.

Choosing and Configuring Persistence Settings

You must configure persistence on a virtual server if you want to maintain the states of connections on the servers represented by that virtual server (for example, connections used in e-commerce). The appliance then uses the configured load balancing method for the initial selection of a server, but forwards to that same server all subsequent requests from the same client.

If persistence is configured, it overrides the load balancing methods once the server has been selected. If the configured persistence applies to a service that is down, the appliance uses the load balancing methods to select a new service, and the new service becomes persistent for subsequent requests from the client. If the selected service is in an Out Of Service state, it continues to serve the outstanding requests but does not accept new requests or connections. After the shutdown period elapses, the existing connections are closed. The following table lists the types of persistence that you can configure.

Table 1. Limitations on Number of Simultaneous Persistent Connections

Persistence Type	Persistent Connections
Source IP, SSL Session ID, Rule, DESTIP, SRCIPDESTIP	250K
CookieInsert, URL passive, Custom Server ID	Memory limit. In case of CookieInsert, if time out is not 0, any number of connections is allowed until limited by memory.

If the configured persistence cannot be maintained because of a lack of resources on an appliance, the load balancing methods are used for server selection. Persistence is maintained for a configured period of time, depending on the persistence type. Some persistence types are specific to certain virtual servers. The following table shows the relationship.

Table 2. Persistence Types Available for Each Type of Virtual Server

Persistence TypeHeader 1	HTTP	HTTPS	TCP	UDP/IP	SSL_Bridge
Source IP	YES	YES	YES	YES	YES
CookieInsert	YES	YES	NO	NO	NO
SSL Session ID	NO	YES	NO	NO	YES
URL Passive	YES	YES	NO	NO	NO
Custom Server ID	YES	YES	NO	NO	NO
Rule	YES	YES	NO	NO	NO
SRCIPDESTIP	N/A	N/A	YES	YES	N/A

DESTIP	N/A	N/A	YES	YES	N/A

You can also specify persistence for a group of virtual servers. When you enable persistence on the group, the client requests are directed to the same selected server regardless of which virtual server in the group receives the client request. When the configured time for persistence elapses, any virtual server in the group can be selected for incoming client requests.

Two commonly used persistence types are persistence based on cookies and persistence based on server IDs in URLs. For more information about all persistence types, see "Persistence and Persistent Connections."

Configuring Persistence Based on Cookies

When you enable persistence based on cookies, the NetScaler adds an HTTP cookie into the Set-Cookie header field of the HTTP response. The cookie contains information about the service to which the HTTP requests must be sent. The client stores the cookie and includes it in all subsequent requests, and the NetScaler uses it to select the service for those requests. You can use this type of persistence on virtual servers of type HTTP or HTTPS.

The NetScaler inserts the cookie <NSC_XXXX>= <ServiceIP> <ServicePort>

where:

- <NSC_XXXX> is the virtual server ID that is derived from the virtual server name.
- <ServiceIP> is the hexadecimal value of the IP address of the service.
- <ServicePort> is the hexadecimal value of the port of the service.

The NetScaler encrypts ServiceIP and ServicePort when it inserts a cookie, and decrypts them when it receives a cookie.

Note: If the client is not allowed to store the HTTP cookie, the subsequent requests do not have the HTTP cookie, and persistence is not honored.

By default, the NetScaler sends HTTP cookie version 0, in compliance with the Netscape specification. It can also send version 1, in compliance with RFC 2109.

You can configure a timeout value for persistence that is based on HTTP cookies. Note the following:

- If HTTP cookie version 0 is used, the NetScaler inserts the absolute Coordinated Universal Time (GMT) of the cookie's expiration (the expires attribute of the HTTP cookie), calculated as the sum of the current GMT time on a NetScaler, and the timeout value.
- If an HTTP cookie version 1 is used, the NetScaler inserts a relative expiration time (Max-Age attribute of the HTTP cookie). In this case, the client software calculates the actual expiration time.

Note: Most client software currently installed (Microsoft Internet Explorer and Netscape browsers) understand HTTP cookie version 0; however, some HTTP proxies understand HTTP cookie version 1.

If you set the timeout value to 0, the NetScaler does not specify the expiration time, regardless of the HTTP cookie version used. The expiration time then depends on the client software, and such cookies are not valid if that software is shut down. This persistence type does not consume any system resources. Therefore, it can accommodate an unlimited number of persistent clients.

An administrator can use the procedure in the following table to change the HTTP cookie version.

To change the HTTP cookie version by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, click Change HTTP Parameters.
3. In the Configure HTTP Parameters dialog box, under Cookie, select Version 0 or Version 1.

Note: For information about the parameters, see "Configuring Persistence Based on Cookies."

To configure persistence based on cookies by using the command line interface

At the command prompt, type the following commands to configure persistence based on cookies and verify the configuration:

- set lb vserver <name> -persistenceType COOKIEINSERT
- show lb vserver <name>

Example

```
> set lb vserver vserver-LB-1 -persistenceType COOKIEINSERT
 Done
> show lb vserver vserver-LB-1
    vserver-LB-1 (10.102.29.60:80) - HTTP   Type: ADDRESS
    .
    .
    .
    Persistence: COOKIEINSERT (version 0)   Persistence Timeout: 2 min
    .
    .
    .
 Done
>
```

To configure persistence based on cookies by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure persistence (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in the Persistence list, select COOKIEINSERT.
4. In the Time-out (min) text box, type the time-out value (for example, 2).
5. Click OK.
6. Verify that the virtual server for which you configured persistence is correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane.

Configuring Persistence Based on Server IDs in URLs

The NetScaler can maintain persistence based on the server IDs in the URLs. In a technique called URL passive persistence, the NetScaler extracts the server ID from the server response and embeds it in the URL query of the client request. The server ID is an IP address and port specified as a hexadecimal number. The NetScaler extracts the server ID from subsequent client requests and uses it to select the server.

URL passive persistence requires configuring either a payload expression or a policy infrastructure expression specifying the location of the server ID in the client requests. For more information about expressions, see "Policy Configuration and Reference."

Note: If the server ID cannot be extracted from the client requests, server selection is based on the load balancing method.

Example: Payload Expression

The expression, URLQUERY contains sid= configures the system to extract the server ID from the URL query of a client request, after matching token sid=. Thus, a request with the URL http://www.citrix.com/index.asp?&sid;=c0a864100050 is directed to the server with the IP address10.102.29.10 and port 80.

The timeout value does not affect this type of persistence, which is maintained as long as the server ID can be extracted from the client requests. This persistence type does not consume any system resources, so it can accommodate an unlimited number of persistent clients.

Note: For information about the parameters, see "Load Balancing."

To configure persistence based on server IDs in URLs by using the command line interface

At the command prompt, type the following commands to configure persistence based on server IDs in URLs and verify the configuration:

- `set lb vserver <name> -persistenceType URLPASSIVE`
- `show lb vserver <name>`

Example

```
> set lb vserver vserver-LB-1 -persistenceType URLPASSIVE
 Done
> show lb vserver vserver-LB-1
    vserver-LB-1 (10.102.29.60:80) - HTTP   Type: ADDRESS
```

```
    .
    .
    .
    Persistence: URLPASSIVE Persistence Timeout: 2 min
    .
    .
    .
 Done
>
```

To configure persistence based on server IDs in URLs by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure persistence (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in the Persistence list, select URLPASSIVE.
4. In the Time-out (min) text box, type the time-out value (for example, 2).
5. In the Rule text box, enter a valid expression. Alternatively, click Configure next to the Rule text box and use the Create Expression dialog box to create an expression.
6. Click OK.
7. Verify that the virtual server for which you configured persistence is correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane.

Configuring Features to Protect the Load Balancing Configuration

You can configure URL redirection to provide notifications of virtual server malfunctions, and you can configure backup virtual servers to take over if a primary virtual server becomes unavailable.

Configuring URL Redirection

You can configure a redirect URL to communicate the status of the appliance in the event that a virtual server of type HTTP or HTTPS is down or disabled. This URL can be a local or remote link. The appliance uses HTTP 302 redirect.

Redirects can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL), the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Note: If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. In this case, a redirect is used when both the primary and backup virtual servers are down.

To configure a virtual server to redirect client requests to a URL by using the command line interface

At the command prompt, type the following commands to configure a virtual server to redirect client requests to a URL and verify the configuration:

- set lb vserver <name> -redirectURL <URL>
- show lb vserver <name>

Example

```
> set lb vserver vserver-LB-1 -redirectURL http://www.newdomain.com/mysite/maintenance
 Done
> show lb vserver vserver-LB-1
    vserver-LB-1 (10.102.29.60:80) - HTTP   Type: ADDRESS
    State: DOWN
    Last state change was at Wed Jun 17 08:56:34 2009 (+666 ms)
    .
    .
    .
    Redirect URL: http://www.newdomain.com/mysite/maintenance
    .
    .
    .
 Done
>
```

To configure a virtual server to redirect client requests to a URL by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure URL redirection (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in the Redirect URL text box, type the URL (for example, `http://www.newdomain.com/mysite/maintenance`), and then click OK.
4. Verify that the redirect URL you configured for the server appears in the Details section at the bottom of the pane.

Configuring Backup Virtual Servers

If the primary virtual server is down or disabled, the appliance can direct the connections or client requests to a backup virtual server that forwards the client traffic to the services. The appliance can also send a notification message to the client regarding the site outage or maintenance. The backup virtual server is a proxy and is transparent to the client.

You can configure a backup virtual server when you create a virtual server or when you change the optional parameters of an existing virtual server. You can also configure a backup virtual server for an existing backup virtual server, thus creating a cascaded backup virtual server. The maximum depth of cascading backup virtual servers is 10. The appliance searches for a backup virtual server that is up and accesses that virtual server to deliver the content.

You can configure URL redirection on the primary for use when the primary and the backup virtual servers are down or have reached their thresholds for handling requests.

Note: If no backup virtual server exists, an error message appears, unless the virtual server is configured with a redirect URL. If both a backup virtual server and a redirect URL are configured, the backup virtual server takes precedence.

To configure a backup virtual server by using the command line interface

At the command prompt, type the following commands to configure a backup server and verify the configuration:

- set lb vserver <name> [-backupVserver <string>]
- show lb vserver <name>

Example

```
> set lb vserver vserver-LB-1 -backupVserver vserver-LB-2
 Done
> show lb vserver vserver-LB-1
    vserver-LB-1 (10.102.29.60:80) - HTTP   Type: ADDRESS
    State: DOWN
    Last state change was at Wed Jun 17 08:56:34 2009 (+661 ms)
    .
    .
    .
    Backup: vserver-LB-2
    .
    .
    .
 Done
>
```

To set up a backup virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the backup virtual server (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in the Backup Virtual Server list, select the backup virtual server (for example, vserver-LB-2, and then click OK.
4. Verify that the backup virtual server you configured appears in the Details section at the bottom of the pane.

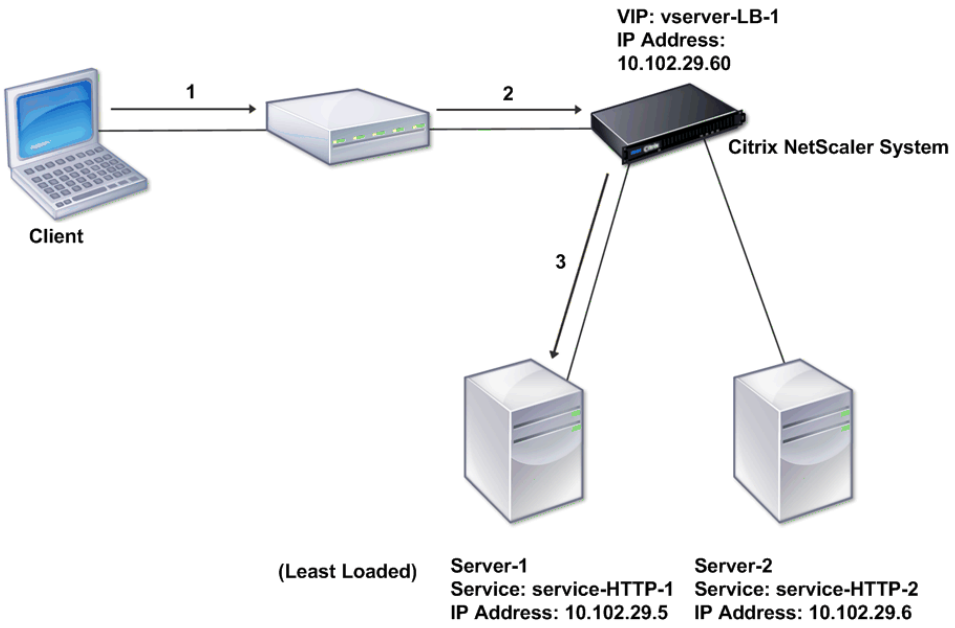
   Note: If the primary server goes down and then comes back up, and you want the backup virtual server to function as the primary server until you explicitly reestablish the primary virtual server, select the Disable Primary When Down check box.

A Typical Load Balancing Scenario

In a load balancing setup, the NetScaler appliances are logically located between the client and the server farm, and they manage traffic flow to the servers.

The following figure shows the topology of a basic load balancing configuration.

Figure 1. Basic Load Balancing Topology



The virtual server selects the service and assigns it to serve client requests. Consider the scenario in the preceding figure, where the services service-HTTP-1 and service-HTTP-2 are created and bound to the virtual server named virtual server-LB-1. Virtual server-LB-1 forwards the client request to either service-HTTP-1 or service-HTTP-2. The system selects the service for each request by using the Least Connections load balancing method. The following table lists the names and values of the basic entities that must be configured on the system.

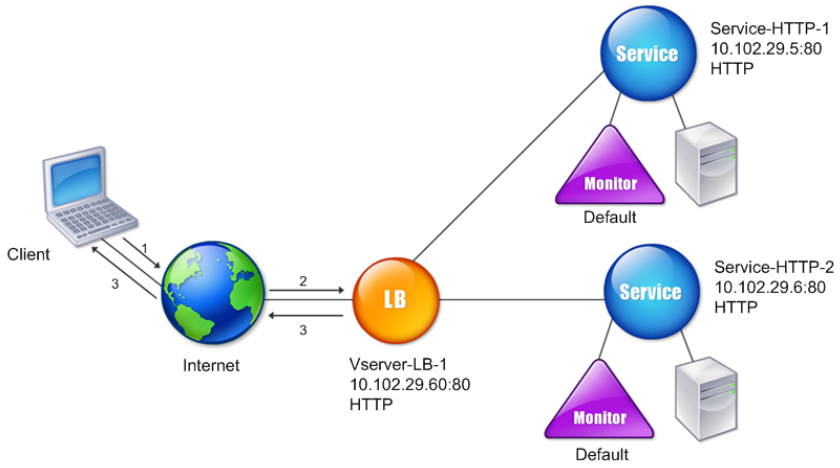
Table 1. LB Configuration Parameter Values

Entity Type	Required parameters and sample values			
	Name	IP Address	Port	Protocol
Virtual Server	vserver-LB-1	10.102.29.60	80	HTTP
Services	service-HTTP-1	10.102.29.5	8083	HTTP
	service-HTTP-2	10.102.29.6	80	HTTP

Monitors	Default	None	None	None

The following figure shows the load balancing sample values and required parameters that are described in the preceding table.

Figure 2. Load Balancing Entity Model



The following tables list the commands used to configure this load balancing setup by using the command line interface.

Table 2. Initial Configuration Tasks

Task	Command
To enable load balancing	enable feature lb
To create a service named service-HTTP-1	add service service-HTTP-1 10.102.29.5 HTTP 80
To create a service named service-HTTP-2	add service service-HTTP-2 10.102.29.6 HTTP 80
To create a virtual server named vserver-LB-1	add lb vserver vserver-LB-1 HTTP 10.102.29.60 80
To bind a service named service-HTTP-1 to a virtual server named vserver-LB-1	bind lb vserver vserver-LB-1 service-HTTP-1
To bind a service named service-HTTP-2 to a virtual server named vserver-LB-1	bind lb vserver vserver-LB-1 service-HTTP-2

For more information about the initial configuration tasks, see "Enabling Load Balancing" and "Configuring Services and a Vserver."

Table 3. Verification Tasks

Task	Command
To view the properties of a virtual server named vserver-LB-1	show lb vserver vserver-LB-1
To view the statistics of a virtual server named vserver-LB-1	stat lb vserver vserver-LB-1
To view the properties of a service named service-HTTP-1	show service service-HTTP-1
To view the statistics of a service named service-HTTP-1	stat service service-HTTP-1
To view the bindings of a service named service-HTTP-1	show service bindings service-HTTP-1

Table 4. Customization Tasks

Task	Command
To configure persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType SOURCEIP -persistenceMask 255.255.255.255 -timeout 2
To configure COOKIEINSERT persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType COOKIEINSERT
To configure URLPassive persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType URLPASSIVE
To configure a virtual server to redirect the client request to a URL on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -redirectURL http://www.newdomain.com/mysite/maintenance
To set a backup virtual server on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -backupVserver vserver-LB-2

For more information about configuring persistence, see "Choosing and Configuring Persistence Settings." For information about configuring a virtual server to redirect a client request to a URL and setting up a backup virtual server, see "Configuring Features to Protect the Load Balancing Configuration."

Accelerating Load Balanced Traffic by Using Compression

Compression is a popular means of optimizing bandwidth usage, and most web browsers support compressed data. If you enable the compression feature, the NetScaler appliance intercepts requests from clients and determines whether the client can accept compressed content. After receiving the HTTP response from the server, the appliance examines the content to determine whether it is compressible. If the content is compressible, the appliance compresses it, modifies the response header to indicate the type of compression performed, and forwards the compressed content to the client.

NetScaler compression is a policy-based feature. A policy filters requests and responses to identify responses to be compressed, and specifies the type of compression to apply to each response. The appliance provides several built-in policies to compress common MIME types such as text/html, text/plain, text/xml, text/css, text/rtf, application/msword, application/vnd.ms-excel, and application/vnd.ms-powerpoint. You can also create custom policies. The appliance does not compress compressed MIME types such as application/octet-stream, binary, bytes, and compressed image formats such as GIF and JPEG.

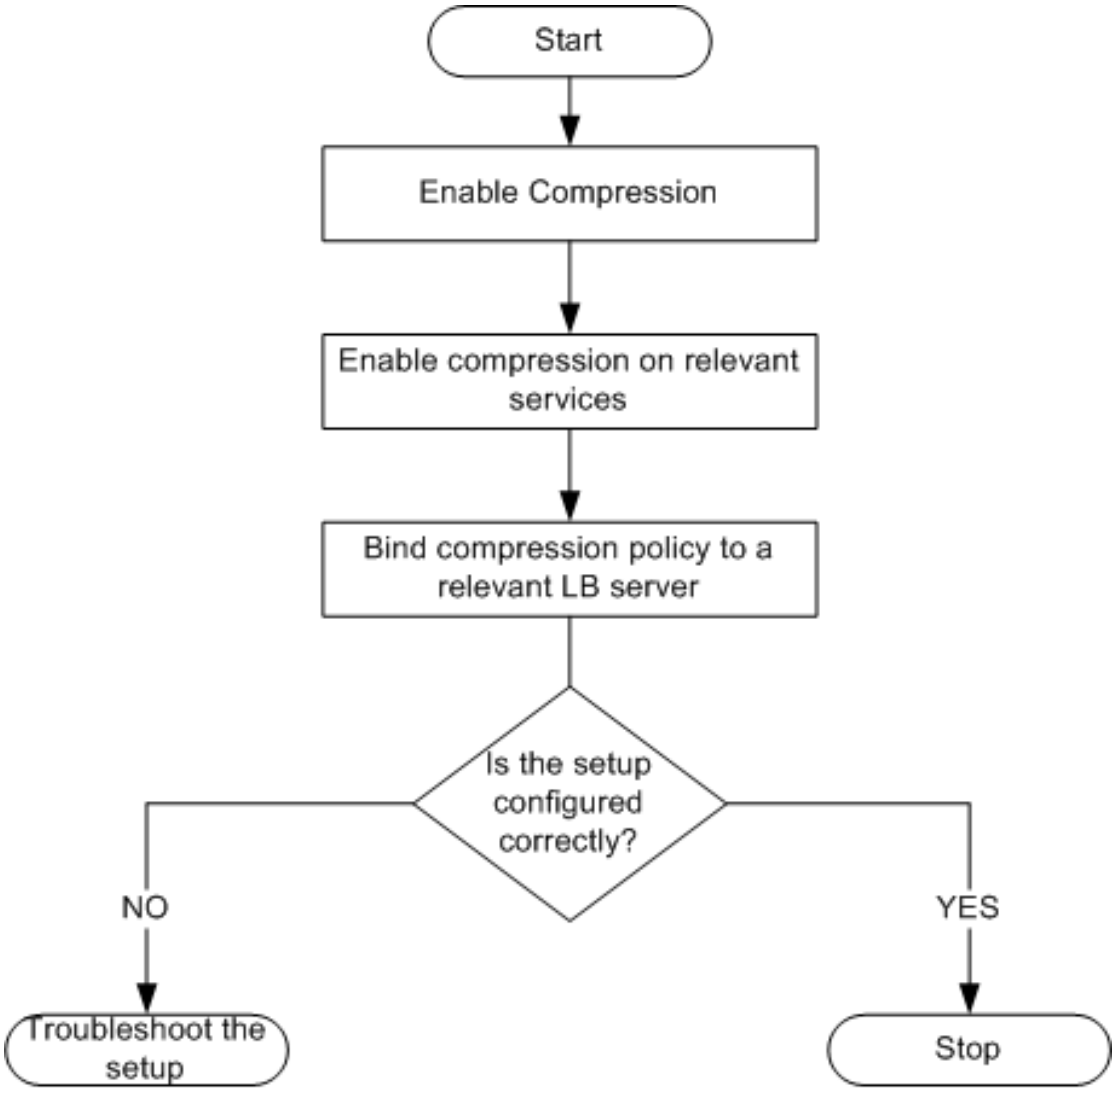
To configure compression, you must enable it globally and on each service that will provide responses that you want compressed. If you have configured virtual servers for load balancing or content switching, you should bind the polices to the virtual servers. Otherwise, the policies apply to all traffic that passes through the appliance.

Note: For more information about compression, see "Compression."

Compression Configuration Task Sequence

The following flow chart shows the sequence of tasks for configuring basic compression in a load balancing setup.

Figure 1. Sequence of Tasks to Configure Compression



Note: The steps in the above figure assume that load balancing has already been configured. For information about configuring load balancing, or for more information about services, see "Load Balancing."

If you want to configure something other than a basic compression setup, (for example, if you need to configure optional parameters in addition to the required parameters) see "Compression."

Enabling Compression

By default, compression is not enabled. You must enable the compression feature to allow compression of HTTP responses that are sent to the client.

To enable compression by using the command line interface

At the command prompt, type the following commands to enable compression and verify the configuration:

- `enable ns feature CMP`
- `show ns feature`

Example

```
> enable ns feature CMP
Done
> show ns feature

     Feature                Acronym          Status
     -------                -------          ------
1)   Web Logging             WL               ON
2)   Surge Protection        SP               OFF
.
7)   Compression Control     CMP              ON
8)   Priority Queuing        PQ               OFF
.
Done
```

To enable compression by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Compression check box, and then click OK.
4. In the Enable/Disable Feature(s)? dialog box, click Yes.

Configuring Services to Compress Data

In addition to enabling compression globally, you must enable it on each service that will deliver files to be compressed. To create a service, see "Configuring Services."

To enable compression on a service by using the command line

At the command prompt, type the following commands to enable compression on a service and verify the configuration:

- set service <name> -CMP YES
- show service <name>

Example

```
> show service SVC_HTTP1
SVC_HTTP1 (10.102.29.18:80) - HTTP
State: UP
Last state change was at Tue Jun 16 06:19:14 2009 (+737 ms)
Time since last state change: 0 days, 03:03:37.200
Server Name: 10.102.29.18
Server ID : 0   Monitor Threshold : 0
Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive(CKA): NO
Access Down Service: NO
TCP Buffering(TCPB): NO
HTTP Compression(CMP): YES
Idle timeout: Client: 180 sec   Server: 360 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: OFF
Down state flush: ENABLED

1)      Monitor Name: tcp-default
State: DOWN     Weight: 1
Probes: 1095    Failed [Total: 1095 Current: 1095]
Last response: Failure - TCP syn sent, reset received.
Response Time: N/A
Done
```

To enable compression on a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, select the service for which you want to configure compression (for example, service-HTTP-1), and then click Open.
3. On the Advanced tab, under Settings, select the Compression check box, and then click OK.
4. Verify that, when the service is selected, `HTTP Compression(CMP): ON` appears in the **Details** section at the bottom of the pane.

Binding a Compression Policy to a Virtual Server

If you bind a policy to a virtual server, the policy is evaluated only by the services associated with that virtual server. You can bind compression policies to a virtual server either from the Configure Virtual Server (Load Balancing) dialog box or from the Compression Policy Manager dialog box. This topic includes instructions to bind compression policies to a load balancing virtual server by using the Configure Virtual Server (Load Balancing) dialog box. For information about how you can bind a compression policy to a load balancing virtual server by using the Compression Policy Manager dialog box, see "Configuring and Binding Policies with the Policy Manager."

To bind or unbind a compression policy to a virtual server by using the command line

At the command prompt, type the following commands to bind or unbind a compression policy to a load balancing virtual server and verify the configuration:

- `(bind|unbind) lb vserver <name> -policyName <string>`
- `show lb vserver <name>`

Example

```
> bind lb vserver lbvip -policyName ns_cmp_msapp
Done
> show lb vserver lbvip
lbvip (8.7.6.6:80) - HTTP       Type: ADDRESS
State: UP
Last state change was at Thu May 28 05:37:21 2009 (+685 ms)
Time since last state change: 19 days, 04:26:50.470
Effective State: UP
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Port Rewrite : DISABLED
No. of Bound Services :  1 (Total)      1 (Active)
Configured Method: LEASTCONNECTION
Current Method: Round Robin, Reason: Bound service's state changed to UP
Mode: IP
Persistence: NONE
Vserver IP and Port insertion: OFF
Push: DISABLED  Push VServer:
Push Multi Clients: NO
Push Label Rule:
```

Bound Service Groups:
1) Group Name: Service-Group-1

1) Service-Group-1 (10.102.29.252: 80) - HTTP State: UP Weight: 1

1) Policy : ns_cmp_msapp Priority:0
Done

To bind or unbind a compression policy to a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server to which you want to bind or unbind a compression policy (for example, Vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Policies tab, click Compression.
4. Do one of the following:
   - To bind a compression policy, click Insert Policy, and then select the policy you want to bind to the virtual server.
   - To unbind a compression policy, click the name of the policy you want to unbind from the virtual server, and then click Unbind Policy.
5. Click OK.

Securing Load Balanced Traffic by Using SSL

The Citrix NetScaler SSL offload feature transparently improves the performance of web sites that conduct SSL transactions. By offloading CPU-intensive SSL encryption and decryption tasks from the local web server to the appliance, SSL offloading ensures secure delivery of web applications without the performance penalty incurred when the server processes the SSL data. Once the SSL traffic is decrypted, it can be processed by all standard services. The SSL protocol works seamlessly with various types of HTTP and TCP data and provides a secure channel for transactions using such data.

To configure SSL, you must first enable it. Then, you configure HTTP or TCP services and an SSL virtual server on the appliance, and bind the services to the virtual server. You must also add a certificate-key pair and bind it to the SSL virtual server. If you use Outlook Web Access servers, you must create an action to enable SSL support and a policy to apply the action. An SSL virtual server intercepts incoming encrypted traffic and decrypts it by using a negotiated algorithm. The SSL virtual server then forwards the decrypted data to the other entities on the appliance for appropriate processing.

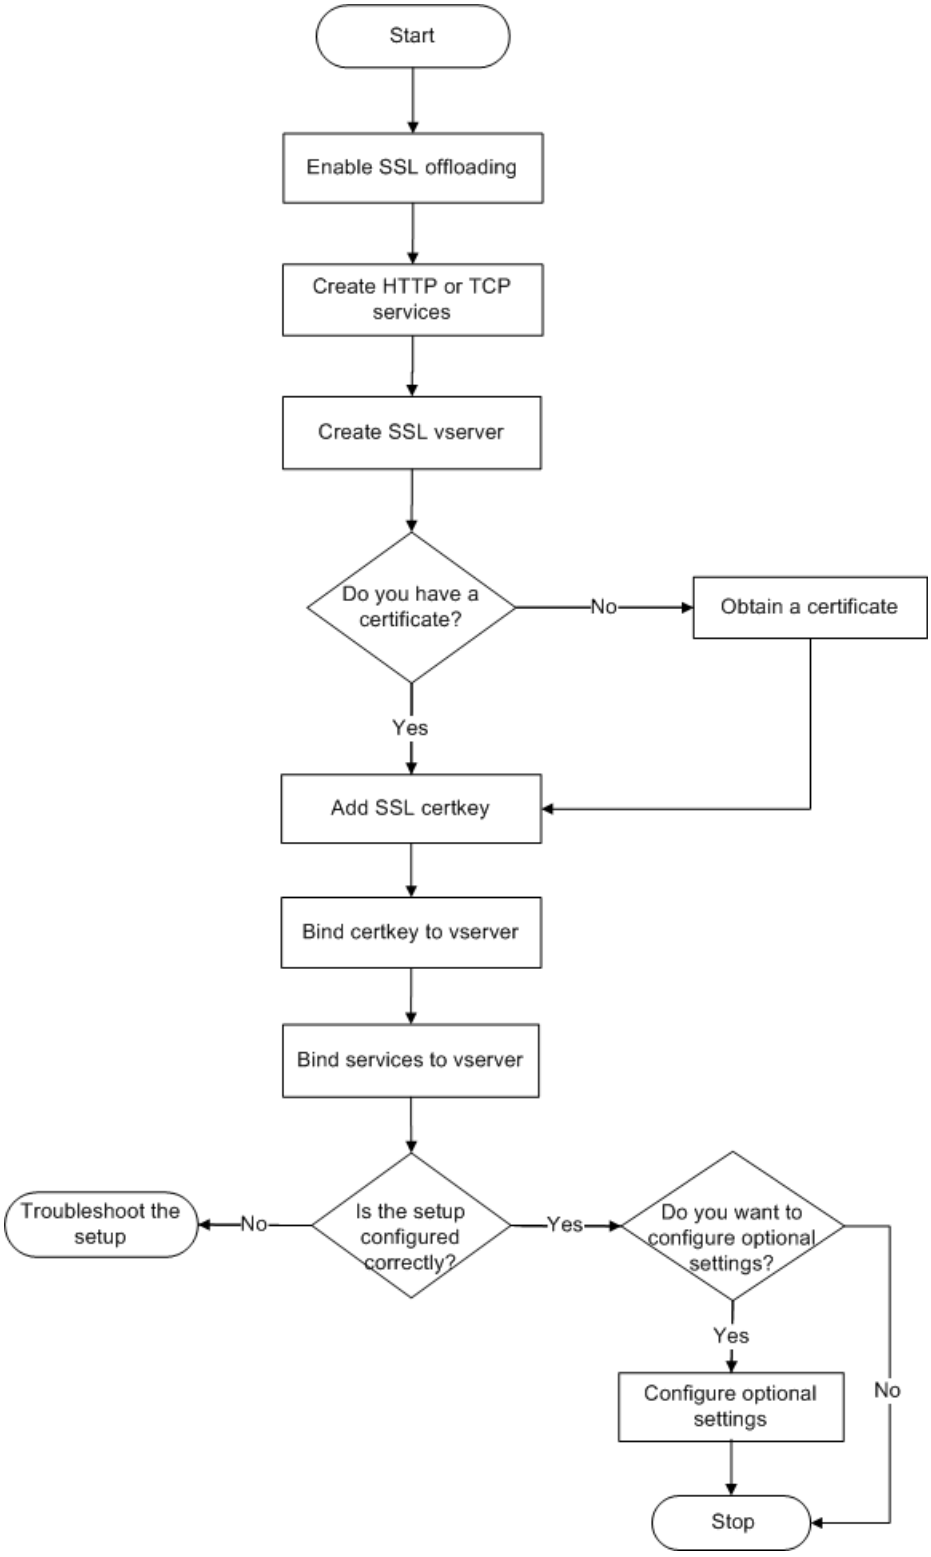
SSL Configuration Task Sequence

To configure SSL, you must first enable it. Then, you must create an SSL virtual server and HTTP or TCP services on the NetScaler. Finally, you must bind a valid SSL certificate and the configured services to the SSL virtual server.

An SSL virtual server intercepts incoming encrypted traffic and decrypts it using a negotiated algorithm. The SSL virtual server then forwards the decrypted data to the other entities on the NetScaler for appropriate processing.

The following flow chart shows the sequence of tasks for configuring a basic SSL offload setup.

Figure 1. Sequence of Tasks to Configure SSL Offloading



Start
Enable SSL offloading
Create HTTP or TCP services
Create SSL vserver
Do you have a certificate?
No
Obtain a certificate
Yes
Add SSL certkey
Bind certkey to vserver
Bind services to vserver
Troubleshoot the setup
No
Is the setup configured correctly?
Yes
Do you want to configure optional settings?
Yes
Configure optional settings
No
Stop

Enabling SSL Offload

You should enable the SSL feature before configuring SSL offload. You can configure SSL-based entities on the appliance without enabling the SSL feature, but they will not work until you enable SSL.

To enable SSL by using the command line interface

At the command prompt, type the following commands to enable SSL Offload and verify the configuration:

- `enable ns feature SSL`
- `show ns feature`

Example

```
> enable ns feature ssl
Done
> show ns feature
Feature Acronym Status
------- ------- ------
1) Web Logging WL ON
2) SurgeProtection SP OFF
3) Load Balancing LB ON . . .
 9) SSL Offloading SSL ON
10) Global Server Load Balancing GSLB ON . .
Done >
```

To enable SSL by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. Select the SSL Offloading check box, and then click OK.
4. In the Enable/Disable Feature(s)? message box, click Yes.

Creating HTTP Services

A service on the appliance represents an application on a server. Once configured, services are in the disabled state until the appliance can reach the server on the network and monitor its status. This topic covers the steps to create an HTTP service.

Note: For TCP traffic, perform the procedures in this and the following topics, but create TCP services instead of HTTP services.

To add an HTTP service by using the command line interface

At the command prompt, type the following commands to add a HTTP service and verify the configuration:

- `add service <name> (<IP> | <serverName>) <serviceType> <port>`
- `show service <name>`

```
> add service SVC_HTTP1 10.102.29.18 HTTP 80
 Done
> show service SVC_HTTP1
        SVC_HTTP1 (10.102.29.18:80) - HTTP
        State: UP
        Last state change was at Wed Jul 15 06:13:05 2009
        Time since last state change: 0 days, 00:00:15.350
        Server Name: 10.102.29.18
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): NO
        HTTP Compression(CMP): YES
        Idle timeout: Client: 180 sec   Server: 360 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED

1)      Monitor Name: tcp-default
              State: UP       Weight: 1
              Probes: 4       Failed [Total: 0 Current: 0]
              Last response: Success - TCP syn+ack received.
              Response Time: N/A
 Done
```

To add an HTTP service by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Services.
2. In details pane, click Add.
3. In the Create Service dialog box, in the Service Name, Server, and Port text boxes, type the name of the service, IP address, and port (for example, `SVC_HTTP1`, `10.102.29.18`, and `80`).
4. In the Protocol list, select the type of the service (for example, `HTTP`).
5. Click Create, and then click Close. The HTTP service you configured appears in the Services page.
6. Verify that the parameters you configured are correctly configured by selecting the service and viewing the Details section at the bottom of the pane.

For more information about services, see "Configuring Services."

Adding an SSL-Based Virtual Server

In a basic SSL offloading setup, the SSL virtual server intercepts encrypted traffic, decrypts it, and sends the clear text messages to the services that are bound to the virtual server. Offloading CPU-intensive SSL processing to the appliance allows the back-end servers to process a greater number of requests.

To add an SSL-based virtual server by using the command line interface

At the command prompt, type the following commands to create an SSL-based virtual server and verify the configuration:

- `add lb vserver <name> <serviceType> [<IPAddress> <port>]`
- `show lb vserver <name>`

Example

```
> add lb vserver vserver-SSL-1 SSL 10.102.29.50 443
Done
> show lb vserver vserver-SSL-1
vserver-SSL-1 (10.102.29.50:443) - SSL Type: ADDRESS
State: DOWN[Certkey not bound] Last state change was at Tue Jun 16 06:33:08 2009 (+176 ms)
Time since last state change: 0 days, 00:03:44.120
Effective State: DOWN Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
No. of Bound Services : 0 (Total) 0 (Active)
Configured Method: LEASTCONNECTION Mode: IP
Persistence: NONE
Vserver IP and Port insertion: OFF
Push: DISABLED Push VServer: Push Multi Clients: NO Push Label Rule: Done
```

Caution: To ensure secure connections, you must bind a valid SSL certificate to the SSL-based virtual server before you enable it.

To add an SSL-based virtual server by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (SSL Offload) dialog box, in the Name, IP Address, and Port text boxes, type the name of the virtual server, IP address, and port (for example, `Vserver-SSL-1`, `10.102.29.50`, and `443`).
4. In the Protocol list, select the type of the virtual server, for example, SSL.
5. Click Create, and then click Close.
6. Verify that the parameters you configured are correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane. The virtual server is marked as DOWN because a certificate-key pair and services have not been bound to it.

Caution: To ensure secure connections, you must bind a valid SSL certificate to the SSL-based virtual server before you enable it.

Binding Services to the SSL Virtual Server

After decrypting the incoming data, the SSL virtual server forwards the data to the services that you have bound to the virtual server.

Data transfer between the appliance and the servers can be encrypted or in clear text. If the data transfer between the appliance and the servers is encrypted, the entire transaction is secure from end to end. For more information about configuring the system for end-to-end security, see "SSL Offload and Acceleration."

To bind a service to a virtual server by using the command line interface

At the command prompt, type the following commands to bind service to the SSL virtual server and verify the configuration:

- `bind lb vserver <name> <serviceName>`
- `show lb vserver <name>`

Example

```
> bind lb vserver vserver-SSL-1 SVC_HTTP1
Done
> show lb vserver vserver-SSL-1 vserver-SSL-1 (10.102.29.50:443) - SSL Type:
ADDRESS State: DOWN[Certkey not bound]
Last state change was at Tue Jun 16 06:33:08 2009 (+174 ms)
Time since last state change: 0 days, 00:31:53.70
Effective State: DOWN Client Idle
Timeout: 180 sec
Down state flush: ENABLED Disable Primary Vserver On Down :
DISABLED No. of Bound Services : 1 (Total) 0 (Active)
Configured Method: LEASTCONNECTION Mode: IP Persistence: NONE Vserver IP and
Port insertion: OFF Push: DISABLED Push VServer: Push Multi Clients: NO Push Label Rule:

1) SVC_HTTP1 (10.102.29.18: 80) - HTTP
State: DOWN Weight: 1
Done
```

To bind a service to a virtual server by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.
2. In the details pane, select a virtual server, and then click Open.
3. On the Services tab, in the Active column, select the check boxes next to the services that you want to bind to the selected virtual server.
4. Click OK.
5. Verify that the Number of Bound Services counter in the Details section at the bottom of the pane is incremented by the number of services that you bound to the virtual server.

Adding a Certificate Key Pair

An SSL certificate is an integral element of the SSL Key-Exchange and encryption/decryption process. The certificate is used during SSL handshake to establish the identity of the SSL server. You can use a valid, existing SSL certificate that you have on the NetScaler appliance, or you can create your own SSL certificate. The appliance supports RSA/DSA certificates of up to 4096 bits.

Note: Citrix recommends that you use a valid SSL certificate that has been issued by a trusted certificate authority. Invalid certificates and self-created certificates are not compatible with all SSL clients.

Before a certificate can be used for SSL processing, you must pair it with its corresponding key. The certificate key pair is then bound to the virtual server and used for SSL processing.

To add a certificate key pair by using the command line interface

At the command prompt, type the following commands to create a certificate key pair and verify the configuration:

- add ssl certKey <certkeyName> -cert <string> [-key <string>]
- show sslcertkey <name>

Example

```
> add ssl certKey CertKey-SSL-1 -cert ns-root.cert -key ns-root.key
 Done
> show sslcertkey CertKey-SSL-1
   Name: CertKey-SSL-1 Status: Valid,
   Days to expiration:4811 Version: 3
   Serial Number: 00 Signature Algorithm: md5WithRSAEncryption Issuer: C=US,ST=California,L=San
   Jose,O=Citrix ANG,OU=NS Internal,CN=de fault
   Validity Not Before: Oct 6 06:52:07 2006 GMT Not After : Aug 17 21:26:47 2022 GMT
   Subject: C=US,ST=California,L=San Jose,O=Citrix ANG,OU=NS Internal,CN=d efault Public Key
   Algorithm: rsaEncryption Public Key
   size: 1024
 Done
```

To add a certificate key pair by using the configuration utility

1. In the navigation pane, expand SSL, and then click Certificates.
2. In the details pane, click Add.
3. In the Install Certificate dialog box, in the Certificate-Key Pair Name text box, type a name for the certificate key pair you want to add, for example, `Certkey-SSL-1`.
4. Under Details, in Certificate File Name, click Browse (Appliance) to locate the certificate. Both the certificate and the key are stored in the /nsconfig/ssl/ folder on the appliance. To use a certificate present on the local system, select Local.
5. Select the certificate you want to use, and then click Select.
6. In Private Key File Name, click Browse (Appliance) to locate the private key file. To use a private key present on the local system, select Local.
7. Select the key you want to use and click Select. To encrypt the key used in the certificate key pair, type the password to be used for encryption in the Password text box.
8. Click Install.
9. Double-click the certificate key pair and, in the Certificate Details window, verify that the parameters have been configured correctly and saved.

Binding an SSL Certificate Key Pair to the Virtual Server

After you have paired an SSL certificate with its corresponding key, you must bind the certificate key pair to the SSL virtual server so that it can be used for SSL processing. Secure sessions require establishing a connection between the client computer and an SSL-based virtual server on the appliance. SSL processing is then carried out on the incoming traffic at the virtual server. Therefore, before enabling the SSL virtual server on the appliance, you need to bind a valid SSL certificate to the SSL virtual server.

To bind an SSL certificate key pair to a virtual server by using the command line interface

At the command prompt, type the following commands to bind an SSL certificate key pair to a virtual server and verify the configuration:

- bind ssl vserver <vServerName> -certkeyName <string>
- show ssl vserver <name>

Example

```
 > bind ssl vserver Vserver-SSL-1 -certkeyName CertKey-SSL-1
Done
> show ssl vserver Vserver-SSL-1

    Advanced SSL configuration for VServer Vserver-SSL-1:
    DH: DISABLED
    Ephemeral RSA: ENABLED Refresh Count: 0
    Session Reuse: ENABLED Timeout: 120 seconds
    Cipher Redirect: ENABLED
    SSLv2 Redirect: ENABLED
    ClearText Port: 0
    Client Auth: DISABLED
    SSL Redirect: DISABLED
    Non FIPS Ciphers: DISABLED
    SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: CertKey-SSL-1 Server Certificate
1) Cipher Name: DEFAULT
  Description: Predefined Cipher Alias
Done
```

To bind an SSL certificate key pair to a virtual server by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.
2. Select the virtual server to which you want to bind the certificate key pair, for example, Vserver-SSL-1, and click Open.
3. In the Configure Virtual Server (SSL Offload) dialog box, on the SSL Settings tab, under Available, select the certificate key pair that you want to bind to the virtual server (for example, Certkey-SSL-1), and then click Add.
4. Click OK.
5. Verify that the certificate key pair that you selected appears in the Configured area.

Configuring Support for Outlook Web Access

If you use Outlook Web Access (OWA) servers on your NetScaler appliance, you must configure the appliance to insert a special header field, FRONT-END-HTTPS: ON, in HTTP requests directed to the OWA servers, so that the servers generate URL links as https:// instead of http://.

Note: You can enable OWA support for HTTP-based SSL virtual servers and services only. You cannot apply it for TCP-based SSL virtual servers and services.

To configure OWA support, do the following:

- Create an SSL action to enable OWA support.
- Create an SSL policy.
- Bind the policy to the SSL virtual server.

Creating an SSL Action to Enable OWA Support

Before you can enable Outlook Web Access (OWA) support, you must create an SSL action. SSL actions are bound to SSL policies and triggered when incoming data matches the rule specified by the policy.

To create an SSL action to enable OWA support by using the command line interface

At the command prompt, type the following commands to create an SSL action to enable OWA support and verify the configuration:

- add ssl action <name> -OWASupport ENABLED
- show SSL action <name>

```
 > add ssl action Action-SSL-OWA -OWASupport enabled
Done
> show SSL action Action-SSL-OWA
  Name: Action-SSL-OWA
  Data Insertion Action: OWA
  Support: ENABLED
Done
```

To create an SSL action to enable OWA support by using the configuration utility

1. In the navigation pane, expand SSL, and then click Policies.
2. In the details pane, on the Actions tab, click Add.
3. In the Create SSL Action dialog box, in the Name text box, type `Action-SSL-OWA`.
4. Under Outlook Web Access, select Enabled.
5. Click Create, and then click Close.
6. Verify that Action-SSL-OWA appears in the **SSL Actions** page.

Creating SSL Policies

SSL policies are created by using the policy infrastructure. Each SSL policy has an SSL action bound to it, and the action is carried out when incoming traffic matches the rule that has been configured in the policy.

To create an SSL policy by using the command line interface

At the command prompt, type the following commands to configure an SSL policy and verify the configuration:

- add ssl policy <name> -rule <expression> -reqAction <string>
- show ssl policy <name>

Example

```
> add ssl policy Policy-SSL-1 -rule ns_true -reqaction Action-SSL-OWA
Done
> show ssl policy Policy-SSL-1
Name: Policy-SSL-1      Rule: ns_true
Action: Action-SSL-OWA  Hits: 0
Policy is bound to following entities
1)      PRIORITY : 0
Done
```

To create an SSL policy by using the configuration utility

1. In the navigation pane, expand SSL, and then click Policies.
2. In the details pane, click Add.
3. In the Create SSL Policy dialog box, in the Name text box, type the name of the SSL Policy (for example, `Policy-SSL-1`).
4. In Request Action, select the configured SSL action that you want to associate with this policy (for example, Action-SSL-OWA). The `ns_true` general expression applies the policy to all successful SSL handshake traffic. However, if you need to filter specific responses, you can create policies with a higher level of detail. For more information about configuring granular policy expressions, see "Understanding Policies and Expressions."
5. In Named Expressions, choose the built-in general expression `ns_true` and click Add Expression. The expression `ns_true` now appears in the Expression text box.
6. Click Create, and then click Close.
7. Verify that the policy is correctly configured by selecting the policy and viewing the Details section at the bottom of the pane.

Binding the SSL Policy to an SSL Virtual Server

After you configure an SSL policy for Outlook Web Access, bind the policy to a virtual server that will intercept incoming Outlook traffic. If the incoming data matches any of the rules configured in the SSL policy, the policy is triggered and the action associated with it is carried out.

To bind an SSL policy to an SSL virtual server by using the command line interface

At the command prompt, type the following commands to bind an SSL policy to an SSL virtual server and verify the configuration:

- bind ssl vserver <vServerName> -policyName <string>
- show ssl vserver <name>

Example

```
> bind ssl vserver Vserver-SSL-1 -policyName Policy-SSL-1
 Done
> show ssl vserver Vserver-SSL-1
        Advanced SSL configuration for VServer Vserver-SSL-1:
        DH: DISABLED
        Ephemeral RSA: ENABLED          Refresh Count: 0
        Session Reuse: ENABLED          Timeout: 120 seconds
        Cipher Redirect: ENABLED
        SSLv2 Redirect: ENABLED
        ClearText Port: 0
        Client Auth: DISABLED
        SSL Redirect: DISABLED
        Non FIPS Ciphers: DISABLED
        SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1)      CertKey Name: CertKey-SSL-1 Server Certificate

1)      Policy Name: Policy-SSL-1
                        Priority: 0
1)      Cipher Name: DEFAULT
        Description: Predefined Cipher Alias
 Done
>
```

To bind an SSL policy to an SSL virtual server by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.
2. In the details pane, select the virtual server (for example, Vserver-SSL-1), and then click Open.
3. In the Configure Virtual Server (SSL Offload) dialog box, click Insert Policy, and then select the policy that you want to bind to the SSL virtual server. Optionally, you can double-click the Priority field and type a new priority level.
4. Click OK.

Features at a Glance

Citrix NetScaler features can be configured independently or in combinations to address specific needs. Although some features fit more than one category, the numerous NetScaler features can generally be categorized as application switching and traffic management features, application acceleration features, and application security and firewall features, and an application visibility feature.

To understand the order in which the features perform their processing, see "Processing Order of Features."

Application Switching and Traffic Management Features

SSL Offloading

Transparently offloads SSL encryption and decryption from web servers, freeing server resources to service content requests. SSL places a heavy burden on an application's performance and can render many optimization measures ineffective. SSL offload and acceleration allow all the benefits of Citrix Request Switching technology to be applied to SSL traffic, ensuring secure delivery of web applications without degrading end-user performance.

For more information, see "SSL Offload and Acceleration."

Access Control Lists

Compares incoming packets to Access Control Lists (ACLs). If a packet matches an ACL rule, the action specified in the rule is applied to the packet. Otherwise, the default action (ALLOW) is applied and the packet is processed normally. For the appliance to compare incoming packets to the ACLs, you have to apply the ACLs. All ACLs are enabled by default, but you have to apply them in order for the NetScaler to compare incoming packets against them. If an ACL is not required to be a part of the lookup table, but still needs to be retained in the configuration, it should be disabled before the ACLs are applied. A NetScaler does not compare incoming packets to disabled ACLs.

For more information, see "Access Control Lists."

Load Balancing

Load balancing decisions are based on a variety of algorithms, including round robin, least connections, weighted least bandwidth, weighted least packets, minimum response time, and hashing based on URL, domain source IP, or destination IP. Both the TCP and UDP protocols are supported, so the NetScaler can load balance all traffic that uses those protocols as the underlying carrier (for example, HTTP, HTTPS, UDP, DNS, NNTP, and general firewall traffic). In addition, the NetScaler can maintain session persistence based on source IP, cookie, server, group, or SSL session. It allows users to apply custom Extended Content Verification (ECV) to servers, caches, firewalls and other infrastructure devices to ensure that these systems are functioning properly and are providing the right content to users. It can also perform health checks using ping, TCP, or HTTP URL, and the user can create monitors based on Perl scripts. To provide high-scale WAN optimization, the CloudBridge appliances deployed at data centers can be load balanced through NetScaler appliances. The bandwidth and number of concurrent sessions can be improved significantly.

For more information, see "Load Balancing."

Content Switching

Determines the server to which to send the request on the basis of configured content switching policies. Policy rules can be based on the IP address, URL, and HTTP headers.

This allows switching decisions to be based on user and device characteristics such as who the user is, what type of agent is being used, and what content the user requested.

For more information, see "Content Switching."

Global Server Load Balancing (GSLB)

Extends the traffic management capabilities of a NetScaler to include distributed Internet sites and global enterprises. Whether installations are spread across multiple network locations or multiple clusters in a single location, the NetScaler maintains availability and distributes traffic across them. It makes intelligent DNS decisions to prevent users from being sent to a site that is down or overloaded. When the proximity-based GSLB method is enabled, the NetScaler can make load balancing decisions based on the proximity of the client's local DNS server (LDNS) in relation to different sites. The main benefit of the proximity-based GSLB method is faster response time resulting from the selection of the closest available site.

For more information, see "Global Server Load Balancing."

Dynamic Routing

Enables routers to obtain topology information, routes, and IP addresses from neighboring routers automatically. When dynamic routing is enabled, the corresponding routing process listens to route updates and advertises routes. The routing processes can also be placed in passive mode. Routing protocols enable an upstream router to load balance traffic to identical virtual servers hosted on two standalone NetScaler units using the Equal Cost Multipath technique.

For more information, see "Configuring Dynamic Routes."

Link Load Balancing

Load balances multiple WAN links and provides link failover, further optimizing network performance and ensuring business continuity. Ensures that network connections remain highly available, by applying intelligent traffic control and health checks to distribute traffic efficiently across upstream routers. Identifies the best WAN link to route both incoming and outbound traffic based on policies and network conditions, and protects applications against WAN or Internet link failure by providing rapid fault detection and failover.

For more information, see " Link Load Balancing."

TCP Optimization

You can use TCP profiles to optimize TCP traffic. TCP profiles define the way that NetScaler virtual servers process TCP traffic. Administrators can use the built-in TCP profiles or configure custom profiles. After defining a TCP profile, you can bind it to a single virtual server or to multiple virtual servers.

Web Interface on NetScaler

Provides access to XenApp and XenDesktop resources, which include applications, content, and desktops. Users access resources through a standard Web browser or by using the Citrix XenApp plug-in. The Web Interface runs as a service on port 8080 on the NetScaler appliance. To create Web Interface sites, Java is executed on Apache Tomcat Web server version 6.0.26 on the NetScaler appliance.

Note: Web Interface is supported only on NetScaler nCore releases.

For more information, see "Web Interface."

CloudBridge

The Citrix NetScaler CloudBridge feature, a fundamental part of the Citrix OpenCloud framework, is a tool used to build a cloud-extended data center. The OpenCloud Bridge enables you to connect one or more NetScaler appliances or NetScaler virtual appliances on the cloud-to your network without reconfiguring your network. Cloud hosted applications appear as though they are running on one contiguous enterprise network. The primary purpose of the OpenCloud Bridge is to enable companies to move their applications to the cloud while reducing costs and the risk of application failure. In addition, the OpenCloud Bridge increases network security in cloud environments. An OpenCloud Bridge is a Layer-2 network bridge that connects a NetScaler appliance or NetScaler virtual appliance on a cloud instance to a NetScaler appliance or NetScaler virtual appliance on your LAN. The connection is made through a tunnel that uses the Generic Routing Encapsulation (GRE) protocol. The GRE protocol provides a mechanism for encapsulating packets from a wide variety of network protocols to be forwarded over another protocol. Then Internet Protocol security (IPsec) protocol suite is used to secure the communication between the peers in the OpenCloud Bridge.

For more information, see "CloudBridge."

DataStream

The NetScaler DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests on the basis of the SQL query being sent.

When deployed in front of database servers, a NetScaler ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and on the basis of database names, user names, character sets, and packet size.

You can configure load balancing to switch requests according to load balancing algorithms, or you can elaborate the switching criteria by configuring content switching to make a decision based on SQL query parameters, such as user name, database names, and command parameters. You can further configure monitors to track the states of database servers.

The advanced policy infrastructure on the NetScaler appliance includes expressions that you can use to evaluate and process the requests. The advanced expressions evaluate traffic associated with MySQL database servers. You can use request-based expressions (expressions that begin with `MYSQL.CLIENT` and `MYSQL.REQ`) in advanced policies to make request switching decisions at the content switching virtual server bind point and response-based expressions (expressions that begin with `MYSQL.RES`) to evaluate server responses to user-configured health monitors.

Note: DataStream is supported for MySQL and MS SQL databases.

For more information, see "DataStream."

Application Acceleration Features

AppCompress

Uses the gzip compression protocol to provide transparent compression for HTML and text files. The typical 4:1 compression ratio yields up to 50% reduction in bandwidth requirements out of the data center. It also results in significantly improved end-user response time, because it reduces the amount of data that must be delivered to the user's browser.

For more information, see "Compression."

Cache Redirection

Manages the flow of traffic to a reverse proxy, transparent proxy, or forward proxy cache farm. Inspects all requests, and identifies non-cacheable requests and sends them directly to the origin servers over persistent connections. By intelligently redirecting non-cacheable requests back to the origin web servers, the NetScaler appliance frees cache resources and increases cache hit rates while reducing overall bandwidth consumption and response delays for these requests.

For more information, see "Cache Redirection."

AppCache

Helps optimize web content and application data delivery by providing a fast in-memory HTTP/1.1 and HTTP/1.0 compliant web caching for both static and dynamic content. This on-board cache stores the results of incoming application requests even when an incoming request is secured or the data compressed, and then reuses the data to fulfill subsequent requests for the same information. By serving data directly from the on-board cache, the appliance can reduce page regeneration times by eliminating the need to funnel static and dynamic content requests to the server.

For more information, see "Integrated Caching."

TCP Buffering

Buffers the server's response and delivers it to the client at the client's speed, thus offloading the server faster and thereby improving the performance of web sites.

For more information, see "TCP Buffering."

Application Security and Firewall Features

Denial of Service Attack (DoS) Defense

Detects and stops malicious distributed denial-of-service (DDoS) attacks and other types of malicious attacks before they reach your servers, preventing them from affecting network and application performance. The NetScaler appliance identifies legitimate clients and elevates their priority, leaving suspect clients unable to consume a disproportionate percentage of resources and cripple your site. The appliance provides application-level protection from the following types of malicious attacks:

- SYN flood attacks
- Pipeline attacks
- Teardrop attacks
- Land attacks
- Fraggle attacks
- Zombie connection attacks

The appliance aggressively defends against these types of attacks by preventing the allocation of server resources for these connections. This insulates servers from the overwhelming flood of packets associated with these events.

The appliance also protects network resources from ICMP based attacks by using ICMP rate limiting and aggressive ICMP packet inspection. It performs strong IP reassembly, drops a variety of suspicious and malformed packets, and applies Access Control Lists (ACLs) to site traffic for further protection.

For more information, see "HTTP Denial-of-Service Protection."

Content Filtering

Provides protection from malicious attacks for web sites at the Layer 7 level. The appliance inspects each incoming request according to user-configured rules based on HTTP headers, and performs the action the user configured. Actions can include resetting the connection, dropping the request, or sending an error message to the user's browser. This allows the appliance to screen unwanted requests and reduces your servers' exposure to attacks.

This feature can also analyze HTTP GET and POST requests and filter out known bad signatures, allowing it to defend your servers against HTTP-based attacks.

For more information, see "Content Filtering."

Responder

Functions like an advanced filter and can be used to generate responses from the appliance to the client. Some common uses of this feature are generation of redirect

responses, user defined responses, and resets.

For more information, see "Responder."

Rewrite

Modifies HTTP headers and body text. You can use the rewrite feature to add HTTP headers to an HTTP request or response, make modifications to individual HTTP headers, or delete HTTP headers. It also enables you to modify the HTTP body in requests and responses.

When the appliance receives a request or sends a response, it checks for rewrite rules, and if applicable rules exist, it applies them to the request or response before passing it on to the web server or client computer.

For more information, see "Rewrite."

Priority Queuing

Prioritizes user requests to ensure that the most important traffic is serviced first during surges in request volume. You can establish priority based on request URLs, cookies, or a variety of other factors. The appliance places requests in a three-tier queue based on their configured priority, enabling business-critical transactions to flow smoothly even during surges or site attacks.

For more information, see "Priority Queuing."

Surge Protection

Regulates the flow of user requests to servers and controls the number of users that can simultaneously access the resources on the servers, queuing any additional requests once your servers have reached their capacity. By controlling the rate at which connections can be established, the appliance blocks surges in requests from being passed on to your servers, thus preventing site overload.

For more information, see "Surge Protection."

Access Gateway

Access Gateway is a secure application access solution that provides administrators granular application-level policy and action controls to secure access to applications and data while allowing users to work from anywhere. It gives IT administrators a single point of control and tools to help ensure compliance with regulations and the highest levels of information security across and outside the enterprise. At the same time, it empowers users with a single point of access—optimized for roles, devices, and networks—to the enterprise applications and data they need. This unique combination of capabilities helps maximize the productivity of today's mobile workforce.

For more information, see "Access Gateway."

Application Firewall

Protects applications from misuse by hackers and malware, such as cross site scripting attacks, buffer overflow attacks, SQL injection attacks, and forceful browsing, by filtering traffic between each protected web server and users that connect to any web site on that web server. The application firewall examines all traffic for evidence of

attacks on web server security or misuse of web server resources, and takes the appropriate action to prevent these attacks from succeeding.

For more information, see "Application Firewall."

Application Visibility Feature

NetScaler Insight Center

NetScaler Insight Center is a high performance collector that provides end-to-end user experience visibility across Web and HDX (ICA) traffic. It collects HTTP and ICA AppFlow records generated by NetScaler ADC appliances and populates analytical reports covering Layer 3 to Layer 7 statistics. NetScaler Insight Center provides in-depth analysis for the last five minutes of real-time data, and for historical data collected for the last one hour, one day, one week, and one month.

HDX (ICA) analytic dashboard enables you to drill down from HDX Users, Applications, Desktops, and even from gateway-level information. Similarly, HTTP analytics provide a bird's eye view of Web Applications, URLs Accessed, Client IP Addresses and Server IP Addresses, and other dashboards. The administrator can drill down and identify the pain points from any of these dashboards, as appropriate for the use case.

EdgeSight for NetScaler

Support for application performance monitoring based on end user experience. This solution leverages the HTML injection feature to obtain various time values, which are used by EdgeSight server for analysis and report generation. EdgeSight for NetScaler provides a way to monitor the performance benefits of a NetScaler and determine potential bottlenecks in a network.

For more information, see "EdgeSight Monitoring for NetScaler."

Enhanced Application Visibility Using AppFlow

The Citrix NetScaler appliance is a central point of control for all application traffic in the data center. It collects flow and user-session level information valuable for application performance monitoring, analytics, and business intelligence applications. AppFlow transmits this information by using the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. IPFIX (the standardized version of Cisco's NetFlow) is widely used to monitor network flow information. AppFlow defines new Information Elements to represent application-level information.

Using UDP as the transport protocol, AppFlow transmits the collected data, called *flow records*, to one or more IPv4 collectors. The collectors aggregate the flow records and generate real-time or historical reports.

AppFlow provides visibility at the transaction level for HTTP, SSL, TCP, and SSL_TCP flows. You can sample and filter the flow types that you want to monitor.

To limit the types of flows to monitor, by sampling and filtering the application traffic, you can enable AppFlow for a virtual server. AppFlow can also provide statistics for the virtual server.

You can also enable AppFlow for a specific service, representing an application server, and monitor the traffic to that application server.

For more information, see "AppFlow."

Stream Analytics

The performance of your web site or application depends on how well you optimize the delivery of the most frequently requested content. Techniques such as caching and compression help accelerate the delivery of services to clients, but you need to be able to identify the resources that are requested most frequently, and then cache or compress those resources. You can identify the most frequently used resources by aggregating real-time statistics about website or application traffic. Statistics such as how frequently a resource is accessed relative to other resources and how much bandwidth is consumed by those resources help you determine whether those resources need to be cached or compressed to improve server performance and network utilization. Statistics such as response times and the number of concurrent connections to the application help you determine whether you must enhance server-side resources.

If the web site or application does not change frequently, you can use products that collect statistical data, and then manually analyze the statistics and optimize the delivery of content. However, if you do not want to perform manual optimizations, or if your web site or application is dynamic in nature, you need infrastructure that can not only collect statistical data but can also automatically optimize the delivery of resources on the basis of the statistics. On the NetScaler appliance, this functionality is provided by the Stream Analytics feature. The feature operates on a single NetScaler appliance and collects run-time statistics on the basis of criteria that you define. When used with NetScaler policies, the feature also provides you with the infrastructure that you need for automatic, real-time traffic optimization.

For more information, see "Stream Analytics."

Optimization

Contents

Optimization

The NetScaler optimization features reduce transaction times between the clients and the servers, and they reduce bandwidth consumption. They also enhance server performance by offloading some tasks and making others more efficient. This collection includes the following topics:

Client keep-alive	Handles multiple requests on a single client connection. The client does not have to negotiate a new connection for each request to the server.
Compression	Compresses HTTP responses sent from the servers to compression-aware browsers. The smaller responses reduce download time and save bandwidth.
Integrated Caching	Stores responses to client requests. Subsequent requests for the same content are served from the NetScaler cache instead of being forwarded to the origin server.
TCP-Buffering	Buffers the server's response and sends it to the client at the client's speed. The server can quickly offload the requested data and then devote its resources to other tasks.
TCP keep-alive	Sends TCP keep-alive probes to check the operational state of the peer.

Client Keep-Alive

The Citrix NetScaler appliance provides features such as client keep-alive to improve the performance of a transaction management environment. Performance of any transaction management environment depends on factors such as bandwidth usage, download time, speed of the server and the client networks, and time consumed to complete a transaction. Client keep-alive improves performance by reducing the time consumed in a transaction. Two other settings that affect connection management include the maximum number of HTTP connections retained in the connection reuse pool and whether or not connection multiplexing is enabled. These variables are configured with HTTP profiles.

Client keep-alive enables multiple client requests to be sent on a single client connection. This feature helps in a transaction management environment where the server closes the client connection after serving the response to the client. The client has to open a new connection for each request to the server leading to a lot of time being consumed for a transaction. The client keep-alive feature of the appliance alleviates this problem by keeping the client-side connection open between the client and the appliance even after the server closes the client connection. This allows multiple client requests to be sent using a single connection. Keeping the client-side connection open saves the packet round trips associated with opening and closing a connection. This is most beneficial to SSL sessions because this eliminates unnecessary termination and open sequences, thus reducing the time taken for a transaction to occur.

Client keep-alive is useful under either of the following conditions:

- When the server does not support client keep-alive.
- When the server supports client keep-alive but an application on the server does not support client keep-alive.

Client keep-alive can be applied to all HTTP services globally, or to a specific service, such as HTTP or SSL. Note that client keep-alive applies only to HTTP and HTTPS services.

The following figure illustrates a typical client keep-alive deployment.

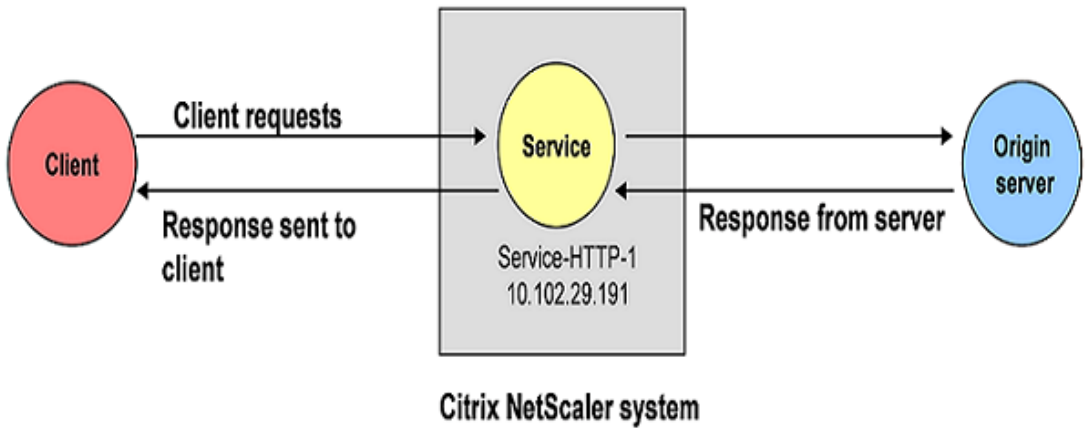

Figure 1. Client Keep-Alive Entity Model

As shown in the figure, to configure client keep-alive, you need to define services and enable client keep-alive for those services. Services represent applications on physical servers. The traffic from the client is intercepted by the configured service and the client request is directed to the origin server. The server sends the response and closes the connection between the server and the appliance. If a “Connection: Close” header is sent, this header is corrupted in the client-side response, and the client-side connection is kept open. As a result, the client does not have to open a new connection for the next request; instead, the connection to the server is reopened.

Note: If a server sends back two “Connection: Close” headers, only one is edited. This results in significant delays on the client rendering of the object because a client does not assume that the object has been delivered completely until the connection is actually closed.

Client Keep-Alive

The Citrix NetScaler appliance provides features such as client keep-alive to improve the performance of a transaction management environment. Performance of any transaction management environment depends on factors such as bandwidth usage, download time, speed of the server and the client networks, and time consumed to complete a transaction. Client keep-alive improves performance by reducing the time consumed in a transaction. Two other settings that affect connection management include the maximum number of HTTP connections retained in the connection reuse pool and whether or not connection multiplexing is enabled. These variables are configured with HTTP profiles.

Client keep-alive enables multiple client requests to be sent on a single client connection. This feature helps in a transaction management environment where the server closes the client connection after serving the response to the client. The client has to open a new connection for each request to the server leading to a lot of time being consumed for a transaction. The client keep-alive feature of the appliance alleviates this problem by keeping the client-side connection open between the client and the appliance even after the server closes the client connection. This allows multiple client requests to be sent using a single connection. Keeping the client-side connection open saves the packet round trips associated with opening and closing a connection. This is most beneficial to SSL sessions because this eliminates unnecessary termination and open sequences, thus reducing the time taken for a transaction to occur.

Client keep-alive is useful under either of the following conditions:

- When the server does not support client keep-alive.
- When the server supports client keep-alive but an application on the server does not support client keep-alive.

Client keep-alive can be applied to all HTTP services globally, or to a specific service, such as HTTP or SSL. Note that client keep-alive applies only to HTTP and HTTPS services.

The following figure illustrates a typical client keep-alive deployment.

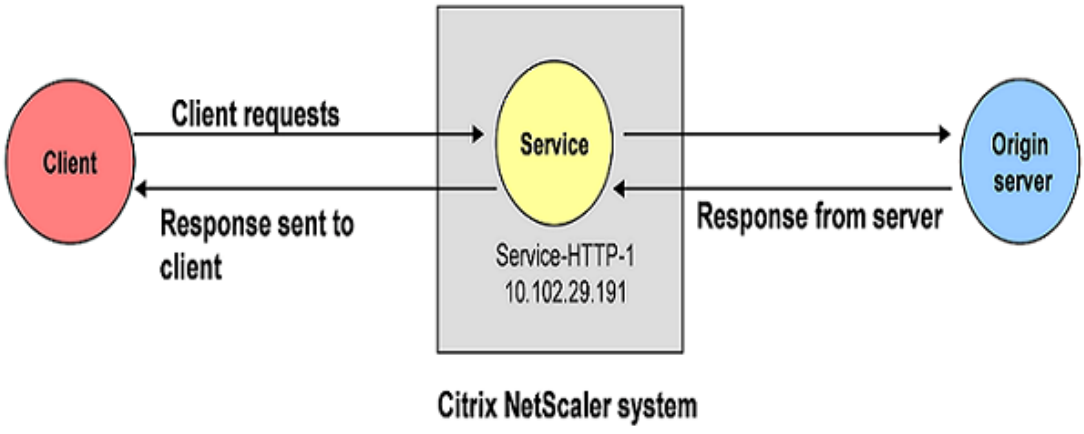

Figure 1. Client Keep-Alive Entity Model

As shown in the figure, to configure client keep-alive, you need to define services and enable client keep-alive for those services. Services represent applications on physical servers. The traffic from the client is intercepted by the configured service and the client request is directed to the origin server. The server sends the response and closes the connection between the server and the appliance. If a “Connection: Close” header is sent, this header is corrupted in the client-side response, and the client-side connection is kept open. As a result, the client does not have to open a new connection for the next request; instead, the connection to the server is reopened.

Note: If a server sends back two “Connection: Close” headers, only one is edited. This results in significant delays on the client rendering of the object because a client does not assume that the object has been delivered completely until the connection is actually closed.

Configuring Client Keep-Alive

To configure the client keep-alive feature, you need to create a service and enable client keep-alive for that service.

The service you configure enables the NetScaler appliance to keep the client-side connection open even after the server has closed the connection between the server and the appliance.

Note that while configuring a service, if the client keep-alive option is not explicitly specified, the service uses the global setting for the client keep-alive connection. For more information, see "Enabling or Disabling Client Keep-Alive Globally."

To create a service with client keep-alive enabled by using the command line interface

At the command prompt, type:

add service (<name> | <IPaddress>) <serviceType> <port> -CKA (YES | NO)

Example

> add service Service-HTTP-1 10.102.29.191 HTTP 80 -CKA YES

To create a service with client keep-alive enabled by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, amongst other service-related configurations, in the Advanced tab, under Settings, select Override Global and then select Client Keep-Alive.
4. Click Create, and then click Close.

Parameter Descriptions (of commands listed in the CLI procedure)

add service

CKA

The state of the Client Keep-Alive feature for the service. Possible values: YES, NO

View description(s) in command reference Top

Enabling or Disabling Client Keep-Alive Globally

The client keep-alive feature is disabled by default. If you enable client keep-alive globally, all new services inherit the global settings by default. The following procedure describes the steps to enable or disable client keep-alive globally.

To enable or disable the client keep-alive mode globally by using the command line interface

At the command prompt, type one of the following commands:

- enable ns mode cka
- disable ns mode cka

To enable or disable the client keep-alive mode globally by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In the Configure Modes dialog box, select or clear the Client Keep-Alive check box.
4. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ns mode

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

disable ns mode

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Enabling or Disabling Client Keep-Alive for a Service

You can enable or disable client keep-alive at the service level. Note that the service level settings take precedence over the global settings. The following procedure describes the steps to enable or disable client keep-alive at the service level.

To enable or disable the client keep-alive mode for a service by using the command line interface

At the command prompt, type:

set service (<name> | <IPaddress>) -CKA (YES | NO)

Example

> set service Service-HTTP-1 -CKA YES

To enable or disable the client keep-alive mode for a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, click the service for which you want to enable or disable client keep-alive, and then click Open.
3. In the Configure Service dialog box, on the Advanced tab, under Settings, select or clear the Client Keep-Alive check box.
4. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set service

name

The name of the service.

IPaddress

The new IP address of the service.

CKA

The state of the Client Keep-Alive feature for the service. Possible values: YES, NO

View description(s) in command reference Top

Configuring Connection Options with HTTP Profiles

An HTTP profile is a collection of configuration settings that is used to control HTTP requests to and responses from virtual servers on a NetScaler appliance. You can use HTTP profiles to configure the maximum number of HTTP connections retained in the connection reuse pool. You can also use HTTP profiles to enable connection multiplexing if you are not sure that it is already enabled (By default, connection multiplexing is enabled.), and to enable Persistence ETag.

When Persistent ETag is enabled, the ETag header includes information about the server that served the content. This ensures that cache validation conditional requests or browser requests, for that content, always reaches the same server. By default, Persistent ETag is disabled.

For more information about HTTP profiles, see "Configuring HTTP Profiles."

To configure the number of connections in the reuse pool by using the command line interface

At the command prompt, type:

set ns httpProfile <name> -maxReusePool <value>

To configure the number of connections in the reuse pool by using the configuration utility

1. Navigate to System > Profiles.
2. In the details pane, on the HTTP Profiles tab, select the HTTP profile for which you want to configure the number of connections, and then click Open.
3. In the Configure HTTP Profiles dialog box, in Max connections in reusepool, specify the maximum number of connections you want to allow in connection reuse pool.
4. Click OK.

To enable connection multiplexing by using the command line interface

At the command prompt, type:

set ns httpProfile <name> -conMultiplex ENABLED

To enable connection multiplexing by using the configuration utility

1. Navigate to System > Profiles.
2. In the details pane, on the HTTP Profiles tab, select the HTTP profile for which you want to enable connection multiplexing, and then click Open.
3. In the Configure HTTP Profiles dialog box, select the Connection Multiplexing check box. Note that this check box is enabled by default.
4. Click OK.

To enable Persistent ETag by using the command line interface

At the command prompt, type:

set ns httpProfile <name> -persistentETag enabled

To enable Persistent ETag by using the configuration utility

1. Navigate to System > Profiles.
2. In the details pane, on the HTTP Profiles tab, select the HTTP profile for which you want to enable Persistent Etag, and then click Open.
3. In the Configure HTTP Profiles dialog box, select the Persistent ETag option. By default, this option is disabled.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns httpProfile

maxReusePool

Maximum connections in reusepool. If set to zero, limit will not be applied. Maximum value: 360000

conMultiplex

Connection multiplexing Possible values: ENABLED, DISABLED Default value: ENABLED

persistentETag

Generate the persistent NetScaler specific ETag for the HTTP response with ETag header. Possible values: ENABLED, DISABLED Default value: DISABLED

View description(s) in command reference Top

Compression

The Citrix NetScaler appliance compression feature compresses the size of HTTP responses sent from servers to compression-aware browsers and thereby improves the performance of Web sites by reducing the download time of Web content. Bandwidth is also saved in the process. Another indirect benefit of HTTP compression is that the data passed between the Web server and the browser is encrypted by virtue of the compression algorithm, adding more security to the data.

After you enable the compression feature and compression is set at the service level, global compression policies are enabled, and the NetScaler can compress data for traffic that matches these policies. You can augment the built-in compression policies by creating new compression actions and policies and binding the policies globally or to particular virtual servers.

When you bind a policy globally, you specify a bind point, which corresponds to a step in the sequence in which traffic is processed. Policies bound to a virtual server have their own place in the sequence. Therefore, binding the policies affects the order in which they are evaluated. Alternatively, you can associate policies with policy labels that are not associated with a bind point. Such policies can be invoked only by other policies.

You can view statistics for compressed data that the NetScaler transmits.

Note: The compression feature uses both classic and default syntax policies. This content is best understood if you are familiar with configuration principles for basic policies, virtual servers, and services. For more information about policies, see "Policies and Expressions." For more information about virtual servers and services, see "Creating a Virtual Server" and "Configuring Services."

The NetScaler can compress HTML and other content that is generated statically or dynamically, including MIME types such as text/html, text/plain, text/xml, text/css, text/rtf, application/msword, application/vnd.ms-excel, and application/vnd.ms-powerpoint.

After you enable the compression feature on the NetScaler and set compression ON for HTTP and SSL services, built-in compression policies are applied to the HTTP and SSL services. You can disable compression on a particular service, and you can create custom compression policies and bind both the built-in and custom compression policies to a load balancing virtual server.

Enabling or Disabling Compression

If you want the NetScaler appliance to compress data, enable the compression feature and set compression ON for the configured service. After enabling compression, the built-in compression policies are in effect, and compression is automatically enabled for any services that you create.

If you want to use compression in a load balancing environment, you also enable the load balancing feature. To compress traffic that is sent over SSL, you also enable the SSL feature.

To enable or disable compression, load balancing, and SSL by using the command line interface

At the command prompt, type one of the following commands:

- enable ns feature cmp lb ssl
- disable ns feature cmp lb ssl

To enable or disable compression, load balancing, and SSL by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, under the Modes and Features group, click Configure basic features.
3. In the Configure Basic Features dialog box, select the Compression check box to enable it; clear the check box to disable it. If appropriate, also select the Load Balancing and SSL Offloading check boxes.
4. Click OK, and click Yes in the Enable/Disable Feature(s)? message box.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ns feature

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

disable ns feature

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Enabling and Disabling Compression for a Service

By default, if the compression feature is disabled, any new service that you create is disabled for compression and uses the built-in compression policies. If you create any services prior to enabling compression, you must manually enable compression for the service.

You can disable or enable compression for HTTP and SSL services.

Compression is in effect for a compression-enabled service once you bind the service to a virtual server. You can bind HTTP services to an HTTP load balancing vserver, and bind SSL services to an SSL load balancing virtual server. The protocol types must match.

To create a compression-enabled service by using the command line interface

At the command prompt, type:

- add service <name> <IPAddress> HTTP <portNumber>
- set service <name> -CMP YES

Example

```
> add service Service-HTTP-1 10.102.29.51 HTTP 80
> set service Service-HTTP-1 -CMP YES
```

To enable or disable service-level compression by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, on the Services tab, select the service for which you want to enable or disable compression, and then click Open.
3. In the Configure Service dialog box, on the Advanced tab, under Settings, select Override Global, and then select or clear the Compression check box.
4. Click OK, and then click Close.

Parameter Descriptions (of commands listed in the CLI procedure)

add service

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

set service

CMP

The state of the HTTP Compression feature for this service. Possible values: YES, NO

View description(s) in command reference Top

Configuring Compression Actions

You associate actions with compression policies. If an HTTP request matches the policy rule, the action is applied to the response. For example, you can configure a compression policy that identifies requests that are sent to a particular server, and associate the policy with an action that compresses data that is sent with the response.

There are four built-in compression actions:

- **COMPRESS:** Uses the GZIP algorithm to compress data for browsers that support either GZIP or both GZIP and DEFLATE. The NetScaler appliance uses the DEFLATE algorithm to compress data for browsers that support the DEFLATE algorithm. If the browser does not support either algorithm, and the action has been set to COMPRESS, the NetScaler appliance does not compress data.
- **NOCOMPRESS:** Does not compress data.
- **GZIP:** Uses the GZIP algorithm to compress data for browsers that support GZIP compression. If the browser does not support the GZIP algorithm the NetScaler appliance does not compress data.
- **DEFLATE:** Uses the DEFLATE algorithm to compress data for browsers that support the DEFLATE algorithm. If the browser does not support the DEFLATE algorithm, and the action has been set to DEFLATE, the NetScaler appliance does not compress data.

Compression actions determine whether and what type of compression the NetScaler appliance applies to a response. After creating an action, you associate the action with one or more compression policies.

To create a compression action by using the command line interface

At the command prompt, type:

add cmp action <name> -cmpType (compress|gzip|deflate|nocompress)

To create a compression action by using the configuration utility

1. In the navigation pane, expand HTTP Compression, and then click Actions.
2. In the details pane, click Add.
3. In the Create Compression Action dialog box, in the Name text box, type the name of the action (for example, Action-CMP-1).
4. Under Compression Type, choose the compression type (for example, GZIP).
5. Click Create, and then click Close.

If you try to delete a built-in action, or any action that is associated with a policy, an error message appears. Only custom actions that have no associated policy can be deleted.

Parameter Descriptions (of commands listed in the CLI procedure)

add cmp action

name

The name of the compression action.

cmpType

The type of compression action. Possible values: compress, gzip, deflate, nocompress

View description(s) in command reference Top

Configuring Compression Policies

A compression policy contains a rule, which is a logical expression that enables the NetScaler appliance to identify the traffic that should be compressed.

When the Citrix NetScaler appliance receives an HTTP response from a server, it evaluates a built-in or custom compression policy to determine whether to compress the response and the type of compression to apply.

There are five built-in classic and advanced and default syntaxcompression policies. These policies are activated globally when you enable compression.

The following table describes the built-in compression policies.

Table 1. Built-in Classic and Advanced and Default Syntax Policies for Compression

Built-in Classic and Advanced Compression Policies	Description
ns_nocmp_mozilla_47 ns_adv_nocmp_mozilla_47	Does not compress CSS files when a request is sent from a Mozilla 4.7 Web browser.
ns_cmp_mscss ns_adv_cmp_mscss	Compresses CSS files when the request is sent from a Microsoft Internet Explorer Web browser.
ns_cmp_msapp ns_adv_cmp_msapp	Compresses files that are generated by the following applications: · Microsoft Office Word · Microsoft Office Excel · Microsoft Office PowerPoint
ns_cmp_content_type ns_adv_cmp_content_type	Compresses data when the response contains the header 'Content-Type' and contains text.
ns_nocmp_xml_ie ns_adv_nocmp_xml_ie	Does not compress when a request is sent from a Microsoft Internet Explorer browser with the response header 'Content-Type' and contains text or xml.

To view built-in compression policies by using the configuration utility

1. In the navigation pane, expand HTTP Compression, and then click Policies.
2. In the details pane, view the built-in compression policies.

You can create a compression policy by using the built-in compression actions and named expressions, or you can use custom actions and expressions.

To create a compression policy by using the command line interface

At the command prompt, type:

add cmp policy <name> -resAction (compress|gzip|deflate|nocompress) -rule <build_in_rule_name>|“<user_defined_rule>”

Example

> add cmp policy Policy-CMP-2 -resAction gzip -rule HTTP.REQ.HEADER(“User-Agent”).CONTAINS(“Mozilla/4.

To create a compression policy by using the configuration utility

1. In the navigation pane, expand HTTP Compression, and then click Policies.
2. In the details pane, click Add.
3. In the Create Compression Policy dialog box, in the Policy Name text box, type the name of the policy.
4. In Response Action, do one of the following:
   - To use a built-in or existing compression action, choose a compression action in the drop-down list.
   - To create a new compression action, click New. In the Create Compression Action dialog box, enter a compression action name and type, and then click Create.
5. In the Expression box, either type the default syntax expression or do one of the following:
   - Click Prefix, and then select the expression prefix you want. Then, select the flow type (REQ or RES), and then enter a period (.) to display a list of functions that can be used with the flow type. Type a period after each function until you have entered the expression you want. Click the Operators button to insert an operator (for example, a Boolean or relational operator).
   - Click Add, and then select a named expression.
6. If you want to evaluate your expression, click Evaluate.
7. If you want to clear the Expression box, click Clear.
8. Click Create, and then click Close.

You can modify the actions and expressions that are associated with a user-defined policy. However, you cannot make any modifications to the built-in compression policies.

You can remove a compression policy if the policy is not bound globally or to a vserver. If the compression policy is bound, you must first unbind it. You cannot remove a built-in compression policy.

Parameter Descriptions (of commands listed in the CLI procedure)

add cmp policy

name

The name of the HTTP compression policy to be created.

resAction

The compression action that needs to be performed when the rule matches. The string value can be either be a created compression action (user-defined) or one of the following built-in compression actions: NOCOMPRESS action - can be used to define a policy that disables compression for the matching policy.COMPRESS action - can be used to enable compression for a specific policy. This action will do GZIP or DEFLATE, based on the browser. GZIP action - can be used to enable GZIP compression for a specific policy. With this action, GZIP compression will be performed if the browser supports GZIP, other wise compression is disabled. DEFLATE action - can be used to enable DEFLATE compression for a specific policy. With this action, DEFLATE compression will be performed if the browser supports DEFLATE, otherwise compression is disabled.

rule

The rule associated with the HTTP compression policy.

View description(s) in command reference Top

Bind Points and Order of Evaluation for Default Syntax Compression Policies

For a default syntax policy to take effect, you must ensure that the policy is invoked at some point during the Citrix NetScaler appliance's processing of traffic. To specify the invocation time, you associate the policy with a bind point. The following are the built-in bind points, listed in order of evaluation:

- **Request-time override.** If a request matches a request-time override policy, by default request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Request-time load balancing virtual server.** If policy evaluation cannot be completed after all the request-time override policies are evaluated, the NetScaler appliance processes request-time policies that are bound to load balancing virtual servers. If the request matches one of these policies, evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Request-time content switching virtual server.** Policies that are bound to this bind point are evaluated after request-time policies that are bound to load balancing virtual servers.
- **Request-time default.** If policy evaluation cannot be completed after all request-time, virtual server-specific policies are evaluated, the NetScaler appliance processes request-time default policies. If the request matches a request-time default policy, by default request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Response-time override.** Similar to request-time override policy evaluation.
- **Response-time load balancing virtual server.** Similar to request-time virtual server policy evaluation.
- **Response-time content switching virtual server.** Similar to request-time virtual server policy evaluation.
- **Response-time default.** Similar to request-time default policy evaluation.

You can associate multiple policies with each bind point. To control the order of evaluation of the policies associated with the bind point you configure a priority level. In the absence of any other flow control information, policies are evaluated according to priority level, starting with the lowest numeric priority value.

You can also bind a given default syntax compression policy to more than one bind point. However, the bind point at which the policy is evaluated first is determined by the order specified in the preceding list. Assigned priority values must be unique within the collection of policies bound to a specific bind point. Additionally, for a given policy, only one binding is allowed per bind point at any given time. You should bind a policy with an INVAL action to a request-time override or a response-time override bind point. To delete a policy, you must first unbind it.

Table 1. Entries to Control Evaluation Flow in a Policy Label

Attribute	Specifies
Name	The name of the policy that you bound to the virtual server.
Bound To	The name of the virtual server to which the policy is bound.
Priority	The priority level used to determine when the policy is evaluated relative to other policies that are bound to this virtual server. Specify an integer. The lower the integer, the higher the priority.
Goto Expression	Determines the next policy to evaluate in this label. Goto can proceed only forward in a policy label. Omitting the Goto expression is the same as specifying END. You can provide one of the following values: · **NEXT:** Go to the policy with the next higher priority. · **END:** Stop evaluation. · **USE_INVOCATION_RESULT:** Applicable if this entry invokes another policy label. If the final Goto in the invoked bank has a value of END, evaluation stops. If the final Goto is anything other than END, the current policy label performs a NEXT. · **Positive number:** Priority number of the next policy to be evaluated. · **Numeric expression:** Expression that produces the priority number of the next policy to be evaluated.
Flow Type	You must specify a flow type to determine whether this policy is evaluated at request time or response time.
Invoke Label Type	Designates a policy label type. The value can be one of the following: · **Request Vserver:** Invokes request-time policies that are associated with a virtual server. · **Response Vserver:** Invokes response-time policies that are associated with a virtual server. · **Policy label:** Invokes another policy label, as identified by the policy label for the bank.
Invoke Label Name	The name of a virtual server or a policy label, depending on the value that you specified for the invocation type.

Finally, you can also bind compression policies to custom bind points—bind points that you create. The bind points that you create are called *policy labels*. For more information about policy labels, see "Creating Policy Labels."

Bind Points and Order of Evaluation for Classic Compression Policies

You can bind a classic compression policy either at the global level or at the virtual server (content switching or load balancing virtual server) level. You can also bind a given compression policy to more than one bind point. The priority values that are assigned to a policy that is bound to various bind points need not have the same value. For example, if you bind a policy called *mycompressionpolicy* both globally and to a load balancing virtual server, you can assign the policy a priority of 10 at the global bind point and a priority of 100 at the virtual server bind point. If you do not assign a policy a priority value, the NetScaler appliance assigns the classic compression policy a default priority value of 0 (zero).

Therefore, the priorities assigned to the classic compression policies that are bound to various bind points at any given time might be an assortment of custom priority values and default values. During classic policy evaluation, priority values are considered first. The NetScaler appliance begins with the policy that has the lowest priority value (the default value of 0, if any, or the next higher custom priority value if none of the policies have a priority value of 0) regardless of the bind point to which the policy is bound. Then, the appliance evaluates policies in ascending order of priority values while moving from one bind point to the other if necessary.

When the NetScaler appliance is evaluating policies based on their priority values, if multiple policies bound to different bind points happen to have the same priority value, the bind points of those policies are considered, with the order of evaluation progressing from the most specific bind point to the least specific bind point. For example, if classic policies are bound globally, to a content switching virtual server, and to a load balancing virtual server, the policies bound to the load balancing virtual server are evaluated first because, in this configuration, the load balancing virtual server represents the most specific bind point. The NetScaler appliance then evaluates the policies that are bound to the content switching virtual server. Finally, the appliance evaluates the policies that are bound at the global level (which is the least specific bind point in this configuration).

Finally, at a given bind point, if two or more policies have the same priority value, the chronological order in which the policies were configured is considered. Among the policies that are bound to the same bind point, with the same priority value, the policy that was configured first is evaluated first, followed by the policy that was configured second, and so on. In this way, the NetScaler appliance evaluates classic policies based first on assigned priorities, then on bind points, and finally on the chronological order in which the policies were configured.

Creating Policy Labels

You can create compression policy labels and configure banks of policies for these new labels.

Policy labels can be considered as abstract bind points that you create. You can create policy labels only for advanced policies. The policies that are bound to a policy label can be evaluated by invoking the policy label from a policy that is bound to one of the following bind points:

- Request-time override
- Request-time default
- Response-time override
- Response-time default
- A virtual server

You can invoke a policy label any number of times, unlike a policy which can only be invoked once.

To create a policy label for compression by using the command line interface

At the command prompt, type:

add cmp policylabel <labelName> -type (REQ | RES)

To create a policy label for compression by using the configuration utility

1. In the navigation pane, expand HTTP Compression, and then click Policy Labels.
2. In the details pane, click Add.
3. In the Create Compression Policy Label dialog box, in Name, specify a name for the policy label.
4. In the Evaluates drop-down list, select whether the policy label will be evaluated at request time (REQ) or response time (RES).
5. Click Insert Policy, and then select the policy, or click New Policy to create a new policy.

   Note: To ensure that the NetScaler appliance processes the policy label at the right time, you can configure an invocation of this label from the policy labels that are associated with the built-in bind points. Select the appropriate policy label of request vserver from the Invoke column field.
6. Click Create, and then click Close.

   Note: You can use the NOPOLICY “dummy” policy to invoke any policy label from another policy label. The NOPOLICY entry is a placeholder that does not process a rule.

Parameter Descriptions (of commands listed in the CLI procedure)

add cmp policylabel

labelName

The name of the HTTP compression policy label to be created.

type

Specifies when policies bound to this policy label will be evaluated. Possible values: REQ, RES

View description(s) in command reference Top

Binding Compression Policies Globally

A global compression policy applies to all services that support compression. When binding the policy, you assign it a priority. The policy is enabled by default upon creation.

To globally bind a compression policy by using the command line interface

At the command prompt, type:

bind cmp global <policyName> -priority <positiveInteger> -state (enabled|disabled)

To unbind a globally bound compression policy by using the command line interface

At the command prompt, type:

unbind cmp global <policyName>

To globally bind a compression policy by using the configuration utility

1. In the navigation pane, expand HTTP Compression, and then click Policies.
2. From the Action drop down list, select Policy Manager.
3. In the Compression Policy Manager dialog box, do one of the following:
   - To bind compression policies by using classic expressions, perform the following:
     - Click Switch to Classic Syntax on the top right corner of the page.
     - Click Global.
     - Click Insert Policy, and then click the policy name that you want to bind.
     - Double-click the Priority field for the policy and set the priority. A lower value causes the policy to be evaluated before policies with a higher priority value.
     - Click Apply Changes.

     Optionally, to configure an expression as described in "Binding Compression Policies Globally", double-click the field in the Expression column, and specify a valid expression.
   - To bind compression policies by using advanced expressions, perform the following:
     - Click Switch to Default Syntax on the top right corner of the page.
     - Select a Request or Response bind point, and then select a second level of binding of either Override Global or Default Global.

       A list of policies appears. These are policies that are bound to this bind point.
     - Click Insert Policy, and then click the policy name that you want to bind.
     - Double-click the Priority field for the policy and set the priority.

       A lower value causes the policy to be evaluated before policies with a higher priority value.
     - Specify other optional values, such as a Goto expression or invocation of an external policy label.

       To configure a Goto expression, double-click the field in the Goto Expression column, and enter valid priority level, the keywords NEXT or END, or an advanced expression.
4. Click Apply Changes, and then click Close.

Parameter Descriptions (of commands listed in the CLI procedure)

bind cmp global

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

unbind cmp global

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Binding Compression Policies to Virtual Servers

When you configure virtual server-based compression, you bind services and compression policies to a virtual server. This causes traffic that flows through a virtual server (to and from the bound services) to be subject to compression policies that you bind to the vserver.

If you bind a policy to a vserver, the policy is evaluated only by compression-enabled services that are bound to this vserver. When binding a policy, you set a priority value. Policies with a lower priority value are evaluated before policies with a higher value. After unbinding a policy from a vserver, the policy ceases to act on the services associated with that vserver.

To bind a compression policy to a load balancing vserver by using the command line interface

At the command prompt, type:

bind lb vserver <vserverName> -policyName <policyName> -priority <positiveInt>

To bind a compression policy to a load balancing vserver by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, click the name of the virtual server, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Policies tab, click Compression.
4. Click either Classic Expression or Advanced Expression. Click Insert Policy and select the policy that you want to bind. Optionally, you can double-click the Priority field and type a new priority level. To invoke another policy label or to configure a policy for a request vserver, from the Invoke drop-down list, make an appropriate selection. If you select a request vserver, you can bind a compression policy for the selected vserver by double-clicking the Invoke field. The Configure Compression Policies dialog box appears.
5. Click OK, and then click Close.

Parameter Descriptions (of commands listed in the CLI procedure)

bind lb vserver

policyName

The SureConnect/priority queuing/Compression/AppSecure/Transform/Filter/Authorization/Rewrite/Responder/Cache/Syslog/Nslog/TMTraffic policy that needs to be bound to the specified load balancing virtual server for SureConnect or priority queuing to be activated on a load balancing virtual server.

View description(s) in command reference Top

Setting Global Compression Parameters

You can customize the way the NetScaler appliance compresses data.

To set global compression parameters by using the command line interface

At the command prompt, type:

set cmp parameter [-cmpLevel <compressionLevel>] [-quantumSize <integer>] [-serverCmp (ON | OFF)] [-minResSize <positiveInteger>] [-cmpBypassPct <positiveInteger>] [-cmpOnPush (ENABLED | DISABLED)] [-policyType (CLASSIC | ADVANCED)]

To set global compression parameters by using the configuration utility

1. In the navigation pane, click HTTP Compression.
2. In the details pane, click Change compression settings.
3. In the Configure Compression Parameters dialog box, configure the settings (for example, set the Quantum size and Compression level), and then click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set cmp parameter

cmpLevel

Compression level. Possible values: optimal, bestspeed, bestcompression Default value: NSCMPLVL_OPTIMAL

quantumSize

Minimum amount of data to compress as one unit. Default value: 57344 Minimum value: 8 Maximum value: 63488

serverCmp

Compression at back-end server. Possible values: ON, OFF Default value: ON

minResSize

Size of the smallest HTTP response that will be compressed.

cmpBypassPct

CPU usage (%) at which NetScaler should start progressively bypassing compression on HTTP requests. Default value: 100 Maximum value: 100

cmpOnPush

Enable/disable compression on PUSH packet Possible values: ENABLED, DISABLED Default value: DISABLED

policyType

The type of the HTTP compression global policy bindings to be used for virtual servers that have no HTTP compression policies bound. Possible values: CLASSIC, ADVANCED Default value: NS_EXPR_TYPE_CLASSIC

View description(s) in command reference Top

Configuring Compression for a Load Balancing Virtual Server

When you configure virtual server-based compression, you bind services and compression policies to a virtual server. This causes traffic that flows through a virtual server to and from the bound services to be subject to compression policies that you bind to the vserver.

When a client request flows through a vserver, compression policies identify whether the client can accept compressed data. The Citrix NetScaler appliance forwards the request to the destination server, as identified by a service that is bound to the load balancing vserver. After the NetScaler appliance receives the response from the server, it determines whether the response is compressible based on the compression policies that are bound to the virtual server. If the content is compressible, it is compressed and forwarded to the client.

Task overview: configuring compression for a load balancing vserver.

1. Enable compression and load balancing, as described in "Enabling and Disabling Compression."
2. Add a vserver, as explained in Creating a Virtual Server" and Configuring an SSL-Based Virtual Server".
3. Add one or more HTTP or SSL services and bind the services to a vserver, as explained in "Creating a Service" and "Binding Services to the Virtual Server."
4. Create compression policies, as described in "Configuring Compression Policies."
5. Bind the compression policies to the vserver, as described in "Binding Compression Policies to Virtual Servers."

Viewing Compression Statistics by Using the Dashboard

The Dashboard utility displays summary and detailed compression statistics in tabular and graphic format.

Note: For more information about the statistics and charts, see the Dashboard help on the Citrix NetScaler appliance.

To view compression statistics by using the Dashboard

1. In the Dashboard utility, in the Select Group list, choose Compression, and then do one or more of the following:
   - To view of summary of compression statistics, click the Summary tab.
   - To view compression statistics by protocol type, click the Details tab.
   - To view the rate of requests processed by the compression feature, click the Chart tab.

Viewing Compression Statistics by Using SNMP

You can collect compression statistics in an SNMP monitor. You can view the following compression statistics by using the SNMP network management application.

Note: For more information about SNMP, see "SNMP."

- Number of compression requests (OID: 1.3.6.1.4.1.5951.4.1.1.50.1)
- Number of compressed bytes transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.2)
- Number of compressible bytes received (OID: 1.3.6.1.4.1.5951.4.1.1.50.3)
- Number of compressible packets transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.4)
- Number of compressible packets received (OID: 1.3.6.1.4.1.5951.4.1.1.50.5)
- Ratio of compressible data received and compressed data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.6)
- Ratio of total data received to total data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.7)

Viewing Additional Compression Statistics

When the NetScaler appliance compresses a response based on a policy, the policy hit counter is incremented. You can view statistics for a compression policy, including the number of hits.

Note: The stat cmp policy command displays statistics only for advanced compression policies.

To view details and hits to a compression policy by using the command line interface

At the command prompt, type:

show cmp policy <name>

To view a summary of compression statistics by using the command line interface

At the command prompt, type:

stat cmp

To view detailed compression statistics by using the command line interface

At the command prompt, type:

stat cmp -detail

To view compression statistics by using the configuration utility

1. In the navigation pane, click HTTP Compression.
2. In the details pane, click the Statistics link.

   Note: To view statistics for an individual policy, expand HTTP Compression, and then click Policies. In the details pane, click the policy for which you want to view statistics.

To view statistics of a compression policy by using the command line interface

At the command prompt, type:

stat cmp policy<name>

Note: Statistics is displayed only for advanced policies.

The output includes the number of hits, rate of hits per second, the number of undefined hits, and the rate of undefined hits on the policy.

To view statistics of a compression policy by using the configuration utility

1. In the navigation pane, expand HTTP Compression, and then click Policies.
2. In the details pane, click Statistics.
3. On the Compression Policy Statistics page, view the statistics of the listed advanced compression policies, or select an advanced policy and click Statistics to display detailed statistics for that policy.

To view statistics of a compression policy label by using the command line interface

At the command prompt, type:

stat cmp policylabel <labelName>

The output of the stat cmp policylabel command includes the number of hits and the rate of hits on the policy label, and the statistics of the policies bound to the policy label.

To view statistics of a compression policy label by using the configuration utility

1. In the navigation pane, expand HTTP Compression, and then click Policy Labels.
2. In the details pane, click Statistics.
3. On the Compression Policy label Statistics page, view the statistics of the listed compression policy labels, or select a policy label and click Statistics to display detailed statistics for that policy label.

Parameter Descriptions (of commands listed in the CLI procedure)

show cmp policy

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

stat cmp

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

stat cmp policy

name

The name of the compress policy for which statistics will be displayed. If not given statistics are shown for all compress policies.

View description(s) in command reference Top

stat cmp policylabel

labelName

The name of the compress policy label for which statistics will be displayed. If not given statistics are shown for all compress policylabels.

View description(s) in command reference Top

Integrated Caching

The integrated cache provides in-memory storage on the Citrix NetScaler appliance and serves Web content to users without requiring a round trip to an origin server. For static content, the integrated cache requires little initial setup. After you enable the integrated cache feature and perform basic setup (for example, determining the amount of NetScaler appliance memory the cache is permitted to use), the integrated cache uses built-in policies to store and serve specific types of static content, including simple Web pages and image files. You can also configure the integrated cache to store and serve dynamic content that is usually marked as non-cacheable by Web and application servers (for example, database records and stock quotes).

When a request or response matches the rule (logical expression) specified in a built-in policy or a policy that you have created, the NetScaler appliance performs the action associated with the policy. By default, all policies store cached objects in and retrieve them from the Default content group, but you can create your own content groups for different types of content.

To enable the NetScaler appliance to find cached objects in a content group, you can configure selectors, which match cached objects against expressions, or you can specify parameters for finding objects in the content group. If you use selectors (which Citrix recommends), configure them first, so that you can specify selectors when you configure content groups. Next, set up any content groups that you want to add, so that they are available when you configure the policies. To complete the initial configuration, create policy banks by binding each policy to a global bind point or a virtual server, or to a label that can be called from other policy banks.

You can tune the performance of the integrated cache, using methods such as pre-loading cached objects before they are scheduled to expire. To manage the handling of cached data once it leaves the NetScaler appliance, you can configure caching-related headers that are inserted into responses. The integrated cache can also act as a forward proxy for other cache servers.

Note: Integrated caching requires some familiarity with HTTP requests and responses. For information about the structure of HTTP data, see *Live HTTP Headers* at "http://livehttpheaders.mozdev.org/."

How the Integrated Cache Works

The integrated cache monitors HTTP and SQL requests that flow through the Citrix NetScaler appliance and compares the requests with stored policies. Depending on the outcome, the integrated cache feature either searches the cache for the response or forwards the request to the origin server. For HTTP requests, the integrated cache feature can also serve partial content from the cache in response to single byte-range and multi-part byte-range requests.

Cached data can be compressed if the client accepts compressed content. You can configure expiration times for a content group, and you can selectively expire entries in a content group.

Data that is served from the integrated cache is a cache hit, and data served from the origin is a cache miss, as described in the following table.

Table 1. Cache Hits and Misses

Transaction Type	Specifies

Cache Hit	Responses that the NetScaler appliance serves from the cache, including: · Static objects, for example, image files and static Web pages · 200 OK pages · 203 Non-Authoritative Response pages · 300 Multiple Choices pages · 301 Moved Permanently pages · 302 Found pages · 304 Not Modified pages These responses are known as positive responses. The NetScaler appliance also caches the following negative responses: · 307 Temporary Redirect pages · 403 Forbidden pages · 404 Not Found pages · 410 Gone pages To further improve performance, you can configure the NetScaler appliance to cache additional types of content.
Storable Cache Miss	For a storable cache miss, the NetScaler appliance fetches the response from the origin server, and stores the response in the cache before serving it to the client.
Non-Storable Cache Miss	A non-storable cache miss is inappropriate for caching. By default, any response that contains the following status codes is a non-storable cache miss: · 201, 202, 204, 205, 206 status codes · All 4xx codes, except 403, 404 and 410 · 5xx status codes

Note: To integrate dynamic caching with your application infrastructure, use the XML API to issue cache commands remotely. For example, you can configure triggers that expire cached responses when a database table is updated.

To ensure the synchronization of cached responses with the data on the origin server, you configure expiration methods. When the NetScaler appliance receives a request that matches an expired response, it refreshes the response from the origin server.

Example of Dynamic Caching

Dynamic caching evaluates HTTP requests and responses based on parameter-value pairs, strings, string patterns, or other data. For example, suppose that a user searches for Bug 31231 in a bug reporting application. The browser sends the following request on the user's behalf:

```
GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&Template=view&TableId=1000
Host: mycompany.net
User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9) Gecko/2008052906 Firefox/3.0
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8
Accept-Language: en-us,en;q=0.5
. . .
```

In this example, GET requests for this bug reporting application always contain the following parameters:

- IssuePage
- RecordID
- Template
- TableId

GET requests do not update or alter the data, so you can configure these parameters in caching policies and selectors, as follows:

- You configure a caching policy that looks for the string mybugreportingsystem and the GET method in HTTP requests. This policy directs matching requests to a content group for bugs.
- In the content group for bugs, you configure a hit selector that matches various parameter-value pairs, including IssuePage, RecordID, and so on.

Note that a browser can send multiple GET requests based on one user action. The following is a series of three separate GET requests that a browser issues when a user searches for a bug based on a bug ID. **Bold** has been added for emphasis:

```
GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&Template=view&TableId=1000
GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=viewbtns&RecordId=31231&TableId=1000
GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=viewbody&RecordId=31231&tableid=1000
```

To fulfill these requests, multiple responses are sent to the user's browser, and the Web page that the user sees is an assembly of the responses.

If a user updates a bug report, the corresponding responses in the cache should be refreshed with data from the origin server. The bug reporting application issues HTTP POST requests when a user updates a bug report. In this example, you configure the following to ensure that POST requests trigger invalidation in the cache:

- A request-time invalidation policy that looks for the string mybugreportingsystem and the POST HTTP request method, and directs matching requests to the content group for bug reports.
- An invalidation selector for the content group for bug reports that expires cached content based on the RecordID parameter. This parameter appears in all of the responses, so the invalidation selector can expire all relevant items in the cache.

The following excerpt shows a POST request that updates the sample bug report. **Bold** has been added for emphasis:

POST /mybugreportingsystem/mybugreport.dll?TransitionForm HTTP/1.1\r\n
User-Agent: Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.0) Opera 7.23 [en]\r\n
Host: mybugreportingsystem\r\n
Cookie:ttSearch.134=%23options%3Afalse%23active%23owner%3Afalse%23unowned%3Afalse%23submitter%3Afa
Cookie2: $Version=1\r\n
. . .
\r\n
ProjectId=2&RecordId=31231&TableId=1000&TransitionId=1&Action=Update&CopyProjectId=0&ReloadForm=0

When the Citrix NetScaler appliance receives this request, it does the following:

- Matches the request with an invalidation policy.
- Finds the content group that is named in the policy.
- Applies the invalidation selector for this content group and expires all responses that match RecordID=31231.

When a user issues a new request for this bug report, the NetScaler appliance goes to the origin server for updated copies of all the responses that are associated with the report instance, stores the responses in the content group, and serves them to the user's browser, which reassembles the report and displays it.

Setting Up the Integrated Cache

To use the integrated cache, you must install the license and enable the feature. After you enable the integrated cache, the Citrix® NetScaler® appliance automatically caches static objects as specified by built-in policies and generates statistics on cache behavior. (Built-in policies have an underscore in the initial position of the policy name.)

Even if the built-in policies are adequate for your situation, you might want to modify the global attributes. For example, you might want to modify the amount of NetScaler appliance memory allocated to the integrated cache.

If you would like to observe cache operation before changing settings, see "Displaying Cached Objects and Cache Statistics."

Note: The NetScaler cache is an in-memory store that is purged when you restart the appliance.

Installing the Integrated Cache License

An integrated cache license is required. For information about licenses, see information about obtaining NetScaler licenses at "http://support.citrix.com/article/ctx121062."

To install the license for the Integrated Caching feature

1. Obtain a license code from Citrix, go to the command line interface, and log in.
2. At the command line interface, copy the license file to the /nsconfig/license folder.
3. Reboot the NetScaler appliance by using the following command:

   reboot

Parameter Descriptions (of commands listed in the CLI procedure)

reboot

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Enabling or Disabling Integrated Cache

When you enable integrated caching, the NetScaler appliance begins caching server responses. If you have not configured any policies or content groups, the built in policies store cached objects in the Default content group.

To enable or disable integrated caching by using the command line interface

At the command prompt, type one of the following commands to enable or disable integrated caching:

- enable ns feature `IC`
- disable ns feature `IC`

To enable or disable integrated caching by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, under the Modes and Features group, click Configure basic features.
3. In the Configure Basic Features dialog box, select the Integrated Caching check box to enable integrated caching, or clear the check box to disable it.
4. In the confirmation message box, click OK, and then click Yes.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ns feature

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

disable ns feature

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Global Attributes for Caching

Global attributes apply to all cached data. You can specify the amount of NetScaler memory allocated to the integrated cache, Via header insertion, a criterion for verifying that a cached object should be served, the maximum length of a POST body permitted in the cache, whether to bypass policy evaluation for HTTP GET requests, and an action to take when a policy cannot be evaluated.

The cache memory capacity is limited only by the memory of the hardware appliance. Also, any packet engine (the central distribution hub of all incoming TCP requests) in the nCore NetScaler appliance is aware of objects cached by other packet engines in the nCore NetScaler appliance.

Note that the default global memory limit is 0. Therefore, even if Integrated Caching is enabled, the NetScaler appliance does not cache any objects. You must explicitly set the global memory limit when integrated caching is enabled.

You can modify the global memory limit configured for caching objects. However, when you update the global memory limit to a value lower than the existing value (for example, from 10 GB to 4 GB), if a higher amount of memory (greater than 4 GB) is already being used to cache objects, the NetScaler continues using that amount of memory.

This means that even though the integrated caching limit is configured to some value, the actual limit used can be higher. This excessive memory is however released when the objects are removed from cache.

The output of the show cache parameter command indicates the configured value (Memory Usage limit) and the actual value being used (Memory usage limit (active value)).

To configure global settings for caching by using the command line interface

At the command prompt, type:

set cache parameter [-memLimit <MBytes>] [-via <string>] [-verifyUsing <criterion>] [-maxPostLen <positiveInteger>] [-prefetchMaxPending <positiveInteger>] [-enableBypass (YES|NO)] [-undefAction (NOCACHE|RESET)]

To configure global settings for caching by using the configuration utility

1. In the navigation pane, click Integrated Caching.
2. In the details pane, click Change cache settings.
3. In the Cache Global Settings dialog box, configure the global settings for caching. For a description of a parameter, hover the mouse cursor over the corresponding field.
4. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set cache parameter

memLimit

The memory limit for Integrated Cache.

via

The string to be inserted in the "Via" header. A Via header is inserted in all responses served from a content group if its insertVia flag is set.

verifyUsing

The criteria for deciding whether a cached object can be served for an incoming HTTP request. a. If the value of this attribute is set to HOSTNAME, then URL , host name and host port values in the incoming HTTP request header must match before a cached object can be served. The IP address and the TCP port of the destination host are not matched. For certain deployments the HOSTNAME setting can be a security risk. A rogue client can access a rogue server via the Integrated Cache using the following HTTP request : GET / HTTP/1.1 Host: sensitive.foo.com Integrated Cache will store the rogue page served by the rogue server. Any subsequent client trying to access the root page from sensitive.foo.com will be served the rogue page. The HOSTNAME setting should only be set if it is certain that no rogue client can access a rogue server via the Integrated Cache. The YES setting can lead to more hits if DNS-based load balancing is in use and the same content can be served by multiple backend servers. b. If the attribute is set to HOSTNAME_AND_IP, then the following items must match: URL, host name, host port in the incoming HTTP request header, and the IP address and TCP port of the destination server. c. If the attribute is set to DNS, then the following items should match: URL, host name and host port in the incoming HTTP request, and the TCP port. The hostname is used to do a DNS lookup of the destination server's IP address, and is compared with the set of addresses returned by the DNS lookup. The default value of this attribute is DNS. Possible values: HOSTNAME, HOSTNAME_AND_IP, DNS

maxPostLen

maximum number of POST body bytes to consider when evaluating parameters for a content group for which you have configured hitParams and invalParams. Default value: 4096 Maximum value: 131072

prefetchMaxPending

The maximum number of outstanding prefetches in the IC.

enableBypass

The bypass parameter. When this value is set to NO, an incoming request will serve a hit if a matching object is found in cache storage, regardless of the cacheability policy configuration. If set to YES, the bound request cacheability policies are evaluated before attempting any hit selection in the cache storage. If the request matches a policy with a NOCACHE action, the request will bypass all cache processing. This flag does not affect processing of requests that match any invalidation policy. Possible values: YES, NO

undefAction

Set the default cache undef action. If an UNDEF event is triggered during policy evaluation and if the current policy's undefAction is not specified, then this global undefAction value is used. Can be NOCACHE or RESET. NOCACHE is the default value of default cache undef action. Possible values: NOCACHE, RESET

View description(s) in command reference Top

Built-in Content Group, Pattern Set, and Policies for the Integrated Cache

The Citrix NetScaler appliance includes a built-in integrated caching configuration that you can use for caching content. The configuration consists of a content group called `ctx_cg_poc`, a pattern set called `ctx_file_extensions`, and a set of integrated cache policies. In the content group `ctx_cg_poc`, only objects that are 500 KB or smaller are cached. The content is cached for 86000 seconds, and the memory limit for the content group is 512 MB. The pattern set is an indexed array of common file extensions for file-type matching.

The following table lists the built-in integrated caching policies. By default, the policies are not bound to any bind point. You must bind them to a bind point if you want the NetScaler appliance to evaluate traffic against the policies. The policies cache objects in the `ctx_cg_poc` content group.

Table 1. Built-in Integrated Caching Policies

me	Policy rule
	`HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).CONTAINS_INDEX(\"ctx_file_extensions\").BETWEEN(101,150)`
	`HTTP.REQ.URL.ENDSWITH(\".css\")`
	`HTTP.REQ.URL.ENDSWITH(\".pdf\")`
	`HTTP.REQ.URL.ENDSWITH(\".js\")`
s	`HTTP.RES.HEADER(\"Content-Type\").CONTAINS(\"application/x-javascript\")`
	`TRUE`

Configuring Selectors and Basic Content Groups

You can configure selectors and apply them to content groups. When you add a selector to one or more content groups, you specify whether the selector is to be used for identifying cache hits or identifying cached objects to be invalidated (expired). Selectors are optional. Alternatively, you can configure content groups to use hit parameters and invalidation parameters. However, Citrix recommends that you configure selectors.

After configuring selectors, or deciding to use parameters instead, you are ready to set up a basic content group. After creating the basic content group, you need to decide how objects should be expired from the cache, and configure cache expiration. You can further modify the cache as described in "Improving Cache Performance" and "Configuring Cookies, Headers, and Polling", but you might first want to configure caching policies.

Note: Content group parameters and selectors are used only at request time, and you typically associate them with policies that use MAY_CACHE or MAY_NOCACHE actions.

Advantages of Selectors

A selector is a filter that locates particular objects in a content group. If you do not configure a selector, the Citrix® NetScaler® appliance looks for an exact match in the content group. This can lead to multiple copies of the same object residing in a content group. For example, a content group that does not have a selector may need to store URLs for host1.domain.com\mypage.htm, host2.domain.com\mypage.htm, and host3.domain.com\mypage.htm. In contrast, a selector can match just the URL (mypage.html, using the expression http.req.url) and the domain (.com, using the expression http.req.hostname.domain), allowing the requests to be satisfied by the same URL.

Selector expressions can perform simple matching of parameters (for example, to find objects that match a few query string parameters and their values). A selector expression can use Boolean logic, arithmetic operations, and combinations of attributes to identify objects (for example, segments of a URL stem, a query string, a string in a POST request body, a string in an HTTP header, a cookie). Selectors can also perform programmatic functions to analyze information in a request. For example, a selector can extract text in a POST body, convert the text into a list, and extract a specific item from the list.

For more information about expressions and what you can specify in an expression, see "Policies and Expressions."

Using Parameters Instead of Selectors

Although Citrix recommends the use of selectors with a content group, you can instead configure hit parameters and invalidation parameters. For example, suppose that you configure three hit parameters in a content group for bug reports: BugID, Issuer, and Assignee. If a request contains BugID=456, with Issuer=RohitV and Assignee=Robert, the NetScaler appliance can serve responses that match these parameter-value pairs.

Invalidation parameters in a content group expire cached entries. For example, suppose that BugID is ab invalidation parameter and a user issues a POST request to update a bug report. An invalidation policy directs the request to this content group, and the invalidation parameter for the content group expires all cached responses that match the BugID value. (The next time a user issues a GET request for this report, a caching policy can enable the NetScaler appliance to refresh the cached entry for the report from the origin server.)

Note that the same parameter can be used as a hit parameter or an invalidation parameter.

Content groups extract request parameters in the following order:

- URL query
- POST body
- Cookie header

After the first occurrence of a parameter, regardless of where it occurred in the request, all its subsequent occurrences are ignored. For example, if a parameter exists both in the URL query and in the POST body, only the one in the URL query is considered.

If you decide to use hit and invalidation parameters for a content group, configure the parameters when you configure the content group.

Note: Citrix recommends that you use selectors rather than parameterized content groups, because selectors are more flexible and can be adapted to more types of data.

Configuring a Selector

A content group can use a hit selector to retrieve cache hits or use an invalidation selector to expired cached objects and fetch new ones from the origin server.

A selector contains a name and a logical expression, called an *advanced expression*.

For more information about advanced expressions, see "Policies and Expressions."

To configure a selector, you assign it a name and enter one or more expressions. As a best practice, a selector expression should include the URL stem and host, unless there is a strong reason to omit them.

To configure a selector by using the command line interface

At the command prompt, type:

add cache selector <selectorName> (<rule> ...)

For information about configuring the expression or expressions, see "To configure a selector expression by using the command line interface."

Examples

```
>add cache selector product_selector "http.req.url.query.value(\"ProductId\")" "http.req.url.query.value(\"Ba
> add cache selector batch_selector "http.req.url.query.value(\"ProductId\")" "http.req.url.query.value(\"Bat
> add cache selector product_id_selector "http.req.url.query.value(\"ProductId\")"
> add cache selector batchnum_selector "http.req.url.query.value(\"BatchNum\")" "http.req.url.query.value(
> add cache selector batchid_selector "http.req.url.query.value(\"depotLocation\")" "http.req.url.query.value
```

To configure a selector by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Cache Selectors.
2. In the details pane, click Add.
3. In the Create Cache Selector dialog box, in the Name text box, type the name of the selector (for example, myDatabase_hitSelector).
4. In the Expressions box, enter the expression that you want to use for matching items in the cache (as described in “To configure a policy or selector expression by using the configuration utility”).
5. Click Create, and then click Close.

Parameter Descriptions (of commands listed in the CLI procedure)

add cache selector

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

About Content Groups

A content group is a container for cached objects that can be served in a response. When you first enable the integrated cache, cacheable objects are stored in a content group named Default. You can create new content groups that have unique properties. For example, you can define separate content groups for image data, bug reports, and stock quotes, and you can configure the stock quote content group to be refreshed more often than the other groups.

You can configure expiration of an entire content group or selected entries in a content group.

The data in a content group can be static or dynamic, as follows:

- **Static content groups**. Finds an exact match between the URL stem and host name on the request and the URL stem and host name of the response.
- **Dynamic content groups**. Looks for objects that contains particular parameter-value pairs, arbitrary strings, or string patterns. Dynamic content groups are useful when caching data that is updated frequently (for example, a bug report or a stock quote).

Process overview: Serving a hit from a content group

1. A user enters search criteria for an item, such as a bug report, and clicks the Find button in an HTML form.
2. The browser issues one or more HTTP GET requests. These requests contain parameters (for example, the bug owner, bug ID, and so on).
3. When the NetScaler appliance receives the requests, it searches for a matching policy, and if it finds a caching policy that matches these requests, it directs the requests to a content group.
4. The content group looks for appropriate objects in the content group, usually based on criteria that you configure in a selector.

   For example, the content group can retrieve responses that match NameField=username and BugID=ID.
5. If it finds matching objects, the NetScaler appliance can serve them to the user's browser, where they are assembled into a complete response (for example, a bug report).

Example: Invalidating an object in a content group

1. A user modifies data (for example, the user modifies the bug report and clicks the Submit button).

2. The browser sends this data in the form of one or more HTTP requests. For example, it can send a bug report in the form of several HTTP POST requests that contain information about the bug owner and bug ID.

3. The NetScaler appliance matches the requests against invalidation policies. Typically, these policies are configured to detect the HTTP POST method.

4. If the request matches an invalidation policy, the NetScaler appliance searches the content group that is associated with this policy, and expires responses that match the configured criteria for invalidation.

   For example, an invalidation selector can find responses that match NameField=username and BugID=ID.

5. The next time the NetScaler appliance receives a GET request for these responses, it fetches refreshed versions from the origin server, caches the refreshed responses, and serves these responses to the user's browser, where they are assembled into a complete bug report.

Setting Up a Basic Content Group

By default, all cached data is stored in the default content group. You can configure additional content groups and specify these content groups in one or more policies.

You can configure content groups for static content, and you must configure content groups for dynamic content. You can modify the configuration of any content group, including the default group.

To set up a basic content group by using the command line interface

At the command prompt, type:

add cache contentgroup <name> (-hitSelector <hitSelectorName> -invalSelector <invalidationSelectorName> | -hitParams <hitParamName> -invalParams <invalidationParamName>) -type <type> [-relExpiry <sec> | -relExpiryMilliSec <msec>] [-heurExpiryParam <positiveInteger>]

Examples

> add cache contentgroup Products_Details –hitSelector product_selector –invalSelector id_selector
> add cache contentgroup bugrep -hitParams IssuePage RecordID Template TableId -invalParams RecordID -r

To set up a basic content group by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, do one of the following:
   - To create a new content group, click Add.
   - To modify an existing content group, select the content group, and then click Open.
3. In the Create Cache Content Group or the Configure Cache Content Group dialog box, set the relevant parameters in Expiry Method and Parameterization tabs.
4. Click Create or OK.

Parameter Descriptions (of commands listed in the CLI procedure)

add cache contentgroup

name

The name of the content group to be created

hitSelector

The selector used for hit selection.

invalSelector

The selector used for invalidation.

hitParams

Use these parameters for parameterized hit evaluation of an object. Up to 128 parameters can be configured.

invalParams

Use these parameters for parameterized invalidation of an object. Up to 8 parameters can be configured.

relExpiry

The relative expiry time in seconds Default value: VAL_NOT_SET Maximum value: 31536000

relExpiryMilliSec

The relative expiry time in milliseconds. Default value: VAL_NOT_SET Maximum value: 86400000

heurExpiryParam

The heuristic expiry time, in percent of the duration since the object was last modified Default value: VAL_NOT_SET Maximum value: 100

View description(s) in command reference Top

Expiring or Flushing Cached Objects

If a response does not have an Expires header or a Cache-Control header with an expiration time (Max-Age or Smax-Age), you must expire objects in a content group by using one of the following methods:

- Configure content group expiration settings to determine whether and how long to keep the object.
- Configure an invalidation policy and action for the content group. For more information, see "Configuring Policies for Caching and Invalidation."
- Expire the content group or objects within it manually.

After a cached response expires, the NetScaler appliance refreshes it the next time the client issues a request for the response. By default, when the cache is full, the NetScaler appliance replaces the least recently used response first.

The following list describes methods for expiring cached responses using settings for a content group. Typically, these methods are specified as a percent or in seconds:

- **Manual**. Manually invalidate all responses in a content group or all responses in the cache.
- **Response-based**. Specific expiration intervals for positive and negative responses. Response-based expiry is considered only if the Last-Modified header is missing in the response.
- **Heuristic expiry**. For responses that have a Last-Modified header, heuristic expiry is a percentage of the time since the response was modified (calculated as current time minus the Last-Modified time, multiplied by the heuristic expiry value). For example, if a Last-Modified header indicates that a response was updated 2 hours ago, and the heuristic expiry setting is 10%, cached objects expire after 0.2 hours. This method assumes that frequently updated responses need to be expired more often.
- **Absolute or relative**. Specify an exact (absolute) time when the response expires every day, in HH:MM format, local time or GMT. Local time may not work in all time zones.

  Relative expiration specifies a number of seconds or milliseconds from the time a cache miss causes a trip to the origin server to the expiration of the response. If you specify relative expiration in milliseconds, enter a multiple of 10. This form of expiration works for all positive responses. Last-Modified, Expires, and Cache-Control headers in the response are ignored.

  Absolute and relative expiration override any expiration information in the response itself.
- **On download**. The option Expire After Complete Response Received expires a response as soon as it is downloaded. This is useful for frequently updated responses, for example, stock quotes. By default, this option is disabled.

Enabling both Flash Cache and Expire After Complete Response Received accelerates the performance of dynamic applications. When you enable both options, the NetScaler appliance fetches only one response for a block of simultaneous requests.

For more information, see "Queuing Requests to the Cache."

- **Pinned**. By default, when the cache is full the NetScaler appliance replaces the least recently used response first. The NetScaler appliance does not apply this behavior to content groups that are marked as pinned.

If you do not configure expiration settings for a content group, the following are additional options for expiring objects in the group:

- Configure a policy with an INVAL action that applies to the content group.
- Enter the names of content groups when configuring a policy that uses an INVAL action.

How Expiration Methods Are Applied

Expiration works differently for positive and negative responses. Positive and negative responses are described in the table, *Expiration of Positive and Negative Responses* mentioned below.

The following are rules of thumb for understanding the expiration method that is applied to a content group:

- You can control whether the NetScaler appliance evaluates response headers when deciding whether to expire an object.
- Absolute and relative expiration cause the NetScaler appliance to ignore the response headers (they override any expiration information in the response).
- Heuristic expiration settings and “Weak Positive” and “Weak Negative” expiration (labeled as **Default** values in the configuration utility) cause the NetScaler appliance to examine the response headers. These settings work together as follows:
  - The value in an Expires or Cache-Control header overrides these content group settings.
  - For positive responses that lack an Expires or Cache-Control header but have a Last-Modified header, the NetScaler appliance compares heuristic expiration settings with the header value.
  - For positive responses that lack an Expires, Cache-Control, or Last-Modified header, NetScaler appliance uses the “weak positive” value.
  - For negative responses that lack an Expires or Cache-Control header, NetScaler appliance uses the “weak negative” value.

For a list of expiration parameters see, "Configuring Periodic Expiration of a Content Group." The following table describes how these methods are applied.

Table 1. Expiration of Positive and Negative Responses

Response Type	Expiration Header Type	Content Group Setting	Period the Object Remains in the Cache
Positive	any header	Expire Content After (relExpiry) with no other settings	Use the value of the Expire Content After setting.
Positive	any header	Expire Content At (absExpiry) with no other settings	Subtract current date from the value of the Expire Content At setting.
Positive	any header	Expire Content After (relExpiry) and Expire content at (absExpiry)	Use the smaller of the two values for the content group settings. See the previous rows in this table.
Positive	Last-Modified (with any other headers)	Heuristic (heurExpiry Param) with any other setting	Subtract the Last-Modified date from the current date, multiply the result by the value of the heuristic expiry setting, and then divide by 100.
Positive	Last-Modified (with any other headers)	Default (positive) (weakPosRel Expiry) and no other setting	Use the value of the Default (positive) expiry setting.
Positive	Expires or Cache-Control: Max-Age header is present Last-Modified header is absent	Heuristic (heurExpiry Param), Default (positive) (weakPosRel Expiry), or both	Subtract the current date from the Expires or the Cache-Control:Max-Age date.
Positive	no caching headers	Default (positive) (weakPosRel Expiry) and any other expiration setting.	Use the value of the Default (positive) setting.

Positive	no caching headers	Heuristic (heurExpiry Param) is present Default (positive) (weakPosRel Expiry) setting is absent	If the Last-Modified header is absent, the response is not cached or it is cached with an Already Expired status. If the Last-Modified header is present, use the heuristic expiry value.
Negative	Expires or Cache-Control:Max-Age	Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings	Subtract the current date from the value of the Expires header, or use the value of the Cache-Control:Max-Age header.
Negative	Expires or Cache-Control headers are absent	Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings	Response is not cached, or is cached with an Already Expired status.
Negative	Expires or Cache-Control:Max-Age	Any setting	Subtract the current date from the Expires or Cache-Control:Max-Age date.
Negative	Expires and Cache-Control:Max-Age headers are absent	Default (negative) (weakNegRel Expiry)	Use the value of the Default (negative) setting.
Negative	Expires and Cache-Control:Max-Age headers are absent	Any setting other than Default (negative) (weakNegRel Expiry)	Object is not cached or is cached with an Already Expired status.

Expiring a Content Group Manually

You can manually expire all of the entries in a content group.

To manually expire all responses in a content group by using the command line interface

At the command prompt, type:

expire cache contentGroup <name>

To manually expire all responses in a content group by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, click the content group that you want to invalidate, and click Invalidate.
3. In the Invalidate Selected Cache Content Group dialog box, click Expire, and then click OK.

To manually expire all responses in the cache by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, click Invalidate All.
3. In the Invalidate All Content Groups dialog box, click Expire All, and then click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

expire cache contentGroup

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Periodic Expiration of a Content Group

You can configure a content group so that it performs selective or full expiration of its entries. The expiration interval can be fixed or relative.

To configure content group expiration by using the command line interface

At the command prompt, type:

set cache contentgroup <name> (-relExpiry|-relExpiryMilliSec|-absExpiry|-absExpiryGMT|-heurExpiryParam|-weakPosRelExpiry|-weakNegRelExpiry| -expireAtLastBye) <expirationValue>

To configure content group expiration by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, click the content group for which you want to set the heuristic expiry parameter, and then click Open.
3. In the Configure Cache Content Group dialog box, on the Expiry Method tab, specify values for the relevant parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
4. Click Create.

Expiring Individual Responses

Expiring a response forces the NetScaler appliance to fetch a refreshed copy from the origin server. Responses that do not have validators, for example, ETag or Last-Modified headers, cannot be revalidated. As a result, flushing these responses has the same effect as expiring them.

To expire a cached response in a content group for static data, you can specify a URL that must match the stored URL. If the cached response is part of a parameterized content group, you must specify the group name as well as the exact URL stem. The host name and the port number must be the same as in the host HTTP request header of the cached response. If the port is not specified, port 80 is assumed.

To expire individual responses in a content group by using the command line interface

At the command prompt, type:

expire cache object -url <URL> -host <hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET|POST]

To expire individual responses in a content group by using the command line interface (selector-based)

At the command prompt, type the following command:

expire cache object -locator <positiveInteger>

To expire a cached response by using the configuration utility

1. View the cached response. For more information, see "Displaying Cached Objects and Cache Statistics."
2. Click the response you want to expire.
3. Click Expire.

To expire a response by using the Lookup tool (selector-based)

1. Find the response that you want to expire. For more information, see "Finding Particular Cached Responses."
2. Click Expire.

Flushing Responses in a Content Group

You can remove, or flush, all responses in a content group, some responses in a group, or all responses in the cache. Flushing a cached response frees up memory for new cached responses.

Note: To flush responses for more than one object at a time, use the configuration utility method. The command line interface does not offer this option.

To flush responses from a content group by using the command line interface

At the command prompt, type:

flush cache contentGroup <name> [-query <queryString> | [-selectorValue <selectorExpressionIDList> -host <hostName>]]

To flush responses from a content group by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In details pane, flush the responses as follows:
   - To flush all responses in all content groups, click Invalidate All. In the Invalidate All Content Groups, click Flush All.
   - To flush responses in a particular content group, select the content group that you want to invalidate, and then click Invalidate. In the Invalidate Selected Cache Content Group dialog box, click Flush.
3. Click OK, and then click Close.

Note: If this content group uses a selector, you can selectively flush responses by entering a string in the Selector value text box, entering a host name in the Host text box. Then click Flush and OK. The Selector value can be a query string of up to 2319 characters that is used for parameterized invalidation.

If the content group uses an invalidation parameter, you can selectively flush responses by entering a string in the Query field.

If the content group uses an invalidation parameter and Invalidate objects belonging to target host is configured, enter strings in the Query and Host fields.

To flush a cached response by using the command line interface

At the command prompt, type:

flush cache object -locator <positiveInteger> | -url <URL> -host <hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET|POST]

To flush a cached response by using the configuration utility

1. Find the cached response. For more information, see "Configuring Global Attributes for Caching."
2. Select the response that you want to expire.
3. Click Flush.

Deleting a Content Group

You can remove a content group if it is not used by any policy that stores responses in the cache. If the content group is bound to a policy, you must first remove the policy. Removing the content group removes all responses stored in that group.

You cannot remove the Default, BASEFILE, or Deltajs group. The Default group stores cached responses that do not belong in any other content group.

To delete a content group by using the command line interface

At the command prompt, type:

rm cache contentgroup<name>

To delete a content group by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and click Content Groups.
2. In the details pane, click the content group name that you want to remove, and click Remove.
3. In the Remove message box, click Yes.

Parameter Descriptions (of commands listed in the CLI procedure)

set cache contentgroup

name

The name of the content group whose attibutes will be changed.

relExpiry

The relative expiry time in seconds. Default value: VAL_NOT_SET Maximum value: 31536000

relExpiryMilliSec

The relative expiry time in milliseconds. Default value: VAL_NOT_SET Maximum value: 86400000

absExpiry

Expiry time for all objects in the content group(up to 4 times a day [local time]).

absExpiryGMT

Expiry time for all objects in the content group(up to 4 times a day [GMT]).

weakPosRelExpiry

Responses with response codes between 200 and 399. (Similar to -relExpiry, but has lesser precedence.) Maximum value: 31536000

weakNegRelExpiry

All negative responses. This value is used only if the expiry time cannot be determined from any other source. Maximum value: 31536000

View description(s) in command reference Top

expire cache object

url

The URL of the object to be expired.

host

The host of the object to be expired.

port

The host port of the object to be expired. Default value: 80 Minimum value: 1

groupName

The name of the content group to be in which the cell is present.

httpMethod

The HTTP request method that caused the object to be stored. Possible values: GET, POST Default value: NS_HTTP_METHOD_GET

locator

The id of the cached object.

View description(s) in command reference Top

flush cache contentGroup

name

The name of the content group whose objects are to be flushed.

query

If a query string is specified, then the selected objects in this group will be flushed using parameterized invalidation. Otherwise, all objects in the group will be flushed.

selectorValue

The value of the selector to be used for flushing objects in the contentgroup.

host

To be set only if parameterized invalidation is being done. Objects belonging only to the specified host will be flushed. The host argument can be provided if and only if -invalRestrictedToHost is set to YES for the given group.

View description(s) in command reference Top

flush cache object

locator

The ID of the cached object.

url

The URL of the object to be flushed.

host

The host of the object to be flushed.

port

The host port of the object to be flushed. Default value: 80 Minimum value: 1

groupName

The name of the content group to be in which the cell is present.

httpMethod

The HTTP request method that caused the object to be stored. Possible values: GET, POST Default value: NS_HTTP_METHOD_GET

View description(s) in command reference Top

rm cache contentgroup

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Policies for Caching and Invalidation

Policies enable the integrated cache to determine whether to try to serve a response from the cache or the origin. The Citrix NetScaler appliance provides built-in policies for integrated caching, and you can configure additional policies. When you configure a policy, you associate it with an action. An action either caches the objects to which the policy applies or invalidates (expires) the objects. Typically, you based caching policies on information in GET and POST requests. You typically base invalidation policies on the presence of the POST method in requests, along with other information. You can use any information in a GET or POST request in a caching or an invalidation policy.

You can view some of the built-in policies in the integrated cache's Policies node in the configuration utility. The built-in policy names begin with an underscore (_).

Actions determine what the NetScaler appliance does when traffic matches a policy. The following actions are available:

- **Caching actions**. Policies that you associate with the CACHE action store responses in the cache and serve them from the cache.
- **Invalidation actions**. Policies that you associate with the INVAL action immediately expire cached responses and refresh them from the origin server. Note that for Web-based applications, invalidation policies often evaluate POST requests.
- **"Do not cache" actions**. Policies that you associate with a NOCACHE action never store objects in the cache.
- **"Provisionally cache" actions**. Policies that you associate with a MAYCACHE or MAYNOCACHE action depend on the outcome of additional policy evaluations.

Although the integrated cache does not store objects specified by the LOCK method, you can invalidate cached objects upon receipt of a LOCK request. For invalidation policies only, you can specify LOCK as a method by using the expression `http.req.method.eq("lock")`. Unlike policies for GET and POST requests, you must enclose the LOCK method in quotes because the NetScaler appliance recognizes this method name as a string only.

After you create a policy, you bind it to a particular point in the overall processing of requests and responses. Although you create a policy before binding it, you should understand how the bind points affect the order of processing before you create your policies.

The policies bound to a particular bind point constitute a policy bank. You can use goto expressions to modify the order of execution in a policy bank. You can also invoke policies in other policy banks. In addition, you can create labels and bind policies to them. Such a label is not associated with a processing point, but the policies bound to it can be invoked from other policy banks.

Actions to Associate with Integrated Caching Policies

The following table describes actions for integrated caching policies.

Table 1. Actions That You Can Associate with an Integrated Caching Policy

Action	Specifies
CACHE	Serves a response from the cache if the response has not expired. If the response must be fetched from the origin server, the NetScaler appliance caches the response before serving it. Even data that is updated and accessed frequently can be cached. For example, stock quotes are updated frequently, but they can be cached so that they can be served quickly to multiple users. If necessary, cached data can be refreshed immediately after it is downloaded. A CACHE action can be overridden by built-in policies.
NOCACHE	Always fetches the response from the origin server and marks the response as non-storable. You typically configure NOCACHE policies for data that is sensitive or personalized.
MAY_CACHE	Used in a request-time policy, this setting provisionally enables a response to be stored in a content group, pending evaluation of response-time policies. The following are possible: · If a matching response-time policy has a CACHE action but does not specify a content group, the response is stored in the Default group unless built-in policies override this policy. · If a matching response-time policy has a CACHE action and specifies the same content group as the one in the request-time policy, the response is stored in the named content group unless built-in policies override this policy. · If a matching response-time policy has a CACHE action but specifies a different content group from the one in the request-time policy, a NOCACHE action is applied. · If a matching response-time policy has a NOCACHE action, perform a NOCACHE action. · If there is no matching response-time policy, a CACHE action is applied, unless a built-in policy overrides this policy.

MAY_NOCACHE	For a request-time policy, this setting provisionally prevents caching the response. At response time, one of following actions is taken: · If no response-time policy matches the request, the final action is NOCACHE. · If a matching response-time policy contains a CACHE action, the final action is CACHE, unless built-in policies override this policy. · If a matching response-time policy contains a NOCACHE action, the final action is NOCACHE. · If a matching response-time policy has a CACHE action but does not specify a content group, the final action is to CACHE the response in the Default content group, unless built-in policies override this policy.
INVAL	Expires cached responses. Depending on how the policy and the content group are configured, all responses in one or more content groups are expired, or selected objects in the content group are expired. **Note:** You can specify INVAL actions in request-time policies only.

Bind Points for a Policy

You can bind the policy to one of the following bind points:

- **A global policy bank**. These are the request-time default, request-time override, response-time default, and response-time override policy banks, as described in "Order of Policy Evaluation."
- **A virtual server**. Policies that you bind to a virtual server are processed after the global override policies and before the global default policies, as described in "Order of Policy Evaluation." Note that when binding a policy to a virtual server, you bind it to either request-time or response-time processing.
- **An ad-hoc policy label**. A policy label is a name assigned to a policy bank. In addition to the global labels, the integrated cache has two built-in custom policy labels:
  - **_reqBuiltinDefaults**. This policy label, by default, is invoked from the request-time default policy bank.
  - **_resBuiltinDefaults**. This policy label, by default, is invoked from the response-time default policy bank.

  You can also define new policy labels. Policies bound to a user-defined policy label must be invoked from within a policy bank for one of the built-in bind points. For more information about creating a policy label, see "Configuring a Policy Label in the Integrated Cache." For more information about policy label invocation, see "Configuring a Policy Bank for Caching."

Important: You should bind a policy with an INVAL action to a request-time override or a response-time override bind point. To delete a policy, you must first unbind it.

Order of Policy Evaluation

For an advanced policy to take effect, you must ensure that the policy is invoked at some point during the NetScaler appliance's processing of traffic. To specify the invocation time, you associate the policy with a bind point. The following are the bind points, listed in order of evaluation:

- **Request-time override**. If a request matches a request-time override policy, by default request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Request-time load balancing virtual server**. If policy evaluation cannot be completed after all the request-time override policies are evaluated, the NetScaler appliance processes request-time policies that are bound to load balancing virtual servers. If the request matches one of these policies, evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Request-time content switching virtual server**. Policies that are bound to this bind point are evaluated after request-time policies that are bound to load balancing virtual servers.

- **Request-time default**. If policy evaluation cannot be completed after all request-time, virtual server-specific policies are evaluated, the NetScaler appliance processes request-time default policies. If the request matches a request-time default policy, by default request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.

- **Response-time override**. Similar to request-time override policy evaluation.

- **Response-time load balancing virtual server**. Similar to request-time virtual server policy evaluation.

- **Response-time content switching virtual server**. Similar to request-time virtual server policy evaluation.

- **Response-time default**. Similar to request-time default policy evaluation.

You can associate multiple policies with each bind point. To control the order of evaluation of the policies associated with the bind point you configure a priority level. In the absence of any other flow control information, policies are evaluated according to priority level, starting with the lowest numeric priority value.

After all integrated caching policies have been evaluated, if there are conflicting actions specified in request-time and response-time policies, the NetScaler appliance determines the final action as specified in the table, "Actions That You Can Associate with an Integrated Caching Policy."

Note: Request-time policies for POST data or cookie headers must be invoked during request-time override evaluation, because the built-in request-time policies in the integrated cache return a NOCACHE action for POST requests and a MAY_NOCACHE action for requests with cookies. Note that you would associate MAY_CACHE or MAY_NOCACHE actions with a request-time policy that points to a parameterized content group. The response time policy determines whether the transaction is stored in the cache.

Configuring a Policy in the Integrated Cache

You configure new policies to handle data that the built-in policies cannot process. You configure separate policies for caching, preventing caching from occurring, and for invalidating cached data. Following are the main components of a policy for integrated caching:

- Rule: A logical expression that evaluates an HTTP request or response.
- Action: You associate a policy with an action to determine what to do with a request or response that matches the policy rule.
- Content groups: You associate the policy with one or more content groups to identify where the action is to be performed.

To configure a policy for caching by using the command line interface

At the command prompt, type:

add cache policy <policyName> -rule <expression> -action CACHE|MAY_CACHE|NOCACHE|MAY_NOCACHE [-storeInGroup <contentGroupName>] [-undefAction NOCACHE|RESET]

Examples

> add cache policy image_cache -rule "http.req.url.contains(\"jpg\") || http.req.url.contains(\"jpeg\")" -actio
> add cache policy bugReportPolicy -rule "http.req.url.query.contains(\"IssuePage\")" -action CACHE -storeIn
> add cache policy my_form_policy -rule "http.req.header(\"Host\")contains(\"my.company.com\") && http.re
> add cache policy viewproducts_policy –rule "http.req.url.contains(\"viewproducts.aspx\")" –action CACHE -s

To configure a policy for invalidation by using the command line interface

At the command prompt, type:

add cache policy <policyName> -rule <expression> -action INVAL [-invalObjects "<contentGroupName1>[,<selectorName1>"]. . .]] | [-invalGroup <contentGroupName1>[, <contentGroupName2>. . .]] [-undefAction NOCACHE|RESET]

Examples

```
> add cache policy invalidation_events_policy -rule "http.req.header(\"Host\")contains(\"my.company.com\")
> add cache policy inval_all -rule "http.req.method.eq(\"POST\") && http.req.url.contains(\"jpeg\")" -action I
> add cache policy bugReportInvalidationPolicy -rule "http.req.url.query.contains(\"TransitionForm\")" -actio
> add cache policy editproducts_policy –rule "http.req.url.contains(\"editproducts.aspx\")" –action INVAL -inv
```

To configure a policy for caching or invalidation by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Policies.
2. In the details pane, do one of the following:
   - To create a new policy for caching or invalidation, click Add.
   - To modify an existing policy for caching or invalidation, select the policy, and then click Open.
3. In the Create Cache Policy or Configure Cache Policy dialog box, specify values for the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
   - Name
   - Action
   - Store in Group
   - Undefined-Result Action
   - Expression
   - Invalidate all objects in the following groups
   - Invalidate selected objects in the following parameterized groups
4. Click Create, and then click Close.

Parameter Descriptions (of commands listed in the CLI procedure)

add cache policy

policyName

The name of the new Integrated Cache policy.

rule

The request/response rule that will trigger the given action. The only actions you can specify with a request rule are: MAY_CACHE, MAY_NOCACHE, and INVAL. You specify a rule using a single expression or a logical combination of expressions (called a compound

expression). You can combine xpressions using the && and || operators. For more information on creating expressions, refer to the add expression CLI command. Note: If a compound expression contains blanks (for example, between an expression name and a logical operator), then the entire argument must be enclosed in double quotes. The following are examples of valid expressions: ns_ext_cgi||ns_ext_asp "ns_non_get && (ns_header_cookie||ns_header_pragma)"

action

The integrated cache action to be applied when the system finds content that matches the rules. Possible values: CACHE, NOCACHE, MAY_CACHE, MAY_NOCACHE, INVAL

storeInGroup

The content group where the object will be stored when the action directive is CACHE

undefAction

A CACHE action, which is used by the policy when the rule evaluation is undefined. The undef action can be NOCACHE or RESET. Possible values: NOCACHE, RESET

invalObjects

The content group(s) where the objects will be invalidated when the action directive is INVAL

View description(s) in command reference Top

Globally Binding an Integrated Caching Policy

When you globally bind a policy, it is available to all virtual servers on the NetScaler appliance.

To bind an integrated caching policy globally by using the command line interface

At the command prompt, type:

bind cache global <policy> -priority <positiveInteger> [-type REQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT] [-gotoPriorityExpression <expression>] [-invoke <labelType> <labelName>]

Example

> bind cache global myCachePolicy -priority 100 -type req_default

Note that the type argument is optional for globally bound policies, to maintain backward compatibility with policies that you defined using earlier versions of the NetScaler appliance. If you omit the type, the policy is bound to REQ_DEFAULT or RES_DEFAULT, depending on whether the policy rule is a response-time or a request-time expression. If the rule contains both request time and response time parameters, it is bound to RES_DEFAULT. Following is an example of a binding that omits the type.

> bind cache global myCache Policy 200

To bind an integrated caching policy globally by using the configuration utility

1. In the navigation pane, click Integrated Caching.
2. In the details pane, click Cache policy manager.
3. In the Cache Policy Manager dialog box, select a Request or Response bind point, and then select a second level of binding of either Override Global or Default Global. A list of policies appears. These are policies that are bound to this bind point.
4. Click Insert Policy and do one of the following:
   - To configure a new policy, click New Policy and configure the new policy as described in "Configuring a Policy in the Integrated Cache."
   - To bind an existing policy, click the name of the policy.
5. Drag and drop the policy to the position in the policy bank where you want it to be evaluated, or manually enter a priority level, as a positive integer, for this entry in the Priority field.
6. Optionally, to configure a Goto expression as described in the "Policies and expressions", double-click the field in the Goto Expression column, and enter valid priority level, the keywords NEXT or END, or an advanced expression. See "Entries to Control Evaluation Flow in a Policy Bank" for details.
7. Optionally, to invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you are adding (a global label or a virtual server bank). In the Invoke Name field, enter the label or virtual server name. See "Entries to Control Evaluation Flow in a Policy Bank" for details.
8. Click Apply Changes.

Parameter Descriptions (of commands listed in the CLI procedure)

bind cache global

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Binding an Integrated Caching Policy to a Virtual Server

When you bind a policy to a virtual server, it is available only to requests and responses that match the policy and that flow through the relevant virtual server.

When using the configuration utility, you can bind the policy using the configuration dialog box for the virtual server. This enables you to view all of the policies from all NetScaler modules that are bound to this virtual server. You can also use the Policy Manager configuration dialog for the integrated cache. This enables you to view only the integrated caching policies that are bound to the virtual server.

To bind an integrated caching policy to a virtual server by using the command line interface

At the command prompt, type:

- bind lb vserver <name>@ -policyName <policyName> -priority <positiveInteger> -type (REQUEST|RESPONSE)
- bind cs vserver <name>@ -policyName <policyName> -priority <positiveInteger> -type (REQUEST|RESPONSE)

To bind an integrated caching policy to a virtual server by using the configuration utility (virtual server method)

1. In the navigation pane, expand the module where you want to bind the caching policy, and then click Virtual Servers. This must be a module in which you can configure virtual servers. The choices are Load Balancing or Content Switching.

2. In the details pane, double-click the name of the virtual server with which you want to associate a policy for Integrated Caching, and then click Open.

3. In the Configure Virtual Server dialog box, click the Policies tab. In the list of policies in this dialog box, Integrated Caching policies can be identified in the Type column by the label Cache. Click the Active check box for the Integrated Caching policy that you want to bind to this bind point.

4. To configure a priority for the policy, double-click the value in the Priority field and enter a new positive integer value. The lower the value, the earlier the policy is evaluated.

5. In the Flow Type field for this entry, select Request or Response.

6. Click OK.

To bind an integrated caching policy to a virtual server by using the configuration utility (Policy Manager method)

1. In the navigation pane, click Integrated Caching.
2. In the details pane, click Cache policy manager.
3. In the Cache Policy Manager dialog box, select a Request or Response bind point, select a second level of binding of either LB Virtual Server or CS Virtual Server, and then select the name of a virtual server. A list of policies appears. These are integrated caching policies that are bound to this virtual server.
4. Click Insert Policy and do one of the following:
   - To configure a new policy, click New Policy and configure the new policy as described in "Configuring a Policy in the Integrated Cache."
   - To bind an existing policy, click the name of the policy.
5. Drag and drop the policy to the position in the policy bank where you want it to be evaluated, or manually enter a priority level, as a positive integer, for this entry in the Priority field.
6. Optionally, configure a Goto expression as described in "Configuring a Policy Bank for Caching."
7. Optionally, to invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you are adding (a global label or a virtual server bank). In the Invoke Name field, enter the label or virtual server name. See "Entries to Control Evaluation Flow in a Policy Bank."
8. Click Apply Changes.

Parameter Descriptions (of commands listed in the CLI procedure)

bind lb vserver

policyName

The SureConnect/priority queuing/Compression/AppSecure/Transform/Filter/Authorization/Rewrite/Responder/Cache/Syslog/Nslog/TMTraffic policy that needs to be bound to the specified load balancing virtual server for SureConnect or priority queuing to be activated on a load balancing virtual server.

View description(s) in command reference Top

bind cs vserver

policyName

The content switch policy name (created with the add cs policy command).

View description(s) in command reference Top

Example: Caching Compressed and Uncompressed Versions of a File

By default, a client that can handle compression can be served uncompressed responses or compressed responses in gzip, deflate, compress, and pack200-gzip format. If the client handles compression, an Accept-Encoding:compression format header is sent in the request. The compression type accepted by the client must match the compression type of the cached object. For example, a cached .gzip file cannot be served in response to a request with an Accept-Encoding:deflate header.

A client that cannot handle compression is served a cache miss if the cached response is compressed.

For dynamic caching, you need to configure two content groups, one for compressed data and one for uncompressed versions of the same data. The following is an example of configuring the selectors, content groups, and policies for serving uncompressed files from the cache to clients that cannot handle compression, and serving compressed versions of the same files to client that can handle compression.

```
add cache selector uncompressed_response_selector http.req.url "http.req.header(\"Host\")"
add cache contentGroup uncompressed_group -hitSelector uncompressed_responst_selector -invalSelector u
add cache policy cache_uncompressed -rule "HTTP.REQ.URL.CONTAINS(\"xyz\") && !HTTP.REQ.HEADER(\"Acc
bind cache global cache_uncompressed -priority 100 -gotoPriorityExpression END -type REQ_OVERRIDE
add cache selector compressed_response_selector HTTP.REQ.URL "HTTP.REQ.HEADER(\"Host\")" "HTTP.REQ.H
add cache contentGroup compressed_group -hitSelector compressed_response_selector
add cache policy cache_compressed -rule "HTTP.REQ.URL.CONTAINS(\"xyz\") && HTTP.REQ.HEADER(\"Accept
bind cache global cache_compressed -priority 200 -gotoPriorityExpression END -type REQ_OVERRIDE
```

Configuring a Policy Bank for Caching

All of the policies that are associated with a particular bind point are collectively known as a policy bank. In addition to configuring priority levels for policies in a bank, you can modify the order of evaluation order in a bank by configuring Goto expressions. You can further modify the evaluation order by invoking an external policy bank from within the current policy bank. You can also configure new policy banks, to which you assign your own labels. Because such policy banks are not bound to any point in the processing cycle, they can be invoked only from within other policy banks. For convenience, policy banks whose labels do not correspond to a built-in bind point are called policy labels.

In addition to controlling order of policy evaluation by binding the policy and assigning a priority level, as described in "Binding Policies That Use the Default Syntax", you can establish the flow within a bank of policies by configuring a Goto expression. A Goto expression overrides the flow that is determined by the priority levels. You can also control the evaluation flow by invoking an external policy bank after evaluating an entry in the current bank. Evaluation always returns to the current bank after evaluation has completed for the external bank.

The following table summarizes the entries to control evaluation in a policy bank.

Table 1. Entries to Control Evaluation Flow in a Policy Bank

Attribute	Specifies
Name	The name of a policy, or, to invoke another policy bank without evaluating the policy, the keyword NOPOLICY. You can specify NOPOLICY more than once in a policy bank, but you can specify a named policy only once.
Priority	An integer. The lower the integer, the higher the priority.

Goto Expression	Determines the next policy or policy bank to evaluate. You can provide one of the following values: · **NEXT**: Go to the policy with the next higher priority. · **END**: Stop evaluation. · **USE_INVOCATION_RESULT**: Applicable if this entry invokes another policy bank. If the final Goto in the invoked bank has a value of END, evaluation stops. If the final Goto is anything other than END, the current policy bank performs a NEXT. · **Positive number**: Priority number of the next policy to be evaluated. · **Numeric expression**: Expression that produces the priority number of the next policy to be evaluated. The Goto can only proceed forward in a policy bank. Omitting the Goto expression is the same as specifying END.
Invocation Type	Designates a policy bank type. The value can be one of the following: · **Request Vserver**: Invokes request-time policies that are associated with a virtual server. · **Response Vserver**: Invokes response-time policies that are associated with a virtual server. · **Policy label**: Invokes another policy bank, as identified by the policy label for the bank.
Invocation Name	Name of a virtual server or a policy label, depending on the value that you specified for the Invocation Type.

The integrated cache has two built-in policy labels, and you can configure additional policy labels:

- **_reqBuiltInDefaults**: This policy label is invoked from the request-time default bind point.
- **_resBuiltInDefaults**: This policy label is invoked from the response-time default bind point.

Note: For information about creating policy labels, see " Configuring a Policy Label in the Integrated Cache."

To invoke a policy label in a caching policy bank by using the command line interface

At the command prompt, type:

bind cache policylabel <labelName> -policname<policyName> -priority<priority> [-gotoPriorityExpression <gotopriorityExpression>] [-invoke <labelType> <labelName>]

To invoke a policy label in a caching policy bank by using the configuration utility

1. In the navigation pane, click Integrated Caching.
2. In the details pane, click Cache policy manager.
3. In the Cache Policy Manager dialog box, select a Request or Response bind point, and then select a second level of binding of either Override Global or Default Global. A list of policies appears. These are policies that are bound to this bind point.
4. If you want to invoke a policy label without evaluating a policy, select Insert Policy and select the keyword NOPOLICY.

   If you want to invoke a policy label after processing a policy, skip this step.
5. To invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name field, enter the label or virtual server name. See "Entries to Control Evaluation Flow in a Policy Bank" for details.
6. Click Apply Changes.

To invoke a caching policy label in a virtual server policy bank by using the command line interface

At the command prompt, type:

- bind lb vserver <name>@ -policyName <policyName>|<NOPOLICY-CACHE> -priority <positiveInteger> -gotoPriorityExpression <expression> -type REQUEST|RESPONSE -invoke <labelType> <labelName>
- bind cs vserver <name> -policyName <policyName>|<NOPOLICY-CACHE> -priority <positiveInteger> -gotoPriorityExpression <expression> -type REQUEST|RESPONSE -invoke <labelType> <labelName>

For more information, see "Entries to Control Evaluation Flow in a Policy Bank."

To invoke a caching policy label in a virtual server policy bank by using the configuration utility

1. In the navigation pane, click Load Balancing or Content Switching, as appropriate, and then click Virtual Servers.

2. Double-click the virtual server where you want to configure the policy bank, and in the Configure Virtual Server dialog box, click the Policies tab.

3. If you are configuring an existing entry in this bank, skip this step. If you are adding a new policy to this policy bank, or you want to use the “dummy” NOPOLICY entry, click Add Policy, and do one of the following:

   - To configure a new policy, click Cache and configure the new policy as described in "Configuring a Policy in the Integrated Cache."

   - To invoke a policy bank without processing a policy a rule, select the NOPOLICY-CACHE option.

   After configuring the new entry, it appears at the bottom of the list of entries with the name of the policy in the Policy Name field.

4. To bind the entry to this policy label, ensure the Active check box is selected.

5. Enter a priority level for this entry in the Priority field. The priority is a positive integer.

6. Optionally, to configure a Goto Expression, double-click the field in the Goto Expression column, and enter valid priority number, the keyword NEXT or END, or an advanced expression. For more information, see "Entries to Control Evaluation Flow in a Policy Bank."

7. To invoke another policy bank, click the field in the Invoke Type column, and select the type of policy bank that you are adding (a global label or a virtual server bank). In the Invoke Name field enter the label or virtual server name. When you are done, click OK. For more information, see "Entries to Control Evaluation Flow in a Policy Bank."

Parameter Descriptions (of commands listed in the CLI procedure)

bind cache policylabel

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind lb vserver

policyName

The SureConnect/priority queuing/Compression/AppSecure/Transform/Filter/Authorization/Rewrite/Responder/Cache/Syslog/Nslog/TMTraffic policy that needs to be bound to

the specified load balancing virtual server for SureConnect or priority queuing to be activated on a load balancing virtual server.

View description(s) in command reference Top

bind cs vserver

policyName

The content switch policy name (created with the add cs policy command).

View description(s) in command reference Top

Configuring a Policy Label in the Integrated Cache

In addition to configuring policies in a policy bank for one of the built-in bind points or a virtual server, you can create caching policy labels and configure banks of policies for these new labels.

A policy label for the integrated cache can be invoked only from one of the bind points that you can view in the Policy Manager in the **Integrated Caching** details pane (request override, request default, response override, or response default) or the built-in policy labels _reqBuiltinDefaults and _resBuiltinDefaults. You can invoke a policy label any number of times unlike a policy, which can only be invoked once.

The configuration utility provides an option to rename a policy label. Renaming a policy label does not affect the process of evaluation of the policies bound to the label.

Note: You can use the NOPOLICY “dummy” policy to invoke any policy label from another policy bank. The NOPOLICY entry is a placeholder that does not process a rule.

To configure a policy label for caching by using the command line interface

At the command prompt, type the following command to create a policy label and verify the configuration:

- add cache policylabel <labelName> -evaluates (REQ|RES)
- show cache policylabel <labelName>

Invoke this policy label from a policy bank. For more information, see "Configuring a Policy Bank for Caching."

To configure a policy label for caching by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Policy Labels.
2. If you are configuring a new policy label, click Add. Then, in the Create Cache Policy Label dialog box, enter a name. To specify whether the policy label is invoked at request time or response time, in the Evaluates drop-down menu, select either REQ or RES, respectively.

   If you are configuring an existing label, from the Policy Labels page, double-click the label.
3. To add a policy to this policy label, click Insert Policy.
4. Optionally, you can invoke other policy labels from this policy label, as described in "Configuring a Policy Bank for Caching."
5. To ensure that the NetScaler appliance processes the policy label at the right time, you configure an invocation of this label in one of the banks that are associated with the built-in bind points, as described in "Configuring a Policy Bank for Caching."

To rename a policy label by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Policy Labels.
2. In the details pane, select the policy label that you want to rename, and then click **Rename**.
3. In the **Rename Cache Policy Label** dialog box, in **Name**, replace the existing name with the name you want.
4. Click **OK**.

Parameter Descriptions (of commands listed in the CLI procedure)

add cache policylabel

evaluates

Gives when policies bound to this label get executed. Possible values: REQ, RES, MSSQL_REQ, MSSQL_RES, MYSQL_REQ, MYSQL_RES

View description(s) in command reference Top

show cache policylabel

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Unbinding and Deleting an Integrated Caching Policy and Policy Label

You can unbind a policy from a policy bank, and you can delete it. To delete the policy, you must first unbind it. You can also remove a policy label invocation and delete a policy label. To delete the policy label, you must first remove any invocations that you have configured for the label.

You cannot unbind or delete the labels for the built-in bind points (request default, request override, response default, and response override).

To unbind a global caching policy by using the command line interface

At the command prompt, type:

unbind cache global <policy>

To unbind a virtual server-specific caching policy by using the command line interface

At the command prompt, type:

(unbind lb vserver|unbind cs vserver) <vserverName> -policyName <policyName> -type (REQUEST|RESPONSE)

To delete a caching policy by using the command line interface

At the command prompt, type:

rm cache policy <policyName>

To unbind a caching policy by using the configuration utility

1. In the navigation pane, click Integrated Caching.
2. In the details pane, click Cache policy manager.
3. In the Cache Policy Manager dialog box, select a Request or Response bind point, select a second level of binding of either LB Virtual Server or CS Virtual Server, and then select the name of a virtual server. A list of policies appears. These are integrated caching policies that are bound to this virtual server.
4. Select the caching policy you want to unbind, and then click Unbind Policy.
5. Click Close.

To delete a policy label invocation by using the configuration utility

1. In the navigation pane, click Integrated Caching.
2. In the details pane, click Cache policy manager.
3. In the Cache Policy Manager dialog box, select a Request or Response bind point, select a second level of binding of either LB Virtual Server or CS Virtual Server, and then select the name of a virtual server. A list of policies appears. These are integrated caching policies that are bound to this virtual server.
4. In the Invoke column for the policy label you want to invoke, click the drop-down list and clear the entry.
5. Click Close.

Parameter Descriptions (of commands listed in the CLI procedure)

unbind cache global

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

rm cache policy

policyName

The name of the cache policy to be removed.

View description(s) in command reference Top

Caching Support for Database Protocols

The integrated cache monitors database requests that flow through the Citrix® NetScaler® appliance and caches them as determined by the cache policies. Users have to configure the cache polices for MYSQL and MSSQL protocols, because the NetScaler does not provide any default policies for these protocols. When configuring the protocols, remember that request based policies currently support CACHE and INVAL actions, while response based policies currently support only NOCACHE action. After configuring the policies, bind them to virtual servers. MYSQL and MSSQL policies, both request and response, can be bound only to virtual servers

Before creating a cache policy, create a cache content group of type MYSQL or MSSQL. When you create a MYSQL or MSSQL cache content group, associate at least one hit selector with it. See "Setting Up a Basic Content Group" for setting up cache content groups.

The following example illustrates the procedure for configuring and verifying cache support for SQL protocols.

```
> enable feature IC
> set cache parameter -memlimit 100
> add cache selector sel1 mssql.req.query.text

> add cache contentgroup cg1  -type "MSSQL" -hitselector "sel1" -invalselector "inval_sel" -relExpiry "500" -ma
 "100"
> add cache policy cp1  -rule "mssql.req.query.command.contains(\"select\")" -action "CACHE" -storeInGroup
> add cache policy cp2  -invalObjects "cg1" -rule "mssql.req.query.text.contains(\"insert\")" -action "INVAL"
> add db user user1  -password "Pass1"
> add service svc_sql_1 10.102.147.70 mssql 64834 -healthMonitor "NO" -downstateflush "ENABLED"
> add lb vserver lb_mssql1 mssql 10.102.147.77 1433  -lbmethod "roundrobin"
> bind lb vserver lb_mssql1 svc_sql_1
> bind lb vserver lb_mssql1 -policyName cp1  -type "REQUEST" -priority "2"
> bind lb vserver lb_mssql1 -policyName cp2  -type "REQUEST" -priority "1"

> show cache selector sel1
    Name:sel1
                Expressions:
                1)mssql.req.query.text
> show cache policy cp1
                Name:cp1
    Rule:mssql.req.query.command.contains("select")
                CacheAction:CACHE
                Stored in group: cg1
                UndefAction:Use Global
              Hits:2
                Undef Hits:0
                Policy is bound to following entities
                1) Bound to:
                        REQ VSERVER lb_mssql1
                        Priority:2
                        GotoPriorityExpression: END
```

Note: The methods for reducing flash crowds, as explained in "Reducing Flash Crowds", are not supported for MYSQL and MSSQL protocols.

Configuring Expressions for Caching Policies and Selectors

A request-time expression examines data in request-time transaction, and a response-time expression examines data in a response-time transaction. In a policy for caching, if an expression matches data in a request or response, the Citrix NetScaler appliance takes the action associated with the policy. In a selector, request-time expressions are used to find matching responses that are stored in a content group.

Before configuring policies and selectors for the integrated cache, you need to know, at minimum, the host names, paths, and IP addresses that appear in HTTP request and response URLs. And you probably need to know the format of entire HTTP requests and responses. Programs such as Live HTTP Headers (http://livehttpheaders.mozdev.org/) or HTTPFox (https://addons.mozilla.org/en-US/firefox/addon/6647) can help you investigate the structure of the HTTP data that your organization works with.

Following is an example of an HTTP GET request for a stock quote program:

```
GET /quote.dll?page=dynamic&mode=data&mode=stock&symbol=CTXS&page=multi&selected=CTXS&random
Host: quotes.mystockquotes.com
User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9) Gecko/2008052906 Firefox/3.0
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8
Accept-Language: en-us,en;q=0.5
Accept-Encoding: gzip,deflate,compress,pack200-gzip
Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7
Keep-Alive: 300
Connection: keep-alive
Referer: http://quotes.mystockquotes.com/quote.dll?mode=stock&symbol=CTXS&page=multi&selected=CTX
Cookie: __qca=1210021679-72161677-10297606
```

When configuring an expression, note the following limitations:

Table 1. Restrictions on Request-Time and Response-Time Expressions

Expression Type	Restrictions
Request	Do not configure request-time expressions in a policy with a CACHE or NOCACHE action. Use MAY_CACHE or MAY_NOCACHE instead.

Response	Configure response-time expressions in caching policies only. · Selectors can use only request-time expressions. · Do not configure response-time expressions in a policy with an INVAL action. Do not configure response-time expressions in a policy with a CACHE action and a parameterized content group. Use the MAY_CACHE action.

Note: For a comprehensive discussion of advanced expressions, see "Policies and Expression."

Expression Syntax

Following are basic components of the syntax:

- Separate keywords with periods (.), as follows:

  ```
  http.req.url
  ```

- Enclose string values in parentheses and quotes, as follows:

  ```
  http.req.url.query.contains("this")
  ```

- When configuring an expression from the command line, you must escape internal quote marks (the quotes that delimit values in the expression, as opposed to the quotes that delimit the expression). One method is to use a slash, as followings:

  ```
  \"abc\"
  ```

Selector expressions are evaluated in order of appearance, and multiple expressions in a selector definition are joined by a logical AND. Unlike selector expressions, you can specify Boolean operators and modify the precedence in an advanced expression for a policy rule.

Configuring an Expression in a Caching Policy or a Selector

Note that on the command line, the syntax for a policy expression is somewhat different from a selector expression. For a comprehensive discussion of advanced expressions, see "Policies and Expressions."

To configure a policy expression by using the command line interface

1. Start the policy definition as described in "Globally Binding an Integrated Caching Policy."

2. To configure the policy rule, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

   The following is an example:

   "http.req.url.contains(\"jpg\")"

3. To add Boolean values, insert &&, ||, or ! operators.

   The following are examples:

   "http.req.url.contains(\"jpg\") || http.req.url.contains(\"jpeg\")"
   "http.req.url.query.contains(\"IssuePage\")"
   "http.req.header(\"Host\")contains(\"my.company.com\") && http.req.method.eq(\"GET\") && http.req.u

4. To configure an order of evaluation for the constituent parts of a compound

   "http.req.url.contains(\"jpg\") || (http.req.url.contains(\"jpeg\") && http.req.method.eq(\"GET\"))"

To configure a selector expression by using the command line interface

1. Start the selector definition as described in "About Content Groups."

2. To configure the selector expression, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

   The following is an example:

   "http.req.url.contains(\"jpg\")"

3. You cannot add Boolean values, insert &&, ||, or ! operators. Enter each expression element delimited in quotes. Multiple expressions in the definition are treated as a compound expression joined by logical ANDs.

   The following are examples:

   "http.req.url.query.value(\"ProductId\")" "http.req.url.query.value(\"BatchNum\")" "http.req.url.query.val

To configure a policy or selector expression by using the configuration utility

1. Start the policy or selector definition as described in "To configure a policy for caching or invalidation by using the configuration utility" or "To configure a selector by using the configuration utility."

2. Click in the Expression field.

3. Click the Prefix icon (the house) and select the first expression prefix from the drop-down list. The options are HTTP, SYS, CLIENT, and SERVER. The next set of applicable options appears in a drop-down list.

4. Double-click the next option to select it, and then type a period (.). Again, a set of applicable options appear in another drop-down list.

5. Continue selecting options until an entry field (indicated by parentheses) appears. When you see an entry field, enter an appropriate value in the parentheses. For example, if you select GT(int) (greater-than, integer format), you specify an integer in the parentheses. Text strings are delimited by quote marks. The following is an example:

   ```
   HTTP.REQ.BODY(1000).BETWEEN("this","that")
   ```

6. To insert an operator between two parts of a compound expression, click the Operators icon (the sigma), and select the operator type. The following is an example of a configured expression with a Boolean OR (signaled by double vertical bars, ||):

   ```
   HTTP.REQ.URL.EQ("www.mycompany.com")||HTTP.REQ.BODY(1000).BETWEEN("this","that")
   ```

7. To insert a named expression, click the down arrow next to the Add icon (the plus sign) and select a named expression. For more information about named expressions, see "Policies and Expressions."

8. To configure an expression using drop-down menus, and to insert built-in expressions, click the Add icon (the plus sign). The Add Expression dialog box works in a similar way to the main dialog box, but it provides drop-down lists for selecting options, and it provides text fields for data entry instead of parentheses. This dialog box also provides a Frequently Used Expressions drop-down list that inserts commonly used expressions. When you are done adding the expression using this dialog box, click OK.

9. To test the expression, click the Evaluate icon (the check mark). In the Advanced Expression Evaluator dialog box, select the Flow Type that matches the expression. In the data field, paste the HTTP request or response that you hope to parse using the expression, and click Evaluate. Click OK to save your expression and close this dialog box.

10. When you are done, click Create and then click Close.

Displaying Cached Objects and Cache Statistics

You can view particular cached objects, and you can view summary statistics on cache hits, misses, and memory usage. The statistics provide insight on the amount of data that is being served from the cache, what items are responsible for the largest performance benefit, and what you can tune to improve cache performance.

Viewing Cached Objects

After enabling caching, you can view details for cached objects. For example, you can view the following items:

- Response sizes and header sizes
- Status codes
- Content groups
- ETag, Last-Modified, and Cache-Control headers
- Request URLs
- Hit parameters
- Destination IP addresses
- Request and response times

To view a list of cached objects by using the command line interface

At the command prompt, type:

show cache object

Table 1. Properties of Cached Objects

Properties	Specifies
Response size (bytes)	The size of the response header and body.
Response header size (bytes)	The size of the header portion of the response.
Response status code	The status code sent with the response.
ETag	The ETag header inserted in the response. Typically, this header indicates whether the response has changed recently.
Last-Modified	The Last-Modified header inserted in the response. This header indicates the date that the response was last changed.
Cache-Control	The Cache-Control header inserted in the response.
Date	The Date header that indicates when the response was sent.

Contentgroup	The content group where the response is stored.
Complex match	If this object was cached on the basis of parameterized values, this field value is YES.
Host	The host specified in the URL that requested this response.
Host port	The listen port for the host specified in the URL that requested this response.
URL	The URL issued for the stored response.
Destination IP	The IP address of the server from which this response was fetched.
Destination port	The listen port for the destination server.
Hit parameters	If the content group that stores the response uses hit parameters, they are listed in this field.
Hit selector	If this content group uses a hit selector, it is listed in this field.
Inval selector	If this content group uses an invalidation selector, it is listed in this field.
Selector Expressions	If this content group uses a selector, this field displays the expression that defines the selection rule.
Request time	The time in milliseconds since the request was issued.
Response time	The time in milliseconds since the cache started to receive the response.
Age	Amount of time the object has been in the cache.
Expiry	Amount of time after which the object is marked as expired.
Flushed	Whether the response has been flushed after expiry.
Prefetch	If Prefetch has been configured for this content group, the amount of time before expiry during which the object is fetched from the origin. Prefetch does not apply to negative objects (for example, 404 "object not found" responses).

Current readers	Approximately the current number of hits being served. When a response with a Content-Length header object is being downloaded, the current misses and the current readers values are each typically 1. When a chunked response object is being downloaded, the current misses value is typically 1, but the current readers value is typically 0, because the chunked response that is served to the client does not come from the integrated caching buffers.
Current misses	The current number of requests that resulted in a cache miss and fetching from the origin server. This value is typically 0 or 1. If Poll Every Time is enabled for a content group, the count can be greater than 1.
Hits	The number of cache hits for this object.
Misses	The number of cache misses for this object.
Compression format	The type of compression applied to this object. Compression formats include gzip, deflate, compress, and pack200-gzip.
HTTP version in response	The version of HTTP that was used to send the response.
Weak etag present in response	Strong etag headers change if the bits of an entity change. Strong headers are based on the octet values of an object. Weak etag headers change if the meaning of an entity changes. Weak etag values are based on semantic identity. Weak etags values start with a "W."
Negative marker cell	A marker object is cacheable, but it does not yet meet all the criteria for being cached. For example, the object may exceed the maximum response size for the content group. A marker cell is created for objects of this type. The next time a user sends a request for this object, a cache miss is served.
Reason marker created	The reason a marker cell was created (for example, “Waiting for minhit,” “Content-length response data is not in group size limit”).
Auto poll every time	If the integrated cache receives an already expired 200 OK response with validators (either the Last-Modified or the ETag response headers) it stores the response and marks it as Auto-PET (automatically poll every time).

NetScaler Etag inserted in response	A variation of the ETag header generated by the NetScaler appliance. A value of YES appears if the NetScaler inserts an Etag in the response.
Full response present in cache	Indicates whether this is a complete response.
Destination IP verified by DNS	Indicates whether DNS resolution was performed when storing the object.
Object stored through a cache forward proxy	Indicates whether this response was stored due to a forward proxy that is configured in the integrated cache.
Object is a Delta basefile	A response that is delta-compressed.
Waiting for minhits	Indicates whether this content group requires a minimum number of origin server hits before caching a response.
Minhit count	If this content group requires a minimum number of origin server hits before caching an object, this field displays a count of the number of hits received so far.
HTTP Request Method	The method, GET or POST, used in the request that obtained this object.
Stored by policy	The name of the caching policy that caused this object to be stored. A value of NOT AVAILABLE indicates that the policy has been deactivated or deleted. A value of NONE indicates that the object did not match a visible policy, but was stored according to internal criteria for caching.
Application firewall metadata exists	This parameter is used when the application firewall and the integrated cache are both enabled. The application firewall analyzes the contents of a response page, stores its metadata (for example, URLs and forms contained in page), and exports the metadata with the response to the cache. The cache stores the page and the metadata, and when the cache serves the page, it sends the metadata back to the request's session.
HTTP callout object, name, type, response	These cells indicate whether this data was stored as a result of an HTTP Callout expression, and provide information about various aspects of the callout and the corresponding response. For more information about HTTP callouts, see "HTTP Callouts".

To view cached objects by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Cache Objects.

   By default, all cached responses are displayed. If you have not yet configured any content groups, all of the responses are in the Default group.

2. To filter the cached responses by content group, click the Content Group Name drop-down menu, and then select the name of a content group.

3. To filter the cached responses by HTTP status code, enter the HTTP status code in the HTTP Status Code dialog box.

4. To filter out marker objects and not-ready objects, click the check box for Ignore Marker Objects and leave the check box for Include Not Ready Objects blank.

   These settings represent objects that can be served from the cache, pending additional information. Marker objects are responses that have not yet reached a minimum number of hits before being cached. Not-ready objects have not yet received response headers.

5. Click Go.

   To view details for a cached object, click it, and then click Details.

6. To save a locator number for later use, right-click the row that contains the object and its locator number, select Copy, and then paste the information into a document.

Parameter Descriptions (of commands listed in the CLI procedure)

show cache object

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Finding Particular Cached Responses

You can find individual items in the cache based on search criteria. There are different methods for finding cached items, depending on whether the content group that contains the data uses hit and invalidation selectors, as follows:

- If the content group uses selectors, you can only conduct the search using the Locator ID for the cached item.
- If the content group does not use selectors, you conduct the search using criteria such as URL, host, content group name, and so on.

When searching for a cached response, you can locate some items by URL and host. If the response is in a content group that uses a selector, you can find it only by using a Locator number (for example, 0x00000000ad7af00000050). To save a Locator number for later use, right-click the entry and select **Copy**. For more information about selectors, see "Configuring Selectors and Basic Content Groups."

To display cached responses in content groups that do not have a selector by using the command line interface

At the command prompt, type:

show cache object [-locator <positiveInteger>] | [(-url <URL> (-host <hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET | POST])) | [-httpStatus<positive integer>] | -group <contentGroupName> | -ignoreMarkerObjects (ON | OFF) | -includeNotReadyObjects (ON | OFF)]

To display cached responses in content groups that have a selector by using the command line interface

At the command prompt, type:

show cache object -locator <locatorString> MarkerObjects (ON | OFF) | -includeNotReadyObjects (ON | OFF) | [-httpStatus<positive integer>]

To display cached responses in content groups that do not have a selector by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Cache Objects.

   If you have not yet configured any content groups, all of the objects are in the Default group.

2. At the top of the details pane, click Find.

3. Enter search criteria, as follows:

   - In the Search In drop-down list, select a search filter, for example, URL. Note that if you are searching for items in a content group that uses a selector, select the Locator option.

   - In the Criterion drop-down list, select the search method, for example, Contains.

   - In Look for, enter the text that is to be matched, for example, **www.myurl.com**.

   - Optionally, restrict the search according to a particular content group, and exclude not ready and marker objects.

4. Click Find Now.

To display cached responses in content groups that have a selector by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Cache Objects.

2. In the details pane, click Look Up.

3. In the Look Up Cache Object dialog box, do one of the following:

   - To find an object that resides in a content group that does not use a selector, click Only static and parameterized groups and enter selection criteria.

     The URL and host IP address are required. For example, you could enter /manual/images/sub.gif as the URL and 10.102.91.160 as the host. The content group name is also required if the content group contains parameterized objects.

   - To find an object that resides in a content group that uses a selector, click All groups including selector-based and, in Locator, enter the locator of the object that you want to view.

4. Click View Details.

5. In the Details dialog box, click any parameter to display its value in the Value box.

Parameter Descriptions (of commands listed in the CLI procedure)

show cache object

locator

The id of the cached object.

url

The URL of the object.

host

The hostname of the object.

port

The host port of the object. Default value: 80 Minimum value: 1

groupName

The name of the content group to be in which the cell is present

httpMethod

The HTTP request method that caused the object to be stored. Possible values: GET, POST Default value: NS_HTTP_METHOD_GET

httpStatus

HTTP status of the object.

group

The name of the content group whose objects should be listed.

ignoreMarkerObjects

Ignore marker objects Possible values: ON, OFF

includeNotReadyObjects

Include objects not-ready for a cache hit Possible values: ON, OFF

View description(s) in command reference Top

Viewing Cache Statistics

The following table summarizes the detailed cache statistics that you can view.

Table 1. Integrated Cache Statistics

Counter	Specifies
Hits	Responses that are found in and served from the integrated cache. Includes static objects such as image files, pages with status codes 200, 203, 300, 301, 302, 304, 307, 403, 404, 410, and responses that match a user-defined policy with a CACHE action..
Misses	Intercepted HTTP requests where the response was ultimately fetched from origin server.
Requests	Total cache hits plus total cache misses.
Non-304 hits	If the user requests an item more than once, and the item in the cache is unchanged since the last time the NetScaler appliance served it, the NetScaler appliance serves a 304 response instead of the cached object. This statistic indicates how many items the NetScaler appliance served from the cache, excluding 304 responses.
304 hits	Number of 304 (object not modified) responses the NetScaler appliance served from the cache.
304 hit ratio (%)	Percentage of 304 responses that the NetScaler appliance served, relative to other responses.
Hit ratio (%)	Percentage of responses that the NetScaler appliance served from the cache (cache hits) relative to responses that could not be served from the cache.
Origin bandwidth saved (%)	An estimate of the processing capacity that the NetScaler appliance saved on the origin server due to serving responses from the cache.
Bytes served by the NetScaler	Total number of bytes that the NetScaler appliance served from the origin server and the cache.

Bytes served by cache	Total number of bytes that the NetScaler appliance served from the cache.
Byte hit ratio(%)	Percentage of data that the NetScaler appliance served from the cache, relative to all of the data in all served responses.
Compressed bytes from cache	Amount of data, in bytes, that the NetScaler appliance served in compressed form.
Storable misses	If the NetScaler appliance does not find a requested object in the cache, it fetches the object from the origin server. This is known as a cache miss. A storable cache miss can be stored in the cache.
Non-storable misses	A non-storable cache miss cannot be stored in the cache.
Misses	All cache misses.
Revalidations	Max-Age setting in a Cache-Control header determines, in number of seconds, when an intervening cache must revalidate the content with the integrated cache before serving it to the user. For more information, see "Inserting a Cache-Control Header."
Successful revalidations	Number of re-validations that have been performed. For more information, see "Inserting a Cache-Control Header."
Conversions to conditional req	A user-agent request for a cached PET object is always converted to a conditional request and sent to the origin server. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Storable miss ratio (%)	Storable cache misses as a percentage of non-storable cache misses.
Successful reval ratio (%)	Successful revalidations as a percentage of all revalidation attempts. For more information, see "Inserting a Cache-Control Header."

Expire at last byte	Number of times that the cache expired content immediately after receiving the last body byte. Only applicable to positive responses, as described in the table "Cache Hits and Misses." For more information, see "Example of Performance Optimization."
Flashcache misses	If you enable Flash Cache, the cache allows only one request to reach the server, eliminating flash crowds. This statistic indicates the number of Flash Cache requests that were cache misses. For more information, "Queuing Requests to the Cache."
Flashcache hits	Number of Flash Cache requests that were cache hits. For more information, see "Queuing Requests to the Cache."
Parameterized inval requests	Requests that match a policy with an invalidation (INVAL) action and a content group that uses an invalidation selector or parameters to selectively expire cached objects in the group.
Full inval requests	Requests that match an invalidation policy where the invalGroups parameter is configured and expires one or more content groups.
Inval requests	Requests that match an invalidation policy and result in expiration of specific cached responses or entire content groups.
Parameterized requests	Number of cache requests that were processed using a policy with a parameterized content group.
Parameterized non-304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where full cached response was found, and the response was not a 304 (object not updated) response.
Parameterized 304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found, and the object was a 304 (object not updated) response.
Total parameterized hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found.

Parameterized 304 hit ratio (%)	Percentage of 304 (object not updated) responses that were found using a parameterized policy, relative to all cache hits.
Poll every time requests	If Poll Every Time is enabled, the NetScaler appliance always consults the origin server before serving a stored object. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Poll every time hits	Number of times a cache hit was found using the Poll Every Time method. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Poll every time hit ratio (%)	Percentage of cache hits using the Poll Every Time method, relative to all searches for cached objects using Poll Every Time. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Maximum memory (KB)	Maximum amount of memory in the NetScaler appliance that is allocated to the cache. For more information, see "Configuring Global Attributes for Caching."
Maximum memory active value (KB)	Maximum amount of memory (active value) that will be set after the memory is actually allocated to the cache. For more information, see "How to Configure the Integrated Caching Feature of a NetScaler Appliance for various Scenarios."
Utilized memory (KB)	Amount of memory that is actually being used.
Memory allocation failures	Number of failed attempts to utilize memory for the purpose of storing a response in the cache.
Largest response so far	Largest response in bytes found in either the cache or the origin server and sent to the client.
Cached objects	Number of objects in the cache, including responses that have not yet been fully downloaded and responses that have been expired but not yet flushed.

Marker objects	Marker objects are created when a response exceeds the maximum or minimum response size for the content group, or has not yet received the minimum number of hits for the content group.
Hits being served	Number of hits that have been served from the cache.
Misses being handled	Responses that were fetched from the origin server, stored in the cache, and then served. Should approximate the number for storable misses. Does not include non-storable misses.

To view summary cache statistics by using the command line interface

At the command prompt, type:

stat cache

To view specific cache statistics by using the command line interface

At the command prompt, type:

stat cache -detail [-fullValues] [-ntimes <positiveInteger>] [-logFile <inputFilename>]

To view summary cache statistics by using the configuration utility

1. Click the Dashboard tab at the top of the page.
2. Scroll down to the Integrated Caching section of the window.
3. To see detailed statistics, click the More... link at the bottom of the table.

To view specific cache statistics by using the configuration utility

1. Click the Reporting tab at the top of the page.
2. Under Built-In Reports, expand Integrated Cache, and then click the report with the statistics you want to view.
3. To save the report as a template, click Save As and name the report. The saved report appears under Custom Reports.

Parameter Descriptions (of commands listed in the CLI procedure)

stat cache

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Improving Cache Performance

You can improve the performance of integrated cache, including handling simultaneous requests for the same cached data, avoiding delays that are associated with refreshing cached responses from the origin server, and ensuring that a response is requested often enough to be worth caching.

Reducing Flash Crowds

Flash crowds occur when many users simultaneously request the same data. All of the requests in a flash crowd can become cache misses if you configured the cache to serve hits only after the entire object is downloaded.

The following techniques can reduce or eliminate flash crowds:

- **PREFETCH**: Refreshes a positive response before it expires to ensure that it never becomes stale or inactive.

  For more information, see "Refreshing a Response Prior to Expiration."

- **Cache buffering**: Starts serving a response to multiple clients as soon as it receives the response header from the origin server, rather than waiting for the entire response to be downloaded.

  The only limit on the number of clients that can download a response simultaneously is the available system resources.

  The Citrix NetScaler appliance downloads and serves responses even if the client that initiated the download halts before the download is complete. If the size of the response exceeds the cache size or if the response is chunked, the cache stops storing the response, but service to the clients is not disrupted.

- **Flash Cache**: Flash Cache queues requests to the cache, and allows only one request to reach the server at a time.

  For more information, see "Queuing Requests to the Cache."

Refreshing a Response Prior to Expiration

To ensure that a cached response is fresh whenever it is needed, the PREFETCH option refreshes a response before its calculated expiration time. The prefetch interval is calculated after receiving the first client request. From that point onward, the NetScaler appliance refreshes the cached response at a time interval that you configure in the PREFETCH parameter.

This setting is useful for data that is updated frequently between requests. It does not apply to negative responses (for example, 404 messages).

To configure prefetch for a content group by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -prefetch YES [-prefetchPeriod <seconds> | -prefetchPeriodMilliSec <milliseconds>] [-prefetchMaxPending <positiveInteger>]

To configure prefetch for a content group by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, click the content group for which you want to set prefetch, and then click Open.
3. In the Configure Cache Content Group dialog box, on the Others tab, under Flash Crowd and Prefetch, select the Prefetch check box.
4. In the Interval text box, enter a value to define an interval that a prefetch can be attempted. This should be shorter than the content group's calculated expiration time. Or, accept the default (heuristic prefetch interval). Note that the value can be in seconds or, if relative expiry is specified in milliseconds on the Expiry Method tab, you can select a value in milliseconds.
5. In the Maximum number of pending prefetches text box, enter a value for the maximum number of prefetches that can be queued for the content group. The minimum value is 0, and the maximum value is 4294967295.
6. Click OK.

Queuing Requests to the Cache

The Flash Cache option queues requests that arrive simultaneously (a flash crowd), retrieves the response, and distributes it to all the clients whose requests are in the queue. If, during this process, the response becomes non-cacheable, the NetScaler appliance stops serving the response from the cache and instead serves the origin server's response to the queued clients. If the response is not available, the clients receive an error message.

Flash Cache is disabled by default. You cannot enable Poll Every Time (PET) and Flash Cache on the same content group.

One disadvantage of Flash Cache is if the server replies with an error (for example, a 404 that is quickly remedied), the error is fanned out to the waiting clients.

Note: If Flash Cache is enabled, in some situations the NetScaler appliance is unable to correctly match the Accept-Encoding header in the client request with the Content-Encoding header in the response. The NetScaler appliance can assume that these headers match and mistakenly serve a hit. As a work-around, you can configure Integrated Caching policies to disallow serving hits to clients that do not have an appropriate Accept-Encoding header.

To enable Flash Cache by using the command line interface

At the command prompt, type:

set cache contentgroup <contentGroupName> -flashcache yes

To enable Flash Cache by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, click the content group for which you want to set the flash cache option, and then click Open.
3. In the Configure Cache Content Group dialog box, on the Others tab, under Flash Crowd and Prefetch, select the Flash Cache check box, and then click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set cache contentgroup

prefetch

The option to refresh an object immediately before it goes stale. Possible values: YES, NO Default value: YES

prefetchPeriod

The duration in seconds of the period during which prefetch should be attempted, immediately before the object's calculated expiry time. Default value: VAL_NOT_SET Maximum value: 4294967294

prefetchPeriodMilliSec

The duration in milliseconds of the period during which prefetch should be attempted, immediately before the calculated expiry time. Default value: VAL_NOT_SET Maximum value: 4294967290

prefetchMaxPending

The maximum number of outstanding prefetches on the contentgroup.

flashcache

The option to do flash cache on Integrated caching. Possible values: YES, NO Default value: NO

View description(s) in command reference Top

Caching a Response after a Client Halts a Download

You can set the Quick Abort parameter to continue caching a response, even if the client halts a request before the response is in the cache.

If the downloaded response size is less than or equal to the Quick Abort size, the NetScaler appliance stops downloading the response. If you set the Quick Abort parameter to 0, all downloads are halted.

To configure quick abort size by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -quickAbortSize <integerInKBytes>

To configure quick abort size by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, click the content group for which you want to set the quick abort size, and then click Add.
3. In the Configure Cache Content Group dialog box, on the Memory tab, in the Quick Abort: Continue caching if more than text box, type an integer value, calculated in kilobytes (KB), and then click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set cache contentgroup

quickAbortSize

The quick abort size. If the client aborts when the downloaded response size is less than or equal to the quick-abort-size, then the Integrated Cache will stop downloading the response. Maximum value: 4194303

View description(s) in command reference Top

Setting a Minimum Number of Server Hits Prior to Caching

You can configure the minimum number of times that a response must be found on the origin server before it can be cached. You should consider increasing the minimum hits if the cache memory fills up quickly and has a lower-than-expected hit ratio.

The default value for the minimum number of hits is 0. This value caches the response after the first request.

To configure the minimum number of hits that are required before caching by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -minhits <positiveInteger>

To configure the minimum number of hits that are required before caching by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, click the content group for which you want to set the minimum hit count, and then click Open.
3. On the Memory tab, in the Do not cache, if hits are less than text box, type the value you want to set, and then click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set cache contentgroup

minhits

The minimum number of accesses for an object to be stored in Cache.

View description(s) in command reference Top

Example of Performance Optimization

In this example, a client accesses a stock quote. Stock quotes are highly dynamic. You configure the integrated cache to serve the same stock quote to concurrent clients without sending multiple requests to the origin server. The stock quote expires after it is downloaded to all of the clients, and the next request for a quote for the same stock is fetched from the origin server. This ensures that the quote is always up to date.

The following task overview describes the steps to configure the cache for the stock quote application.

Task overview: Configuring caching for a stock quote application

1. Create a content group for stock quotes.

   For more information, see "About Content Groups."

   Configure the following for this content group:

   - On the Expiry Method tab, select the Expire after complete response received check box.

   - On the Others tab, select the Flash Cache check box, and click Create.
2. Add a cache policy to cache the stock quotes.

   For more information, see "Configuring a Policy in the Integrated Cache."

   Configure the following for the policy:

   - In the Action and Store in Group lists, select CACHE and select the group that you defined in the previous step.

   - Click Add, and in the Add Expression dialog box configure an expression that identifies stock quote requests, for example:

     ```
     http.req.url.contains("cgi-bin/stock-quote.pl")
     ```
3. Activate the policy.

   For more information, see "Globally Binding an Integrated Caching Policy." In this example, you bind this policy to request-time override processing and set the priority to a low value.

Configuring Cookies, Headers, and Polling

This section describes the procedures to configure how the cache manages cookies, HTTP headers, and origin server polling, including modifying default behavior that causes the cache to diverge from documented standards, overriding HTTP headers that might cause cacheable content to not be stored in the cache, and configuring the cache to always poll the origin for updated content under specialized circumstances.

Divergence of Cache Behavior from the Standards

By default, the integrated cache conforms to the following standards:

- RFC 2616, “Hypertext Transfer Protocol HTTP/1.1”
- The caching behaviors described in RFC 2617, “HTTP Authentication: Basic and Digest Access Authentication”
- The caching behavior described in RFC 2965, “HTTP State Management Mechanism”

The built-in policies and the Default content group attributes ensure conformance with most of these standards.

The default integrated cache behavior diverges from the specifications as follows:

- There is limited support for the Vary header.

  By default, any response containing a Vary header is considered to be non-cacheable unless it is compressed. A compressed response contains `Content-Encoding: gzip`, `Content-Encoding: deflate`, or `Content-Encoding: pack200-gzip` and is cacheable even if it contains the `Vary: Accept-Encoding` header.

- The integrated cache ignores the values of the headers `Cache-Control: no-cache` and `Cache-Control: private`.

  For example, a response that contains `Cache-Control: no-cache=”Set-Cookie”` is treated as if the response contained `Cache-Control: no-cache`. By default, the response is not cached.

- An image (Content-Type = image/*) is always considered cacheable even if an image response contains Set-Cookie or Set-Cookie2 headers, or if an image request contains a Cookie header.

  The integrated cache removes Set-Cookie and Set-Cookie2 headers from a response before caching it. This diverges from RFC 2965. You can configure RFC-compliant behavior as follows:

  ```
  add cache policy rfc_compliant_images_policy -rule "http.res.header.set-cookie2.exists || http.res.heac
  bind cache global rfc_compliant_images_policy -priority 100 -type REQ_OVERRIDE
  ```

- The following Cache-Control headers in a request force an RFC-compliant cache to reload a cached response from the origin server:

  ```
  Cache-control: max-age=0
  ```

Cache-control: no-cache

To guard against Denial of Service attacks, this behavior is not the default. For more information, see "Inserting a Cache-Control Header."

- By default, the caching module considers a response to be cacheable unless a response header states otherwise.

  To make this behavior RFC 2616 compliant, set -weakPosRelExpiry and -weakNegResExpiry to 0 for all content groups.

Removing Cookies from a Response

Cookies are often personalized for a user, and typically should not be cached. The Remove Response Cookies parameter removes Set-Cookie and Set-Cookie2 headers before caching a response. By default, the Remove Response Cookies option for a content group prevents caching of responses with Set-Cookie or Set-Cookie2 headers.

Note that when images are cached, the built-in behavior is to remove the Set-Cookie and Set-Cookie2 headers before caching, no matter how the content group is configured.

Note: Citrix recommends that you accept the default Remove Response Cookies for every content group that stores embedded responses, for example, images.

To configure Remove Response Cookies for a content group by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -removeCookies YES

To configure Remove Response Cookies for a content group by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, click the content group for which you want to enable or disable the remove response cookies option, and then click Open.
3. In the Configure Cache Content Group, on the Others tab, under Settings, select or clear the Remove response cookies check box, and then click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set cache contentgroup

removeCookies

The option to remove cookies from response. Possible values: YES, NO Default value: YES

View description(s) in command reference Top

Inserting HTTP Headers at Response Time

The integrated cache can insert HTTP headers in responses that result from cache hits. The Citrix® NetScaler® appliance does not alter headers in responses that result from cache misses.

The following table describes headers that you can insert in a response.

Table 1. Different HTTP Headers You Can Insert in a Response That Is Served from the Cache

Header	Specifies
Age	Provides the age of the response in seconds, calculated from the time the response was generated at the origin server. By default, the cache inserts an Age header for every response that is served from the cache.
Via	Lists protocols and recipients between the start and end points for a request or a response. The NetScaler appliance inserts a Via header in every response that it serves from the cache. The default value of the inserted header is “NS-CACHE-9.2:last octet of the NetScaler IP address.” For more information, see "Configuring Global Attributes for Caching."
ETag	The cache supports response validation using Last-Modified and ETag headers to determine if a response is stale. The cache inserts an ETag in a response only if it caches the response and the origin server has not inserted its own ETag header. The ETag value is an arbitrary unique number. The ETag value for a response changes if it is refreshed from the origin server, but it stays the same if the server sends a 304 (object not updated) response. Origin servers typically do not generate validators for dynamic content because dynamic content is considered non-cacheable. You can override this behavior. With ETag header insertion, the cache is permitted to not serve full responses. Instead, the user agent is required to cache the dynamic response sent by the integrated cache the first time. To force a user agent to cache a response, you configure the integrated cache to insert an ETag header and replace the origin-provided Cache-Control header.

Cache-Control	The NetScaler appliance typically does not modify cacheability headers in responses that is serves from the origin server. If the origin server sends a response that is labeled as non-cacheable, the client treats the response as non-cacheable even if the NetScaler appliance caches the response. To cache dynamic responses in a user agent, you can replace Cache-Control headers from the origin server. This applies only to user agents and other intervening caches. They do not affect the integrated cache. For more information, see "Inserting a Cache-Control Header."

Inserting an Age, Via, or ETag Header

The following procedures describe how to insert Age, Via, and ETag headers.

To insert an Age, Via, or Etag header by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -insertVia YES -insertAge YES -insertETag YES

To insert an Age, Via, or Etag header by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, click the content group for which you want to insert Age, Via, or Etag headers, and then click Open.
3. In the Configure Cache Content Group dialog box, on the Others tab, under HTTP Header Insertions, select or clear the Via, Age, or ETag check boxes, as needed. The values for the other header types are calculated automatically. Note that you configure the Via value in the main settings for the cache.
4. Click OK.

Inserting a Cache-Control Header

When the integrated cache replaces a Cache-Control header that the origin server inserted, it also replaces the Expires header. The new Expires header contains an expiration time in the past. This ensures that HTTP/1.0 clients and caches (that do not understand the Cache-Control header) do not cache the content.

To insert a Cache-Control header by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -cacheControl <value>

To insert a Cache-Control header by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, click the content group for which you want to configure cache-control, and then click Open.
3. In the Configure Cache Content Group dialog box, on the Expiry Method tab, clear the heuristic and default expiry settings if any are set, and in the Expire content after text box, type a value in seconds. For example, a value of 3600 expires cached responses after 3600 seconds (one hour).
4. On the Others tab, under HTTP Header Insertions, in the Cache-Control text box, type the header you want to insert, for example, **private**, **max-age=0**, or click Configure and set the Cache-Control directives that you want to insert in responses that are sent to user agents and intervening caches.

Parameter Descriptions (of commands listed in the CLI procedure)

set cache contentgroup

name

The name of the content group whose attibutes will be changed.

insertVia

The option to insert a Via header. Possible values: YES, NO Default value: YES

insertAge

The option to insert an Age header. Possible values: YES, NO Default value: YES

insertETag

The option to insert an ETag header. Possible values: YES, NO Default value: YES

cacheControl

The option to insert a Cache-Control header.

View description(s) in command reference Top

Ignoring Cache-Control and Pragma Headers in Requests

By default, the caching module processes Cache-Control and Pragma headers. The following tokens in Cache-Control headers are processed as described in RFC 2616.

- max-age
- max-stale
- only-if-cached
- no-cache

A Pragma: no-cache header in a request is treated in the same way as a Cache-Control: no-cache header.

If you configure the caching module to ignore Cache-Control and Pragma headers, a request that contains a Cache-Control: No-Cache header causes the NetScaler appliance to retrieve the response from the origin server, but the cached response is not updated. If the caching module processes Cache-Control and Pragma headers, the cached response is refreshed.

The following table summarizes the implications of various settings for these headers and the Ignore Browser's Reload Request setting.

Table 1. Outcome of Settings for Ignoring Reload Requests, Cache-Control, and Pragma Headers

Setting for Ignore Cache-Control and Pragma Headers	Setting for Ignore Browser's Reload Request	Outcome
Yes	Yes or No	Ignore the Cache-Control and Pragma headers from the client, including the Cache-Control: no-cache directive.
No	Yes	The Cache-Control: no-cache header produces a cache miss, but a response that is already in the cache is not refreshed.
No	No	A request that contains a Cache-Control: no-cache header causes a cache miss and the stored response is refreshed.

To ignore Cache-Control and Pragma headers in a request by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -ignoreReqCachingHdrs YES

To ignore browser reload requests by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -ignoreReloadReq NO

Note that by default, the -ignoreReloadReq parameter is set to YES.

To ignore Cache-Control and Pragma headers in a request by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, click the content group for which you want to ignore cache-control and pragma headers, and then click Open.
3. In the Configure Cache Content Group dialog box, on the Others tab, under Settings, select the Ignore Cache-control and Pragma Headers in Requests check box, and then click OK.

Example of a Policy to Ignore Cache-Control Headers

In the following example, you configure a request-time override policy to cache responses that contain Content-type: image/* regardless of the Cache-Control header in the response.

To configure a request-time override policy to cache all responses with image/*

1. Flush the cache using the Invalidate All option.

   For more information, see "Flushing Responses in a Content Group."

2. Configure a new cache policy, and direct the policy to a particular content group. For more information, see "Configuring a Policy in the Integrated Cache."

3. Ensure the content group that the policy uses is configured to ignore Cache-Control headers, as described in "Ignoring Cache-Control and Pragma Headers in Requests."

4. Bind the policy to the request-time override policy bank.

   For more information, see "Globally Binding an Integrated Caching Policy."

Parameter Descriptions (of commands listed in the CLI procedure)

set cache contentgroup

name

The name of the content group whose attibutes will be changed.

ignoreReqCachingHdrs

The option to ignore the Cache-control and Pragma headers in the incoming request. Possible values: YES, NO Default value: YES

ignoreReloadReq

For a request, the option to force the system to reload a cached object from the origin. To guard against Denial of Service attacks, you should set this flag to YES. To get RFC-compliant behavior, you should set it to NO. Possible values: YES, NO Default value: YES

View description(s) in command reference Top

Polling the Origin Server Every Time a Request Is Received

You can configure the NetScaler appliance to always consult the origin server before serving a stored response. This is known as Poll Every Time (PET). When the NetScaler appliance consults the origin server and the PET response has not expired, a full response from the origin server does not overwrite cached content. This property is useful when serving client-specific content.

After a PET response expires, the NetScaler appliance refreshes it when the first full response arrives from the origin server.

The Poll Every Time (PET) function works as follows:

- For a cached response that has validators in the form of an ETag or a Last-Modified header, if the response expires it is automatically marked PET and cached.
- You can configure PET for a content group.

  If you configure a content group as PET, every response in the content group is marked PET. The PET content group can store responses that do not have validators. Responses that are automatically marked PET are always expired. Responses that belong to a PET content group can expire after a delay, based on how you configure the content group.

Two types of requests are affected by polling:

- **Conditional Requests**: A client issues a conditional request to ensure that the response that it has is the most recent copy.

  A user-agent request for a cached PET response is always converted to a conditional request and sent to the origin server. A conditional request has validators in If-Modified-Since or If-None-Match headers. The If-Modified-Since header contains the time from the Last-Modified header. An If-None-Match header contains the response's ETag header value.

  If the client's copy of the response is fresh, the origin server replies with 304 Not Modified. If the copy is stale, a conditional response generates a 200 OK that contains the entire response.
- **Non-Conditional Requests**: A non-conditional request can only generate a 200 OK that contains the entire response.

The following table summarizes response types based on the origin server's response

Table 1. How Responses Are Affected by Poll Every Time

Origin Server Response	Action

Send the full response	The origin server sends the response as-is to the client. If the cached response has expired, it is refreshed.
304 Not Modified	The following header values in the 304 response are merged with the cached response and the cached response is served to the client: · Date · Expires · Age · Cache-Control header Max-Age and S-Maxage tokens
401 Unauthorized 400 Bad Request 405 Method Not Allowed 406 Not Acceptable 407 Proxy Authentication Required	The origin's response is served as-is to the client. The cached response is not changed.
Any other error response, for example, 404 Not Found	The origin's response is served as-is to the client. The cached response is removed.

Note: The Poll Every Time parameter treats the affected responses as non-storable.

To configure poll every time by using the command line interface

At the command prompt, type:

add cache contentgroup <contentGroupName> -pollEveryTime YES

To configure poll every time by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Content Groups.
2. In the details pane, click a cache content group, and then click Open.
3. On the Others tab, click Poll every time (validate cached content with origin for every request).

PET and Client-Specific Content

The PET function can ensure that content is customized for a client. For example, a Web site that serves content in multiple languages examines the Accept-Language request header to select the language for the content that it is serving. For a multi-language Web site where English is the predominant language, all English language content can be cached in a PET content group. This ensures that every request goes to the origin server to determine the language for the response. If the response is English, and the content has not changed, the origin server can serve a 304 Not Modified to the cache.

The following example shows commands to cache English responses in a PET content group, configure a named expression that identifies English responses in the cache, and configure a policy that uses this content group and named expression. Bold is used for emphasis:

```
add cache contentgroup EnglishLanguageGroup -pollEveryTime YES
add expression containsENExpression –rule "http.res.header(\"Content-Language\").contains(\"en\")"
add cache policy englishPolicy -rule containsENExpression -action CACHE -storeInGroup englishLanguageGrou
bind cache policy englishPolicy -priority 100 -precedeDefRules NO
```

PET and Authentication, Authorization, and Auditing

Outlook Web Access (OWA) is a good example of dynamically generated content that benefits from PET. All mail responses (*.EML objects) have an ETag validator that enables them to be stored as PET responses.

Every request for a mail response travels to the origin server, even if the response is cached. The origin server determines whether the requestor is authenticated and authorized. It also verifies that the response exists in the origin server. If all results are positive, the origin server sends a 304 Not Modified response.

Parameter Descriptions (of commands listed in the CLI procedure)

add cache contentgroup

pollEveryTime

Use this parameter to specify whether to poll every time for the objects in this content group Possible values: YES, NO Default value: NO

View description(s) in command reference Top

Configuring the Integrated Cache as a Forward Proxy

The integrated cache can service as a forward proxy device that passes requests to other NetScaler appliances or to other types of cache servers. You configure the integrated cache as a forward proxy by identifying the IP addresses of the cache server or servers. After configuring the forward proxy, the NetScaler appliance sends requests that contain the configured IP address on to the cache server instead of involving the integrated cache.

To configure the NetScaler as a forward cache proxy by using the command line interface

At the command prompt, type:

add cache forwardProxy <IPAddress> <port>

To configure the NetScaler as a forward cache proxy by using the configuration utility

1. In the navigation pane, expand Integrated Caching, and then click Forward Proxy.
2. In the details pane, click Add.
3. Enter the IP address and port of the cache server, and then click Create.
4. Enter a second IP address and port, or click Close.

Parameter Descriptions (of commands listed in the CLI procedure)

add cache forwardProxy

IPAddress

The IP address of the forward proxy.

port

The port of the forward proxy. Minimum value: 1

View description(s) in command reference Top

Example of an Integrated Caching Configuration

The following task overview provides one method of setting up and testing an end-to-end configuration for integrated caching.

Task overview: an Integrated Caching configuration

1. Configure the load balancing virtual servers for your environment, and bind services to them.
2. Enable the integrated cache.
3. Check the expiration settings of the Default content group and ensure there is enough time for objects to remain in the cache.
4. Check the memory settings and ensure there is enough room to store cached objects.
5. Configure a caching policy that stores responses in the cache. The policy can be very general for ease of testing. For example, the following rule produces a hit for any GET request:

   ```
   http.req.method.eq(GET)
   ```

6. Open a browser and enter `http://your_load_balancing_virtual_ip_address/known_content_on_the_destination server`. For example, if you have a Web server that contains a top-level file named myfile.txt and a virtual server that services the Web server with an IP address of 22.222.22.22, you could enter the following URL:

   ```
   http://22.222.22.22/myfile.txt
   ```

7. In the configuration utility click Cache Objects, or at the command line enter `show cache object`. If the expected object does not appear in the cache, check for conflicting caching policies. You can also ping the named destination server where the object of interest resides to see whether the IP address is the same as the one that you configured as a service on your virtual server. Finally, you can look in the configuration utility under Integrated Caching, on the landing page for Policies, in the Hits column for the policy, to see if the Citrix® NetScaler® appliance did use the intended policy to evaluate the request for the cached object.

The following is an example of a test configuration. The service IP address corresponds to a valid destination on the internet, and the load balancing virtual server IP address corresponds to a valid IP address in your network. You would send a browser request to the IP address for the virtual server:

```
enable ns feature lb ic
add service myTestService 11.111.11.11 HTTP 80 -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED -usip NO
```

```
add lb vserver myTestLBVserver HTTP 10.100.10.10 80 -persistenceType NONE -cltTimeout 180
bind lb vserver myTestLBVserver myTestService
add cache policy myCachePolicy -rule "http.req.method.eq(\"GET\")" -action cache
bind cache global myCachePolicy -priority 1 -type req_override
```

Parameter Descriptions (of commands listed in the CLI procedure)

show cache object

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Default Settings for the Integrated Cache

The Citrix NetScaler integrated cache feature provides built-in policies with default settings as well as initial settings for the Default content group. The information in this section defines the parameters for the built-in policies and Default content group.

Default Caching Policies

The integrated cache has built-in policies. The NetScaler appliance evaluates the policies in a particular order, as discussed in the following sections.

You can override these built-in policies with a user-defined policy that is bound to a request-time override or response-time override policy bank.

Note that if you configured policies prior to release 9.0 and specified the -precedeDefRules parameter when binding the policies, they are automatically assigned to override-time bind points during migration.

Viewing the Default Policies

The built-in policy names start with an underscore (_). You can view the built-in policies from the command line and the administrative console using the show cache policy command.

Default Request Policies

You can override the following built-in request time policies by configuring new policies and binding them to the request-time override processing point. In the following policies, note that the MAY_NOCACHE action stipulates that the transaction is cached only when there is a user-configured or built-in CACHE directive at response time.

The following policies are bound to the _reqBuiltinDefaults policy label. They are listed in priority order.

1. Do not cache a response for a request that uses any method other than GET.

   The policy name is **_nonGetReq**. The following is the policy rule:

   ```
   !HTTP.REQ.METHOD.eq(GET)
   ```

2. Set a NOCACHE action for a request with header value that contains If-Match or If-Unmodified-Since.

   The policy name is **_advancedConditionalReq**. The following is the policy rule:

   ```
   HTTP.REQ.HEADER("If-Match").EXISTS ||
   HTTP.REQ.HEADER("If-Unmodified-Since").EXISTS
   ```

3. Set a MAY_NOCACHE action for a request with the following header values: Cookie, Authorization, Proxy-authorization or a request which contains the NTLM or Negotiate header.

   The policy name is **_personalizedReq**. The following is the policy rule:

```
HTTP.REQ.HEADER("Cookie").EXISTS ||
HTTP.REQ.HEADER("Authorization").EXISTS ||
HTTP.REQ.HEADER("Proxy-Authorization").EXISTS ||
HTTP.REQ.IS_NTLM_OR_NEGOTIATE
```

Default Response Policies

You can override the following default response-time policies by configuring new policies and binding them to the response-time override processing point.

The following policies are bound to the **_resBuiltinDefaults** policy label and are evaluated in the order in which they are listed:

1. Do not cache HTTP responses unless they are of type 200, 304, 307, 203 or if the types are between 400 and 499 or between 300 and 302.

   The policy name is **_uncacheableStatusRes**. The following is the policy rule:

   ```
   !((HTTP.RES.STATUS.EQ(200)) || (HTTP.RES.STATUS.EQ(304)) ||
   (HTTP.RES.STATUS.BETWEEN(400,499)) ||
   (HTTP.RES.STATUS.BETWEEN(300, 302)) || (HTTP.RES.STATUS.EQ(307))||
   (HTTP.RES.STATUS.EQ(203)))
   ```

2. Do not cache an HTTP response if it has a Vary header with a value of anything other than Accept-Encoding.

   The compression module inserts the Vary: Accept_Encoding header. The name of this expression is **_uncacheableVaryRes**. The following is the policy rule:

   ```
   ((HTTP.RES.HEADER("Vary").EXISTS) &&
   ((HTTP.RES.HEADER("Vary").INSTANCE(1).LENGTH > 0) || (!HTTP.RES.HE
   ADER("Vary").STRIP_END_WS.SET_TEXT_MODE(IGNORECASE).eq("Accept-Enc
   oding"))))
   ```

3. Do not cache a response if its Cache-Control header value is No-Cache, No-Store, or Private, or if the Cache-Control header is not valid.

   The policy name is **_uncacheableCacheControlRes**. The following is the policy rule:

   ```
   ((HTTP.RES.CACHE_CONTROL.IS_PRIVATE) ||
   (HTTP.RES.CACHE_CONTROL.IS_NO_CACHE) ||
   (HTTP.RES.CACHE_CONTROL.IS_NO_STORE) ||
   (HTTP.RES.CACHE_CONTROL.IS_INVALID))
   ```

4. Cache responses if the Cache-Control header has one of the following values: Public, Must-Revalidate, Proxy-Revalidate, Max-Age, S-Maxage.

   The policy name is **_cacheableCacheControlRes**. The following is the policy rule:

   ```
   ((HTTP.RES.CACHE_CONTROL.IS_PUBLIC) ||
   (HTTP.RES.CACHE_CONTROL.IS_MAX_AGE) ||
   (HTTP.RES.CACHE_CONTROL.IS_MUST_REVALIDATE) ||
   (HTTP.RES.CACHE_CONTROL.IS_PROXY_REVALIDATE) ||
   (HTTP.RES.CACHE_CONTROL.IS_S_MAXAGE))
   ```

5. Do not cache responses that contain a Pragma header.

   The name of the policy is **_uncacheablePragmaRes**. The following is the policy rule:

   ```
   HTTP.RES.HEADER("Pragma").EXISTS
   ```

6. Cache responses that contain an Expires header.

   The name of the policy is **_cacheableExpiryRes**. The following is the policy rule:

   ```
   HTTP.RES.HEADER("Expires").EXISTS
   ```

7. If the response contains a Content-Type header with a value of Image, remove any cookies in the header and cache it.

   The name of the policy is **_imageRes**. The following is the policy rule:

   ```
   HTTP.RES.HEADER("Content-Type").SET_TEXT_MODE(IGNORECASE).STARTSWI
   TH("image/")
   ```

   You could configure the following content group to work with this policy:

   ```
   add cache contentgroup nocookie_group -removeCookies YES
   ```

8. Do not cache a response that contains a Set-Cookie header.

   The name of the policy is **_ personalizedRes**. The following is the policy rule:

   ```
   HTTP.RES.HEADER("Set-Cookie").EXISTS ||
   HTTP.RES.HEADER("Set-Cookie2").EXISTS
   ```

Restrictions on Default Policies

You cannot override the following built-in request time policies with user-defined policies.

These policies are listed in priority order.

1. Do not cache any responses if the corresponding HTTP request lacks a GET or POST method.

2. Do not cache any responses for a request if the HTTP request URL length plus host name exceeds 1744 byes.

3. Do not cache a response for a request that contains an If-Match header.

4. Do not cache a request that contains an If-Unmodified-Since header.

   Note that this is different from the If-Modified-Since header.

5. Do not cache a response if the server does not set an expiry header.

You cannot override the following built-in response time policies. These policies are evaluated in the order in which they are listed:

1. Do not cache responses that have an HTTP response status code of 201, 202, 204, 205, or 206.

2. Do not cache responses that have an HTTP response status code of 4xx, with the exceptions of status codes 403, 404, and 410.

3. Do not cache responses if the response type is FIN terminated, or the response does not have one of the following attributes: Content-Length, or Transfer-Encoding: Chunked.

4. Do not cache the response if the caching module cannot parse its Cache-Control header.

Initial Settings for the Default Content Group

When you first enable integrated caching, the NetScaler appliance provides one predefined content group named the Default content group. The following table shows the settings for this group.

Table 1. Predefined Settings for the Default Content Group

Parameter	Description	Default Value
Hit parameters	The hit parameters contain the parameter names that are significant for generating a response. In parameterized hit selection, NetScaler appliance matches the URL stem byte-for-byte, matches normalized values of the hit parameters, and matches the target service information.	none
Invalidation Parameters	These parameters mark a cached object as obsolete during parameterized selection. Specific objects, or all objects in a content group, are selected if the values of the invalidation parameters in the object and in the request are same after normalization. The invalidation parameters are a subset of the hit parameters.	none
Poll Every Time	Poll every time for the objects in this content group.	NO

Ignore reload request	Specifies whether a request can force the system to reload a cached object from the origin. To guard against Denial of Service attacks, you must set this flag to YES. To get RFC-compliant behavior you should set it to NO.	YES
Remove Response Cookies	If this option is disabled for a content group, and if the response contains cookies, the cookies are stored and served with every cache hit. By default, the remove cookies option is enabled for a content group, to prevent the integrated cache from storing any responses with Set-Cookie or Set-Cookie2 headers unless the response is an image.	YES
Prefetch	The Prefetch option refreshes an object when it is about to expire. This ensures that the object remains stale or inactive (and therefore it cannot be served) for a shorter duration of time.	YES
Prefetch period	This duration in seconds during which prefetch should be attempted, immediately before the object's calculated expiry time.	heuristic
Maximum outstanding prefetches	The number of items that can be subjected to a prefetch at a time.	4294967295
Flashcache	Determines whether to enable queuing of client requests and simultaneous distribution of responses to all clients in the queue.	NO
Expire at last byte	Determines whether to expire a cached response immediately after serving it.	NO

Insert Via header	Defines a string to be inserted in a Via header. By default, a Via header is inserted in all responses served from a content group. The Via header is not inserted for responses that are served by the origin server.	YES
Insert Age header	The Age header contains information about the age of the object in seconds as calculated by the integrated cache.	YES
Insert ETag header	With ETag header insertion, the integrated cache does not serve full responses on repeat requests. This is done by forcing the user agent to cache the dynamic response sent by the cache the first time.	YES
Cache-control header	You can enable caching of dynamic objects in the user agent by replacing the Cache-Control headers that are inserted by the origin server. You must configure the new Cache-Control header to be inserted in the content group.	NONE
Quick abort size	If the size of an object that is being downloaded is less than or equal to the quick abort value, and a client aborts during the download, the cache stops downloading the response. If the object is larger than the quick abort size, the cache continues to download the response.	4194303 KBytes (maximum)
Minimum Response Size	You can control memory use by setting a minimum response size. Cached objects must be larger than the minimum response size.	0 KBytes

Maximum Response Size	You can control memory use by setting a maximum response size. Cached objects must be smaller than the maximum response size.	80 KBytes
Memory usage limit	Sets the maximum amount of memory that the cache can use. The effective limit is based on the available memory of the NetScaler appliance. The minimum value is 0 and the maximum value is unlimited.	UNLIMITED
Ignore caching headers in request	Disregards Cache-Control and Pragma headers in HTTP requests.	YES
MinHits configured	Number of hits that are required to qualify a response for storage in this content group.	0
Always evaluate policies		NO
Pinned	By default, when the cache is full the NetScaler appliance replaces the least recently used response first. The NetScaler appliance does not apply this behavior to content groups that are marked as pinned.	NO
Lazy DNS resolution	If set to YES, DNS resolution is performed for responses only if the destination IP address in the request does not match the destination IP address of the cached response.	YES

TCP Buffering

The TCP buffering feature improves the performance of a transaction management environment by adding a speed-matching mechanism between a fast server network and a slow client network and buffering a server's response before delivering it to the client at the client's speed. The server can quickly offload the requested data and then devote its resources to other tasks. Any required retransmission of packets from a server to a client is also done by the Citrix® NetScaler® appliance.

TCP buffering is bypassed for some NetScaler features, including SSL, compression, and caching, because these features perform their own type of buffering. However, TCP buffering is performed for non-compressible and non-cacheable responses from the server, even when compression and caching are enabled. TCP buffering is also skipped for small responses that can fit in a single packet.

You enable or disable the TCP buffering feature globally and on a per-service basis. You can also set the size and memory limit of the buffer.

Note: This content is best understood if you are familiar with creating services and binding them to vservers. For more information, see "Creating a Service" and "Binding Services to a Virtual Server."

Enabling or Disabling TCP Buffering Globally

TCP buffering is disabled on the appliance by default. When you enable TCP buffering globally, all new services are enabled for TCP buffering by default.

To enable or disable the TCP buffering mode globally by using the command line interface

At the command prompt, type one of the following commands:

- enable ns mode TCPB
- disable ns mode TCPB

To enable or disable the TCP buffering mode globally by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under the Modes and Features group, click Configure modes.
3. In the Configure Modes dialog box, select or clear the TCP Buffering check box.
4. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ns mode

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

disable ns mode

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Enabling or Disabling TCP Buffering for a Service

You can enable or disable TCP buffering at the service level.

Note: Service level settings take precedence over the global settings.

To enable or disable the TCP buffering mode for a service by using the command line interface

At the command prompt, type:

set service <name>@ -TCPB (YES | NO)

To enable or disable the TCP buffering mode for a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, click the service for which you want to enable or disable TCP buffering, and then click Open.
3. In the Configure Service dialog box, on the Advanced tab, under Settings, select or clear the TCP Buffering check box.
4. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set service

TCPB

The state of the TCP Buffering feature for this service. Possible values: YES, NO

View description(s) in command reference Top

Setting TCP Buffering Parameters

You can configure two TCP buffering parameters: buffer size and memory usage limit. For best performance, set the connection buffer size so that most responses can fit in the TCP buffer. If integrated caching is not enabled, to provide maximum buffering capacity, increase the memory usage limit to up to half the total system memory.

To set TCP buffering parameters by using the command line interface

At the command prompt, type:

set ns tcpbufParam -size <positiveInteger> -memLimit <positiveInteger>

To set TCP buffering parameters by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, under Settings, click Change TCP parameters.
3. In the Configure TCP Parameters dialog box, under TCP Buffering, in the Buffer Size (KBytes) text box, type the size of the TCP buffer you want to set, for example, 128.
4. In the Memory Usage Limit (MBytes) text box, type the maximum memory size that you want to use for buffering, for example, 128.
5. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns tcpbufParam

size

The size (in KBytes) of the TCP buffer per connection. Default value: 64 Minimum value: 4 Maximum value: 20480

memLimit

The maximum memory that can be used for buffering, in megabytes. Default value: 64

View description(s) in command reference Top

TCP Keep-Alive

The TCP keep-alive feature monitors TCP connection to verify if the peers are up. It sends keep-alive probes at regular intervals to each peer. A peer that acknowledges the probes, is considered to be UP. A peer that does not respond after a specified number of attempts, is considered to be DOWN. By default, the NetScaler appliance does not send keep-alive probes for TCP connections. You can enable the appliance to send TCP keep-alive probes to the peer connections by using the command-line interface or configuration utility.

Note: TCP keep-alive is configured through the set ns tcpProfile command and is not the same as the Client keep-alive. Client keep-alive applies to HTTP and HTTPS applications, and needs no additional configuration. TCP keep-alive is configurable and can be applied to any service using TCP transport, including HTTP and HTTPS.

Configuring Keep-Alive in TCP Profiles

A TCP profile is a collection of configuration settings used to control TCP requests to and responses from virtual servers on a NetScaler appliance. You can use the TCP profile to enable the NetScaler appliance to send TCP keep-alives to the client and server connections. By default, NetScaler does not send keep-alives for TCP connections. You can enable NetScaler appliance to send TCP keep-alive probes to the peer connections by using the command-line interface or configuration utility.

When TCP keep-alive feature is enabled, with the default settings, the appliance probes any TCP connection that has been idle for 15 minutes. If the appliance does not receive a response from the peer within 75 seconds, it sends a second probe. If no response to that probe is received within 75 seconds, the appliance sends a third, final probe. If no response to the final probe is received within 75 seconds, the appliance resets the connection.

By default, this feature is disabled. In addition to enabling the keep-alive feature, you can change the default values for connection idle time, number of probes to send to the peer, and the interval at which to send probes.

In the CLI, use the following command to change the default settings:

set ns tcpProfile <name> [-KA ENABLED] [-KAconnIdleTime <positive_integer>] [-KAmaxProbes <positive_integer>] [-KAprobeInterval <positive_integer>].

In the configuration utility, you can change the settings in the System > Profiles > TCP Profiles >Add TCP Profile or Configure TCP Profile dialog box.

For more information about TCP Profiles, see "Configuring TCP Profiles."

When you configure the TCP profile on a virtual server or service, if the idle time-out of the virtual server or service is less than the keep-alive connection idle time, then the connection might be closed at the idle time-out of the virtual server, even before a keep-alive probe can be sent. Make sure that the idle time-out is not lower than keep-alive connection idle time.

By default, Netscaler will does not close a connection that is responding to keep-alive probes. That can be a security concern. If you would like to close a connection after some time, irrespective of keep-alive status, you can perform the following configuration:

1. Set the idle time-out of the virtual server or service to the maximum time that you want the connection to be open.

2. Set the KAprobeUpdateLastActivity parameter to DISABLED by using the set ns tcpProfile command.

This will ignore keep-alive activity on the connection, and close the connection at time-out value, as if it were idle.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns tcpProfile

name

Name of the TCP profile

KA

Send periodic TCP keep-alive probes to check if peer is still up Possible values: ENABLED, DISABLED Default value: DISABLED

KAconnIdleTime

How long the connection should be idle, in seconds, before sending a keep-alive probe Default value: NSTCP_KA_DEFAULT_CONN_IDLETIME Minimum value: 1 Maximum value: 4095

KAmaxProbes

How many keep-alive probes to send, when not acknowledged, before assuming peer to be down Default value: NSTCP_KA_DEFAULT_PROBE_COUNT Minimum value: 1 Maximum value: 255

KAprobeInterval

Time interval (seconds) before the next probe, if peer does not respond Default value: NSTCP_KA_DEFAULT_INTERVAL Minimum value: 1 Maximum value: 4095

Contents

System

The following topics provide information of the NetScaler system.

Administration	Manages and monitors the NetScaler appliance by using built-in features such as authentication and authorization, SNMP management, audit logging, web server logging, NTP management, and Reporting tool.
AppFlow	Provides information about the reporting capabilities of AppFlow feature of the NetScaler.
AutoScale	Describes how users of Citrix® CloudPlatform can use the AutoScale feature on the NetScaler appliance to enable automatic scaling of their applications.
CloudBridge	Provides help in reducing the cost of moving your applications to the cloud, reduce the risk of application failure, and increase network efficiency in your cloud environment.
Clustering	A setup of multiple nCore NetScaler appliances that ensure high availability, high throughput, and scalability of a deployment of NetScaler appliances.
EdgeSight Monitoring for NetScaler	Monitors the end-user experience with web applications that are served in a NetScaler environment.
Flex Tenancy	A methodology that allows you to tune a group of NetScaler VPX instances to the unique characteristics and needs of individual applications in a complex Web 2.0 setup.
High Availability	A setup of two NetScaler appliances that ensure the high availability of NetScaler appliances.
Networking	Provides information for configuring the various networking components on the NetScaler appliance.
Web Interface	Provides access to Citrix® XenApp™ and Citrix® XenDesktop® applications.

Administration

The following topics provide a conceptual reference and instructions for managing and monitoring the Citrix NetScaler appliance by using built-in features, such as command policies, Simple Network Management (SNMP), audit logging, web server logging, Network Time Protocol (NTP), and the Reporting tool.

Authentication and Authorization	Configure authentication and authorization to manage access to the NetScaler and different parts of the NetScaler configuration.
SNMP	Learn how SNMP works with NetScaler and how to configure SNMP V1, V2, and V3 on NetScaler.
Audit Logging	Configure the NetScaler audit server log to log and monitor the NetScaler states and status information. Also, learn how to configure audit server logging on a server system and for a deployment scenario.
Web Server Logging	Configure web server log to maintain a history of the page requests that originate from the NetScaler.
Advanced Configurations	Learn how to set advanced configurations, such as NTP, PMTU, and auto detected services, on the NetScaler.
Reporting Tool	Learn how to use the Reporting tool to view performance statistics as reports with graphs that are based on statistics collected by the nscollect utility.

Administration

The following topics provide a conceptual reference and instructions for managing and monitoring the Citrix NetScaler appliance by using built-in features, such as command policies, Simple Network Management (SNMP), audit logging, web server logging, Network Time Protocol (NTP), and the Reporting tool.

Authentication and Authorization	Configure authentication and authorization to manage access to the NetScaler and different parts of the NetScaler configuration.
SNMP	Learn how SNMP works with NetScaler and how to configure SNMP V1, V2, and V3 on NetScaler.
Audit Logging	Configure the NetScaler audit server log to log and monitor the NetScaler states and status information. Also, learn how to configure audit server logging on a server system and for a deployment scenario.
Web Server Logging	Configure web server log to maintain a history of the page requests that originate from the NetScaler.
Advanced Configurations	Learn how to set advanced configurations, such as NTP, PMTU, and auto detected services, on the NetScaler.
Reporting Tool	Learn how to use the Reporting tool to view performance statistics as reports with graphs that are based on statistics collected by the nscollect utility.

Authentication and Authorization

To configure NetScaler authentication and authorization, you must first define the users who have access to the NetScaler appliance, and then you can organize these users into groups. After configuring users and groups, you need to configure command policies to define types of access, and assign the policies to users and/or groups.

You must log on as an administrator to configure users, groups, and command policies. The default NetScaler administrator user name is *nsroot*. After logging on as the default administrator, you should change the password for the nsroot account. Once you have changed the password, no user can access the NetScaler appliance until you create an account for that user. If you forget the administrator password after changing it from the default, you can reset it to nsroot.

Configuring Users and Groups

You must define your users by configuring accounts for them. To simplify the management of user accounts, you can organize them into groups.

You can also customize the command-line prompt for a user. Prompts can be defined in a user’s configuration, in a user-group configuration, and in the global configuration. The prompt displayed for a given user is determined by the following order of precedence:

1. Display the prompt as defined in the user's configuration.
2. Display the prompt as defined in the group configuration for the user’s group.
3. Display the prompt as defined in the system global configuration.

You can now specify a time-out value for inactive CLI sessions for a system user. If a user's CLI session is idle for a time that exceeds the time-out value, the NetScaler appliance terminates the connection. The timeout can be defined in a user’s configuration, in a user-group configuration, and in the global configuration. The time-out for inactive CLI sessions for a user is determined by the following order of precedence:

1. Time-out value as defined in the user's configuration.
2. Time-out value as defined in the group configuration for the user’s group.
3. Time-out value as defined in the system global configuration.

Configuring User Accounts

To configure user accounts, you simply specify user names and passwords. You can change passwords and remove user accounts at any time.

To create a user account by using the command line interface

At the command prompt, type the following commands to create a user account and verify the configuration:

- add system user <userName> [-promptString <string>] [-timeout <secs>]
- show system user <userName>

Example

> add system user johnd -promptString user-%u-at-%T

Enter password:
Confirm password:

To configure a user account by using the configuration utility

Navigate to System > Users, create the user.

Parameter Descriptions (of commands listed in the CLI procedure)

add system user

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show system user

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring User Groups

After configuring a user group, you can easily grant the same access rights to everyone in the group. To configure a group, you create the group and bind users to the group. You can bind each user account to more than one group. Binding user accounts to multiple groups may allow more flexibility when applying command policies.

To create a user group by using the command line interface

At the command prompt, type the following commands to create a user group and verify the configuration:

- add system group <groupName> [-promptString <string>] [-timeout <secs>]
- show system group <groupName>

Example

> add system group Managers -promptString Group-Managers-at-%h

To bind a user to a group by using the command line interface

At the command prompt, type the following commands to bind a user account to a group and verify the configuration:

- bind system group <groupName> -userName <userName>
- show system group <groupName>

Example

> bind system group Managers -userName user1

To configure a user group by using the configuration utility

Navigate to System > Groups, add create the group.

Note: To add members to the group, under the Members section, click Add. Select users from the Available list and add them to the Configured list.

Parameter Descriptions (of commands listed in the CLI procedure)

add system group

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show system group

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind system group

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Command Policies

Command policies regulate which commands, command groups, vservers, and other entities that users and user groups are permitted to use.

The appliance provides a set of built-in command policies, and you can configure custom policies. To apply the policies, you bind them to users and/or groups.

Here are the key points to keep in mind when defining and applying command policies.

- You cannot create global command policies. Command policies must be bound directly to the users and groups on the appliance.
- Users or groups with no associated command policies are subject to the default (DENY-ALL) command policy, and are therefore unable to execute any configuration commands until the proper command policies are bound to their accounts.
- All users inherit the policies of the groups to which they belong.
- You must assign a priority to a command policy when you bind it to a user account or group account. This enables the appliance to determine which policy has priority when two or more conflicting policies apply to the same user or group.
- The following commands are available by default to any user and are unaffected by any command you specify:

  help, show cli attribute, set cli prompt, clear cli prompt, show cli prompt, alias, unalias, history, quit, exit, whoami, config, set cli mode, unset cli mode, and show cli mode.

Built-in Command Policies

The following table describes the built-in policies.

Table 1. Built-in Command Policies

Policy name	Allows
read-only	Read-only access to all show commands except show ns runningConfig, show ns ns.conf, and the show commands for the NetScaler command group.
operator	Read-only access and access to commands to enable and disable services and servers.
network	Full access, except to the set and unset SSL commands, show ns ns.conf, show ns runningConfig, and show gslb runningConfig commands.

superuser	Full access. Same privileges as the nsroot user.

Creating Custom Command Policies

Regular expression support is offered for users with the resources to maintain more customized expressions, and for those deployments that require the flexibility that regular expressions offer. For most users, the built-in command policies are sufficient. Users who need additional levels of control but are unfamiliar with regular expressions may want to use only simple expressions, such as those in the examples provided in this section, to maintain policy readability.

When you use a regular expression to create a command policy, keep the following in mind.

- When you use regular expressions to define commands that will be affected by a command policy, you must enclose the commands in double quotation marks. For example, to create a command policy that includes all commands that begin with *show*, type the following:

  ```
  "^show .*$"
  ```

  To create a command policy that includes all commands that begin with *rm*, type the following:

  ```
  "^rm .*$"
  ```

- Regular expressions used in command policies are not case sensitive.

The following table lists examples of regular expressions:

Table 2. Examples of Regular Expressions for Command Policies

Command specification	Matches these commands
"^rm\s+.*$"	All remove actions, because all remove actions begin with the *rm* string, followed by a space and additional parameters and flags.
"^show\s+.*$"	All show commands, because all show actions begin with the *show* string, followed by a space and additional parameters and flags.
"^shell$"	The shell command alone, but not combined with any other parameters or flags.
"^add\s+vserver\s+.*$"	All create vserver actions, which consist of the *add vserver* command followed by a space and additional parameters and flags.
"^add\s+(lb\s+vserver)\s+.*"	All create lb vserver actions, which consist of the add lb vserver command followed by a space and additional parameters and flags.

The following table shows the command specifications for each of the built-in command policies.

Table 3. Expressions Used in the Built-in Command Policies

Policy name	Command specification regular expression
read-only	(^man.*)|(^show\s+(?!system)(?!configstatus)(?!ns ns\.conf)(?!ns savedconfig)(?!ns runningConfig)(?!gslb runningConfig)(?!audit messages)(?!techsupport).*)|(^stat.*)
operator	(^man.*)|(^show\s+(?!system)(?!configstatus)(?!ns ns\.conf)(?!ns savedconfig)(?!ns runningConfig)(?!gslb runningConfig)(?!audit messages)(?!techsupport).*)|(^stat.*)|(^(enable|disable) (server|service).*)
network	^(?!clear ns config.*)(?!scp.*)(?!set ssl fips)(?!reset ssl fips)(?!diff ns config)(?!shell)(?!reboot)(?!batch)\S+\s+(?!system)(?!configstatus)(?!ns ns\.conf)(?!ns savedconfig)(?!ns runningConfig)(?!gslb runningConfig)(?!techsupport).*
superuser	.*

To create a command policy by using the command line interface

At the command prompt, type the following commands to create a command policy and verify the configuration:

- add system cmdPolicy <policyname> <action> <cmdspec>
- show system cmdPolicy <policyName>

Example

> add system cmdPolicy read_all ALLOW (^show\s+(!system)(!ns ns.conf)(!ns runningConfig).*)|(^stat.*)

To configure a command policy by using the configuration utility

Navigate to System > Command Policies, and create the command policy.

Binding Command Policies to Users and Groups

Once you have defined your command policies, you must bind them to the appropriate user accounts and groups. When you bind a policy, you must assign it a priority so that the appliance can determine which command policy to follow when two or more applicable command policies are in conflict.

Command policies are evaluated in the following order:

- Command policies bound directly to users and the corresponding groups are evaluated according to priority number. A command policy with a lower priority number is evaluated before one with a higher priority number. Therefore, any privileges the lower-numbered command policy explicitly grants or denies are not overridden by a higher-numbered command policy.
- When two command policies, one bound to a user account and other to a group, have the same priority number, the command policy bound directly to the user account is evaluated first.

To bind command policies to a user by using the command line interface

At the command prompt, type the following commands to bind a command policy to a user and verify the configuration:

- bind system user <userName> -policyName <policyName> <priority>
- show system user <userName>

Example

> bind system user user1 -policyName read_all 1

To bind command policies to a user by using the configuration utility

Navigate to System > Users, select the user and bind command policies. Optionally, you can modify the default priority to ensure that the policy is evaluated in the proper order.

To bind command policies to a group by using the command line interface

At the command prompt, type the following commands to bind a command policy to a user group and verify the configuration:

- bind system group <groupName> -policyName <policyName> <priority>
- show system group <groupName>

Example

> bind system group Managers -policyName read_all 1

To bind command policies to a group by using the configuration utility

Navigate to System > Groups, select the group and bind command policies. Optionally, you can modify the default priority to ensure that the policy is evaluated in the proper order.

Resetting the Default Administrator (nsroot) Password

The nsroot account provides complete access to all features of the appliance. Therefore, to preserve security, the nsroot account should be used only when necessary, and only individuals whose duties require full access should know the password for the nsroot account. Frequently changing the nsroot password is advisable. If you lose the password, you can reset it to the default and then change it.

To reset the nsroot password, you must boot the appliance into single user mode, mount the file systems in read/write mode, and remove the set NetScaler user nsroot entry from the ns.conf file. You can then reboot, log on with the default password, and choose a new password.

To reset the nsroot password

1. Connect a computer to the console port of the NetScaler ADC and log on.

   Note: You cannot log on by using SSH to perform this procedure; you must connect directly to the appliance.

2. Reboot the NetScaler ADC.

3. Press CTRL+C when the following message appears:

   ```
   Press [Ctrl-C] for command prompt, or any other key to boot
   immediately.

   Booting [kernel] in # seconds.
   ```

4. Run the following command to start the NetScaler in a single user mode:

   boot -s

   Note: If boot -s does not work, then try reboot -- -s and appliance will reboot in single user mode.

   After the appliance boots, it displays the following message:

   ```
   Enter full path name of shell or RETURN for /bin/sh:
   ```

5. Press ENTER key to display the # prompt, and type the following commands to mount the file systems:

   a. Run the following command to check the disk consistency:

      fsck /dev/ad0s1a

      Note: Your flash drive will have a specific device name depending on your NetScaler; hence, you have to replace ad0s1a in the preceding command with the appropriate device name.

   b. Run the following command to display the mounted partitions:

      df

      If the flash partition is not listed, you need to mount it manually.

   c. Run the following command to mount the flash drive:

      mount /dev/ad0s1a /flash

6. Run the following command to change to the nsconfig directory:

   cd /flash/nsconfig

7. Run the following commands to rewrite the `ns.conf` file and remove the set of system commands defaulting to the nsroot user:

a. Run the following command to create a new configuration file that does not have commands defaulting to the nsroot user:

   grep –v “set system user nsroot” ns.conf > new.conf

b. Run the following command to make a backup of the existing configuration file:

   mv ns.conf old.ns.conf

c. Run the following command to rename the new.conf file to ns.conf:

   mv new.conf ns.conf

8. Run the following command to reboot the NetScaler:

   reboot

9. Log on using the default nsroot user credentials.

10. Run the following command to reset the nsroot user password:

    set system user nsroot <New_Password>

Example of a User Scenario

The following example shows how to create a complete set of user accounts, groups, and command policies and bind each policy to the appropriate groups and users. The company, Example Manufacturing, Inc., has three users who can access the NetScaler appliance:

- **John Doe.** The IT manager. John needs to be able to see all parts of the NetScaler configuration but does not need to modify anything.
- **Maria Ramiez.** The lead IT administrator. Maria needs to be able to see and modify all parts of the NetScaler configuration except for NetScaler commands (which local policy dictates must be performed while logged on as nsroot).
- **Michael Baldrock.** The IT administrator in charge of load balancing. Michael needs to be able to see all parts of the NetScaler configuration, but needs to modify only the load balancing functions.

The following table shows the breakdown of network information, user account names, group names, and command policies for the sample company.

Table 1. Sample Values for Creating Entities

Field	Value	Note
NetScaler host name	ns01.example.net	N/A
User accounts	johnd, mariar, and michaelb	John Doe, IT manager, Maria Ramirez, IT administrator and Michael Baldrock, IT administrator.
Groups	Managers and SysOps	All managers and all IT administrators.
Command Policies	read_all, modify_lb, and modify_all	Allow complete read-only access, Allow modify access to load balancing, and Allow complete modify access.

The following description walks you through the process of creating a complete set of user accounts, groups, and command policies on the NetScaler appliance named ns01.example.net.

The description includes procedures for binding the appropriate user accounts and groups to one another, and binding appropriate command policies to the user accounts and groups.

This example illustrates how you can use prioritization to grant precise access and privileges to each user in the IT department.

The example assumes that initial installation and configuration have already been performed on the NetScaler.

Configuration steps

1. Use the procedure described in "Configuring User Accounts" to create user accounts **johnd**, **mariar**, and **michaelb**.

2. Use the procedure described in "Configuring User Groups" to create user groups **Managers** and **SysOps**, and then bind the users **mariar** and **michaelb** to the **SysOps** group and the user **johnd** to the **Managers** group.

3. Use the procedure described in "Creating Custom Command Policies" to create the following command policies:

   - **read_all** with action **Allow** and command spec "(^show\s+(?!system)(?!ns ns.conf)(?!ns runningConfig).*)|(^stat.*)"

   - **modify_lb** with action as **Allow** and the command spec "^set\s+lb\s+.*$"

   - **modify_all** with action as **Allow** and the command spec **"^\S+\s+(?!system).*"**

4. Use the procedure described in "Binding Command Policies to Users and Groups" to bind the **read_all** command policy to the **SysOps** group, with priority value **1**.

5. Use the procedure described in "Binding Command Policies to Users and Groups" to bind the **modify_lb** command policy to user **michaelb**, with priority value **5**.

The configuration you just created results in the following:

- John Doe, the IT manager, has read-only access to the entire NetScaler configuration, but he cannot make modifications.

- Maria Ramirez, the IT lead, has near-complete access to all areas of the NetScaler configuration, having to log on only to perform NetScaler-level commands.

- Michael Baldrock, the IT administrator responsible for load balancing, has read-only access to the NetScaler configuration, and can modify the configuration options for load balancing.

The set of command policies that applies to a specific user is a combination of command policies applied directly to the user's account and command policies applied to the group(s) of which the user is a member.

Each time a user enters a command, the operating system searches the command policies for that user until it finds a policy with an ALLOW or DENY action that matches the command. When it finds a match, the operating system stops its command policy search and allows or denies access to the command.

If the operating system finds no matching command policy, it denies the user access to the command, in accordance with the NetScaler appliance's default deny policy.

Note: When placing a user into multiple groups, take care not to cause unintended user command restrictions or privileges. To avoid these conflicts, when organizing your users in groups, bear in mind the NetScaler command policy search procedure and policy ordering rules.

Configuring External User Authentication

External user authentication is the process of authenticating the users of the Citrix NetScaler appliance by using an external authentication server. The NetScaler supports LDAP, RADIUS, and TACACS+ authentication servers. To configure external user authentication, you must create authentication policies. You can configure one or many authentication policies, depending on your authentication needs. An authentication policy consists of an expression and an action. Authentication policies use NetScaler classic expressions, which are described in detail in "Policy Configuration and Reference."

After creating an authentication policy, you bind it to the system global entity and assign a priority to it. You can create simple server configurations by binding a single authentication policy to the system global entity. Or, you can configure a cascade of authentication servers by binding multiple policies to the system global entity. If no authentication policies are bound to the system, users are authenticated by the onboard system.

Configuring LDAP Authentication

You can configure the NetScaler appliance to authenticate user access with one or more LDAP servers. LDAP authorization requires identical group names in Active Directory, on the LDAP server, and on the appliance. The characters and case must also be the same.

By default, LDAP authentication is secured by using SSL/TLS protocol. There are two types of secure LDAP connections. In the first type, the LDAP server accepts the SSL/TLS connection on a port separate from the port used to accept clear LDAP connections. After users establish the SSL/TLS connection, LDAP traffic can be sent over the connection. The second type allows both unsecure and secure LDAP connections and is handled by a single port on the server. In this scenario, to create a secure connection, the client first establishes a clear LDAP connection. Then the LDAP command StartTLS is sent to the server over the connection. If the LDAP server supports StartTLS, the connection is converted to a secure LDAP connection by using TLS.

The port numbers for LDAP connections are:

- 389 for unsecured LDAP connections
- 636 for secure LDAP connections
- 3268 for Microsoft unsecure LDAP connections
- 3269 for Microsoft secure LDAP connections

LDAP connections that use the StartTLS command use port number 389. If port numbers 389 or 3268 are configured on the appliance, it tries to use StartTLS to make the connection. If any other port number is used, connection attempts use SSL/TLS. If StartTLS or SSL/TLS cannot be used, the connection fails.

When configuring the LDAP server, the case of the alphabetic characters must match that on the server and on the appliance. If the root directory of the LDAP server is specified, all of the subdirectories are also searched to find the user attribute. In large directories, this can affect performance. For this reason, Citrix recommends that you use a specific organizational unit (OU).

The following table lists examples of user attribute fields for LDAP servers.

Table 1. User Attribute Fields for LDAP Servers

LDAP server	User attribute	Case sensitive?
Microsoft Active Directory	Server sAMAccountName	No
Novell eDirectory	cn	Yes
IBM Directory Server	uid	Yes
Lotus Domino	CN	Yes
Sun ONE directory (formerly iPlanet)	uid or cn	Yes

The following table lists examples of the base distinguished name (DN).

Table 2. Examples of Base Distinguished Name

LDAP server	Base DN
Microsoft Active Directory	DC=citrix, DC=local
Novell eDirectory	dc=citrix, dc=net
IBM Directory Server	cn=users
Lotus Domino	OU=City, O=Citrix, C=US
Sun ONE directory (formerly iPlanet)	ou=People, dc=citrix, dc=com

The following table lists examples of the bind distinguished name (DN).

Table 3. Examples of Bind Distinguished Name

LDAP server	Bind DN
Microsoft Active Directory	CN=Administrator, CN=Users, DC=citrix, DC=local
Novell eDirectory	cn=admin, dc=citrix, dc=net
IBM Directory Server	LDAP_dn
Lotus Domino	CN=Notes Administrator, O=Citrix, C=US
Sun ONE directory (formerly iPlanet)	uid=admin, ou=Administrators, ou=TopologyManagement, o=NetscapeRoot

To configure LDAP authentication by using the command line interface

At the command prompt, do the following:

1. Create an LDAP action.

   add authentication ldapAction <name> {-serverIP <ip_addr|ipv6_addr|*> | {-serverName <string>}} >] [-authTimeout <positive_integer>] [-ldapBase <string>] [-ldapBindDn <string>] {-ldapBindDnPassword } [-ldapLoginName <string>] [-groupAttrName <string>] [-subAttributeName <string>]

   Example:

   add authentication ldapAction ldap70 -serverIP <IP> -authTimeout 30 -ldapBase "CN=xxxxx,DC=xxxx,DC=x

2. Create an LDAP policy.

   add authentication ldapPolicy <name> <rule> [<reqAction>]

   Example:

   add authentication ldappolicy ldap_pol ns_true ldap70

3. Bind the LDAP policy to the following bind points at which the policy will be evaluated.

   - **System Global**: bind system global <policyName> [-priority <positive_integer>]
   - **VPN Global**: bind vpn global <policyName> [-priority <positive_integer>]
   - **Authentication Server**: bind authentication vserver <name> [-policy <string> [-priority <positive_integer>]
   - **VPN Server**: bind vpn vserver <name> [-policy <string> [-priority <positive_integer>]

To configure LDAP authentication by using the configuration utility

1. Navigate to System > Authentication.
2. On the Policies tab, click Add.
3. In Name, type a name for the policy.
4. In Authentication Type, select LDAP.
5. Next to Server, click New.
6. In Name, type the name of the server.
7. Under Server, in IP Address and Port, type the IP address and port number of the LDAP server.
8. Under Connection Settings, provide the following information:
   - In Base DN (location of users), type the base DN under which users are located.

     Base DN is usually derived from the Bind DN by removing the user name and specifying the group where in which are located. Examples of syntax for base DN are:

     ou=users, dc=ace, dc=com
     cn=Users, dc=ace, dc=com

   - In Administrator Bind DN, type the administrator bind DN for queries to the LDAP directory. Examples for syntax of bind DN are:

     domain/user name
     ou=administrator, dc=ace, dc=com
     user@domain.name (for Active Directory)
     cn=Administrator, cn=Users, dc=ace, dc=com

     For Active Directory, the group name specified as cn=groupname is required. The group name that is defined in the appliance must be identical to the group name that is defined on the LDAP server. For other LDAP directories, the group name either is not required or, if required, is specified as ou=groupname.

     The appliance binds to the LDAP server, using the administrator credentials, and then searches for the user. After locating the user, the appliance unbinds the administrator credentials and rebinds with the user credentials.

   - In Administrator Password and Confirm Administrator Password, type the administrator password for the LDAP server.
9. To retrieve additional LDAP settings automatically, click Retrieve Attributes. The fields under Other Settings then populate automatically. If you do not want to do this, skip to Step 12.
10. Under Other Settings, in Server Logon Name Attribute, type the attribute under which the appliance should look for user logon names for the LDAP server that you are

configuring. The default is `samAccountName`.

11. In Group Attribute, leave the default memberOf for Active Directory or change it to that of the LDAP server type you are using. This attribute enables the appliance to obtain the groups associated with a user during authorization.

12. In Security Type, select the security type. If you select PLAINTEXT or TLS for security, use port number 389. If you select SSL, use port number 636.

13. To allow users to change their LDAP password, select Allow Password Change. If you select PLAINTEXT as the security type, allowing users to change their passwords is not supported.

14. Click Create.

15. In the Create Authentication Policy dialog box, next to Named Expressions, select the expression, click Add Expression, click Create, and click Close.

After the LDAP server settings are configured on the appliance, bind the policy to the system global entity. For more information about binding authentication policies globally, see "Binding the Authentication Policies to the System Global Entity."

Determining attributes in the LDAP directory

If you need help determining your LDAP directory attributes, you can easily look them up with the free LDAP browser from Softerra.

You can download the LDAP browser from the Softerra LDAP Administrator Web site at http://www.ldapbrowser.com. After the browser is installed, set the following attributes:

- The host name or IP address of your LDAP server.
- The port of your LDAP server. The default is 389.
- The base DN field can be left blank.
- The information provided by the LDAP browser can help you determine the base DN needed for the Authentication tab.
- The Anonymous Bind check determines whether the LDAP server requires user credentials for the browser to connect to it. If the LDAP server requires credentials, leave the check box cleared.

After completing the settings, the LDAP browser displays the profile name in the left pane and connects to the LDAP server.

Parameter Descriptions (of commands listed in the CLI procedure)

add authentication ldapAction

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

add authentication ldapPolicy

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring RADIUS Authentication

You can configure the NetScaler appliance to authenticate user access with one or more RADIUS servers. If you are using RSA SecurID, SafeWord, or Gemalto Protiva products, use a RADIUS server.

Your configuration might require using a network access server IP address (NAS IP) or a network access server identifier (NAS ID). When configuring the appliance to use a RADIUS authentication server, use the following guidelines:

- If you enable use of the NAS IP, the appliance sends its configured IP address to the RADIUS server, rather than the source IP address used in establishing the RADIUS connection.
- If you configure the NAS ID, the appliance sends the identifier to the RADIUS server. If you do not configure the NAS ID, the appliance sends its host name to the RADIUS server.
- When the NAS IP is enabled, the appliance ignores any NAS ID that was configured by using the NAS IP to communicate with the RADIUS server.

To configure RADIUS authentication by using the configuration utility

1. Navigate to System > Authentication.
2. On the Policies tab, click Add.
3. In Name, type a name for the policy.
4. In Authentication Type, select RADIUS.
5. Next to Server, click New.
6. In Name, type a name for the server.
7. Under Server, in IP Address, type the IP address of the RADIUS server.
8. In Port, type the port. The default is 1812.
9. Under Details, in Secret Key and Confirm Secret Key, type the RADIUS server secret.
10. In NAS ID, type the identifier number, and then click Create.
11. In the Create Authentication Policy dialog box, next to Named Expressions, select the expression, click Add Expression, click Create, and click Close.

After the RADIUS server settings are configured on the appliance, bind the policy to the system global entity. For more information about binding authentication policies globally,

see "Binding the Authentication Policies to the System Global Entity."

Choosing RADIUS authentication protocols

The NetScaler appliance supports implementations of RADIUS that are configured to use any of several protocols for user authentication, including:

- Password Authentication Protocol
- Challenge-Handshake Authentication Protocol (CHAP)
- Microsoft Challenge-Handshake Authentication Protocol (MS-CHAP Version 1 and Version 2)

If your deployment of the appliance is configured to use RADIUS authentication and your RADIUS server is configured to use Password Authentication Protocol, you can strengthen user authentication by assigning a strong shared secret to the RADIUS server. Strong RADIUS shared secrets consist of random sequences of uppercase and lowercase letters, numbers, and punctuation, and are at least 22 characters long. If possible, use a random character generation program to determine RADIUS shared secrets.

To further protect RADIUS traffic, assign a different shared secret to each appliance or virtual server. When you define clients on the RADIUS server, you can also assign a separate shared secret to each client. If you do this, you must configure separately each policy that uses RADIUS authentication.

Shared secrets are configured on the appliance when a RADIUS policy is created.

Configuring IP address extraction

You can configure the appliance to extract the IP address from a RADIUS server. When a user authenticates with the RADIUS server, the server returns a framed IP address that is assigned to the user. The following are attributes for IP address extraction:

- Allows a remote RADIUS server to supply an IP address from the internal network for a user logged on to the appliance.
- Allows configuration for any RADIUS attribute using the type ipaddress, including those that are vendor encoded.

When configuring the RADIUS server for IP address extraction, you configure the vendor identifier and the attribute type.

The vendor identifier enables the RADIUS server to assign an IP address to the client from a pool of IP addresses that are configured on the RADIUS server. The vendor ID and attributes are used to make the association between the RADIUS client and the RADIUS server. The vendor ID is the attribute in the RADIUS response that provides the IP address of the internal network. A value of zero indicates that the attribute is not vendor encoded. The attribute type is the remote IP address attribute in a RADIUS response. The minimum value is one and the maximum value is 255.

A common configuration is to extract the RADIUS attribute *framed IP address*. The vendor ID is set to zero or is not specified. The attribute type is set to eight.

To configure IP address extraction by using the configuration utility

1. Navigate to System > Authentication > Radius, and select a policy.
2. Modify the server parameters and set relevant values in Group Vendor Identifier and Group Attribute Type fields.

Configuring TACACS+ Authentication

You can configure a TACACS+ server for authentication. Similar to RADIUS authentication, TACACS+ uses a secret key, an IP address, and the port number. The default port number is 49. To configure the appliance to use a TACACS+ server, provide the server IP address and the TACACS+ secret. The port needs to be specified only when the server port number in use is something other than the default port number of 49.

To configure TACACS+ authentication by using the configuration utility

1. Navigate to System > Authentication.
2. On the Policies tab, click Add.
3. In Name, type a name for the policy.
4. In Authentication Type, select TACACS.
5. Next to Server, click New.
6. In Name, type a name for the server.
7. Under Server, type the IP address and port number of the TACACS+ server.
8. Under TACACS server information, in TACACS Key and Confirm TACACS key, type the key.
9. In Authorization, select ON and click Create.
10. In the Create Authentication Policy dialog box, next to Named Expressions, select the expression, click Add Expression, click Create, and click Close.

After the TACACS+ server settings are configured on the appliance, bind the policy to the system global entity. For more information about binding authentication policies globally, see "Binding the Authentication Policies to the System Global Entity."

Binding the Authentication Policies to the System Global Entity

When the authentication policies are configured, bind the policies to the system global entity.

To bind an authentication policy to system global using the command line interface

At the command line prompt, do the following:

bind system global <policyName> [-priority <positive_integer>]

Example:

bind system global ldappol1 -priority 10

To bind an authentication policy to system global using the configuration utility

1. Navigate to System > Authentication.
2. On the Policies tab, click Global Bindings.
3. Click Insert Policy and under Policy Name, select the policy and click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

bind system global

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

SNMP

You can use Simple Network Management Protocol (SNMP) to configure the SNMP agent on the Citrix NetScaler appliance to generate asynchronous events, which are called *traps*. The traps are generated whenever there are abnormal conditions on the NetScaler. The traps are then sent to a remote device called a *trap listener*, which signals the abnormal condition on the NetScaler appliance. Or, you can query the SNMP agent for System-specific information from a remote device called an *SNMP manager*. The agent then searches the management information base (MIB) for the data requested and sends the data to the SNMP manager.

The SNMP agent on the NetScaler can generate traps compliant with SNMPv1 and SNMPv2 only. For querying, the SNMP agent supports SNMP version 1 (SNMPv1), SNMP version 2 (SNMPv2), and SNMP version 3 (SNMPv3).

The following figure illustrates a network with a NetScaler that has SNMP enabled and configured. In the figure, each SNMP network management application uses SNMP to communicate with the SNMP agent on the NetScaler. The SNMP agent searches its management information base (MIB) to collect the data requested by the SNMP Manager and provides the information to the application.

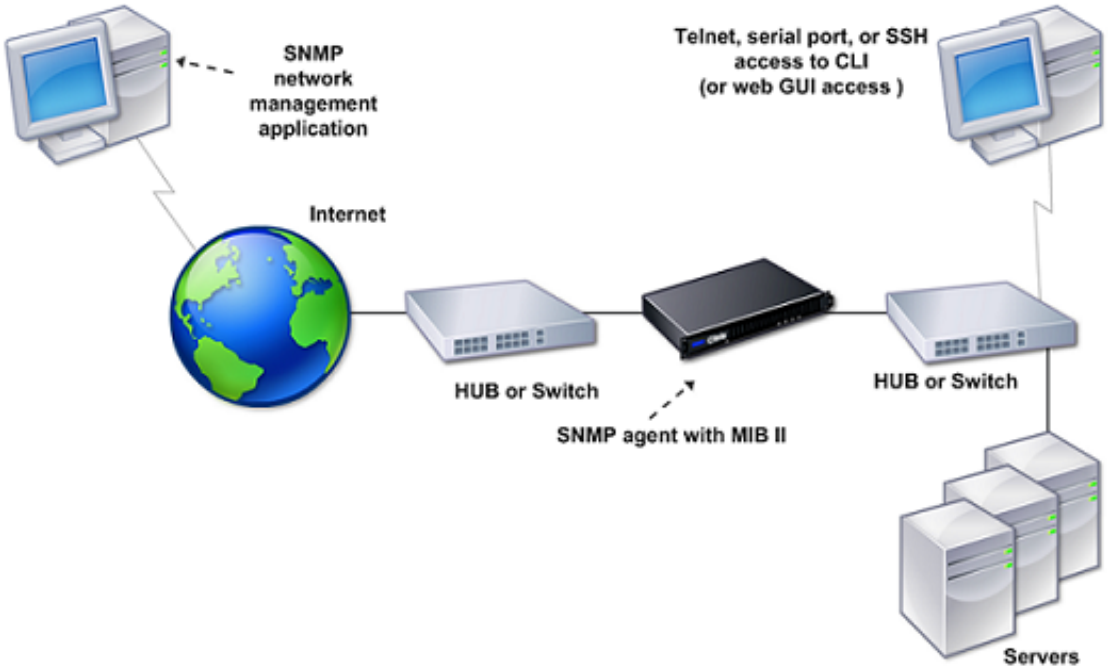

Figure 1. *NetScaler Supporting SNMP*

Importing MIB Files to the SNMP Manager and Trap Listener

To monitor a NetScaler appliance, you must download the MIB object definition files. The MIB files include the following:

- MIB-2 groups SYSTEM, IF, ICMP, UDP, and SNMP.
- NetScaler-specific configuration and statistics.

You can obtain the MIB object definition files from the /netscaler/snmp directory or from the Downloads tab of the NetScaler GUI.

If the SNMP management application is other than *WhatsUpGold*, download the following files to the SNMP management application:

- NS-MIB-smiv1.mib. Used by SNMPv1 managers and trap listeners.
- NS-MIB-smiv2.mib. Used by SNMPv2 and SNMPv3 managers and SNMPv2 trap listeners.

If the SNMP management application is *WhatsUpGold*, download the following files to the SNMP management application:

- mib.txt
- traps.txt

Configuring the NetScaler to Generate SNMP Traps

You can configure the NetScaler appliance to generate asynchronous events, which are called *traps*. The traps are generated whenever there are abnormal conditions on the appliance. The traps are sent to a remote device called a *trap listener*. This helps administrators monitor the appliance and respond promptly to any issues.

The NetScaler appliance provides a set of condition entities called *SNMP alarms*. When the condition in any SNMP alarm is met, the appliance generates SNMP trap messages that are sent to the configured trap listeners. For example, when the LOGIN-FAILURE alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a login failure on the appliance.

To configure the NetScaler appliance to generate traps, you need to enable and configure alarms. Then, you specify trap listeners to which the appliance will send the generated trap messages.

Enabling an SNMP Alarm

The NetScaler appliance generates traps only for SNMP alarms that are enabled. Some alarms are enabled by default, but you can disable them.

When you enable an SNMP alarm, the appliance generates corresponding trap messages when some events occur. Some alarms are enabled by default.

To enable an SNMP alarm by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- enable snmp alarm `<trapName>`
- show snmp alarm `<trapName>`

To enable an SNMP alarm by using the configuration utility

1. Navigate to System > SNMP > Alarms, and select the alarm.
2. Click Actions and select Enable.

Parameter Descriptions (of commands listed in the CLI procedure)

enable snmp alarm

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show snmp alarm

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Alarms

The NetScaler appliance provides a set of condition entities called *SNMP alarms*. When the condition set for an SNMP alarm is met, the appliance generates SNMP traps messages that are sent to the configured trap listeners. For example, when the LOGIN-FAILURE alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a login failure on the appliance.

You can assign an SNMP alarm with a severity level. When you do this, the corresponding trap messages are assigned that severity level.

The following are the severity levels, defined on the appliance, in decreasing order of severity.

- Critical
- Major
- Minor
- Warning
- Informational

For example, if you set a warning severity level for the SNMP alarm named LOGIN-FAILURE, the trap messages generated when there is a login failure will be assigned with the warning severity level.

You can also configure an SNMP alarm to log the corresponding trap messages generated whenever the condition on that alarm is met.

To configure an SNMP alarm by using the command line interface

At the command prompt, type the following commands to configure an SNMP alarm and verify the configuration:

- set snmp alarm <trapName> [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-time <secs>] [-state (ENABLED | DISABLED)] [-severity <severity>] [-logging (ENABLED | DISABLED)]
- show snmp alarm <trapName>

To configure SNMP alarms by using the configuration utility

Navigate to System > SNMP > Alarms, select an alarm and configure the alarm parameters.

Parameter Descriptions (of commands listed in the CLI procedure)

set snmp alarm

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show snmp alarm

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring SNMPv1 or SNMPv2 Traps

After configuring the alarms, you need to specify the trap listener to which the appliance sends the trap messages. Apart from specifying parameters such as IP or IPv6 address and the destination port of the trap listener, you can specify the type of trap (either generic or specific) and the SNMP version.

You can configure a maximum of 20 trap listeners for receiving either generic or specific traps.

You can also configure the appliance to send SNMP trap messages with a source IP address other than the NetScaler IP (NSIP or NSIP6) address to a particular trap listener. For a trap listener that has an IPv4 address, you can set the source IP to either a mapped IP (MIP) address or a subnet IP (SNIP) address configured on the appliance. For a trap listener that has an IPv6 address, you can set the source IP to subnet IPv6 (SNIP6) address configured on the appliance.

You can also configure the appliance to send trap messages to a trap listener on the basis of a severity level. For example, if you set the severity level as Minor for a trap listener, all trap messages of the severity level equal to or greater than Minor (Minor, Major, and Critical) are sent to the trap listener.

If you have defined a community string for the trap listener, you must also specify a community string for each trap that is to be sent to the listener. A trap listener for which a community string has been defined accepts only trap messages that include a community string matching the community string defined in the trap listener. Other trap messages are dropped.

To add an SNMP trap by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp trap <trapClass> <trapDestination> -version (V1 | V2) -destPort <port> -communityName <string> -srcIP <ip_addr> -severity <severity>
- show snmp trap

Example

```
> add snmp trap specific 10.102.29.3 -version V2 -destPort 80 -communityName com1 -severity Major
```

To configure SNMP Traps by using the configuration utility

Navigate to System > SNMP > Traps, and create the SNMP trap.

Parameter Descriptions (of commands listed in the CLI procedure)

add snmp trap

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show snmp trap

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Enabling Unconditional SNMP Trap Logging

By default, the NetScaler appliance logs any SNMP trap messages (for SNMP alarms in which logging is enabled) when at least one trap listener is specified on the appliance. However, you can specify that SNMP trap messages be logged even when no trap listeners are configured.

To enable unconditional SNMP trap logging by using the command line interface

At the command prompt, type the following commands to configure unconditional SNMP trap logging and verify the configuration:

- set snmp option -snmpTrapLogging (ENABLED | DISABLED)
- show snmp option

To enable unconditional SNMP trap logging by using the configuration utility

Navigate to System > SNMP, click Change SNMP Options and select SNMP Trap Logging.

Parameter Descriptions (of commands listed in the CLI procedure)

set snmp option

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show snmp option

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring the NetScaler for SNMP v1 and v2 Queries

You can query the NetScaler SNMP agent for system-specific information from a remote device called *SNMP managers*. The agent then searches the management information base (MIB) for the data requested and sends the data to the SNMP manager.

The following types of SNMP v1 and v2 queries are supported by the SNMP agent:

- GET
- GET NEXT
- ALL
- GET BULK

You can create strings called *community strings* and associate each of these to query types. You can associate one or more community strings to each query type. Community string are passwords and used to authenticate SNMP queries from SNMP managers.

For example, if you associate two community strings, such as **abc** and **bcd**, to the query type GET NEXT, the SNMP agent on the NetScaler appliance considers only those GET NEXT SNMP query packets that contain **abc** or **bcd** as the community string.

Specifying an SNMP Manager

You must configure the NetScaler appliance to allow the appropriate SNMP managers to query it. You must also provide the SNMP manager with the required NetScaler-specific information. You can add up to a maximum of 100 SNMP managers or networks.

For an IPv4 SNMP manager you can specify a host name instead of the manager's IP address. If you do so, you must add a DNS name server that resolves the host name of the SNMP manager to its IP address. You can add up to a maximum of five host-name based SNMP managers.

Note: The appliance does not support use of host names for SNMP managers that have IPv6 addresses. You must specify the IPv6 address.

If you do not configure at least one SNMP manager, the appliance accepts and responds to SNMP queries from all IP addresses on the network. If you configure one or more SNMP managers, the appliance accepts and responds only to SNMP queries from those specific IP addresses.

If you remove an SNMP manager from the configuration, that manager can no longer query the appliance.

To add SNMP managers by specifying IP addresses by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp manager <IPAddress> ... [-netmask <netmask>]
- show snmp manager

Example

```
> add snmp manager 10.102.29.10 10.102.29.15 10.102.29.30
```

To add an SNMP manager by specifying its host name by using the command line interface

Important: If you specify the SNMP manager’s host name instead of its IP address, you must configure a DNS name server to resolve the host name to the SNMP manager’s IP address. For more information, see "Adding a Name Server."

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp manager <IPAddress> [-domainResolveRetry <integer>]
- show snmp manager

Example

> add nameserver 10.103.128.15

> add snmp manager engwiki.eng.example.net –domainResolveRetry 10

To add an SNMP manager by using the configuration utility

1. Navigate to System > SNMP > Managers, and create the SNMP manager.

   Important: If you specify the SNMP manager's host name instead of its IPv4 address, you must configure a DNS name server to resolve the host name to the SNMP manager's IP address. For more information, see "Adding a Name Server."

   Note: The appliance does not support host names for SNMP managers that have IPv6 addresses.

Parameter Descriptions (of commands listed in the CLI procedure)

add snmp manager

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show snmp manager

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Specifying an SNMP Community

You can create strings called *community strings* and associate them with the following SNMP query types on the appliance:

- GET
- GET NEXT
- ALL
- GET BULK

You can associate one or more community strings to each query types. For example, when you associate two community strings, such as **abc** and **bcd**, to the query type GET NEXT, the SNMP agent on the appliance considers only those GET NEXT SNMP query packets that contain **abc** or **bcd** as the community string.

If you do not associate any community string to a query type then the SNMP agent responds to all SNMP queries of that type.

To specify an SNMP community by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp community <communityName> <permissions>
- show snmp community

Example

> add snmp community com all

To configure an SNMP community string by using the configuration utility

Navigate to System > SNMP > Community, and create the SNMP community.

Parameter Descriptions (of commands listed in the CLI procedure)

add snmp community

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show snmp community

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring SNMP Alarms for Rate Limiting

Citrix NetScaler appliances such as the NetScaler MPX 10500, 12500, and 15500 are rate limited. The maximum throughput (Mbps) and packets per second (PPS) are determined by the license purchased for the appliance. For rate-limited platforms, you can configure SNMP traps to send notifications when throughput and PPS approach their limits and when they return to normal.

Throughput and PPS are monitored every seven seconds. You can configure traps with high-threshold and normal-threshold values, which are expressed as a percentage of the licensed limits. The appliance then generates a trap when throughput or PPS exceeds the high threshold, and a second trap when the monitored parameter falls to the normal threshold. In addition to sending the traps to the configured destination device, the NetScaler logs the events associated with the traps in the /var/log/ns.log file as EVENT ALERTSTARTED and EVENT ALERTENDED.

Exceeding the throughput limit can result in packet loss. You can configure SNMP alarms to report packet loss.

For more information about SNMP alarms and traps, see "Configuring the NetScaler to generate SNMP v1 and v2 Traps."

Configuring an SNMP Alarm for Throughput or PPS

To monitor both throughput and PPS, you must configure separate alarms.

To configure an SNMP alarm for the throughput rate by using the command line interface

At the command prompt, type the following commands to configure the SNMP alarm and verify the configuration:

- set snmp alarm PF-RL-RATE-THRESHOLD [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-state (**ENABLED** | **DISABLED**)] [-severity <severity>] [-logging (**ENABLED** | **DISABLED**)]
- show snmp alarm PF-RL-RATE-THRESHOLD

Example

```
> set snmp alarm PF-RL-RATE-THRESHOLD -thresholdValue 70 -normalValue 50
```

To configure an SNMP alarm for PPS by using the command line interface

At the command prompt, type the following commands to configure the SNMP alarm for PPS and verify the configuration:

- set snmp alarm PF-RL-PPS-THRESHOLD [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-state (**ENABLED** | **DISABLED**)] [-severity <severity>] [-logging (**ENABLED** | **DISABLED**)]
- show snmp alarm PF-RL-PPS-THRESHOLD

Example

```
> set snmp alarm PF-RL-PPS-THRESHOLD -thresholdValue 70 -normalValue 50
```

To configure an SNMP alarm for throughput or PPS by using the configuration utility

1. Navigate to System > SNMP > Alarms, and select PF-RL-RATE-THRESHOLD (for throughput rate) or PF-RL-PPS-THRESHOLD (for packets per second).

2. Set the alarm parameters and enable the selected SNMP alarm.

Parameter Descriptions (of commands listed in the CLI procedure)

set snmp alarm

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show snmp alarm

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring SNMP Alarm for Dropped Packets

You can configure an alarm for packets dropped as a result of exceeding the throughput limit and an alarm for packets dropped as a result of exceeding the PPS limit.

To configure an SNMP alarm for packets dropped because of excessive throughput, by using the command line interface

At the command prompt, type:

set snmp alarm PF-RL-RATE-PKTS-DROPPED [-state (**ENABLED** | **DISABLED**)] [-severity <severity>] [-logging (**ENABLED** | **DISABLED**)]

To configure an SNMP alarm for packets dropped because of excessive PPS, by using the command line interface

At the command prompt, type:

set snmp alarm PF-RL-PPS-PKTS-DROPPED [-state (**ENABLED** | **DISABLED**)] [-severity <severity>] [-logging (**ENABLED** | **DISABLED**)]

To configure an SNMP alarm for dropped packets by using the configuration utility

1. Navigate to System > SNMP > Alarms, and select PF-RL-RATE-PKTS-DROPPED (for packets dropped because of excessive throughput) or PF-RL-PPS-PKTS-DROPPED (for packets dropped because of excessive PPS).

2. Set the alarm parameters and enable the selected SNMP alarm.

Parameter Descriptions (of commands listed in the CLI procedure)

set snmp alarm

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring the NetScaler for SNMPv3 Queries

Simple Network Management Protocol Version 3 (SNMPv3) is based on the basic structure and architecture of SNMPv1 and SNMPv2. However, SNMPv3 enhances the basic architecture to incorporate administration and security capabilities, such as authentication, access control, data integrity check, data origin verification, message timeliness check, and data confidentiality.

To implement message level security and access control, SNMPv3 introduces the user-based security model (USM) and the view-based access control model (VACM).

- **User-Based Security Model.** The user-based security model (USM) provides message-level security. It enables you to configure users and security parameters for the SNMP agent and the SNMP manager. USM offers the following features:
  - **Data integrity:** To protect messages from being modified during transmission through the network.
  - **Data origin verification:** To authenticate the user who sent the message request.
  - **Message timeliness:** To protect against message delays or replays.
  - **Data confidentiality:** To protect the content of messages from being disclosed to unauthorized entities or individuals.
- **View-Based Access Control Model.** The view-based access control model (VACM) enables you to configure access rights to a specific subtree of the MIB based on various parameters, such as security level, security model, user name, and view type. It enables you to configure agents to provide different levels of access to the MIB to different managers.

The Citrix NetScaler supports the following entities that enable you to implement the security features of SNMPv3:

- SNMP Engines
- SNMP Views
- SNMP Groups
- SNMP Users

These entities function together to implement the SNMPv3 security features. Views are created to allow access to subtrees of the MIB. Then, groups are created with the required security level and access to the defined views. Finally, users are created and assigned to the groups.

Note: The view, group, and user configuration are synchronized and propagated to the secondary node in a high availability (HA) pair. However, the engine ID is neither propagated nor synchronized as it is unique to each NetScaler appliance.

To implement message authentication and access control, you need to:

- Set the Engine ID
- Configure Views
- Configure Groups
- Configure Users

Setting the Engine ID

SNMP engines are service providers that reside in the SNMP agent. They provide services such as sending, receiving, and authenticating messages. SNMP engines are uniquely identified using engine IDs.

The NetScaler appliance has a unique engineID based on the MAC address of one of its interfaces. It is not necessary to override the engineID. However, if you want to change the engine ID, you can reset it.

To set the engine ID by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- set snmp engineId <engineID>
- show snmp engineId

Example

> set snmp engineId 8000173f0300c095f80c68

To set the engine ID by using configuration utility

Navigate to System > SNMP > Users, click Configure Engine ID and type an engine ID.

Parameter Descriptions (of commands listed in the CLI procedure)

set snmp engineId

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show snmp engineId

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring a View

SNMP views restrict user access to specific portions of the MIB. SNMP views are used to implement access control.

To add an SNMP view by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp view <name> <subtree> -type (included | excluded)
- show snmp view <name>

Example

> add snmp view View1 -type included

To configure an SNMP view by using the configuration utility

Navigate to System > SNMP > Views, and create the SNMP view.

Parameter Descriptions (of commands listed in the CLI procedure)

add snmp view

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show snmp view

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring a Group

SNMP groups are logical aggregations of SNMP users. They are used to implement access control and to define the security levels. You can configure an SNMP group to set access rights for users assigned to that group, thereby restricting the users to specific views.

You need to configure an SNMP group to set access rights for users assigned to that group.

To add an SNMP group by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp group <name> <securityLevel> -readViewName <string>
- show snmp group <name> <securityLevel>

Example

> add snmp group edocs_group2 authPriv -readViewName edocs_read_view

To configure an SNMP group by using the configuration utility

Navigate to System > SNMP > Groups, and create the SNMP group.

Parameter Descriptions (of commands listed in the CLI procedure)

add snmp group

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show snmp group

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring a User

SNMP users are the SNMP managers that the agents allow to access the MIBs. Each SNMP user is assigned to an SNMP group.

You need to configure users at the agent and assign each user to a group.

To configure a user by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp user <name> -group <string> [-authType (MD5 | SHA) {-authPasswd } [-privType (DES | AES) {-privPasswd }]]
- show snmp user <name>

Example

> add snmp user edocs_user -group edocs_group

To configure an SNMP user by using the configuration utility

Navigate to System > SNMP > Users, and create the SNMP user.

Parameter Descriptions (of commands listed in the CLI procedure)

add snmp user

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show snmp user

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Audit Logging

Auditing is a methodical examination or review of a condition or situation. The Audit Logging feature enables you to log the NetScaler states and status information collected by various modules in the kernel and in the user-level daemons. For audit logging, you have the options to configure SYSLOG, the native NSLOG protocol, or both.

SYSLOG is a standard protocol for logging. It has two components□ the SYSLOG auditing module, which runs on the NetScaler appliance, and the SYSLOG server, which can run on the underlying FreeBSD operating system (OS) of the NetScaler appliance or on a remote system. SYSLOG uses user data protocol (UDP) for the transfer of data.

Similarly, the native NSLOG protocol has two components□ the NSLOG auditing module, which runs on the NetScaler appliance, and the NSLOG server, which can run on the underlying FreeBSD OS of the NetScaler appliance or on a remote system. NSLOG uses transmission control protocol (TCP) for transfer of data.

When you run NSLOG or a SYSLOG server, it connects to the NetScaler appliance. The NetScaler appliance then starts sending all the log information to the SYSLOG or NSLOG server, and the server can filter the log entries before storing them in a log file. An NSLOG or SYSLOG server can receive log information from more than one NetScaler appliance and a NetScaler appliance can send log information to more than one SYSLOG server or NSLOG server.

The log information that a SYSLOG or NSLOG server collects from a NetScaler appliance is stored in a log file in the form of messages. These messages typically contain the following information:

- The IP address of a NetScaler appliance that generated the log message
- A time stamp
- The message type
- The predefined log levels (Critical, Error, Notice, Warning, Informational, Debug, Alert, and Emergency)
- The message information

To configure audit logging, you first configure the audit modules on the NetScaler that involves creating audit policies and specifying the NSLOG server or SYSLOG server information. You then install and configure the SYSLOG or the NSLOG server on the underlying FreeBSD OS of the NetScaler appliance or on a remote system.

Note: Because SYSLOG is an industry standard for logging program messages and because various vendors provide support, this documentation does not include SYSLOG server configuration information.

The NSLOG server has its own configuration file (auditlog.conf). You can customize logging on the NSLOG server system by making additional modifications to the configuration file (auditlog.conf).

Configuring the NetScaler Appliance for Audit Logging

Policies define the SYSLOG or NSLOG protocol, and server actions define what logs are sent where. For server actions, you specify the system information, which runs the SYSLOG or the NSLOG server.

The NetScaler logs the following information related to TCP connections:

- Source port
- Destination port
- Source IP
- Destination IP
- Number of bytes transmitted and received
- Time period for which the connection is open

Note:

- You can enable TCP logging on individual load balancing vservers. You must bind the audit log policy to a specific load balancing vserver that you want to log.
- When using the NetScaler as the audit log server, by default, the ns.log file is rotated (new file is created) when the file size reaches 100K and the last 25 copies of the ns.log are archived and compressed with gzip. To accommodate more archived files after 25 files, the oldest archive is deleted. You can modify the 100K limit or the 25 file limit by updating the following entry in the /etc/newsyslog.conf file:

  ```
  /var/log/ns.log  600  25  100  *  Z
  ```

  where, 25 is the number of archived files to be maintained and 100K is the size of the ns.log file after which the file will be archived.

Configuring Audit Servers

You can configure audit server actions for different servers and for different log levels.

To configure a SYSLOG server action by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> [-dateFormat (MMDDYYYY | DDMMYYYY)]
- show audit syslogAction [<name>]

Example

```
> add audit syslogaction audit-action1 10.102.1.1 -loglevel INFORMATIONAL -dateformat MMDDYYYY
```

To configure an NSLOG server action by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add audit nslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> [-dateFormat (MMDDYYYY | DDMMYYYY)]
- show audit nslogAction [<name>]

Example

```
> add audit nslogAction nslog-action1 10.102.1.3 -serverport 520 -loglevel INFORMATIONAL -dateFormat MMD
```

To configure an auditing server action by using the configuration utility

1. In the navigation pane, expand System, expand Auditing, and then click Policies.
2. In the details pane, on the Servers tab, click Add.
3. In the Create Auditing Server dialog box, configure the auditing server. For a description of a parameter, hover the mouse cursor over the corresponding field.
4. Click Create, and then click Close.

To configure an auditing server action by using the configuration utility

Parameter Descriptions (of commands listed in the CLI procedure)

add audit syslogAction

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show audit syslogAction

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

add audit nslogAction

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show audit nslogAction

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Audit Policies

The audit policies define the SYSLOG or NSLOG protocol.

To configure a SYSLOG policy by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add audit syslogPolicy <name> <rule> <action>
- show audit syslogPolicy [<name>]

Example

> add audit syslogpolicy syslog-pol1 ns_true audit-action1

To configure an NSLOG policy by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add audit nslogPolicy <name> <rule> <action>
- show audit nslogPolicy [<name>]

Example

> add audit nslogPolicy nslog-pol1 ns_true nslog-action1

To configure an audit server policy by using the configuration utility

1. In the navigation pane, expand System, expand Auditing, and then click Policies.
2. In the details pane, on the Policies tab, click Add.
3. In the Create Auditing Policy dialog box, configure the audit policy. For a description of a parameter, hover the mouse cursor over the corresponding field.
4. Click Create, and then click Close.

To configure an audit server policy by using the configuration utility

Parameter Descriptions (of commands listed in the CLI procedure)

add audit syslogPolicy

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show audit syslogPolicy

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

add audit nslogPolicy

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show audit nslogPolicy

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Binding the Audit Policies Globally

You must globally bind the audit log policies to enable logging of all NetScaler system events. By defining the priority level, you can set the evaluation order of the audit server logging. Priority 0 is the highest and is evaluated first. The higher the priority number, the lower is the priority of evaluation.

To configure a SYSLOG policy by using the command line interface

At the command prompt, type:

- bind system global [<policyName> [-priority <positive_integer>]]
- show system global

Example

> bind system global nslog-pol1 -priority 20

To globally bind the audit policy by using the configuration utility

1. In the navigation pane, expand System, expand Auditing, and then click Policies.
2. In the details pane, on the Policies tab, click Global Bindings.
3. In the Bind/Unbind Auditing Global Policies dialog box, click Insert Policy.
4. Select a policy from the drop-down list that appears under Policy Name, and click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

bind system global

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show system global

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Policy-Based Logging

You can configure policy-based logging for rewrite and responder policies. Audit messages are then logged in a defined format when the rule in a policy evaluates to TRUE. To configure policy-based logging, you configure an audit-message action that uses default syntax expressions to specify the format of the audit messages, and associate the action with a policy. The policy can be bound either globally or to a load balancing or content switching virtual server. You can use audit-message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats.

Pre Requisites

- User Configurable Log Messages (userDefinedAuditlog) option is enabled for when configuring the audit action server to which you want to send the logs in a defined format. For more information about enabling policy-based logging on an audit action server, see "Binding the Audit Policies Globally."
- The related audit policy is bound to system global. For more information about binding audit policies to system global, see "Binding the Audit Policies Globally."

Configuring an Audit Message Action

You can configure audit message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats. Audit-message actions use expressions to specify the format of the audit messages.

To create an audit message action by using the command line interface

At the command prompt, type:

add audit messageaction <name> <logLevel> <stringBuilderExpr> [-logtoNewnslog (YES|NO)] [-bypassSafetyCheck (YES|NO)]

Example

> add audit messageaction log-act1 CRITICAL '"Client:"+CLIENT.IP.SRC+" accessed "+HTTP.REQ.URL' -bypassSa

To configure an audit message action by using the configuration utility

Navigate to System > Auditing > Message Actions, and create the audit message action.

Binding Audit Message Action to a Policy

After you have created an audit message action, you must bind it to a rewrite or responder policy. For more information about binding log message actions to a rewrite or responder policy, see "Rewrite" or "Responder".

Parameter Descriptions (of commands listed in the CLI procedure)

add audit messageaction

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Installing and Configuring the NSLOG Server

During installation, the NSLOG server executable file (auditserver) is installed along with other files. The auditserver executable file includes options for performing several actions on the NSLOG server, including running and stopping the NSLOG server. In addition, you use the auditserver executable to configure the NSLOG server with the IP addresses of the NetScaler appliances from which the NSLOG server will start collecting logs. Configuration settings are applied in the NSLOG server configuration file (auditlog.conf).

Then, you start the NSLOG server by executing the auditserver executable. The NSLOG server configuration is based on the settings in the configuration file. You can further customize logging on the NSLOG server system by making additional modifications to the NSLOG server configuration file (auditlog.conf).

Attention: The version of the NSLOG server package must be the same as that of the NetScaler. For example, if the version of the NetScaler is 10.1 Build 125.9, the NSLOG server must also be of the same version.

The following table lists the operating systems on which the NSLOG server is supported.

Table 1. Supported Platforms for the NSLOG Server

Operating system	Software requirements	Remarks
Windows	· Windows XP Professional · Windows Server 2003 · Windows 2000/NT · Windows Server 2008 · Windows Server 2008 R2	
Linux	· RedHat Linux 4 or later · SUSE Linux Enterprise 9.3 or later	
FreeBSD	FreeBSD 6.3 or later	For NetScaler 10.5, use only FreeBSD 8.4.
Mac OS	Mac OS 8.6 or later	Not supported on NetScaler 10.1 and later releases.

The minimum hardware specifications for the platform running the NSLOG server are as follows:

- Processor- Intel x86 ~501 megahertz (MHz)

- RAM - 512 megabytes (MB)
- Controller - SCSI

Installing NSLOG Server on the Linux Operating System

Log on to the Linux system as an administrator. Use the following procedure to install the NSLOG server executable files on the system.

To install the NSLOG server package on a Linux operating system

1. At a Linux command prompt, type the following command to copy the NSauditserver.rpm file to a temporary directory:

   ```
   cp <path_to_cd>/Utilities/auditserver/Linux/NSauditserver.rpm /tmp
   ```

2. Type the following command to install the NSauditserver.rpm file:

   ```
   rpm -i NSauditserver.rpm
   ```

   This command extracts the files and installs them in the following directories:

   - /usr/local/netscaler/etc
   - /usr/local/netscaler/bin
   - /usr/local/netscaler/samples

To uninstall the NSLOG server package on a Linux operating system

1. At a command prompt, type the following command to uninstall the audit server logging feature:

   ```
   rpm -e NSauditserver
   ```

2. For more information about the NSauditserver RPM file, use the following command:

   ```
   rpm -qpi *.rpm
   ```

3. To view the installed audit server files use the following command:

   ```
   rpm -qpl *.rpm
   ```

   *.rpm: Specifies the file name.

Installing NSLOG Server on the FreeBSD Operating System

Before you can install the NSLOG server, you have to copy the NSLOG package from the NetScaler product CD or download it from www.citrix.com. The NSLOG package has the following name format `AuditServer _<release number>-<build number>.zip` (for example, `AuditServer_9.3-51.5.zip`). This package contains NSLOG installation packages for all supported platforms.

Note: NSLOG server is not supported on the underlying FreeBSD OS of the NetScaler appliance.

To download NSLOG package from www.Citrix.com

1. In a web browser, go to www.citrix.com.
2. In the menu bar, click Log In.
3. Enter your login credentials, and then click Log In.
4. In the menu bar, click Downloads.
5. Search to find the page that provides the appropriate release number and build.
6. On that page, under Audit Servers, click Download to download the NSLOG package, having the format `AuditServer_<release number>-<build number>.zip` , to your local system (for example, `AuditServer_9.3-51.5.zip`).

To install the NSLOG server package on a FreeBSD operating system

1. On the system to which you have downloaded the NSLOG package `AuditServer_<release number>-<build number>.zip` (for example, `AuditServer_9.3-51.5.zip`), extract the FreeBSD NSLOG server package `audserver_bsd-<release number>-<build number>.tgz` (for example, `audserver_bsd-9.3-51.5.tgz`) from the package.

2. Copy the FreeBSD NSLOG server package `audserver_bsd-<release number>-<build number>.tgz` (for example, `audserver_bsd-9.3-51.5.tgz`) to a directory on a system running FreeBSD OS.

3. At a command prompt for the directory into which the FreeBSD NSLOG server package was copied, run the following command to install the package:

   ```
   pkg_add audserver_bsd-<release number>-<build number>.tgz
   ```

   Example

   pkg_add audserver_bsd-9.3-51.5.tgz

   The following directories are extracted:

   - <root directory extracted from the FreeBSD NSLOG server package tgz file>\netscaler\bin (for example, `/var/auditserver/netscaler/bin`)
   - <root directory extracted from the FreeBSD NSLOG server package tgz file>\netscaler\etc (for example, `/var/auditserver/netscaler/etc`)
   - <root directory extracted from the FreeBSD NSLOG server package tgz file>\netscaler\samples (for example, `/var/auditserver/samples`)

4. At a command prompt, type the following command to verify that the package is installed:

   ```
   pkg_info | grep NSaudserver
   ```

To uninstall the NSLOG server package on a FreeBSD operating system

At a command prompt, type:

```
pkg_delete NSaudserver
```

Installing NSLOG Server Files on the Windows Operating System

Before you can install the NSLOG server, you have to copy the NSLOG package from the NetScaler product CD or download it from www.citrix.com. The NSLOG package has the following name format `AuditServer _<release number>-<build number>.zip` (for example, `AuditServer_9.3-51.5.zip`). This package contains NSLOG installation packages for all supported platforms.

To download NSLOG package from www.Citrix.com

1. In a web browser, go to www.citrix.com.
2. In the menu bar, click Log In.
3. Enter your login credentials, and then click Log In.
4. In the menu bar, click Downloads.
5. Search to find the page that provides the appropriate release number and build.
6. On that page, under Audit Servers, click Download to download the NSLOG package, having the format `AuditServer_<release number>-<build number>.zip` , to your local system (for example, `AuditServer_9.3-51.5.zip`).

To install NSLOG server on a Windows operating system

1. On the system, where you have downloaded the NSLOG package `AuditServer_<release number>-<build number>.zip` (for example, `AuditServer_9.3-51.5.zip`), extract `audserver_win-<release number>-<build number>.zip` (for example, `audserver_win-9.3-51.5.zip`) from the package.

2. Copy the extracted file `audserver_<release number>-<build number>.zip` (for example, `audserver_win-9.3-51.5.zip`) to a Windows system on which you want to install the NSLOG server.

3. Unzip the `audserver_<release number>-<build number>.zip` file (for example, `audserver_win-9.3-51.5.zip`).

4. The following directories are extracted:

   a. <root directory extracted from the Windows NSLOG server package zip file>\bin (for example, `C:\audserver_win-9.3-51.5\bin`)

   b. <root directory extracted from the Windows NSLOG server package zip file>\etc (for example, `C:\audserver_win-9.3-51.5\ etc`)

   c. < root directory extracted from the Windows NSLOG server package zip file >\samples (for example, `C:\audserver_win-9.3-51.5\ samples`)

5. At a command prompt, run the following command from the <root directory extracted from the Windows `NSLOG server package zip file>\bin path:`

   `audserver` -install -f <directorypath>**auditlog.conf**

   <directorypath>: Specifies the path to the configuration file (`auditlog.conf`). By default, log.conf is under <root directory extracted from Windows `NSLOG server package zip file>\samples` directory. But you can copy auditlog.conf to your desired directory.

To uninstall the NSLOG server on a Windows operating system

At a command prompt, run the following from the `<root directory extracted from Windows NSLOG server package zip file>\bin path:`

`audserver` -remove

NSLOG Server Command Options

The following table describes the commands that you can use to configure audit server options.

Table 1. Audit Server Options

Audit server commands	Specifies
`audserver -help`	The available Audit Server options.
`audserver -addns -f` <path to configuration file>	The system that gathers the log transaction data. You are prompted to enter the IP address of the NetScaler appliance. Enter the valid user name and password.
`audserver -verify -f` <path to configuration file>	Check for syntax or semantic errors in the configuration file (for example, auditlog.conf).
`audserver -start -f` <path to configuration file>	Start audit server logging based on the settings in the configuration file (auditlog.conf). Linux only: To start the audit server as a background process, type the ampersand sign (&) at the end of the command.
`audserver -stop` (Linux only)	Stops audit server logging when audit server is started as a background process. Alternatively, use the Ctrl+C key to stop audit server logging.
`audserver -install -f` <path to configuration file> (Windows only)	Installs the audit server logging client as a service on Windows.
`audserver -startservice` (Windows Only)	Start the audit server logging service, when you enter this command at a command prompt. You can also start audit server logging from Start > Control Panel > Services. **Note:** Audit server logging starts by using the configuration settings in the configuration file, for example, auditlog.conf file specified in the audit server install option.

`audserver -stopservice` (Windows Only)	Stop audit server logging.
`audserver -remove`	Removes the audit server logging service from the registry.

Run the `audserver` command from the directory in which the audit server executable is present:

- On Windows: \ns\bin
- On Solaris and Linux: \usr\local\netscaler\bin

The audit server configuration files are present in the following directories:

- On Windows: \ns\etc
- On Linux: \usr\local\netscaler\etc

The audit server executable is started as `./auditserver` in Linux and FreeBSD.

Adding the NetScaler Appliance IP Addresses on the NSLOG Server

In the configuration file (auditlog.conf), add the IP addresses of the NetScaler appliances whose events must be logged.

To add the IP addresses of the NetScaler appliance

At a command prompt, type the following command:

audserver -addns -f <directorypath>\auditlog.conf

<directorypath>: Specifies the path to the configuration file (auditlog.conf).

You are prompted to enter the information for the following parameters:

NSIP: Specifies the IP address of the NetScaler appliance, for example, 10.102.29.1.

Userid: Specifies the user name, for example, nsroot.

Password: Specifies the password, for example, nsroot.

If you add multiple NetScaler IP addresses (NSIP), and later you do not want to log all of the NetScaler appliance event details, you can delete the NSIPs manually by removing the NSIP statement at the end of the auditlog.conf file. For a high availability (HA) setup, you must add both primary and secondary NetScaler IP addresses to auditlog.conf by using the audserver command. Before adding the IP address, make sure the user name and password exist on the system.

Verifying the NSLOG Server Configuration File

Check the configuration file (audit log.conf) for syntax correctness to enable logging to start and function correctly.

To verify configuration, at a command prompt, type the following command:

audserver -verify -f <directorypath>\auditlog.conf

<directorypath>: Specifies the path to the configuration file (audit log.conf).

Running the NSLOG Server

To start audit server logging

Type the following command at a command prompt:

```
audserver -start -f <directorypath>\auditlog.conf
```

<directorypath>: Specifies the path to the configuration file (audit log.conf).

To stop audit server logging that starts as a background process in FreeBSD or Linux

Type the following command:

```
audserver -stop
```

To stop audit server logging that starts as a service in Windows

Type the following command:

```
audserver -stopservice
```

Customizing Logging on the NSLOG Server

You can customize logging on the NSLOG server by making additional modifications to the NSLOG server configuration file (log.conf). Use a text editor to modify the log.conf configuration file on the server system.

To customize logging, use the configuration file to define filters and log properties.

- **Log filters.** Filter log information from a NetScaler appliance or a set of NetScaler appliances.
- **Log properties.** Each filter has an associated set of log properties. Log properties define how to store the filtered log information.

Creating Filters

You can use the default filter definition located in the configuration file (audit log.conf), or you can modify the filter or create a new filter. You can create more than one log filter.

Note: For consolidated logging, if a log transaction occurs for which there is no filter definition, the default filter is used (if it is enabled.) The only way you can configure consolidated logging of all the NetScaler appliances is by defining the default filter.

To create a filter

At the command prompt, type the following command in the configuration file (auditlog.conf) :

filter <filterName> [IP <ip>] [NETMASK <mask>] [ON | OFF]

<filterName>: Specify the name of the filter (maximum of 64 alphanumeric characters).

<ip>: Specify the IP addresses.

<mask>: Specify the subnet mask to be used on a subnet.

Specify ON to enable the filter to log transactions, or specify OFF to disable the filter. If no argument is specified, the filter is ON

Examples

```
filter F1 IP 192.168.100.151 ON
```

To apply the filter F2 to IP addresses 192.250.100.1 to 192.250.100.254:

```
filter F2 IP 192.250.100.0 NETMASK 255.255.255.0 ON
```

filterName is a required parameter if you are defining a filter with other optional parameters, such as IP address, or the combination of IP address and Netmask.

Specifying Log Properties

Log properties associated with the filter are applied to all the log entries present in the filter. The log property definition starts with the key word BEGIN and ends with END as illustrated in the following example:

```
BEGIN <filtername>
   logFilenameFormat ...
   logDirectory ...
   logInterval ...
   logFileSizeLimit ....
END
```

Entries in the definition can include the following:

- **LogFilenameFormat** specifies the file name format of the log file. The name of the file can be of the following types:
  - Static: A constant string that specifies the absolute path and the file name.
  - Dynamic: An expression that includes the following format specifiers:
    - Date (%{format}t)
    - % creates file name with NSIP

  Example

  LogFileNameFormat Ex%{%m%d%y}t.log

  This creates the first file name as Exmmddyy.log. New files are named: Exmmddyy.log.0, Exmmddyy.log.1, and so on. In the following example, the new files are crated when the file size reaches 100MB.

  Example

  ```
  LogInterval size
  LogFileSize 100
  LogFileNameFormat Ex%{%m%d%y}t
  ```

  Caution: The date format %t specified in the LogFilenameFormat parameter overrides the log interval property for that filter. To prevent a new file being created every day instead of when the specified log file size is reached, do not use %t in the LogFilenameFormat parameter.
- **logDirectory** specifies the directory name format of the log file. The name of the file can be either of the following:

- Static: Is a constant string that specifies the absolute path and file name.
- Dynamic: Is an expression containing the following format specifiers:
  - Date (%{format}t)
  - % creates directory with NSIP

The directory separator depends on the operating system. In Windows, use the directory separator \.

Example:

LogDirectory dir1\dir2\dir3

In the other operating systems (Linux, FreeBsd, Mac, etc.), use the directory separator /.

- **LogInterval** specifies the interval at which new log files are created. Use one of the following values:
  - Hourly: A file is created every hour. Default value.
  - Daily: A file is created very day at midnight.
  - Weekly: A file is created every Sunday at midnight.
  - Monthly : A file is created on the first day of the month at midnight.
  - None: A file is created only once, when audit server logging starts.
  - Size: A file is created only when the log file size limit is reached.

Example

LogInterval Hourly

- **LogFileSizeLimit** specifies the maximum size (in MB) of the log file. A new file is created when the limit is reached.

  Note that you can override the loginterval property by assigning size as its value.

  The default LogFileSizeLimit is 10 MB.

  Example

  LogFileSizeLimit 35

Default Settings for the Log Properties

The following is an example of the default filter with default settings for the log properties:

```
begin default
 logInterval Hourly
 logFileSizeLimit 10
 logFilenameFormat  auditlog%{%y%m%d}t.log
 end default
```

Following are two examples of defining the default filters:

Example 1

```
Filter f1 IP 192.168.10.1
```

This creates a log file for NSI 192.168.10.1 with the default values of the log in effect.

Example 2

```
Filter f1 IP 192.168.10.1
begin f1
   logFilenameFormat logfiles.log
end f1
```

This creates a log file for NSIP 192.168.10.1. Since the log file name format is specified, the default values of the other log properties are in effect.

Sample Configuration File (audit.conf)

Following is a sample configuration file:

```
##############################
# This is the Auditserver configuration file
# Only the default filter is active
# Remove leading # to activate other filters
##############################
MYIP <NSAuditserverIP>
MYPORT 3023
#   Filter filter_nsip  IP <Specify the NetScaler IP address to filter on > ON
#   begin filter_nsip
#       logInterval         Hourly
#       logFileSizeLimit    10
#       logDirectory        logdir\%A\
#       logFilenameFormat   nsip%{%d%m%Y}t.log
#   end filter_nsip
Filter default
begin default
   logInterval      Hourly
   logFileSizeLimit    10
   logFilenameFormat   auditlog%{%y%m%d}t.log
end default
```

Web Server Logging

You can use the Web server logging feature to send logs of HTTP and HTTPS requests to a client system for storage and retrieval. This feature has two components:

- The Web log server, which runs on the NetScaler.
- The NetScaler Web Logging (NSWL) client, which runs on the client system.

When you run the NetScaler Web Logging (NSWL) client:

1. It connects to the NetScaler.
2. The NetScaler buffers the HTTP and HTTPS request log entries before sending them to the client.
3. The client can filter the entries before storing them.

To configure Web server logging, you first enable the Web logging feature on the NetScaler and configure the size of the buffer for temporarily storing the log entries. Then, you install NSWL on the client system. You then add the NetScaler IP address (NSIP) to the NSWL configuration file. You are now ready to start the NSWL client to begin logging. You can customize Web server logging by making additional modifications to the NSWL configuration file (log.conf).

Configuring the NetScaler for Web Server Logging

To configure the NetScaler for web server logging you are required to only enable the Web Server Logging feature. Optionally, you can perform the following configurations:

- Modify the size of the buffer (default size is 16 MB) that stores the logged information before it is sent to the NetScaler Web Logging (NSWL) client.
- Specify the custom HTTP headers that you want to export to the NSWL client. You can configure a maximum of two HTTP request and two HTTP response header names.

To configure web server logging by using the command line interface

At the command prompt, perform the following operations:

- Enable the web server logging feature.

  enable ns feature WL

- [Optional] Modify the buffer size for storing the logged information.

  set ns weblogparam -bufferSizeMB <size>

  Note: To activate your modification, you must disable and then re-enable the Web server logging feature.

- [Optional] Specify the custom HTTP header names that you want to export.

  set ns weblogparam [-customReqHdrs <*string*> ...] [-customRspHdrs <*string*> ...]

  Example

  > set ns weblogparam -customReqHdrs Accept-Encoding X-Forwarded -customRspHdrs Content-Encoding

To configure web server logging by using the configuration utility

Navigate to System > Settings and perform the following operations:

- To enable the web server logging feature, click Change Advanced Features and select Web Logging.

- To modify the buffer size, click Change Global System Settings and under Web Logging, enter the buffer size.
- To specify the custom HTTP headers to be exported, click Change Global System Settings and under Web Logging, specify the header values.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ns feature

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

set ns weblogparam

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Installing the NetScaler Web Logging (NSWL) Client

During installation, the NSWL client executable file (nswl) is installed along with other files. The nswl executable file provides a list of options that you can use. For details, see Configuring the NSWL Client.

Attention: The version of the NSWL client must be the same as that of the NetScaler. For example, if the version of the NetScaler is 10.1 Build 125.9, the NSWL client must also be of the same version.

The following table lists the operating systems on which the NSWL client can be installed.

Table 1. Supported Platforms for the NSWL Client with hardware requirements

Operating system	Version	Hardware requirements	Remarks
Windows	· Windows XP Professional · Windows Server 2003 · Windows 2000/NT · Windows Server 2008 · Windows Server 2008 R2	Processor - Intel x86 ~501 MHz RAM - 512 MB Controller - SCSI	
Mac OS	Mac OS 8.6 or later	-	Not supported on NetScaler 10.1 and later releases.
Linux	· RedHat Linux 4 or later · SUSE Linux Enterprise 9.3 or later	Processor - Intel x86 ~501 MHz RAM - 512 MB Controller - SCSI	
Solaris	Solaris Sun OS 5.6 or later	Processor - UltraSPARC-IIi 400 MHz RAM - 512 MB Controller - SCSI	Not supported on NetScaler 10.5 and later releases.

FreeBSD	FreeBSD 6.3 or later	Processor - Intel x86 ~501 MHz RAM - 512 MB Controller - SCSI	For NetScaler 10.5, use only FreeBSD 8.4.
AIX	AIX 6.1	-	Not supported on NetScaler 10.5 and later releases.

If the NSWL client system cannot process the log transaction because of a CPU limitation, the Web log buffer overruns and the logging process reinitiates.

Caution: Reinitiation of logging can result in loss of log transactions.

To temporarily solve a NSWL client system bottleneck caused by a CPU limitation, you can tune the Web server logging buffer size on the NetScaler appliance. To solve the problem, you need a client system that can handle the site's throughput.

Downloading the NSWL Client

You can obtain the NSWL client package from either the NetScaler product CD or the Citrix downloads site. Within the package there are separate installation packages for each supported platforms.

To download the NSWL client package from the Citrix site

1. Open the URL: https://www.citrix.com/downloads.html.
2. Log in to the site using your credentials.
3. Open the page for the required release number and build.
4. In the page, under Weblog Clients, click Download. The package has the name format as follows: Weblog-<release number>-<build number>.zip.

Installing the NSWL Client on a Solaris System

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_solaris-<release number>-<build number>.tar file from the package.
2. Copy the extracted file to a Solaris system on which you want to install the NSWL client.
3. Extract the files from the tar file with the following command:

   tar xvf nswl_solaris-9.3-51.5.tar

   A directory NSweblog is created in the temporary directory, and the files are extracted to the NSweblog directory.
4. Install the package with the following command:

   pkgadd -d

   The list of available packages appears. In the following example, one NSweblog package is shown:

   1 NSweblog NetScaler Weblogging (SunOS,sparc) 7.0
5. You are prompted to select the packages. Select the package number of the NSweblog to be installed.

   After you select the package number and press Enter, the files are extracted and installed in the following directories:

   - /usr/local/netscaler/etc
   - /usr/local/netscaler/bin
   - /usr/local/netscaler/samples
6. To check whether the NSWL package is installed, execute the following command:

   pkginfo | grep NSweblog

   Note: To uninstall the NSWL package, execute the following command:

   pkgrm NSweblog

Installing the NSWL Client on a Linux System

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_linux-<release number>-<build number>.rpm file from the package.
2. Copy the extracted file to a system, running Linux OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

   rpm -i nswl_linux-9.3-51.5.rpm

   This command extracts the files and installs them in the following directories.

   - /usr/local/netscaler/etc
   - /usr/local/netscaler/bin
   - /usr/local/netscaler/samples

   Note: To uninstall the NSWL package, execute the following command:

   rpm -e NSweblog

   Note: To get more information about the NSweblog RPM file, execute the following command:

   rpm -qpi *.rpm

   Note: To view the installed Web server logging files, execute the following command:

   rpm -qpl *.rpm

Installing the NSWL Client on a FreeBSD System

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_bsd-<release number>-<build number>.tgz file from the package.
2. Copy the extracted file to a system, running FreeBSD OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

   pkg_add nswl_bsd-9.3-51.5.tgz

   This command extracts the files and installs them in the following directories.

   - /usr/local/netscaler/etc
   - /usr/local/netscaler/bin
   - /usr/local/netscaler/samples

   Note: To uninstall the NSWL package, execute the following command:

   pkg_delete NSweblog

4. To verify that the package is installed, execute the following command:

   pkg_info | grep NSweblog

Installing the NSWL Client on a Mac System

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_macos-<release number>-<build number>.tgz file from the package.
2. Copy the extracted file to a system, running Mac OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

   pkg_add nswl_macos-9.3-51.5.tgz

   This command extracts the files and installs them in the following directories:

   - /usr/local/netscaler/etc
   - /usr/local/netscaler/bin
   - /usr/local/netscaler/samples

   Note: To uninstall the NSWL package, execute the following command:

   pkg_delete NSweblog

4. To verify that the package is installed, execute the following command:

   pkg_info | grep NSweblog

Installing the NSWL Client on a Windows System

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_win-<release number>-<build number>.zip file from the package.
2. Copy the extracted file to a Windows system on which you want to install the NSWL client.
3. On the Windows system, unzip the file in a directory (referred as <NSWL-HOME>). The following directories are extracted: bin, etc, and samples.
4. At the command prompt, run the following command from the <NSWL-HOME>\bin directory:

   nswl -install -f <directorypath>\log.conf

   where,

   <directorypath> refers to the path of the configuration file (log.conf). By default, the file is in the <NSWL-HOME>\etc directory. However, you can copy the configuration file to any other directory.

   Note: To uninstall the NSWL client, at the command prompt, run the following command from the <NSWL-HOME>\bin directory:

   > nswl -remove

Installing the NSWL Client on a AIX System

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_aix-<release number>-<build number>.rpm file from the package.
2. Copy the extracted file to a system, running AIX OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

   rpm -i nswl_aix-9.3-51.5.rpm

   This command extracts the files and installs them in the following directories.

   - /usr/local/netscaler/etc
   - /usr/local/netscaler/bin
   - /usr/local/netscaler/samples

   Note: To uninstall the NSWL package, execute the following command:

   rpm -e NSweblog

   Note: To get more information about the NSweblog RPM file, execute the following command:

   rpm -qpi *.rpm

   Note: To view the installed Web server logging files, execute the following command:

   rpm -qpl *.rpm

Configuring the NSWL Client

After installing the NSWL client, you can configure the NSWL client using the nswl executable. These configurations are then stored in the NSWL client configuration file (log.conf).

Note: You can further customize logging on the NSWL client system by making additional modifications to the NSWL configuration file (log.conf). For details, see Customizing Logging on the NSWL Client System.

The following table describes the commands that you can use to configure the NSWL client.

NSWL command	Specifies
nswl -help	The available NSWL help options.
nswl -addns -f <path-to-configuration-file>	The system that gathers the log transaction data. You are prompted to enter the IP address of the NetScaler appliance. Enter a valid user name and password.
nswl -verify -f <path-to-configuration-file>	Check for syntax or semantic errors in the configuration file.
nswl -start -f <path-to-configuration-file>	Start the NSWL client based on the settings in the configuration file. **Note:** For Solaris and Linux: To start Web server logging as a background process, type the ampersand sign (&) at the end of the command.
nswl -stop (Solaris and Linux only)	Stop the NSWL client if it was started as a background process; otherwise, use CTRL+C to stop Web server logging.
nswl -install -f <path-to-configuration-file> (Windows only)	Install the NSWL client as a service in Windows.
nswl -startservice (Windows only)	Start the NSWL client by using the settings in the configuration file specified in the nswl install option. You can also start NSWL client from Start > Control Panel > Services.
nswl -stopservice (Windows only)	Stops the NSWL client.
nswl -remove	Remove the NSWL client service from the registry.

Run the following commands from the directory in which the NSWL executable is located:

- Windows: \ns\bin
- Solaris and Linux: \usr\local\netscaler\bin

The Web server logging configuration files are located in the following directory path:

- Windows: \ns\etc
- Solaris and Linux: \usr\local\netscaler\etc

The NSWL executable is started as .\nswl in Linux and Solaris.

Adding the IP Addresses of the NetScaler Appliance

In the NSWL client configuration file (log.conf), add the NetScaler IP address (NSIP) from which the NSWL client will start collecting logs.

To add the NSIP address of the NetScaler appliance

1. At the client system command prompt, type:

   `nswl -addns -f` < directorypath > `\log.conf`

   < directorypath >: Specifies the path to the configuration file (log.conf).

2. At the next prompt, enter the following information:

   - **NSIP**: Specify the IP address of the NetScaler appliance.
   - Username and Password: Specify the `nsroot` user credentials of the NetScaler appliance.

Note: If you add multiple NetScaler IP addresses (NSIP), and later you do not want to log all of NetScaler system log details, you can delete the NSIPs manually by removing the NSIP statement at the end of the log.conf file. During a failover setup, you must add both primary and secondary NetScaler IP addresses to the log.conf by using the command. Before adding the IP address, make sure the user name and password exist on the NetScaler appliances.

Verifying the NSWL Configuration File

To make sure that logging works correctly, check the NSWL configuration file (log.conf) on the client system for syntax errors.

To verify the configuration in the NSWL configuration file

At the client system command prompt, type:

`nswl` -verify -f <directorypath>\log.conf

< directorypath >: Specifies the path to the configuration file (log.conf).

Running the NSWL Client

To start Web server logging

At the client system command prompt, type:

`nswl -start -f <directorypath>\log.conf`

<directorypath>: Specifies the path to the configuration file (log.conf).

To stop Web server logging started as a background process on the Solaris or Linux operating systems

At the command prompt, type:

`nswl -stop`

To stop Web server logging started as a service on the Windows operating system

At the command prompt, type:

`nswl -stopservice`

Customizing Logging on the NSWL Client System

You can customize logging on the NSWL client system by making additional modifications to the NSWL client configuration file (log.conf). Use a text editor to modify the log.conf configuration file on the client system.

To customize logging, use the configuration file to define filters and log properties.

- **Log filters.** Filter log information based on the host IP address, domain name, and host name of the Web servers.
- **Log properties.** Each filter has an associated set of log properties. Log properties define how to store the filtered log information.

Sample Configuration File

Following is a sample configuration file:

```
##########
# This is the NSWL configuration file
# Only the default filter is active
# Remove leading # to activate other filters
##########
##########
# Default filter (default on)
# W3C Format logging, new file is created every hour or on reaching 10MB file size,
# and the file name is Exyymmdd.log
##########
Filter default
begin default
	logFormat		W3C
	logInterval		Hourly
	logFileSizeLimit	10

#       logInterval           Daily
#       logFileSizeLimit       10
logFilenameFormat /ns/prod/vhost/%v/Ex%{%m%d%y}t
#end VHOST_F

########## END FILTER CONFIGURATION ##########
```

Creating Filters

You can use the default filter definition located in the configuration file (log.conf), or you can modify the filter or create a new filter. You can create more than one log filter.

Note: Consolidated logging, which logs transactions for which no filter is defined, uses the default filter if it is enabled. Consolidated logging of all servers can be done by defining only the default filter.

If the server hosts multiple Web sites and each Web site has its own domain name, and each domain is associated with a virtual server, you can configure Web server logging to create a separate log directory for each Web site. The following table displays the parameters for creating a filter.

Table 1. Parameters for Creating a Filter

Parameter	Specifies
filterName	Name of the filter. The filter name can include alphanumeric characters and cannot be longer than 59 characters. Filter names longer than 59 characters are truncated to 59 characters.
HOST name	Host name of the server for which the transactions are being logged.
IP ip	IP address of the server for which transactions are to be logged (for example, if the server has multiple domains that have one IP address).
IP ip 2...ip n:	Multiple IP addresses (for example, if the server domain has multiple IP addresses).
ip6 ip	IPv6 address of the server for which transactions are to be logged.
IP ip NETMASK mask	IP addresses and netmask combination to be used on a subnet.
ON | OFF	Enable or disable the filter to log transactions. If no argument is selected, the filter is enabled (ON).

To create a filter

To create a filter, enter the following command in the log.conf file:

- `filter` <filterName> <HOST name> | [IP<ip>] | [IP<ip 2...ip n>] | <IP ip NETMASK mask> [ON | OFF]

- `filter` <filterName> <HOST name> | [IP6 ip/<prefix length>] [ON | OFF]

To create a filter for a virtual server

To create a filter for a virtual server, enter the following command in the log.conf file:

`filter` <filterName> <VirtualServer IP address>

Example

In the following example, you specify an IP address of 192.168.100.0 and netmask of 255.255.255.0. The filter applies to IP addresses 192.168.100.1 through 192.168.100.254.

Filter F1 HOST www.netscaler.com ON
Filter F2 HOST www.netscaler.com IP 192.168.100.151 ON
Filter F3 HOST www.netscaler.com IP 192.168.100.151 192.165.100.152 ON
Filter F4 IP 192.168.100.151
Filter F5 IP 192.168.100.151 HOST www.netscaler.com OFF
Filter F6 HOST www.netscaler.com HOST www.xyz.com HOST www.abcxyz.com IP 192.168.100.200 ON

Specifying Log Properties

Log properties are applied to all log entries associated with the filter. The log property definition begins with the keyword BEGIN and ends with END as illustrated in the following example:

```
BEGIN <filtername>
 logFormat ...
 logFilenameFormat ...
 logInterval ...
 logFileSize ....
 logExclude ....
 logTime ….
 END
```

Entries in the definition can include the following:

- **LogFormat** specifies the Web server logging feature that supports NCSA, W3C Extended, and custom log file formats.

  By default, the logformat property is w3c. To override, enter custom or NCSA in the configuration file, for example:

  ```
  LogFormat NCSA
  ```

  Note: For the NCSA and custom log formats, local time is used to time stamp transactions and for file rotation.

- **LogInterval** specifies the intervals at which new log files are created. Use one of the following values:

  - Hourly: A file is created every hour.
  - Daily: A file is created every day at midnight. Default value.
  - Weekly: A file is created every Sunday at midnight.
  - Monthly: A file is created on the first day of the month at midnight.
  - None: A file is created only once, when Web server logging starts.

  Example

  ```
  LogInterval Daily
  ```

- **LogFileSizeLimit** specifies the maximum size of the log file in MB. It can be used with any log interval (weekly, monthly, and so on.) A file is created when the maximum file size limit is reached or when the defined log interval time elapses.

To override this behavior, specify the size as the loginterval property so that a file is created only when the log file size limit is reached.

The default LogFileSizeLimit is 10 MB.

Example

```
LogFileSizeLimit 35
```

- **LogFilenameFormat** specifies the file name format of the log file. The name of the file can be of the following types:
  - Static: Specifies a constant string that contains the absolute path and file name.
  - Dynamic: Specifies an expression containing the following format:
    - Server IP address (%A)
    - Date (%{format}t)
    - URL suffix (%x)
    - Host name (%v)

Example

```
LogFileNameFormat Ex%{%m%d%y}t.log
```

This command creates the first file name as Exmmddyy.log, then every hour creates a file with file name: Exmmddyy.log.0, Exmmddyy.log.1,..., Exmmddyy.log.n.

Example

```
LogInterval size
LogFileSize 100
LogFileNameFormat Ex%{%m%d%y}t
```

Caution: The date format %t specified in the LogFilenameFormat command overrides the log interval property for that filter. To prevent a new file being created every day instead of when the specified log file size is reached, do not use %t in the LogFilenameFormat.

- **LogExclude** prevents logging of transactions with the specified file extensions.

Example

```
LogExclude .html
```

This command creates a log file that excludes log transactions for *.html files.

- **LogTime** specifies log time as either GMT or LOCAL.

The defaults are:

- NCSA log file format: LOCAL
- W3C log file format: GMT.

Understanding the NCSA and W3C Log Formats

The NetScaler supports the following standard log file formats:

- NCSA Common Log Format
- W3C Extended Log Format

NCSA Common Log Format

If the log file format is NCSA, the log file displays log information in the following format:

Client_IP_address -User_Name [Date:Time -TimeZone] "Method Object HTTP_version" HTTP_StatusCode BytesSent

To use the NCSA Common log format, enter NCSA in the LogFormat argument in the log.conf file.

The following table describes the NCSA Common log format.

Table 1. NCSA Common Log Format

Argument	Specifies
Client _IP_address	The IP address of the client computer.
User Name	The user name.
Date	The date of the transaction.
Time	The time when the transaction was completed.
Time Zone	The time zone (Greenwich Mean Time or local time).
Method	The request method (for example; GET, POST).
Object	The URL.
HTTP_version	The version of HTTP used by the client.
HTTP_StatusCode	The status code in the response.
Bytes Sent	The number of bytes sent from the server.

W3C Extended Log Format

An extended log file contains a sequence of lines containing ASCII characters terminated by either a Line Feed (LF) or the sequence Carriage Return Line Feed (CRLF.) Log file generators must follow the line termination convention for the platform on which they are run.

Log analyzers must accept either LF or CRLF form. Each line may contain either a directive or an entry. If you want to use the W3C Extended log format, enter W3C as the Log-Format argument in the log.conf file.

By default, the standard W3C log format is defined internally as the custom log format, shown as follows:

```
%{%Y-%m-%d%H:%M:%S}t %a %u %S %A %p %m %U %q %s %j %J %T %H %+{user-agent}i %+{cookie} i%+{referer}i
```

For a description of the meaning of this each custom format, see "Appendix A: Arguments for Defining a Custom Log Format." You can also change the order or remove some fields in this W3C log format. For example:

```
logFormat W3C %{%Y-%m-%d%H:%M:%S}t %m %U
```

W3C log entries are created with the following format:

```
#Version: 1.0
#Fields: date time cs-method cs-uri
#Date: 12-Jun-2001 12:34
2001-06-12 12:34:23 GET /sports/football.html
2001-06-12 12:34:30 GET /sports/football.html
```

Entries

Entries consist of a sequence of fields relating to a single HTTP transaction. Fields are separated by white space; Citrix recommends the use of tab characters. If a field in a particular entry is not used, a dash (-) marks the omitted field.

Directives

Directives record information about the logging process. Lines beginning with the pound sign (#) contain directives.

The following table describes the directives.

Table 2. Directive Descriptions

Directive	Description

Version: <integer>.<integer>	Displays the version of the extended log file format used. This document defines version 1.0.
Fields: [<specifier>...]	Identifies the fields recorded in the log.
Software: <string>	Identifies the software that generated the log.
Start-Date: <date> <time>	Displays the date and time at which the log was started.
End-Date: <date> <time>	Displays the date and time at which logging finished.
Date: <date> <time>	Displays the date and time when the entry was added.
Remark: <text>	Displays comments. Analysis tools ignore data recorded in this field.

Note: The Version and Fields directives are required. They precede all other entries in the log file.

Example

The following sample log file shows the log entries in W3C Extended log format:

```
#Version: 1.0
#Fields: time cs-method cs-uri
#Date: 12-Jan-1996 00:00:00
00:34:23 GET /sports/football.html
12:21:16 GET /sports/football.html
12:45:52 GET /sports/football.html
12:57:34 GET /sports/football.html
```

Fields

The Fields directive lists a sequence of field identifiers that specify the information recorded in each entry. Field identifiers may have one of the following forms:

- **identifier:** Relates to the transaction as a whole.
- **prefix-identifier:** Relates to information transfer between parties defined by the value *prefix*.
- **prefix (header):** Specifies the value of the HTTP header field header for transfer between parties defined by the value *prefix*. Fields specified in this manner always have the type <string>.

The following table describes defined prefixes.

Table 3. Prefix Descriptions

Prefix	Specifies
c	Client
s	Server
r	Remote
cs	Client to server
sc	Server to client
sr	Server to remote server (prefix used by proxies)
rs	Remote server to server (prefix used by proxies)
x	Application-specific identifier

Examples

The following examples are defined identifiers that use prefixes:

cs-method: The method in the request sent by the client to the server.

sc(Referer): The Referer field in the reply.

c-ip: The IP address of the client.

Identifiers

The following table describes the W3C Extended log format identifiers that do not require a prefix.

Table 4. W3C Extended Log Format Identifiers (No Prefix Required)

Identifier	Description
date	The date on which the transaction was done.
time	The time when the transaction is done.
time-taken	The time taken (in seconds) for the transaction to complete.
bytes	The number of bytes transferred.
cached	Records whether a cache hit has occurred. A zero indicates a cache miss.

The following table describes the W3C Extended log format identifiers that require a prefix.

Table 5. W3C Extended Log Format Identifiers (Requires a Prefix)

Identifier	Description
IP	The IP address and the port number.
dns	The DNS name.
status	The status code.

comment	The comment returned with status code.
method	The method.
url	The URL.
url-stem	The stem portion of the URL.
url-query	The query portion of the URL.

The W3C Extended Log file format allows you to choose log fields. These fields are shown in the following table.

Table 6. W3C Extended Log File Format (Allows Log Fields)

Field	Description
Date	The date on which the transaction is done.
Time	The time when the transaction is done.
Client IP	The IP address of the client.
User Name	The user name.
Service Name	The service name, which is always HTTP.
Server IP	The server IP address.
Server Port	The server port number
Method	The request method (for example; GET, POST).
Url Stem	The URL stem.
Url Query	The query portion of the URL.
Http Status	The status code in the response.
Bytes Sent	The number of bytes sent to the server (request size, including HTTP headers).
Bytes Received	The number of bytes received from the server (response size, including HTTP headers).
Time Taken	The time taken for transaction to complete, in seconds.
Protocol Version	The version number of HTTP being used by the client.
User Agent	The User-Agent field in the HTTP protocol.
Cookie	The Cookie field of the HTTP protocol.
Referer	The Referer field of the HTTP protocol.

Creating a Custom Log Format

You can customize the display format of the log file data manually or by using the NSWL library. By using the custom log format, you can derive most of the log formats that Apache currently supports.

Creating a Custom Log Format by Using the NSWL Library

Use one of the following NSWL libraries depending on whether the NSWL executable has been installed on a Windows or Solaris host computer:

- **Windows:** The nswl.lib library located in \ns\bin directory on the system manager host computer.
- **Solaris:** The libnswl.a library located in /usr/local/netscaler/bin.

To create the custom log format by using the NSWL Library

1. Add the following two C functions defined by the system in a C source file:

   ns_userDefFieldName() : This function returns the string that must be added as a custom field name in the log record.

   ns_userDefFieldVal() : This function implements the custom field value, then returns it as a string that must be added at the end of the log record.

2. Compile the file into an object file.
3. Link the object file with the NSWL library (and optionally, with third party libraries) to form a new NSWL executable.
4. Add a %d string at the end of the logFormat string in the configuration file (log.conf).

Example

```
##########
# A new file is created every midnight or on reaching 20MB file size,
# and the file name is /datadisk5/netscaler/log/NS<hostname>/Nsmmddyy.log and create digital
#signature field for each record.
BEGIN CACHE_F
   logFormat   custom "%a - "%{user-agent}i" [%d/%B/%Y %T -%g] "%x" %s %b%{referrer}i "%{user-agent}i" "%{coo
   logInterval         Daily
   logFileSizeLimit        20
   logFilenameFormat       /datadisk5/netscaler/log/%v/NS%{%m%d%y}t.log
END CACHE_F
```

Creating a Custom Log Format Manually

To customize the format in which log file data should appear, specify a character string as the argument of the LogFormat log property definition. For more information, see "Appendix A: Arguments for Defining a Custom Log Format." The following is an example where character strings are used to create a log format:

```
LogFormat Custom ""%a - "%{user-agent}i" %[%d/%m/%Y]t %U %s %b %T"
```

- The string can contain the “c” type control characters \n and \t to represent new lines and tabs.
- Use the <Esc> key with literal quotes and backslashes.

The characteristics of the request are logged by placing % directives in the format string, which are replaced in the log file by the values.

If the %v (Host name) or %x (URL suffix) format specifier is present in a log file name format string, the following characters in the file name are replaced by an underscore symbol in the log configuration file name:

" * . / : < > ? \ |

Characters whose ASCII values lie in the range of 0-31 are replaced by the following:

%<ASCII value of character in hexadecimal>.

For example, the character with ASCII value 22 is replaced by %16.

Caution: If the %v format specifier is present in a log file name format string, a separate file is opened for each virtual host. To ensure continuous logging, the maximum number of files that a process can have open should be sufficiently large. See your operating system documentation for a procedure to change the number of files that can be opened.

Creating Apache Log Formats

You can derive from the custom logs most of the log formats that Apache currently supports. The custom log formats that match Apache log formats are:

NCSA/combined: LogFormat custom `%h %l %u [%t] "%r" %s %B "%{referer}i" "%{user-agent}i"`

NCSA/Common: LogFormat custom `%h %l %u [%t] "%r" %s %B`

Referer Log: LogFormat custom `"%{referer}i" -> %U`

Useragent: LogFormat custom `%{user-agent}i`

Similarly, you can derive the other server log formats from the custom formats.

Arguments for Defining a Custom Log Format

The following table describes the data that you can use as the Log Format argument string:

Table 1. Custom Log Format

Argument	Specifies
%a	Remote IPv4 address.
%A	Local IPv4 address.
%a6	Remote IPv6 address.
%A6	Local IPv6 address.
%B	Bytes sent, excluding the HTTP headers (response size).
%b	Bytes received, excluding the HTTP headers (request size).
%d	User-defined field.
%g	Greenwich Mean Time offset (for example, -0800 for Pacific Standard Time).
%h	Remote host.
%H	Request protocol.
%{Foobar}i	Contents of the Foobar: header line(s) in the request sent to the server. The system supports the User-Agent, Referer and cookie headers. The + after the % in this format informs the logging client to use the + as a word separator.
%j	Bytes received, including headers (request size)
%J	Bytes sent, including headers (response size)
%l	Remote log name (from identd, if supplied).
%m	Request method.
%M	Time taken to serve the request (in microseconds)
%{Foobar}o	Contents of Foobar: header line(s) in the reply. USER-AGENT, Referer, and cookie headers (including set cookie headers) are supported.

%p	Canonical port of the server serving the request.
%q	Query string (prefixed with a question mark (?) if a query string exists).
%r	First line of the request.
%s	Requests that were redirected internally, this is the status of the original request.
%t	Time, in common log format (standard English time format).
%{format}t	Time, in the form given by format, must be in the strftime(3) format. For format descriptions, see "Appendix B: Time Format Definition."
%T	Time taken to serve the request, in seconds.
%u	Remote user (from auth; may be bogus if return status (%s) is 401).
%U	URL path requested.
%v	Canonical name of the server serving the request.
%V	Virtual server IPv4 address in the system, if load balancing, content switching, and/or cache redirection is used.
%V6	Virtual server IPv6 address in the system, if load balancing, content switching, and/or cache redirection is used.

For example, if you define the log format as `%+{user-agent}i`, and if the user agent value is Citrix NetScaler system Web Client, then the information is logged as NetScaler system+Web+Client. An alternative is to use double quotation marks. For example, `“%{user-agent}i”` logs it as “Citrix NetScaler system Web Client.” Do not use the <Esc> key on strings from `%.. .r, %. . .i` and, `%. . .o`. This complies with the requirements of the Common Log Format. Note that clients can insert control characters into the log. Therefore, you should take care when working with raw log files.

Time Format Definition

The following table lists the characters that you can enter as the format part of the %{format}t string described in the Custom Log Format table of "Arguments for Defining a Custom Log Format." Values within brackets ([ ]) show the range of values that appear. For example, [1,31] in the %d description in the following table shows %d ranges from 1 to 31.

Table 1. Time Format Definition

Argument	Specifies
%%	The same as %.
%a	The abbreviated name of the week day for the locale.
%A	The full name of the week day for the locale.
%b	The abbreviated name of the month for the locale.
%B	The full name of the month for the locale.
%C	The century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by a 0.
%d	The day of month [1,31]; single digits are preceded by 0.
%e	The day of month [1,31]; single digits are preceded by a blank.
%h	The abbreviated name of the month for the locale.
%H	The hour (24-hour clock) [0,23]; single digits are preceded by a 0.
%I	The hour (12-hour clock) [1,12]; single digits are preceded by a 0.
%j	The number of the day in the year [1,366]; single digits are preceded by 0.
%k	The hour (24-hour clock) [0,23]; single digits are preceded by a blank.
%l	The hour (12-hour clock) [1,12]; single digits are preceded by a blank.
%m	The number of the month in the year [1,12]; single digits are preceded by a 0.
%M	The minute [00,59]; leading 0 is permitted but not required.

%n	Inserts a new line.
%p	The equivalent of either a.m. or p.m. for the locale.
%r	The appropriate time representation in 12-hour clock format with %p.
%S	The seconds [00,61]; the range of values is [00,61] rather than [00,59] to allow for the occasional leap second and for the double leap second.
%t	Inserts a tab.
%u	The day of the week as a decimal number [1,7]. 1 represents Sunday, 2 represents Tuesday and so on.
%U	The number of the week in the year as a decimal number [00,53], with Sunday as the first day of week 1.
%w	The day of the week as a decimal number [0,6]. 0 represents Sunday.
%W	Specifies the number of the week in the year as a decimal number [00,53]. Monday is the first day of week 1.
%y	The number of the year within the century [00,99]. For example, 5 would be the fifth year of that century.
%Y	The year, including the century (for example, 1993).

Note: If you specify a conversion that does not correspond to any of the ones described in the preceding table, or to any of the modified conversion specifications listed in the next paragraph, the behavior is undefined and returns 0.

The difference between %U and %W (and also between modified conversions %OU and %OW) is the day considered to be the first day of the week. Week number 1 is the first week in January (starting with a Sunday for %U, or a Monday for %W). Week number 0 contains the days before the first Sunday or Monday in January for %U and %W.

Advanced Configurations

If you enable path maximum transmission unit (PMTU) discovery, the NetScaler can use it to determine the maximum transmission unit of any Internet channel. For more efficient data transfer, you can configure TCP window scaling and selective acknowledgment. You can view statistics associated with HTTP request and response sizes. For applying a specific HTTP and TCP settings to vservers and services, you can configure HTTP and TCP profiles.

Configuring Clock Synchronization

You can configure your NetScaler appliance to synchronize its local clock with a Network Time Protocol (NTP) server. This ensures that its clock has the same date and time settings as the other servers on your network.

You can configure clock synchronization on your appliance by adding NTP server entries to the ntp.conf file from either the configuration utility or the command line interface, or by manually modifying the ntp.conf file and then starting the NTP daemon (NTPD). The clock synchronization configuration does not change if the appliance is restarted, upgraded, or downgraded. However, the configuration does not get propagated to the secondary NetScaler in a high availability setup.

Note: If you do not have a local NTP server, you can find a list of public, open access, NTP servers at the official NTP site, http://www.ntp.org, under Public Time Servers List. Before configuring your NetScaler to use a public NTP server, be sure to read the Rules of Engagement page (link included on all Public Time Servers pages).

Setting Up Clock Synchronization

To configure clock synchronization, you must add NTP servers and then enable NTP synchronization.

To add an NTP server by using the command line interface

At the command prompt, type the following commands to add an NTP server and verify the configuration:

- add ntp server (<serverIP> | <serverName>) [-minpoll <positive_integer>] [-maxpoll <positive_integer>]
- show ntp server

Example

> add ntp server 10.102.29.30 -minpoll 6 -maxpoll 11

To configure an NTP server by using the configuration utility

Navigate to System > NTP Servers, and create the NTP server.

Parameter Descriptions (of commands listed in the CLI procedure)

add ntp server

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ntp server

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Starting the NTP Daemon

When you enable NTP synchronization, the NetScaler starts the NTP daemon and uses the NTP server entries in the ntp.conf file to synchronize its local time setting. If you do not want to synchronize the appliance time with the other servers in the network, you can disable NTP synchronization, which stops the NTP daemon (NTPD).

To enable NTP synchronization by using the command line interface

At the command prompt, type one of the following commands:

enable ntp sync

To enable NTP synchronization by using the configuration utility

Navigate to System > NTP Servers, click Action and select NTP Synchronization.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ntp sync

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Clock Synchronization Manually

You can configure clock synchronization manually by logging on to the NetScaler and editing the ntp.conf file.

To enable clock synchronization on your NetScaler by modifying the ntp.conf file

1. Log on to the command line interface.
2. Switch to the shell prompt.
3. Copy the /etc/ntp.conf file to /nsconfig/ntp.conf, unless the /nsconfig directory already contains an ntp.conf file.
4. Check the /nsconfig/ntp.conf file for the following entries and, if they are present, remove them:

   restrict localhost

   restrict 127.0.0.2
5. Add the IP address for the desired NTP server to the /nsconfig/ntp.conf file, beneath the file's server and restrict entries.

   Note: For security reasons, there should be a corresponding restrict entry for each server entry.
6. If the /nsconfig directory does not contain a file named rc.netscaler, create the file.
7. Add the following entry to /nsconfig/rc.netscaler: `/usr/sbin/ntpd -c /nsconfig/ntp.conf -l /var/log/ntpd.log &`

   This entry starts the ntpd service, checks the ntp.conf file, and logs messages in the /var/log directory.

   This process runs every time the NetScaler is restarted.
8. Reboot the NetScaler to enable clock synchronization.

   Note:

   If you want to start the time synchronization process without restarting the NetScaler, run the following command from the shell prompt:

   ```
   /usr/sbin/ntpd -c /nsconfig/ntp.conf -l /var/log/ntpd.log &
   ```

Viewing the System Date and Time

To change the system date and time, you must use the shell interface to the underlying FreeBSD OS. However, to view the system date and time, you can use the command line interface or the configuration utility.

To view the system date and time by using the command line interface

At the command prompt, type:

show ns config

To view the system date and time by using the configuration utility

Navigate to System and select the System Information tab to view the system date.

Parameter Descriptions (of commands listed in the CLI procedure)

show ns config

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring TCP Window Scaling

The TCP window scaling option, which is defined in RFC 1323, increases the TCP receive window size beyond its maximum value of 65,535 bytes. This option is required for efficient transfer of data over long fat networks (LFNs).

A TCP window determines the amount of outstanding (unacknowledged by the recipient) data a sender can send on a particular connection before receiving any acknowledgment from the receiver. The main purpose of the window is flow control.

The window size field in the TCP header is 16 bits, which limits the ability of the sender to advertise a window size larger than 65535 (2^16 - 1). The TCP window scale extension expands the definition of the TCP window by applying a scale factor to the value in the 16 bit window size field of the TCP header. (Although RFC 1323 describes expanding the definition to up to 30 bits, NetScaler window scaling expands the definition of the TCP window to up to 24 bits.) The scale factor is carried in the new TCP window scale field. This field is sent only in a SYN packet (a segment with the SYN bit on)

To fit a larger window size value into the 16-bit field, the sender right shifts the value by the number of bit positions specified by the scale factor. The receiver left shifts the value by the same number of positions. Therefore, the actual window size is equivalent to:

(2^<scale factor>) * <received window size>

Before configuring window scaling, make sure that:

- You do not set a high value for the scale factor, because this could have adverse effects on the appliance and the network.
- You have enabled selective acknowledgment (SACK).
- You do not configure window scaling unless you clearly know why you want to change the window size.
- Both hosts in the TCP connection send a window scale option during connection establishment. If only one side of a connection sets this option, windows scaling is not used for the connection.
- Each connection for same session is an independent Window Scaling session. For example, when a client's request and the server's response flow through the appliance, it is possible to have window scaling between the client and the appliance without window scaling between the appliance and the server.

By default, window scaling is not enabled.

To configure window scaling by using the command line interface

At the command prompt, type the following commands to configure window scaling and verify the configuration:

- set ns tcpParam -WS (ENABLED | DISABLED) -WSVal <positive_integer>
- show ns tcpParam

Example

```
> set ns tcpParam -WS ENABLED -WSVal 6
```

To configure window scaling by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, under Settings, click Configure TCP Parameters.
3. In the Configure TCP Parameters dialog box, under TCP Window Scaling, select the Windows Scaling check box to enable window scaling and set the window scaling Factor.
4. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns tcpParam

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns tcpParam

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Selective Acknowledgment (SACK)

NetScaler appliances support Selective Acknowledgment (SACK), as defined in RFC 2018. Using SACK, the data receiver (either a NetScaler appliance or a client) notifies the sender about all the segments that have been received successfully. As a result, the sender (either a NetScaler appliance or a client) needs to retransmit only those segments that were lost during transmission. This improves the performance of data transmission. SACK is important in long fat networks (LFNs). By default, SACK is disabled.

To enable Selective Acknowledgment (SACK) by using the command line interface

At the command prompt, type the following commands to enable Selective Acknowledgment (SACK) and verify the configuration:

- set ns tcpParam -SACK (ENABLED | DISABLED)
- show ns tcpParam

Example

```
> set ns tcpParam -SACK ENABLED
```

To enable Selective Acknowledgment (SACK) by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, under Settings, click Change TCP Parameters.
3. In the Configure TCP Parameters dialog box, under TCP, select the Selective Acknowledgment check box. For a description of a parameter, hover the mouse cursor over the check box.
4. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns tcpParam

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns tcpParam

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Clearing the NetScaler Configuration

You have the following three options for clearing the NetScaler configuration.

Basic level. Clearing your configuration at the basic level clears all settings except the following:

- NSIP, MIP(s), and SNIP(s)
- Network settings (Default Gateway, VLAN, RHI, NTP, and DNS settings)
- HA node definitions
- Feature and mode settings
- Default administrator password (nsroot)

Extended level. Clearing your configuration at the extended level clears all settings except the following:

- NSIP, MIP(s), and SNIP(s)
- Network settings (Default Gateway, VLAN, RHI, NTP, and DNS settings)
- HA node definitions

Feature and mode settings revert to their default values.

Full level. Clearing your configuration at the full level returns all settings to their factory default values. However, the NSIP and default gateway are not changed, because changing them could cause the appliance to lose network connectivity.

To clear the configuration by using the command line interface

At the command prompt, type:

clear ns config -force <level>

Example: To forcefully clear the basic configurations on an appliance.

clear ns config -force basic

To clear the configuration by using the configuration utility

Navigate to System > Diagnostics and, in the Maintenance group, click Clear Configuration and select the configuration level to be cleared from the appliance.

Parameter Descriptions (of commands listed in the CLI procedure)

clear ns config

Viewing the HTTP Band Statistics

You can view HTTP band statistics to obtain useful information such as:

- Average request/response band size.
- The size range to which most requests/responses belong.
- Contribution of HTTP pages, in a certain size range, to the overall HTTP traffic.

To view HTTP request and response size statistics by using the command line interface

At the command prompt, type:

show protocol httpBand –type (REQUEST|RESPONSE)

Example

> show protocol httpBand -type REQUEST

To view HTTP request and response size statistics by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, under Settings, click HTTP data band statistics.
3. In the HTTP Data Band Statistics dialog box, view the HTTP request and HTTP response size statistics on the Request and Response tabs, respectively.

You can also modify the band range for HTTP request or response size statistics.

To modify the band range by using the command line interface

At the command prompt, type:

set protocol httpBand reqBandSize <value> respBandSize <value>

Example

```
> set protocol httpBand reqBandSize 300 respBandSize 2048
```

To modify the band range by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, under Settings, click HTTP data band statistics.
3. In the HTTP Data Band Statistics dialog box, select the Request or the Response tab.
4. Click Configure and in the dialog box, specify the band size.
5. Click Close.

Parameter Descriptions (of commands listed in the CLI procedure)

show protocol httpBand

Configuring HTTP Profiles

An HTTP profile is a collection of HTTP parameter settings that can be applied to virtual servers and services. An HTTP profile can be reused on multiple virtual servers or services.

You can use built-in HTTP profiles or configure custom profiles. The following table describes the built-in HTTP profiles.

Table 1. Built-in HTTP Profiles

Built-in profile	Description
nshttp_default_strict_validation	Settings for deployments that require strict validation of HTTP requests and responses.
nshttp_default_profile	The default global HTTP settings for the appliance.

To add an HTTP profile by using the command line interface

At the command prompt, type the following commands to add an HTTP profile and verify the configuration:

- add ns httpProfile <name> [-maxReusePool <positive_integer>] [-dropInvalReqs (ENABLED | DISABLED)] [-markHttp09Inval (ENABLED | DISABLED)] [-markConnReqInval (ENABLED | DISABLED)] ...
- show ns httpProfile <name>

Example

> add ns httpProfile http_profile1 -maxReusePool 30 -dropInvalReqs ENABLED -markHttp09Inval ENABLED -ma

To add an HTTP profile by using the configuration utility

1. Navigate to System > Profiles.
2. In the details pane, click the HTTP Profiles tab, and then click Add.
3. In the Create HTTP Profile dialog box, configure the parameters for the HTTP profile. For a description of a parameter, hover the mouse cursor over the corresponding field.
4. Click Create.

Parameter Descriptions (of commands listed in the CLI procedure)

add ns httpProfile

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns httpProfile

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring WebSocket Connections

WebSocket protocol allows browsers and other clients to create a bi-directional, full duplex TCP connection to the servers. It allows data to be passed back and forth without a request/response model, and so enables live content and creation of real-time games.

The initial handshake is HTTP compliant to satisfy any intermediate devices. During the handshake, the HTTP client connection is upgraded to a WebSocket connection in an HTTP compliant manner. After the upgrade is successful, this connection can be used like a normal TCP connection and does not have to follow any HTTP protocol semantics. When such a connection goes through, the NetScaler appliance tries to interpret any data transfer after the handshake as HTTP, and fails. The WebSocket connections are marked as non-trackable and invalid.

If the HTTP profile that is bound to the virtual server is configured to drop invalid requests, the appliance abruptly closes and resets the connection. However, when the HTTP profile is configured to allow WebSocket connections, the appliance understands the WebSocket handshake. The connection is still marked as non-trackable but it is not marked invalid, and the connection is not dropped.

Configuring WebSocket connections by using the command line interface

At the command prompt, type the following commands to enable websocket connections and verify the configuration:

- set ns httpProfile <name> -webSocket (ENABLED | DISABLED)
- show ns httpProfile <name>

Example: To enable websocket on HTTP profile.

```
> set ns httpProfile http_profile1 -webSocket ENABLED
```

Configuring WebSocket connections by using the configuration utility

1. Navigate to System > Profiles.
2. In the details pane, click the HTTP Profiles tab.
3. Select the HTTP profile for which you want to enable WebSocket connections, and then click Open.
4. In the Configure HTTP Profile dialog box, select the Enable WebSocket connections check box. For a description of the parameter, hover the mouse cursor over the check box.
5. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns httpProfile

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns httpProfile

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring TCP Profiles

A Transmission Control Protocol (TCP) profile is a collection of TCP parameter settings that can be applied to virtual servers and services. A TCP profile can be reused on multiple virtual servers or services. You can use built-in TCP profiles or configure custom profiles. The following table describes the built-in TCP profiles.

Table 1. Built-in TCP Profiles

Built-in profile	Description
nstcp_default_tcp_lfp	This profile is useful for long fat pipe networks (WAN) on the client side. Long fat pipe networks have long delay, high bandwidth lines with minimal packet drops.
nstcp_default_tcp_lnp	This profile is useful for long narrow pipe networks (WAN) on the client side. Long narrow pipe networks have considerable packet loss once in a while.
nstcp_default_tcp_lan	This profile is useful for back-end server connections, where these servers reside on the same LAN as the appliance.
nstcp_default_tcp_lfp_thin_stream	This profile is similar to the nstcp_default_tcp_lfp profile; however, the settings are tuned for small size packet flows.
nstcp_default_tcp_lnp_thin_stream	This profile is similar to the nstcp_default_tcp_lnp profile; however, the settings are tuned for small size packet flows.
nstcp_default_tcp_lan_thin_stream	This profile is similar to the nstcp_default_tcp_lan profile; however, the settings are tuned to small size packet flows.
nstcp_default_tcp_interactive_stream	This profile is similar to the nstcp_default_tcp_lan profile; however, it has a reduced delayed ACK timer and ACK on PUSH packet settings.
nstcp_internal_apps	This profile is useful for internal applications on the appliance (for example, GSLB sitesyncing). This contains tuned window scaling and SACK options for the desired applications. This profile should not be bound to applications other than internal applications.

nstcp_default_profile	This profile represents the default global TCP settings on the appliance.

To add a TCP profile by using the command line interface

At the command prompt, type the following commands to add a TCP profile and verify the configuration:

- add ns tcpProfile <name> [-WS (ENABLED | DISABLED)] [-SACK (ENABLED | DISABLED)] [-WSVal <positive_integer>] [-nagle (ENABLED | DISABLED)] [-ackOnPush (ENABLED | DISABLED)] [-maxBurst <positive_integer>] ...
- show ns tcpProfile

Example

> add ns tcpProfile tcp_profile1 -nagle DISABLED -ackOnPush ENABLED -maxBurst 10 -initialCwnd 6 -delayedA

To add a TCP profile by using the configuration utility

1. Navigate to System > Profiles.
2. In the details pane, click on the TCP Profiles tab and then click Add.
3. In the Create TCP Profiles dialog box, configure the parameters for the TCP profile. For a description of a parameter, hover the mouse cursor over the corresponding field.
4. Click Create.

Parameter Descriptions (of commands listed in the CLI procedure)

add ns tcpProfile

show ns tcpProfile

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Specifying a TCP Buffer Size

You can set the TCP buffer size, both globally and for individual virtual servers and services, through TCP profiles. The value that you set is the minimum value that is advertised by the appliance, and this buffer size is reserved when a client initiates a connection that is associated with an endpoint-application function, such as compression or SSL. The managed application can request a larger buffer, but if it requests a smaller buffer, the request is not honored, and the specified buffer size is used. If the TCP buffer size is set both at the global level and at the entity level (virtual server or service level), the buffer specified at the entity level takes precedence. If the buffer size that you specify for a service is not the same as the buffer size that you specify for the virtual server to which the service is bound, the appliance uses the buffer size specified for the virtual server for the client-side connection and the buffer size specified for the service for the server-side connection. However, for optimum results, make sure that the values specified for a virtual server and the services bound to it have the same value. The buffer size that you specify is used only when the connection is associated with endpoint-application functions, such as SSL and compression.

You set the TCP buffer size in a custom, entity-level TCP profile by setting the bufferSize parameter for the profile. To apply the buffer size setting specified in a custom, entity-level profile, you bind the profile to the virtual server or service. You set the global TCP buffer size by setting the bufferSize parameter in the global TCP profile `nstcp_default_profile`. You do not bind `nstcp_default_profile` to an entity. The settings in `nstcp_default_profile` are automatically applied globally.

Note: A high TCP buffer value could limit the number of connections that can be made to the appliance. Additionally, the global TCP parameter recvBuffSize, which was set by the use of the set ns tcpParam command, has been deprecated. You can now specify the buffer size only through TCP profiles.

To set the TCP buffer size in an entity-level TCP profile by using the command line interface

At the command prompt, type the following commands to set the TCP buffer size and verify the configuration:

- set ns tcpProfile <name> -bufferSize <positive_integer>
- show ns tcpProfile <name>

Example: To set the buffer size to 12000 bytes.

```
> set ns tcpProfile profile1 -bufferSize 12000
```

Note: You can set the TCP buffer size in the global TCP profile by specifying the profile name as *nstcp_default_profile*.

To set the TCP buffer size in a TCP profile by using the configuration utility

1. Navigate to System > Profiles.
2. In the details pane, click the TCP Profiles tab.
3. Select the profile for which you want to set the TCP buffer size and then click Open.

   Note: Select **nstcp_default_profile** if you want to set the TCP buffer size in the global TCP profile, .
4. In the Configure TCP Profile dialog box, set the TCP buffer size as required. For a description of the parameter, hover the mouse cursor over the text box.
5. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns tcpProfile

show ns tcpProfile

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Optimizing the TCP Maximum Segment Size for a Virtual Server Configuration

You can specify the Maximum Segment Size (MSS) that the NetScaler appliance advertises to a client when the client initiates a connection to a virtual server on the appliance. You can configure the MSS for the virtual servers configured on the appliance in two ways:

- You can set the MSS for each virtual server to a value of your choice in a TCP profile.
- You can set the `learnVsvrMSS` global TCP parameter to `ENABLED` to enable MSS learning for all the virtual servers configured on the appliance.

If you know the optimal MSS value for a given virtual server, you can specify the MSS in a TCP profile and bind the profile to the virtual server. When a client initiates a connection with the virtual server, the appliance advertises the specified MSS value to the client. However, if the appliance is also configured to learn the optimum MSS value from bound services (as described in the following section), the learned MSS value takes precedence, and the value specified in the TCP profile is used only until the appliance learns the optimum MSS value. The appliance uses the learned MSS value until the appliance is restarted. If the appliance is restarted, the appliance defaults to the MSS value specified in the virtual server's TCP profile until it learns the MSS value again.

Specifying the MSS Value in a TCP Profile

If you know the optimal MSS value for a given virtual server, you can specify the MSS in a TCP profile and bind the profile to the virtual server. When a client initiates a connection with the virtual server, the NetScaler appliance advertises the specified MSS value to the client.

To specify the MSS value in a TCP profile by using the command line interface

At the command prompt, type the following commands to specify the MSS value in a TCP profile and verify the configuration:

- add ns tcpProfile <name> -mss <positive_integer>
- show ns tcpProfile

> add ns tcpProfile tcp_prof1 -mss 1000

To specify the MSS value in a TCP profile by using the configuration utility

1. Navigate to System > Profiles.
2. In the details pane, do one of the following:
   - To create a TCP profile, click **Add**.
   - To specify the MSS in an existing TCP profile, click the name of the profile, and then click **Open**.
3. In the Create TCP Profile or Configure TCP Profile dialog box, specify the name and the MSS value. For a description of a parameter, hover the mouse cursor over the corresponding field.
4. Click **Create** or **OK**.

Parameter Descriptions (of commands listed in the CLI procedure)

add ns tcpProfile

Configuring the NetScaler to Learn the MSS Value from Bound Services

If you set the global TCP parameter `learnVsvrMSS` to `ENABLED`, the appliance learns the most frequently used MSS value for each configured virtual server. When a client connects to a virtual server, the appliance advertises to the client the MSS value that is optimum for that virtual server. The optimum value is the MSS of the service or subset of bound services that are most frequently selected during load balancing. Consequently, each virtual server configuration uses its own MSS value. This enhancement enables the appliance to optimize the consumption of system resources.

The default value of the `learnVsvrMSS` parameter is `DISABLED`. When enabled, MSS learning is applicable only to virtual servers of type TCP, HTTP, and FTP.

To configure the appliance to learn the MSS for a virtual server by using the command line interface

At the command prompt, type the following commands to configure the appliance to learn the MSS for a virtual server and verify the configuration:

- set ns tcpParam -learnVsvrMSS (ENABLED|DISABLED)
- show ns tcpParam

Example

```
> set ns tcpParam -learnVsvrMSS ENABLED
```

To configure the appliance to learn the MSS for a virtual server by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, under Settings, click Change TCP parameters.
3. In the Configure TCP Parameters dialog box, select the **Learn MSS** check box.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns tcpParam

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns tcpParam

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Call Home

The Call Home feature monitors your NetScaler appliance for common error conditions. Call Home registers your appliance with the Citrix Technical Support server. If your appliance is successfully registered with the Support server, Call Home automatically uploads system data to that server in the event that one of the conditions occurs. The NetScaler Appliance keeps a full log of all upload events. If you are unable to correct the problem after reviewing the appliance's log, you can contact the Citrix Technical Support team and open a service request. The team can analyze the uploaded system data and recommend possible solutions.

Following is a typical set up for Call Home.

The process flow for using Call Home can be categorized as follows:

- Registration of the NetScaler appliance to the Citrix Technical Support server.
- Uploading of the appliance's data to the Citrix Technical Support server. The support server has the following URL: https://taas.citrix.com/.
- Opening a Technical Support case (Optional).

Registration of the NetScaler appliance. The appliance has to be registered to the Citrix Technical Support server before Call Home can upload the system data to the server when predefined error conditions occur on the appliance. Enabling the Call Home feature on the NetScaler appliance initiates the registration process. The process flow is as follows:

1. The Call Home process sends the unique serial number of the appliance to the Citrix Technical Support server.
2. The server checks its database for an active technical support service contract for the appliance.
3. If there is an active technical support service contract, the support server registers the NetScaler appliance for Call Home and sends a successful-registration response to the appliance. If there is no active technical support service contract, the server sends a registration-failure response to the NetScaler appliance.
4. The NetScaler appliance stores the status of the registration in its memory.

The following table lists the error conditions that Call Home monitors on a NetScaler Appliance:

Table 1. List of error conditions monitored by Call Home

Error Condition	Indicates	Call Home Monitoring Interval	Corresponding SNMP Alarm Name
Compact flash drive errors	The compact flash drive on the appliance that encountered read or write errors.	6 hours	COMPACT-FLASH-ERRORS
Hard disk drive errors	The hard drives on the appliance that encountered read or write errors.	6 hours	HARD-DISK-DRIVE-ERRORS
Power supply unit failure	One of the power supply units on the NetScaler appliance has failed.	7 seconds	POWER-SUPPLY-FAILURE
SSL card failure	One of the SSL cards on the NetScaler appliance has failed.	7 seconds	SSL-CARD-FAILED
Warm restart	The appliance has warm restarted due to a failure of a system process.	After every restart of the NetScaler appliance.	WARM-RESTART-EVENT

Uploading of appliance's data to the Support server. An error condition triggers the following sequence of events:

1. The Call Home process checks the registration status, which is stored on the appliance. If the status indicates successful registration, the process advances to the next step.

2. The Call Home process runs a script that collects all of the system related data in a tar file, which is called the *Call Home* tar file. The data in the tar file includes configurations, logs, and statistics. Call Home locally saves the tar file at /var/tmp/support/callhome.

3. Call Home uploads a copy of the tar file to the Citrix Technical Support server. The Appliance logs the uploading of the tar file in a log file named *callhome.log* located at /var/log. You can also configure the CALLHOME-UPLOAD-EVENT SNMP alarm to generate an SNMP alert whenever Call Home uploads a tar file.

4. If the SNMP alarm related to the error condition is enabled, the SNMP agent on the appliance generates an SNMP trap message and sends it to all of the configured SNMP trap destinations. For more information about configuring SNMP alarms and trap destinations, see "Configuring the NetScaler to Generate SNMPv1 and SNMPv2 Traps."

Note: Call Home creates the Call Home tar file and uploads it to the CITRIX tech support server for only the first occurrence of a particular error condition since the appliance was last restarted. If you want the NetScaler appliance to send you alerts each time a particular error condition occurs, configure the corresponding SNMP alarm for the error condition.

The Call Home tar file has the following name format:

`collector_callhome_<NSIP of the appliance>_<P for Primary or standalone, or S for Secondary>_<date>_<hours, in 24 hr format, according to the local time zone>_<minutes>.tar.gz`. For example, `collector_callhome_10.105.13.100_P_2Feb2012_20_30.tar.gz`.

Opening a Technical Support Service Request . After you review the logs and SNMP trap messages for Call Home upload events, you have the option of contacting the Citrix Technical Support team and opening a service request. For more information about contacting the team and opening a service request, see http://support.citrix.com/article/CTX132307.

The Support team can then analyze the system data in the uploaded Call Home tar files and sends recommendations for possible solutions to the administrator's email address.

Before you begin configuring Call Home, do the following:

- Make sure that the NetScaler appliance is connected to the Internet.
- Make sure that you have an active Citrix Technical Support service contract for the appliance.

Configuring Call Home on the NetScaler appliance consists of the following tasks:

1. **Enable the Call Home feature**. When you enable the Call Home feature, the Call Home process registers the appliance with the Citrix Technical Support server. The registration takes some time to complete. During that time, the appliance displays the status as IN PROGRESS. When the registration is complete, the appliance displays the status as SUCCESSFUL.

   Note: While upgrading the NetScaler appliance from an older release to release 10.1 or later, the NetScaler appliance prompts you to enable the Call Home feature in one of the following cases:

   - The Call Home feature is not supported in the older release.
   - The Call Home feature is disabled in the older release.
2. **(Optional) Specify the administrator's email address**. The Call Home process sends the email address to the Support server, where it is stored for future correspondence regarding Call Home.
3. **Enable the CALLHOME-UPLOAD-EVENT SNMP alarm**. The SNMP agent on the NetScaler appliance generates a trap message and sends to all the configured SNMP trap destinations. The message includes the status of uploading of the Call Home tar file by the Call Home process. For more information about configuring SNMP alarms and trap destinations, see "Configuring the NetScaler to Generate SNMPv1 and SNMPv2 Traps."
4. **(Optional) Enable all of the corresponding SNMP alarms**. Call Home creates and uploads a Call Home tar file for the first occurrence of a monitored error condition since the appliance was last restarted. If you want to be alerted each time the error condition occurs, you can configure the corresponding SNMP alarm for the error condition. Table 1 lists all the corresponding SNMP alarms. For more information about configuring SNMP alarms and trap destinations, see "Configuring the NetScaler to Generate SNMPv1 and SNMPv2 Traps."

To enable Call Home by using the command line interface

At the command prompt, type:

enable ns feature ch

To check the status of the appliance's registration to the Support server by using the command line interface

At the command prompt, type:

show callhome

Example

```
> enable ns feature ch
Done

> show callhome
 Callhome feature: ENABLED
 Registration with Citrix upload server IN PROGRESS

 E-mail address configured:

 Trigger event               State     First occurrence   Latest occurrence
 -------------              -----     ----------------   -----------------
 1) Compact flash errors       Enabled   ..                ..
 2) Hard disk drive errors     Enabled   ..                ..
 3) Power supply unit failure  Enabled   ..                ..
 4) SSL card failure           Enabled   ..                ..
 5) Warm restart               Enabled   N/A               ..
 Done

> show callhome
Callhome feature: ENABLED
Registration with Citrix upload server SUCCESSFUL

Done
```

To specify the administrator's email address by using the command line interface

At the command prompt, type:

- set callhome -emailAddress <string>
- show callhome

Example

```
> set callhome -emailAddress exampleadmin@example.com
Done

> show callhome
 E-mail address configured: exampleadmin@example.com

 Trigger event               State     First occurrence   Latest occurrence
 -------------               -----     ----------------   -----------------
 1) Compact flash errors      Enabled   ..                  ..
 2) Hard disk drive errors    Enabled   ..                 ..
 3) Power supply unit failure Enabled   ..                  ..
 4) SSL card failure          Enabled   ..                ..
 5) Warm restart              Enabled   N/A                ..
 Done
```

To enable Call Home by using the configuration utility

Navigate to System > Settings, click Configure Advanced Features and select the Call Home option.

To check the status of the appliance's registration with the Support server by using the configuration utility

Navigation to System > Diagnostics and, in the Technical Support Tools group, select Call Home option to view the status of registration.

To specify the administrator's email address by using the configuration utility

Navigation to System > Diagnostics and, in the Technical Support Tools group, select Call Home option to specify the administrator's email address.

Reporting Tool

Use the Citrix® NetScaler® Reporting tool to view NetScaler performance statistics data as reports. Statistics data are collected by the nscollect utility and are stored in a database. When you want to view certain performance data over a period of time, the Reporting tool pulls out specified data from the database and displays them in charts.

Reports are a collection of charts. The Reporting tool provides built-in reports as well as the option to create custom reports. In a report, you can modify the charts and add new charts. You can also modify the operation of the data collection utility, nscollect, and stop or start its operation.

Using the Reporting Tool

The Reporting tool is a Web-based interface accessed from the Citrix® NetScaler® appliance. Use the Reporting tool to display the performance statistics data as reports containing graphs. In addition to using the built-in reports, you can create custom reports, which you can modify at any time. Reports can have between one and four charts. You can create up to 256 custom reports.

To invoke the Reporting tool

1. Use the Web browser of your choice to connect to the IP address of the NetScaler (for example, http://10.102.29.170/). The Web Logon screen appears.
2. In the User Name text box, type the user name assigned to the NetScaler.
3. In the Password text box, type the password.
4. In the Start in drop-down box, select Reporting.
5. Click Login.

The following screen shots show the report toolbar and the chart toolbar, which are frequently referenced in this documentation.

Figure 1. *Report Toolbar*

Figure 2. *Chart Toolbar*

Working with Reports

You can plot and monitor statistics for the various functional groups configured on the NetScaler over a specified time interval. Reports enable you to troubleshoot or analyze the behavior of your appliance. There are two types of reports: built-in reports and custom reports. Report content for built-in or custom reports can be viewed in a graphical format or a tabular format. The graphical view consists of line, area, and bar charts that can display up to 32 sets of data (counters). The tabular view displays the data in columns and rows. This view is useful for debugging error counters.

The default report that is displayed in the Reporting tool is CPU vs. Memory Usage and HTTP Requests Rate. You can change the default report view by displaying the report you want as your default view, and then clicking Default Report.

Reports can be generated for the last hour, last day, last week, last month, last year, or you can customize the duration.

You can do the following with reports:

- Toggle between a tabular view of data and a graphical view of data.
- Change the graphical display type, such as bar chart or line chart.
- Customize charts in a report.
- Export the chart as an Excel comma-separated value (CSV) file.
- View the charts in detail by zooming in, zooming out, or using a drag-and-drop operation (scrolling).
- Set a report as the default report for viewing whenever you log on.
- Add or remove counters.
- Print reports.
- Refresh reports to view the latest performance data.

Using Built-in Reports

The Reporting tool provides built-in reports for frequently viewed data. Built-in reports are available for the following functional groups: System, Network, SSL, Compression, Integrated Cache, Access Gateway, and Citrix® Application Firewall™. By default, the built-in reports are displayed for the last day. However, you can view the reports for the last hour, last week, last month, or last year.

Note: You cannot save changes to built-in reports, but you can save a modified built-in report as a custom report.

To display a built-in report

1. In the left pane of the Reporting tool, under Built-in Reports, expand a group (for example, SSL).

2. Click a report (for example, SSL > All Backend Ciphers).

Creating and Deleting Reports

You can create your own custom reports and save them with user-defined names for reuse. You can plot different counters for different groups based on your requirements. You can create up to 256 custom reports.

You can either create a new report or save a built-in report as a custom report. By default, a newly created custom report contains one chart named System Overview, which displays the CPU Usage counter plotted for the last day. You can customize the interval and set the data source and time zone from the report toolbar. Within a report, you can use the chart toolbars to add, modify, or delete charts, as described in "Working with Charts."

By default, newly created custom reports contain one chart named System Overview that displays a CPU Usage counter plotted for the last day.

To create a custom report

1. In the Reporting tool, on the report toolbar, click Create, or if you want to create a new custom report based on an existing report, open the existing report, and then click Save As.

2. In Report Name box, type a name for the custom report.

3. Do one of the following:

   - To add the report to an existing folder, in Create in or Save in, click the down arrow to choose an existing folder, and then click OK.

   - To create a new folder to store the report, click the Click to add folder icon, in Folder Name, type the name of the folder, and in Create in, specify where you want the new folder to reside in the hierarchy, and then click OK.

   Note: You can create up to 128 folders.

To delete a custom report

1. In the left pane of the Reporting tool, next to Custom Reports, click the Click to manage custom reports icon.

2. Select the check box that corresponds with the report you want to delete, and then click Delete.

   Note: When you delete a folder, all the contents of that folder are deleted.

Modifying the Time Interval

By default, built-in reports display data for the last day. However, if you want to change the time interval for a built-in report, you can save the report as a custom report. The new interval applies to all charts in the report. The following table describes the time-interval options.

Table 1. Time Intervals

Time interval	Displays
 Last Hour	Statistics data collected for the last hour.
 Last Day	Statistics data collected for the last day (24 hours).
 Last Week	Statistics data collected for the last week (7 days).
 Last Month	Statistics data collected for the last month (31 days).
 Last Year	Statistics data collected for the last year (365 days).
 Custom	Statistics data collected for a time period that you are prompted to specify.

To modify the time interval

1. In the left pane of the Reporting tool, click a report.
2. On the report toolbar, click Duration, and then click a time interval.

Setting the Data Source and Time Zone

You can retrieve data from different data sources to display them in the reports. You can also define the time zone for the reports and apply the currently displayed report's time selection to all the reports, including the built-in reports.

To set the data source and time zone

1. In the Reporting tool, on the report toolbar, click Settings.
2. In the Settings dialog box, in Data Source, select the data source from which you want to retrieve the counter information.
3. Do one or both of the following:
   - If you want the tool to remember the time period for which a chart is plotted, select the Remember time selection for charts check box.
   - If you want the reports to use the time settings of your NetScaler appliance, select the Use Appliance's time zone check box.

Exporting and Importing Custom Reports

You can share reports with other NetScaler administrators by exporting reports. You can also import reports.

To export or import custom reports

1. In the left pane of the Reporting tool, next to Custom Reports, click the Click to manage custom reports icon.
2. Select the check box that corresponds with the report you want to export or import, and then click Export or Import.

   Note: When you export the file, it is exported in a .gz file format.

Working with Charts

Use charts to plot and monitor counters or groups of counters. You can include up to four charts in one report. In each chart, you can plot up to 32 counters. The charts can use different graphical formats (for example, area and bar). You can move the charts up or down within the report, customize the colors and visual display for each counter in a chart, and delete a chart when you do not want to monitor it.

In all report charts, the horizontal axis represents time and the vertical axis represents the value of the counter.

Adding a Chart

When you add a chart to a report, the System Overview chart appears with the CPU Usage counter plotted for the last one day. To plot a different group of statistics or select a different counter, see "Modifying a Chart."

Note: If you add charts to a built-in report, and you want to retain the report, you must save the report as a custom report.

Use the following procedure to add a chart to a report.

To add a chart to a report

1. In the left pane of the Reporting tool, click a report.
2. Under the chart where you want to add the new chart, click the Add icon.

Modifying a Chart

You can modify a chart by changing the functional group for which the statistics are displayed and by selecting different counters.

To modify a chart

1. In the left pane of the Reporting tool, click a report.
2. Under the chart that you want to modify, click Counters.
3. In the dialog box that appears, in the Title box, type a name for the chart.
4. Next to Plot chart for, do one of the following:
   - To plot counters for global counters, such as Integrated Cache and Compression, click System global statistics.
   - To plot entity counters for entity types, such as Load Balancing and GSLB, click System entities statistics.
5. In Select group, click the desired entity.
6. Under Counters, in Available, click the counter name(s) that you want to plot, and then click the > button.
7. If you selected System entities statistics in step 4, on the Entities tab, under Available, click the entity instance name(s) you want to plot, and then click the > button.
8. Click OK.

Viewing a Chart

You can specify the graphical formats of the plotted counters in a chart. Charts can be viewed as line charts, spline charts, step-line charts, scatter charts, area charts, bar charts, stacked area charts, and stacked bar charts. You can also zoom in, zoom out, or scroll inside the plot area of a chart. You can zoom in or out for all data sources for 1 hour, 1 day, 1 week, 1 month, 1 year, and 3 years.

Other options for customizing the view of a chart include customizing the axes of the charts, changing the background and edge color of the plot area, customizing the color and size of the grids, and customizing the display of each data set (counter) in a chart.

Data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.

Whenever you modify a built-in report, you need to save the report as a custom report to retain your changes.

To change the graph type of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart you want to view, on the chart toolbar, click Customize.
3. On the Chart tab, under Category, click Plot type, and then click the graph type you want to display for the chart. If you want to display the graph is 3D, select the Use 3D check box.

To refocus a chart with detailed data

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Zoom In, and do one or both of the following:
   - To refocus the chart to display data for a specific time window, drag and drop the cursor from the start time to the end time. For example, you can view data for a one-hour period on a certain day.
   - To refocus the chart to display data for a data point, simply click once on chart where you want to zoom in and get more detailed information.
3. Once you have the desired range of time for which you want to view detailed data, on the report toolbar, click Tabular View. Tabular view displays the data in numeric form in rows and columns.

To view numeric data for a graph

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Tabular View. To return to the graphical view, click Graphical View.

   Note: You can also view the numeric data in the graphical view by hovering your cursor over the notches in the gridlines.

To scroll through time in a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Scroll, and then click inside the chart and drag the cursor in the direction for which you want to see data for a new time period. For example, if you want to view data in the past, click and drag to the left.

To change the background color and text color of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the axes, click Customize.
3. On the Chart tab, under Category, click one or more of the following:
   - To change the background color, click Background Color, and then select the options for color, transparency, and effects.
   - To change the text color, click Text Color, and then select the options for color, transparency, and effects.

To customize the axes of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the axes, click Customize.
3. On the Chart tab, under Category, click one or more of the following:
   - To change the scale of the left y-axis, click Left Y-Axis, and then select the scale you want.
   - To change the scale of the right y-axis, click Right Y-Axis, in Data set to plot, select the date set, and then select the scale you want.

     Note: The data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.
   - To plot each data set in its own hidden y-axis, click Multiple Axes, and then click Enable.

To change the background color, edge color, and gridlines for a plot area of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the plot area, click Customize.
3. On the Plot Area tab, under Category, click one or more of the following:
   - To change the background color and edge color of the chart, click Background Color and Edge Color, and then select the options for color, transparency, and effects.
   - To change the horizontal or vertical grids of the chart, click Horizontal Grids or Vertical Grids, and then select the options for displaying the grids, grid width, grid color, transparency, and effects.

To change the color and graph type of a data set

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the display of the data set (counters), click Customize.
3. On the Data Set tab, in Select Data Set, select the data set (counter) for which you want to customize the graphical display.

   Note: The data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.
4. Under Category, do one of more of the following:
   - To change the background color, click Color, and then select the options for color, transparency, and effects.
   - To change the graph type, click Plot type, and then select the graph type you want to display for the data set. If you want to display the graph as 3D, select the Use 3D check box.

Exporting Chart Data to Excel

For further data analysis, you can export charts to Excel in a comma-separated value (CSV) format.

To export chart data to Excel

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart with the data you want to export to Excel, click Export.

Deleting a Chart

If you do not want to use a chart, you can remove it from the report. You can permanently remove charts from custom reports only. If you delete a chart from a built-in report and want to retain the changes, you need to save the report as a custom report.

To delete a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart that you want to delete, click the Delete icon.

Examples

To display the trend report for CPU usage and memory usage for the last week

1. In the left pane of the Reporting tool, under Built-in Reports, expand System.
2. Click the report CPU vs. Memory Usage and HTTP Requests Rate.
3. In the right pane, on the report toolbar, click Duration, and then click Last Week.

To compare the bytes received rate and the bytes transmitted rate between two interfaces for the last week

1. In the right pane, on the report toolbar, click Create.
2. In the Report Name box, type a name for the custom report (for example, `Custom_Interfaces`), and then click OK. The report is created with the default System Overview chart, which displays the CPU Usage counter plotted for the last hour.
3. Under System Overview, on the chart toolbar, click Counters.
4. In the counter selection pane, in Title, type a name for the chart (for example, `Interfaces bytes data`).
5. In Plot chart for, click System entities statistics, and then in Select Group, select Interface.
6. On the Entities tab, click the interface name(s) you want to plot (for example, 1/1 and 1/2), and then click the > button.
7. On the Counters tab, click Bytes received (Rate) and Bytes transmitted (Rate) and then click the > button.
8. Click OK.
9. On the report toolbar, click Duration, and then click Last Week.

Stopping and Starting the Data Collection Utility

The data collection utility, nscollect, runs automatically when you start the NetScaler ADC. This utility retrieves the application performance data and stores it in the form of data sources on the ADC. You can create up to 32 data sources. The default data source is /var/log/db/default.

The data collection utility creates databases for global counters and entity-specific counters, and uses this data to generate reports. Global-counter databases are created at /var/log/db/<DataSourceName> . The entity-specific databases are created based on the entities configured on the NetScaler, and a separate folder is created for each entity type in /var/log/db/<DataSourceName/EntityNameDB>.

Nscollect retrieves data once every 5 minutes. It retains data in 5-minute granularity for one day, hourly for the last 30 days, and daily for three years.

You might have to stop and restart the data collection utility if data is not updated accurately or the reports display corrupted data.

To stop nscollect

At the command prompt, type:

/netscaler/nscollect stop

To start nscollect on the local system

At the command prompt, type:

/netscaler/nscollect start

AppFlow

The Citrix NetScaler appliance is a central point of control for all application traffic in the data center. It collects flow and user-session level information valuable for application performance monitoring, analytics, and business intelligence applications. It also collects web page performance data and database information. AppFlow transmits the information by using the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. IPFIX (the standardized version of Cisco's NetFlow) is widely used to monitor network flow information. AppFlow defines new Information Elements to represent application-level information, web page performance data, and database information.

Using UDP as the transport protocol, AppFlow transmits the collected data, called *flow records*, to one or more IPv4 collectors. The collectors aggregate the flow records and generate real-time or historical reports.

AppFlow provides visibility at the transaction level for HTTP, SSL, TCP, and SSL_TCP flows. You can sample and filter the flow types that you want to monitor.

AppFlow use actions and policies to send records for a selected flow to specific set of collectors. An AppFlow action specifies which set of collectors will receive the AppFlow records. Policies, which are based on Advanced expressions can be configured to select flows for which flow records will be sent to the collectors specified by the associated AppFlow action.

To limit the types of flows, you can enable AppFlow for a virtual server. AppFlow can also provide statistics for the virtual server.

You can also enable AppFlow for a specific service, representing an application server, and monitor the traffic to that application server.

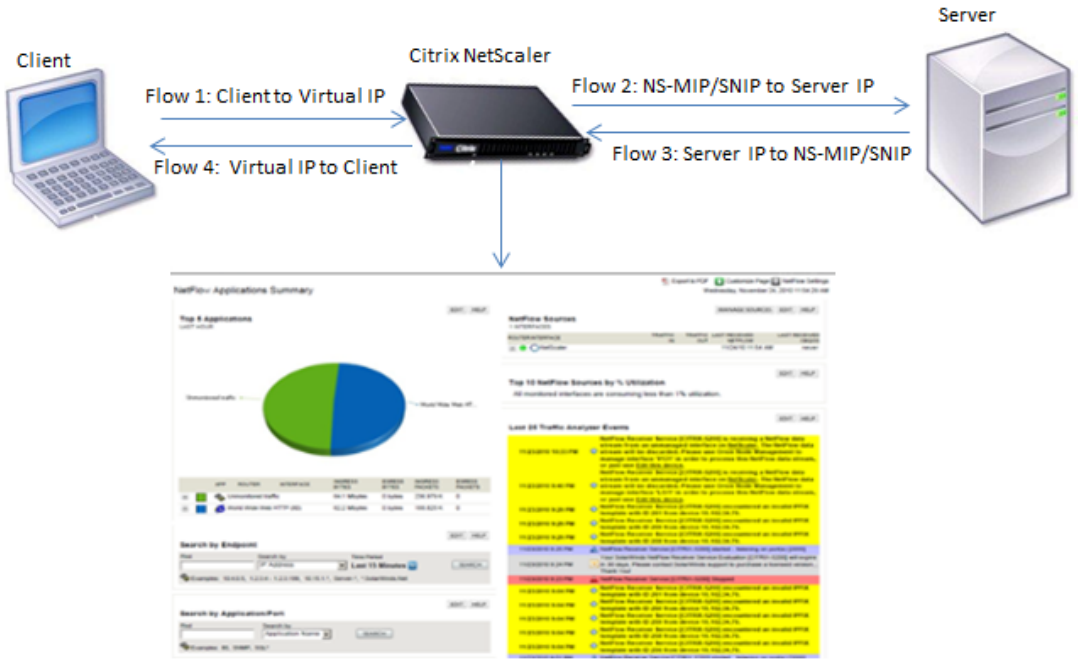
Note: This feature is supported only on NetScaler nCore builds.

How AppFlow Works

In the most common deployment scenario, inbound traffic flows to a Virtual IP address (VIP) on the NetScaler appliance and is load balanced to a server. Outbound traffic flows from the server to a mapped or subnet IP address on the NetScaler and from the VIP to the client. A flow is a unidirectional collection of IP packets identified by the following five tuples: sourceIP, sourcePort, destIP, destPort, and protocol.

The following figure describes how the AppFlow feature works.

Figure 1. NetScaler Flow Sequence



As shown in the figure, the network flow identifiers for each leg of a transaction depend on the direction of the traffic.

The different flows that form a flow record are:

Flow1: <Client-IP, Client-Port, VIP-IP, VIP-port, Protocol>

Flow2: <NS-MIP/SNIP, NS-port, Server-IP, Server-Port, Protocol>

Flow3: <Server-IP, Server-Port, NS-MIP/SNIP, NS-Port, Protocol>

Flow4: <VIP-IP, VIP-port, Client-IP, Client-Port, Protocol>

To help the collector link all four flows in a transaction, AppFlow adds a custom transactionID element to each flow. For application-level content switching, such as HTTP, it is possible for a single client TCP connection to be load balanced to different backend TCP connections for each request. AppFlow provides a set of records for each transaction.

Flow Records

AppFlow records contain standard NetFlow or IPFIX information, such as time stamps for the beginning and end of a flow, packet count, and byte count. AppFlow records also contain application-level information (such as HTTP URLs, HTTP request methods and response status codes, server response time, and latency), web page performance data (such as page load time, page render time, and time spent on the page), and database information (such as database protocol, database response status and database response size). IPFIX flow records are based on templates that need to be sent before sending flow records.

Templates

AppFlow defines a set of templates, one for each type of flow. Each template contains a set of standard Information Elements (IEs) and Enterprise-specific Information Elements (EIEs). IPFIX templates define the order and sizes of the Information Elements (IE) in the flow record. The templates are sent to the collectors at regular intervals, as described in RFC 5101.

A template can include the following EIEs:

transactionID

An unsigned 32-bit number identifying an application-level transaction. For HTTP, this corresponds to a request and response pair. All flow records that correspond to this request and response pair have the same transaction ID. In the most common case, there are four uniflow records that correspond to this transaction. If the NetScaler generates the response by itself (served from the integrated cache or by a security policy), there may be only two flow records for this transaction.

connectionID

An unsigned 32-bit number identifying a layer-4 connection (TCP or UDP). The NetScaler flows are usually bidirectional, with two separate flow records for each direction of the flow. This information element can be used to link the two flows.

For the NetScaler, connectionID is an identifier for the connection data structure to track the progress of a connection. In an HTTP transaction, for instance, a given connectionID may have multiple transactionID elements corresponding to multiple requests that were made on that connection.

tcpRTT

The round trip time, in milliseconds, as measured on the TCP connection. This can be used as a metric to determine the client or server latency on the network.

httpRequestMethod

An 8-bit number indicating the HTTP method used in the transaction. An options template with the number-to-method mapping is sent along with the template.

httpRequestSize

An unsigned 32-bit number indicating the request payload size.

httpRequestURL

The HTTP URL requested by the client.

httpUserAgent

The source of incoming requests to the Web server.

httpResponseStatus

An unsigned 32-bit number indicating the response status code.

httpResponseSize

An unsigned 32-bit number indicating the response size.

httpResponseTimeToFirstByte

An unsigned 32-bit number indicating the time taken to receive the first byte of the response.

httpResponseTimeToLastByte

An unsigned 32-bit number indicating the time taken to receive the last byte of the response.

flowFlags

An unsigned 64-bit flag used to indicate different flow conditions.

EIEs for web page performance data

clientInteractionStartTime

Time at which the browser receives the first byte of the response to load any objects of the page such as images, scripts, and stylesheets.

clientInteractionEndTime

Time at which the browser received the last byte of response to load all the objects of the page such as images, scripts, and stylesheets.

clientRenderStartTime

Time at which the browser starts to render the page.

clientRenderEndTime

Time at which browser finished rendering the entire page, including the embedded objects.

EIEs for database information

dbProtocolName

An unsigned 8-bit number indicating the database protocol. Valid values are 1 for MS SQL and 2 for MySQL.

dbReqType

An unsigned 8-bit number indicating the database request method used in the transaction. For MS SQL, valid values are 1 is for QUERY, 2 is for TRANSACTION, and 3 is for RPC. For valid values for MySQL, see the MySQL documentation.

dbReqString

Indicates the database request string without the header.

dbRespStatus

An unsigned 64-bit number indicating the status of the database response received from the web server.

dbRespLength

An unsigned 64-bit number indicating the response size.

dbRespStatString

The response status string received from the web server.

Configuring the AppFlow Feature

You configure AppFlow in the same manner as most other policy-based features. First, you enable the AppFlow feature. Then you specify the collectors to which the flow records are sent. After that, you define actions, which are sets of configured collectors. Then you configure one or more policies and associate an action to each policy. The policy tells the NetScaler appliance to select requests the flow records of which are sent to the associated action. Finally, you bind each policy either globally or to specific vservers to put it into effect.

You can further set AppFlow parameters to specify the template refresh interval and to enable the exporting of httpURL, httpCookie, and httpReferer information. On each collector, you must specify the NetScaler IP address as the address of the exporter.

Note: For information about configuring the NetScaler as an exporter on the collector, see the documentation for the specific collector.

The configuration utility provides tools that help users define the policies and actions that determine exactly how the NetScaler appliance export records for a particular flow to a set of collectors(action.) The command line interface provides a corresponding set of CLI-based commands for experienced users who prefer a command line.

Enabling AppFlow

To be able to use the AppFlow feature, you must first enable it.

Note: AppFlow can be enabled only on nCore NetScaler appliances.

To enable the AppFlow feature by using the command line interface

At the command prompt, type one of the following commands:

enable ns feature `AppFlow`

To enable the AppFlow feature by using the configuration utility

Navigate to System > Settings, click Configure Advanced Features and select the AppFlow option.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ns feature

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Specifying a Collector

A collector receives flow records generated by the NetScaler appliance. To be able to send flow records, you must specify at least one collector. You can specify up to four. However, you cannot export the same data to multiple collectors. You can remove unused collectors. By default, the collector listens to IPFIX messages on UDP port 4739. You can change the default port, when configuring the collector. Similarly, by default, NSIP is used as the source IP for appflow traffic. You can change this default source IP to a SNIP or MIP address when configuring a collector.

To specify a collector by using the command line interface

At the command prompt, type the following commands to add a collector and verify the configuration:

- add appflow collector <*name*> -IPAddress <*ipaddress*> -port <*port_number*> -netprofile <*netprofile_name*>
- show appflow collector <*name*>

Example

> add appflow collector col1 -IPaddress 10.102.29.251 -port 8000 -netprofile n2

To specify a collector by using the configuration utility

In the navigation pane, expand AppFlow, and then click Collectors, and create the AppFlow collector.

Parameter Descriptions (of commands listed in the CLI procedure)

add appflow collector

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show appflow collector

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring an AppFlow Action

An AppFlow action is a set collectors, to which the flow records are sent if the associated AppFlow policy matches.

To configure an AppFlow action by using the command line interface

At the command prompt, type the following commands to configure an Appflow action and verify the configuration:

- add appflow action <name> --collectors <string> ... [-comment <string>]
- show appflow action

Example

> add appflow action apfl-act-collector-1-and-3 -collectors collector-1 collecter-3

To configure an AppFlow action by using the configuration utility

1. In the navigation pane, expand AppFlow, and then click Actions.
2. In the details pane, do one of the following:
   - To create a new action, click Add.
   - To modify an existing action, select the action, and then click Open.
3. In the Add AppFlow Action or Configure AppFlow Action dialog box, type a name for the new action or the name of an existing action, respectively.
4. Do one of the following to associate collectors with the action:
   - If the collectors that you want are listed, click the corresponding check boxes.
   - If you want to specify all the collectors, click Activate All.
   - If you want to specify a new collector, click Add.
5. Click Create or OK, depending on whether you are creating a new action or modifying an existing action.
6. Click Close. A message appears in the status bar, stating that the configuration has been successfully implemented.

Parameter Descriptions (of commands listed in the CLI procedure)

add appflow action

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show appflow action

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring an AppFlow Policy

After you configure an AppFlow action, you must next configure an AppFlow policy. An AppFlow policy is based on a rule, which consists of one or more expressions.

Note: For creating and managing AppFlow policies, the configuration utility provides assistance that is not available at the command line interface.

To configure an AppFlow policy by using the command line interface

At the command prompt, type the following command to add an AppFlow policy and verify the configuration:

- add appflow policy <name> <rule> <action>
- show appflow policy <name>

Example

```
> add appflow policy apfl-pol-tcp-dsprt client.TCP.DSTPORT.EQ(22) apfl-act-collector-1-and-3
```

To configure an AppFlow policy by using the configuration utility

In the navigation pane, expand AppFlow, and then click Policies, and create the AppFlow policy.

To add an expression by using the Add Expression dialog box

1. In the Add Expression dialog box, in the first list box choose the first term for your expression.

   HTTP

   The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.

   SYS

   The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

   CLIENT

   The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

   When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.

2. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.

3. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

Parameter Descriptions (of commands listed in the CLI procedure)

add appflow policy

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show appflow policy

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Binding an AppFlow Policy

To put a policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the NetScaler, or to a specific virtual server, so that the policy applies only to the traffic related to that virtual server.

When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

In the NetScaler operating system, policy priorities work in reverse order—the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is performed first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you globally bind it. You can then add additional policies at any time without having to change the priority of an existing policy.

To globally bind an AppFlow policy by using the command line interface

At the command prompt, type the following command to globally bind an AppFlow policy and verify the configuration:

- bind appflow global <policyName> <priority> [<gotoPriorityExpression [-type <type>] [-invoke (<labelType> <labelName>)]
- show appflow global

Example

bind appflow global af_policy_lb1_10.102.71.190 1 NEXT -type REQ_OVERRIDE -invoke vserver google

To bind an AppFlow policy to a specific virtual server by using the command line interface

At the command prompt, type the following command to bind an appflow policy to a specific virtual server and verify the configuration:

bind lb vserver <name> -policyname <policy_name> -priority <priority>

Example

bind lb vserver google -policyname af_policy_google_10.102.19.179 -priority 251

To globally bind an AppFlow policy by using the configuration utility

In the navigation pane, expand AppFlow, click AppFlow policy Manager and select the relevant Bind Point (Default Global) and Connection Type, and then bind the AppFlow policy.

To bind an AppFlow policy to a specific virtual server by using the configuration utility

In the navigation pane, expand Load Balancing, and then click Virtual Servers, select the virtual server, and click Policies, and bind the AppFlow policy.

Parameter Descriptions (of commands listed in the CLI procedure)

bind appflow global

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show appflow global

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind lb vserver

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Enabling AppFlow for Virtual Servers

If you want to monitor only the traffic through certain virtual servers, enable AppFlow specifically for those virtual servers. You can enable AppFlow for load balancing, content switching, cache redirection, SSL VPN, GSLB, and authentication virtual servers.

To enable AppFlow for a virtual server by using the command line interface

At the command prompt, type:

set cs vserver <name> <protocol> <IPAddress> <port> -appflowLog ENABLED

Example

> set cs vserver Vserver-CS-1 HTTP 10.102.29.161 80 -appflowLog ENABLED

To enable AppFlow for a virtual server by using the configuration utility

In the navigation pane, expand the feature node for which you want to enable AppFlow, and then click Virtual Servers, and enable AppFlow Logging option. For example, to enable AppFlow for a content switching virtual server, expand Content Switching and then click Virtual Servers.

Parameter Descriptions (of commands listed in the CLI procedure)

set cs vserver

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Enabling AppFlow for a Service

You can enable AppFlow for services that are to be bound to the load balancing virtual servers.

To enable AppFlow for a service by using the command line interface

At the command prompt, type:

set service <name> -appflowLog ENABLED

Example

set service ser -appflowLog ENABLED

To enable AppFlow for a service by using the configuration utility

In the navigation pane, expand Load Balancing, and then click Services, select the service, and enable AppFlow Logging option.

Parameter Descriptions (of commands listed in the CLI procedure)

set service

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Setting the AppFlow Parameters

You can set AppFlow parameters to customize the exporting of data to the collectors.

To set the AppFlow Parameters by using the command line interface

At the command prompt, type the following commands to set the AppFlow parameters and verify the settings:

- set appflow param [-templateRefresh <secs>] [-appnameRefresh <secs>] [-flowRecordInterval <secs>] [-udpPmtu <positive_integer>] [-httpUrl (**ENABLED** | **DISABLED**)] [-httpCookie (**ENABLED** | **DISABLED**)] [-httpReferer (**ENABLED** | **DISABLED**)] [-httpMethod (**ENABLED** | **DISABLED**)] [-httpHost (**ENABLED** | **DISABLED**)] [-httpUserAgent (**ENABLED** | **DISABLED**)] [-httpXForwardedFor (**ENABLED** | **DISABLED**)][-clientTrafficOnly (**YES** | **NO**)]
- show appflow Param

Example

> set appflow Param -templateRefresh 240 -udpPmtu 128 -httpUrl enabled

To set the AppFlow parameters by using the configuration utility

In the navigation pane, click AppFlow, select Change AppFlow Settings, and specify relevant AppFlow parameters.

Parameter Descriptions (of commands listed in the CLI procedure)

set appflow param

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show appflow Param

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Example: Configuring AppFlow for DataStream

The following example illustrates the procedure for configuring AppFlow for DataStream using the command line interface.

```
> enable feature appflow
> add db user sa password freebsd
> add lbvserver lb0 MSSQL 10.102.147.97 1433 -appflowLog ENABLED
> add service sv0 10.103.24.132 MSSQL 1433 -appflowLog ENABLED
> bind lbvserver lb0 sv0
> add appflow collector col0 -IPAddress 10.102.147.90
> add appflow action act0 -collectors col0
> add appflow policy pol0 "mssql.req.query.text.contains(\"select\")" act0
> bind lbvserver lb0 -policyName pol0 -priority 10
```

When the Netscaler appliance receives a database request, the appliance evaluates the request against a configured policy. If a match is found, the details are sent to the AppFlow collector configured in the policy.

Exporting Performance Data of Web Pages to AppFlow Collector

The EdgeSight Monitoring application provides web page monitoring data with which you can monitor the performance of various Web applications served in a Netscaler environment. You can now export this data to AppFlow collectors to get an in-depth analysis of the web page applications. AppFlow, which is based on IPFIX standard, provides more specific information about web application performance than does EdgeSight monitoring alone.

You can configure both load balancing and content switching virtual servers to export EdgeSight Monitoring data to AppFlow collectors. Before configuring a virtual server for AppFlow export, associate an Appflow action with the EdgeSight Monitoring responder policy.

The following web page performance data is exported to AppFlow:

- **Page Load Time**. Elapsed time, in milliseconds, from when the browser starts to receive the first byte of a response until the user starts to interact with the page. At this stage, all the page content might not be loaded.
- **Page Render Time**.Elapsed time, in milliseconds, from when the browser receives the first byte of response until either all page content has been rendered or the page load action has timed out.
- **Time Spent on the Page**. Time spent by users on a page. Represents the period of time from one page request to the next one.

AppFlow transmits the performance data by using the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. The AppFlow templates use the following enterprise-specific Information Elements (EIEs) to export the information:

- **Client Load End Time**. Time at which the browser received the last byte of a response to load all the objects of the page such as images, scripts, and stylesheets.
- **Client Load Start Time.**Time at which the browser receives the first byte of the response to load any objects of the page such as images, scripts, and stylesheets.
- **Client Render End Time**. Time at which browser finished rendering the entire page, including the embedded objects.
- **Client Render Start Time**. Time at which the browser started rendering the page.

Prerequisites for Exporting Performance Data of Web Pages to AppFlow Collectors

Before associating the AppFlow action with the AppFlow policy, verify that the following prerequisites have been met:

- The AppFlow feature has been enabled and configured. For instructions, see "Configuring the AppFlow feature".
- The Responder feature has been enabled. For instructions, see "Enabling a Responder Feature".
- The EdgeSight Monitoring feature has been enabled. For instructions, see "Enabling an Application for EdgeSight Monitoring."
- EdgeSight Monitoring has been enabled on the load balancing or content switching virtual servers bound to the services of applications for which you want to collect the performance data. For instructions, see "Enabling an Application for EdgeSight Monitoring."

Associating an AppFlow Action with the EdgeSight Monitoring Responder Policy

To export the web page performance data to the AppFlow collector, you must associate an AppFlow action with the EdgeSight Monitoring responder policy. An AppFlow action specifies which set of collectors receive the traffic.

To associate an AppFlow action with the EdgeSight Monitoring Responder policy by using the command line interface

At the command prompt, type:

set responder policy <name> -appflowAction <action_Name>

Example

set responder policy pol -appflowAction actn

To associate an AppFlow action with the EdgeSight Monitoring Responder policy by using the configuration utility

1. In the navigation page, expand **Responder**, and then click **Policies**.
2. In the details pane, select an EdgeSight Monitoring responder policy, and then click **Open**.
3. In the **Configure Responder Policy** dialog box, in the **AppFlow Action** drop-down list, select the AppFlow action associated with the collectors to which you want to send the web-page performance data.
4. Click **OK**.

Configuring a Virtual Server to Export EdgeSight Statistics to Appflow Collectors

To export EdgeSight statistics information from a virtual server to the AppFlow collector, you must associate an AppFlow action with the virtual server.

To associate an AppFlow action with a Load Balancing or Content Switching virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing or Content Switching, and then click Virtual Servers.
2. In the details pane, select a virtual server, or multiple virtual servers, and then click Enable EdgeSight Monitoring.
3. In the Enable EdgeSight Monitoring dialog box, select the Export EdgeSight statistics to Appflow check box.
4. From the Appflow Action drop-down list, select the AppFlow action. The AppFlow action defines the list of AppFlow collectors to which it exports EdgeSight Monitoring statistics. If you have selected multiple load balancing virtual servers, the same AppFlow Action will be associated with the responder policies bound to them. You can later change the AppFlow Action configured for each of the selected Load Balancing virtual server individually, if required.
5. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set responder policy

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

AutoScale: Automatic Scaling in the Citrix CloudPlatform Environment

Note: The AutoScale feature is supported only on NetScaler 10.e.

Efficient hosting of applications in a cloud requires continuous optimization of application availability. To meet increasing demand, you have to scale network resources upward. When demand subsides, you need to scale down to avoid the unnecessary cost of idle resources. To minimize the cost of running the application by deploying only as many instances as are necessary during any given period of time, you have to constantly monitor traffic. However, monitoring traffic manually is not a feasible option. For the application environment to be able to scale up or down rapidly, you need to automate the processes of monitoring traffic and of scaling resources up and down whenever necessary.

If your organization uses Citrix CloudPlatform to deploy and manage the cloud environment, a Citrix NetScaler appliance can automatically scale users' applications as needed. The CloudPlatform elastic load balancing feature includes a feature called *AutoScale*. A CloudPlatform user can use the AutoScale feature to specify thresholds for various conditions for automatically scaling the application fleet upward and downward. The scale-up and scale-down conditions can vary from simple use cases, such as a server's CPU usage, to complex use cases, such as a combination of a server's CPU usage and responsiveness. CloudPlatform, in turn, configures the NetScaler appliance to load balance traffic to the application virtual machines (VMs), monitor application thresholds and performance, and trigger scale-up and scale-down actions to add or remove VMs to or from the application fleet.

The CloudPlatform user performs all AutoScale configuration tasks by using the CloudPlatform user interface or APIs. The CloudPlatform user:

1. Creates a load balancing rule, with the necessary load balancing algorithm and stickiness.

2. Configures AutoScale parameters by specifying the application instance template, the minimum number of instances to maintain, the maximum number of instances permitted, scale-up and scale-down policies, and other information necessary for the functioning of the feature.

3. Submits the configuration.

For information about configuring a load balancing rule and AutoScale, see *Citrix CloudPlatform 3.0.5 (powered by Apache CloudStack) Administrator's Guide*, at http://support.citrix.com/article/CTX134823.

When the CloudPlatform user completes the AutoScale configuration, CloudPlatform uses the NetScaler NITRO API to push all the necessary configuration commands to the NetScaler appliance. As the NetScaler administrator, you do not have to perform any tasks for configuring AutoScale on the NetScaler appliance. However, you might have to be aware of certain prerequisites, and you might have to troubleshoot the configuration if issues arise in the AutoScale configuration. To troubleshoot the configuration, you have to be aware of how CloudPlatform works and what configuration CloudPlatform pushes to the NetScaler

appliance. You also need a working knowledge of how to troubleshoot issues on a NetScaler appliance.

How AutoScale Works

When the CloudPlatform user completes the AutoScale configuration, CloudPlatform uses the NetScaler NITRO API to create an AutoScale-related configuration on the NetScaler appliance. For information about the configuration commands that CloudPlatform uses to configure the NetScaler appliance, see "NetScaler Configuration Details."

The following diagram shows the sequence of operations, beginning with CloudPlatform pushing the AutoScale configuration to the NetScaler appliance. The events are numbered in the order in which they occur, and are described below.

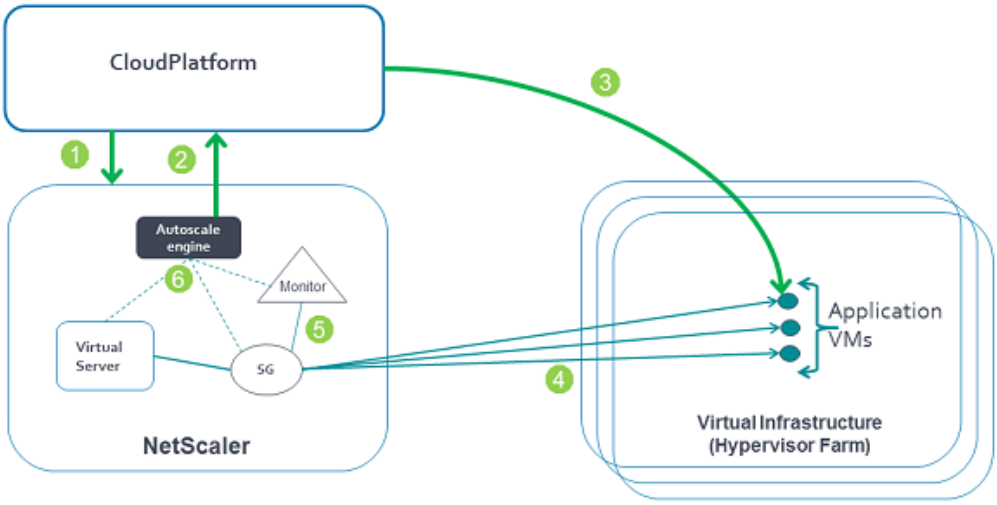


Figure 1. AutoScale Architecture

When the CloudPlatform user submits the AutoScale configuration, the following events occur:

1. CloudPlatform uses the NetScaler NITRO API to push the AutoScale configuration to the NetScaler appliance, creating AutoScale-related entities on the appliance. The entities include a load balancing virtual server, a service group, and monitors.

2. The AutoScale engine on the NetScaler appliance sends API requests to CloudPlatform to initially deploy the minimum number of virtual machines required.

3. CloudPlatform provisions the minimum number of instances (VMs) on the hypervisors (virtualization hosts) that it manages.

4. The NetScaler appliance discovers the IP addresses assigned by CloudPlatform to the newly created VMs and binds them, as services, to the service group representing them. The NetScaler appliance can then load balance traffic to the VMs.

5. NetScaler monitors bound to the service group start monitoring the load by collecting SNMP metrics from the instances.

6. The AutoScale engine on the NetScaler appliance monitors the metrics collected from the VMs and triggers scale-up and scale-down events whenever the metrics breach the configured threshold for the specified period. As part of the scale-up trigger, the NetScaler AutoScale engine sends an API request to CloudPlatform to deploy a new VM. After the virtual machine is deployed, the AutoScale engine binds the service representing the VM (IP address and port) to the service group and, after the configured quiet time, starts forwarding load balanced traffic to the new virtual machine. Likewise, as part of the scale-down trigger, the NetScaler AutoScale engine selects a VM, stops forwarding new requests to that instance, and waits for the configured quiet time (to allow for the processing of current requests to complete) before it sends an API request to CloudPlatform to destroy the chosen instance.

In this way, the NetScaler appliance monitors the application and triggers scale-up and scale-down events on the basis of application load and/or performance.

Supported Environment

AutoScale is supported in the following environment:

- Citrix CloudPlatform 3.0.5.
- Citrix NetScaler MPX/SDX/virtual appliance running Citrix NetScaler release 10.e and later.
- SNMP v1/v2.

Prerequisites

Before you set up AutoScale, do the following:

- Make sure that CloudPlatform is reachable from the NetScaler appliance. You can do so by logging on to the NetScaler appliance and sending ping requests to the CloudPlatform server's IP address.
- Make sure that the network service offering used in CloudPlatform includes the NetScaler appliance as an external load balancing device.
- Use a CloudPlatform and NetScaler release that supports AutoScale. For information about NetScaler releases that support AutoScale, see "Supported Environment."

If you have to troubleshoot an AutoScale setup, you also have to know the prerequisites for setting up AutoScale in CloudPlatform. See the "Prerequisites" section of "Configuring AutoScale" in the *Citrix CloudPlatform 3.0.5 (powered by Apache CloudStack) Administrator's Guide*, at http://support.citrix.com/article/CTX134823.

NetScaler Configuration Details

The following table describes the AutoScale configuration commands that are used by Citrix CloudPlatform to configure a NetScaler appliance.

Table 1. NetScaler Configuration for AutoScale

Troubleshooting

Before you attempt to resolve an AutoScale issue, make sure that the prerequisites have been adhered to, on both the CloudPlatform server and the NetScaler appliance, as described in "Prerequisites." If that does not resolve the issue, your problem could be one of the following.

The AutoScale configuration was successfully configured in CloudPlatform. Yet, the minimum number of VMs has not been created.

- Recommend that the CloudPlatform user deploy one VM manually in the network before configuring AutoScale. Ask the user to remove the AutoScale configuration from the NetScaler appliance or the load balancer from the network, manually deploy one VM (preferably using the template created for the AutoScale configuration), and then create the AutoScale configuration.
- Verify that the CloudPlatform user has configured the VM template in such a way that the VMs that are created from the template can accept traffic without manual intervention. If a provisioned VM cannot accept traffic automatically, the metric remains above the threshold, and the AutoScale configuration continues to provision additional VMs, as designed. To remedy the issue, disable AutoScale from CloudPlatform, fix the template, and then enable AutoScale.
- Verify that the CloudPlatform user has not exceeded the limit for the number of VMs imposed by the user's account.
- Verify that the CloudPlatform server is up and is reachable from the NetScaler appliance.
- Verify that the CloudPlatform log file, management-server.log, has reported the successful creation of the AutoScale configuration in CloudPlatform.
- Verify that the scale-up policy that is responsible for initial scale up (the policy name is prefixed with Cloud-AutoScale-Policy-Min) is receiving hits.

The AutoScale configuration is rapidly spawning a large number of VMs

- Verify that the CloudPlatform user has configured the VM template in such a way that the VMs that are created from the template can accept traffic without manual intervention. If a provisioned VM cannot accept traffic automatically, the metric remains above the threshold, and the AutoScale configuration continues to provision additional VMs, as designed. To remedy the issue, disable AutoScale from CloudPlatform, fix the template, and then enable AutoScale.
- Verify that the quiet time that the CloudPlatform user has configured in the AutoScale configuration is sufficient to ensure even traffic distribution to all the VMs, including the new VM. If the quiet time is too low, and traffic distribution has not stabilized, the metrics might remain above the threshold, and additional VMs might be spawned.

When I ran the top command on my VM, I noticed that the CPU usage on my VM had breached the threshold that was configured for the scale-up action in AutoScale. Yet, the application is not scaling up.

- Verify that the CloudPlatform user has installed an SNMP agent in the VM template, and that the SNMP agent is up and running on every VM.
- Verify that the CloudPlatform user has not exceeded the limit for the number of VMs imposed by the user's account.
- Verify that the CloudPlatform user has correctly configured the SNMP parameters to collect metrics from the VM (for example, the community string and the port).
- Verify that the scale-up or scale-down policy is receiving hits.
- Verify that the CloudPlatform server is up, and that the CloudPlatform server is reachable from the NetScaler appliance.

One or more additional VMs have been created, but they are not accepting traffic (that is, VMs have been created, but the average value of the metrics is still above the threshold)

- Verify that the user has configured the templates in such a way that the VMs created from the templates can start serving traffic without any manual intervention.
- Verify that the service is running on the VMs, on the configured member port.
- Send a ping request to the gateway (virtual router), from the VM that is not accepting traffic.

The AutoScale configuration has been deleted, but the VMs continue to exist

- The VMs might not be deleted immediately after the AutoScale configuration is deleted. Wait for about 5 minutes after you have deleted the AutoScale configuration, and then check again.
- If the destruction of VMs has not commenced after 5 minutes, you might have to delete the VMs manually.

Clustering

A NetScaler cluster is a group of nCore appliances working together as a single system image. Each appliance of the cluster is called a *node*. The cluster can include as few as 2 or as many as 32 NetScaler nCore hardware or virtual appliances as nodes.

The client traffic is distributed between the nodes to provide high availability, high throughput, and scalability.

To create a cluster, you must add the appliances as cluster nodes, set up communication between the nodes, set up links to the client and server networks, configure the appliances, and configure the distribution of client and server traffic.

NetScaler Features Supported on a Cluster

The following table provides the NetScaler features that are supported or not supported in different NetScaler versions.

Note: The entry "Node-level" in the table indicates that the feature is supported only on individual cluster nodes.

NetScaler Feature	10	10.1	10.5
Basic load balancing	Yes	Yes	Yes
Load balancing persistency	Yes	Yes	Yes
SIP	Yes	Yes	Yes
maxClient	Yes	Yes	Yes
Spillover (connection and dynamic)	Yes	Yes	Yes
Spillover based on bandwidth	Yes	Yes	Yes
SSL (advanced policies)	Yes	Yes	Yes
SSL (classic policies)	No	No	No
SSL FIPS	No	No	No
SSL Certificate Bundle	No	No	No
Content switching	Yes	Yes	Yes
Content switching actions	No	Yes	Yes
Policy-based logging for content switching policies	No	Yes	Yes
DataStream	Yes	Yes	Yes
DNS load balancing	Yes	Yes	Yes
Rate limiting	No	Yes	Yes
Action analytics	No	Yes	Yes
Branch Repeater load balancing	No	Yes	Yes
GSLB	No	No	Yes

RTSP	No	No	No
DNSSEC	No	No	No
DNS64	No	No	No
FTP	No	No	No
TFTP	No	No	No
Connection mirroring	No	No	No
Compression control	Yes	Yes	Yes
Content filtering	Yes	Yes	Yes
TCP buffering	Yes	Yes	Yes
Cache redirection	Yes	Yes	Yes
Integrated caching	Node-Level	Node-level	Node-level
Large shared cache	No	Node-level	Node-level

DSR using TOS	No	No	No
Finer Startup-RR Control	Node-level	Node-level	Node-level
XML XSM	No	No	No
DHCP RA	No	No	No
Bridge Group	No	No	Yes (supported from NetScaler 10.5 Build 52.1115.e onwards)
Network Bridge	No	No	No
Web Interface on NetScaler (WIonNS)	No	No	No
EdgeSight Monitoring	No	No	No
Metrics tables - Local	No	No	No
DNS Caching	Node-level	Node-level	Node-level
Call Home	Node-level	Node-level	Node-level
NetScaler Gateway or SSL VPN	No	No	Node-level
CloudBridge Connector	No	No	No

Hardware and Software Requirements

Appliances that you add to a NetScaler cluster must:

- Be NetScaler nCore appliances. Clustering of NetScaler Classic appliances is not supported.
- Be of the same platform type (physical appliances or virtual appliances).
- Be of the same platform model type (for physical appliances).
- Be on the same subnet.
- Have the following licenses:

Till NetScaler 10.5 Build 51.10	For NetScaler 10.5 Build 52.11 and later releases
A separate cluster license file is required. This file must be copied to the /nsconfig/license/ directory of the configuration coordinator.	No separate cluster license is required.
Because of the separate cluster license file, cluster is available with Standard, Enterprise, and Platinum licenses.	Cluster is licensed with the Enterprise and Platinum licenses. Cluster is not available for Standard license.
All cluster nodes must have the same licenses.	All cluster nodes must have the same licenses.

- Be of the same software version and build.
- Be initially configured and connected to a common client-side and server-side network.

Note: For a cluster of virtual appliances, that has large configurations, it is recommended to use 6 GB RAM for each node of the cluster.

How Clustering Works

A NetScaler cluster is formed by grouping NetScaler appliances that satisfy the requirements specified in Hardware and Software Requirements.

The cluster must be configured through a management address called the *cluster IP address*. Configurations that are performed on the cluster IP address are propagated to all the cluster nodes.

Note: The NetScaler restricts the configurations that you can perform by accessing individual cluster nodes through their NetScaler IP (NSIP) address. These configurations are not propagated across the cluster nodes. For more information, see Operations Supported on Individual Cluster Nodes.

The cluster IP address is owned by a cluster node that is referred to as the *configuration coordinator*. The following figure shows a cluster configured through a cluster IP address:

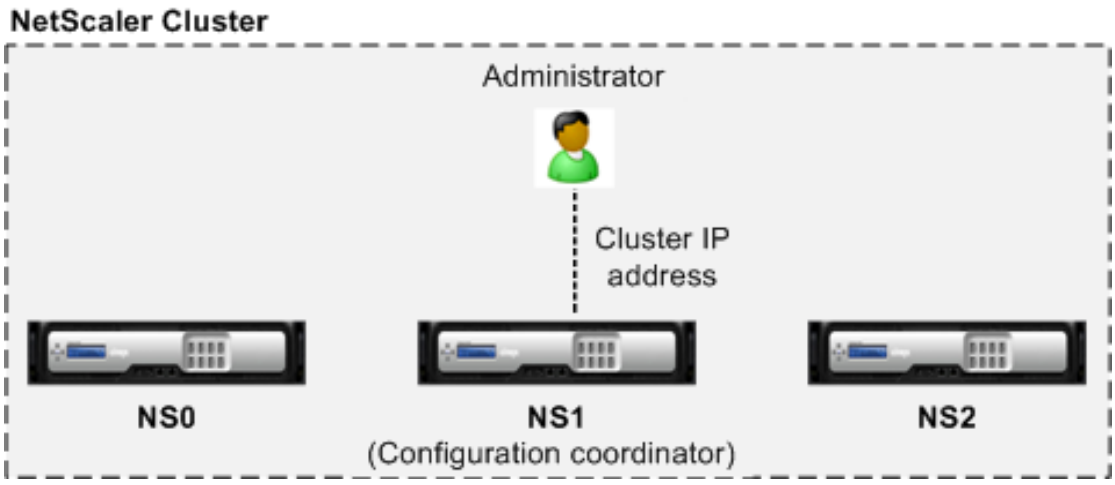

Figure 1. Configuring the NetScaler cluster

Synchronization Across Cluster Nodes

When a node is added to a cluster, the configurations and the files (SSL certificates, licenses, DNS, and so on) that are available on the configuration coordinator are synchronized to the newly added cluster node.

When an existing cluster node, that was intentionally disabled or that had failed, is once again added, the cluster compares the configurations available on the node with the configurations available on the configuration coordinator. If there is a mismatch in configurations, the node is synchronized by using one of the following:

- **Full synchronization.** If the difference between configurations exceeds 255 commands, all the configurations of the configuration coordinator are applied to the node that is rejoining the cluster. The node remains operationally unavailable for the duration of the synchronization.

- **Incremental Synchronization.** If the difference between configurations is less than or equal to 255 commands, only the configurations that are not available are applied to the node that is rejoining the cluster. The operational state of the node remains unaffected.

Command Propagation

While the above section talks about synchronizing the configurations of a configuration coordinator to a newly added (or re-added) node, the NetScaler also automatically propagates the configurations to all the existing cluster nodes as and when the configurations are performed.

Note: Because the cluster configurations are based on a quorum of the available nodes, a command is propagated to the other cluster nodes only when a majority of the nodes are in synch. If a majority of the nodes are not in synch or are in the process of synchronizing, the new commands cannot be accepted and therefore command propagation is temporarily halted.

Striped and Spotted IP Addresses

In a clustered deployment, VIP and SNIP addresses, can be striped or spotted.

- A *striped IP address* is active on all the nodes of the cluster. IP addresses configured on the cluster without specifying an owner node are active on all the cluster nodes.
- A *spotted IP address* is active on and owned exclusively by one node. IP addresses configured on the cluster by specifying an owner node are active only on the node that is specified as the owner.

The following figure shows striped and spotted IP addresses in a three-node cluster.

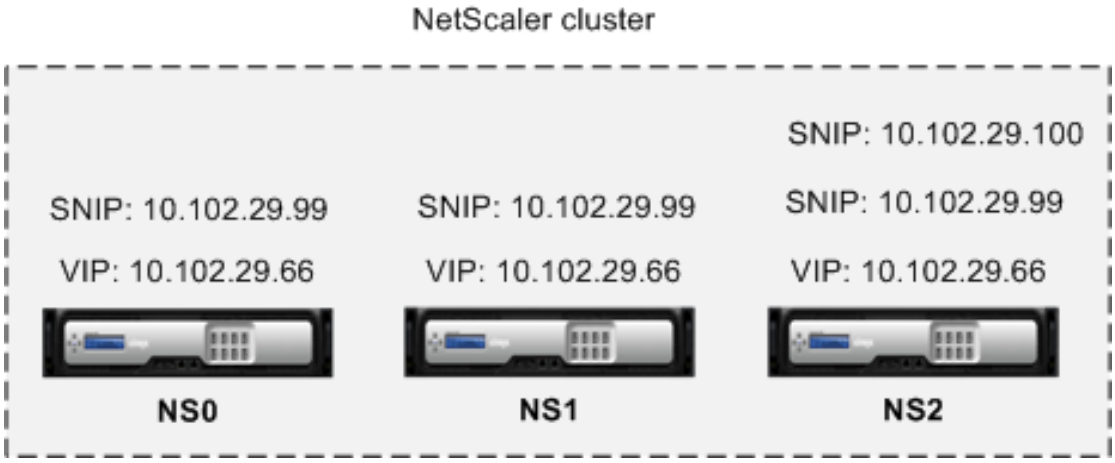

Figure 1. Three-node cluster with striped and spotted IP addresses

In the above figure, the VIP address 10.102.29.66 and SNIP address 10.102.29.99 is striped on all the cluster nodes. The SNIP address 10.102.29.100 is spotted on node NS2.

The following table shows the NetScaler-owned IP addresses that can be striped or spotted:

Table 1. Striped and Spotted IP addresses

NetScaler-owned IP addresses	Striped IP addresses	Spotted IP addresses
NSIP	No	Yes
Cluster IP address	No	No
VIP	Yes	No
SNIP	Yes	Yes (recommended)

Note:

- The cluster IP address is not a striped or spotted IP address. It is a floating IP address that is owned by the configuration coordinator, which is not a fixed node.

- Citrix recommends that you use only spotted IP addresses. You can use striped IP addresses only if there is a shortage of IP addresses. The use of striped IP addresses can result in ARP flux issues.

Communication in a Cluster Setup

The interfaces of NetScaler appliances that are added to a cluster, are prefixed with a node ID. This helps identify the cluster node to which the interface belongs. Therefore, the interface identifier c/u, where c is the controller number and u is the unit number, now becomes *n*/*c*/*u*, where n is the node ID. For example, in the following figure, interface 1/2 of node NS0 is represented as 0/1/2, interface 1/1 of node NS1 is represented as 1/1/1, and interface 1/4 of node NS2 is represented as 2/1/4.

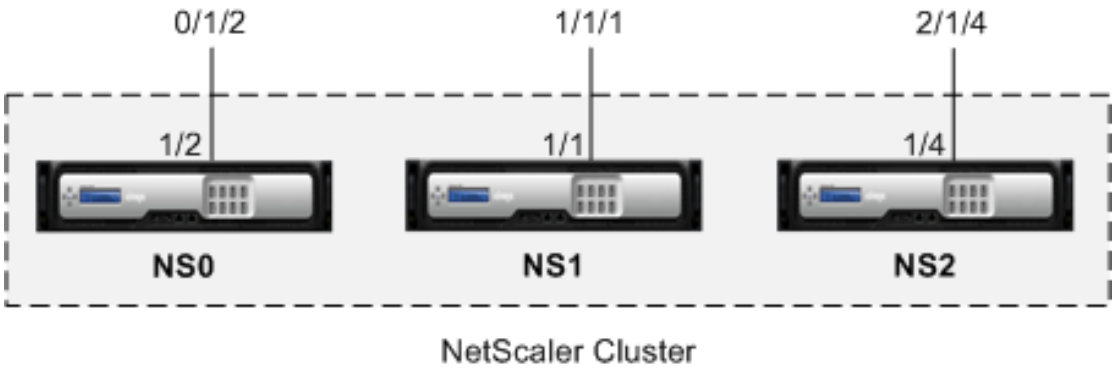

Figure 1. Interface naming convention in a cluster

Server communication

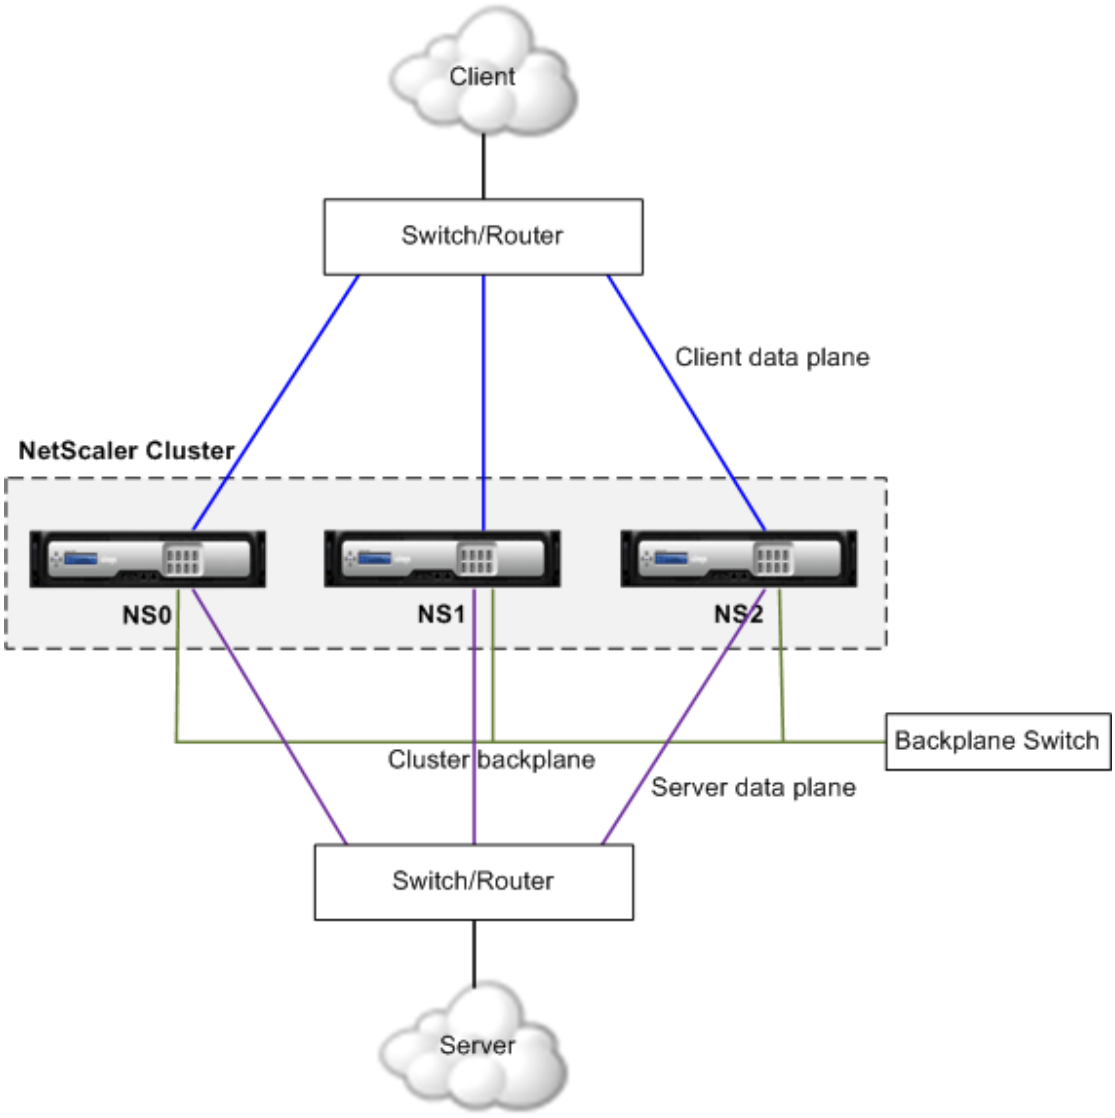
The cluster communicates with the server through the physical connections between the cluster node and the server-side connecting device. The logical grouping of these physical connections is called the *server data plane*.

Client communication

The cluster communicates with the client through the physical connections between the cluster node and the client-side connecting device. The logical grouping of these physical connections is called the *client data plane*.

Inter-node communication

The cluster nodes communicate with each other by using the *cluster backplane*. The backplane is a set of connections in which one interface of each node is connected to a common switch, which is called the *cluster backplane switch*. Each node of the cluster uses a special MAC address to communicate with other nodes through the backplane.



The following figure shows the logical grouping of the physical connections to form the client data plane, server data plane, and cluster backplane. Figure 2. Cluster communication interfaces

Traffic Distribution in a Cluster Setup

In a cluster setup, external networks view the collection of NetScaler appliances as a single entity. So, the cluster must select a single node that must receive the traffic. The cluster does this selection by using Equal Cost Multiple Path (ECMP) or cluster link aggregation traffic distribution mechanism. The selected node is called the *flow receiver*.

The flow receiver gets the traffic and then, using internal cluster logic determines the node that must process the traffic. This node is called the *flow processor*. The flow receiver steers the traffic to the flow processor over the backplane.

Note: The flow receiver and flow processor must be nodes capable of serving traffic.

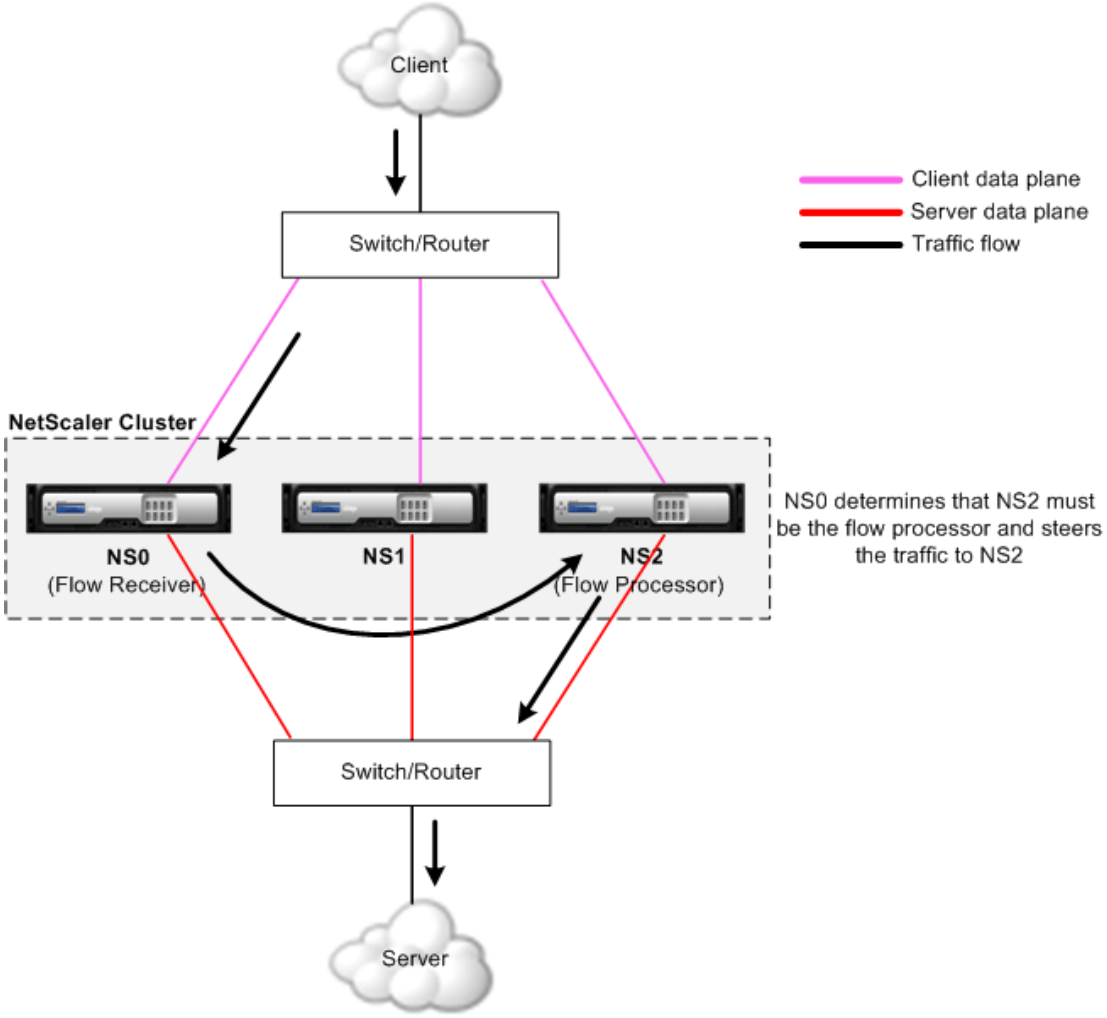


Figure 1. Traffic distribution in a cluster

The above figure shows a client request flowing through the cluster. The client sends a request to a virtual IP (VIP) address. A traffic distribution mechanism configured on the

client data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the node that must process the traffic, and steers the request to that node (unless the flow receiver selects itself as the flow processor).

The flow processor establishes a connection with the server. The server processes the request and sends the response to the subnet IP (SNIP) address that sent the request to the server.

- If the SNIP address is a striped IP address, the traffic distribution mechanism configured on the server data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the flow processor, and steers the request to the flow processor through the cluster backplane.
- If the SNIP address is a spotted IP address, the node that owns the SNIP address receives the response from the server.

In an asymmetric cluster topology (all cluster nodes are not connected to the external switch), you must use *linksets* either exclusively or combined with ECMP or cluster link aggregation. For more information, see Using Linksets.

Cluster and Node States

For a cluster to be functional, a majority of the nodes (n/2 + 1) must be online and be able to serve traffic by satisfying the following criteria:

- Admin state must be ACTIVE
- Operational state must be ACTIVE
- Health status must be UP

The following table describes the states of a cluster.

Type	Description
Admin	An admin state is configured when you add the node to the cluster. It indicates the purpose of the node, which can be in one of the following states: · **Active.** Nodes in this state serve traffic if they are operationally active and healthy. · **Passive.** Nodes in this state do not serve traffic but are in sync with the cluster. This is the default state of a cluster node. · **Spare.** Nodes in this state do not serve traffic but are in sync with the cluster. Spare nodes act as backup nodes for the cluster. If one of the nodes in the ACTIVE admin state becomes unavailable, a spare node becomes operationally active and starts serving traffic. **Note:** Whether the spare node remains operationally active depends on the preemption parameter of the add cluster instance command. If preemption is disabled, the spare node continues to serve traffic even if a node in ACTIVE admin state comes back online. If preemption is enabled, when a node in ACTIVE admin state comes back online, it preempts the spare node and starts serving traffic. The spare node goes back to inactive state.
Operational	When a node is part of a cluster, its operational state can change to ACTIVE, INACTIVE, or UNKNOWN. There are a number of reasons for a node being in INACTIVE or UNKNOWN state. Review the ns.log file or error counters to help determine the exact reason. **Note:** Passive nodes are always operationally INACTIVE. Spare nodes are ACTIVE only when they are serving traffic. Else, they are operationally INACTIVE.
Health	Depending on its health, a node can either be UP or NOT UP. To view the reasons for a node being in NOT UP state, run the show cluster node command for that node.

Routing in a Cluster

Routing in a cluster works in much the same way as routing in a standalone system. A few points to note:

- Routing runs only on spotted SNIP addresses and NSIP addresses.
- All routing configurations must be performed from the cluster IP address and the configurations are propagated to the other cluster nodes.
- Node-specific routing configurations must be performed by using the owner-node argument as follows:

```
!
interface vlan97
!
router ospf
 owner-node 0
  ospf router-id 97.131.0.1
 exit-owner-node
 owner-node 1
  ospf router-id 97.131.0.2
 exit-owner-node
 owner-node 2
  ospf router-id 97.131.0.3
 exit-owner-node
 redistribute kernel
 network 97.0.0.0/8 area 0
!
```

- Retrieve node-specific routing configurations by specifying the node(s) in the owner-node argument as follows:

```
> vtysh
ns# owner-node 0 1
ns(node-0 1)# show cluster state
ns(node-0 1)# exit-owner-node
```

- Clear node-specific routing configurations by specifying the node(s) in the owner-node argument as follows:

```
> vtysh
ns# owner-node 0 1
ns(node-0 1)# clear config
ns(node-0 1)# exit-owner-node
```

- Routing protocol daemons can run and adjacencies can be formed on active and inactive nodes of a cluster.
- Only active nodes advertise host routes to VIP addresses.

- Active and inactive nodes can learn dynamic routes and install them into the routing table.

- Routes learnt on a node are propagated to other nodes in the cluster only if route propagation is configured. This is mostly needed in asymmetric topologies where the unconnected nodes may not be able to form adjacencies.

  ns(config)# ns route-install propagate

  Note: Make sure that route propagation is not configured in a symmetric cluster topology as it can result in making the node unavailable to the cluster.

Setting up a NetScaler Cluster

To set up a cluster, begin by setting up the inter-node communication. Then, create the cluster by adding the first node to the cluster and by assigning a cluster IP address to that node. After you have created the cluster, you can add more nodes to the cluster.

Every appliance that you want to add to the cluster must:

- Be NetScaler nCore appliances. Clustering of NetScaler Classic appliances is not supported.
- Be of the same platform type (physical appliances or virtual appliances).
- Be of the same platform model type (for physical appliances).
- Be on the same subnet.
- Have the following licenses:

Till NetScaler 10.5 Build 51.10	For NetScaler 10.5 Build 52.11 and later releases
A separate cluster license file is required. This file must be copied to the /nsconfig/license/ directory of the configuration coordinator.	No separate cluster license is required.
Because of the separate cluster license file, cluster is available with Standard, Enterprise, and Platinum licenses.	Cluster is licensed with the Enterprise and Platinum licenses. Cluster is not available for Standard license.
All cluster nodes must have the same licenses.	All cluster nodes must have the same licenses.

- Be of the same software version and build.
- Be initially configured and connected to a common client-side and server-side network.

Setting up Inter-Node Communication

The nodes in a cluster communicate with each other through the cluster backplane.

To set up the cluster backplane, do the following for every node

1. Identify the network interface that you want to use for the backplane.
2. Connect an Ethernet or optical cable from the selected network interface to the cluster backplane switch.

For example, to use interface 1/2 as the backplane interface for node 4, connect a cable from the 1/2 interface of node 4 to the backplane switch.

Important points to note while setting up the cluster backplane

- Do not use the appliance's management interface (0/1) as the backplane interface.
- Interfaces used for the backplane must not be used for the client data plane or server data plane.
- You can configure a link aggregate (LA) channel to optimize the throughput of the cluster backplane.
- The backplane interfaces of all nodes of a cluster must be connected to the same switch and bound to the same L2 VLAN. The backplane interfaces, by default, have presence on all L3 VLANs configured on the cluster.
- If you have multiple clusters with the same cluster instance ID, make sure that the backplane interfaces of each cluster are bound to a different VLAN.
- It is recommended that you dedicate a separate switch only for the backplane, so that large amounts of traffic are handled seamlessly.
- The backplane interface is always monitored, regardless of the HA monitoring settings of that interface.
- In a cluster that is deployed on a XenServer and with MAC spoofing enabled, the NIC (XenServer Vswitch) can drop packets sent on the backplane. You must disable MAC spoofing on the XenServer.
- In a cluster that is deployed on a HyperV and with MAC spoofing disabled on the backplane interface, the steered packets are dropped. You must enable MAC spoofing to form a cluster on the HyperV.
- The Maximum Transmission Unit (MTU) for interfaces of the backplane switch must be greater than or equal to 1512 bytes, if features like MBF, L2 policies, ACLs, routing in CLAG deployments are configured. The MTU on the cluster backplane is automatically

updated.

Creating a NetScaler Cluster

To create a cluster, you must create a cluster instance and configure a cluster IP address on the first appliance that you add to the cluster. This node is called the configuration coordinator. As the name suggests, all cluster configurations are performed on this node, by accessing it through the cluster IP address. The role of a cluster configuration coordinator is not fixed to a specific cluster node. It can change over time. For example, if the current configuration coordinator fails, the cluster elects one of the other nodes as the new configuration coordinator, which then owns the cluster IP address.

The configurations of the appliance are cleared by implicitly executing the clear ns config `extended` command.

Note:

- The default VLAN and NSVLAN are not cleared from the appliance. Therefore, if you want the NSVLAN on the cluster, make sure it is created before the appliance is added to the cluster.
- The SNIP addresses and all VLAN configurations are cleared from the appliance.

To create a cluster by using the command line interface

1. Log on to an appliance (for example, appliance with NSIP address 10.102.29.60) that you want to add to the cluster.
2. Add a cluster instance.

   add cluster instance <clId>

   Note: Make sure that the cluster instance ID is unique within a LAN.
3. Add the appliance to the cluster.

   add cluster node <nodeId> <IPAddress> -state <state> -backplane <interface_name>

   Example

   Adding a node for a L2 cluster (all cluster nodes are in the same network).

   > add cluster node 0 10.102.29.60 -state PASSIVE -backplane 0/1/1
4. Add the cluster IP address (for example, 10.102.29.61) on this node.

   add ns ip <IPAddress> <netmask> -type `clip`

   Example

   > add ns ip 10.102.29.61 255.255.255.255 -type clip
5. Enable the cluster instance.

   enable cluster instance <clId>
6. Save the configuration.

   save ns config
7. Warm reboot the appliance.

   reboot -warm

   Verify the cluster configurations by using the show cluster instance command. Verify that the output of the command displays the NSIP address of the appliance as a node of the cluster.

To create a cluster by using the configuration utility

1. Log on to an appliance (for example, an appliance with NSIP address 10.102.29.60) that you intend to add to the cluster.
2. Navigate to System > Cluster.
3. In the details pane, click the Manage Cluster link.
4. In the Cluster Configuration dialog box, set the parameters required to create a cluster. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click Create.
6. In the Configure cluster instance dialog box, make sure that the Enable cluster instance check box is selected.
7. In the Cluster Nodes pane, select the node and click Open.
8. In the Configure Cluster Node dialog box, set the State.
9. Click OK, and then click Save.
10. Warm reboot the appliance.

Adding a Node to the Cluster

You can seamlessly scale the size of a cluster to include a maximum of 32 nodes. When an appliance is added to the cluster, the licenses on that appliance are checked against the licenses available on the configuration coordinator. If the licenses match, the appliance is added to the cluster. The existing configurations of the appliance are cleared, and the cluster configurations are synchronized with the node.

There can be an intermittent drop in traffic while the synchronization is in progress.

Note: If you use the command line interface to add a node, the new node does not become a functional part of the cluster until you join it to the cluster. After logging on to the cluster IP address and adding the node, log on to that node and join the node to the cluster. Alternatively, you can add the node from the command line and use the configuration utility to join the node to the cluster. If you use the configuration utility, you need only log on to the cluster IP address and add the node. The newly added node is automatically joined to the cluster.

Important: Before you add the node, make sure that you have set up the backplane interface for that node. Additional considerations include the following:

- If you want the NSVLAN on the cluster, make sure that the NSVLAN is created on the appliance before it is added to the cluster.
- Citrix recommends that you add the node as a passive node. Then, after joining the node to the cluster, complete the node specific configuration from the cluster IP address. Run the force cluster sync command if the cluster has only spotted IP addresses, has L3 VLAN binding, or has static routes.
- When an appliance with a preconfigured link aggregate (LA) channel is added to a cluster, the LA channel continues to exist in the cluster environment. The LA channel is renamed from LA/x to nodeId/LA/x, where LA/x is the LA channel identifier.

To add a node to the cluster by using the command line interface

1. Log on to the cluster IP address and, at the command prompt, do the following:
   a. Add the appliance (for example, 10.102.29.70) to the cluster.

      add cluster node <nodeId> <IPAddress> -state <state> -backplane <interface_name>

      Example

      > add cluster node 1 10.102.29.70 -state PASSIVE -backplane 1/1/1

   b. Save the configuration.

      save ns config
2. Log on to the newly added node (for example, 10.102.29.70) and do the following:
   a. Join the node to the cluster.

      join cluster -clip <ip_addr> -password <password>

      Example

      > join cluster -clip 10.102.29.61 -password nsroot

   b. Save the configuration.

      save ns config

   c. Warm reboot the appliance.

      reboot -warm

To add a node to the cluster by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, click Add to add the new node (for example, 10.102.29.70).
4. In the Create Cluster Node dialog box, configure the new node. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click Create. When prompted to perform a warm reboot, click Yes.

To join a previously added node to the cluster by using the configuration utility

If you have used the command line to add a node to the cluster, but have not joined the node to the cluster, you can use the following procedure.

1. Log on to the node that you want to join to the cluster (for example, 10.102.29.70).
2. Navigate to System > Cluster.
3. In the details pane, under Get Started, click the Join Cluster link.
4. In the Join to existing cluster dialog box, set the cluster IP address and the nsroot password of the configuration coordinator. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click OK.

Removing a Cluster Node

Removing a node from a cluster is a two-step process:

1. Remove the reference to the cluster instance from the node. The cluster configurations are cleared from the node by internally executing the clear ns config command with extended as the argument specifying the level of execution. The SNIP addresses and all VLAN configurations (except the default VLAN and NSVLAN) are also cleared from the appliance.

2. Remove the node from the cluster.

Note:

- When you remove a node that is the configuration coordinator, all current cluster IP address sessions are invalidated. Another cluster node is selected as the configuration coordinator, and the cluster IP address is assigned to that node. You must start a new cluster IP address session.

- To delete the cluster, you must remove each node individually. When you remove the last node, the cluster IP address(es) are deleted.

To remove a cluster node by using the command line interface

1. Log on to the node that you want to remove from the cluster and do the following:

   a. Remove the reference to the cluster instance.

      rm cluster instance <clId>

   b. Save the configuration.

      save ns config

   Note: To remove the last node of a cluster, you must only remove the cluster instance from that node. The node is automatically removed from the cluster.

2. Log on to the cluster IP address and do the following:

   a. Remove the node from which you removed the cluster instance.

      rm cluster node <nodeId>

   b. Save the configuration.

      save ns config

   Note: Make sure you do not run the rm cluster node command from the local node as this results in inconsistent configurations between the configuration coordinator and the node.

To remove a cluster node by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, select the node that you want to remove, and click Remove.

Parameter Descriptions (of commands listed in the CLI procedure)

rm cluster instance

Removing a Node from a Cluster Deployed Using Cluster Link Aggregation

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism, you must make sure that the node is made passive so that it does not receive any traffic and then, on the upstream switch, remove the corresponding interface from the channel.

For detailed information on cluster link aggregation, see Using Cluster Link Aggregation.

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism

1. Log on to the cluster IP address.
2. Set the state of the cluster node that you want to remove to PASSIVE.

   set cluster node <nodeId> -state PASSIVE
3. On the upstream switch, remove the corresponding interface from the channel by using switch-specific commands.

   Note: You do not have to manually remove the nodes interface on the cluster link aggregation channel. It is automatically removed when the node is deleted in the next step.
4. Remove the node from the cluster.

   rm cluster node <nodeId>

Parameter Descriptions (of commands listed in the CLI procedure)

set cluster node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

rm cluster node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Viewing the Details of a Cluster

You can view the details of the cluster instance and the cluster nodes by logging on to the cluster IP address.

To view details of a cluster instance by using the command line interface

Log on to the cluster IP address and, at the command prompt, type:

show cluster instance <clId>

Note: When executed from the NSIP address of a cluster node that is not the configuration coordinator, this command displays the status of the cluster on this node.

To view details of a cluster node by using the command line interface

Log on to the cluster IP address and, at the command prompt, type:

show cluster node <nodeId>

To view details of a cluster instance by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, under Get Started, click the Manage Cluster link to view the details of the cluster.

To view details of a cluster node by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, click the node for which you want to view the details.

Parameter Descriptions (of commands listed in the CLI procedure)

show cluster instance

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show cluster node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Distributing Traffic Across Cluster Nodes

After you have created the NetScaler cluster and performed the required configurations, you must deploy Equal Cost Multiple Path (ECMP) or cluster Link Aggregation (LA) on the client data plane (for client traffic) or server data plane (for server traffic). These mechanisms distribute external traffic across the cluster nodes.

Using Equal Cost Multiple Path (ECMP)

With the Equal Cost Multiple Path (ECMP) mechanism, the router has equal-cost routes to VIP addresses with the next hops as the active nodes of the cluster. The router uses a stateless hash-based mechanism to distribute traffic across the routes.

Note: Routes are limited to the maximum number of ECMP routes supported by the upstream router.

To use ECMP, you must first enable the required routing protocol (OSPF, RIP, BGP, or ISIS) on the cluster IP address. You must bind the interfaces and the spotted IP address (with dynamic routing enabled) to a VLAN. Configure the selected routing protocol and redistribute the kernel routes on the ZebOS by using the vtysh shell.

You must perform similar configurations on the cluster IP address and on the external connecting device.

Note:

- All routing configurations must be done through the cluster IP address. No configurations must be performed on individual cluster nodes.
- Make sure that the licenses on the cluster support dynamic routing, otherwise ECMP does not work.
- ECMP is not supported for wildcard virtual servers since RHI needs a VIP address to advertise to a router and wildcard virtual servers do not have associated VIP addresses.

You must have detailed knowledge of routing protocols to use ECMP. For more information, see "Configuring Dynamic Routes. For more information on routing in a cluster, see "Routing in a Cluster".

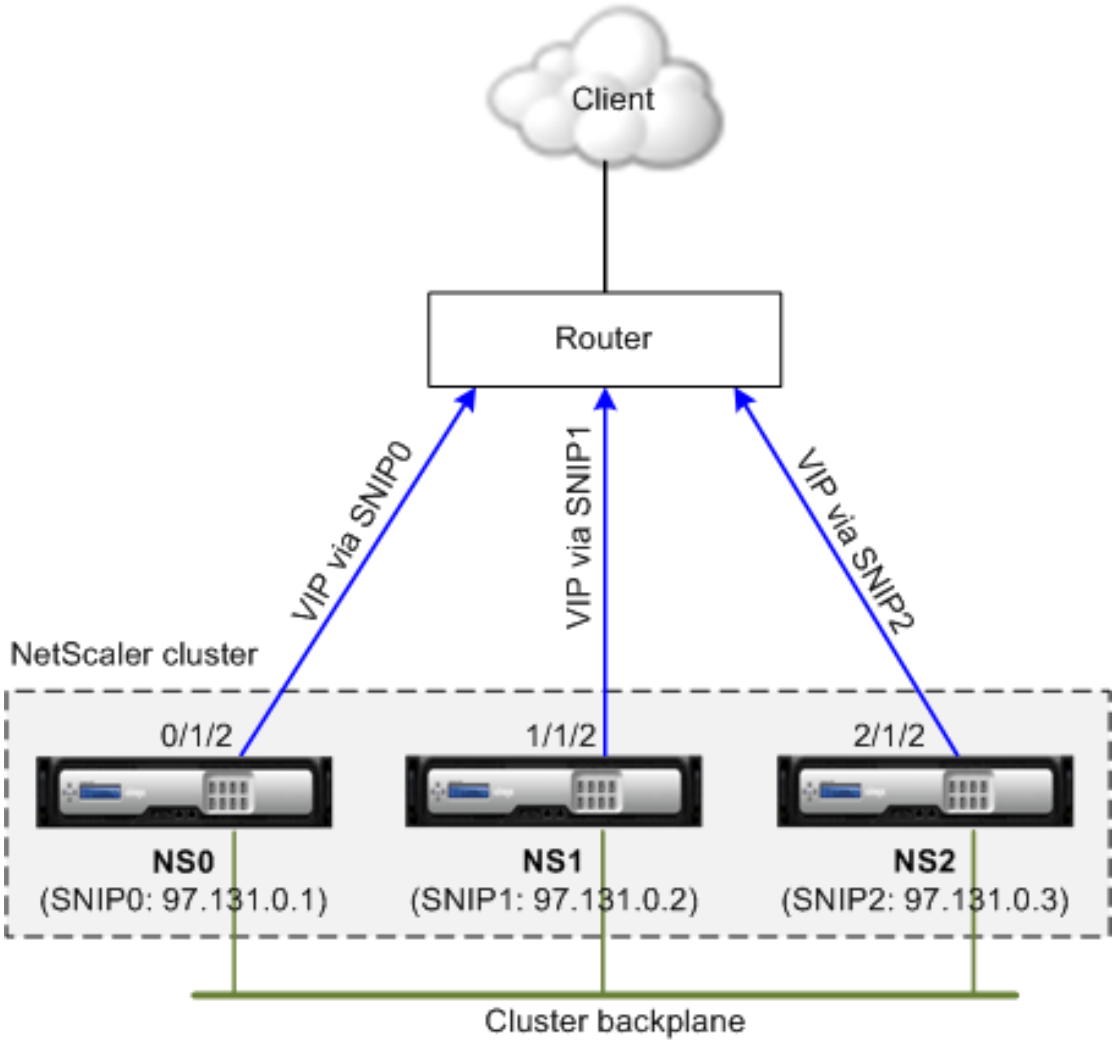

Figure 1. ECMP topology

As seen in the above figure, the ECMP router can reach the VIP address via SNIP0, SNIP1, or SNIP2.

To configure ECMP on the cluster by using the command line interface

1. Log on to the cluster IP address.
2. Enable the routing protocol.

   enable ns feature <feature>

   Example: To enable the OSPF routing protocol.

   > enable ns feature ospf

3. Add a VLAN.

   add vlan <id>

   Example

   > add vlan 97

4. Bind the interfaces of the cluster nodes to the VLAN.

   bind vlan <id> -ifnum <interface_name>

   Example

   > bind vlan 97 -ifnum 0/1/2 1/1/2 2/1/2

5. Add a spotted SNIP address for each node and enable dynamic routing on it.

   add ns ip <SNIP> <netmask> -ownerNode <positive_integer> -dynamicRouting ENABLED

   Example

   > add ns ip 97.131.0.1 255.0.0.0 -ownerNode 0 -dynamicRouting ENABLED -type SNIP
   > add ns ip 97.131.0.2 255.0.0.0 -ownerNode 1 -dynamicRouting ENABLED -type SNIP
   > add ns ip 97.131.0.3 255.0.0.0 -ownerNode 2 -dynamicRouting ENABLED -type SNIP

6. Bind one of the spotted SNIP addresses to the VLAN. When you bind one spotted SNIP address to a VLAN, all other spotted SNIP addresses defined on the cluster in that subnet are automatically bound to the VLAN.

   bind vlan <id> -IPAddress <SNIP> <netmask>

   Example

   > bind vlan 97 -ipAddress 97.131.0.1 255.0.0.0

   Note: You can use NSIP addresses of the cluster nodes instead of adding SNIP addresses. If so, you do not have to perform steps 3 - 6.

7. Configure the routing protocol on ZebOS using vtysh shell.

   Example: To configure OSPF routing protocol on node IDs 0, 1, and 2.

   ```
   > vtysh

   !
   interface vlan97
   !
   router ospf
    owner-node 0
     ospf router-id 97.131.0.1
    exit-owner-node
    owner-node 1
     ospf router-id 97.131.0.2
    exit-owner-node
    owner-node 2
     ospf router-id 97.131.0.3
    exit-owner-node
    redistribute kernel
    network 97.0.0.0/8 area 0
   !
   ```

   Note: For VIP addresses to be advertised, RHI setting must done by using the vserverRHILevel parameter as follows:

   add ns ip <IPAddress> <netmask> -type VIP -vserverRHILevel <vserverRHILevel>

   For OSPF specific RHI settings, there are additional settings that can be done as follows:

   add ns ip <IPAddress> <netmask> -type VIP -ospfLSAType (TYPE1 | TYPE5) -ospfArea <positive_integer>

   Use the add ns ip6 command to perform the above commands on IPv6 addresses.

8. Configure ECMP on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

   ```
   //For OSPF (IPv4 addresses)
   Global config:
   Configure terminal
   feature ospf

   Interface config:
   Configure terminal
   interface Vlan10
      no shutdown
      ip address 97.131.0.5/8

   Configure terminal
   router ospf 1
   network 97.0.0.0/8 area 0.0.0.0
   --------------------------------
   ```

```
//For OSPFv3 (IPv6 addresses)
Global config:
Configure terminal
feature ospfv3

Configure terminal
interface Vlan10
   no shutdown
   ipv6 address use-link-local-only
   ipv6 router ospfv3 1 area 0.0.0.0

Configure terminal
router ospfv3 1
```

Using Cluster Link Aggregation

Cluster link aggregation, as the name suggests, is a group of interfaces of cluster nodes. It is an extension of NetScaler link aggregation. The only difference is that, while link aggregation requires the interfaces to be from the same device, in cluster link aggregation, the interfaces are from different nodes of the cluster.

For more information about link aggregation, see "Configuring Link Aggregation".

Cluster link aggregation can be either static or dynamic.

For example, consider a three-node cluster where all three nodes are connected to the upstream switch. A cluster LA channel (CLA/1) is formed by binding interfaces 0/1/2, 1/1/2, and 2/1/2.

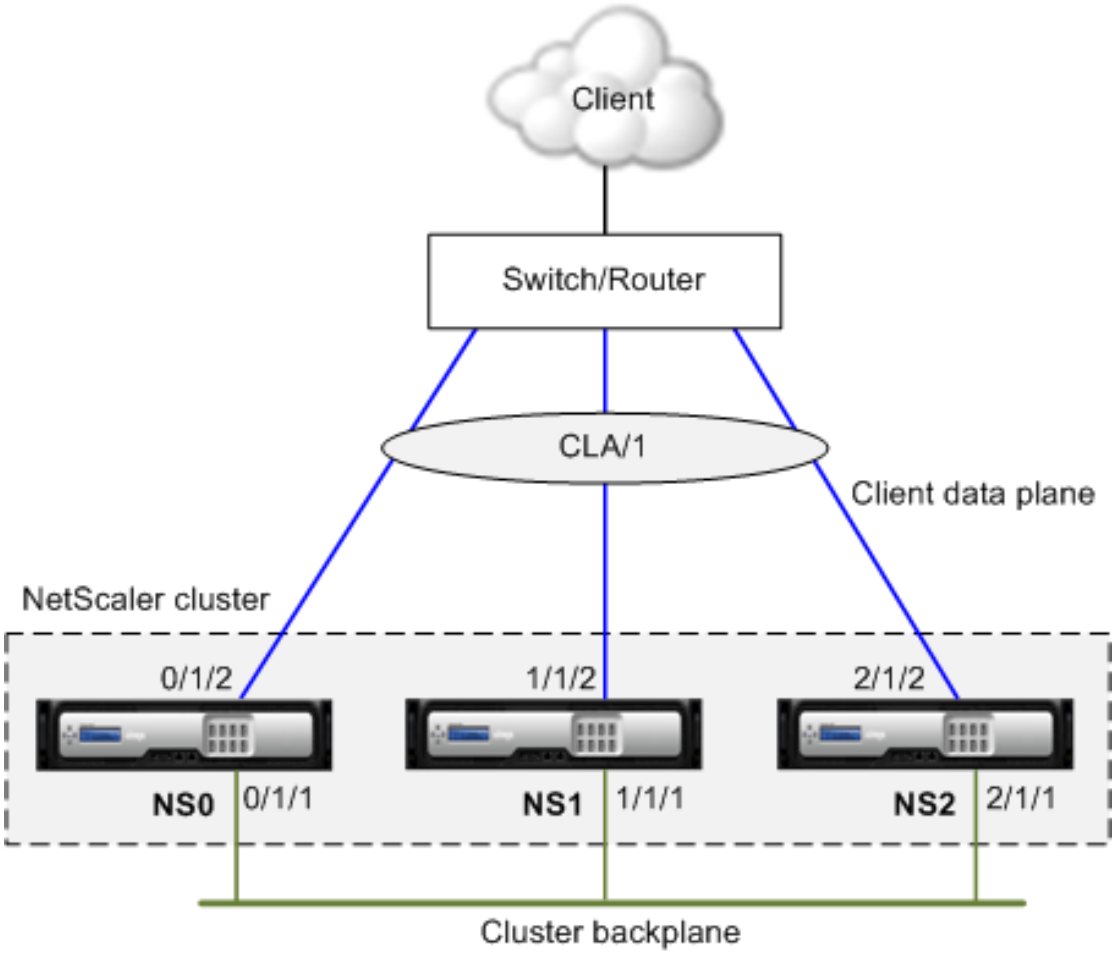

Figure 1. Cluster Link Aggregation topology

A cluster LA channel has the following attributes:

- Each channel has a unique MAC agreed upon by cluster nodes.

- The channel can bind both local and remote nodes' interfaces.
- A maximum of four cluster LA channels are supported in a cluster.
- Backplane interfaces cannot be part of a cluster LA channel.
- When an interface is bound to a cluster LA channel, the channel parameters have precedence over the network interface parameters. A network interface can be bound to one channel only.

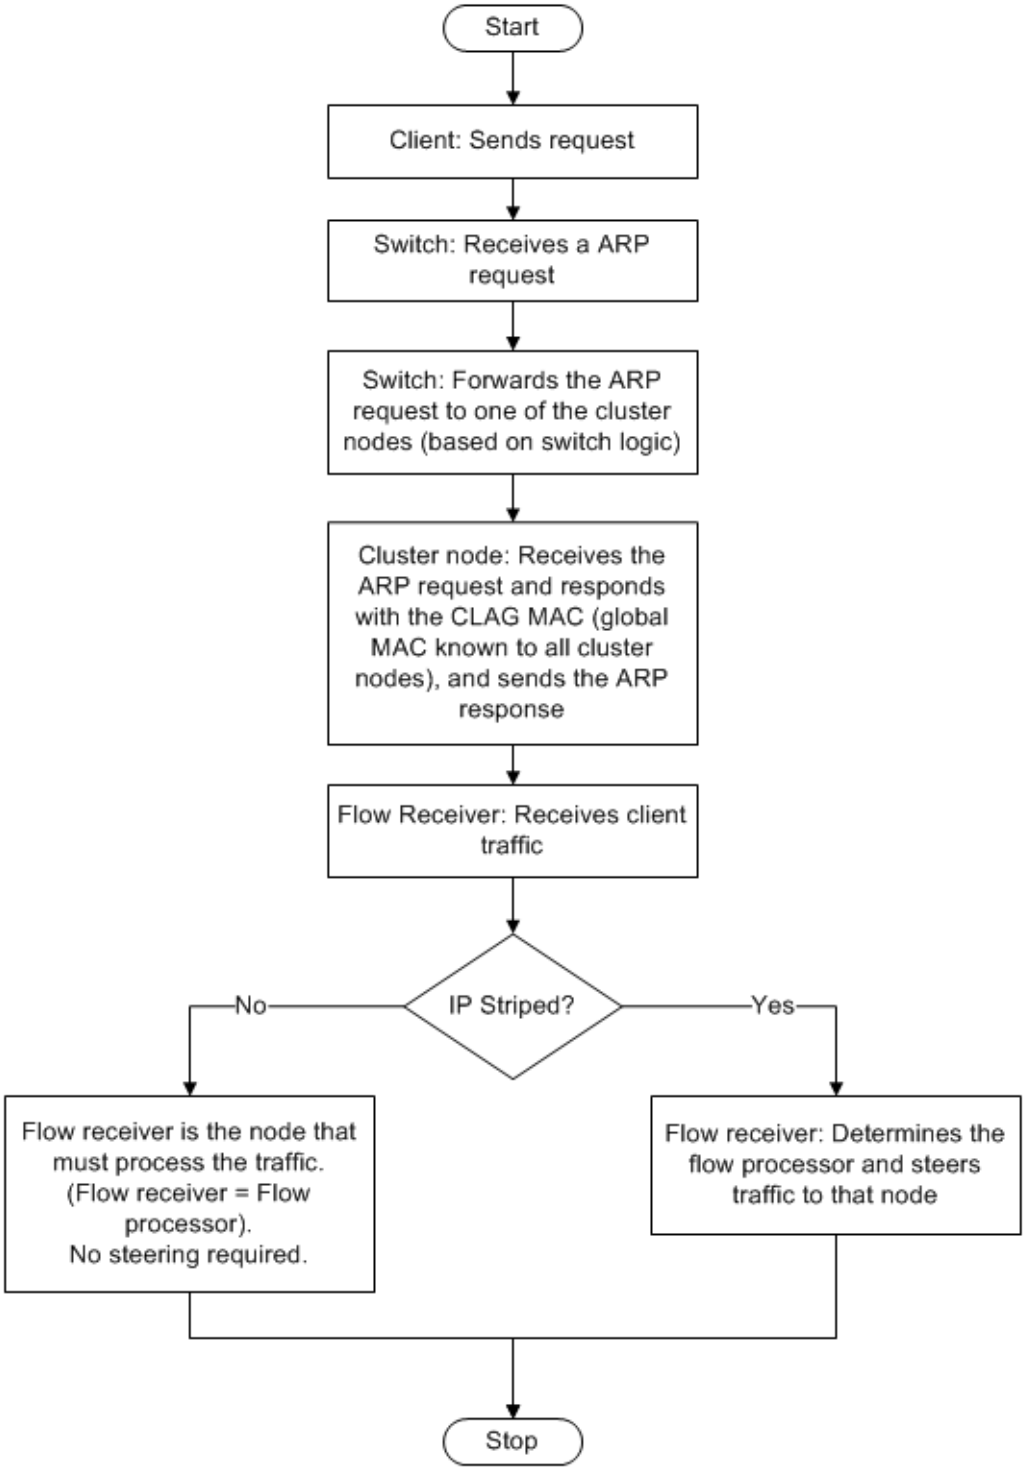

Figure 2. Traffic distribution flow using cluster LA

Static Cluster Link Aggregation

You must configure a static cluster LA channel on the cluster IP address and on the external connecting device. If possible, configure the upstream switch to distribute traffic based on IP address or port instead of MAC address.

For more information about configuring a static LA channel, see "Configuring Link Aggregation Manually".

To configure a static cluster LA channel by using the command line interface

1. Log on to the cluster IP address.

   Note: Make sure that you configure the cluster LA channel on the cluster IP address before configuring link aggregation on the external switch. Otherwise, the switch will forward traffic to the cluster even though the cluster LA channel is not configured. This can lead to loss of traffic.

2. Create a cluster LA channel.

   add channel <id> -speed <speed>

   Example

   > add channel CLA/1 -speed 1000

   Note: You must not specify the speed as AUTO. Rather, you must explicitly specify the speed as 10, 100, 1000, or 10000. Only interfaces that have the speed matching the <speed> attribute in the cluster LA channel are added to the active distribution list.

3. Bind the required interfaces to the cluster LA channel. Make sure that the interfaces are not used for the cluster backplane.

   bind channel <id> <ifnum>

   Example

   > bind channel CLA/1 0/1/2 1/1/2 2/1/2

4. Verify the configurations.

   show channel <id>

   Example

   > show channel CLA/1

   Note: You can bind the cluster LA channel to a VLAN by using the bind vlan command. The interfaces of the channel are automatically bound to the VLAN.

5. Configure static LA on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1). Similar configurations must be performed on other switches.

   Global config:
   Configure terminal

   Interface level config:

   interface Ethernet2/47

```
    switchport
    switchport access vlan 10
    channel-group 7 mode on
    no shutdown

interface Ethernet2/48
    switchport
    switchport access vlan 10
    channel-group 7 mode on
    no shutdown
```

Parameter Descriptions (of commands listed in the CLI procedure)

add channel

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind channel

show channel

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Dynamic Cluster Link Aggregation

Dynamic cluster LA channel uses Link Aggregation Control Protocol (LACP). For more information about configuring a dynamic LA channel, see "Configuring Link Aggregation by Using the Link Aggregation Control Protocol".

You must perform similar configurations on the cluster IP address and on the external connecting device. If possible, configure the upstream switch to distribute traffic based on IP address or port instead of MAC address.

Points to remember:

- Enable LACP (by specifying the LACP mode as either ACTIVE or PASSIVE).

  Note: Make sure the LACP mode is not set as PASSIVE on both the NetScaler cluster and the external connecting device.

- Specify the same LACP key on each interface that you want to be the part of the channel. For creating a cluster LA channel, the LACP key can have a value from 5 through 8. For example, if you set the LACP key on interfaces 0/1/2, 1/1/2, and 2/1/2 to 5, CLA/1 is created. The interfaces 0/1/2, 1/1/2, and 2/1/2 are automatically bound to CLA/1. Similarly, if you set the LACP key to 6, CLA/2 channel is created.

- Specify the LAG type as Cluster.

To configure a dynamic cluster LA channel by using the command line interface

On the cluster IP address, for each interface that you want to add to the cluster LA channel, type:

```
set interface <id> -lacpMode <lacpMode> -lacpKey <positive_integer> -lagType CLUSTER
```

Example: To configure a cluster LA channel for 3 interfaces.

```
> set interface 0/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
> set interface 1/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
> set interface 2/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
```

Note: Optionally, you can enable link redundancy support on the dynamic LA interface or channel as follows:

- set interface CLA/1 -lr ON

- set channel CLA/2 -lr ON

Similarly, configure dynamic LA on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1). Similar configurations must be performed on other switches.

Global config:
Configure terminal
feature lacp
Interface level config:

```
interface Ethernet2/47
   switchport
   switchport access vlan 10
   channel-group 7 mode active
   no shutdown

interface Ethernet2/48
   switchport
   switchport access vlan 10
   channel-group 7 mode active
   no shutdown
```

Parameter Descriptions (of commands listed in the CLI procedure)

set interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

set channel

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Using Linksets

Linksets must be used when some cluster nodes are not physically connected to the external network. In such a cluster topology, the unconnected cluster nodes use the interfaces specified in the linkset to communicate with the external network through the cluster backplane. Linksets are typically used in scenarios when the connecting devices have insufficient ports to connect the cluster nodes.

Additionally, linksets must be used in the following scenarios:

- For topologies that require MAC-based Forwarding (MBF).
- To improve manageability of ACL and L2 policies involving interfaces. You must define a linkset of the interfaces and add ACL and L2 policies based on linksets.

Linksets must be configured only through the cluster IP address.

For example, consider a three node cluster where the upstream switch has only two ports available. Using linksets, you can connect two nodes to the switch and leave the third node unconnected. In the following figure, a linkset (LS/1) is formed by binding the interfaces 0/1/2 and 1/1/2. NS2 is the unconnected node of the cluster.

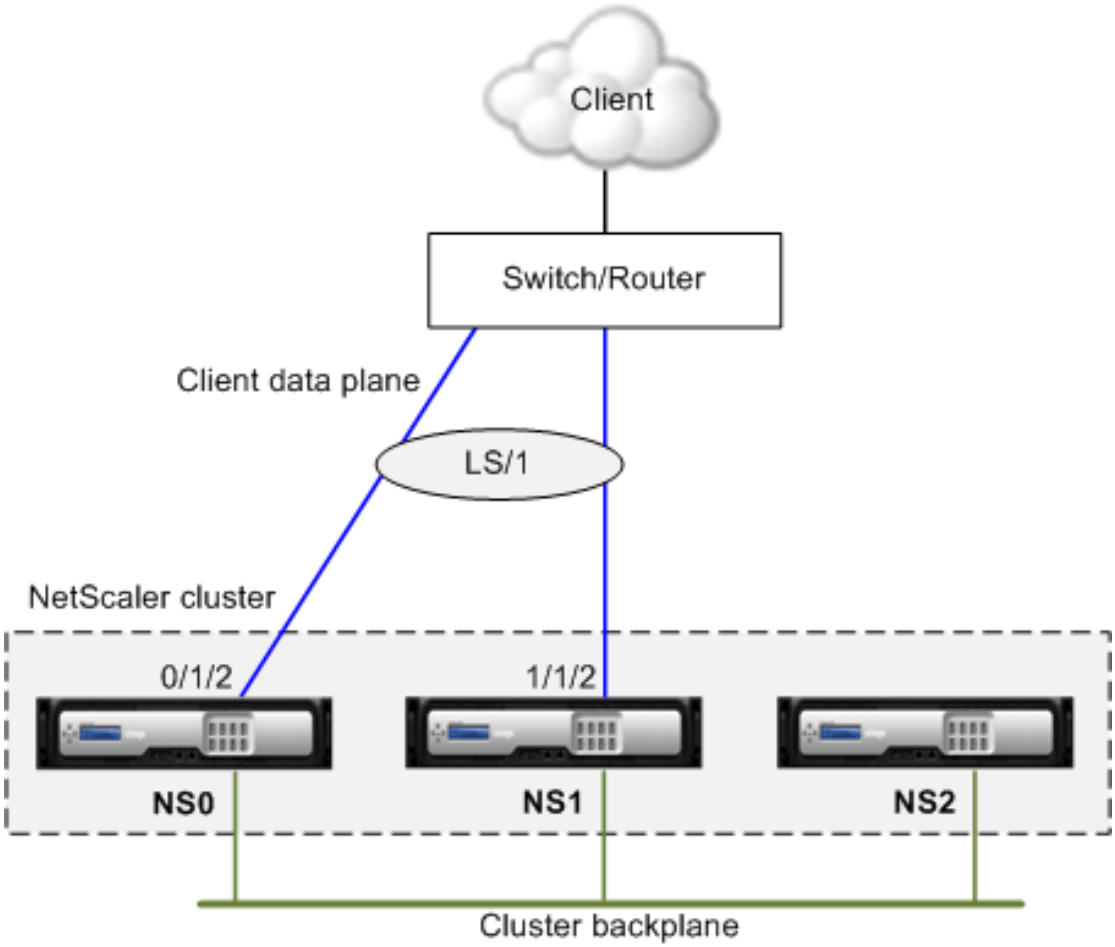

Figure 1. Linksets topology

The linkset informs NS2 that it can use interfaces 0/1/2 and 1/1/2 to communicate with the network devices. All traffic to and from NS2 is now routed through interfaces 0/1/2 or 1/1/2.

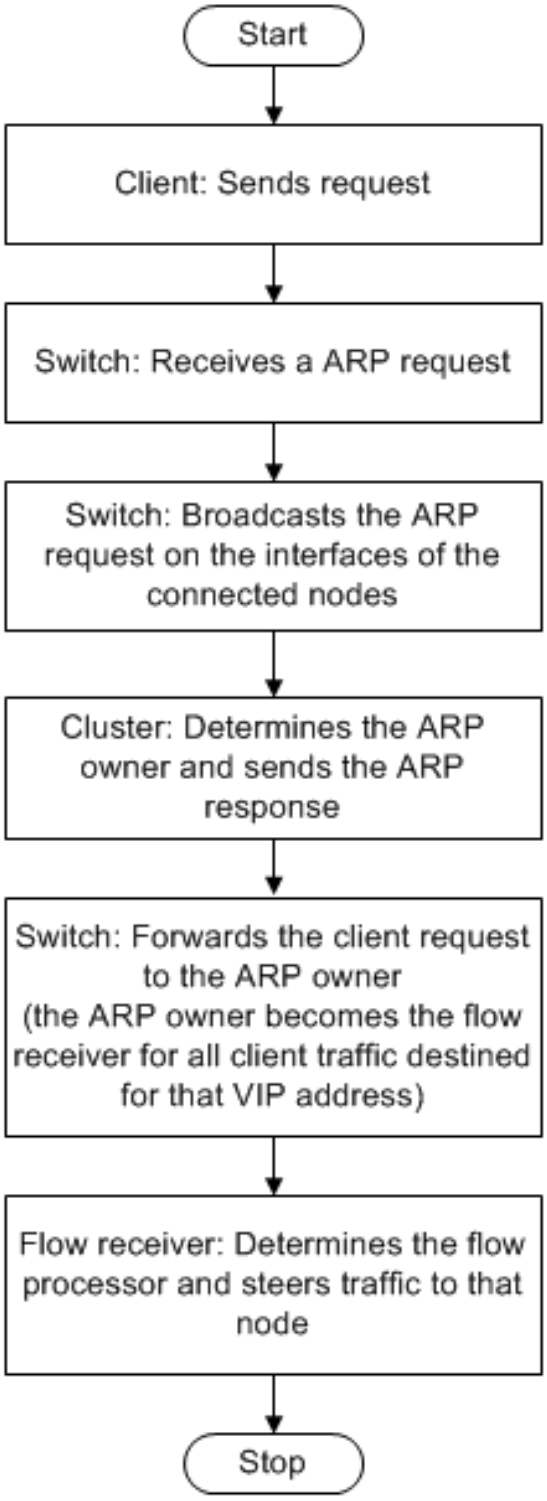

Figure 2. Traffic distribution flow using linksets

To configure a linkset by using the command line interface

1. Log on to the cluster IP address.
2. Create a linkset.

   add linkset <id>

   Example

   > add linkset LS/1

3. Bind the required interfaces to the linkset. Make sure the interfaces are not used for the cluster backplane.

   bind linkset <id> -ifnum <interface_name> ...

   Example

   > bind linkset LS/1 -ifnum 0/1/2 1/1/2

4. Verify the linkset configurations.

   show linkset <id>

   Example

   > show linkset LS/1

   Note: You can bind the linkset to a VLAN by using the bind vlan command. The interfaces of the linkset are automatically bound to the VLAN.

To configure a linkset by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to Network > Linkset.
3. In the details pane, click Add.
4. In the Create Linkset dialog box:
   a. Specify the name of the linkset by setting the Linkset parameter.
   b. Specify the Interfaces to be added to the linkset and click Add. Repeat this step for each interface you want to add to the linkset.
5. Click Create, and then click Close.

Parameter Descriptions (of commands listed in the CLI procedure)

add linkset

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind linkset

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show linkset

Managing the NetScaler Cluster

After you have created a cluster and configured the required traffic distribution mechanism, the cluster is able to serve traffic. During the lifetime of the cluster, you can perform cluster tasks such as configuring nodegroups, disabling nodes of a cluster, discovering NetScaler appliances, viewing statistics, synchronizing cluster configurations, cluster files, and the time across the nodes, and upgrading or downgrading the software of cluster nodes.

Configuring Nodegroups for Datacenter Redundancy

As described in Cluster Nodegroups, a nodegroup can be used for two purposes. Here, we describe the procedure to create a nodegroup that can be used for providing datacenter redundancy. To understand the configurations for defining such a nodegroup, let us use an example of a 12 node cluster, where you define 3 nodegroups each of 3 nodes.

In this setup, one nodegroup must be defined as active and the others will be defined as spare nodegroups.

Configuring a nodegroup for datacenter redundancy by using the command line interface

1. Log on to the cluster IP address.
2. Create the active nodegroup and bind the required cluster nodes.

   To create the active nodegroup

   add cluster nodegroup ng1 -state ACTIVE

   To bind the three cluster nodes to the nodegroup

   bind cluster nodegroup ng1 -node n1

   bind cluster nodegroup ng1 -node n2

   bind cluster nodegroup ng1 -node n3
3. Create the spare nodegroup and bind the requisite nodes.

   To create the active nodegroup

   add cluster nodegroup ng2 -state SPARE -priority <integer>

   To bind the three cluster nodes to the nodegroup

   bind cluster nodegroup ng2 -node n4

   bind cluster nodegroup ng2 -node n5

   bind cluster nodegroup ng2 -node n6
4. Create another spare nodegroup and bind the requisite nodes.

   To create the active nodegroup

   add cluster nodegroup ng3 -state SPARE -priority <integer>

To bind the three cluster nodes to the nodegroup

bind cluster nodegroup ng3 -node n7

bind cluster nodegroup ng3 -node n8

bind cluster nodegroup ng3 -node n9

Disabling a Cluster Node

You can temporarily remove a node from a cluster by disabling the cluster instance on that node. A disabled node is not synchronized with the cluster configurations and is unable to serve traffic. When the node is enabled again, it is automatically synchronized with the cluster configurations. For more information, see Cluster Synchronization.

Note: If the configurations of a non-configuration coordinator node are modified (through the NSIP address of the node) after it is disabled, the configurations are not automatically synchronized on that node. You must manually synchronize the configurations as described in Synchronizing Cluster Configurations.

To disable a cluster node by using the command line interface

At the command prompt of the node that you want to disable, type:

disable cluster instance <clId>

Note: To disable the cluster, run the disable cluster instance command on the cluster IP address.

To disable a cluster node by using the configuration utility

1. Log on to the node that you want to disable.
2. Navigate to System > Cluster.
3. In the details pane, under Get Started, click Manage Cluster.
4. In the Configure cluster instance dialog box, unselect the Enable cluster instance check box.
5. Click OK.

   Note: To disable the cluster instance on all the nodes, perform the above procedure on the cluster IP address.

Parameter Descriptions (of commands listed in the CLI procedure)

disable cluster instance

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Discovering NetScaler Appliances

You can discover NetScaler appliances present in the same subnet as the NSIP address of the configuration coordinator. The discovered appliances can then be added to the cluster.

Note: This operation is available only through the configuration utility.

To discover appliances by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, at the bottom of the page, click Discover NetScalers.
4. In the Discover NetScalers dialog box, set the following parameters:
   - IP address range - Specify the range of IP addresses within which you want to discover appliances. For example, you can search for all NSIP addresses between 10.102.29.4 to 10.102.29.15 by specifying this option as 10.102.29.4 - 15.
   - Backplane interface - Specify the interfaces to be used as the backplane interface. This is an optional parameter. If you do not specify this parameter, you must update it after the node is added to the cluster.
5. Click OK.
6. Select the appliances that you want to add to the cluster.
7. Click OK.

Viewing the Statistics of a Cluster

You can view the statistics of a cluster instance and cluster nodes to evaluate the performance or to troubleshoot the operation of the cluster.

To view the statistics of a cluster instance by using the command line interface

At the command prompt of the cluster IP address, type:

stat cluster instance <clId>

To view the statistics of a cluster node by using the command line interface

At the command prompt of the cluster IP address, type:

stat cluster node <nodeid>

Note: When executed from the cluster IP address, this command displays the cluster level statistics. However, when executed from the NSIP address of a cluster node, the command displays node level statistics.

To view the statistics of a cluster instance by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, in the center of the page, click Statistics.

To view the statistics of a cluster node by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, select a node and click Statistics to view the statistics of the node. To view the statistics of all the nodes, click Statistics without selecting a specific node.

Parameter Descriptions (of commands listed in the CLI procedure)

stat cluster instance

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

stat cluster node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Synchronizing Cluster Configurations

NetScaler configurations that are available on the configuration coordinator are synchronized to the other nodes of the cluster when:

- A node joins the cluster
- A node rejoins the cluster
- A new command is executed through the cluster IP address.

Additionally, you can forcefully synchronize the configurations that are available on the configuration coordinator (full synchronization) to a specific cluster node. Make sure you synchronize one cluster node at a time, otherwise the cluster can get affected.

To synchronize cluster configurations by using the command line interface

At the command prompt of the appliance on which you want to synchronize the configurations, type:

force cluster sync

To synchronize cluster configurations by using the configuration utility

1. Log on to the appliance on which you want to synchronize the configurations.
2. Navigate to System > Cluster.
3. In the details pane, under Utilities, click Force cluster sync.
4. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

force cluster sync

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Synchronizing Cluster Files

The files available on the configuration coordinator are called cluster files. These files are automatically synchronized on the other cluster nodes when the node is added to the cluster and periodically, during the lifetime of the cluster. Additionally, you can manually synchronize the cluster files.

The directories and files from the configuration coordinator that are synchronized are:

- /nsconfig/ssl/
- /var/netscaler/ssl/
- /var/vpn/bookmark/
- /nsconfig/dns/
- /nsconfig/htmlinjection/
- /netscaler/htmlinjection/ens/
- /nsconfig/monitors/
- /nsconfig/nstemplates/
- /nsconfig/ssh/
- /nsconfig/rc.netscaler
- /nsconfig/resolv.conf
- /nsconfig/inetd.conf
- /nsconfig/syslog.conf
- /nsconfig/snmpd.conf
- /nsconfig/ntp.conf
- /nsconfig/httpd.conf
- /nsconfig/sshd_config
- /nsconfig/hosts
- /nsconfig/enckey
- /var/nslw.bin/etc/krb5.conf
- /var/nslw.bin/etc/krb5.keytab

- /var/lib/likewise/db/
- /var/download/
- /var/wi/tomcat/webapps/
- /var/wi/tomcat/conf/Catalina/localhost/
- /var/wi/java_home/lib/security/cacerts
- /var/wi/java_home/jre/lib/security/cacerts
- /nsconfig/license/
- /nsconfig/rc.conf

To synchronize cluster files by using the command line interface

At the command prompt of the cluster IP address, type:

sync cluster files <mode>

To synchronize cluster files by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, under Utilities, click Synchronize cluster files.
4. In the Synchronize cluster files dialog box, select the files to be synchronized in the Mode drop-down box.
5. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

sync cluster files

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Synchronizing Time on Cluster Nodes

The cluster uses Precision Time Protocol (PTP) to synchronize the time across cluster nodes. PTP uses multicast packets to synchronize the time. If there are some issues in time synchronization, you must disable PTP and configure Network Time Protocol (NTP) on the cluster.

To enable/disable PTP by using the command line interface

At the command prompt of the cluster IP address, type:

set ptp -state disable

To enable/disable PTP by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, under Utilities, click Configure PTP Settings.
4. In the Enable/Disable PTP dialog box, select whether you want to enable or disable PTP.
5. Click OK.

Parameter Descriptions (of commands listed in the CLI procedure)

set ptp

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Upgrading or Downgrading the Cluster Software

All cluster nodes must be running the same software version. To upgrade or downgrade the software of a cluster, you must upgrade or downgrade the software on each node, one node at a time.

When the software on a node is upgraded or downgraded, the node is not removed from the cluster. The node continues to be a part of the cluster and serves client traffic uninterrupted, except for the down-time when the node reboots after it is upgraded or downgraded. However, due to software version mismatch among the cluster nodes, configuration propagation is disabled and is enabled only after all the cluster nodes are of the same version.

Since configuration propagation is disabled during upgrading on downgrading a cluster, you cannot perform any configurations through the cluster IP address during this time. However, you can perform node-level configurations through the NSIP address of individual nodes, but you must make sure that you perform the same configurations on all the nodes to maintain them in synch.

Note:

- You cannot add cluster nodes while upgrading or downgrading the cluster software version.
- You cannot execute the start nstrace command from the cluster IP address when the cluster is being upgraded. However, you can get the trace of individual nodes by performing this operation on individual cluster nodes through their NetScaler IP (NSIP) address.
- Configurations can be lost during the downgrade of the cluster.

To upgrade or downgrade the software of the cluster nodes

1. Make sure the cluster is stable and the configurations are synchronized on all the nodes.
2. Upgrade or downgrade the software of the cluster.
    a. Upgrade or downgrade the software of a cluster node. For detailed information about upgrading and downgrading the software of an appliance, see "Upgrading or Downgrading the System Software".
    b. Save the configurations.
    c. Reboot the appliance.
    d. Repeat the above two steps for each of the other cluster nodes.

        Note:

        - Citrix recommends that you wait for the previous node to become active before upgrading or downgrading the next node.
        - If you have configured a cluster before NetScaler 10.5 Build 52.11, the cluster will work with the separate cluster license file. No changes are required.
        - When you configure a new cluster in Build 52.11 and then downgrade, the cluster will not work as it now expects the separate cluster license file.

Use Cases

Some scenarios in which a cluster can be deployed:

- Creating a Two-Node Cluster
- Migrating an HA Setup to a Cluster Setup
- Migrating an HA Setup to a Cluster Setup without Downtime
- Setting Up GSLB in a Cluster
- Using Cache Redirection in a Cluster
- Using Cluster LA Channel with Linksets
- Backplane on LA Channel
- Common Interface for Client and Server and Dedicated Interfaces for Backplane
- Common Switch for Client, Server, and Backplane
- Common Switch for Client and Server and Dedicated Switch for Backplane
- Different Switch for Every Node
- Sample Cluster Configurations

Creating a Two-Node Cluster

A two-node cluster is an exception to the rule that a cluster is functional only when a minimum of (n/2 +1) nodes, where n is the number of cluster nodes, are able to serve traffic. If that formula were applied to a two-node cluster, the cluster would fail if one node went down (n/2 +1=2).

A two-node cluster is functional even if only one node is able to serve traffic.

Creating a two node cluster is the same as creating any other cluster. You must add one node as the configuration coordinator and the other node as the other cluster node.

Note: Incremental configuration synchronization is not supported in a two-node cluster. Only full synchronization is supported.

Migrating an HA Setup to a Cluster Setup

An existing high availability (HA) setup can be migrated to a cluster setup by first removing the appliances from the HA setup and then creating the NetScaler cluster. This approach will result in a downtime for the application.

Consider an HA setup with appliances NS0 (10.102.97.131) and NS1 (10.102.97.132). NS0 is the primary and NS1 is the secondary appliance of the HA setup.

To convert a HA setup to cluster setup by using the NetScaler command line

1. Log on to each HA node and remove it from the HA setup.

   rm HA node <id>

   Example

   rm HA node 1

2. Go to the shell on one of the HA nodes and copy the ns.conf file to another .conf file (for example, ns_backup.conf).

3. On both the nodes, identify the network interfaces to be used for the cluster backplane. Make sure to configure the backplane switch appropriately.

4. Create the cluster on one of the appliances (for example, 10.102.97.131).

   ```
   //On the NSIP address of the first appliance
   add cluster instance 1
   add cluster node 0 10.102.97.131 -state ACTIVE -backplane 0/1/1
   add ns ip 10.102.97.133 255.255.255.255 -type CLIP
   enable cluster instance 1
   save ns config
   reboot -warm
   ```

5. Add the other appliance to the cluster.

   ```
   //On the cluster IP address
   add cluster node 1 10.102.97.132 -state ACTIVE -backplane 1/1/1

   //On the NSIP address of the appliance
   join cluster -clip 10.102.97.133 -password nsroot
   save ns config
   reboot -warm
   ```

6. After the two nodes are up and active, log on to the cluster IP address and modify the backed-up configuration file as follows:

   a. Remove the features that are not supported on a cluster. For the list of unsupported features, see NetScaler Features Supported by a Cluster. This is an optional step. If you do not perform this step, the execution of unsupported commands will fail.

   b. Remove the configurations that have interfaces, or update the interface names from the c/u convention to the n/c/u convention.

      Example

      add vlan 10 -ifnum 0/1

      should be changed to

add vlan 10 -ifnum 0/0/1 1/0/1

c. The backup configuration file can have SNIP addresses or MIP addresses. These addresses are striped on all the cluster nodes. It is recommended that you add spotted IP addresses for each node.

Example

```
add ns ip 1.1.1.1 255.255.255.0 -ownerNode 0
add ns ip 1.1.1.2 255.255.255.0 -ownerNode 1
```

d. Update the hostname to specify the owner node.

Example

```
set ns hostname ns0 -ownerNode 0
set ns hostname ns1 -ownerNode 1
```

e. Change all other relevant networking configuration that depend on spotted IPs. For example, L3 VLAN, RNAT configuration which uses SNIPs as NATIP, INAT rules that refers to SNIPs/MIPs).

7. Apply configurations from the backup configuration file to the configuration coordinator through the cluster IP address.

   batch -fileName <input_filename>

   Example

   batch -f ns_backup.conf

8. Configure appropriate client traffic distribution mechanism (ECMP, cluster LA or linksets).

9. Save the configuration.

   save ns config

The appliances of the HA setup are migrated to a cluster setup.

Parameter Descriptions (of commands listed in the CLI procedure)

rm HA node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

batch

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

save ns config

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Migrating an HA Setup to a Cluster Setup without Downtime

An existing high availability (HA) setup can be migrated to a cluster setup by first removing the secondary appliance from the HA setup and using that appliance to create a single-node cluster. Then, after the cluster becomes operational and serves traffic, the primary appliance of the HA setup is added to the cluster. This approach will not result in a downtime for the application.

Consider an HA setup with appliances NS0 (10.102.97.131) and NS1 (10.102.97.132). NS0 is the primary and NS1 is the secondary appliance of the HA setup.

To convert a HA setup to cluster setup (without downtime) by using the NetScaler command line

1. Go to the shell on one of the HA nodes and copy the ns.conf file to another .conf file (for example, ns_backup.conf).

   Note: Make sure HA pair is stable with respect to configurations.

2. Log on to the secondary appliance NS1 and clear all the configurations. This removes the secondary appliance from the HA setup and makes it a standalone appliance.

   clear ns config full

   Note:

   - The configurations are cleared to make sure that NS1 does not start owning the VIPs once it becomes a standalone appliance.

   - At this stage, NS0 is still active and continues to serve traffic.

3. Create a cluster on appliance NS1 and configure it as a PASSIVE node.

   ```
   //On the NSIP address of node NS1
   add cluster instance 1
   add cluster node 0 10.102.97.131 -state PASSIVE -backplane 0/1/1
   add ns ip 10.102.97.133 255.255.255.255 -type CLIP
   enable cluster instance 1
   save ns config
   reboot -warm
   ```

4. Modify the backed-up configuration file.

   a. Remove the features that are not supported on a cluster. For the list of unsupported features, see NetScaler Features Supported by a Cluster. This is an optional step. If you do not perform this step, the execution of unsupported commands will fail.

   b. Remove the configurations that have interfaces, or update the interface names from the c/u convention to the n/c/u convention.

      Example

      add vlan 10 -ifnum 0/1

      should be changed to

      add vlan 10 -ifnum 0/0/1 1/0/1

   c. The backup configuration file can have SNIP addresses or MIP addresses. These addresses are striped on all the cluster nodes. It is recommended that you add spotted IP addresses for each node.

      Example

```
add ns ip 1.1.1.1 255.255.255.0 -ownerNode 0
add ns ip 1.1.1.2 255.255.255.0 -ownerNode 1
```

d. Update the hostname to specify the owner node.

Example

```
set ns hostname ns0 -ownerNode 0
set ns hostname ns1 -ownerNode 1
```

e. Change all other relevant networking configuration that depend on spotted IPs. For example, L3 VLAN, RNAT configuration which uses SNIPs as NATIP, INAT rules that refers to SNIPs/MIPs).

5. On the cluster, do the following:

a. Make the topological changes to the cluster by connecting the cluster backplane, the cluster link aggregation channel, and so on.

b. Apply configurations from the backup configuration file to the configuration coordinator through the cluster IP address.

```
batch -f ns_backup.conf
```

c. Configure external traffic distribution mechanisms like ECMP or cluster link aggregation.

6. Switch-over the traffic from the HA setup to the single-node cluster setup.

a. Disable all interfaces on the primary appliance NS0.

```
disable interface <interface id>
```

b. Configure the cluster node as an ACTIVE node.

```
set cluster node 0 -state ACTIVE
```

Note: There can be a small amount (in the order of seconds) of downtime between disabling the interfaces and making the cluster node active.

7. On the primary appliance NS0, do the following:

a. Clear all the configurations.

```
clear ns config full
```

b. Enable all the interfaces.

```
enable interface <interface id>
```

c. Add the appliance to the cluster.

```
//On the cluster IP address (in this sample, 10.102.97.133)
add cluster node 1 10.102.97.132 -state PASSIVE -backplane 1/1/1
```

```
//On the NSIP address of the appliance
join cluster -clip 10.102.97.133 -password nsroot
save ns config
reboot -warm
```

d. Perform the required topological and configuration changes.

e. Configure NS0 as an ACTIVE node.

```
set cluster node 1 -state ACTIVE
```

The appliances of the HA setup are migrated to a cluster setup without any downtime for the application.

Setting Up GSLB in a Cluster

Note: Supported from NetScaler 10.5 Build 52.11 onwards.

To set up GSLB in a cluster you must bind the different GSLB entities to a node group. The node group must have a single member node.

Note:

- The parent-child topology of GSLB is not supported in a cluster.
- If you have configured the static proximity GSLB method, make sure that the static proximity database is present on all the cluster nodes. This happens by default if the database file is available at the default location. However, if the database file is maintained in a directory other than /var/netscaler/locdb/, you must manually synch the file to all the cluster nodes.

To set up GSLB in a cluster by using the command line interface

Log on to the cluster IP address and perform the following operations at the command prompt:

1. Configure the different GSLB entities. For information, see Configuring Global Server Load Balancing.

   Note: When creating the GSLB site, make sure that you specify the cluster IP address and public cluster IP address (needed only when the cluster is deployed behind a NAT device). These parameters are required to ensure the availability of the GSLB auto-sync functionality.

   add gslb site <siteName> <siteType> <siteIPAddress> -publicIP <ip_addr> -clip <ip_addr> <publicCLIP>

2. Create a cluster node group.

   add cluster nodegroup <name> [-sticky (YES | NO)]

   Note: Enable the sticky option if you want to set up GSLB based on VPN users.

3. Bind a single cluster node to the node group.

   bind cluster nodegroup <name> -node <nodeId>

4. Bind the local GSLB site to the nodegroup.

   bind cluster nodegroup <name> -gslbSite <string>

   Note: Make sure that the IP address of the local GSLB site IP address is striped (available across all cluster nodes).

5. Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

   To bind the ADNS service:

   bind cluster nodegroup <name> -service <string>

   To bind the DNS load balancing virtual server:

   bind cluster nodegroup <name> -vServer <string>

6. Bind the GSLB virtual server to the node group.

   bind cluster nodegroup <name> -vServer <string>

7. [Optional] To setup GSLB based on VPN users, bind the VPN virtual vserver to the GSLB node group.

   bind cluster nodegroup <name> -vServer <string>

8. Verify the configurations.

   show gslb runningConfig

To set up GSLB in a cluster by using the graphical user interface

Log on to the cluster IP address and perform the following operations in the Configuration tab:

1. Configure the GSLB entities.

   Navigate to Traffic Management > GSLB to perform the required configurations.

2. Create a node group and perform other node group related configurations.

   Navigate to System > Cluster > Node Groups to perform the required configurations.

For the detailed configurations to be performed, see the description provided in the CLI procedure mentioned above.

Parameter Descriptions (of commands listed in the CLI procedure)

add gslb site

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show gslb runningConfig

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Using Cache Redirection in a Cluster

Cache redirection in a cluster works in the same way as it does on a standalone NetScaler appliance. The only difference is that the configurations are done on the cluster IP address. For more information on cache redirection, see "Cache Redirection."

Points to remember when using cache redirection in transparent mode on a cluster:

- Before configuring cache redirection, make sure that you have connected all nodes to the external switch and that you have linksets configured. Otherwise, client requests will be dropped.
- When MAC mode is enabled on a load balancing virtual server, make sure MBF mode is enabled on the cluster by using the enable ns mode `MBF` command. Otherwise, the requests are sent to origin server directly instead of being sent to the cache server.

Using L2 Mode in a Cluster Setup

Note: Supported from NetScaler 10.5 and later releases.

To use L2 mode in a cluster setup, you must make sure of the following:

- Spotted IP addresses must be available on all the nodes as required.
- Linksets must be used to communicate with the external network.
- Asymmetric topologies or asymmetric cluster LA groups are not supported.
- Cluster LA group is recommended.
- Traffic is distributed between the cluster nodes only for deployments where services exist.

Using Cluster LA Channel with Linksets

In an asymmetric cluster topology, some cluster nodes are not connected to the upstream network. In such a case, you must use linksets. To optimize the performance, you can bind the interfaces that are connected to the switch as a cluster LA channel and then bind the channel to a linkset.

To understand how a combination of cluster LA channel and linksets can be used, consider a three-node cluster for which the upstream switch has only two ports available. You can connect two of the cluster nodes to the switch and leave the other node unconnected.

Note: Similarly, you can also use a combination of ECMP and linksets in an asymmetric topology.

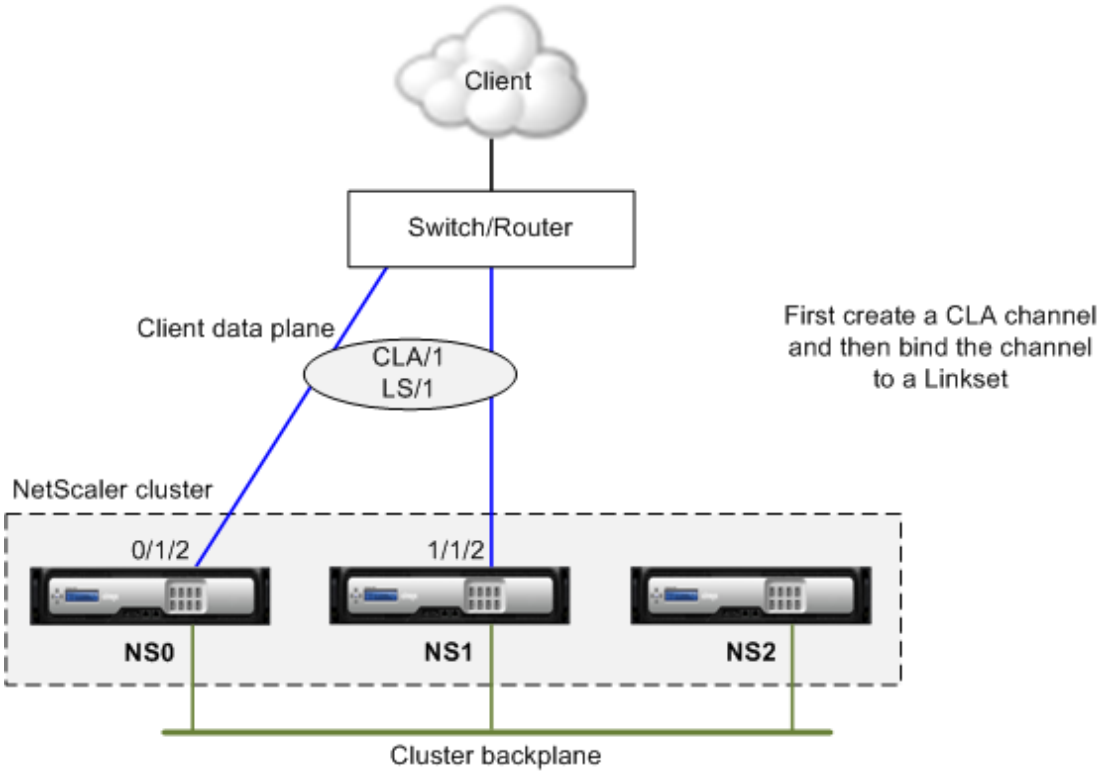

Figure 1. Linksets and cluster LA channel topology

To configure cluster LA channel and linksets by using the NetScaler command line

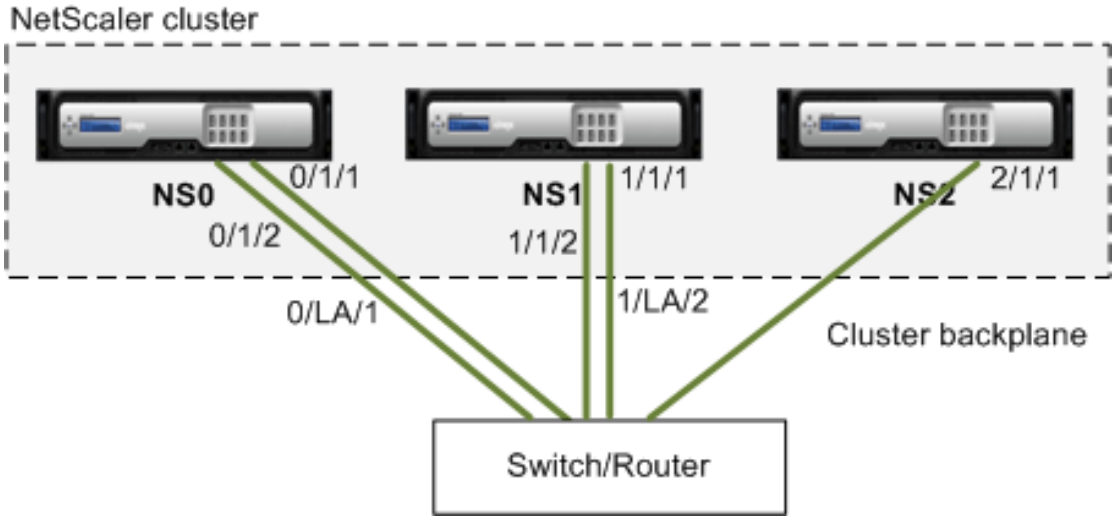
1. Log on to the cluster IP address.
2. Bind the connected interfaces to a cluster LA channel.

   add channel CLA/1 –ifnum 0/1/2 1/1/2
3. Bind the cluster LA channel to the linkset.

   add linkset LS/1 -ifnum CLA/1

Backplane on LA Channel

In this deployment, LA channels are used for the cluster backplane.



NS0 - nodeId: 0, NSIP: 10.102.29.60

NS1 - nodeId: 1, NSIP: 10.102.29.70

NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with the backplane interfaces as LA channels

1. Create a cluster of nodes NS0, NS1, and NS2.

    a. Log on to the first node that you want to add to the cluster and do the following:

    ```
    create cluster instance 1
    add cluster node 0 10.102.29.60 -state ACTIVE
    enable cluster instance 1
    add ns ip 10.102.29.61 255.255.255.255 -type CLIP
    save ns config
    reboot -warm
    ```

    b. Log on to the cluster IP address and do the following:

    ```
    add cluster node 1 10.102.29.70 -state ACTIVE
    add cluster node 2 10.102.29.80 -state ACTIVE
    ```

    c. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

    ```
    join cluster -clip 10.102.29.61 -password nsroot
    save ns config
    reboot -warm
    ```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. Log on to the cluster IP address and do the following:

   a. Create the LA channels for nodes NS0 and NS1.

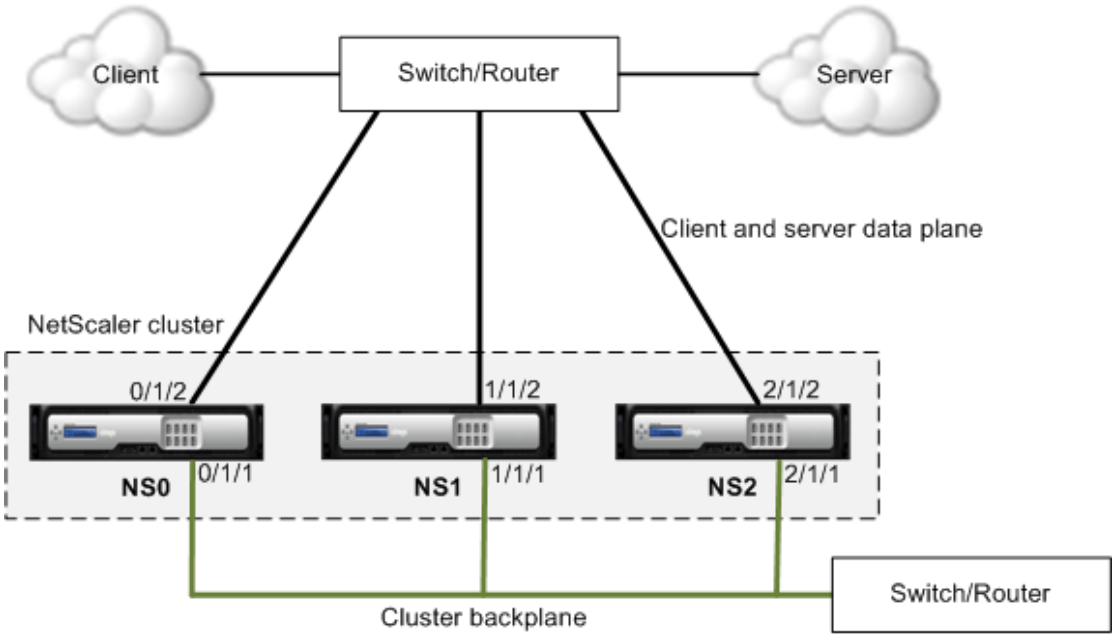
      ```
      add channel 0/LA/1 -ifnum 0/1/1 0/1/2
      add channel 1/LA/2 -ifnum 1/1/1 1/1/2
      ```

   b. Configure the backplane for the cluster nodes.

      ```
      set cluster node 0 -backplane 0/LA/1
      set cluster node 1 -backplane 1/LA/2
      set cluster node 2 -backplane 2/1/1
      ```

Common Interfaces for Client and Server and Dedicated Interfaces for Backplane

This is a one-arm deployment of the NetScaler cluster. In this deployment, the client and server networks use the same interfaces to communicate with the cluster. The cluster backplane uses dedicated interfaces for inter-node communication.



NS0 - nodeId: 0, NSIP: 10.102.29.60

NS1 - nodeId: 1, NSIP: 10.102.29.70

NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with a common interface for the client and server and a different interface for the cluster backplane

1. Create a cluster of nodes NS0, NS1, and NS2.

    a. Log on to the first node that you want to add to the cluster and do the following:

```
create cluster instance 1
add cluster node 0 10.102.29.60 -state ACTIVE -backplane 0/1/1
enable cluster instance 1
add ns ip 10.102.29.61 255.255.255.255 -type CLIP
save ns config
```

```
reboot -warm
```

b. Log on to the cluster IP address and do the following:

```
add cluster node 1 10.102.29.70 -state ACTIVE -backplane 1/1/1
add cluster node 2 10.102.29.80 -state ACTIVE -backplane 2/1/1
```

c. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
join cluster -clip 10.102.29.61 -password nsroot
save ns config
reboot -warm
```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. On the cluster IP address, create VLANs for the backplane interfaces and for the client and server interfaces.

```
//For the backplane interfaces
add vlan 10
bind vlan 10 0/1/1 1/1/1 2/1/1

//For the interfaces that are connected to the client and server networks.
add vlan 20
bind vlan 20 0/1/2 1/1/2 2/1/2
```

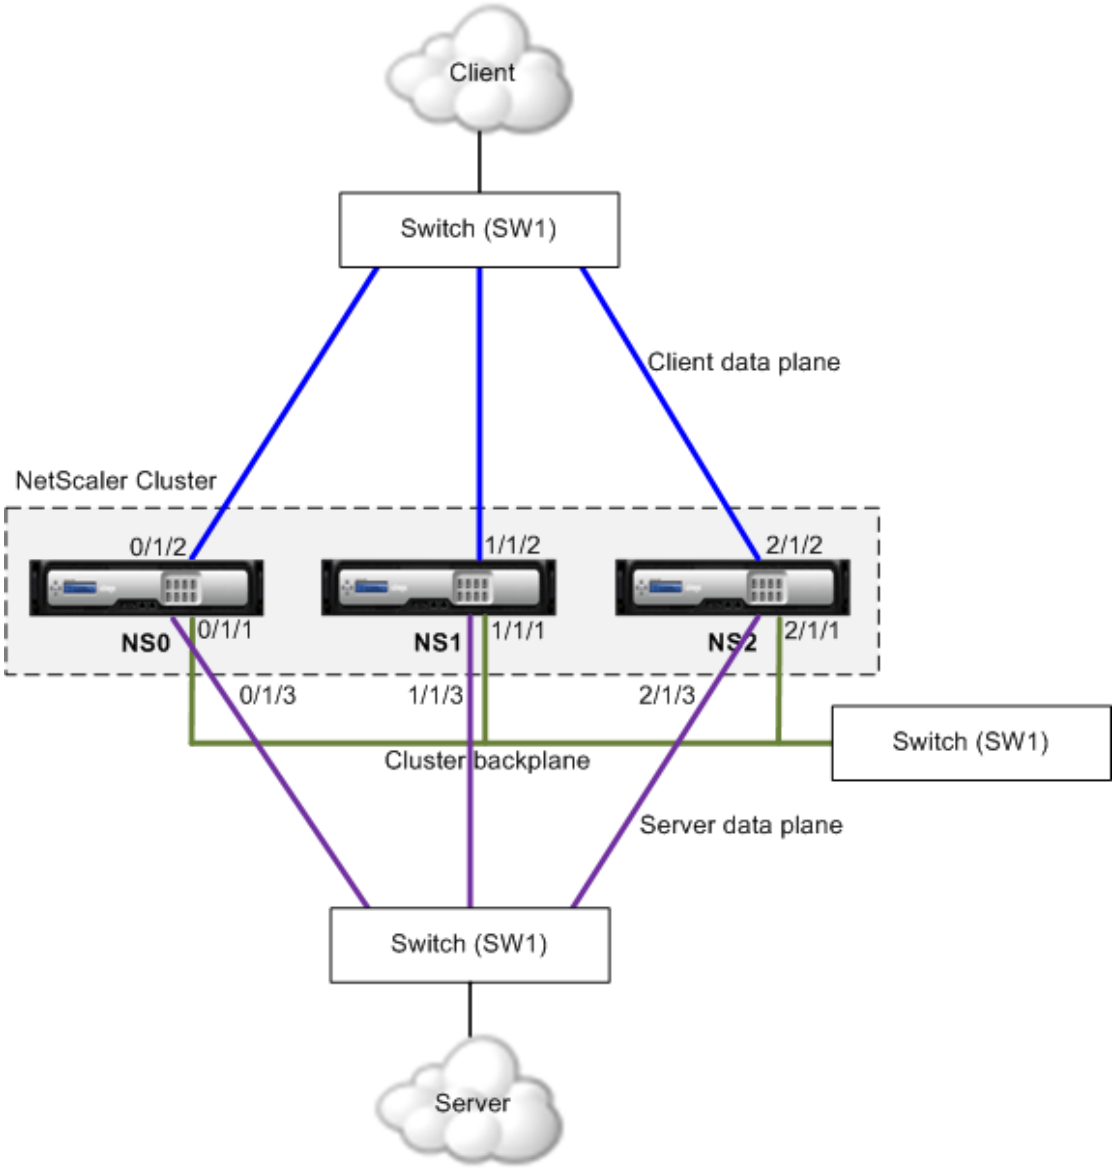
3. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

```
//For the backplane interfaces. Repeat for each interface...
interface Ethernet2/47
switchport access vlan 100
switchport mode access
end

//For the interfaces connected to the client and server networks. Repeat for each interface...
interface Ethernet2/47
switchport access vlan 200
switchport mode access
end
```

Common Switch for Client, Server, and Backplane

In this deployment, the client, server, and backplane use dedicated interfaces on the same switch to communicate with the NetScaler cluster.



NS0 - nodeId: 0, NSIP: 10.102.29.60

NS1 - nodeId: 1, NSIP: 10.102.29.70

NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with a common switch for the client, server, and backplane

1. Create a cluster of nodes NS0, NS1, and NS2.

   a. Log on to the first node that you want to add to the cluster and do the following:

      ```
      create cluster instance 1
      add cluster node 0 10.102.29.60 -state ACTIVE -backplane 0/1/1
      enable cluster instance 1
      add ns ip 10.102.29.61 255.255.255.255 -type CLIP
      save ns config
      reboot -warm
      ```

   b. Log on to the cluster IP address and do the following:

      ```
      add cluster node 1 10.102.29.70 -state ACTIVE -backplane 1/1/1
      add cluster node 2 10.102.29.80 -state ACTIVE -backplane 2/1/1
      ```

   c. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

      ```
      join cluster -clip 10.102.29.61 -password nsroot
      save ns config
      reboot -warm
      ```

   As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

   ```
   //For the backplane interfaces
   add vlan 10
   bind vlan 10 0/1/1 1/1/1 2/1/1

   //For the client-side interfaces
   add vlan 20
   bind vlan 20 0/1/2 1/1/2 2/1/2

   //For the server-side interfaces
   add vlan 30
   bind vlan 30 0/1/3 1/1/3 2/1/3
   ```

3. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

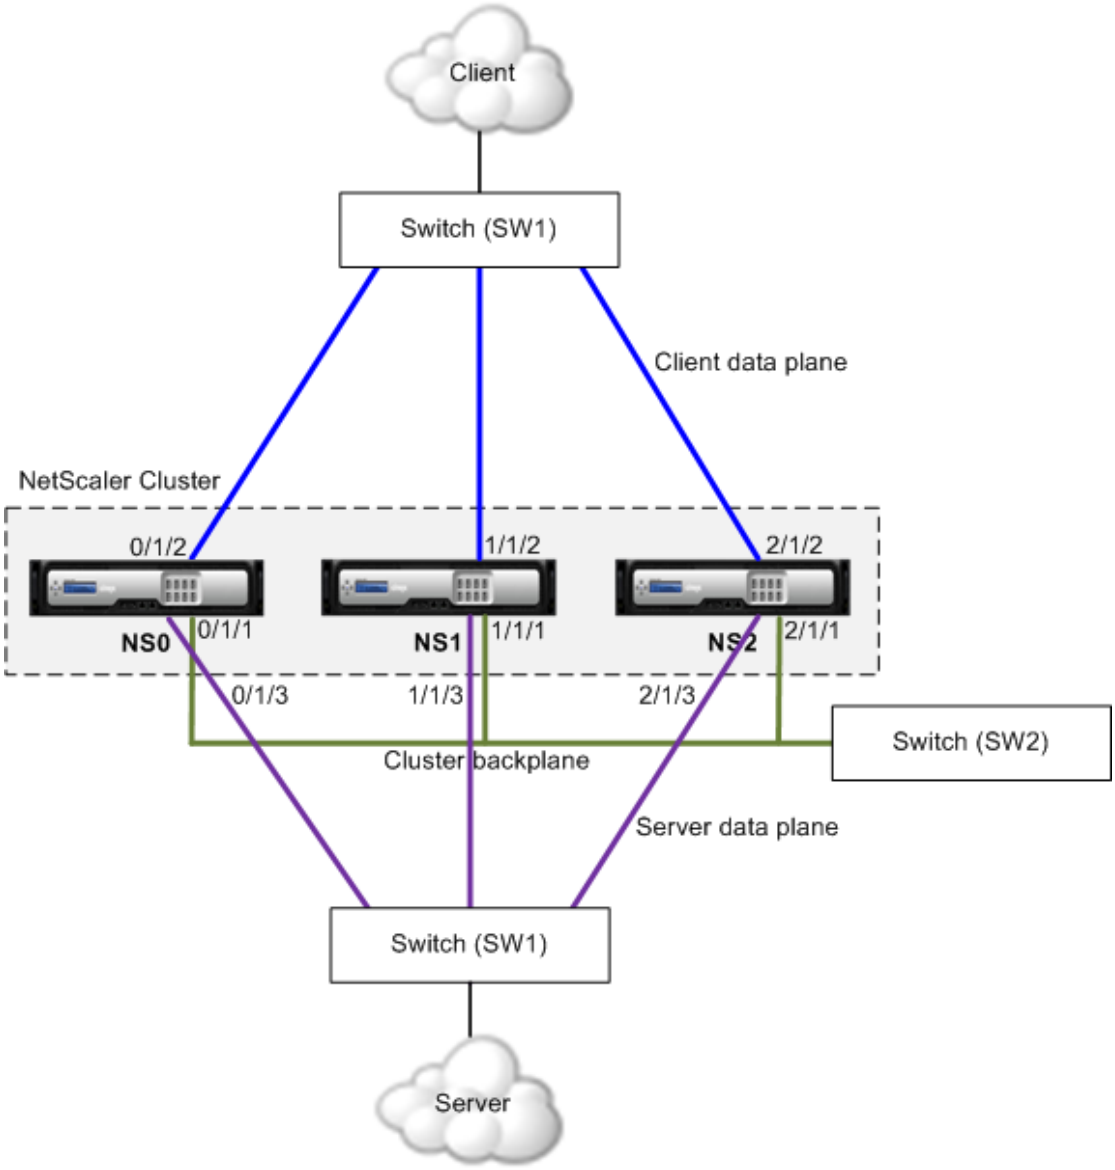
   ```
   //For the backplane interfaces. Repeat for each interface...
   interface Ethernet2/47
   switchport access vlan 100
   switchport mode access
   end
   ```

```
//For the client interfaces. Repeat for each interface...
interface Ethernet2/48
switchport access vlan 200
switchport mode access
end

//For the server interfaces. Repeat for each interface...
interface Ethernet2/49
switchport access vlan 300
switchport mode access
end
```

Common Switch for Client and Server and Dedicated Switch for Backplane

In this deployment, the clients and servers use different interfaces on the same switch to communicate with the NetScaler cluster. The cluster backplane uses a dedicated switch for inter-node communication.



NS0 - nodeId: 0, NSIP: 10.102.29.60

NS1 - nodeId: 1, NSIP: 10.102.29.70

NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with the same switch for the clients and servers and a different switch for the cluster backplane

1. Create a cluster of nodes NS0, NS1, and NS2.

   a. Log on to the first node that you want to add to the cluster and do the following:

      ```
      create cluster instance 1
      add cluster node 0 10.102.29.60 -state ACTIVE -backplane 0/1/1
      enable cluster instance 1
      add ns ip 10.102.29.61 255.255.255.255 -type CLIP
      save ns config
      reboot -warm
      ```

   b. Log on to the cluster IP address and do the following:

      ```
      add cluster node 1 10.102.29.70 -state ACTIVE -backplane 1/1/1
      add cluster node 2 10.102.29.80 -state ACTIVE -backplane 2/1/1
      ```

   c. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

      ```
      join cluster -clip 10.102.29.61 -password nsroot
      save ns config
      reboot -warm
      ```

   As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

   ```
   //For the backplane interfaces
   add vlan 10
   bind vlan 10 0/1/1 1/1/1 2/1/1

   //For the client-side interfaces
   add vlan 20
   bind vlan 20 0/1/2 1/1/2 2/1/2

   //For the server-side interfaces
   add vlan 30
   bind vlan 30 0/1/3 1/1/3 2/1/3
   ```

3. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

   ```
   //For the backplane interfaces. Repeat for each interface...
   interface Ethernet2/47
   switchport access vlan 100
   switchport mode access
   ```

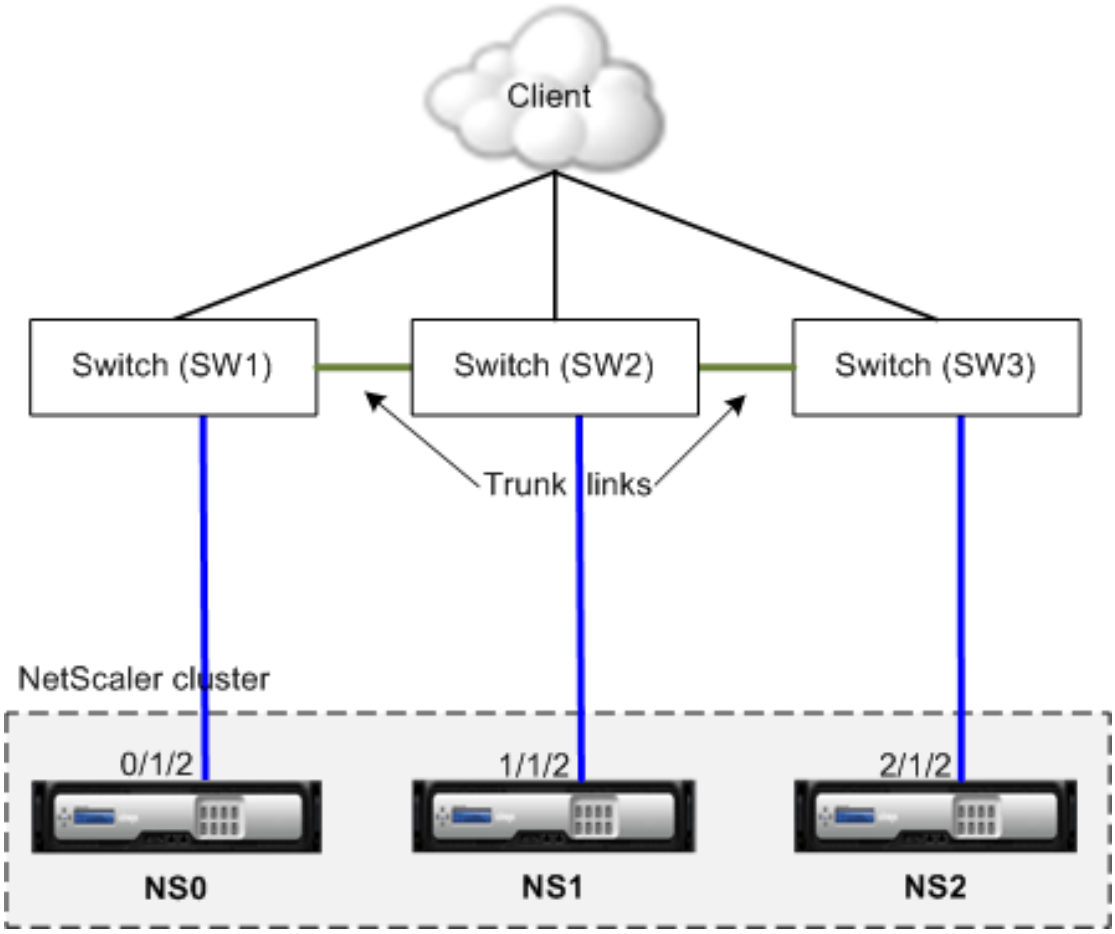
```
end

//For the client interfaces. Repeat for each interface...
interface Ethernet2/48
switchport access vlan 200
switchport mode access
end

//For the server interfaces. Repeat for each interface...
interface Ethernet2/49
switchport access vlan 300
switchport mode access
end
```

Different Switch for Every Node

In this deployment, each cluster node is connected to a different switch and trunk links are configured between the switches.



The cluster configurations will be the same as the other deployments scenarios. Most of the client-side configurations will be done on the client-side switches.

Sample Cluster Configurations

The following example can be used to configure a four-node cluster with ECMP, cluster LA, or Linksets.

1. Create the cluster.
    a. Log on to first node.
    b. Add the cluster instance.

        add cluster instance 1

    c. Add the first node to the cluster.

        add cluster node 0 10.102.33.184 -backplane 0/1/1

    d. Enable the cluster instance.

        enable cluster instance 1

    e. Add the cluster IP address.

        add ns ip 10.102.33.185 255.255.255.255 -type CLIP

    f. Save the configurations.

        save ns config

    g. Warm reboot the appliance.

        reboot -warm
2. Add the other three nodes to the cluster.
    a. Log on to cluster IP address.
    b. Add the second node to the cluster.

        add cluster node 1 10.102.33.187 -backplane 1/1/1

    c. Add the third node to the cluster.

        add cluster node 2 10.102.33.188 -backplane 2/1/1

    d. Add the fourth node to the cluster.

        add cluster node 3 10.102.33.189 -backplane 3/1/1
3. Join the added nodes to the cluster. This step is not applicable for the first node.
    a. Log on to each newly added node.

b. Join the node to the cluster.

```
join cluster -clip 10.102.33.185 -password nsroot
```

c. Save the configuration.

```
save ns config
```

d. Warm reboot the appliance.

```
reboot -warm
```

4. Configure the NetScaler cluster through the cluster IP address.

```
// Enable load balancing feature
enable ns feature lb

// Add a load balancing virtual server
add lb vserver first_lbvserver http
....
....
```

5. Configure any one of the following (ECMP, cluster LA, or Linkset) traffic distribution mechanisms for the cluster.

- **ECMP**

a. Log on to the cluster IP address.

b. Enable the OSPF routing protocol.

```
enable ns feature ospf
```

c. Add a VLAN.

```
add vlan 97
```

d. Bind the interfaces of the cluster nodes to the VLAN.

```
bind vlan 97 -ifnum 0/1/4 1/1/4 2/1/4 3/1/4
```

e. Add a spotted SNIP on each node and enable dynamic routing on it.

```
add ns ip 1.1.1.10 255.255.255.0 -ownerNode 0 -dynamicRouting ENABLED
add ns ip 1.1.1.11 255.255.255.0 -ownerNode 1 -dynamicRouting ENABLED
add ns ip 1.1.1.12 255.255.255.0 -ownerNode 2 -dynamicRouting ENABLED
add ns ip 1.1.1.13 255.255.255.0 -ownerNode 3 -dynamicRouting ENABLED
```

f. Bind one of the SNIP addresses to the VLAN.

```
bind vlan 97 -ipAddress 1.1.1.10 255.255.255.0
```

g. Configure the routing protocol on ZebOS by using vtysh shell.

- **Static cluster LA**

a. Log on to the cluster IP address.

b. Add a cluster LA channel.

```
add channel CLA/1 -speed 1000
```

c. Bind the interfaces to the cluster LA channel.

```
bind channel CLA/1 0/1/5 1/1/5 2/1/5 3/1/5
```

d. Perform equivalent configuration on the switch.

- **Dynamic cluster LA**

a. Log on to the cluster IP address.

b. Add the interfaces to the cluster LA channel.

```
set interface 0/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
set interface 1/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
set interface 2/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
set interface 3/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
```

c. Perform equivalent configuration on the switch.

- **Linksets.** Assume that the node with nodeId 3 is not connected to the switch. You must configure a linkset so that the unconnected node can use the other node interfaces to communicate with the switch.

a. Log on to the cluster IP address.

b. Add a linkset.

```
add linkset LS/1
```

c. Bind the connected interfaces to the linkset.

```
bind linkset LS/1 -ifnum 0/1/6 1/1/6 2/1/6
```

6. Update the state of the cluster nodes to ACTIVE.

```
set cluster node 0 -state ACTIVE
set cluster node 1 -state ACTIVE
set cluster node 2 -state ACTIVE
set cluster node 3 -state ACTIVE
```

Troubleshooting the NetScaler Cluster

If a failure occurs in a NetScaler cluster, the first step in troubleshooting is to get information on the cluster instance and the cluster nodes by running the `show cluster instance <clId>` and `show cluster node <nodeId>` commands respectively.

If you are not able to find the issue by using the above two approaches, you can use one of the following:

- **Isolate the source of the failure.** Try bypassing the cluster to reach the server. If the attempt is successful, the problem is probably with the cluster setup.
- **Check the commands recently executed.** Run the history command to check the recent configurations performed on the cluster. You can also review the ns.conf file to verify the configurations that have been implemented.
- **Check the ns.log files.** Use the log files, available in the /var/log/ directory of each node, to identify the commands executed, status of commands, and the state changes.
- **Check the newnslog files.** Use the newnslog files, available in the /var/nslog/ directory of each node, to identify the events that have occurred on the cluster nodes. You can view multiple newnslog files as a single file, by copying the files to a single directory, and then running the following command:

  nsconmsg -K newnslog-node<id> -K newnslog.node<id> -d current

If you still cannot resolve the issue, you can try tracing the packets on the cluster or use the `show techsupport -scope cluster` command to send the report to the technical support team.

Tracing the Packets of a NetScaler Cluster

The NetScaler operating system provides a utility called *nstrace* to get a dump of the packets that are received and sent out by an appliance. The utility stores the packets in trace files. You can use these files to debug problems in the flow of packets to the cluster nodes. The trace files must be viewed with the *Wireshark* application. For traces collected in native (.cap) mode, it is important to use the internal version of Wireshark, which can understand native packets.

Some salient aspects of the nstrace utility are:

- Can be configured to trace packets selectively by using classic expressions and default expressions.
- Can capture the trace in multiple formats: nstrace format (.cap) and TCP dump format (.pcap).
- Can aggregate the trace files of all cluster nodes on the configuration coordinator.
- Can merge multiple trace files into a single trace file (only for .cap files).

You can use the nstrace utility from the NetScaler command line or the NetScaler shell.

To trace packets of a standalone appliance

Run the start nstrace command on the appliance. The command creates trace files in the /var/nstrace/<date-timestamp> directory. The trace file names are of the form nstrace<id>.cap.

You can view the status by executing the show nstrace command. You can stop tracing the packets by executing the stop nstrace command.

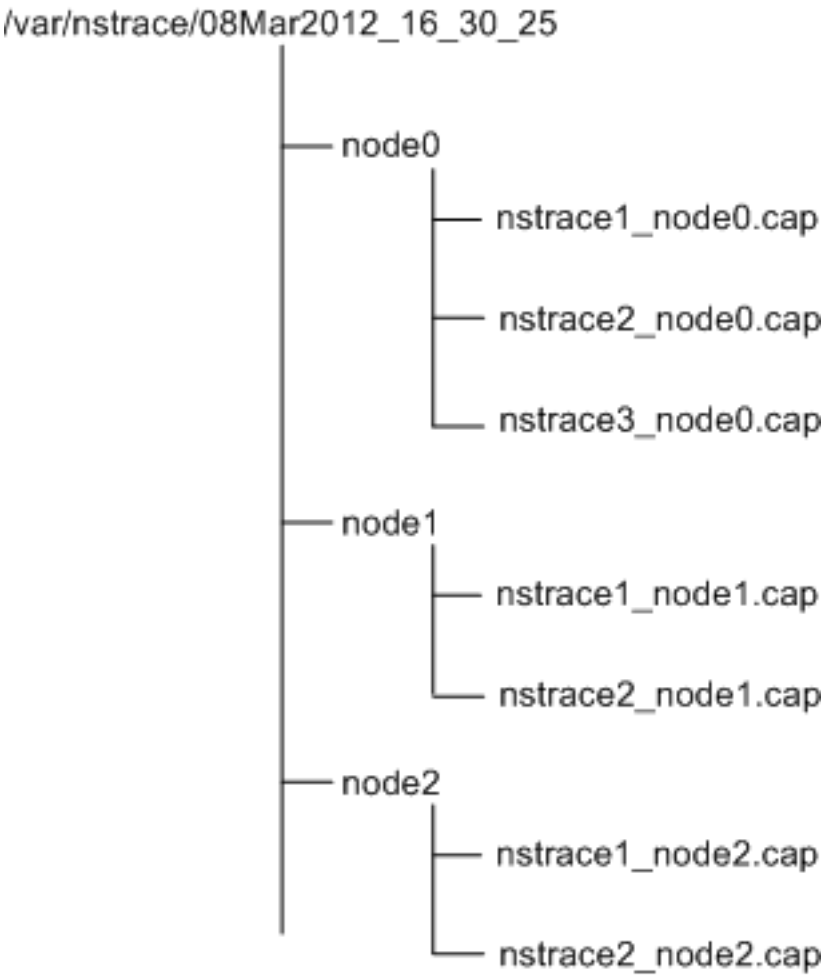
Note: You can also run the nstrace utility from the NetScaler shell by executing the nstrace.sh file. However, it is recommended that you use the nstrace utility through the NetScaler command line interface.

To trace packets of a cluster

You can trace the packets on all the cluster nodes and obtain all the trace files on the configuration coordinator.

Run the start nstrace command on the cluster IP address. The command is propagated and executed on all the cluster nodes. The trace files are stored in individual cluster nodes in the /var/nstrace/<date-timestamp> directory. The trace file names are of the form nstrace<id>_node<id>.cap.

You can use the trace files of each node to debug the nodes operations. But if you want the trace files of all cluster nodes in one location, you must run the stop nstrace command on the cluster IP address. The trace files of all the nodes are downloaded on the cluster configuration coordinator in the /var/nstrace/<date-timestamp> directory as follows:



Merge multiple trace files

You can prepare a single file from the trace files (supported only for .cap files) obtained from the cluster nodes. The single trace files gives you a cumulative view of the trace of the cluster packets. The trace entries in the single trace file are sorted based on the time the packets were received on the cluster.

To merge the trace files, at the NetScaler shell, type:

`nstracemerge.sh` -srcdir <DIR> -dstdir <DIR> -filename <name> -filesize <num>

where,

- srcdir is the directory from which the trace files are merged. All trace files within this directory are merged into a single file.
- dstdir is the directory where the merged trace file are created.

- filename is the name of the trace file that is created.
- filesize is the size of the trace file.

Examples

Following are some examples of using the nstrace utility to filter packets.

- To trace the packets on the backplane interfaces of three nodes:

  Using classic expressions:

  start nstrace -filter "INTF == 0/1/1 && INTF == 1/1/1 && INTF == 2/1/1"

  Using default expressions:

  start nstrace -filter "CONNECTION.INTF.EQ("0/1/1") && CONNECTION.INTF.EQ("1/1/1") && CONNECTION.

- To trace the packets from a source IP address 10.102.34.201 or from a system whose source port is greater than 80 and the service name is not "s1":

  Using classic expressions

  start nstrace -filter "SOURCEIP == 10.102.34.201 || (SVCNAME != s1 && SOURCEPORT > 80)"

  Using default expressions

  start nstrace -filter "CONNECTION.SRCIP.EQ(10.102.34.201) || (CONNECTION.SVCNAME.NE("s1") && CONN

Troubleshooting Common Issues

While joining a node to the cluster, I get the following message, "ERROR: Invalid interface name/number." What must I do to resolve this error?

This error occurs if you provided an invalid or incorrect backplane interface while using the add cluster node command to add the node. To resolve this error, verify the interface you provided while adding the node. Make sure that you have not specified the appliance's management interface as the backplane interface, and that the <nodeId> bit of the interface is the same as the node's Id. For example, if the nodeId is 3, the backplane interface must be 3/<c>/<u>.

While joining a node to the cluster, I get the following message, "ERROR: Clustering cannot be enabled, because the local node is not a member of the cluster." What must I do to resolve this error?

This error occurs when you try to join a node without adding the node's NSIP to the cluster. To resolve this error, you must first add the node's NSIP address to the cluster by using the add cluster node command and then execute the join cluster command.

While joining a node to the cluster, I get the following message, "ERROR: Connection refused." What must I do to resolve this error?

This error can occur due to the following reasons:

- **Connectivity problems.** The node cannot connect to the cluster IP address. Try pinging the cluster IP address from the node that you are trying to join.
- **Duplicate cluster IP address.** Check to see if the cluster IP address exists on some non-cluster node. If it does, create a new cluster IP address and try re-joining the cluster.

While joining a node to the cluster, I get the following message, "ERROR: License mismatch between the configuration coordinator and the local node." What must I do to resolve this error?

The appliance that you are joining to the cluster must have the same licenses as the configuration coordinator. This error occurs when the licenses on the node you are joining do not match the licenses on the configuration coordinator. To resolve this error, run the following commands on both the nodes and compare the outputs.

From the command line:

- show ns hardware
- show ns license

From the shell:

- nsconmsg -g feature -d stats
- ls /nsconfig/license

- View the contents of the /var/log/license.log file

What must I do when the configurations of a cluster node are not in synch with the cluster configurations?

In most cases, the configurations are automatically synchronized between all the cluster nodes. However, if you feel that the configurations are not synchronized on a specific node, you must force the synchronization by executing the force cluster sync command from the node that you want to synchronize. For more information, see " Synchronizing Cluster Configurations".

When configuring a cluster node, I get the following message, "ERROR: Session is read-only; connect to the cluster IP address to modify the configuration."

All configurations on a cluster must be done through the cluster IP address and the configurations are propagated to the other cluster nodes. All sessions established through the NetScaler IP (NSIP) address of individual nodes are read-only.

Why does the node state show "INACTIVE" when the node health shows "UP"?

A healthy node can be in the INACTIVE state for a number of reasons. A scan of ns.log or error counters can help you determine the exact reason.

How can I resolve the health of a node when its health shows "NOT UP"?

Node health " **Not UP**" indicates that there are some issues with the node. To know the root cause, you must run the show cluster node command. This command displays the node properties and the reason for the node failure.

What must I do when the health of a node shows as "NOT UP" and the reason indicates that configuration commands have failed on a node?

This issue arises when some commands are not executed on the cluster nodes. In such cases, you must make sure that the configurations are synchronized using one of the following options:

- If some of the cluster nodes are in this state, you must perform the force cluster synchronization operation on those nodes. For more information, see "Synchronizing Cluster Configurations".

- If all cluster nodes are in this state, you must disable and then enable the cluster instance on all the cluster nodes.

When I run the set vserver command, I get the following message, "No such resource." What must I do to resolve this issue?

The `set vserver` command is not supported in clustering. The `unset vserver`, `enable vserver`, `disable vserver`, and `rm vserver` commands are also not supported. However, the `show vserver` command is supported.

I cannot configure the cluster over a Telnet session. What must I do?

Over a telnet session, the cluster IP address can be accessed only in read-only mode. Therefore, you cannot configure a cluster over a telnet session.

I notice a significant time difference across the cluster nodes. What must I do to resolve this issue?

When PTP packets are dropped due to backplane switch or if the physical resources are over-committed in a virtual environment, the time will not get synchronized.

To synchronize the times, you must do the following on the cluster IP address:

1. Disable PTP.

   set ptp -state `disable`

2. Configure Network Time Protocol (NTP) for the cluster. For more information, see "Setting up Clock Synchronization".

What must I do, if there is no connectivity to the cluster IP address and the NSIP address of a cluster node?

If you cannot access to the cluster IP address or the NSIP of a cluster node, you must access the appliance through the serial console. For more information, see "Using the Command Line Interface".

If the NSIP address is reachable, you can SSH to the cluster IP address from the shell by executing the following command at the shell prompt:

ssh nsroot@<cluster IP address>

What must I do to recover a cluster node that has connectivity issues?

To recover a node that has connectivity issues:

1. Disable the cluster instance on that node (since you cannot execute commands from the NSIP of a cluster node).

2. Execute the commands required to recover the node.

3. Enable the cluster instance on that node.

Some nodes of the cluster have two default routes. How can I remove the second default route from the cluster node?

To delete the additional default route, do the following on each node that has the extra route:

1. Disable the cluster instance.

   disable cluster instance <clId>

2. Remove the route.

   rm route <network> <netmask> <gateway>

3. Enable the cluster instance.

   enable cluster instance <clId>

Parameter Descriptions (of commands listed in the CLI procedure)

Clustering FAQs

How many NetScaler appliances can I have in a cluster?

A NetScaler cluster can include as few as 2 or as many as 32 NetScaler nCore hardware or virtual appliances.

Can a cluster have NetScaler appliances from different networks?

No. The current cluster implementation requires that all cluster nodes be in the same network.

Can a NetScaler appliance be a part of multiple clusters?

No. An appliance can belong to only one cluster.

How can I set the hostname for a cluster node?

The hostname of a cluster node must be specified by executing the set ns hostname command through the cluster IP address. For example, to set the hostname of the cluster node with ID 2, the command is:

> set ns hostname hostName1 -ownerNode 2

What is a cluster IP address? What is its subnet mask?

The cluster IP address is the management address of a NetScaler cluster. All cluster configurations must be performed by accessing the cluster through this address. The subnet mask of the cluster IP address is fixed at 255.255.255.255.

Can I automatically detect NetScaler appliances so that I can add them to a cluster?

Yes. The configuration utility allows you to discover appliances that are present in the same subnet as the NSIP address of the configuration coordinator. For more information, see "Discovering NetScaler Appliances".

Why are the network interfaces of a cluster represented in 3-tuple (n/u/c) notation instead of the regular 2-tuple (u/c) notation?

When an appliance is part of a cluster, you must be able to identify the node to which the network interface belongs. Therefore, the network interface naming convention for cluster nodes is modified from u/c to n/u/c, where n denotes the node Id.

I have multiple standalone appliances, each of which has different configurations. Can I add them to a single cluster?

Yes. You can add appliances that have different configurations to a single cluster. However, when the appliance is added to the cluster, the existing configurations are cleared. To use the configurations that are available on each of the individual appliances, you must:

1. Create a single *.conf file for all the configurations.

2. Edit the configuration file to remove features that are not supported in a cluster environment.

3. Update the naming convention of interfaces from 2-tuple (u/c) format to 3-tuple (n/u/c) format.

4. Apply the configurations to the configuration coordinator node of the cluster by using the batch command.

Can I migrate the configurations of a standalone NetScaler appliance or an HA setup to the clustered setup?

No. When a node is added to a clustered setup, its configurations are implicitly cleared by using the clear ns config command (with the extended option). In addition, the SNIP addresses and all VLAN configurations (except default VLAN and NSVLAN) are cleared. Therefore, it is recommended that you back up the configurations before adding the appliance to a cluster. Before using the backed-up configuration file for the cluster, you must:

1. Edit the configuration file to remove features that are not supported in a cluster environment.

2. Update the naming convention of interfaces from two-tuple (x/y) format to three-tuple (x/y/z) format.

3. Apply the configurations to the configuration coordinator node of the cluster by using the batch command.

How can I configure/unconfigure the NSVLAN on a cluster?

- To make the NSVLAN available in a cluster, make sure that each appliance has the same NSVLAN configured before it is added to cluster.

- To remove the NSVLAN from a cluster node, first remove the node from the cluster and then delete the NSVLAN from the appliance.

Can a cluster node that is not connected to the client or server network still serve traffic?

Yes. The cluster supports a traffic distribution mechanism called linksets, which allows unconnected nodes to serve traffic by using the interfaces of connected nodes. The unconnected nodes communicate with the connected nodes through the cluster backplane. For more information, see "Using Linksets".

Can I execute commands from the NSIP address of a cluster node?

No. Access to individual cluster nodes through the NetScaler IP (NSIP) addresses is read-only. Therefore, when you log on to the NSIP address of a cluster node you can only view the configurations and the statistics. You cannot configure anything. However, there are some operations you can execute from the NSIP address of a cluster node. For more information, see "Operations Supported on Individual Nodes".

Can I disable configuration propagation among cluster nodes?

No, you cannot explicitly disable the propagation of cluster configurations among cluster nodes. However, during a software upgrade or downgrade, a version mismatch can

automatically disable configuration propagation.

Can I change the NSIP address or change the NSVLAN of a NetScaler appliance when it is a part of the cluster?

No. To make such changes you must first remove the appliance from the cluster, perform the changes, and then add the appliance to the cluster.

Does the NetScaler cluster support L2 and L3 Virtual Local Area Networks (VLANs)?

Yes. A cluster supports VLANs between cluster nodes. The VLANs must be configured on the cluster IP address.

- **L2 VLAN.** You can create a layer2 VLAN by binding interfaces that belong to different nodes of the cluster.

- **L3 VLAN.** You can create a layer3 VLAN by binding IP addresses that belong to different nodes of the cluster. The IP addresses must belong to the same subnet. Make sure that one of the following criteria is satisfied. Otherwise, the L3 VLAN bindings can fail.

  - All nodes have an IP address on the same subnet as the one bound to the VLAN.

  - The cluster has a striped IP address and the subnet of that IP address is bound to the VLAN.

  When you add a new node to a cluster that has only spotted IPs, the sync happens before spotted IP addresses are assigned to that node. In such cases, L3 VLAN bindings can be lost. To avoid this loss, either add a striped IP or add the L3 VLAN bindings on the NSIP of the newly added node.

How can I configure SNMP on a NetScaler cluster?

SNMP monitors the cluster, and all the nodes of the cluster, in the same way that it monitors a standalone appliance. The only difference is that SNMP on a cluster must be configured through the cluster IP address. When generating hardware specific traps, two additional varbinds are included to identify the node of the cluster: node ID and NSIP address of the node.

For detailed information about configuring SNMP, see "SNMP".

What details must I have available when I contact technical support for cluster-related issues?

The NetScaler provides a `show techsupport -scope cluster` command that extracts configuration data, statistical information, and logs of all the cluster nodes. You must run this command on the cluster IP address.

The output of this command is saved in a file named collector_cluster_<nsip_CCO>_P_<date-timestamp>.tar.gz which is available in the /var/tmp/support/cluster/ directory of the configuration coordinator.

Send this archive to the technical support team to debug the issue.

Can I use striped IP addresses as the default gateway of servers?

In case of cluster deployments, make sure the default gateway of the server points to a striped IP address (if you are using a NetScaler-owned IP address). For example, in case

of LB deployments with USIP enabled, the default gateway must be a striped SNIP address.

Can I view routing configurations of a specific cluster node from the cluster IP address?

Yes. You can view and clear the configurations specific to a node by specifying the owner node while entering the vtysh shell.

For example, to view the output of a command on nodes 0 and 1, the command is as follows:

```
> vtysh
ns# owner-node 0 1
ns(node-0 1)# show cluster state
ns(node-0 1)# exit-cluster-node
ns#
```

How can I specify the node for which I want to set the LACP system priority?

Applicable for NetScaler 10.1 and later releases.

In a cluster, you must set that node as the owner node by using the set lacp command.

For example: To set the LACP system priority for node with ID 2:

```
> set lacp -sysPriority 5 -ownerNode 2
```

How can I configure IP tunnels in a cluster?

Applicable for NetScaler 10.1 and later releases.

Configuring IP tunnels in a cluster is the same as on a standalone appliance. The only difference is that in a cluster setup, the local IP address must be a striped SNIP or MIP address. For more information, see "Configuring IP Tunnels".

How can I add a failover interface set (FIS) on the nodes of a NetScaler cluster?

Applicable for NetScaler 10.5 and later releases.

On the cluster IP address, specify the ID of the cluster node on which the FIS must be added.

add fis <name> -ownerNode <nodeId>

Note:

- The FIS name for each cluster node must be unique.
- A cluster LA channel can be added to a FIS. You must make sure that the cluster LA channel has a local interface as a member interface.

For more information on FIS, see "Configuring FIS".

Are Net Profiles supported on a cluster?

Applicable for NetScaler 10.5 and later releases.

Net profiles are now supported on a NetScaler cluster. You can bind spotted IP addresses to a net profile which can then be bound to spotted lbvserver or service (defined using a node group) with the following recommendations:

Note:

- If the "strict" parameter of the node group is "Yes", the net profile must contain a minimum of one IP address from each node of the node group member.
- If the "strict" parameter of the node group is "No", the net profile must include at least one IP address from each of the cluster nodes.
- If the above recommendations are not followed, the net profile configurations will not be honored and the USIP/USNIP settings will be used.

Parameter Descriptions (of commands listed in the CLI procedure)

add fis

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Operations Not Propagated to Cluster Nodes

Unless specified otherwise, all operations performed on the cluster IP address, are propagated to other cluster nodes. The exceptions to this rule are:

shutdown

Shuts down only the configuration coordinator.

reboot

Reboots only the configuration coordinator.

rm cluster instance

Removes the cluster instance from the node that you are executing the command on.

Operations Supported on Individual Cluster Nodes

Access to cluster nodes through their NSIP addresses, is read-only. However, NetScaler allows you to perform the following operations on individual cluster nodes by accessing their NSIP address. These operations, when executed from the NSIP address, are not propagated to other cluster nodes.

Note: All the show and statistics commands are allowed as they do not involve any change in configurations.

- cluster instance (set | rm | enable | disable)
- cluster node (set | rm)
- nstrace (start | show | stop)
- interface (set | enable | disable)
- force cluster sync
- sync cluster files
- disable ntp sync
- save ns config
- reboot
- shutdown

For example, when you execute the command disable interface `1/1/1` from the NSIP address of a cluster node, the interface is disabled only on that node. Since the command is not propagated, the interface 1/1/1 remains enabled on all the other cluster nodes.

CloudBridge

As a tool for building a cloud-extended data center, the Citrix NetScaler® CloudBridge™ feature is a fundamental part of the Citrix® Cloud framework. This feature can reduce the cost of moving your applications to the cloud, reduce the risk of application failure, and increase network efficiency in your cloud environment.

With the CloudBridge feature, you can create a network bridge (or more than one) connecting one or more cloud computing instances-virtual servers in the cloud-to your network without reconfiguring your network. Cloud-hosted applications appear as though they are running on one contiguous enterprise network.

Setting up a network bridge involves configuring two NetScaler appliances or virtual appliances, one on each side of the bridge. On each appliance, you configure one or more GRE tunnels and configure IPSec on the tunnel or tunnels. You then assign a name to the network bridge and bind the GRE tunnel(s) to it. Optionally, you can bind VLANs and IP addresses to the network bridge.

If you need only one GRE tunnel, you can use an alternative configuration method in which you configure all of the network bridge elements in one dialog box in the configuration utility. You can add more tunnels later.

CloudBridge is a complete network solution - **available as a standalone physical or virtual appliance, or integrated into NetScaler Platinum edition** - enabling enterprises to transparently shift web and application servers to the cloud while keeping the database safely within the enterprise datacenter.

Terminology

The Citrix CloudBridge VPX™ product is a virtual instance that can be hosted on Amazon Web Services (AWS), Citrix XenServer®, VMware ESX or ESXi, and Microsoft Hyper-V virtualization platforms. The Citrix CloudBridge MPX™ product is a physical appliance that you can install in your private enterprise network.

Note: These topics focuses primarily on CloudBridge VPX.

The term CloudBridge can also refer to the connection that you create between the two private networks by using CloudBridge appliances or instances. Networks connected by a CloudBridge function like a single network. The CloudBridge is transparent to the user. To configure a CloudBridge, you:

1. Create a network bridge
2. Create an IPSec profile
3. Create a GRE tunnel with the IPSec profile
4. Bind the tunnel to the network bridge.

CloudBridge VPX License

After the initial instance launch, CloudBridge VPX for AWS requires a license. If you are bringing your own license (BYOL), see the VPX Licensing Guide at: http://support.citrix.com/article/CTX122426.

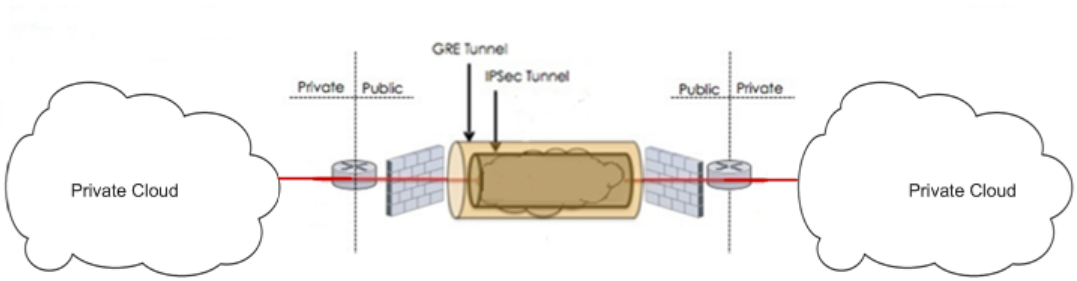
You have to:

1. Use the licensing portal within MyCitrix to generate a valid license.
2. Upload the license to the instance.

If this is a **paid** marketplace instance, then you do not need to install a license. The correct feature set and performance will activate automatically.

CloudBridge Architecture

You can configure a CloudBridge between a data center and AWS, between a data center and a data center, or between two VPCs in AWS clouds. Setting up a CloudBridge involves configuring a CloudBridge appliance or instance on each side of the bridge. On each appliance or instance, you configure a network bridge and one or more GRE tunnels with IPSec enabled. You then assign a name to the network bridge and bind the IPSec tunnel(s) to it. Optionally, with CloudBridge MPX, you can bind VLANs and IP addresses to the network bridge.



The following figure illustrates the topology of a seamless network with a secure tunnel.
Figure 1. CloudBridge Architecture

CloudBridge VPX and MPX support all the features of a NetScaler appliance, except the virtual MAC (vMAC) addresses, Layer 2 (L2) mode, and link aggregation control protocol (LACP). VLAN tagging is supported on the CloudBridge VPX virtual appliances hosted on the XenServer and VMware ESX platforms.

Generic Routing Encapsulation

The network bridge extends layer 2 bridging to connect a CloudBridge virtual appliance residing in a cloud to a CloudBridge virtual appliance on your LAN or in your cloud. The connection is established by using a Generic Routing Encapsulation (GRE) tunnel. The GRE protocol provides a mechanism for encapsulating packets from a wide variety of network protocols. The GRE protocol encapsulates packets by adding a GRE header and a GRE IP header to the packets.

Internet Protocol Security

CloudBridge supports the use of the open-standard Internet Protocol security (IPSec) protocol suite to secure the communication between the connected peers.

In a CloudBridge, IPSec ensures:

- Data integrity

- Data origin authentication
- Data confidentiality (encryption)
- Protection against anti-replay attacks

CloudBridge uses IPSec transport mode to:

- Protect data exchanged between the two hosts
- Secure the IP packet using Encapsulating Security Payload (ESP).
- Encapsulate the IPSec/ESP packet over the GRE tunnel

The IPSec/ESP header is inserted after the GRE header, and an ESP trailer is inserted at the end of the encrypted payload.

CloudBridge also supports the NAT implementation defined in RFCs 3947 and 3948, for the CloudBridge peers to communicate with peers behind NAT devices.

To secure the communication across the network bridge, the two peers use Internet Key Exchange (IKE) and IPSec to:

- Authenticate each other, using one of the following authentication methods:
    - **Pre-shared key authentication**. A text string called a pre-shared key is manually configured on each peer. The pre-shared keys of the peers are matched against each other for authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on each of the peers.
    - **Digital certificates authentication**. The initiator (sender) peer signs message interchange data by using its private key and the other receiver peer uses the sender's public key to verify the signature. Typically, the public key is exchanged in messages containing an X.509v3 certificate. This certificate provides a level of assurance that a peer's identity as represented in the certificate is associated with a particular public key.
- Negotiate to reach agreement on:
    - ESP security protocol
    - Encryption algorithm
    - Cryptographic algorithms for data authentication

This agreement upon the ESP, encryption algorithm and authentication algorithm is called a security association (SA). SAs function in the simplex communication mode. SA is used to encrypt the outgoing packets and decrypt the incoming packets.

SAs expire after a specified length of time, which is called the *lifetime*. The two peers use the Internet Key Exchange (IKE) protocol to negotiate new cryptographic keys and establish new SAs. The purpose of the limited lifetime is to prevent attackers from cracking a key.

Branch Repeater

Citrix Branch Repeater accelerates Wide Area Networks, providing LAN-like performance for applications running across enterprise data centers and public clouds. Branch Repeaters offer a broad base of protocol acceleration support and market-leading VDI acceleration for Citrix XenDesktop. Branch Repeater appliances work in pair at either side of the WAN.

For more information about Branch Repeater appliances, see Branch Repeaters.

Consider an example of a CloudBridge setup where CloudBridge appliances CB1 and CB2 are CloudBridge peers. To enable WAN optimization in the CloudBridge set up, Branch Repeater appliances BR1 and BR2 are paired with CloudBridge appliances CB1 and CB2, respectively.

Following is the traffic flow in this example:

1. The CloudBridge CB1 at one end sends the data to Branch Repeater appliance BR1.
2. BR1 compresses the data and sends it to CloudBridge CB1.
3. CB1 sends the compressed data to its peer, CloudBridge CB2.
4. CB2 sends the compressed data to Branch Repeater BR2 for decompression.
5. BR2 decompresses the data and sends it to CloudBridge CB2.
6. CloudBridge CB2 forwards the data.

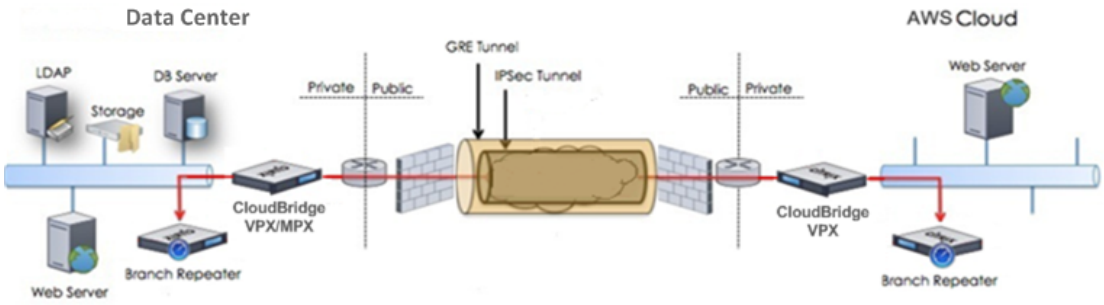
CloudBridge Topologies

You can deploy CloudBridge for seamless connectivity between CloudBridge VPX instances in the data center and in an AWS cloud, between two CloudBridge VPX instances in two different VPCs in AWS clouds, or between two CloudBridge instances in two different data centers. The advantage of CloudBridge is that you can leverage the resources between two locations for optimal use and performance.

Amazon Web Services provides a highly reliable, scalable, secure, low-cost infrastructure platform in the cloud. You can leverage AWS to run and deploy applications without having to wait for the infrastructure to be set up. AWS provides flexibility in your choice of a platform and development language. You can install any platform and programming model that meets your business requirement. Once the deployment is complete, all the applications and services hosted on the cloud appear local to the user.

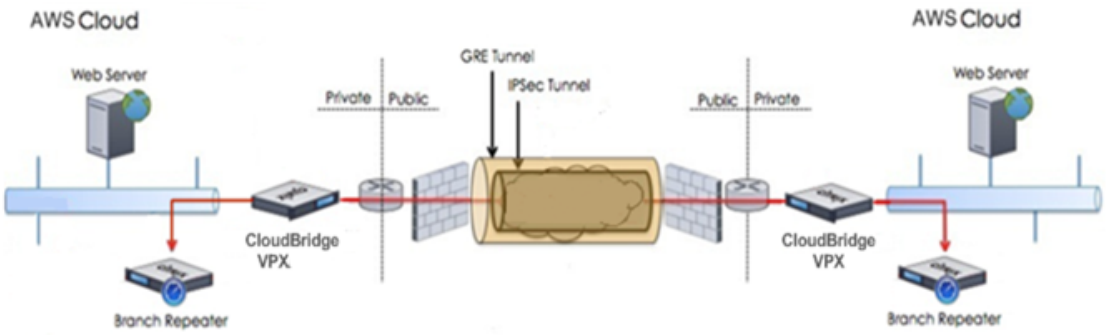
Between Data Center and AWS

You can connect your data center to AWS or AWS to data center by using CloudBridge to leverage the infrastructure and computing capabilities of the data center and the AWS cloud. With AWS, you can extend your network without initial capital investment or the cost of maintaining the extended network infrastructure. You can scale your infrastructure up or down, as required. For example, you can lease more server capabilities when the demand increases.



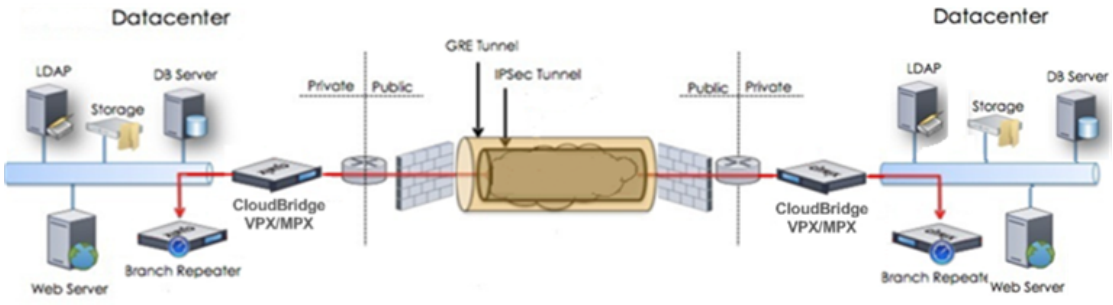
AWS to AWS

You can deploy a CloudBridge between two CloudBridge VPX instances/MPX appliances in two different VPCs in AWS cloud to implement redundancy and failure protection. This setup helps in optimal utilization of infrastructure and resources across the two AWS clouds. This deployment is primarily used to provide backup for the applications and services running in one cloud instance.



Data Center to Data Center

You can deploy a CloudBridge between two CloudBridge VPX instances/MPX appliances in two different data centers to implement redundancy and failure protection. This setup helps achieve optimal utilization of infrastructure and resources across two data centers. This deployment is primarily used to provide backup for the applications and services running in one data center.



Installing NetScaler VPX on AWS

You can now launch an instance of Citrix® NetScaler VPX within Amazon Web Services (AWS). NetScaler VPX is available as an Amazon Machine Image (AMI) in AWS marketplace. NetScaler VPX on AWS enables customers to leverage AWS Cloud computing capabilities and use NetScaler load balancing and traffic management features for their business needs. NetScaler on AWS supports all the traffic management features of a physical NetScaler appliance. NetScaler instances running in AWS can be deployed as standalone instances or in HA pairs.

How NetScaler VPX on AWS Works

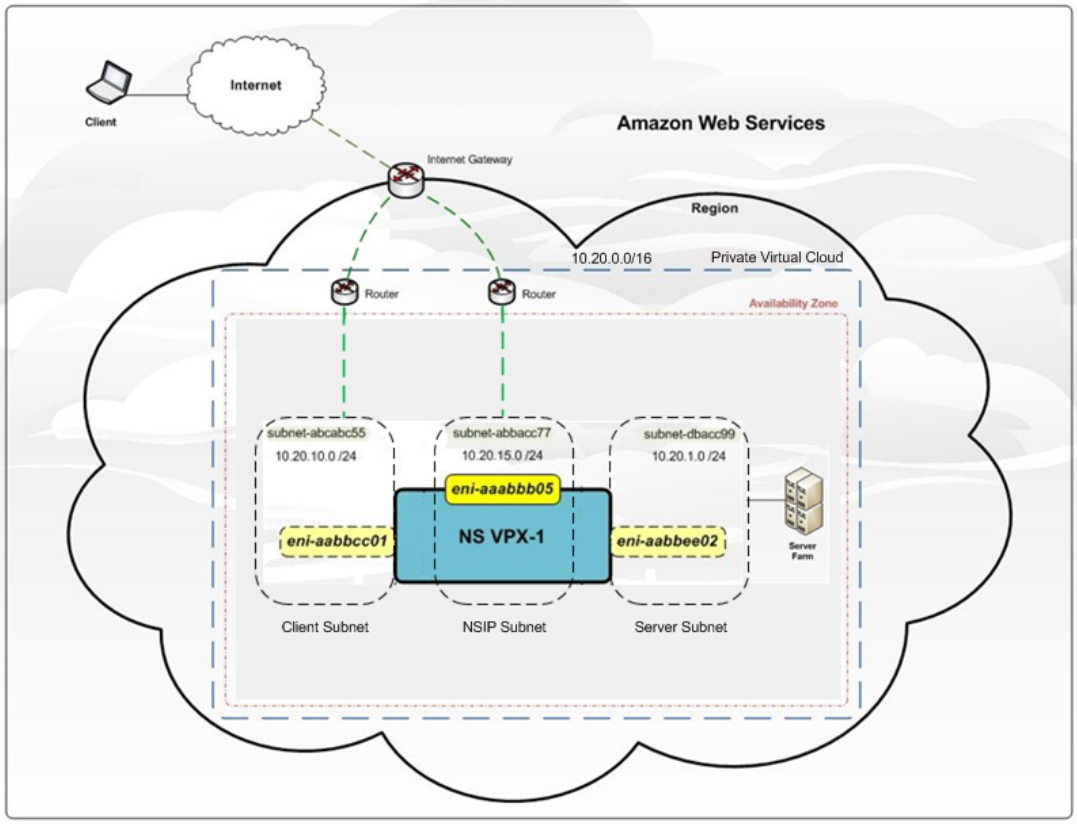
AWS offers different types of web services, such as Amazon Simple Storage Services (S3), Amazon Elastic Cloud Compute (EC2), and Amazon Virtual Private Cloud (VPC). Amazon VPC allows you to run AWS resources (for example, EC2 instances) in a private, virtual network. Amazon EC2 instances are available as instance types that map to hardware archetypes on the basis of factors such as number of EC2 Compute Units (ECU), number of virtual cores, and memory size.

The NetScaler VPX AMI is packaged as an EC2 instance that is launched within an AWS VPC. The VPX AMI instance requires a minimum of 2 virtual CPUs and 2 GB of memory. An EC2 instance launched within an AWS VPC can also provide the multiple interfaces, multiple IP addresses per interface, and public and private IP addresses needed for VPX configuration. Currently, on Amazon AWS, VPX can be launched only within a VPC, because each VPX instance requires at least three IP addresses. (Although VPX on AWS can be implemented with one or two elastic network interfaces, Citrix recommends three network interfaces for a standard VPX on AWS installation.) AWS currently makes multi-IP functionality available only to instances running within an AWS VPC. A VPX instance in a VPC can be used to load balance servers running in EC2 instances.

An Amazon VPC allows you to create and control a virtual networking environment, including your own IP address range, subnets, route tables, and network gateways.

Note: By default, you can create up to 5 VPC instances per AWS region for each AWS account. You can request higher VPC limits by submitting Amazon's request form (http://aws.amazon.com/contact-us/vpc-request/).

VPX on AWS Architecture



An EC2 instance of NetScaler VPX (AMI image) is launched within the AWS VPC. The following figure shows a typical VPX on AWS deployment.Figure 1. VPX on AWS Architecture

The figure shows a simple topology of an AWS VPC with a NetScalerVPX deployment. The AWS VPC has:

1. A single Internet gateway to route traffic in and out of the VPC.
2. Network connectivity between the Internet gateway and the Internet.
3. Three subnets, one each for management, client, and server.
4. Network connectivity between the Internet gateway and the two subnets (management and client).
5. A single NetScaler VPX deployed within the VPC. The VPX instance has three Elastic Network Interfaces (ENIs), one attached to each subnet.

Supported EC2 instances

The NetScaler AMI can be launched on any of the following EC2 instance types:

- m1.large

- m1.xlarge

For more information about Amazon EC2 instances, see:
http://docs.amazonwebservices.com/AWSEC2/latest/UserGuide/instance-types.html

ENI Support

The following table lists the EC2 instance types and corresponding number of supported ENIs and number of private IP addresses per ENI.

Table 1. EC2 Support for ENIs and IP Addresses

Instance Name	Number of ENIs	Private IP Addresses per ENI
m1.large	3	10
m1.xlarge	4	15

Limitations and Usage Guidelines

- The clustering feature is not supported for VPX.
- For HA to work as expected, associate a dedicated NATing device to management Interface or associate EIP to NSIP. For more information on NAT, in the AWS documentation, see NAT Instances.
- Data traffic and management traffic should be segregated by using ENIs belonging to different subnets.
- Only the NSIP address should be present on the management ENI.
- If a NAT instance is used for security instead of assigning an EIP to the NSIP, appropriate VPC level routing changes are required. For instructions on making VPC level routing changes, in the AWS documentation, see "Scenario 2: VPC with Public and Private Subnets."
- A VPX instance can be moved from one EC2 instance type to another (for example, from m1.large to an m1.xlarge).
- For storage options for VPX on AWS, Citrix recommends EBS, because it is durable and the data is available even after it is detached from instance.
- Dynamic addition of ENIs to VPX is not supported. You have to restart the VPX instance to apply the update. Citrix recommends you to stop the standalone or HA instance, attach the new ENI, and then restart the instance.
- You can assign multiple IP addresses to an ENI. The maximum number of IP addresses per ENI is determined by the EC2 instance type, see EC2 Support for ENIs and IP Addresses.
- Citrix recommends that you avoid using the enable and disable interface commands on NetScaler VPX interfaces.
- Due to Amazon AWS limitations, these features are not supported:
  - IPV6
  - Gratuitous ARP(GARP)
  - L2 mode
  - Tagged VLAN
  - Dynamic Routing
  - Virtual MAC (VMAC)

Launching the NetScaler VPX for AWS AMI

You can launch a Citrix NetScaler VPX AMI within an Amazon Web Services (AWS) Virtual Private Cloud (VPC) in one of two ways:

1. Using the Amazon GUI and CLI toolkit.
2. Using a Citrix authored CloudFormation template.
3. Using the Amazon 1-Click launch.

Launching NetScaler VPX for AWS by Using the Amazon GUI and CLI toolkit

To launch a NetScaler VPX AMI within an Amazon Web Services (AWS) Virtual Private Cloud (VPC) by using the Amazon GUI and CLI toolkit, you need:

- An AWS account
- An AWS Virtual Private cloud (VPC)
- The AWS API toolkit (if creating a VPX instance with three or more ENIs).
- An IAM account

Creating an AWS Account

To launch a NetScaler VPX AMI in an Amazon Web Services (AWS) Virtual Private Cloud (VPC), you need an AWS account. You can create an AWS account for free at www.aws.amazon.com.

Creating an AWS Virtual Private Cloud (VPC)

Citrix recommends at least three IP addresses for a NetScaler instance. Currently, the only support that AWS provides for instances with multiple IP addresses is for instances within an AWS VPC.

To create an AWS VPC, first launch the AWS GUI console. For instructions for using the AWS GUI console, see http://docs.amazonwebservices.com/AmazonVPC/latest/GettingStartedGuide/GetStarted.html?r=2900.

To create an AWS VPC

1. Use the VPC with a Single Public Subnet Only option to create a new AWS VPC in an AWS availability zone.
2. Create additional subnets within the AWS VPC. Citrix recommends that you create at least three subnets, of the following types:
   - One subnet for NetScaler management traffic. You place the NetScaler management IP(NSIP) on this subnet.
   - One or more subnets for client-access (user-to-NetScaler) traffic, through which clients connect to one or more virtual IP (VIP) addresses assigned to NetScaler load balancing virtual servers.

- One or more subnets for the server-access (NetScaler-to-server) traffic, through which your servers connect to NetScaler-owned subnet IP (SNIP) addresses.

  For more information about NetScaler load balancing and virtual servers, virtual IP addresses (VIPs), and subnet IP addresses (SNIPs), see: .

Note:

- All subnets should be in the same availability zone.
- You can launch a NetScaler AMI in an AWS VPC with a single subnet. In this configuration, the management traffic, client-side traffic, and server-side traffic all use the same subnet, and high availability (HA) cannot be configured.
- You can launch the NetScaler AMI into an AWS VPC with two subnets. In this configuration, one subnet is used for management traffic, and the other subnet is used for both client-side and server-side traffic. This topology supports NetScaler HA.

3. Create an Internet gateway and attach it to the VPC instance.
4. Create routing tables for all traffic flowing into or out of the VPC. You need routes for access to the NSIP and to any client-facing VIP addresses. Traffic leaving the VPC must be routed through the Internet Gateway of the AWS VPC.

   Note:

   - Make sure that you associate management and client subnets with the routing table.
   - Add a default route to the routing table for the traffic flowing out of the VPC. Set the Destination to 0.0.0.0/0, and the Target as the Internet gateway address.
5. Create a security group and open the required ports.

Setting-up the AWS API Toolkit

The AWS GUI console does not allow you to launch instances with more than two ENIs. For a standard deployment, you have to create at least three ENIs for a VPC instance (though it is possible to launch a NetScaler AMI with one or two ENIs). To create three or more ENIs for a NetScaler instance, you must use the AWS CLI. To use the AWS CLI, you must install the AWS API toolkit.

The AWS API toolkit is available for download at http://aws.amazon.com/developertools/351/. To install the AWS API toolkit, complete the following tasks on a Windows or Linux machine:

1. Download the AWS API Toolkit.
2. Download X.509 certificate files and X.509 private key file.
3. Download the private key.
4. Convert the downloaded private key (.pem file) for SSH connectivity.
5. Configure the AWS API Toolkit environment on your Windows or Linux computer.

To download the AWS API toolkit

1. In a web browser, open the following website: http://aws.amazon.com/developertools/351/.
2. On the Amazon EC2 API Tools page, in the Download section, click Download the Amazon EC2 API Tools.
3. Save the file, ec2-api-tools.zip, to a local disk and use a file compression utility (for example, WinZip) to extract the files.

To download the X.509 certificate file and X.509 private key file

1. In your browser, open the following website: http://aws.amazon.com/.
2. Click My Account/Console, and then click Security Credentials.
3. On the Amazon Web Services Sign in page, use your Amazon account credentials to sign in.
4. On the Security Credentials page, in the Access Credentials section, on the X.509 Certificates tab, click Create a New Certificate.
5. In the X509 Certificate Created dialog box, Click Download Private Key File and save the private key file to a secure folder on your local drive.
6. Click Download X.509 Certificate and save the certificate to a secure folder on your local drive.
7. Click Close.

Note: The Private Key File can be downloaded only at the time of creating a certificate. However, you can download the certificate at any time after creating it.

To download private key for SSH connectivity

1. In your browser, open the following website:http://aws.amazon.com/ .
2. Click **My Account/Console.**
3. On the **Amazon Web Services Sign in** page, use your Amazon account credentials to sign in.
4. In the **Service** pane, in **Amazon Web Services**, click **EC2**.
5. In the **Navigation** section, in **Network and Security**, click **Key Pairs**.
6. In the **Key Pairs** pane, click **Create Key Pair**.
7. In the **Create Key Pair** dialog box, type the name for key pair and click **Create**.
8. Download the Key Pair to the local disk and click **Close**.

To convert the downloaded private key for SSH connectivity

For SSH connections from a management machine using Putty, you must convert the .pem file (Private Key) into .ppk file. The .ppk file is the private key for SSH connections to the NetScaler VPX instance hosted in the AWS environment. To convert the .pem file

to a .ppk file, use the Putty application's PuttyGen utility. Make sure that the key pairs and certificate files are stored in an unshared and secured directory. After the conversion, you can use SSH to securely connect to the management address of the VPX on AWS instance.

To configure the AWS API Toolkit environment on a Windows machine

1. Move the certificate files to an unshared folder (for example, aws-ec2-api-tools).

2. Move the extracted AWS API toolkit folder to the unshared folder (for example, the aws-ec2-api-tools folder created in example in Step 1).

3. Create a batch file to configure the specific AWS environment in the unshared folder (aws-ec2-api-tools if you used the example in the preceding two steps). Following is an example of the batch file. The file location used in this example is C:\aws-vpc-config\ and the file name is set-aws-environment.bat.

   ```
   rem Setup Amazon EC2 Command-Line Tools

   set JAVA_HOME="C:\Program Files\Java\jre7\"

   set EC2_HOME="C:\aws-ec2-api-tools\"

   set PATH=%PATH%;%EC2_HOME%\bin

   set EC2_PRIVATE_KEY=C:\aws-ec2-security-files\pk-3T6ACCLBEDGD3O3
   SMAM7YDI76VP5HXSU.pem

   set EC2_CERT=C:\aws-ec2-security-files\cert-3T6ACCLBEDGD3O3SMAM7
   YDI76VP5HXSU.pem

   set EC2_URL=https://<aws-region>.ec2.amazonaws.com
   ```

4. Open the command prompt and run the batch file. For the file in the above example, type:

   ```
   C:\aws-vpc-config> set-aws-environment.bat
   ```

5. Run the ec2ver command to verify that the AWS toolkit is installed properly. For example:

   ```
   C:\aws-vpc-config>ec2ver 1.5.6.1 2012-06-15
   ```

To configure the AWS API Toolkit on a Linux machine

1. Move the certificate files to an unshared folder (for example, aws-ec2-api-tools).

2. Move the extracted AWS API toolkit folder to the unshared folder (for example, the aws-ec2-api-tools folder created in example in Step 1).

3. Create a shell script to configure the specific AWS environment in the unshared folder (aws-ec2-api-tools if you used the example in the preceding two steps). Following is an example of the batch file. In this example, the file location used is C:\aws-vpc-config\ and the file name used is set-aws-environment.bat.

   ```
   # Setup Amazon EC2 Command-Line Tools
   ```

```
export EC2_HOME=~/ec2-api-tools-1.5.6.0

export EC2_URL= https://us-east-1.ec2.amazonaws.com

export
PATH=$EC2_HOME/bin:/usr/bin:$/usr/sbin:/usr/local/sbin:/sbin

export EC2_PRIVATE_KEY=~/pk-XOX3NS2UPZL6BGLFO7PM5OGLYBDPBUCB.pem

export EC2_CERT=~/cert-XOX3NS2UPZL6BGLFO7PM5OGLYBDPBUCB.pem

export JAVA_HOME=/usr

export PS1="AWS PROMPT >"
```

4. Run the ec2ver command to verify that the AWS toolkit is installed properly. For example:

```
AWS PROMPT >ec2ver

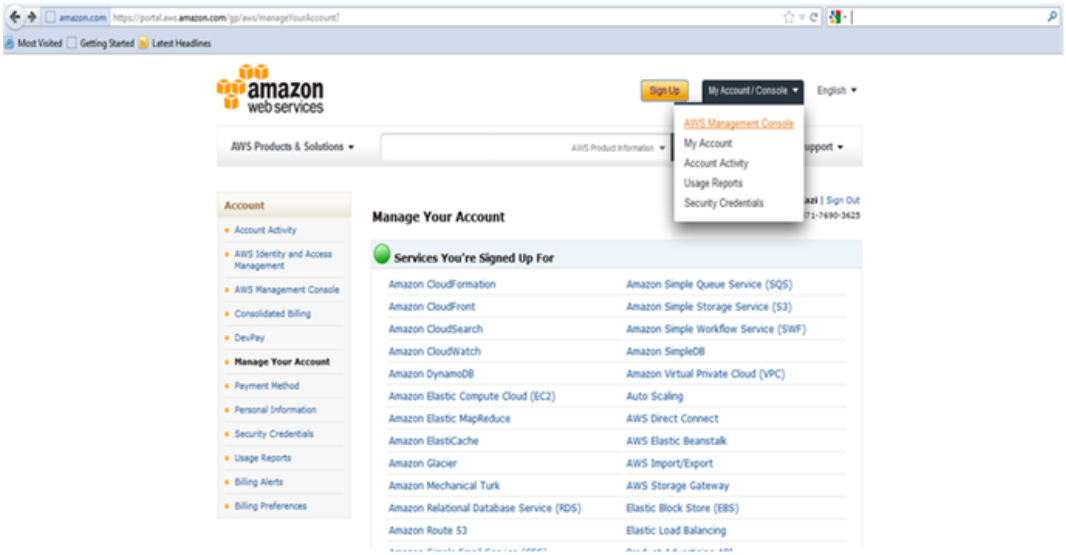
1.5.6.1 2012-06-15
```

Creating an IAM Account

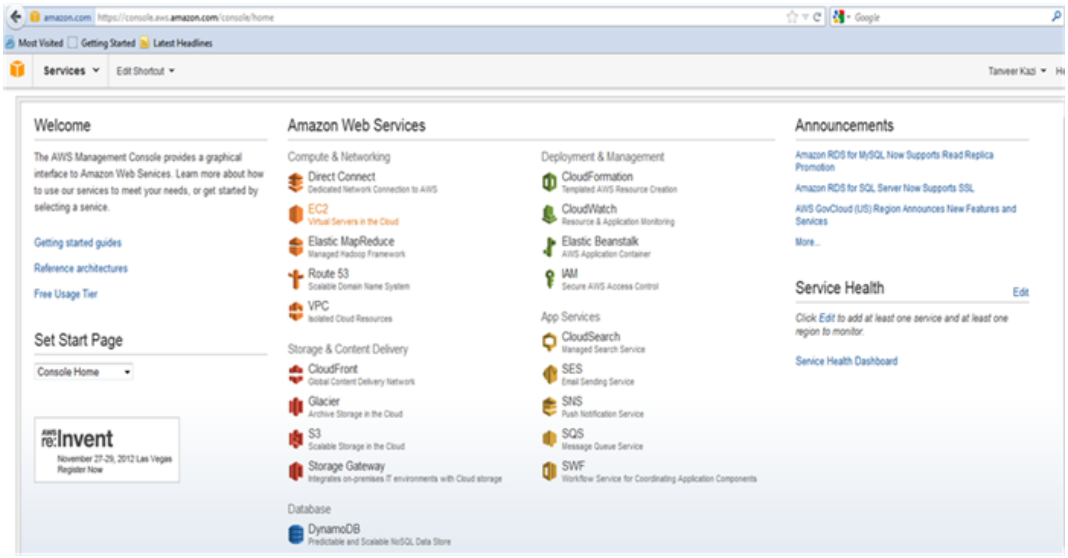
Before you launch the VPX AMI instance, you have to create a new IAM user account with the Access and Secret keys. The Access and Secret key credentials from the new IAM user are required for launching the NetScaler AMI instance. To create a new IAM user for NetScaler, complete the following steps.

1. 

   In a web browser, open the website at www.aws.amazon.com and log on with AWS credentials.
2. Click My Account/Console, and then click AWS Management Console.

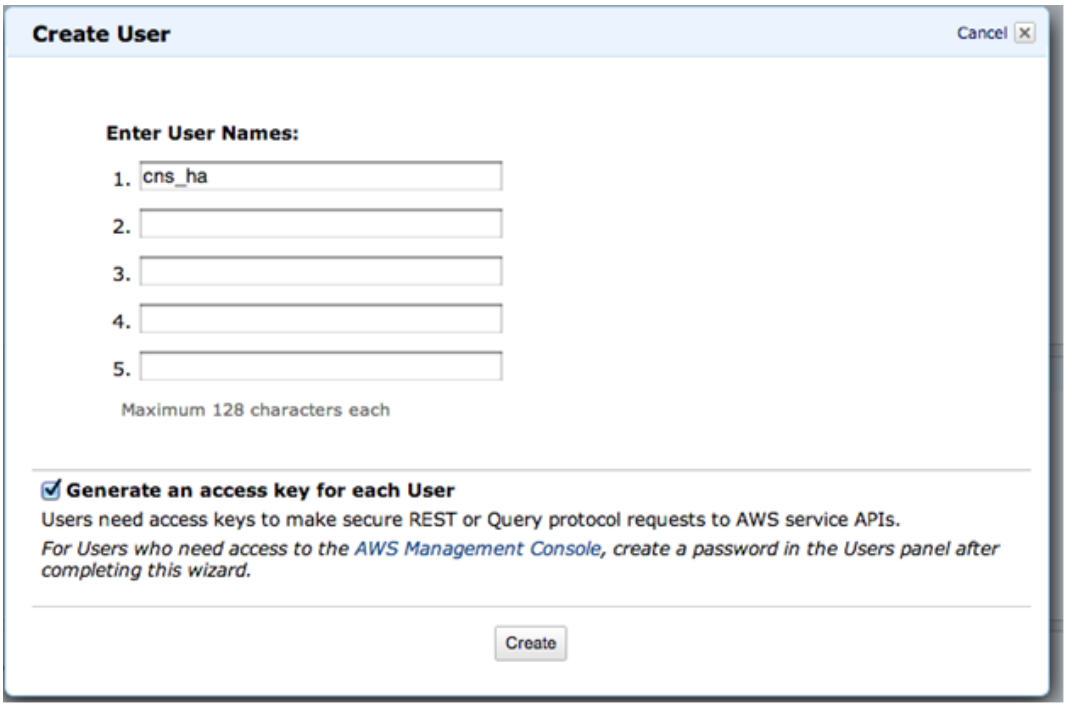


3. On the Amazon Web Services page, click IAM.



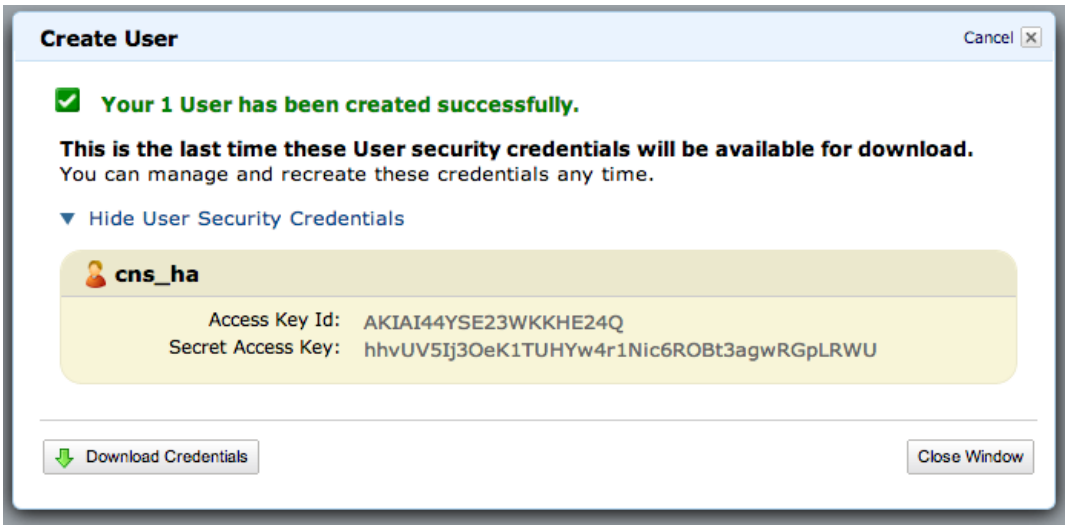
4. 
In the Navigation pane, click Users, and then click Create New Users.

5. In the Create User dialog box, in one of the Enter User Names text boxes, type a user name (for example, cns_ha). Also select the Generate an access key for each User check box, and then click Create.

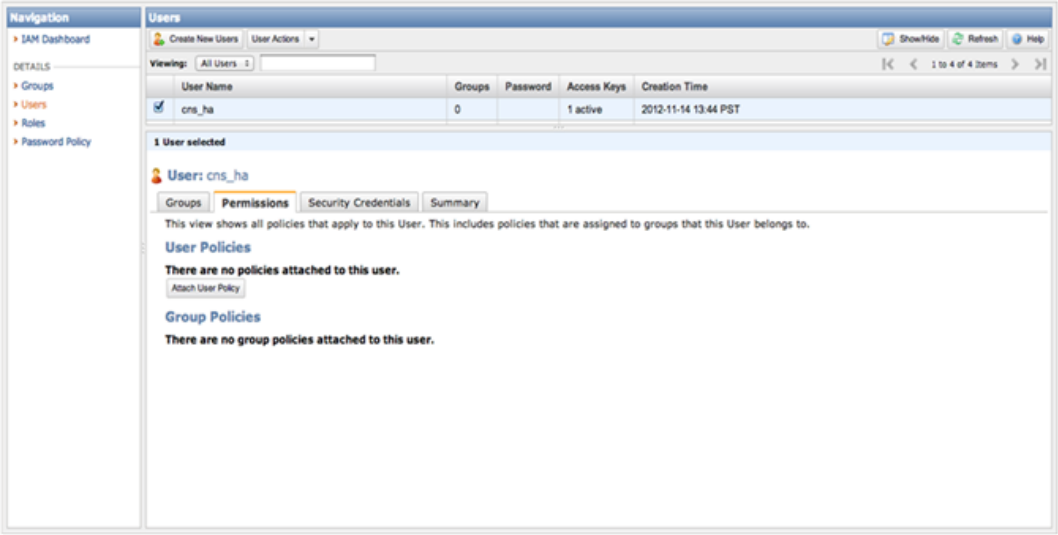


6. After a new IAM user is created, click Download Credentials to download the Access and Secret Keys to a safe location. These keys are required for launching NetScaler AMI. Click Close.

   Note: The Access Key ID and Secret Access Key values are used to create the key-pair file and to launch an instance.

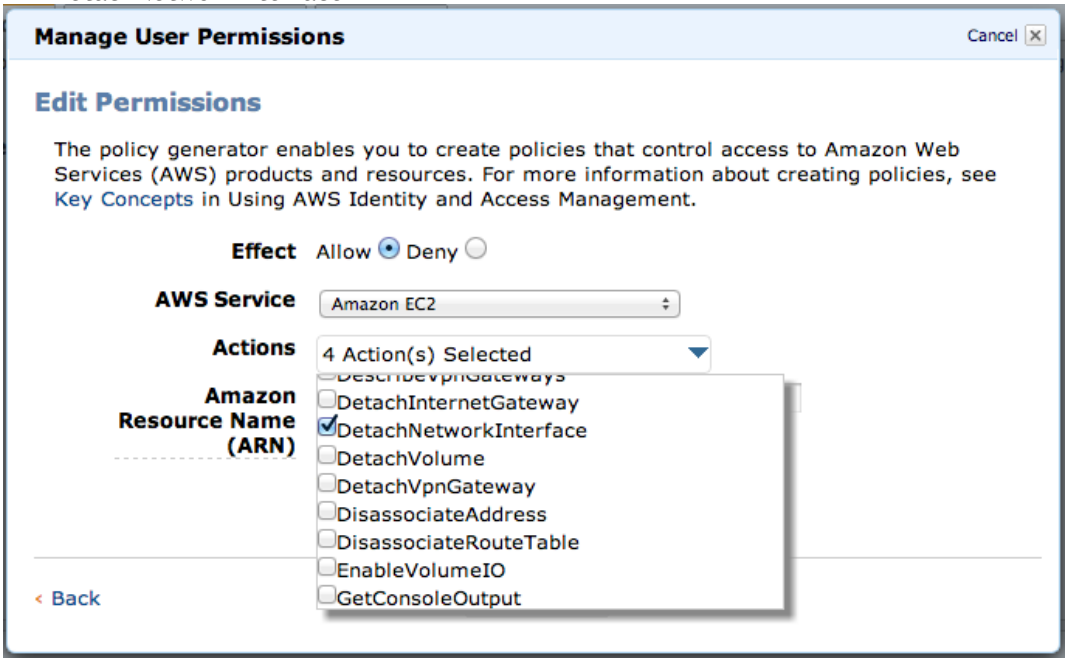


7. In the Users pane, select the newly created IAM user and click the Permissions tab. Then, click Attach User Policy to set policies for the user.

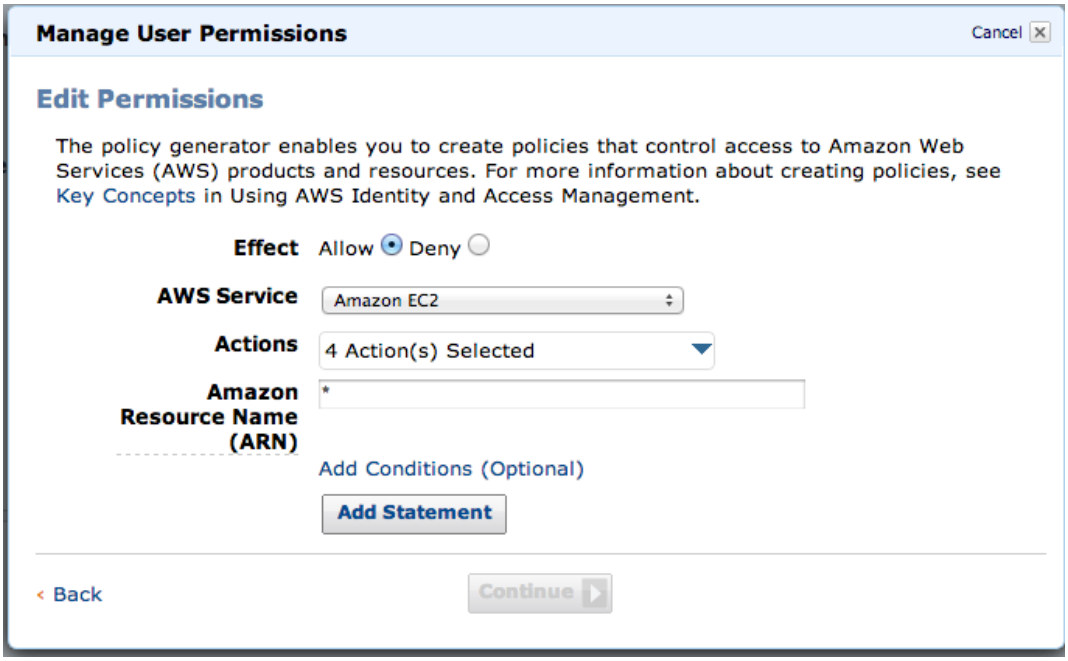


8. In the Manage User Permissions dialog box, next to Effect, select the Allow option. For AWS Service, select Amazon EC2. From the Actions drop-down list, select the following four actions:

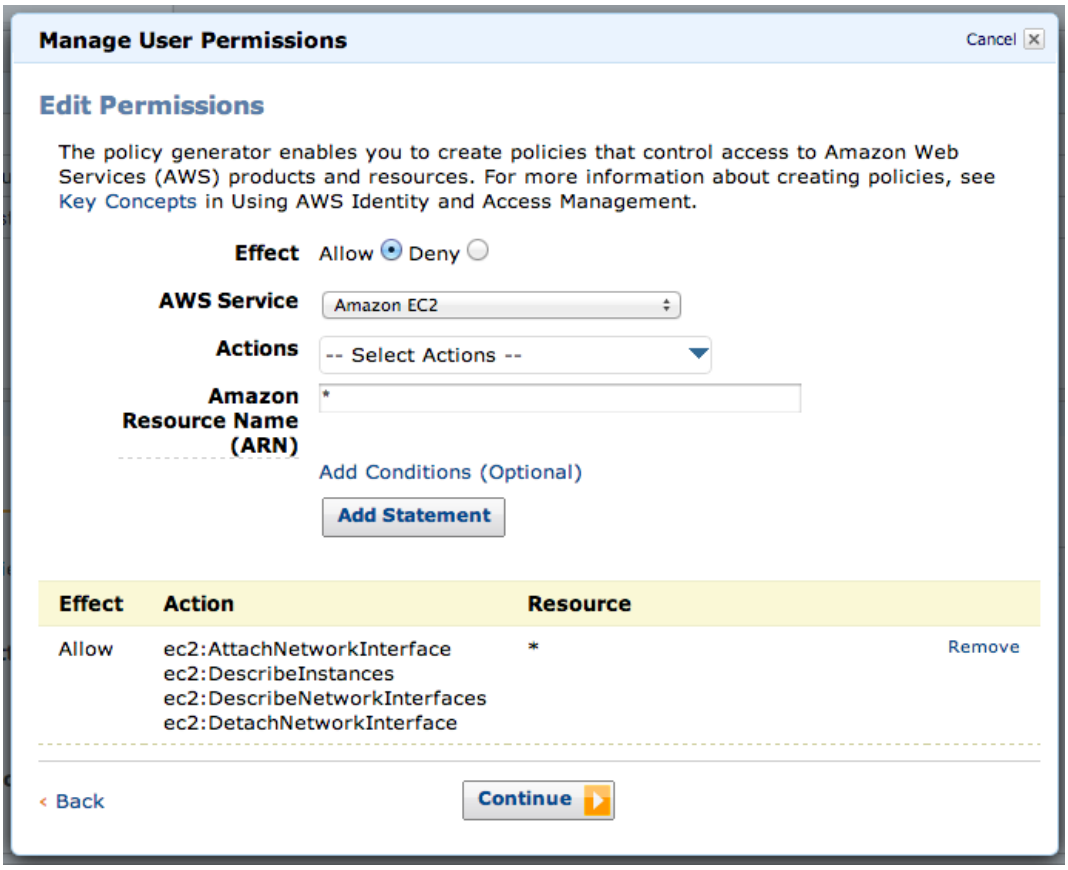
   - AttachNetworkInterface
   - DescribeInstances
   - DescribeNetworkInterfaces
   - DetachNetworkInterface



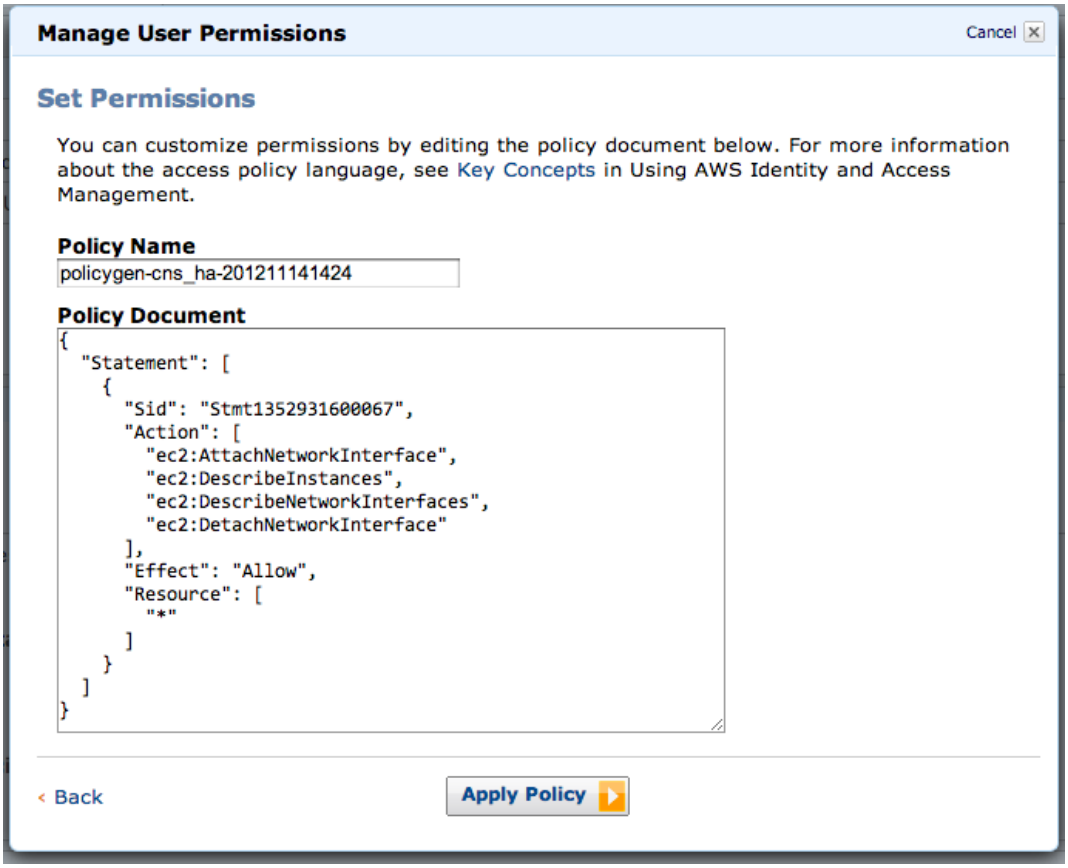
9. Click Add Statement.



10. Click Continue.



11. Click Apply Policy to set the new permissions for the selected user.



Launching the NetScaler AMI

Use the AWS CLI to launch the NetScaler AMI in an AWS VPC. Use the ec2-run-instances command. For information about the ec2-run-instances command, see http://docs.amazonwebservices.com/AWSEC2/latest/CommandLineReference/ApiReference-cmd-RunInstances.html.

Following are Windows and Linux examples of running the command to launch a single NetScaler instance. The EC2 instance type is m1.large. It is configured with the following entities:

- NetScaler AMI named ami-bd2986d4.
- Three ENIs (named NSIP, CLIENT-SIDE, and SERVER-SIDE) associated with the three subnets (15fa057e, 1547ba7e, and 1547ba7e) within the VPC.
- A single IP address for the NSIP ENI.
- Multiple private IP addresses (for multiple VIPs) on the CLIENT-SIDE ENI.
- Multiple private IPs (for multiple SNIPs) on the SERVER-SIDE ENI.

On a Windows platform:

```
C:\aws-vpc-config>ec2-run-instances ami-bd2986d4 -n 1 -t m1.large -k keyPairName -f
keyPairFile -a :0:subnet-15fa057e:"NSIP":10.20.15.21 -a :1:subnet-1547ba7e:"CLIENT-SIDE
```

":10.20.10.21::::"10.20.10.22,10.20.10.23,10.20.10.24,10.20.10.25,10.20.10.26,10.20.10.27,10.20.10.28,10.20.10.29,10.20.10.30" -a :2:subnet-cc47baa7:"SERVER-SIDE":10.20.1.21::::"10.20.1.22,10.20.1.23,10.20.1.24,10.20.1.25,10.20.1.26,10.20.1.27,10.20.1.28,10.20.1.29,10.20.1.30"

Note: The keyPairFile file contains the access and secret keys.

On a Linux platform:

AWS PROMPT > ec2-run-instances ami-bd2986d4 -n 1 -t m1.large -k keyPairName -f keyPairFile -a :0:subnet-15fa057e:"NSIP":10.20.15.21 -a :1:subnet-1547ba7e:"CLIENT-SIDE":10.20.10.21::::10.20.10.22,10.20.10.23,10.20.10.24,10.20.10.25,10.20.10.26,10.20.10.27,10.20.10.28,10.20.10.29,10.20.10.30 -a :2:subnet-cc47baa7:"SERVER-SIDE":10.20.1.21::::10.20.1.22,10.20.1.23,10.20.1.24,10.20.1.25,10.20.1.26,10.20.1.27,10.20.1.28,10.20.1.29,10.20.1.30

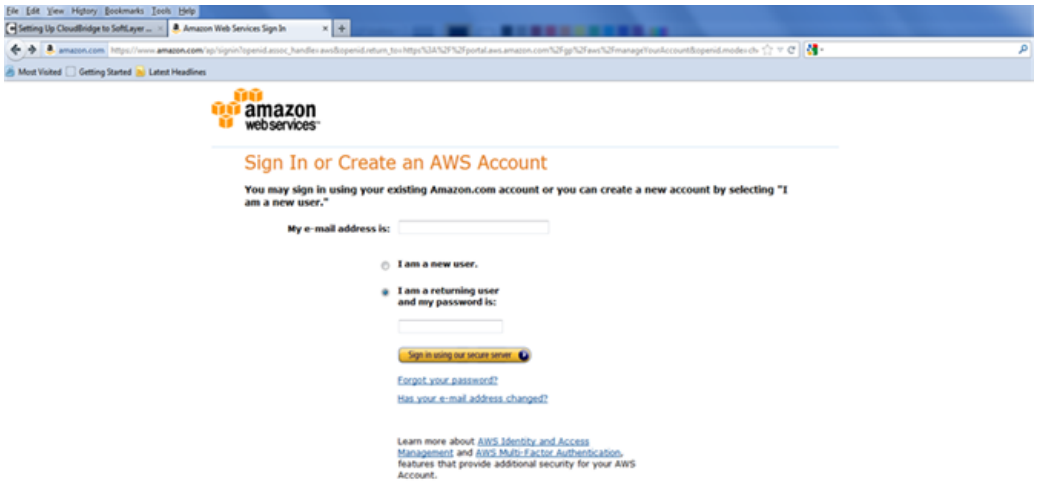
Note: The keyPairFile file contains the access and secret keys.

The command returns the instance ID and the associated information. You can see the instance running within your AWS GUI Console.

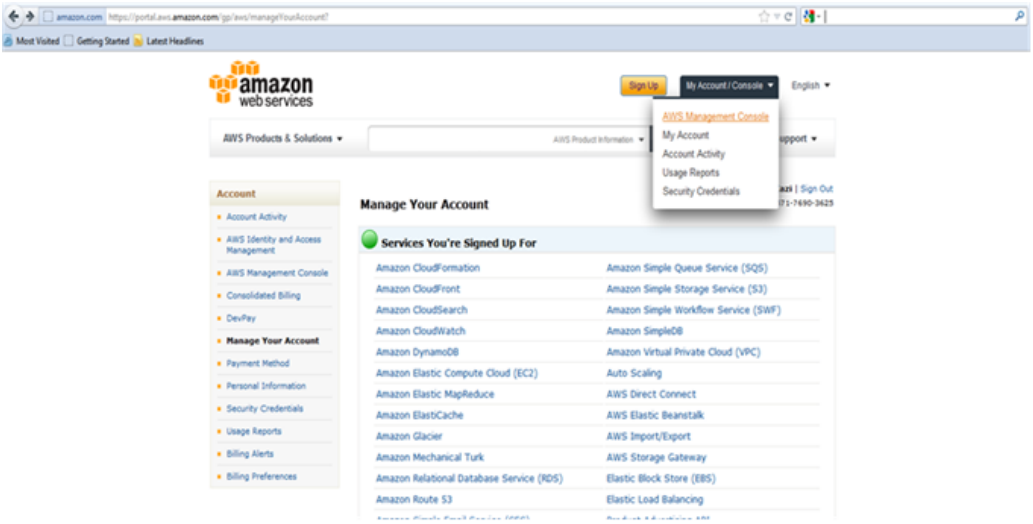
Note: Make sure that the environment variable EC2_URL points to the region where you want to launch the VPX instance.

To access the EC2 instance

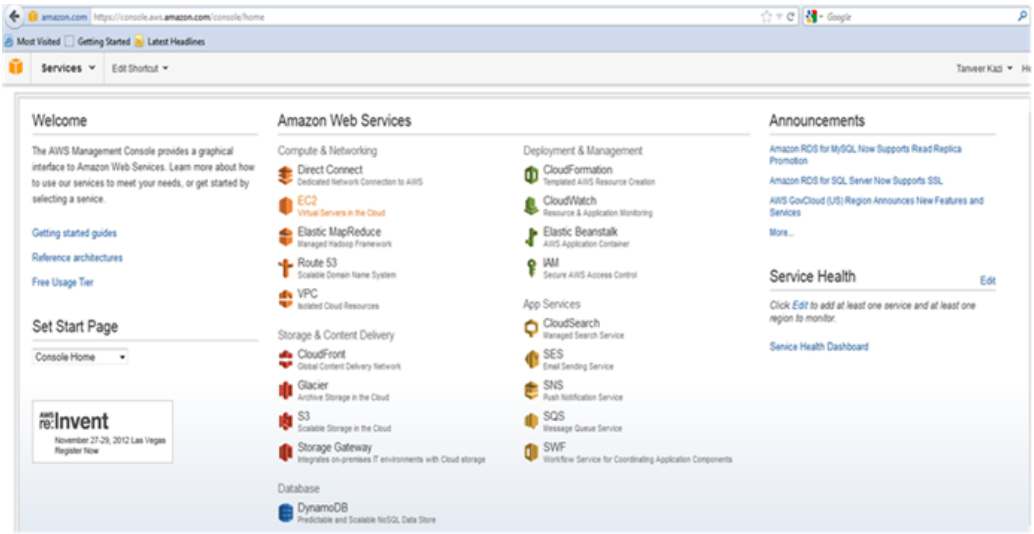
1. In a web browser, open the website at www.aws.amazon.com and log on with AWS credentials.



2. Click My Account/Console, and then click AWS Management Console.

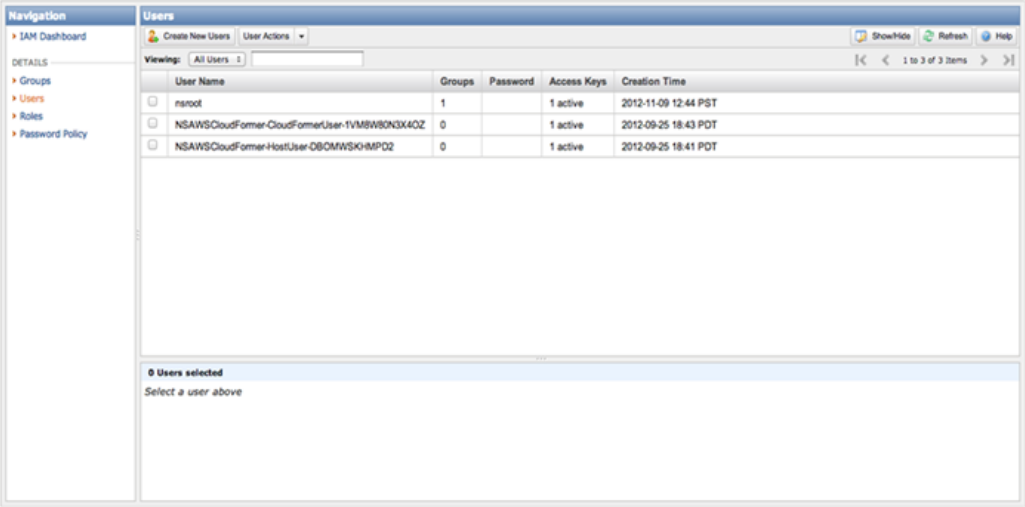


3. On the Amazon Web Services page, click EC2.



4. On the Amazon EC2 Console Dashboard page, in the Navigation pane, click Instances and verify that all of the NetScaler VPX instances are configured with the IP addresses that you specified when you used the ec2-run-instances command.

   Note: The VPX instance or instances can take from five to ten minutes to start running.



The ec2-run-instances command does not allow associating AWS elastic IP with an ENI. To associate one or more EIPs with an ENI in the Navigation pane, in the NETWORK & SECURITY area, click Elastic IPs and associate EIPs with Private IP addresses for any of the VIPs that need to be externally routable.

You must also associate the instance ENIs with appropriate security groups. Go to the Network Interfaces section, right-click on the individual ENI, and select the Change Security Groups option. You can then associate a proper VPC security group.

Using the Citrix CloudFormation Template to launch CloudBridge VPX for AWS

Using the Citrix Cloud Formation Template to launch NetScaler VPX for AWS

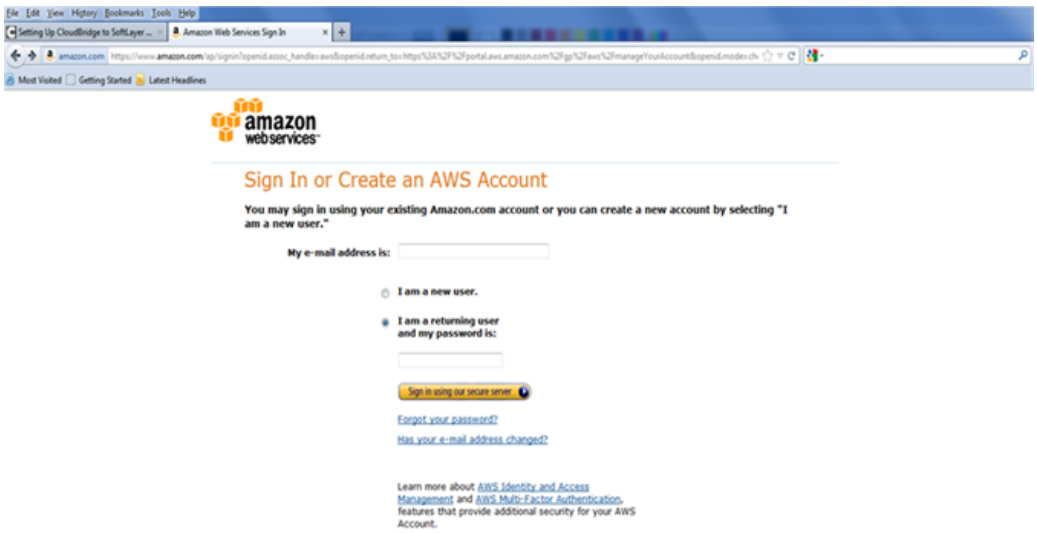
Citrix also provides a CloudFormation template that can be used to automate NetScaler instance launch. The tool requires an existing VPC environment. It launches a NetScaler instance with three ENIs. Therefore, to use the CloudFormation template, make sure that you have the following:

1. AWS account
2. AWS VPC
3. Three subnets within the VPC
4. A security group to use for the NetScaler instances ENIs

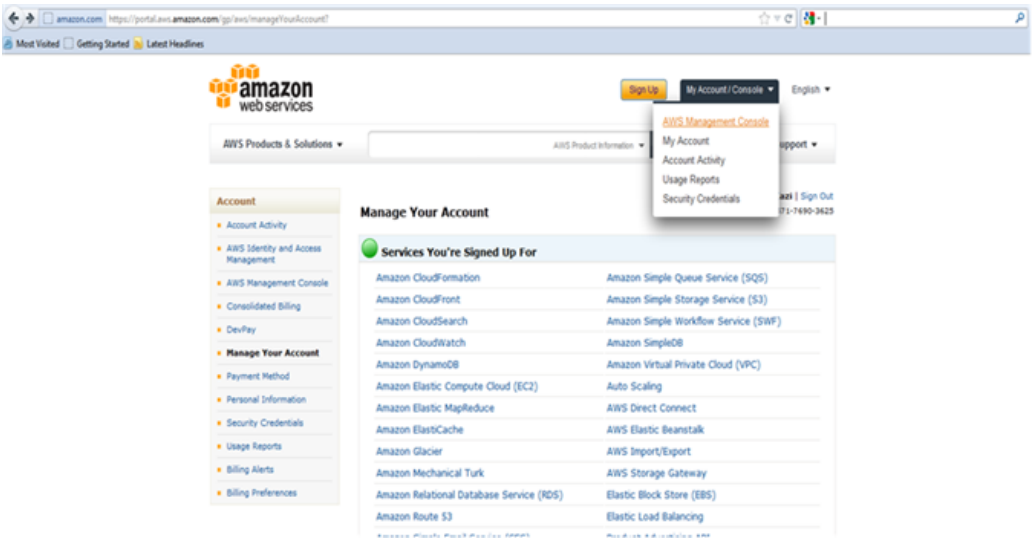
Refer to Creating an AWS Virtual Private Cloud (VPC) for information about how to configure subnets and security groups within a VPC. After configuring the required subnets and security groups, you can launch the NetScaler VPX AMI in AWS VPC. The CloudFormation tool provides functionality to launch a single NetScaler VPX instance or, to create a high availability environment, a pair of NetScaler VPX instances.

Launching a single NetScaler VPX instance in AWS

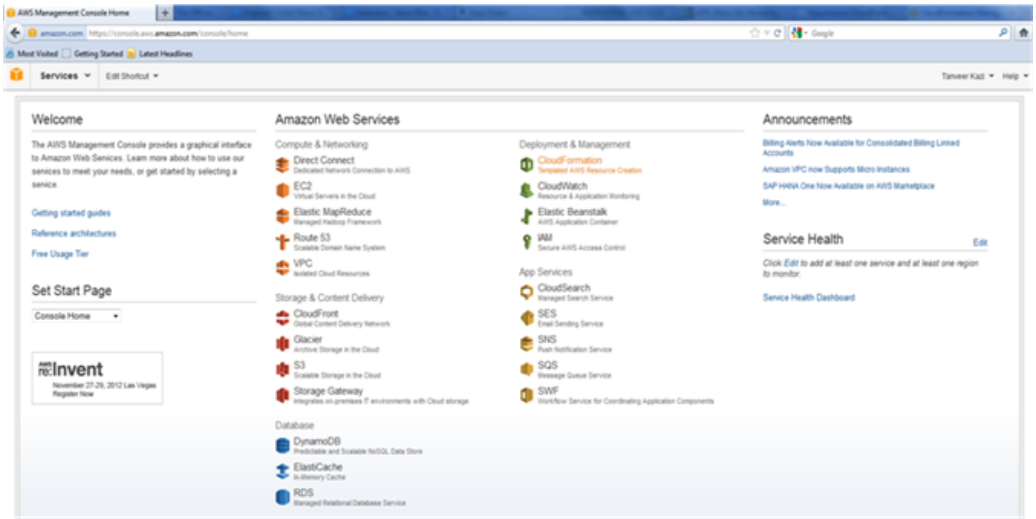
1. In a web browser, open the website at www.aws.amazon.comand log on with AWS credentials.



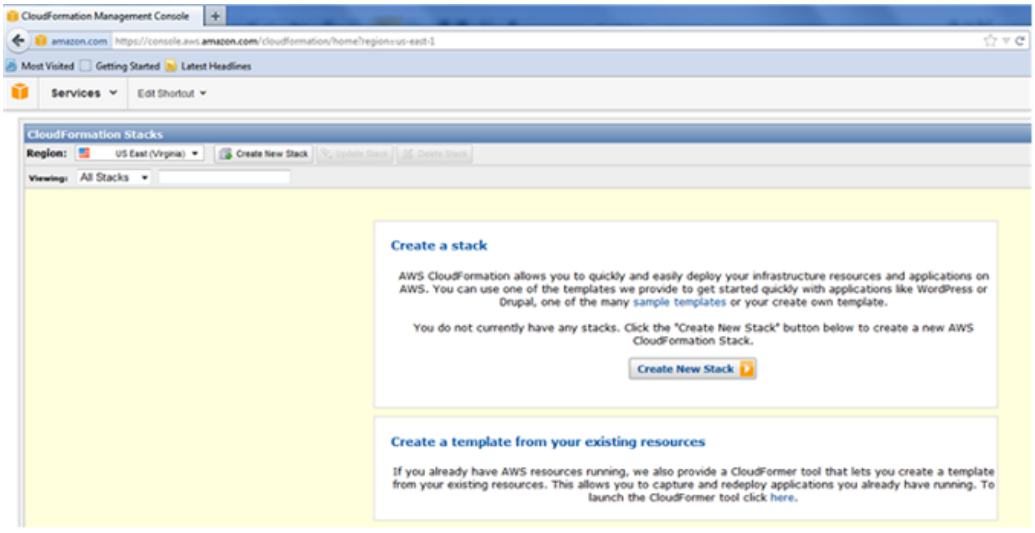
2. Click My Account/Console, and then click AWS Management Console.



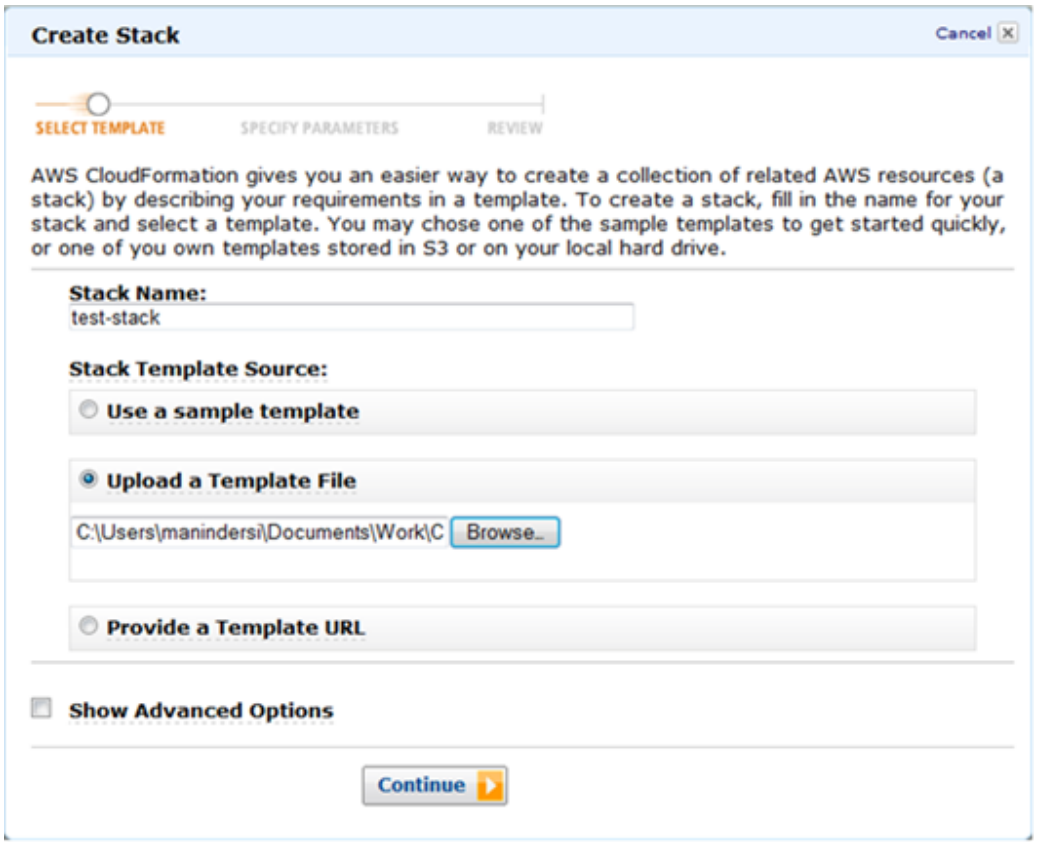
3. On the Amazon Web Services page, click Cloud Formation in the Deployment & Management section.



4. On the CloudFormation Stacks page, select the Region in which you plan to deploy the NetScaler VPX instance, and then click Create New Stack.



5. In the Create Stack dialog box, specify a value for Stack Name, select the Upload a Template File option, and then click Browse. Select the template for a standalone NetScaler VPX from the local drive, and then click Continue.



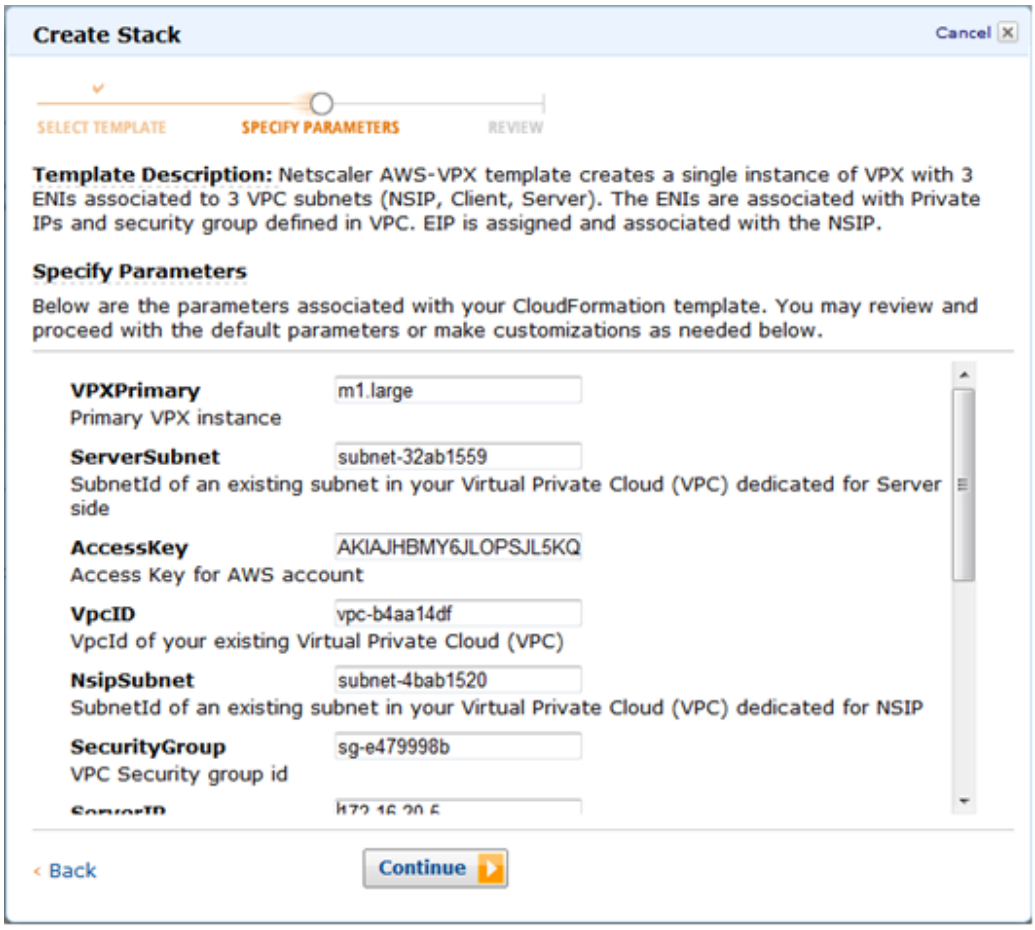
Note:

6. In the next pane, specify values for:

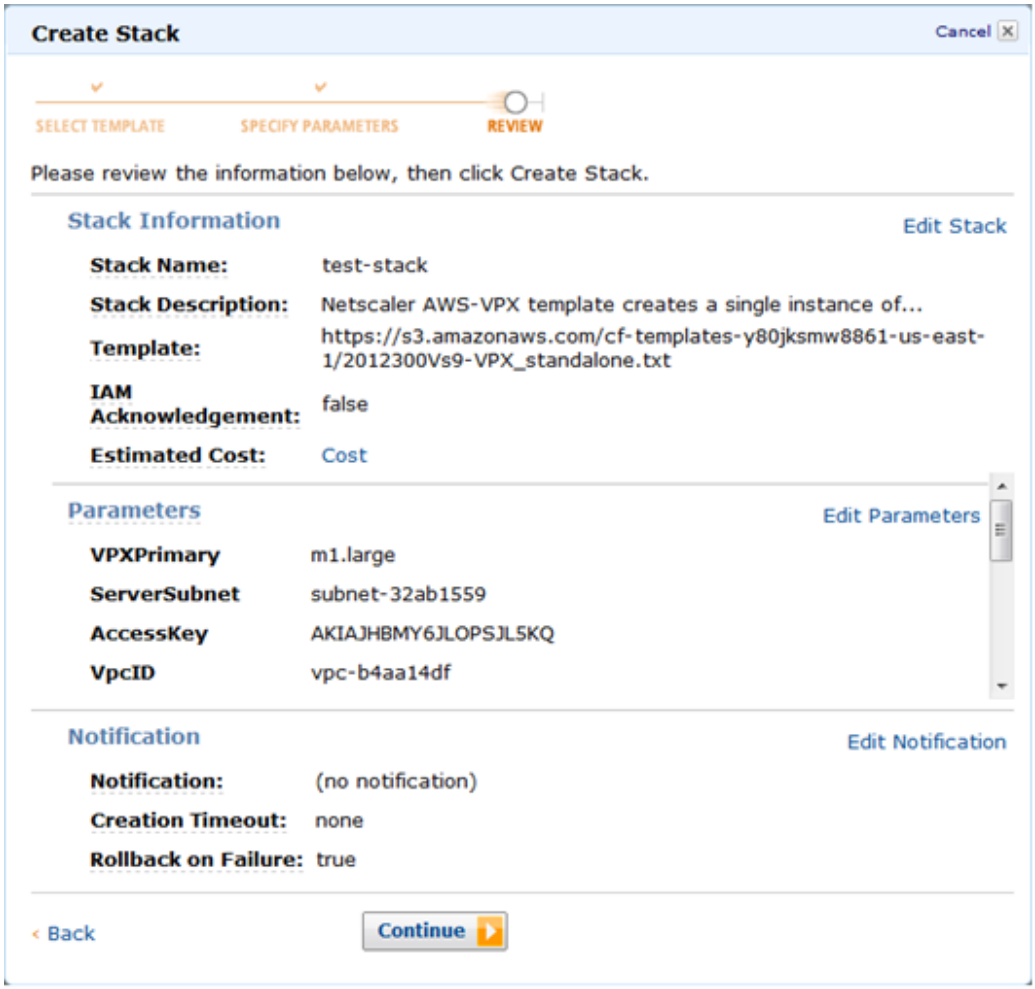
   - **VpcID** : An identifier to assign to the Virtual Private Cloud (VPC).
   - **NsipSubnet** : Subnet in which the NSIP is configured in the VPC
   - **ServerSubnet**: Subnet in which the server farm is configured in the VPC
   - **ClientSubnet**: SubnetId in which the client side is configured in the VPC
   - **SecurityGroup**: VPC Security group ID
   - **VPXPrimary**: Name of the primary VPX instance type
   - **AccessKey**: Access Key for IAM user account
   - **SecretKey**: Secret Key for IAM user account
   - **TenancyType**: Instance tenancy type, can be default or dedicated
   - **NsIP**: Private IP assigned to the NSIP ENI. The last octet of NSIP should be between 5 and 254.

- **ServerIP**: Private IP assigned to the Server ENI. The last octet should be between 5 and 254.
- **ClientIP**: Private IP assigned to the Client ENI. The last octet should be between 5 and 254.
- **KeyName**: Name of an existing EC2 KeyPair to enable SSH access to the instances.

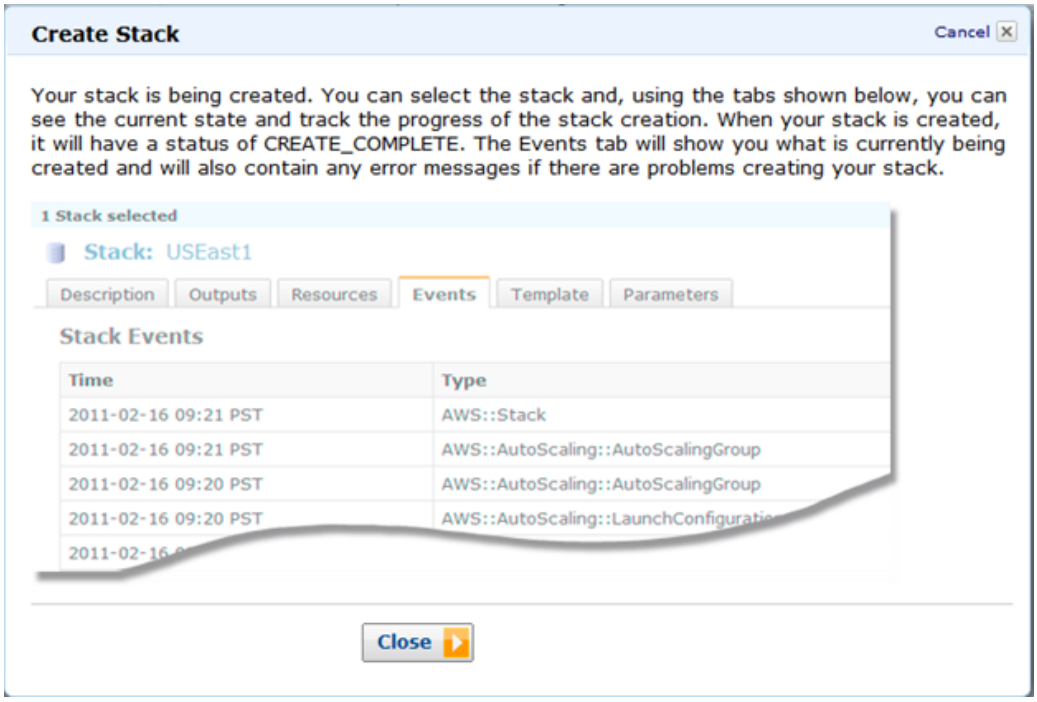
Note: Make sure that the VPC, subnets, security groups, routes and gateway associations are already configured.



7. Click Continue.
8. Review the values in the Create Stack dialog box.



9. Click Continue to create a Stack.



10. Click Close to close the Create Stack dialog box.

11. The new stack that you created appears on the CloudFormation Stacks page.

Note:

- Currently, the CloudFormation utility does not provide the functionality to add secondary IP addresses. Use the AWS console, after deploying a NetScaler VPX instance, to add the secondary IP addresses to the ENIs.
- The CloudFormation scripts for the standalone and HA pair VPX instances have the latest AMIs for the five supported regions. You have to update the scripts to synchronize with the latest AMIs.
- The script automatically selects the correct AMI for the region in which the VPX instance is being deployed.
- By default, all the ENIs are attached to one security group, use the AWS console to attach an ENI to a different security group.
- EIPs are automatically allocated and assigned to an instance. If the EIP limit exceeds the threshold for the region, the CloudFormation script fails and displays an error message.

Collaborating to Deliver High-Quality Products and Content Launching NetScaler VPX by using the AWS 1-Click

1-Click helps you to launch an instance of NetScaler VPX on AWS, quickly as compared to other launching methods, with the default options. After the instance is launched on AWS, you can modify these options by using either the AWS CLI or the AWS GUI.

The default options include the following elastic network interfaces (ENIs) for the NetScaler instance:

- **Management Interface**—Associates a subnet for management related traffic. You add the NetScaler management IP (NSIP) address to this subnet.
- **Public Interface**—Associates a subnet for the client-access (user-to-NetScaler) traffic. You add one or more virtual IP (VIP) addresses on this subnet.
- **Private Interface**—Associates a subnet for server-access (NetScaler-to-server) traffic. You add subnet IP (SNIP) addresses on this subnet.

Before you begin launching an instance of NetScaler VPX on AWS, consider the following points :

- For security reasons, none of the elastic IP addresses are attached to the ENIs of the NetScaler VPX instance launched by using 1-Click. This means that the NetScaler VPX instance (including the management IP address) is not reachable from outside the AWS Virtual Private Cloud (VPC). If your VPC uses a Virtual Gateway or other method to provide a VPN access to the VPC, you can administer the instance by using the IP address of the network interface in the management subnet. If you do not have VPN access to your VPC, Citrix recommends that you set up a jump box instance within the VPC, and then use this as the source for accessing or managing other instances within the VPC. For instructions to create an SSH jump box, see https://s3.amazonaws.com/awsmp-usageinstructions/Creating_and_using_VPC.txt.
- Three default security policies are created. A policy each is attached to the management, public and private interfaces, respectively.
    - The security policy for the management interface allows traffic from a set of ports.
    - The security policies for the public and private interfaces block all the traffic to or from these interfaces. You can later modify these security groups to filter the desired traffic.
- High Availability configuration is not supported for a NetScaler VPX instance launched by using AWS 1-click.

Before you begin launching an instance of NetScaler VPX on AWS, make sure that you have the following:

- An AWS account
- An AWS Virtual Private Cloud (VPC)
- Three subnets within the AWS VPC (one each for management interface, public interface, and private interface of the NetScaler instance)
- An IAM key pair

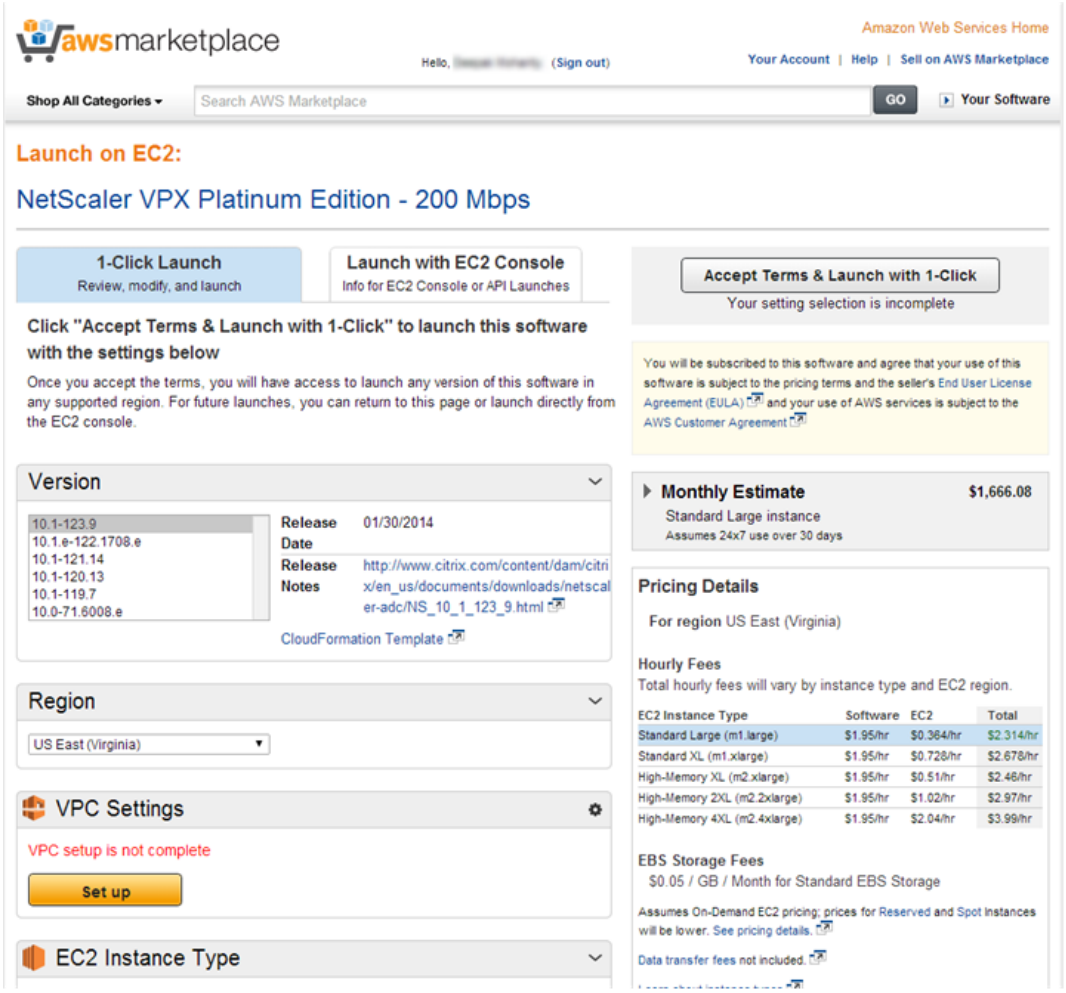
For information about creating an AWS account, a VPC, subnets in a VPC, and an IAM key pair, see Launching NetScaler VPX for AWS by Using the Amazon GUI and CLI toolkit.

To launch an instance of NetScaler VPX on AWS by using 1-Click

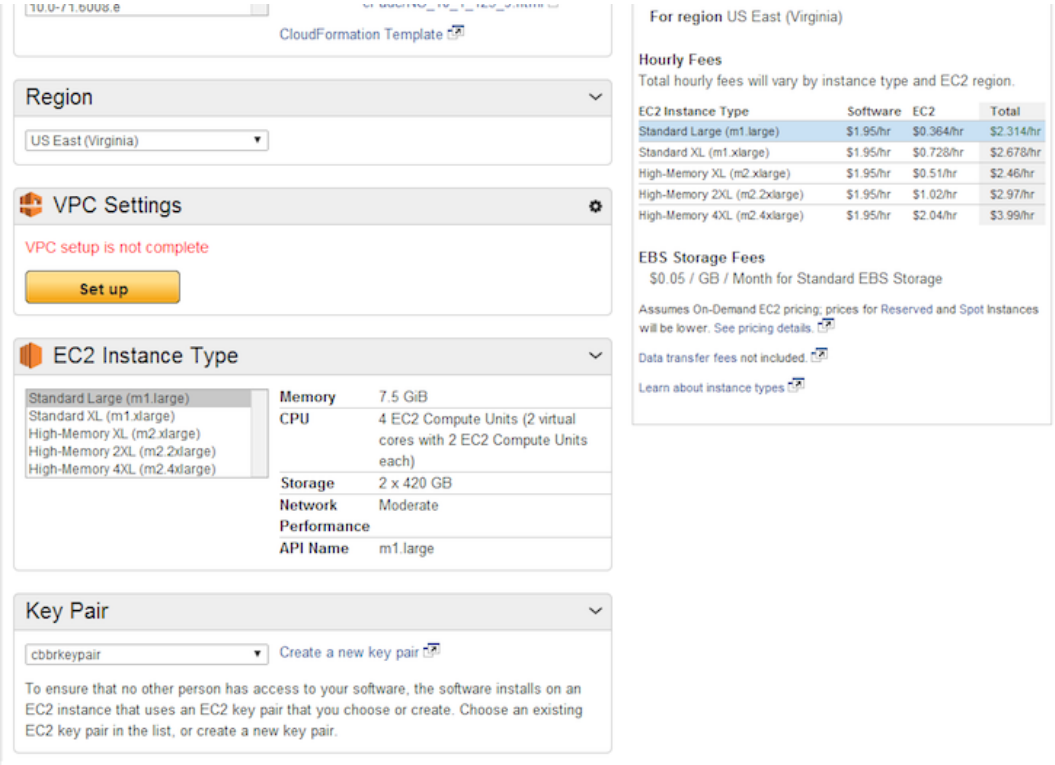
1. Log on to the AWS marketplace (https://aws.amazon.com/marketplace) by using your Amazon AWS credentials.
2. In the search field, type NetScaler VPX to search for the NetScaler AMI, and click Go.
3. 
On the search result page, click the desired Citrix NetScaler VPX offering.

4. 
   On the Citrix NetScaler VPX page, click Continue.
5. Click the 1-Click Launch tab. On the 1-Click Launch tab, specify values for the following fields:

   - Version
   - Region
   - EC2 Instance type
   - Key Pair



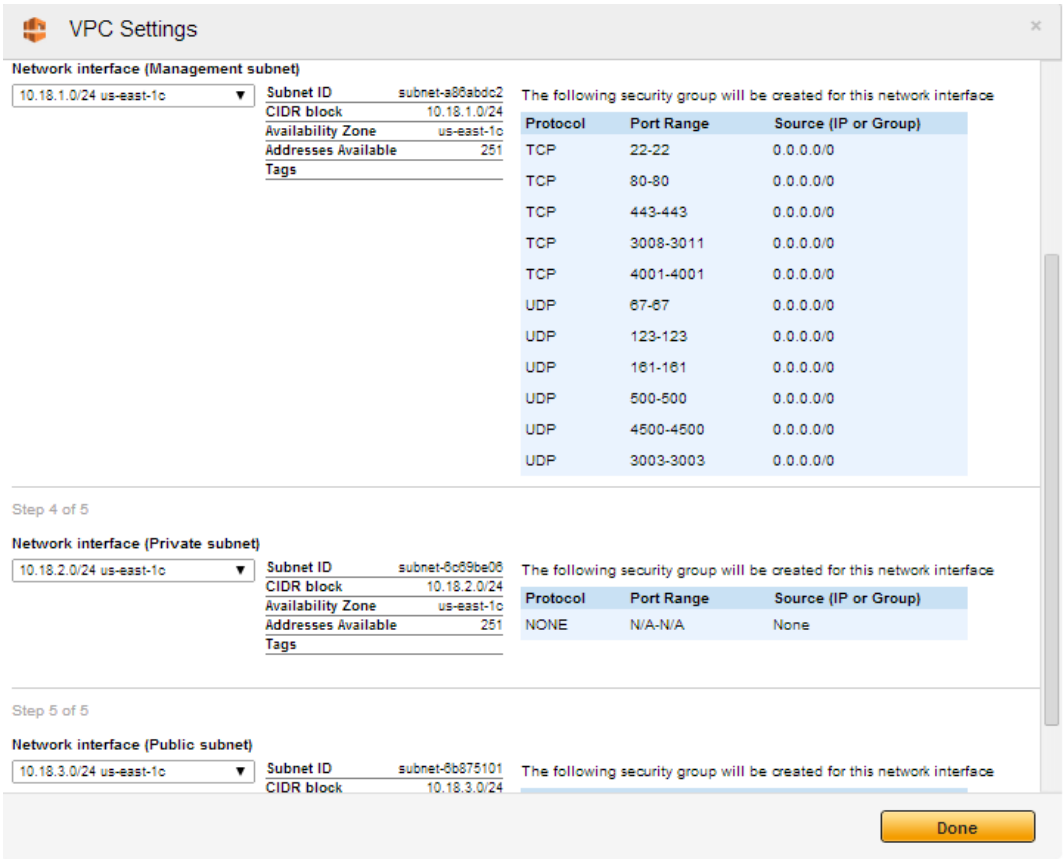
6. On the VPC Settings pane, click Setup.



7. On the VPC Settings page, specify values for the following fields, and then click Done:

   - VPC
   - Network Interface (Management subnet)
   - Network Interface (Private subnet)
   - Network Interface (Public subnet)

   Note: You need to make sure that the subnets attached to these ENIs are different from each other. Attaching the same subnet to more than one ENI might cause routing issues.



VPC Settings
Network interface (Management subnet)

Done

8. 
Click Accept Terms & Launch with 1-Click.

After few minutes, the NetScaler instance is launched with three ENIs. You can now connect to the NSIP address (the IP address on the management ENI) of the instance by using the NetScaler CLI or NetScaler GUI and start configuring the NetScaler features, for example, load balancing.

Verifying the NetScaler VPX on AWS Installation

When the NetScaler instance is running, you can access the instance through the NetScaler GUI or the NetScaler CLI by connecting to the EIP associated with the management ENI (NSIP). For example, use the following addressing notation in a web browser:

http://<Elastic_IP> (unsecured access)

or

https://<Elastic_IP> (secured access)

Note:

- To access a NetScaler instance through SSH, provide the .pem file.
- You can use the AWS GUI console to manually add the private IP addresses for SNIPs on server subnets and VIPs on client subnets.
- If you want to access the NSIP from the Internet, you must assign an EIP to the NSIP address of each NetScaler instance. Also, make sure that the NSIP subnet is associated with a routing table that has a default route set to the Internet gateway.
- If you want VIP addresses to be accessible through the Internet, you must associate an EIP with each VIP address that is defined in the configuration.
- The following are the default login credentials to access a NetScaler instance:
  - Username—nsroot
  - Password—nsroot

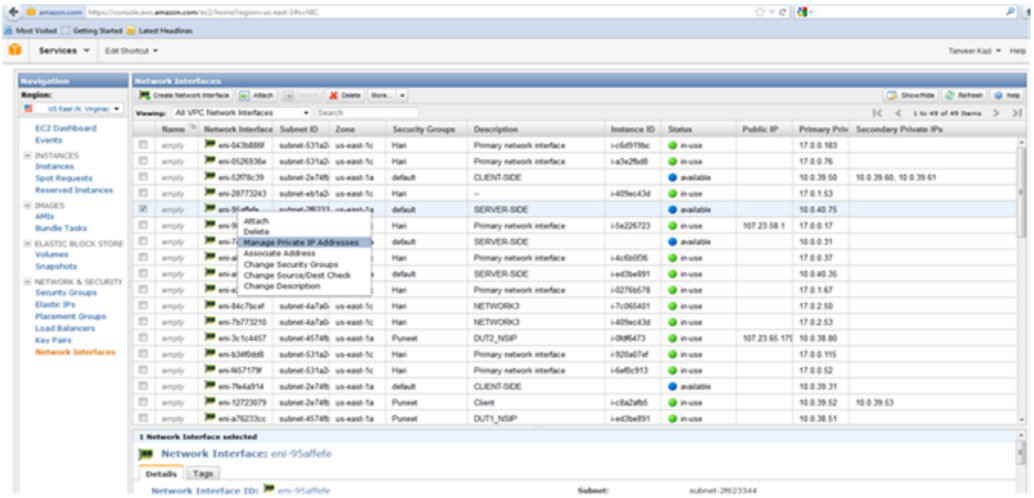
Attaching Additional IP Addresses to an Instance

You can attach additional IP addresses to an instance as follows:

1. Add a secondary IP address to an ENI.
2. Associate an EIP with the secondary IP address that you created.

To add a secondary IP address to the ENI

1. In a web browser, open the website at www.aws.amazon.com and log on with AWS credentials.
2. Click My Account/Console, and then click AWS Management Console.
3. On the Amazon Web Services page, click EC2.
4. On the Amazon EC2 Console's Dashboard page, in the Navigation pane, in NETWORK & SECURITY, click Network Interfaces.
5. In the Network Interfaces pane, right-click the ENI attached to the subnet, and then select the Manage Private IP Addresses option from the pop-up menu.



6. In the Manage Private IP Addresses dialog box, click Assign a secondary private IP address and either let AWS automatically assign an IP address or type an IP address in the auto-assign text-field. Click Yes, Update.

Associating an EIP with the secondary IP

Complete the following steps to associate an EIP with a secondary IP address:

1. On the Amazon EC2 Console Dashboard page, in the Navigation pane, in NETWORK & SECURITY, click Elastic IPs.
2. In the Addresses pane, click Allocate New Address.
3. In the Allocate New Address dialog box, select VPC from the EIP used in drop-down list and click Yes, Allocate.
4. Select the newly allocated EIP, and click Associate Address.
5. In the Associate Address dialog box, select, from the **Instance** and the **Private IP address** drop-down lists, the instance and private address that you want to associate with the EIP. Then, click Yes, Associate.

Downloading a NetScaler VPX License

After the initial instance launch, NetScaler VPX for AWS requires a license. If you are bringing your own license (BYOL), see the *VPX Licensing Guide* at http://support.citrix.com/article/CTX122426

You have to:

1. Use the licensing portal within MyCitrix to generate a valid license.
2. Upload the license to the instance.

If this is a **paid** marketplace instance, then you do not need to install a license. The correct feature set and performance will activate automatically.

Load Balancing Servers in different Availability Zones

A NetScaler instance can be used to load balance servers running in the same availability zone, or in:

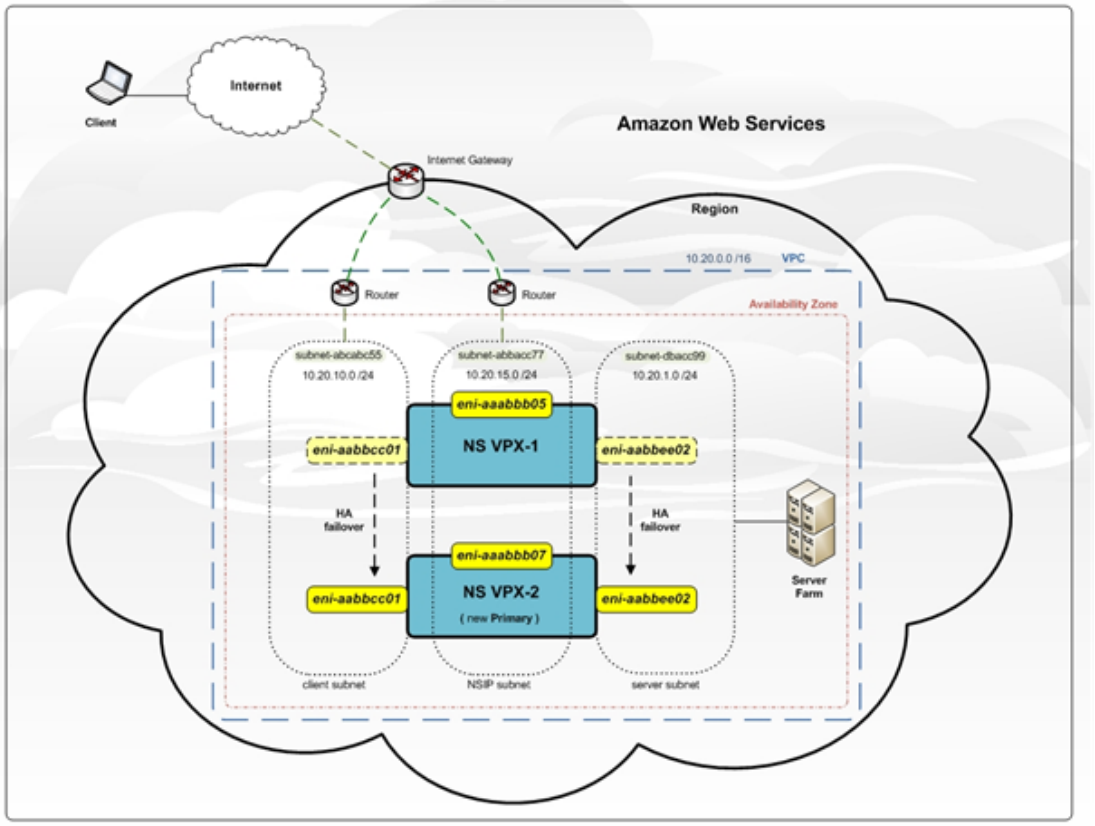
- A different availability zone (AZ) in the same AWS VPC
- A different AWS region
- AWS EC2 in a VPC

To enable NetScaler to load balance servers running outside the AWS VPC that the NetScaler instance is in, configure the NetScaler to use EIPs to route traffic through the Internet gateway, as follows:

1. Configure a SNIP on the NetScaler by using the NetScaler CLI or the NetScaler GUI
2. Enable traffic to be routed out of the AZ, by creating a public facing subnet for the server-side traffic.
3. Add an Internet gateway route to the routing table, using the AWS GUI console.
4. Associate the routing table you just updated with the server-side subnet.
5. Associate an EIP with the server-side private IP address that is mapped to a NetScaler SNIP address.

High Availability

Two Citrix® NetScaler® VPX™ instances in AWS can be configured as a high availability (HA) pair. With one instance configured as the primary node and the other as the secondary node, the primary node accepts connections and manages servers while the secondary node monitors the primary. If, for any reason, the primary node is unable to accept connections, the secondary node takes over.



The following figure shows an example of the HA deployment architecture for NetScaler VPX on AWS. Figure 1. NetScaler VPX on AWS - HA Deployment

To deploy HA for VPX on AWS, you must configure at least two ENIs on the primary instance and a single ENI on the secondary instance. On each instance, configure the NetScaler IP (NSIP) address (the management address) on the default ENI. On the primary instance, use the additional ENIs for client and server connections.

For instructions on obtaining access and secret keys, in the AWS documentation, see "How Do I Get Security Credentials?" and "Creating, Modifying, and Viewing User Access Keys (AWS Management Console)." For instructions to create an IAM user and set permissions, see "Creating an IAM Account."

Example format for a key file is:

ACCESS_KEY="AKIAJPBBBBBBBVA2PR2OHJNA"
SECRET_KEY="d75KxU7ukd44444NNNNtrrAOgynwBdJoSiooP"

Note: For HA failover to work:

1. The NSIP addresses for each NetScaler instance in an HA pair must be configured on the default ENI of the instance.
2. Both the primary and secondary instances must have EIPs associated with the NSIP or NAT configured to handle outgoing traffic in order to have access to the AWS API servers.
3. Client and server traffic (data-plane traffic) must not be configured on the default ENI.
4. Access and secret keys associated with the user's AWS Identity and Access Management (IAM) account. If the correct key information is not used when creating VPX instances, the HA deployment will fail. The access and secret keys are required for sending Query APIs to the AWS server.
5. Nameservers/DNS servers are configured at VPC level using DHCP options.

Notes on HA:

- Because Amazon does not allow any broadcast/multicast packets in AWS, HA is implemented by migrating data-plane ENIs from the primary to the secondary (new primary) VPX instance when the primary VPX instance fails.
- To deploy HA for VPX on AWS, you must configure at least two ENIs on the primary instance and a single ENI on the secondary instance.
- Because the default ENI cannot be moved to another VPX instance, you should not use the default ENI for data.
- The message AWSCONFIG IOCTL NSAPI_HOTPLUG_INTF success output 0 indicates that the two data ENI's have successfully attached to the secondary instance (the new primary).
- Failover might take up to 20 seconds due to the AWS detach/attach ENI mechanism.
- Upon failover, the failed instance always restarts.
- The secondary node always has one ENI interface (for management) and the primary node can have up to four ENIs.
- The heartbeat packets are received only on the management interface.
- **The AWS debug messages are available in the log file, /var/log/ns.log, on the VPX instance**.

Configuring High Availability for VPX on AWS

To deploy HA for two VPX instances on AWS, you must create the primary NetScaler VPX instances with three ENIs and the secondary NetScaler VPX with a single ENI.

Following is an example of launching a primary VPX instance with three ENIs:

C:\aws-vpc-config>ec2-run-instances ami-bd2986d4 -n 1 -t m1.large -k keyPairName -f ./keyPairFile -a :0:subnet-15fa057e:"NSIP":10.20.15.21 -a :1:subnet-1547ba7e:"CLIENT-SIDE":10.20.10.21::::"10.20.10.22,10.20.10.23,10.20.10.24,10.20.10.25,10.20.10.26,10.20.10.27,10.20.10.28,10.20.10.29,10.20.10.30" -a :2:subnet-cc47baa7:"SERVER-SIDE":10.20.1.21::::"10.20.1.22,10.20.1.23,10.20.1.24,10.20.1.25,10.20.1.26,10.20.1.27,10.20.1.28,10.20.1.29,10.20.1.30"

Following is an example of launching a secondary VPX instance with a single ENI:

C:\aws-vpc-config>ec2-run-instances ami-bd2986d4 -n 1 -t m1.large -k keyPairName -f keyPairFile -a :0:subnet-15fa057e:"NSIP":10.20.15.31

Note: The keyPairFile argument contains the access and secret key. (You cannot change the keyPairFile associated with a VPC instance after it is created.)

After the two NetScaler instances are UP, configure the HA pairing on both the instances. You have to configure the instance with two or more ENIs before configuring HA on the instance with one ENI. Use the add HA node command, from within the NetScaler CLI, or from the NetScaler GUI. For example:

On the VPX instance with two or more ENIs:

add HA node 1 10.20.15.31

On the VPX instance with one ENI:

add HA node 1 10.20.15.21

After you enter add HA node commands, the two nodes form an HA pair, and configuration information is synchronized between the two VPX instances.

To remove HA from NetScaler VPX pair

You can remove HA configuration from the NetScaler VPX pair by using the remove ha node command. You have to remove the HA configuration from the secondary NetScaler VPX before removing the HA configuration from the primary NetScaler VPX.

For example, on the Secondary NetScaler VPX instance, at the NetScaler command line, type:

```
remove ha node

save config
```

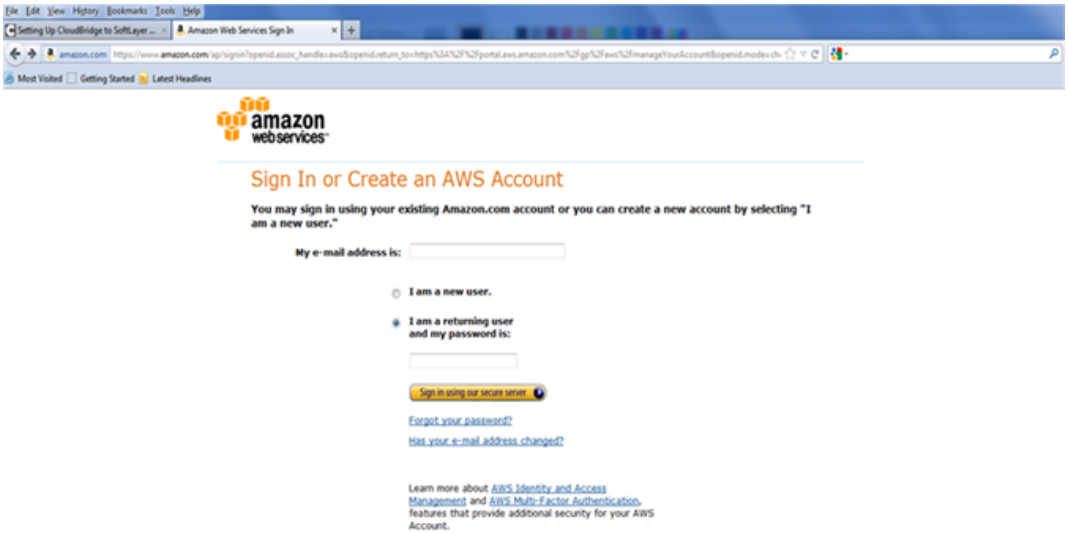
On the Primary NetScaler VPX instance, at the NetScaler command line, type:

```
remove ha node

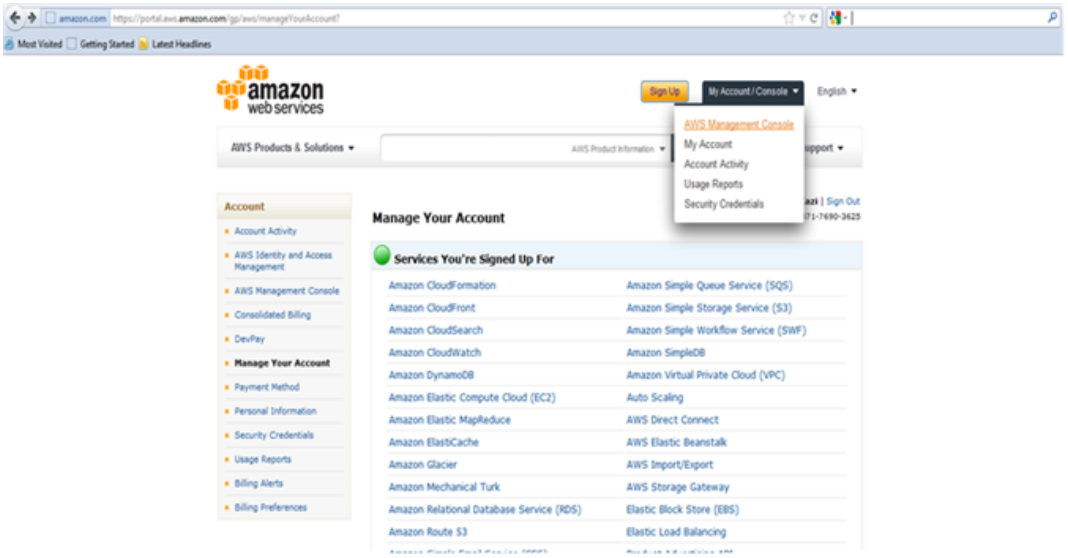
save config
```

Launching NetScaler VPX pairs for HA by using Citrix CloudFormation

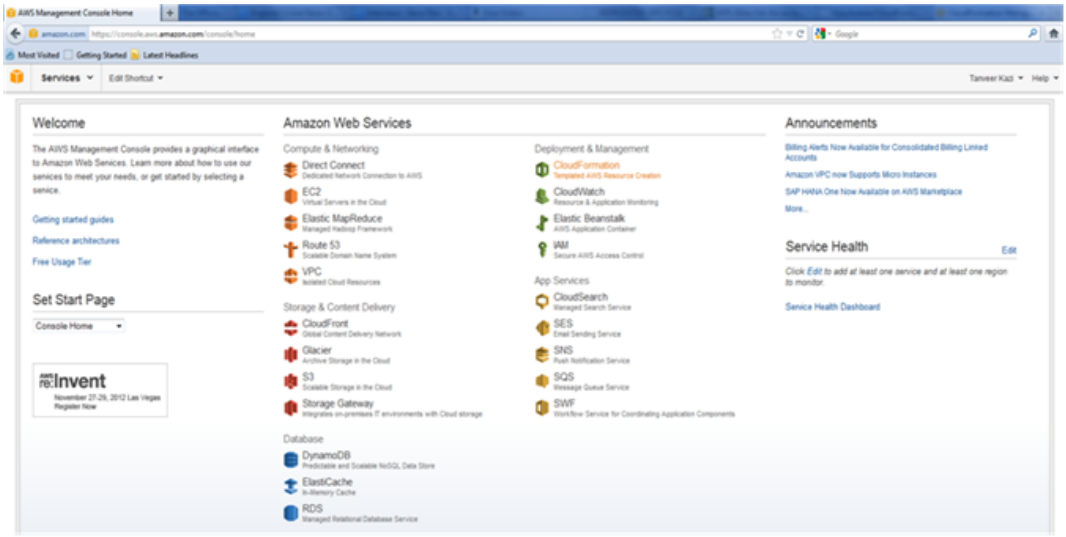
1. In a web browser, open the website at www.aws.amazon.com and log on with AWS credentials.



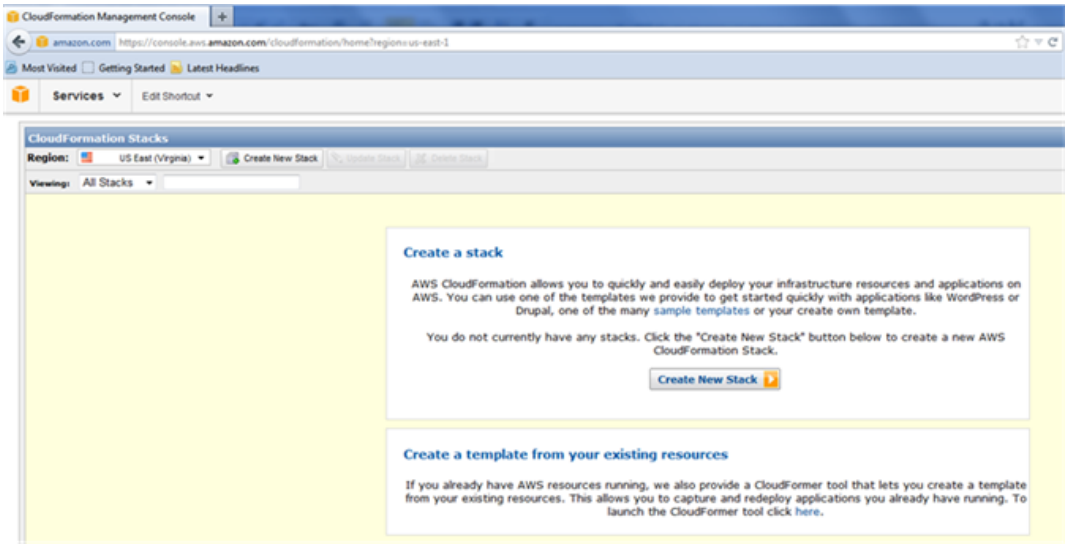
2. Click My Account/Console, and then click AWS Management Console.



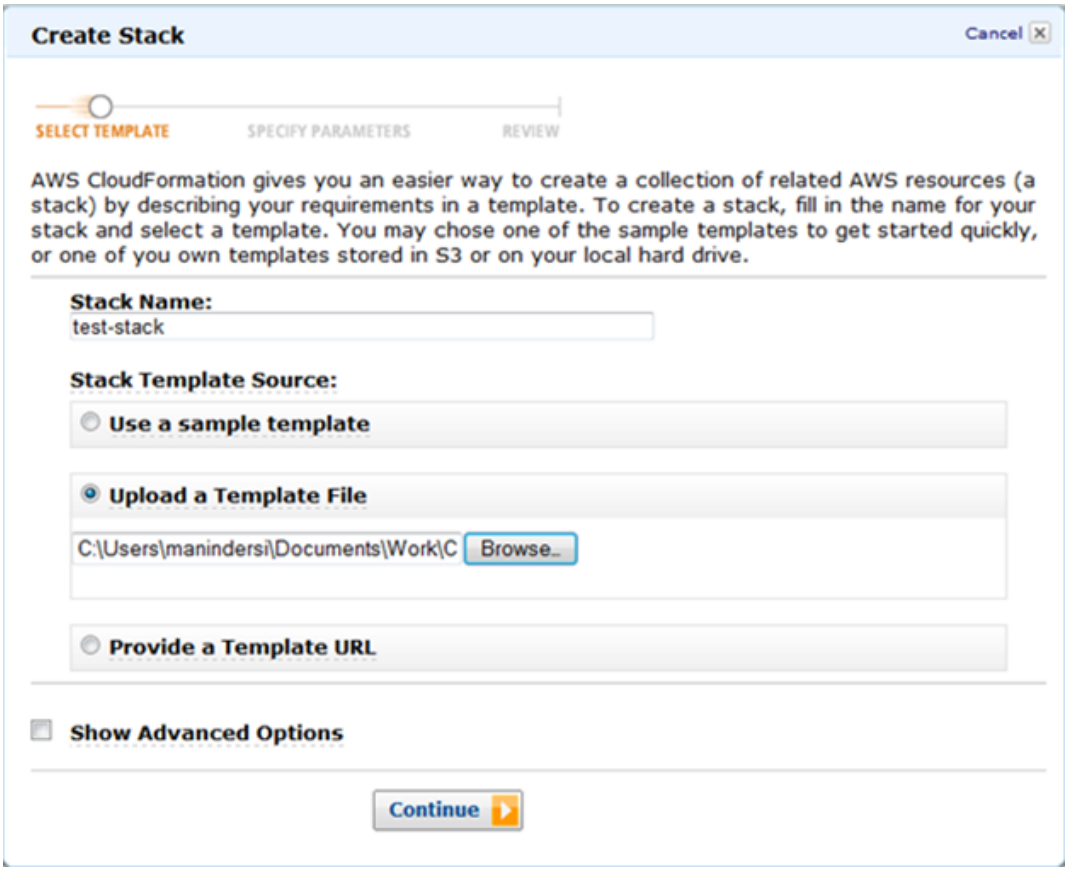
3. On the Amazon Web Services page, in the Deployment & Management section, click Cloud Formation.



4. On the CloudFormation Stacks page, select the Region in which you plan to deploy the NetScaler VPX instance, and then click Create New Stack.



5. In the Create Stack dialog box, specify value for Stack Name, select the Upload a Template File option, and then click Browse. Select the template for HA NetScaler VPX from the local drive, and then click **Continue**.



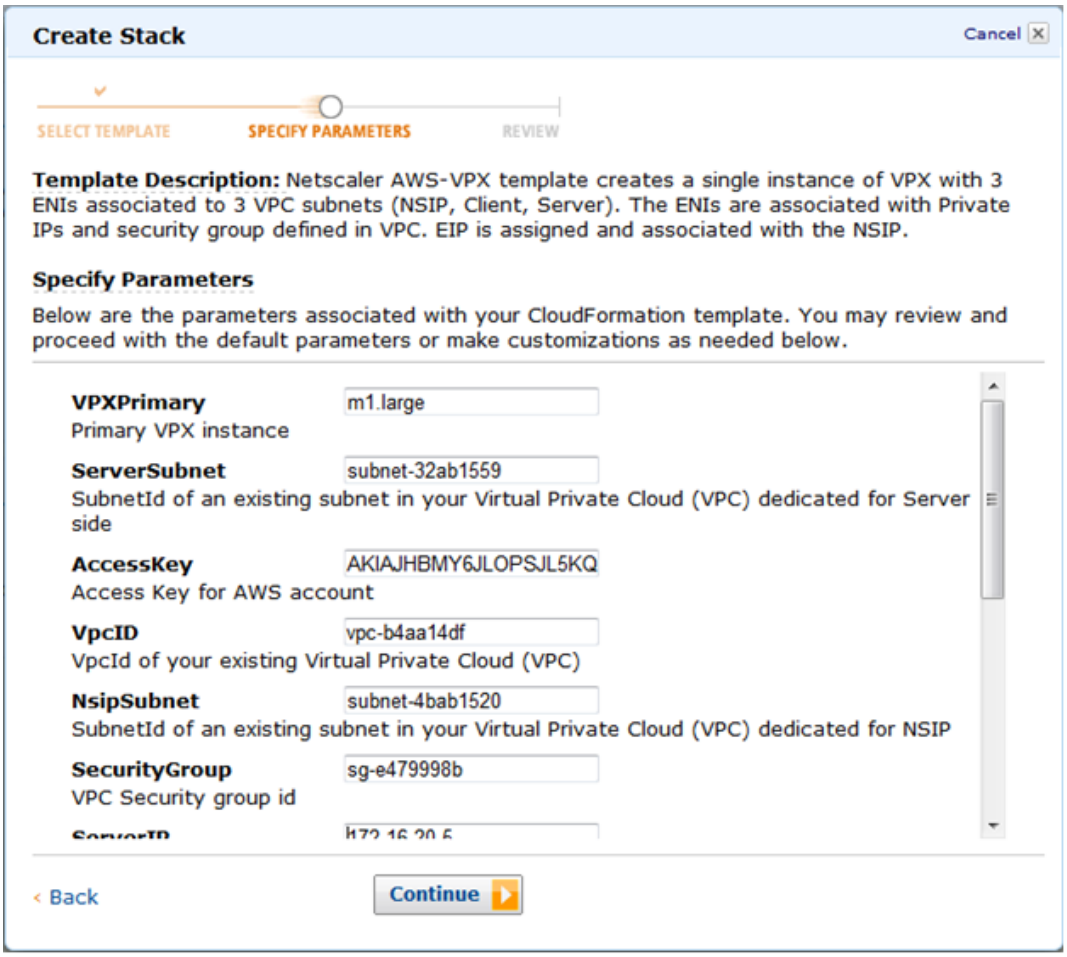
6. In the next pane, specify values for:

   - **VpcID**: An identifier to assign to the Virtual Private Cloud (VPC).
   - **NsipSubnet**: Subnet in which the NSIP is configured in VPC.
   - **ServerSubnet**: Subnet in which the server farm is configured in VPC.
   - **ClientSubnet**: SubnetId in which the client side is configured in VPC.
   - **SecurityGroup**: VPC Security group id.
   - **VPXPrimary**: Name of Primary VPX instance type.
   - **AccessKey**: Access Key for IAM user account.
   - **SecretKey**: Secret Key for IAM user account.
   - **TenancyType**: Instance tenancy type, can be default or dedicated.
   - **NsIP**: Private IP assigned to the NSIP ENI. The last octet of NSIP should be between 5 and 254.
   - **NsIPSec**: Private IP assigned to the NSIP ENI of Secondary. last octet has to be between 5 and 254.
   - **ServerIP**: Private IP assigned to the Server ENI. The last octet should be between 5 and 254.

- **ClientIP**: Private IP assigned to the Client ENI. The last octet should be between 5 and 254.

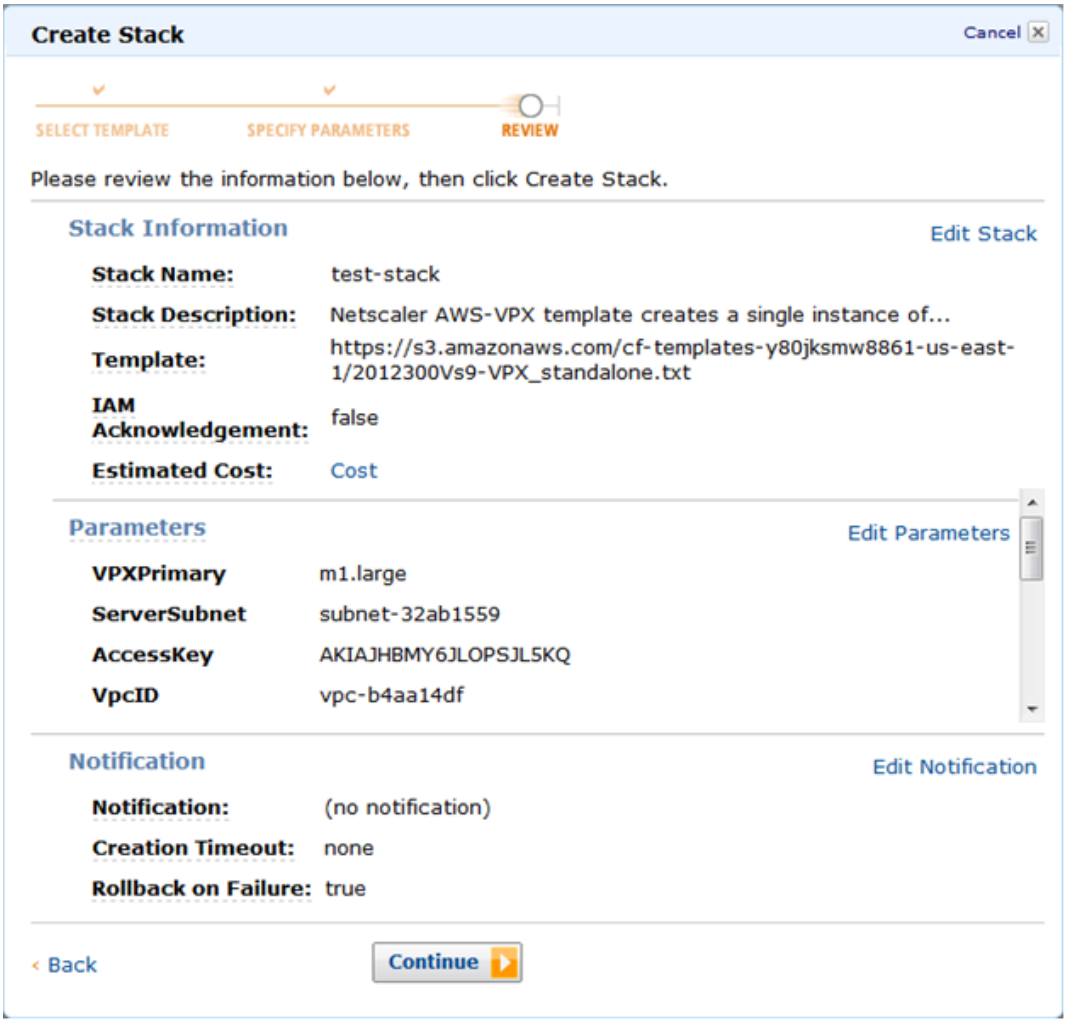
- **KeyName**: Name of an existing EC2 KeyPair to enable SSH access to the instances.

Note: Make sure that the VPC, subnets, security groups, routes associations, gateway associations are already configured.

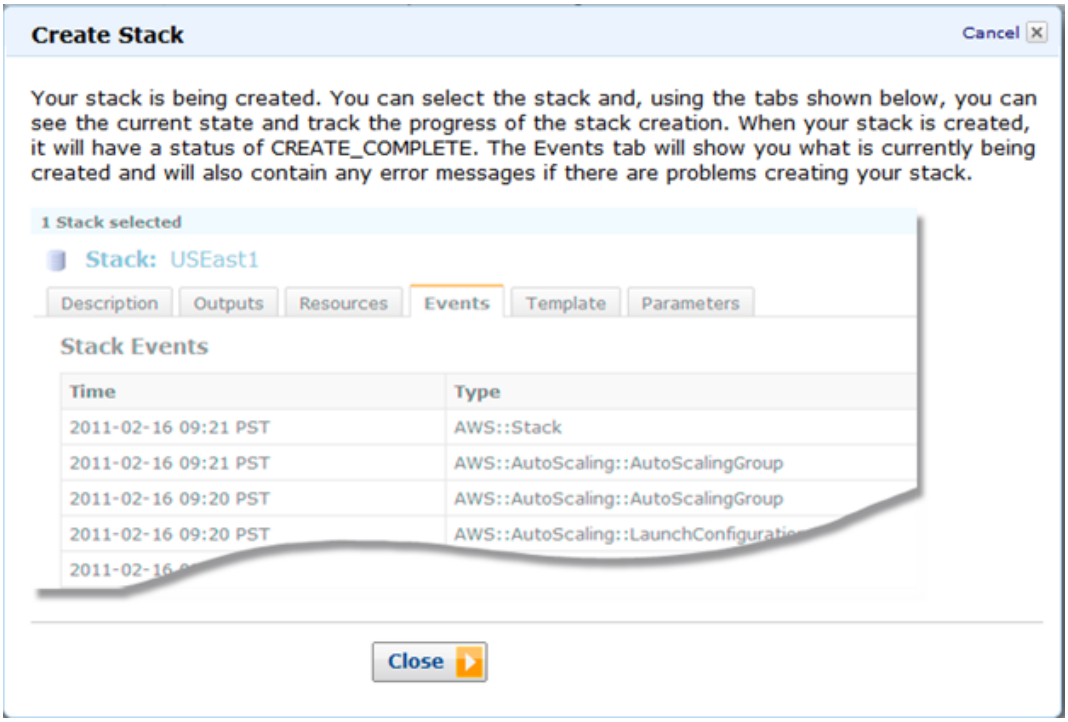


7. Click Continue.

8. Review the specified values in the Create Stack dialog box.



9. Click Continue to create a Stack.



10. Click Close to close the Create Stack dialog box.

11. The new stack that you created appears on the CloudFormation Stacks page.

Upgrading a NetScaler VPX instance on AWS

You can upgrade the EC2 instance type, throughput, software edition, and the system software of a NetScaler VPX running on AWS. For certain types of upgrades, Citrix recommends using the High Availability Configuration method to minimize downtime.

Note:

- NetScaler software release 10.1.e-124.1308.e or later for a NetScaler VPX AMI (including both utility license and customer license) does not support the M1 and M2 instance families.
- Because of changes in NetScaler instance support, downgrading from 10.1.e-124 or a later release to 10.1.123.x or an earlier release is not supported.
- Most of the upgrades do not require the launch of a new AMI, and the upgrade can be done on the current NetScaler AMI instance. If you do want to upgrade to a new NetScaler AMI instance, use the high availability configuration method.

Changing the EC2 Instance Type of a NetScaler VPX Instance on AWS

If your NetScaler VPX instances are running release 10.1.e-124.1308.e or later, you can change the EC2 instance type from the AWS console as follows:

1. Stop the VPX instance.
2. Change the EC2 instance type from the AWS console.
3. Start the instance.

You can also use the above procedure to change the EC2 instance type for a release, earlier than 10.1.e-124.1308.e, unless you want to change the instance type to M3. In that case, you must first follow the standard NetScaler upgrade procedure, at , to upgrade the NetScaler software to 10.1.e-124 or a later release, and then follow the above steps.

Upgrading the Throughput or Software Edition for a NetScaler VPX Instance on AWS

To upgrade the software edition (for example, to upgrade from standard to platinum edition) or throughput (for example, to upgrade from 200 mbps to 1000mbps), the method depends on the instance's license.

Using a customer license (Bring-Your-Own-License)

If you are using a customer license, you can purchase and download the new license from the Citrix Licensing portal (MyCitrix), and then install the license on the VPX instance. For more information about downloading and installing a license from the MyCitrix portal, see the VPX Licensing Guide.

Using a utility license (Utility license with hourly fee)

AWS does not support direct upgrades for fee-based instances. To upgrade the software edition or throughput of a fee based NetScaler VPX instance, launch a new AMI with the desired license and capacity and migrate the older instance configuration to the new instance. This can be achieved by using a NetScaler high availability configuration as described in "Upgrading to a New NetScaler AMI Instance by Using a NetScaler High Availability Configuration."

Upgrading the System Software of a NetScaler VPX Instance on AWS

If you need to upgrade a NetScaler instance running 10.1.e-124.1308.e or a later release, follow the standard NetScaler upgrade procedure at .

If you need to upgrade a NetScaler instance running a release older than 10.1.e-124.1308.e to 10.1.e-124.1308.e or a later release, first upgrade the system software, and then change the instance type to M3 as follows:

1. Stop the VPX instance.
2. Change the EC2 instance type from the AWS console.
3. Start the instance.

Upgrading to a New NetScaler AMI Instance by Using a NetScaler High Availability Configuration

To use the high availability method of upgrading to a new NetScaler AMI instance, perform the following tasks:

- Create a new instance with the desired EC2 instance type, software edition, throughput, or software release from the AWS marketplace.
- Configure high availability between the old instance (to be upgraded) and the new instance. After high availability is configured between the old and the new instance, configuration from the old instance is synchronized to the new instance.
- Force an HA failover from the old instance to the new instance. As a result, the new instance becomes primary and starts receiving traffic.
- Stop, and reconfigure or remove the old instance from AWS.

Prerequisites and Points to Consider

- Make sure you understand how high availability works between two NetScaler VPX instances on AWS. For more information about high availability configuration between two NetScaler VPX instances on AWS, see High Availability.
- You must create the new instance in the same availability zone as the old instance, having the exact same security group and subnet.
- High availability setup requires access and secret keys associated with the user's AWS Identity and Access Management (IAM) account for both instances. If the correct key information is not used when creating VPX instances, the HA setup fails. For more information about creating an IAM account for a VPX instance, see Creating an IAM Account.
- You must use the EC2 console to create the new instance. You cannot use the AWS 1-click launch, because it does not accept the access and secret keys as the input.
- The new instance should have only one ENI interface.

To upgrade a NetScaler VPX Instance by using a high availability configuration

1. Configure high availability between the old and the new instance. To configure high availability between two NetScaler VPX instances, at the NetScaler command prompt of each intance, type:
   - add ha node <nodeID> <IPaddress of the node to be added>
   - save config

   Example

At the NetScaler command prompt of the old instance, type:
> add ha node 30 192.0.2.30
Done
At the NetScaler command prompt of the new instance, type:
> add ha node 10 192.0.2.10
Done

Note the following:

- In the HA setup, the old instance is the primary node and the new instance is the secondary node.
- The NSIP IP address is not copied from the old instance to the new instance. Therefore, after the upgrade, your new instance has a different management IP address from the previous one.
- The nsroot account password of the new instance is set to that of the old instance after HA synchronization.

For more information about high availability configuration between two NetScaler VPX instances on AWS, see High Availability.

2. Force an HA failover. To force a failover in a high availability configuration, at the NetScaler command prompt of either of the instances, type:

   - force HA failover

   As the result of forcing a failover, the ENIs of the old instance are migrated to the new instance and traffic flows through the new instance (the new primary node). The old instance (the new secondary node) restarts.

   If the following warning message appears, type N to abort the operation:

   WARNING]:Force Failover may cause configuration loss, peer health not optimum. Reason(s):
   HA version mismatch
   HA heartbeats not seen on some interfaces
   Please confirm whether you want force-failover (Y/N)?

   The warning message appears because the system software of the two VPX instances is not HA compatible. As a result, the configuration of the old instance cannot be automatically synced to the new instance during a forced failover.

   Following is the workaround for this issue:

   a. At the NetScaler shell prompt of the old instance, type the following command to create a backup of the configuration file (ns.conf):

      - copy /nsconfig/ns.conf to /nsconfig/ns.conf.bkp

   b. Remove the following line from the backup configuration file (ns.conf.bkp):

      - set ns config -IPAddress <IP> -netmask <MASK>

        For example, set ns config -IPAddress 192.0.2.10 -netmask 255.255.255.0

   c. Copy the old instance's backup configuration file (ns.conf.bkp) to the /nsconfig directory of the the new instance.

d. At the NetScaler shell prompt of the new instance, type the following command to load the old instance's configuration file (ns.conf.bkp) on the new instance:

   - batch -f /nsconfig/ns.conf.bkp

e. Save the configuration on the new instance.

   - Save conifg

f. At the NetScaler command prompt of either of the nodes, type the following command to force a failover, and then type Y for the warning message to confirm the force failover operation:

   - force ha failover

   Example

   > force ha failover

   WARNING]:Force Failover may cause configuration loss, peer health not optimum.
   Reason(s):
   HA version mismatch
   HA heartbeats not seen on some interfaces
   Please confirm whether you want force-failover (Y/N)? Y

3. Remove the HA configuration, so that the two instances are no longer in an HA configuration. First remove the HA configuration from the secondary node and then remove the HA configuration from the primary node.

   To remove an HA configuration between two NetScaler VPX instances, at the command prompt of each instance, type:

   - remove ha node <nodeID>

   - save config

   For more information about high availability configuration between two NetScaler instances on AWS, see High Availability.

   Example

   At the NetScaler command prompt of the old instance (new secondary node), type:
   > remove ha node 30
   Done
   > save config
   Done
   At the NetScaler command prompt of the new instance (new primary node), type:
   > remove ha node 10
   Done
   > save config
   Done

Troubleshooting the NetScaler VPX on AWS

Amazon does not provide console access to a NetScaler VPX virtual instance. To troubleshoot, you have to use the AWS GUI to view the activity log. You can debug only if the network is connected. To view an instance's system log, right-click the instance and select system log.

Citrix provides support for fee based NetScaler VPX instances (utility license with hourly fee) on AWS. To file a support case, find your AWS account number and support PIN code, and call Citrix support. You will also be asked for your name and email address. To find the support PIN, log on to the NetScaler configuration utility and navigate to the System page.

Installing CloudBridge VPX in a Data Center

The Citrix CloudBridge VPX virtual appliance can be hosted on Citrix XenServer®, VMware ESX or ESXi, and Microsoft Hyper-V virtualization platforms.

Installing NetScaler Virtual Appliances on XenServer

To install NetScaler virtual appliances on Citrix XenServer, you must first install XenServer on a machine with adequate system resources. To perform the NetScaler virtual appliance installation, you use Citrix XenCenter, which must be installed on a remote machine that can connect to the XenServer host through the network.

Note: After the initial configuration of the NetScaler appliance, if you want to upgrade the appliance to the latest software release, see Upgrading or Downgrading the System Software.

Prerequisites for Installing NetScaler Virtual Appliances on XenServer

Before you begin installing a virtual appliance, do the following:

- Install XenServer® version 5.6 or later on hardware that meets the minimum requirements.
- Install XenCenter® on a management workstation that meets the minimum system requirements.
- Obtain virtual appliance license files. For more information about virtual appliance licenses, see the *NetScaler VPX Licensing Guide* at http://support.citrix.com/article/ctx122426.

XenServer Hardware Requirements

The following table describes the minimum hardware requirements for a XenServer platform running NetScaler.

Table 1. Minimum System Requirements for XenServer Running NetScaler nCore virtual appliance

Component	Requirement
CPU	2 or more 64-bit x86 CPUs with virtualization assist (Intel-VT or AMD-V) enabled **Note:** To run NetScaler virtual appliance, hardware support for virtualization must be enabled on the XenServer host. Make sure that the BIOS option for virtualization support is not disabled. Consult your BIOS documentation for more details.
RAM	3 gigabytes (GB)
Disk space	Locally attached storage (PATA, SATA, SCSI) with 40 GB of disk space **Note:** XenServer installation creates a 4 GB partition for the XenServer host control domain; the remaining space is available for NetScaler virtual appliance and other virtual machines.
Network Interface Card (NIC)	One 1-Gbps NIC Recommended: Two 1-Gbps NICs

For information about installing XenServer, see the XenServer documentation at http://support.citrix.com/product/xens/.

The following table lists the virtual computing resources that XenServer must provide for each NetScaler nCore virtual appliance .

Table 2. Minimum Virtual Computing Resources Required for Running NetScaler ncore virtual appliance

Component	Requirement
Memory	2 GB
Virtual CPU (VCPU)	2
Virtual network interfaces	2

Note: For production use of NetScaler virtual appliance, Citrix recommends that CPU priority (in virtual machine properties) be set to the highest level, in order to improve scheduling behavior and network latency.

XenCenter System Requirements

XenCenter® is a Windows client application. It cannot run on the same machine as the XenServer® host. The following table describes the minimum system requirements.

Table 3. Minimum System Requirements for XenCenter Installation

Component	Requirement
Operating system	Windows 7, Windows XP, Windows Server 2003, or Windows Vista
.NET framework	Version 2.0 or later
CPU	750 megahertz (MHz) Recommended: 1 gigahertz (GHz) or faster
RAM	1 GB Recommended: 2 GB
Network Interface Card (NIC)	100 megabits per second (Mbps) or faster NIC

For information about installing XenCenter, see the XenServer documentation at http://support.citrix.com/product/xens/.

Installing NetScaler Virtual Appliances on XenServer by Using XenCenter

After you have installed and configured XenServer and XenCenter, you can use XenCenter to install virtual appliances on XenServer. The number of virtual appliances that you can install depends on the amount of memory available on the hardware that is running XenServer.

After you have used XenCenter to install the initial NetScaler virtual appliance (.xva image) on XenServer, you have the option to use Command Center to provision NetScaler virtual appliance. For more information, see the Command Center documentation.

To install NetScaler virtual appliances on XenServer by using XenCenter

1. Start XenCenter on your workstation.
2. On the Server menu, click Add.
3. In the Add New Server dialog box, in the Hostname text box, type the IP address or DNS name of the XenServer that you want to connect to.
4. In the User Name and Password text boxes, type the administrator credentials, and then click Connect. The XenServer name appears in the navigation pane with a green circle, which indicates that the XenServer is connected.
5. In the navigation pane, click the name of the XenServer on which you want to install NetScaler virtual appliance.
6. On the VM menu, click Import.
7. In the Import dialog box, in Import file name, browse to the location at which you saved the NetScaler virtual appliance .xva image file. Make sure that the Exported VM option is selected, and then click Next.
8. Select the XenServer on which you want to install the virtual appliance, and then click Next.
9. Select the local storage repository in which to store the virtual appliance, and then click Import to begin the import process.
10. You can add, modify, or delete virtual network interfaces as required. When finished, click Next.
11. Click Finish to complete the import process.

    Note: To view the status of the import process, click the **Log** tab.
12. If you want to install another virtual appliance, repeat steps 5 through 11.

Installing NetScaler Virtual Appliances on VMware ESX

Important: You cannot install standard VMware Tools or upgrade the VMware Tools version available on a NetScaler virtual appliance. VMware Tools for a NetScaler virtual appliance are delivered as part of the NetScaler software release.

Before installing NetScaler virtual appliances on VMware ESX, make sure that VMware ESX Server is installed on a machine with adequate system resources. To install NetScaler virtual appliances on VMware ESXi version 4.0 or later, you use VMware vSphere client. The client or tool must be installed on a remote machine that can connect to VMware ESX through the network.

After the installation, you can use vSphere client or vSphere Web Client to manage virtual appliances on VMware ESX 4.0 or later release.

Note:

The VMware vSphere client shows the guest operating system as "Sun Solaris 10" for NetScaler virtual machine. This is by design because VMware ESXi does not recognize FreeBSD.

After the initial configuration of the NetScaler appliance, if you want to upgrade the appliance to the latest software release, see "Upgrading or Downgrading the System Software."

Prerequisites for Installing NetScaler Virtual Appliances on VMware

Before you begin installing a virtual appliance, do the following:

- Install VMware ESX version 4.1 or later on hardware that meets the minimum requirements.
- Install VMware Client on a management workstation that meets the minimum system requirements.
- Download the NetScaler virtual appliance setup files.
- Label the physical network ports of VMware ESX.
- Obtain NetScaler license files. For more information about NetScaler virtual appliance licenses, see the *NetScaler VPX Licensing Guide* at http://support.citrix.com/article/ctx131110.

VMware ESX Hardware Requirements

The following table describes the minimum system requirements for VMware ESX servers running NetScaler ncore virtual appliance.

Table 1. Minimum System Requirements for VMware ESX Servers Running NetScaler nCore virtual appliance

Component	Requirement
CPU	2 or more 64-bit x86 CPUs with virtualization assist (Intel-VT or AMD-V) enabled **Note:** To run NetScaler virtual appliance, hardware support for virtualization must be enabled on the VMware ESX host. Make sure that the BIOS option for virtualization support is not disabled. For more information, see your BIOS documentation.
RAM	3 GB
Disk space	40 GB of disk space available
Network	One 1-Gbps NIC; Two 1-Gbps NICs recommended (The network interfaces must be Intel E1000.)

For information about installing VMware ESX, see http://www.vmware.com/.

The following table lists the virtual computing resources that the VMware ESX server must provide for each NetScaler ncore virtual appliance.

Table 2. Minimum Virtual Computing Resources Required for Running NetScaler ncore virtual appliance

Component	Requirement
Memory	2 GB
Virtual CPU (VCPU)	2 **Important:** Do not modify the system resources to create a virtual CPU (VCPU) in addition to the two CPUs already allotted to the virtual appliance.
Virtual network interfaces	1 **Note:** With ESX 4.0 or later, you can install a maximum of 10 virtual network interfaces if the VPX hardware is upgraded version to 7 or higher.
Disk space	20 GB **Note:** This is in addition to any disk requirements for the hypervisor.

Note: For production use of NetScaler virtual appliance, the full memory allocation must be reserved. CPU cycles (in MHz) equal to at least the speed of one CPU core of the ESX should also be reserved.

VMware vSphere Client System Requirements

VMware vSphere is a client application that can run on Windows and Linux operating systems. It cannot run on the same machine as the VMware ESX server. The following table describes the minimum system requirements.

Table 3. Minimum System Requirements for VMware vSphere Client Installation

Component	Requirement
Operating system	For detailed requirements from VMware, search for the "vSphere Compatibility Matrixes" PDF file at http://kb.vmware.com/.
CPU	750 megahertz (MHz); 1 gigahertz (GHz) or faster recommended
RAM	1 GB; 2 GB recommended
Network Interface Card (NIC)	100 Mbps or faster NIC

OVF Tool 1.0 System Requirements

OVF Tool is a client application that can run on Windows and Linux systems. It cannot run on the same machine as the VMware ESX server. The following table describes the minimum system requirements.

Table 4. Minimum System Requirements for OVF Tool Installation

Component	Requirement
Operating system	For detailed requirements from VMware, search for the "OVF Tool User Guide" PDF file at http://kb.vmware.com/.
CPU	750 MHz minimum, 1 GHz or faster recommended.
RAM	1 GB Minimum, 2 GB recommended.
Network Interface Card (NIC)	100 Mbps or faster NIC

For information about installing OVF, search for the "OVF Tool User Guide" PDF file at http://kb.vmware.com/.

Downloading the NetScaler virtual appliance Setup Files

The NetScaler virtual appliance setup package for VMware ESX follows the Open Virtual Machine (OVF) format standard. You can download the files from MyCitrix.com. You need a My Citrix account to log on. If you do not have a My Citrix account, access the home page at http://www.mycitrix.com, click the New Users link, and follow the instructions to create a new My Citrix account.

Once logged on, navigate the following path from the My Citrix home page:

MyCitrix.com > Downloads > NetScaler > Virtual Appliances.

Copy the following files to a workstation on the same network as the ESX server. Copy all three files into the same folder.

- NSVPX-ESX-<release number>-<build number>-disk1.vmdk (for example, NSVPX-ESX-9.3-39.8-disk1.vmdk)
- NSVPX-ESX-<release number>-<build number>.ovf (for example, NSVPX-ESX-9.3-39.8.ovf)
- NSVPX-ESX-<release number>-<build number>.mf (for example, NSVPX-ESX-9.3-39.8.mf)

Labeling the Physical Network Ports of VMware ESX

Before installing a NetScaler virtual appliance, label of all the interfaces that you plan to assign to virtual appliances, in a unique format. Citrix recommends the following format: NS_NIC_1_1, NS_NIC_1_2, and so on. In large deployments, labeling in a unique format helps in quickly identifying the interfaces that are allocated to the NetScaler virtual appliance among other interfaces used by other virtual machines, such as Windows and Linux. Such labeling is especially important when different types of virtual machines share the same interfaces.

To label the physical network ports of VMware ESX server

1. Log on to the VMware ESX server by using the vSphere client.
2. On the vSphere client, select the Configuration tab, and then click Networking.
3. At the top-right corner, click Add Networking.
4. In the Add Network Wizard, for **Connection Type**, select **Virtual Machine**, and then click Next.
5. Scroll through the list of vSwitch physical adapters, and choose the physical port that will map to interface 1/1 on the virtual appliances.
6. Enter NS_NIC_1_1 as the name of the vSwitch that will be associated with interface 1/1 of the virtual appliances.
7. Click Next to finish the vSwitch creation. Repeat the procedure, beginning with step 2, to add any additional interfaces to be used by your virtual appliances. Label the interfaces sequentially, in the correct format (for example, NS_NIC_1_2).

Installing NetScaler Virtual Appliances on VMware ESX 4.0 or Later

After you have installed and configured VMware ESX 4.0 or later, you can use the VMware vSphere client to install virtual appliances on the VMware ESX. The number of virtual appliances that you can install depends on the amount of memory available on the hardware that is running VMware ESX.

To install NetScaler virtual appliances on VMware ESX 4.0 or later by using VMware vSphere Client

1. Start the VMware vSphere client on your workstation.
2. In the IP address / Name text box, type the IP address of the VMware ESX server that you want to connect to.
3. In the User Name and Password text boxes, type the administrator credentials, and then click Login.
4. On the File menu, click Deploy OVF Template.
5. In the Deploy OVF Template dialog box, in Deploy from file, browse to the location at which you saved the NetScaler virtual appliance setup files, select the .ovf file, and click Next.
6. Map the networks shown in the virtual appliance OVF template to the networks that you configured on the ESX host. Click Next to start installing a virtual appliance on VMware ESX. When installation is complete, a pop-up window informs you of the successful installation.
7. You are now ready to start the NetScaler virtual appliance. In the navigation pane, select the NetScaler virtual appliance that you have just installed and, from the right-click menu, select Power On. Click the Console tab to emulate a console port.
8. If you want to install another virtual appliance, repeat steps 4 through 6.

Installing NetScaler Virtual Appliances on VMware ESX 3.5

To install virtual appliances on ESX 3.5, you need to use the VMware OVF tool, version 1.0. The number of virtual appliances that you can install depends on the amount of memory available on the hardware that is running VMware ESX. After installation, you can use the VMware Infrastructure (VI) client 2.5 to manage the virtual appliances on VMware ESX version 3.5.

Note: You cannot use version 4.0 of the vSphere client for installing virtual appliances on ESX 3.5. If you connect the vSphere 4.0 client to ESX 3.5, the vSphere client downgrades to VI client version 2.5, which supports only the OVF 0.9 standard. The NetScaler virtual appliance installation package is based on the OVF 1.0.

To install NetScaler virtual appliances on VMware ESX 3.5 by using the VMware OVF Tool

1. On your workstation, open the command-line interface and execute the following command:

   ```
   ovftool <path of the NetScaler VPX OVF file>
   vi://<Username>:<Password>@<IP address of the ESX server>
   ```

   For example, in Windows command shell, type:

   ```
   ovftool c:/NetScalerVPX vi://root:free@<10.217.20.14>
   ```

2. When the OVF tool has installed the virtual appliances on the ESX server, use the VI client to log on to the VMware ESX server on which you performed the installation.

3. In the navigation pane, right-click a virtual appliance that you want to enable, and then click **Power On**. Repeat this for each virtual appliance you want to enable.

4. Click the Console tab to emulate a console port.

Installing Citrix NetScaler Virtual Appliances on Microsoft Hyper-V Servers

To install Citrix NetScaler virtual appliances on Microsoft Windows Server, you must first install Windows Server, with the Hyper-V role enabled, on a machine with adequate system resources. While installing the Hyper-V role, be sure to specify the network interface cards (NICs) on the server that Hyper-V will use to create the virtual networks. You can reserve some NICs for the host. Use Hyper-V Manager to perform the NetScaler virtual appliance installation.

NetScaler virtual appliance for Hyper-V is delivered in virtual hard disk (VHD) format. It includes the default configuration for elements such as CPU, network interfaces, and hard-disk size and format. After you install NetScaler virtual appliance, you can configure the network adapters on virtual appliance, add virtual NICs, and then assign the NetScaler IP address, subnet mask, and gateway, and complete the basic configuration of the virtual appliance.

Note:

After the initial configuration of the NetScaler appliance, if you want to upgrade the appliance to the latest software release, see "Upgrading or Downgrading the System Software."

Prerequisites for Installing NetScaler Virtual Appliance on Microsoft Servers

Before you begin installing a virtual appliance, do the following:

- Enable the Hyper-V role on Windows Servers . For more information, see http://technet.microsoft.com/en-us/library/ee344837(WS.10).aspx.
- Download the virtual appliance setup files.
- Obtain NetScaler virtual appliance license files. For more information about NetScaler virtual appliance licenses, see the *NetScaler VPX Licensing Guide* at http://support.citrix.com/article/ctx131110.

Microsoft Server Hardware Requirements

The following table describes the minimum system requirements for Microsoft Servers .

Table 1. Minimum System Requirements for Microsoft Servers

Component	Requirement
CPU	1.4 GHz 64-bit processor
RAM	3 GB
Disk Space	32 GB or greater

The following table lists the virtual computing resources for each NetScaler virtual appliance.

Table 2. Minimum Virtual Computing Resources Required for Running NetScaler Virtual Appliance

Component	Requirement
RAM	2 GB
Virtual CPU	2
Disk Space	20 GB
Virtual Network Interfaces	1

Downloading the NetScaler Virtual Appliance Setup Files

NetScaler virtual appliance for Hyper-V is delivered in virtual hard disk (VHD) format. You can download the files from MyCitrix.com. You will need a My Citrix account to log on. If you do not have a My Citrix account, access the home page at http://www.mycitrix.com, click the New Users link, and follow the instructions to create a new My Citrix account.

To download the NetScaler virtual appliance setup files

1. In a Web browser, go to http://www.citrix.com/ and click My Citrix.
2. Type your user name and password.
3. Click Downloads.
4. In Search Downloads by Product, select NetScaler.
5. Under Virtual Appliances, click NetScaler VPX.
6. Copy the compressed file to your server.

Installing NetScaler Virtual Appliance on Microsoft Servers

After you have enabled the Hyper-V role on Microsoft Server and extracted the virtual appliance files, you can use Hyper-V Manager to install NetScaler virtual appliance. After you import the virtual machine, you need to configure the virtual NICs by associating them to the virtual networks created by Hyper-V.

You can configure a maximum of eight virtual NICs. Even if the physical NIC is DOWN, the virtual appliance assumes that the virtual NIC is UP, because it can still communicate with the other virtual appliances on the same host (server).

Note: You cannot change any settings while the virtual appliance is running. Shut down the virtual appliance and then make changes.

To install NetScaler Virtual Appliance on Microsoft Server by using Hyper-V Manager

1. To start Hyper-V Manager, click **Start**, point to **Administrative Tools**, and then click **Hyper-V Manager**.
2. In the navigation pane, under Hyper-V Manager, select the server on which you want to install NetScaler virtual appliance.
3. On the **Action** menu, click **Import Virtual Machine**.
4. In the **Import Virtual Machine** dialog box, in **Location**, specify the path of the folder that contains the NetScaler virtual appliance software files, and then select **Copy the virtual machine (create a new unique ID)**. This folder is the parent folder that contains the Snapshots, Virtual Hard Disks, and Virtual Machines folders.

   Note: If you received a compressed file, make sure that you extract the files into a folder before you specify the path to the folder.
5. Click **Import**.
6. Verify that the virtual appliance that you imported is listed under **Virtual Machines**.
7. To install another virtual appliance, repeat steps 2 through 6.

   Important: Make sure that you extract the files to a different folder in step 4.

To configure virtual NICs on the NetScaler Virtual Appliance

1. Select the virtual appliance that you imported, and then on the **Action** menu, select **Settings**.
2. In the **Settings for** <virtual appliance name> dialog box, click **Add Hardware** in the left pane.
3. In the right pane, from the list of devices, select **Network Adapter**.
4. Click **Add**.
5. Verify that **Network Adapter** (**not connected**) appears in the left pane.
6. Select the network adapter in the left pane.
7. In the right pane, from the **Network** drop-down list, select the virtual network to connect the adapter to.
8. To select the virtual network for additional network adapters that you want to use, repeat steps 6 and 7.
9. Click **Apply**, and then click **OK**.

To configure NetScaler Virtual Appliance

1. Right-click the virtual appliance that you previously installed, and then select **Start**.
2. Access the console by double-clicking the virtual appliance.
3. Type the NetScaler IP address, subnet mask, and gateway for your virtual appliance.

You have completed the basic configuration of your virtual appliance. Type the IP address in a Web browser to access the virtual appliance.

Configuring CloudBridge for Common Deployment Scenarios

To create a CloudBridge, you can perform the configuration tasks on the CloudBridge VPX instance at either of the sites that you want to bridge. You must specify the IP addresses of the CloudBridge VPX instances at the two sites (for example, the IP address of the instance in the data center and the IP address of the instance in AWS). You also need to configure the IPSec security settings. For more information on common CloudBridge topologies, see CloudBridge Topologies

Configuring CloudBridge between a Data Center and AWS

Before configuring CloudBridge between your local data center and a remote AWS cloud (to extend your network and leverage the cloud capabilities), make sure that you have publically accessible IP addresses for both locations. These publically accessible IP addresses are used to create a connection between the two locations.

You have to log on to the local CloudBridge instance and provide the AWS credentials (Access key and Secret Access key) and IP address of the remote CloudBridge instance in the AWS cloud.

To configure CloudBridge from a CloudBridge instance in the data center to a CloudBridge instance in AWS by using the configuration utility

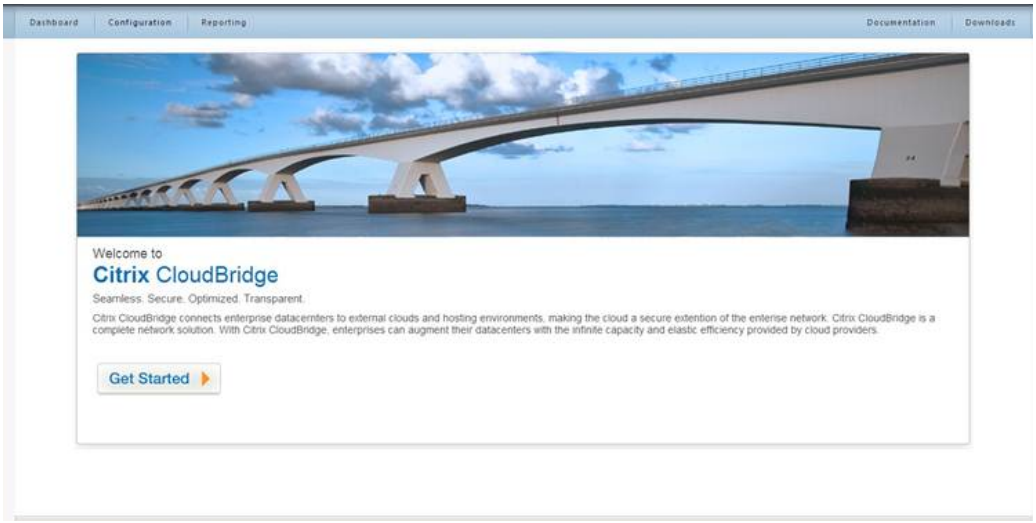
1. Access the configuration utility by using a web browser to connect to the IP address of the CloudBridge instance in the datacenter.

2. On the Configuration tab, in the Navigation pane, click CloudBridge.

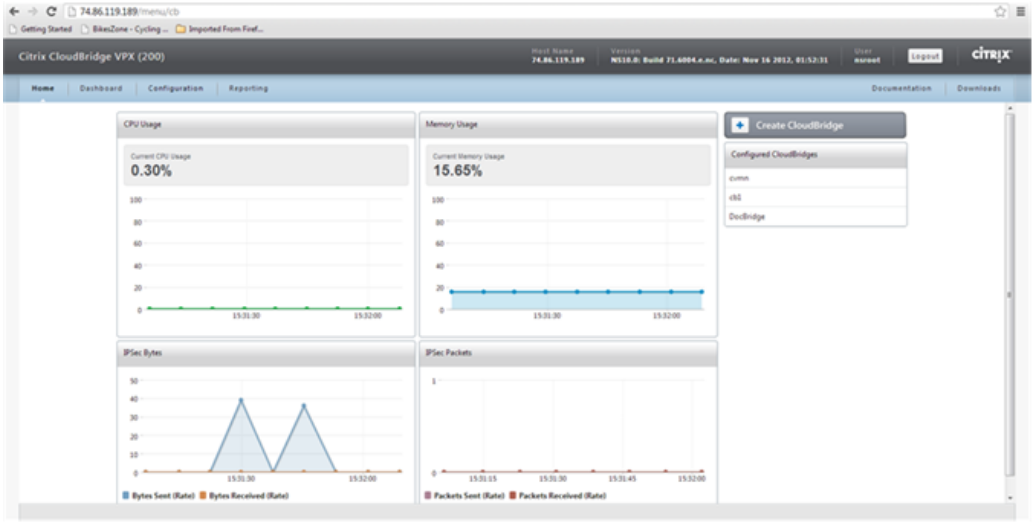
   Note: This screen appears only when you are using platinum edition license. For other licenses, you are taken to the Step 4 or Step 5 depending on whether CloudBridge is already configured on the CloudBridge VPX instance.

3. In the right pane, under Getting Started, click Create/Monitor CloudBridge.

4. Click **Get Started**.

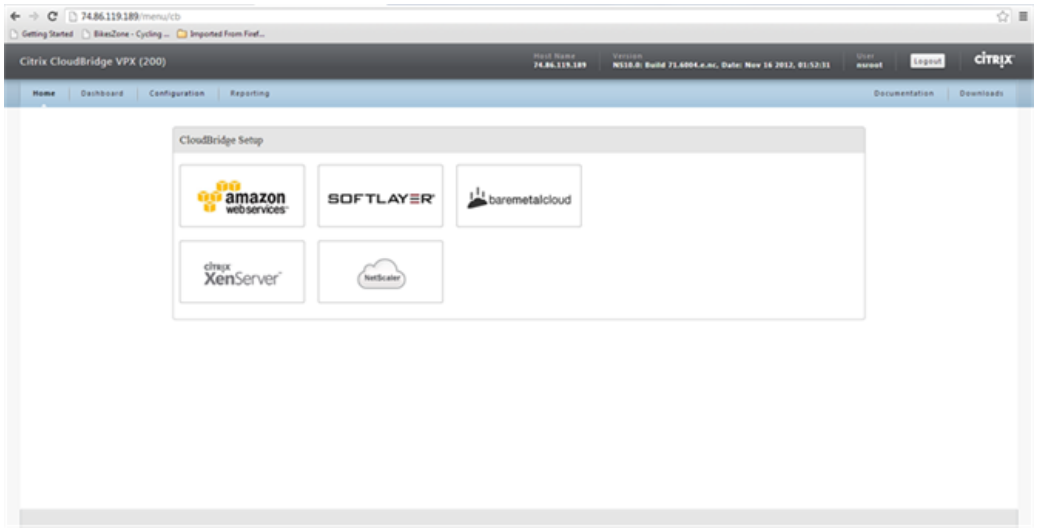


Note: If you already have a network bridge configured on the CloudBridge VPX instance, this screen does not appear. Instead, you are taken to the Citrix CloudBridge VPX page. Click Create CloudBridge to proceed.

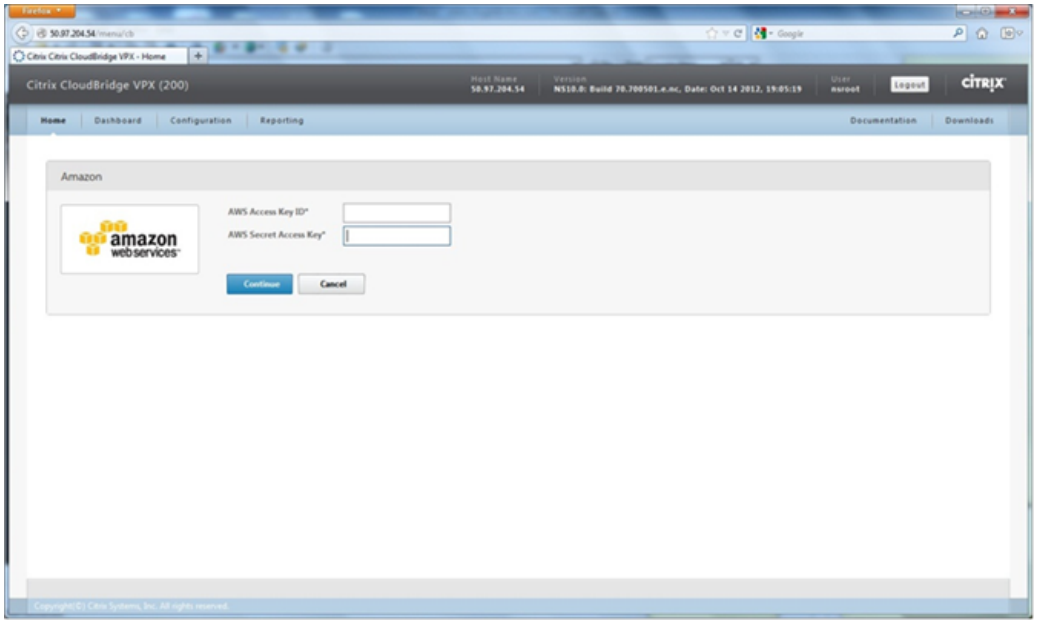


Note: If you are configuring first network bridge on an instance, this screen does not appear. Instead, after the **Get Started** page you are taken to the next page (**CloudBridge Setup**).

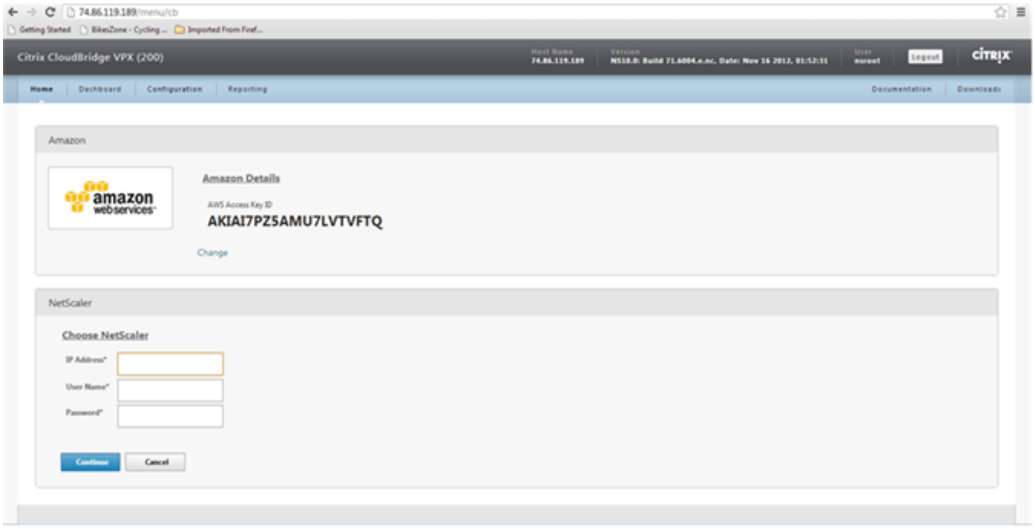
5. In the CloudBridge Setup pane, click amazon web services.



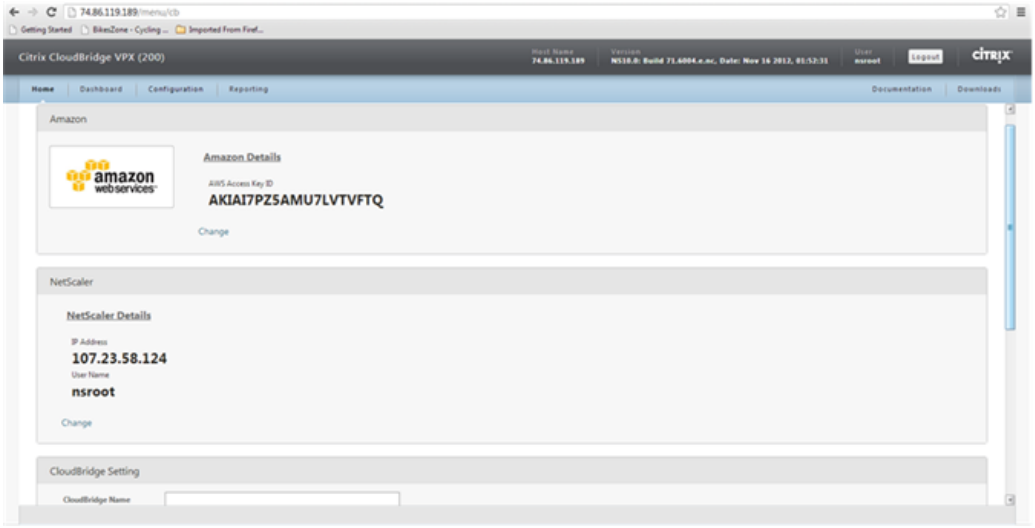
6. In the **Amazon** pane, enter the values for the access keys in the**AWS Access Key ID** and **AWS Secret Access Key** text boxes, and then click **Continue**. You can obtain these access keys from the AWS GUI console.



7. In the NetScaler pane, either select an IP address from the IP Address drop-down list or type the IP address, user name, and password in the corresponding text boxes for the CloudBridge VPX instance in AWS, and then click Continue. The IP address should be a publicly accessible address.



8. In the CloudBridge Setting pane, in the CloudBridge Name text box, type the name of the CloudBridge that you want to create.



9. Under Local Setting, from the Subnet IP drop-down list, select the subnet IP address of the local CloudBridge instance.

10. Under Remote Setting, from the Subnet IP drop-down list, select the subnet IP address of the CloudBridge VPX instance on the AWS.

11. Select the NetScaler Behind NAT checkbox and, in the IP Address text box, type the public IP address (EIP) that is mapped to the subnet IP you selected in step 10.

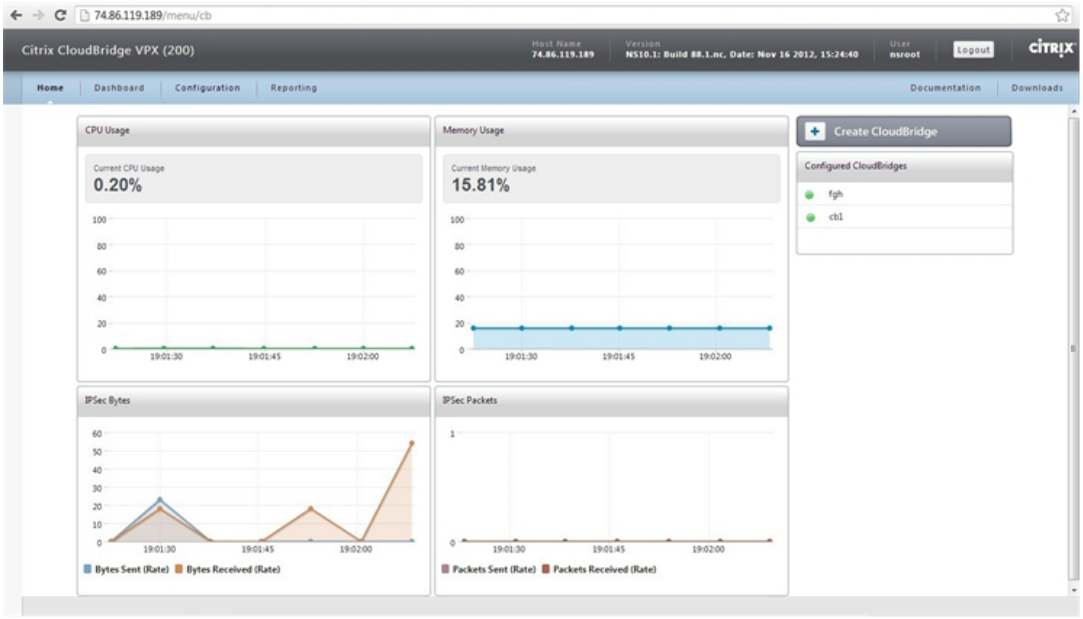
12. Under Security Settings, from the Encryption Algorithm and Hash Algorithm drop-down lists, select the algorithms that you want to use.

13. Select the Specify Key option and, in the Pre Shared Security Key text box, type the security key.

14. Click Done.

The new CloudBridge instance appears on the **Home** page. The current status of the CloudBridge is indicated in the **Configured CloudBridges** pane. A green dot indicates

that the tunnel is up. A red dot indicates that the tunnel is down.



To configure CloudBridge from a CloudBridge instance in the data center to a CloudBridge instance in AWS by using the command line

To set up a CloudBridge, on the CloudBridge instance in the data center:

- Create a network bridge
- Configure an IPsec profile
- Create a GRE tunnel with the IPsec profile
- Bind the IPsec tunnel to the network bridge

To create a network bridge by using the command line

At the local CloudBridge instance (in the data center) command prompt, type:

add netbridge <name>

Parameter for configuring a network bridge

name

Name of the CloudBridge that you are configuring. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equal (=), and hyphen (-) characters.

To configure IPsec profile by using the command line

At the local CloudBridge instance (in the data center) command prompt, type:

addipsec profile <name> [-encAlgo (AES | 3DES) ...] [-hashAlgo<hashAlgo> ...] [-lifetime<positive_integer>] (-psk |(-publickey<string>-privatekey<string>-peerPublicKey<string>))

Parameters for configuring IPsec profile

name

Name for an IPsec configuration. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

encAlgo

Encryption algorithm to be used in IPsec configuration for a CloudBridge. Possible values: AES, 3DES.

hashAlgo

Encryption algorithm to be used in IPsec configuration for a CloudBridge. Possible values: HMAC_SHA1, HMAC_SHA256, HMAC_MD5. Default: HMAC_SHA1.

lifetime

Time, in seconds, after which the security association expires. After expiration, new SAs are established, and new cryptographic keys are negotiated between the peers connected by the CloudBridge. Maximum value: 31536000. Default: 28800.

psk

Text string, called the pre-shared key, to be manually configured on each peer. The pre-shared keys of the peers are matched against each other for authentication before security associations are established. Therefore, for the authentication to be successful, you must configure the same pre-shared key on both of the peers of the CloudBridge. Maximum Length: 63 characters.

livenessCheckInterval

Time, in seconds, after which a notify payload is sent to check the status of the peer (UP or DOWN). Additional payloads are sent as per the retransmit interval setting. Zero value disables liveliness checks.

retransmissiontime

Time, in seconds, after which an IKE retry message is sent to a peer. The retry message is sent upto three times. Each failure doubles the amount of time before sending another retry message.

publickey

A local digital certificate to be used to authenticate the local CloudBridge appliance to the remote peer before establishing IPsec security associations. The same certificate should be present and set for the Peer Public Key parameter in the remote peer.

privatekey

Private key of the local digital certificate.

peerPublicKey

Digital certificate of the remote peer. This certificate is used to authenticate the remote peer to the local peer before establishing IPsec security associations. The same certificate should be present and set for the Public key parameter in the remote peer.

To create a GRE tunnel with IPsec profile by using the command line

At the local CloudBridge instance (in the data center) command prompt type:

add iptunnel <name><remoteIp><remoteSubnetMask><localIp>-type -protocol (GRE) -ipsecprofile<name>

Parameters for creating a GRE tunnel with IPsec profile

name

Name of the IP Tunnel. This alphanumeric string is required and cannot be changed after the service group is created. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

remoteIp

A public IP address of the remote CloudBridge appliance,in AWS, used to set up the tunnel.

remoteSubnetMask

Subnet mask of the remote IP address of the tunnel.

localIp

A public address of the local CloudBridge instance used to set up the tunnel. Possible values: Auto, MIP, SNIP, and VIP. Default: Auto.

protocol

The protocol to be used in setting up the IP tunnel. Select GRE to set up a GRE tunnel.

ipsecProfileName

Name of the IPsec profile that is used for securing communication in the GRE tunnel. If this parameter is not specified, the default profile (ns_ipsec_default_profile) is configured and, if this parameter is set to none, a GRE tunnel is created.

To bind an IPsec tunnel to the network bridge by using the command line

At the local CloudBridge instance (in the data center) command prompt, type:

bindnetbridge <name> [-tunnel <name>] [-vlan <id>] [-IPAddress <ip_addr | ipv6_addr>]

Parameters for binding IPsec tunnel to the network bridge

name

Name of the CloudBridge that you are configuring.Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

tunnel

Name of the GRE tunnel to be associated with the CloudBridge.

VLAN

Identifier of the local VLAN that needs to be extended to the cloud.

IPAddress

The IPV4 subnet that needs to be extended to the cloud.

Configuring CloudBridge between Two CloudBridge VPX Instances in two Different VPCs in AWS

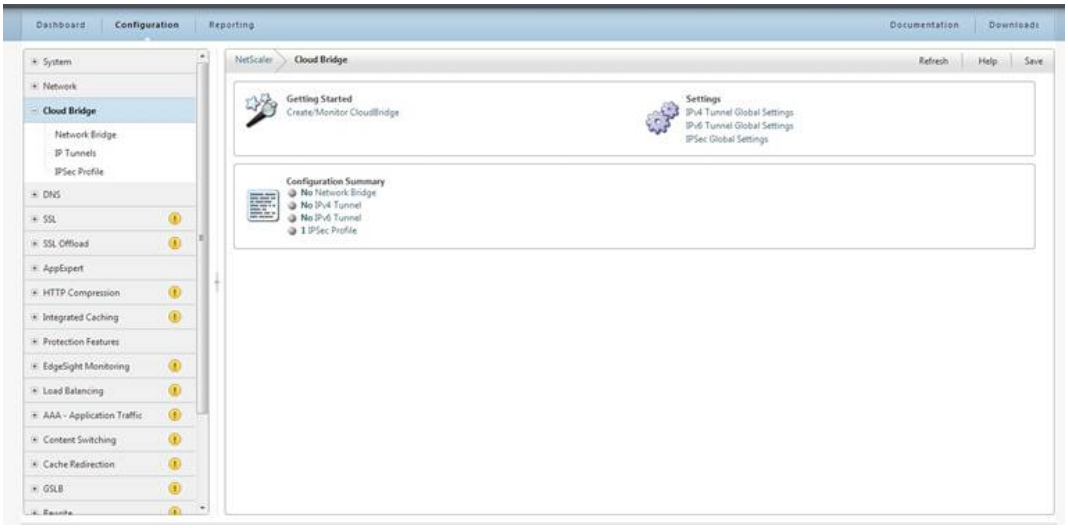
Before configuring a CloudBridge between two VPC instances (to extend your network and implement redundancy and backup functionality), make sure that you have publically accessible IP addresses for both the VPCs. These publically accessible IP addresses are used to create the connection between the two VPC locations.

You must log on to the CloudBridge VPX instance in one of the AWS VPC and connect to the CloudBridge VPX instance in the other AWS VPC (consider this one to be the remote cloud). To create the connection, use the remove instance's AWS credentials (Access key and Secret Access key) and IP address.

To configure a CloudBridge between two CloudBridge VPX instances in different VPCs by using the configuration utility

1. Access the configuration utility by using the web browser to connect to the IP address of one of the CloudBridge instances in AWS.

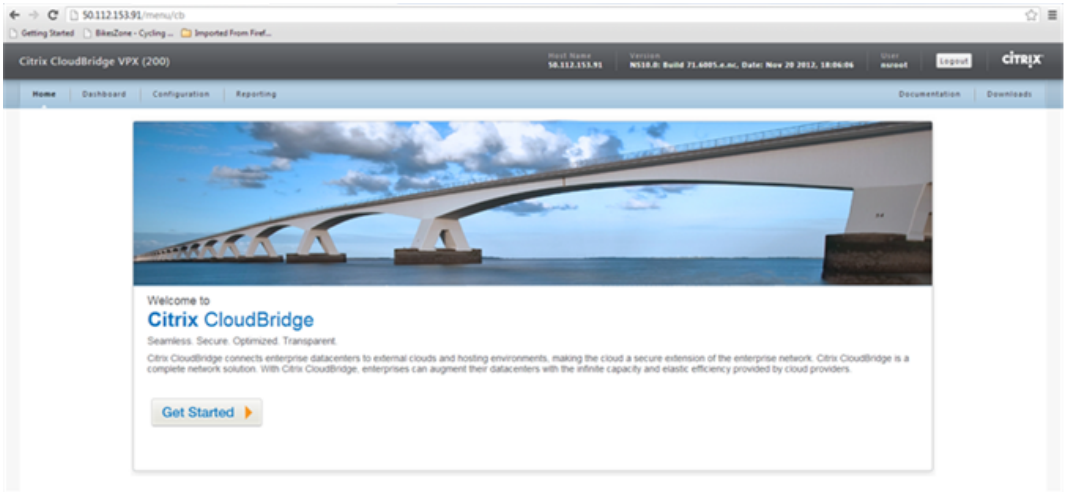
2. On the Configuration tab, in the Navigation pane, click CloudBridge.



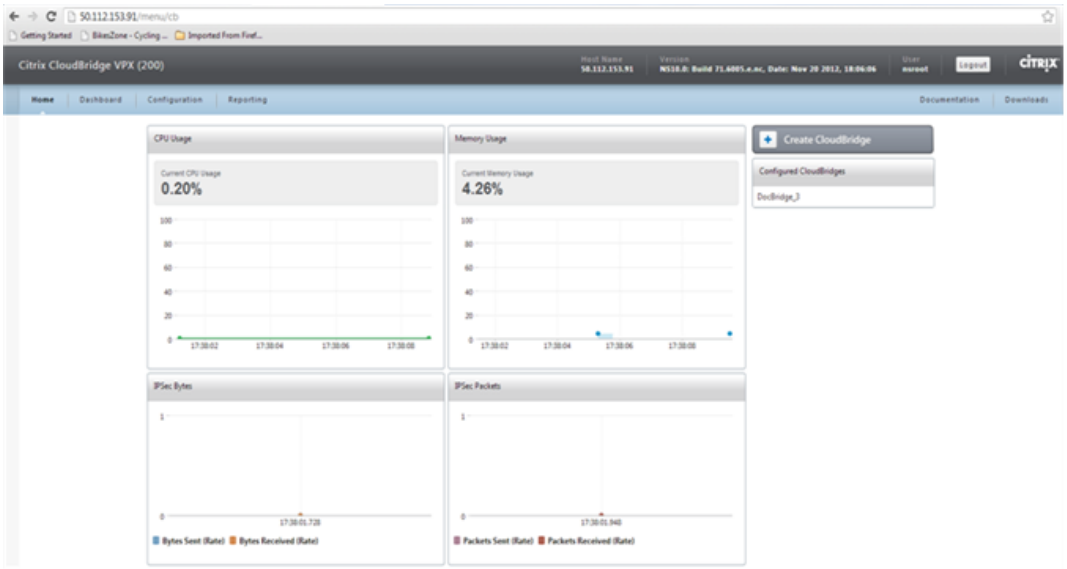
Note: This screen appears only when you are using a platinum edition license. For other licenses, you are taken to Step 4 or Step 5 depending on whether CloudBridge is already configured on the CloudBridge VPX instance.

3. In the right pane, under Getting Started, click Create/Monitor CloudBridge.

4. Click Get Started.

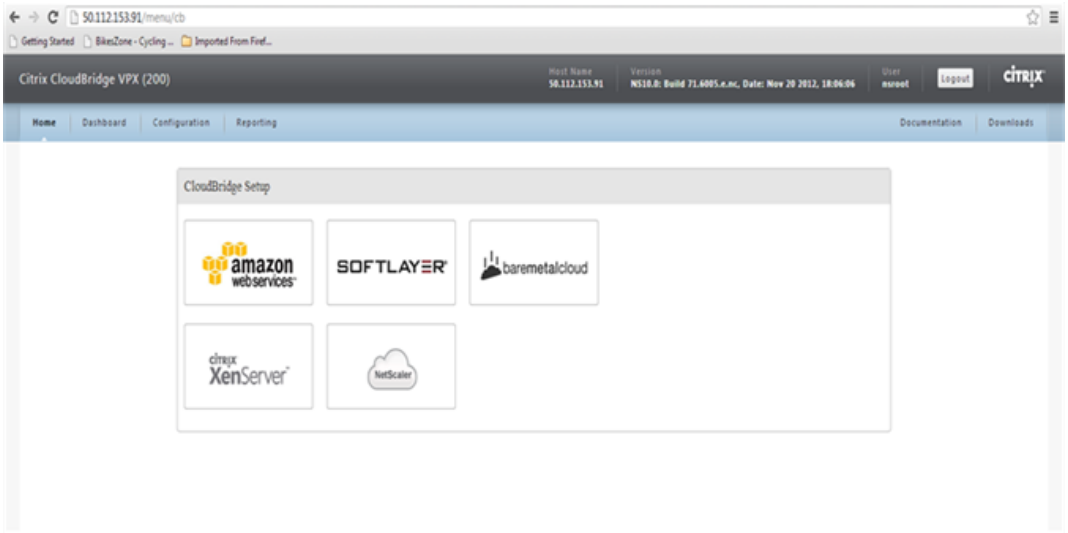


Note: If you already have a network bridge configured on the CloudBridge VPX instance, this screen does not appear. Instead, you are taken to the Citrix CloudBridge VPX page. Click Create CloudBridge to proceed.

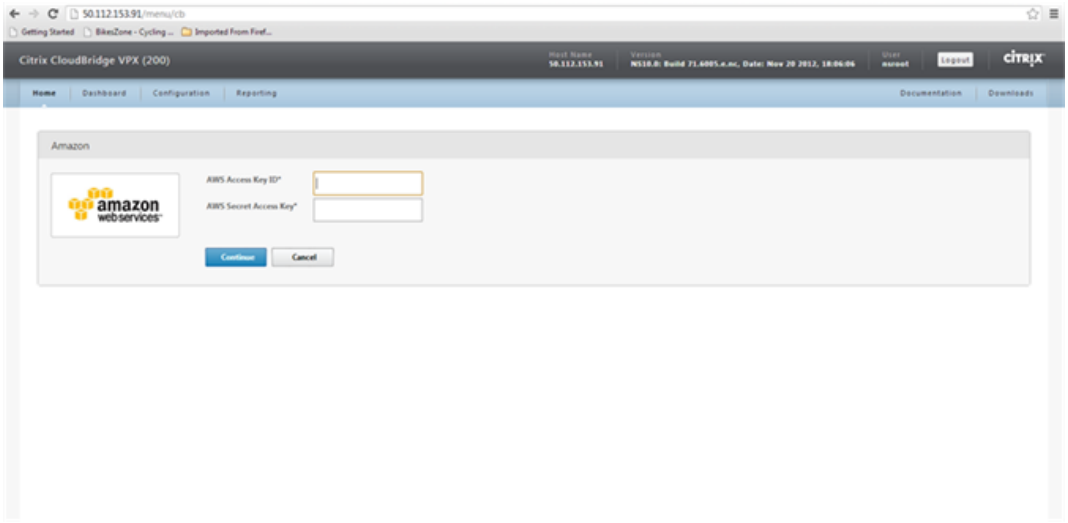


Note: If you are configuring the first network bridge on an instance, this screen does not appear. Instead, after the Get Started page you are taken to the next page (**CloudBridge Setup**).

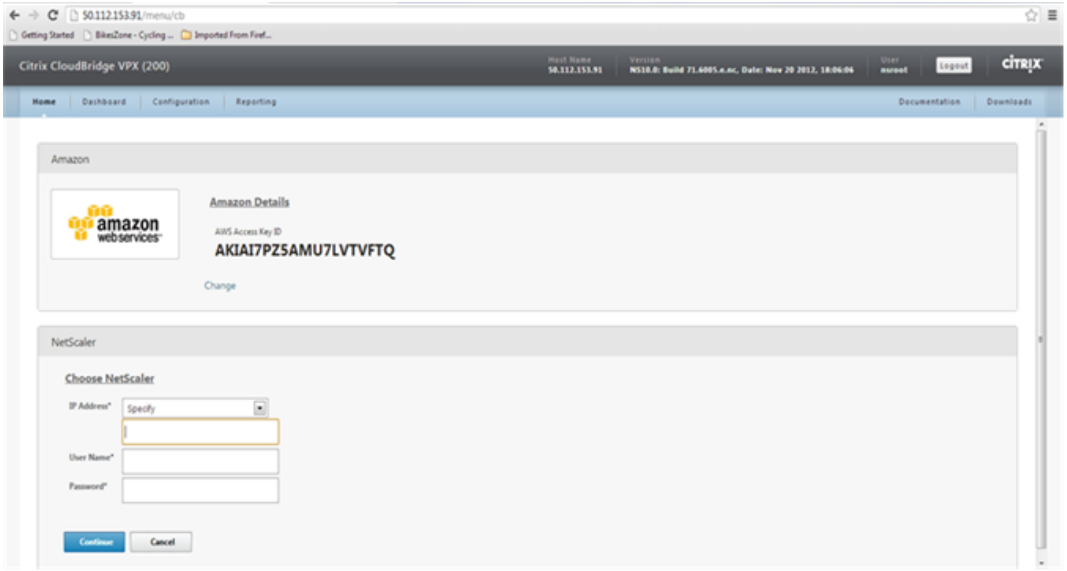
5. In the CloudBridge Setup pane, click amazon web services.



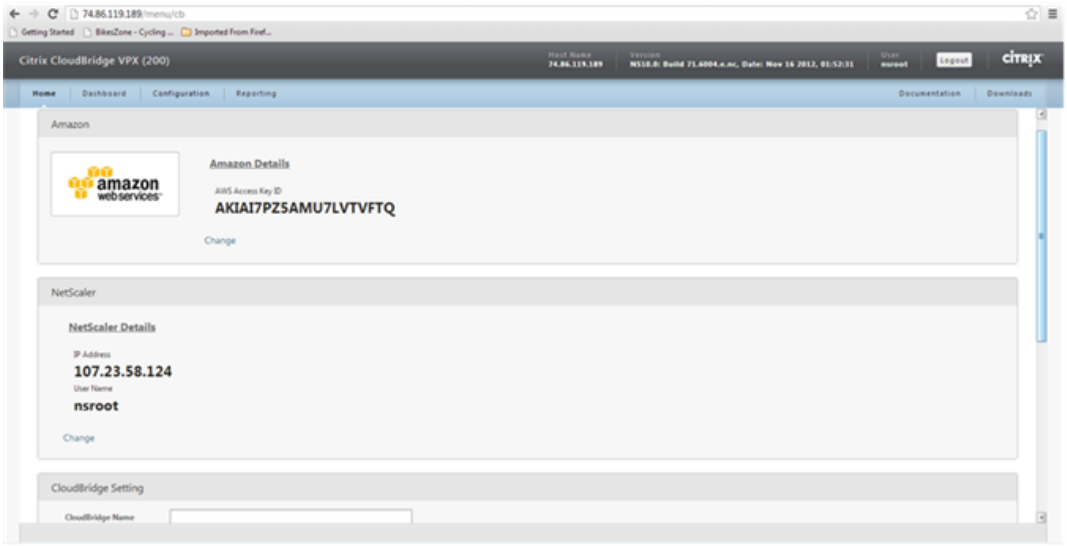
6. In the Amazon pane, type the values for the access keys in the AWS Access Key ID and AWS Secret Access Key text boxes, and then click Continue. You can obtain these access keys from the AWS GUI console.



7. In the NetScaler pane, either select an IP address from the IP Address drop-down list or type the IP address, user name, and password in the corresponding text boxes for the local CloudBridgeVPX instance in the AWS cloud, and then click Continue. The IP address should be a publicly accessible address.



8. In the CloudBridge Setting pane, in the CloudBridge Name text box, type the name of the CloudBridge that you want to create.



9. Under **Local Setting**, from the Subnet IP drop-down list, select the subnet IP address of the local CloudBridge instance.

10. Select the NetScaler Behind NAT checkbox and, in the IP Address text box, type the public IP address (EIP) that is mapped to the subnet IP you selected in step 9.

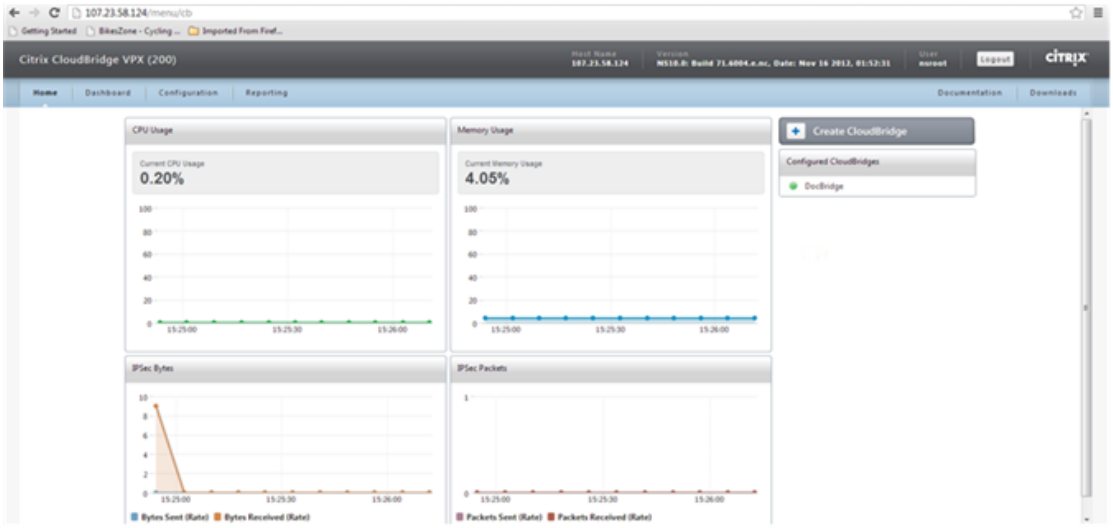
11. Under **Remote Setting**, from the Subnet IP drop-down list, select the subnet IP address of the remote CloudBridge instance.

12. Select the **NetScaler Behind NAT** checkbox and, in the **IP Address** text box, type the public IP address (EIP) that is mapped to the subnet IP you selected in step 11.

13. Under **Security Settings**, from the **Encryption Algorithm** and **Hash Algorithm** drop-down lists, select the algorithms that you want to use.

14. Select the **Specify Key** option and, in the **Pre Shared Security Key** text box, type the security key. Click **Done**.

The new CloudBridge instance appears on the **Home** page. The current status of the CloudBridge is indicated in the **Configured CloudBridge** pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.



To configure a CloudBridge between two CloudBridge VPX instances in different VPCs by using the command line

To set up a CloudBridge between two CloudBridge VPX instances in different VPCs:

- Create a network bridge
- Configure an IPSec profile
- Create a GRE tunnel with the IPSec profile
- Bind the IPSec tunnel with the network bridge

To create a network bridge by using the command line

At the local CloudBridge instance (in the local VPC) command prompt, type:

add netbridge <*name*>

Parameter for configuring a network bridge

name

Name of the CloudBridge that you are configuring must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

To configure IPSec profile by using the command line

At the local CloudBridge instance (in the local VPC) command prompt, type:

addipsec profile <name> [-encAlgo (AES | 3DES) ...] [-hashAlgo<hashAlgo> ...]
[-lifetime<positive_integer>] (-psk
|(-publickey<string>-privatekey<string>-peerPublicKey<string>))

Parameters for configuring an IPSec profile

name

Name for an IPSec configuration. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

encAlgo

Encryption algorithm to be used in IPSec configuration for a CloudBridge. Possible values: AES, 3DES.

hashAlgo

Encryption algorithm to be used in IPSec configuration for a CloudBridge. Possible values: HMAC_SHA1, HMAC_SHA256, HMAC_MD5. Default: HMAC_SHA1.

lifetime

Time, in seconds, after which the security association expires. After expiration, new SAs are established, and new cryptographic keys are negotiated between the peers connected by the CloudBridge. Maximum value: 31536000. Default: 28800.

psk

Text string, called the pre-shared key, to be manually configured on each peer. The pre-shared keys of the peers are matched against each other for authentication before security associations are established. Therefore, for the authentication to be successful, you must configure the same pre-shared key on both of the peers of the CloudBridge. Maximum Length: 63 characters.

livenessCheckInterval

Time, in seconds, after which a notify payload is sent to check the status of the peer (UP or DOWN). Additional payloads are sent as specified by the retransmit interval setting. A value of zero disables liveliness checks.

retransmissiontime

Time, in seconds, after which an IKE retry message is sent to a peer. The retry message is sent upto three times. Each failure doubles the amount of time before sending another retry message.

publickey

A local digital certificate to be used to authenticate the local CloudBridge appliance to the remote peer before establishing IPSec security associations. The same certificate should be present and set for the Peer Public Key parameter in the remote peer.

privatekey

Private key of the local digital certificate.

peerPublicKey

Digital certificate of the remote peer. This certificate is used to authenticate the remote peer to the local peer before establishing IPSec security associations. The same certificate should be present and set for the Public key parameter in the remote peer.

To create a GRE tunnel with IPSec profile by using the command line

At the local CloudBridge instance (in the local VPC) command prompt type:

add iptunnel <name><remoteIp><remoteSubnetMask><localIp>-type -protocol (GRE) -ipsecprofile<name>

Parameters for creating a GRE tunnel with IPSec profile

name

Name of the IP Tunnel. This alphanumeric string is required and cannot be changed after the service group is created. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.),

space, colon (:), at (@), equals (=), and hyphen (-) characters.

remoteIp

A public IP address of the remote CloudBridge appliance, in AWS, used to set up the tunnel.

remoteSubnetMask

Subnet mask of the remote IP address of the tunnel.

localIp

A public address of the local CloudBridge instance used to set up the tunnel. Possible values: Auto, MIP, SNIP, and VIP. Default: Auto.

protocol

The protocol to be used in setting up the IP tunnel. Select GRE to set up a GRE tunnel.

ipsecProfileName

Name of the IPSec profile that is used for securing communication in the GRE tunnel. If this parameter is not specified, the default profile (ns_ipsec_default_profile) is configured and, if this parameter is set to none, a GRE tunnel is created.

To bind IPSec tunnel to the network bridge by using the command line

At the local CloudBridge instance (in the local VPC) command prompt, type:

bindnetbridge<name> [-tunnel<name>] [-vlan<id>] [-IPAddress<ip_addr|ipv6_addr>]

Parameters for binding IPSec tunnel to the network bridge

name

Name of the CloudBridge that you are configuring.Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

tunnel

Name of the GRE tunnel to be associated with the CloudBridge.

VLAN

Identifier of the local VLAN that needs to be extended to the cloud.

IPAddress

The IPV4 subnet that needs to be extended to the cloud.

Parameter Descriptions (of commands listed in the CLI procedure)

add netbridge

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

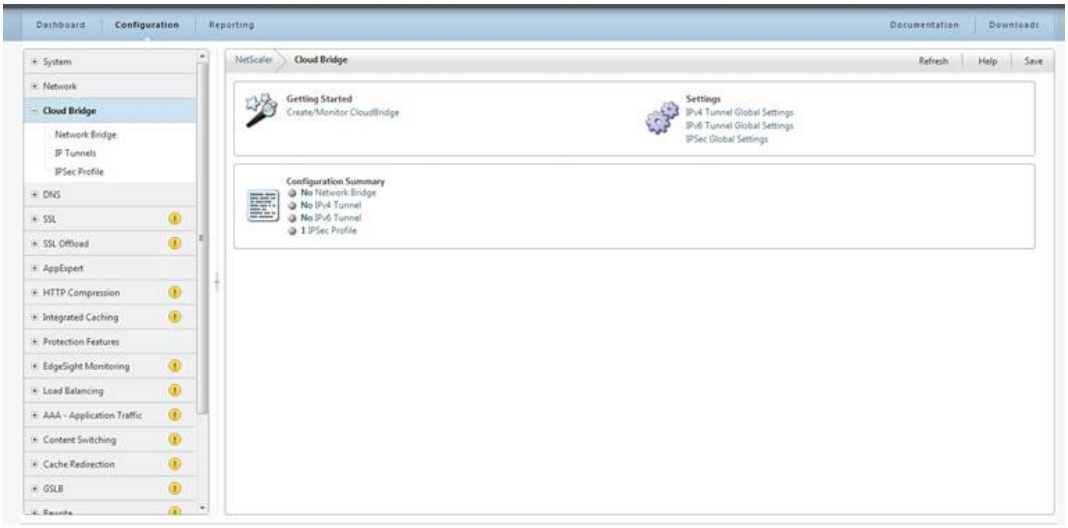
Configuring CloudBridge from AWS to Data Center

To configure a CloudBridge between AWS cloud and your data center from the CloudBridge VPX instance in the AWS cloud, you log on into the CloudBridge VPX instance in AWS and connect to the CloudBridge instance in the data center.

To configure CloudBridge from a CloudBridge VPX in the AWS cloud to a CloudBridge instance in the data center by using the configuration utility

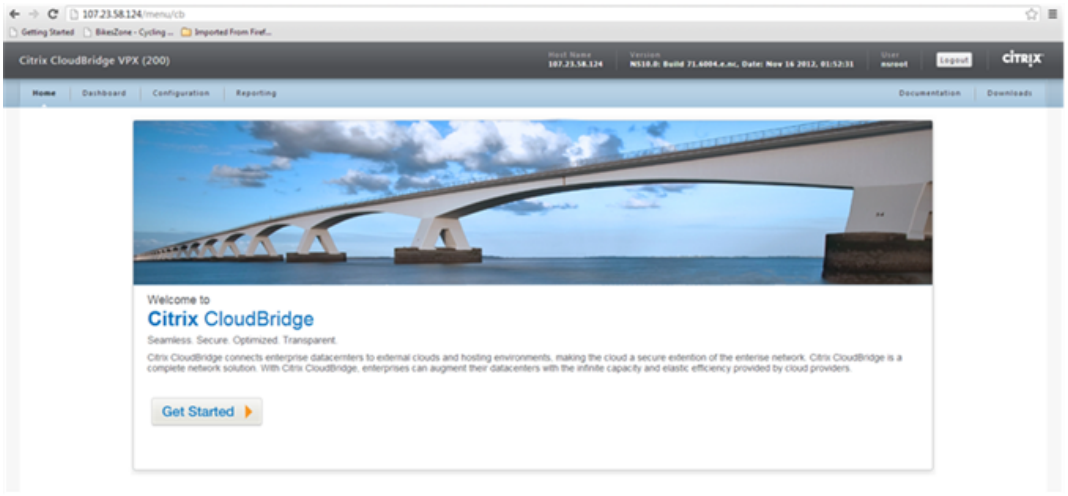
1. Access the configuration utility by using a web browser to connect to the IP address of the CloudBridge instance in the AWS cloud.

2. On the Configuration tab, in the Navigation pane, click CloudBridge.

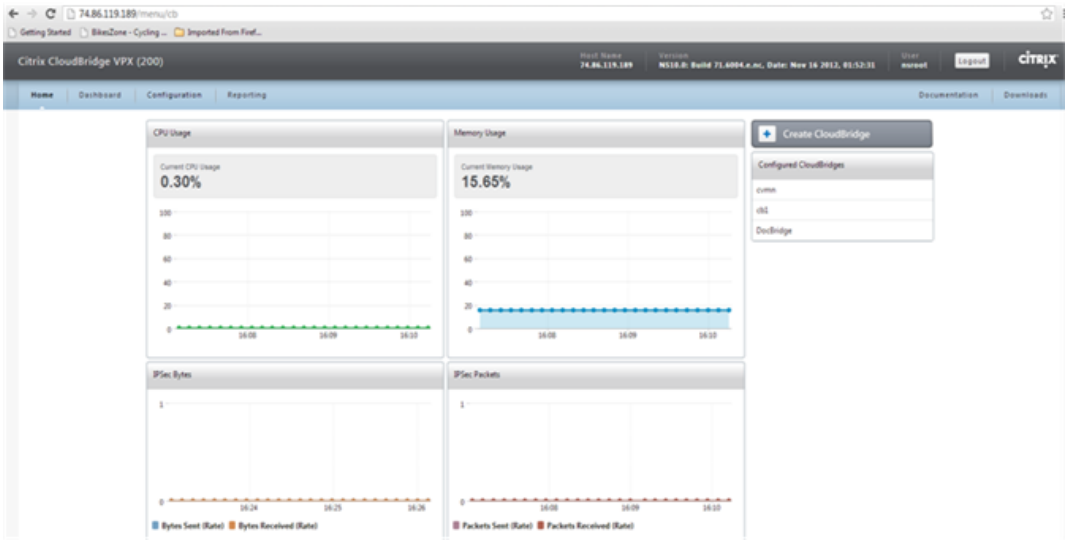


3. In the right pane, under **Getting Started**, click Create/Monitor CloudBridge.

4. Click Get Started.

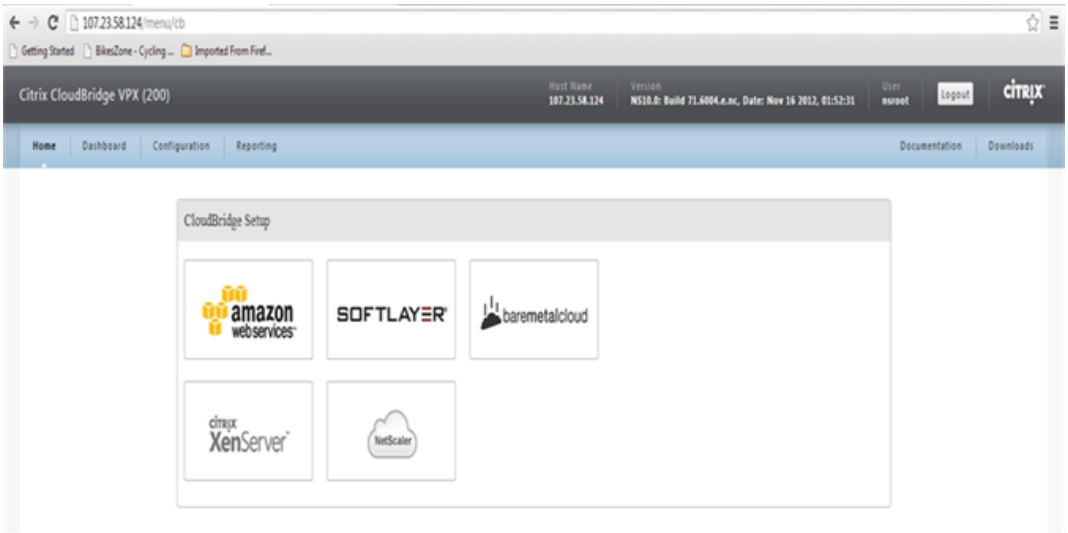


Note: If you already have a network bridge configured on the CloudBridge VPX, this screen does not appear. Instead, you are taken to the **CitrixCloudBridge VPX** page. Click **Create CloudBridge** to proceed.

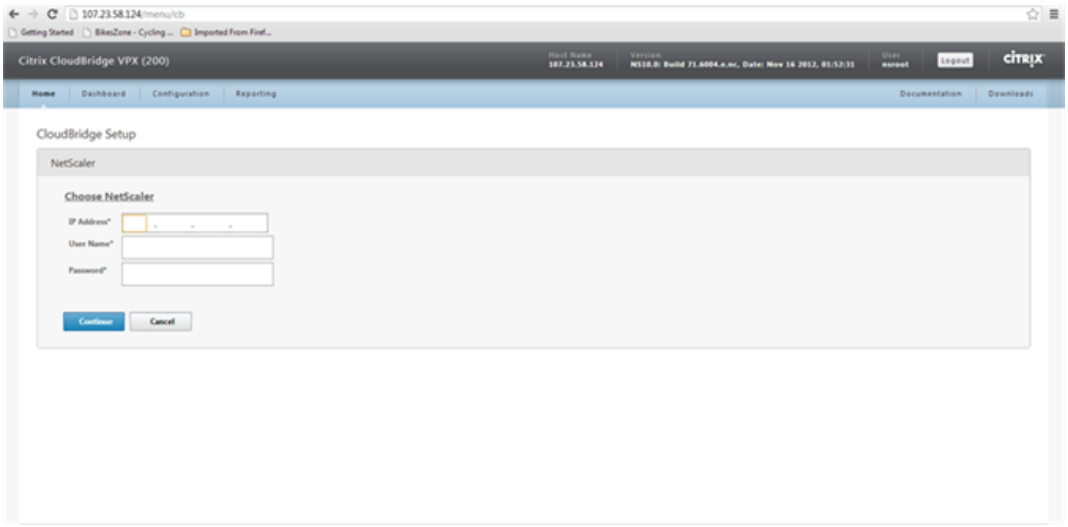


Note: If you are configuring first network bridge on an instance, this screen does not appear. Instead, after the **Get Started** page you are taken to the next page (**CloudBridge Setup**).

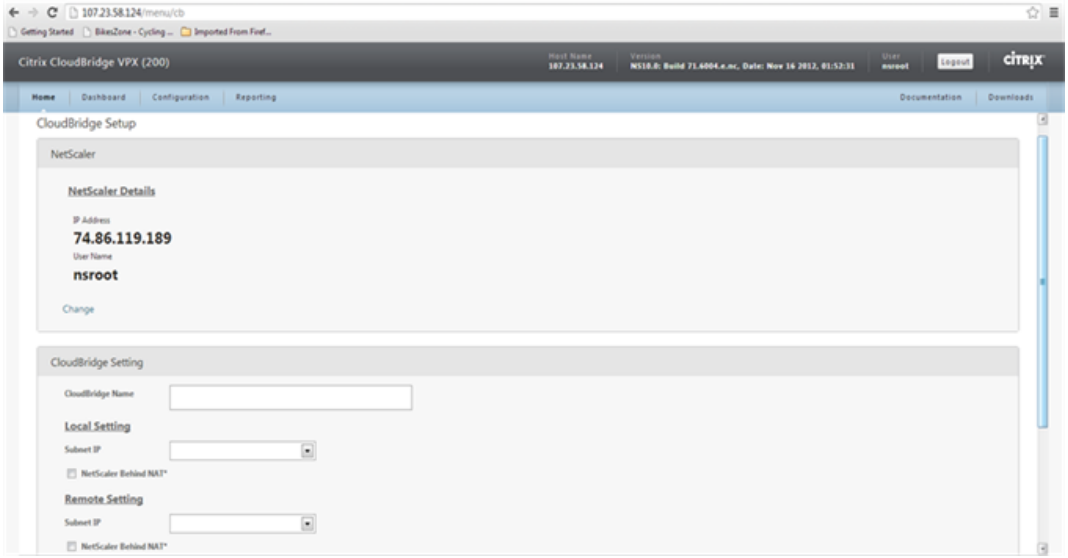
5. In the CloudBridge Setup pane, click NetScaler.



6. In the NetScaler pane, type values in the **IP Address**, **User Name**, and **Password** text boxes for the CloudBridge VPX instance on AWS, and then click Continue. The IP address should be a publicly accessible address.



7. In the **CloudBridge Setting** pane, in the **CloudBridge Name** text box, type the name of the CloudBridge that you want to create.



8. Under **Local Setting**, from the **Subnet IP** drop-down list, select the subnet IP address of the CloudBridge VPX appliance on AWS.

9. Under **Remote Setting**, from the **Subnet IP** drop-down list, select the subnet IP address of the CloudBridge instance in the data center. The subnet IP address should not be the NSIP.

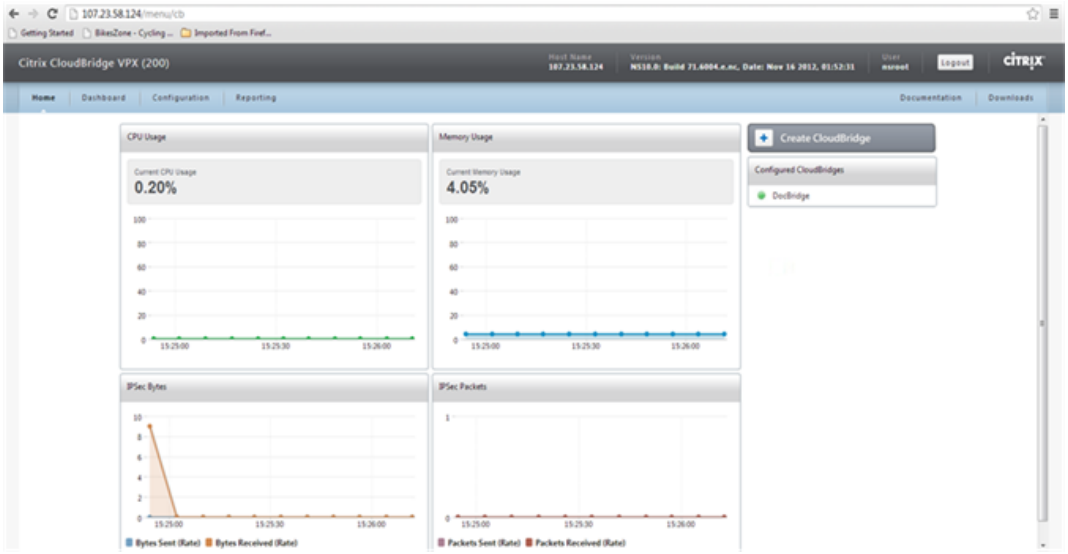
10. Select the **NetScaler Behind NAT** checkbox and, in the **IP Address** text box, type the public IP address (EIP) that is mapped to the subnet IP you selected in step 9.

11. Under **Security Settings**, from the **Encryption Algorithm** and **Hash Algorithm** drop-down lists, select the algorithms that you want to use.

12. Select the **Specify Key** option and, in the **Pre Shared Security Key** text box, type the security key.

13. Click **Done**.

The new CloudBridge instance appears on the **Home** page. The current status of the CloudBridge is indicated in the **Configured CloudBridges** pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.



To configure CloudBridge from a CloudBridge VPX in the AWS cloud to a CloudBridge instance in the data center by using the command line

To set up a CloudBridge, on the CloudBridge instance in the AWS:

- Create a network bridge
- Configure an IPsec profile
- Create a GRE tunnel with the IPsec profile
- Bind the IPsec tunnel to the network bridge

To create a network bridge by using the command line

At the local CloudBridge instance (in the AWS VPC) command prompt, type:

addnetbridge<name>

Parameter for configuring a network bridge

name

Name of the CloudBridge that you are configuring. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equal (=), and hyphen (-) characters.

To configure an IPsec profile by using the command line

At the local CloudBridge instance (in the AWS VPC) command prompt, type:

addipsec profile<name> [-encAlgo (AES | 3DES) ...] [-hashAlgo<hashAlgo> ...] [-lifetime<positive_integer>] (-psk |(-publickey<string> -privatekey<string> -peerPublicKey<string>))

Parameters for configuring an IPsec profile

name

Name for an IPsec configuration.Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equal (=), and hyphen (-) characters.

encAlgo

Encryption algorithm to be used in IPsec configuration for a CloudBridge. Possible values: AES, 3DES.

hashAlgo

Encryption algorithm to be used in IPsec configuration for a CloudBridge. Possible values: HMAC_SHA1, HMAC_SHA256, HMAC_MD5. Default: HMAC_SHA1.

lifetime

Time, in seconds, after which the security association expires. After expiration, new SAs are established, and new cryptographic keys are negotiated between the peers connected by the CloudBridge. Maximum value: 31536000. Default: 28800.

psk

Text string, called the pre-shared key, to be manually configured on each peer. The pre-shared keys of the peers are matched against each other for authentication before security associations are established. Therefore, for the authentication to be successful, you must configure the same pre-shared key on both of the peers of the CloudBridge. Maximum Length: 63 characters.

livenessCheckInterval

Time, in seconds, after which a notify payload is sent to check the status of the peer (UP or DOWN). Additional payloads are sent as specified by the retransmit interval setting. A value of zero disables liveliness checks.

retransmissiontime

Time, in seconds, after which an IKE retry message is sent to a peer. The retry message is sent upto three times. Each failure doubles the amount of time before sending another retry message.

publickey

A local digital certificate to be used to authenticate the local CloudBridge appliance to the remote peer before establishing IPsec security associations. The same certificate should be present and set for the Peer Public Key parameter in the remote peer.

privatekey

Private key of the local digital certificate.

peerPublicKey

Digital certificate of the remote peer. This certificate is used to authenticate the remote peer to the local peer before establishing IPsec security associations. The same certificate should be present and set for the Public key parameter in the remote peer.

To create GRE tunnel with an IPsec profile by using the command line

At the local CloudBridge instance (in the AWS VPC) command prompt type:

add iptunnel <name> <remoteIp> <remoteSubnetMask> <localIp> -type -protocol (GRE) -ipsecprofile <name>

Parameters for creating a GRE tunnel with IPsec profile

name

Name of the IP Tunnel. This alphanumeric string is required and cannot be changed after the service group is created. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equal (=), and hyphen (-) characters.

remoteIp

A public IP address of the remote CloudBridge appliance, in the data center, used to set up the tunnel.

remoteSubnetMask

Subnet mask of the remote IP address of the tunnel.

localIp

A public address of the local CloudBridge instance used to set up the tunnel. Possible values: Auto, MIP, SNIP, and VIP. Default: Auto.

protocol

The protocol to be used in setting up the IP tunnel. Select GRE to set up a GRE tunnel.

ipsecProfileName

Name of the IPsec profile that is used for securing communication in the GRE tunnel. If this parameter is not specified, the default profile (ns_ipsec_default_profile) is configured and, if this parameter is set to none, a GRE tunnel is created.

To bind IPsec tunnel to the network bridge by using the command line

At the local CloudBridge instance (in the AWS VPC) command prompt, type:

bindnetbridge<name> [-tunnel<name>] [-vlan<id>] [-IPAddress<ip_addr|ipv6_addr>]

Parameters for binding an IPsec tunnel to the network bridge

name

Name of the CloudBridge that you are configuring. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

tunnel

Name of the GRE tunnel to be associated with the CloudBridge.

VLAN

Identifier of the local VLAN that needs to be extended to the cloud.

IPAddress

The IPV4 subnet that needs to be extended to the cloud.

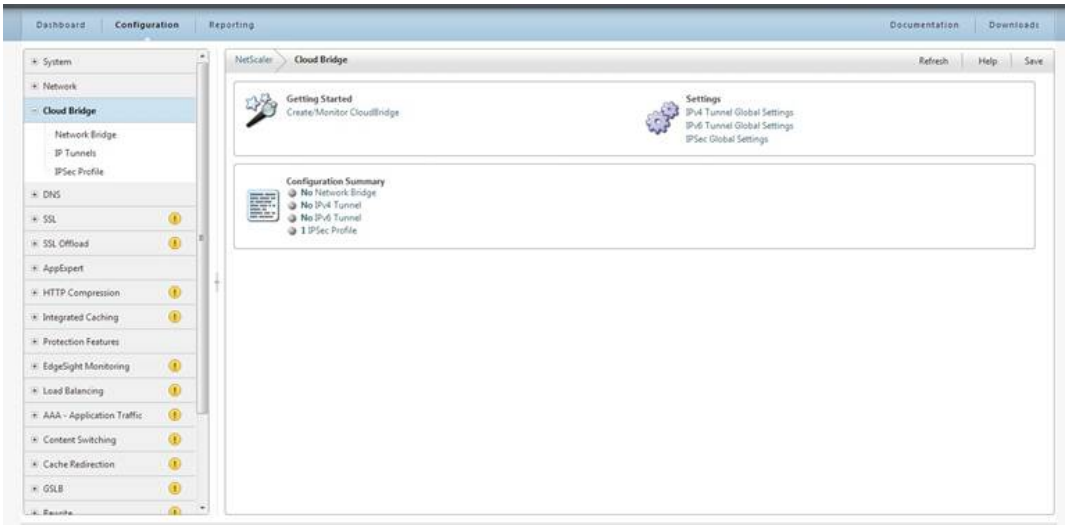
Configuring a CloudBridge between Two Data Centers

You can configure a CloudBridge between two different data centers to extend your network without reconfiguring the setup, and leverage the capabilities of the two data centers. Having a CloudBridge configured between the two geographically separated data centers enables you to implement redundancy and safeguard your setup from failure. The applications available across the two data centers appear as local to the user.

To configure CloudBridge between two CloudBridge instances in two different data centers by using the configuration utility

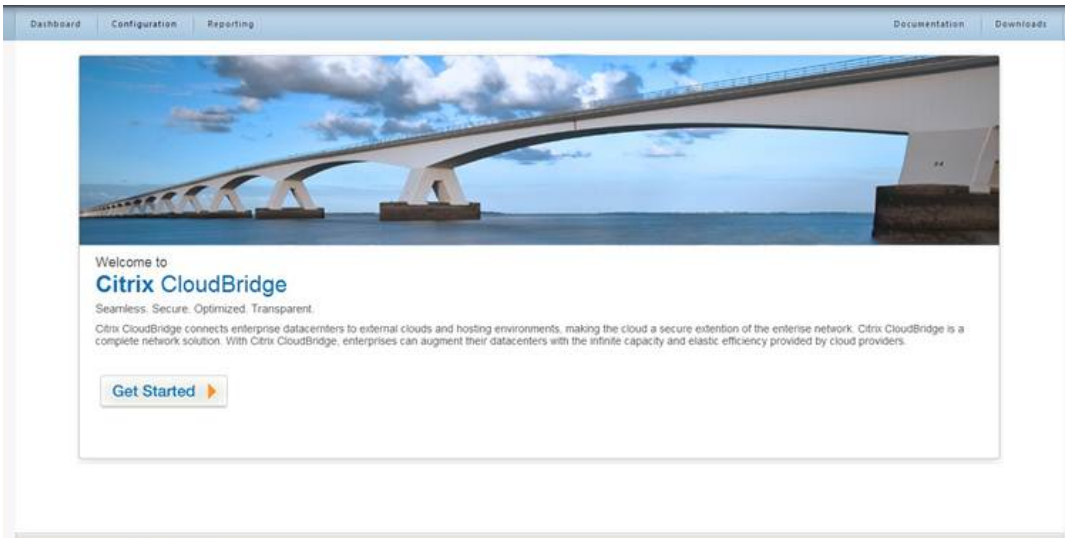
1. Access the configuration utility by using a web browser to connect to the IP address of the CloudBridge instance in the local data center.

2. On the **Configuration** tab, in the Navigation pane, click CloudBridge.

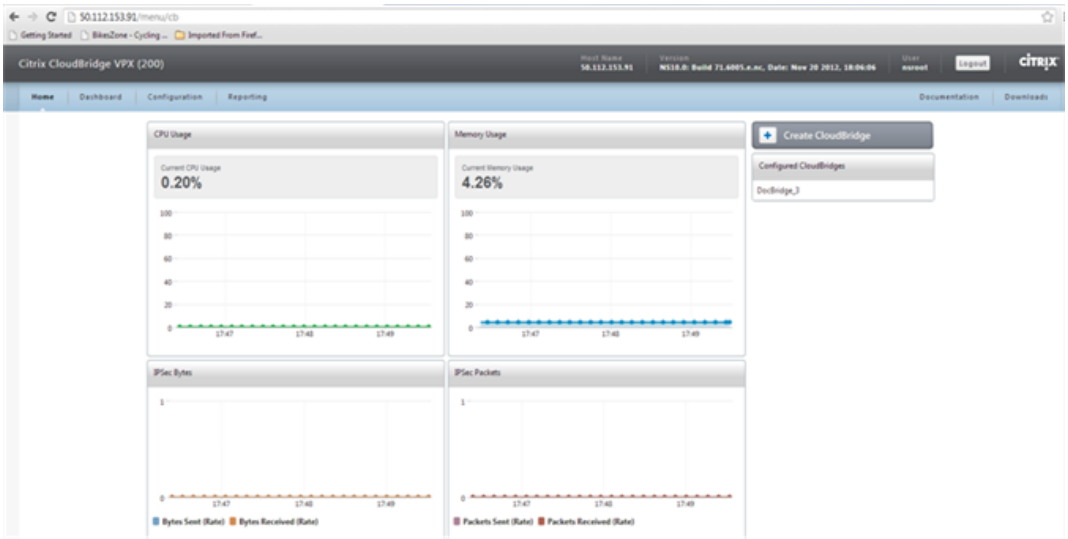


3. In the right pane, under **Getting Started**, click Create/Monitor CloudBridge.

4. Click Get Started.

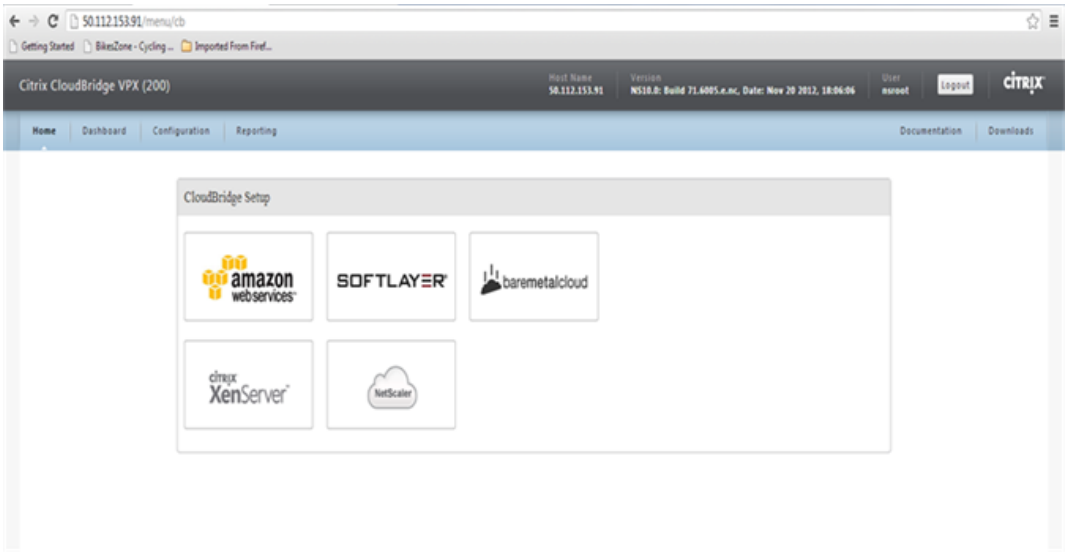


Note: If you already have a network bridge configured on the CloudBridge VPX, this screen does not appear. Instead, you are taken to the **CitrixCloudBridge VPX** page. Click **Create CloudBridge** to proceed.

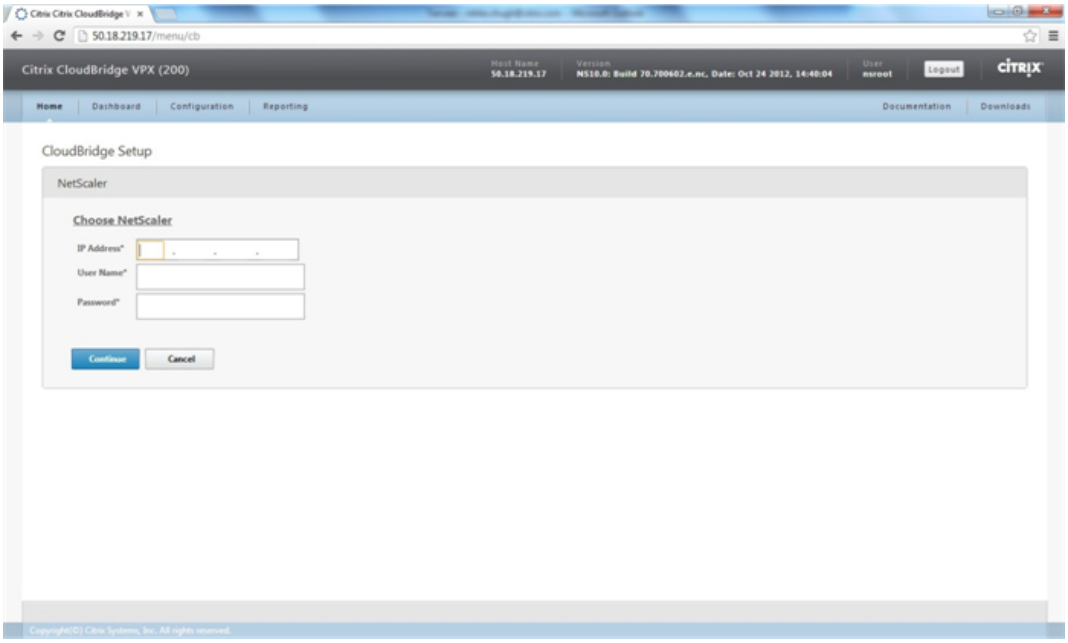


Note: If you are configuring the first network bridge on an instance, this screen does not appear. Instead, after the **Get Started** page you are taken to the next page (**CloudBridge Setup**).

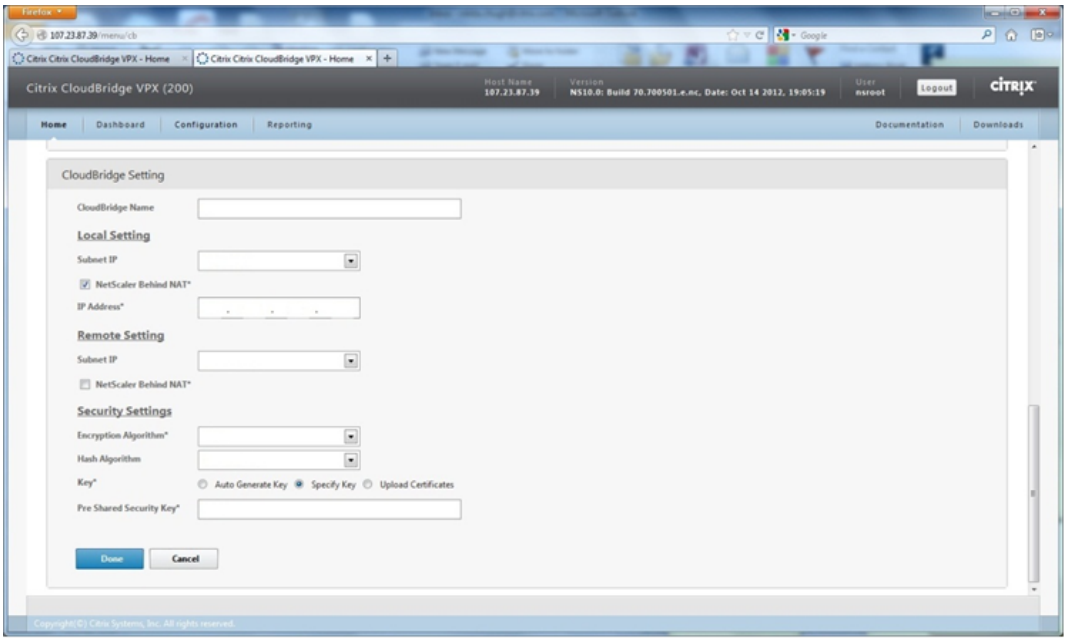
5. In the CloudBridge Setup pane, click NetScaler.



6. In the NetScaler pane, type values in the **IP Address**, **User Name**, and **Password** text boxes for the local CloudBridge instance in the data center, and then click Continue. The IP address should be a publicly accessible address.



7. In the **CloudBridge Setting** pane, in the **CloudBridge Name** text box, type the name of the CloudBridge that you want to create.



8. Under **Local Setting**, from the **Subnet IP** drop-down list, select the subnet IP address of the CloudBridge instancein the local data center.

9. Under **Remote Setting**, from the **Subnet IP** drop-down list, select the subnet IP address of the CloudBridge instance in the remote data center.

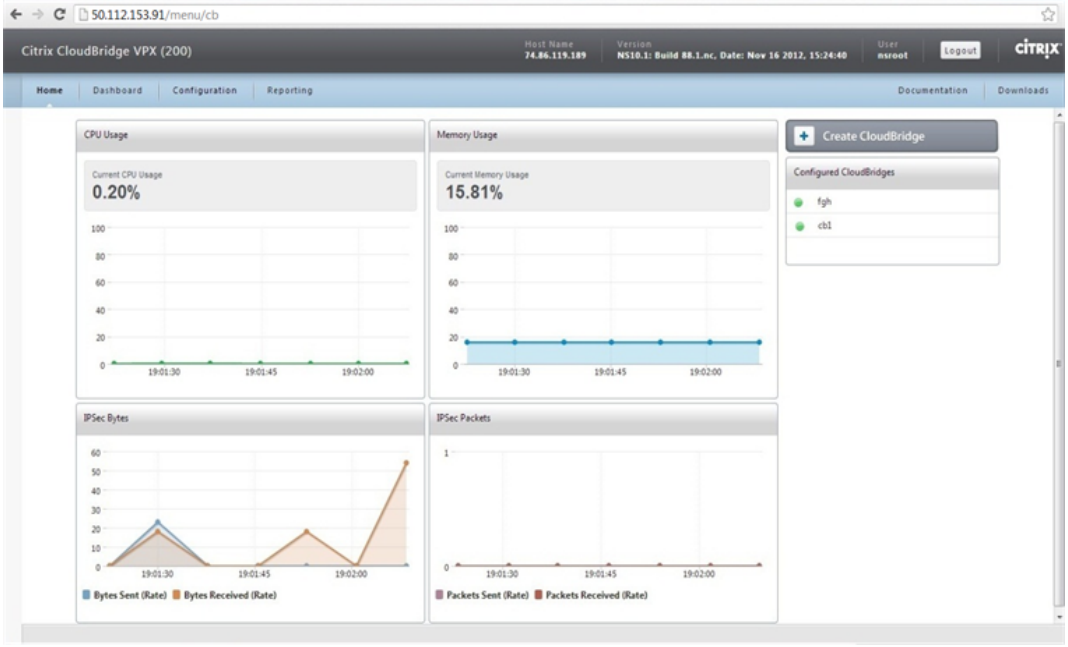
10. Select the **NetScaler Behind NAT** checkbox and, in the **IP Address** text box, type the public IP address (EIP) that is mapped to the subnet IP that you selected in step 9.

11. Under **Security Settings**, from the **Encryption Algorithm** and **Hash Algorithm** drop-down lists, select the algorithms that you want to use.

12. Select the **Specify Key** option and, in the **Pre Shared Security Key** text box, type the security key.

13. Click **Done**.

    The new CloudBridge instance appears on the**Home** page. The current status of the CloudBridge is indicated in the **Configured CloudBridges** pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.



To configure CloudBridge between two CloudBridge instances in two different data centers by using the command line

To set up a CloudBridge, between two CloudBridge VPX instances in two different data centers:

- Create a network bridge
- Configure an IPSec profile
- Create a GRE tunnel with the IPSec profile
- Bind the IPSec tunnel to the network bridge

To create a network bridge by using the command line

At the CloudBridge instance (in the local data center) command prompt, type:

addnetbridge<name>

Parameter for configuring a network bridge

name

Name of the CloudBridge that you are configuring.Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at sign (@), equal sign (=), and hyphen (-) characters.

To configure an IPSec profile by using the command line

At the CloudBridge instance (in the local data center) command prompt, type:

addipsec profile<name> [-encAlgo (AES | 3DES) ...] [-hashAlgo<hashAlgo> ...] [-lifetime<positive_integer>] (-psk |(-publickey<string> -privatekey<string> -peerPublicKey<string>))

Parameters for configuring an IPSec profile

name

Name for an IPSec configuration. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

encAlgo

Encryption algorithm to be used in IPSec configuration for a CloudBridge. Possible values: AES, 3DES.

hashAlgo

Encryption algorithm to be used in IPSec configuration for a CloudBridge. Possible values: HMAC_SHA1, HMAC_SHA256, HMAC_MD5. Default: HMAC_SHA1.

lifetime

Time, in seconds, after which the security association expires. After expiration, new SAs are established, and new cryptographic keys are negotiated between the peers connected by the CloudBridge. Maximum value: 31536000. Default: 28800.

psk

Text string, called the pre-shared key, to be manually configured on each peer. The pre-shared keys of the peers are matched against each other for authentication before security associations are established. Therefore, for the authentication to be successful, you must configure the same pre-shared key on both of the peers of the CloudBridge. Maximum Length: 63 characters.

livenessCheckInterval

Time, in seconds, after which a notify payload is sent to check the status of the peer (UP or DOWN). Additional payloads are sent as specified by the retransmit interval setting. A value of zero disables liveliness checks.

retransmissiontime

Time, in seconds, after which an IKE retry message is sent to a peer. The retry message is sent upto three times. Each failure doubles the amount of time before sending another

retry message.

publickey

A local digital certificate to be used to authenticate the local CloudBridge appliance to the remote peer before establishing IPSec security associations. The same certificate should be present and set for the Peer Public Key parameter in the remote peer.

privatekey

Private key of the local digital certificate.

peerPublicKey

Digital certificate of the remote peer. This certificate is used to authenticate the remote peer to the local peer before establishing IPSec security associations. The same certificate should be present and set for the Public key parameter in the remote peer.

To create a GRE tunnel with IPSec profile by using the command line

At the CloudBridge instance (in the local data center) command prompt type:

add iptunnel <name><remoteIp><remoteSubnetMask><localIp>-type -protocol (GRE) -ipsecprofile<name>

Parameters for creating a GRE tunnel with an IPSec profile

name

Name of the IP Tunnel. This alphanumeric string is required and cannot be changed after the service group is created. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

remoteIp

A public IP address of the remote CloudBridge appliance, in the data center, used to set up the tunnel.

remoteSubnetMask

Subnet mask of the remote IP address of the tunnel.

localIp

A public address of the local CloudBridge instance used to set up the tunnel. Possible values: Auto, MIP, SNIP, and VIP. Default: Auto.

protocol

The protocol to be used in setting up the IP tunnel. Select GRE to set up a GRE tunnel.

ipsecProfileName

Name of the IPSec profile that is used for securing communication in the GRE tunnel. If this parameter is not specified, the default profile (ns_ipsec_default_profile) is

configured and, if this parameter is set to none, a GRE tunnel is created.

To bind an IPSec tunnel to the network bridge by using the command line

At the CloudBridge instance (in the local data center) command prompt, type:

bindnetbridge<name> [-tunnel<name>] [-vlan<id>] [-IPAddress<ip_addr|ipv6_addr>]

Parameters for binding IPSec tunnel to the network bridge

name

Name of the CloudBridge that you are configuring. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equal (=), and hyphen (-) characters.

tunnel

Name of the GRE tunnel to be associated with the CloudBridge.

VLAN

Identifier of the local VLAN that needs to be extended to the cloud.

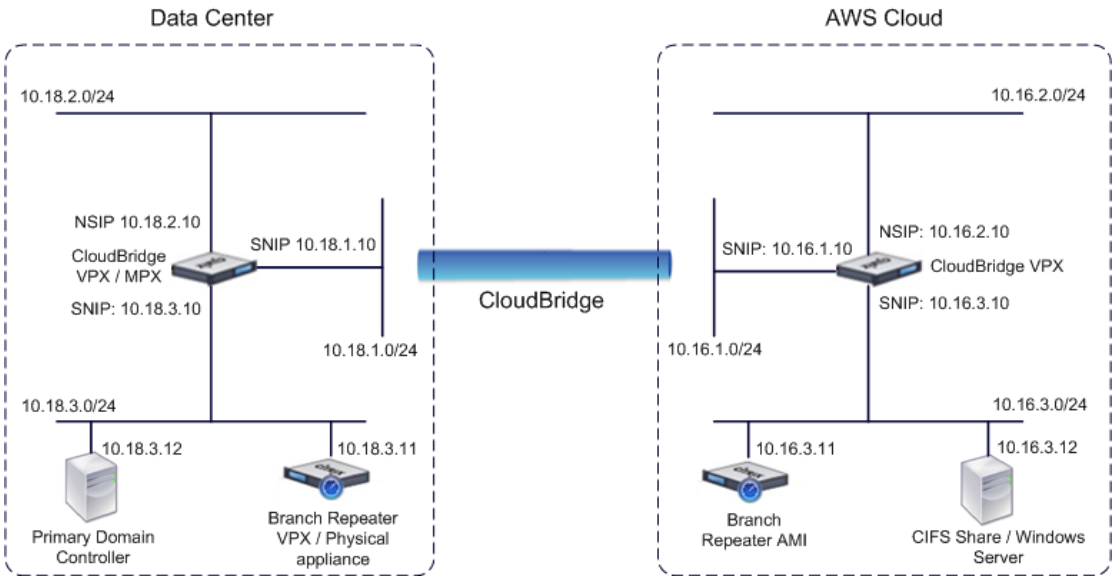
IPAddress

The IPV4 subnet that needs to be extended to the cloud.

WAN Optimization for CloudBridge tunnel

You should configure the CloudBridge appliances at both ends of the CloudBridge tunnel to send traffic through the Branch Repeater appliances.

Consider an example where a CloudBridge tunnel is configured between Amazon Web Services (AWS) cloud and a data center. For optimizing the traffic flow in CloudBridge tunnel, on the AWS end, you configure and launch a Branch Repeater virtual appliance (AMI) on AWS and pair it with a CloudBridge virtual appliance (VPX) on AWS. On the data center end, you configure a Branch Repeater virtual appliance (VPX)/physical appliance and pair it with a CloudBridge VPX/MPX appliance.



The following table lists the settings used in the AWS cloud end.

Entities	Settings
Subnets used for the CloudBridge tunnel setup	10.16.1.0/24
	10.16.2.0/24
	10.16.3.0/24
CloudBridge VPX settings	
Instance Name	CloudBridge-Cloud
SNIP	10.16.1.10
SNIP	10.16.3.10
NSIP	10.16.2.10

Branch Repeater AMI settings	
Instance Name	BranchRepeater-Cloud
IP Address	10.16.3.11

The following table lists the settings used in the data center end.

Entities	Settings
Subnets used for the CloudBridge tunnel setup	10.18.1.0/24
	10.18.2.0/24
	10.18.3.0/24
CloudBridge VPX/MPX settings	
SNIP	10.18.1.10
SNIP	10.18.3.10
NSIP	10.18.2.10
Branch Repeater VPX/physical appliance settings	
IP Address	10.18.3.11

You need to perform the following tasks for pairing Branch Repeaters appliances to the CloudBridge tunnel endpoints.

- **Instantiating a Branch Repeater virtual appliance (AMI) on AWS**. This task involves installing, configuring, and launching a Branch Repeater virtual appliance (AMI) on the AWS in the same AWS region where the CloudBridge VPX is running. After the Branch Repeater AMI is instantiated, you need to disable the Source/Destination check feature of the AMI instance from the AWS management interface. Then, you must enable SNMP Monitoring on the Branch Repeater AMI instance and grant SNMP monitoring access to the paired CloudBridge VPX on AWS by using the Branch Repeater management graphical user interface.

- **Setting up a Branch Repeater virtual appliance (VPX)/physical appliance in the data center**. This task involves deploying and configuring a Branch Repeater physical appliance or installing, configuring, and launching a Branch Repeater virtual appliance (VPX) in a virtualization platform in the datacenter.

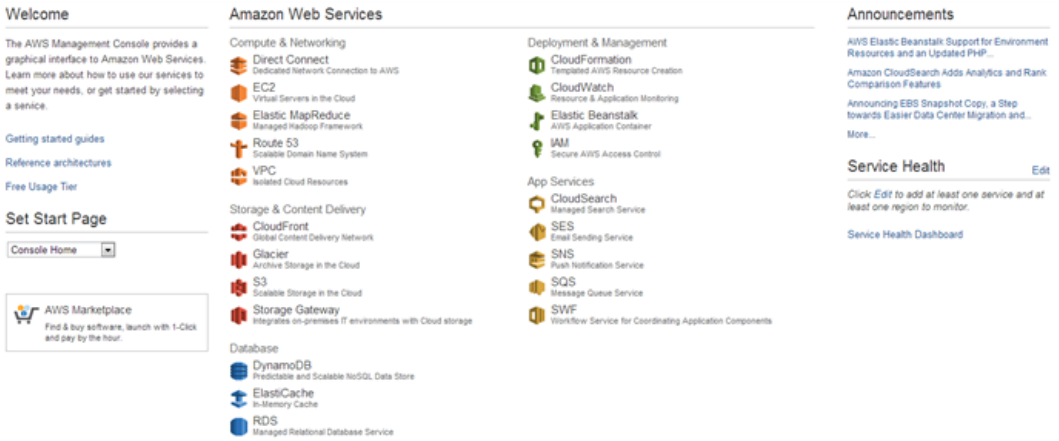
- **Redirecting traffic to the Branch Repeater appliances**. This task involves the use of Dynamic Load Balancing wizard for Citrix Branch Repeater on the CloudBridge appliance to pair with the respective Branch Repeater appliance at either ends of the CloudBridge.

Instantiating a Branch Repeater Virtual Appliance (AMI) on AWS

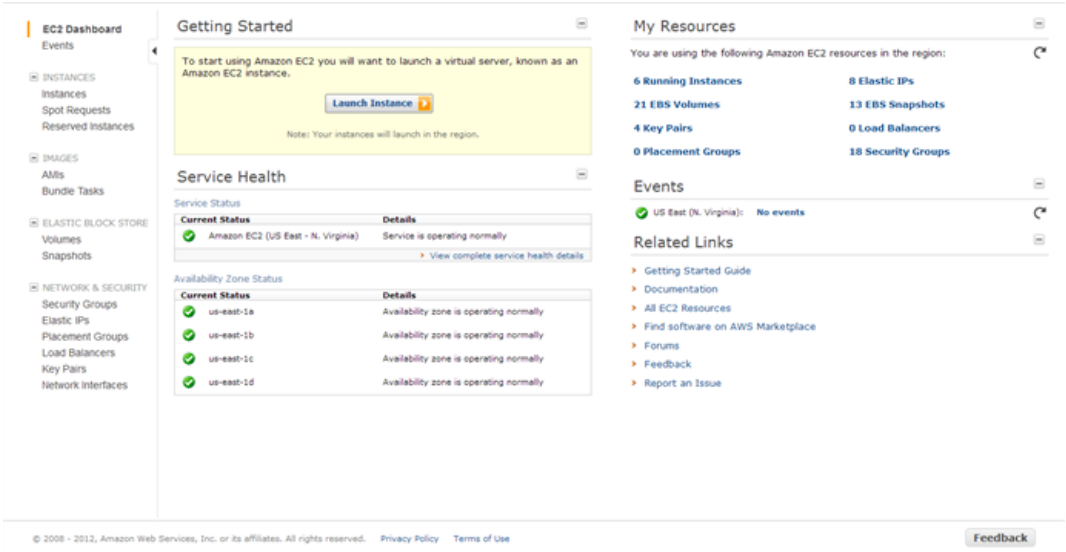
To install a Branch Repeater virtual appliance in an AWS VPC, you need an AWS account. You can create an AWS account at http://aws.amazon.com/. Branch Repeater is available as an Amazon Machine Image (AMI) in AWS Marketplace.

To instantiate a Branch Repeater virtual appliance (AMI) on AWS

1. In a web browser, type http://aws.amazon.com/.
2. Click My Account/Console, and then click My Account to open the Amazon Web Services Sign in page.
3. Use your Amazon account credentials to sign in.
4. On the Manage Your Account page, in the Account section, click the AWS Management Console link.
5. On the AWS Management Console page, click Sign in to the AWS Console to log on to the Management Console page.
6. On the Amazon Web Services page, click EC2 in the Compute & Networking section.



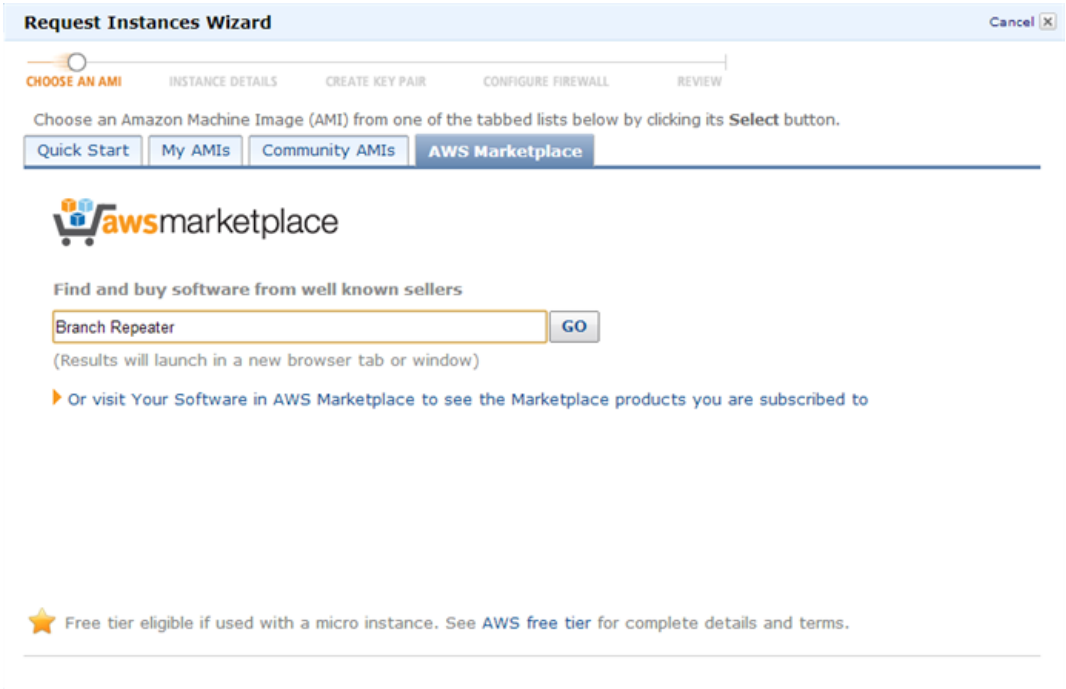
7. On the Amazon EC2 Console Dashboard page, in the Getting Started section, click Launch Instance.



8. In the Create a New Instance dialog box, select AWS Marketplace, and then click Continue to open the Request Instance Wizard.

9. In the Request Instance Wizard dialog box, click AWS Marketplace tab.

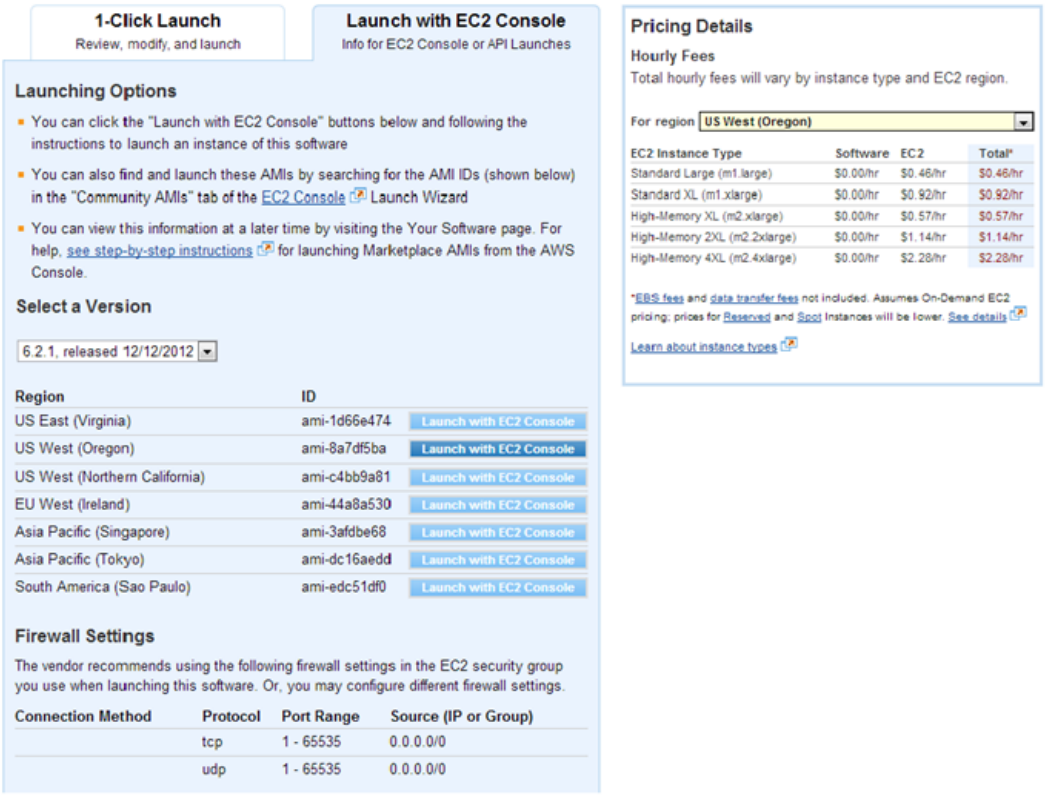
10. In the Search text field, type `Branch Repeater` to search for the Branch Repeater AMI, and click Go.



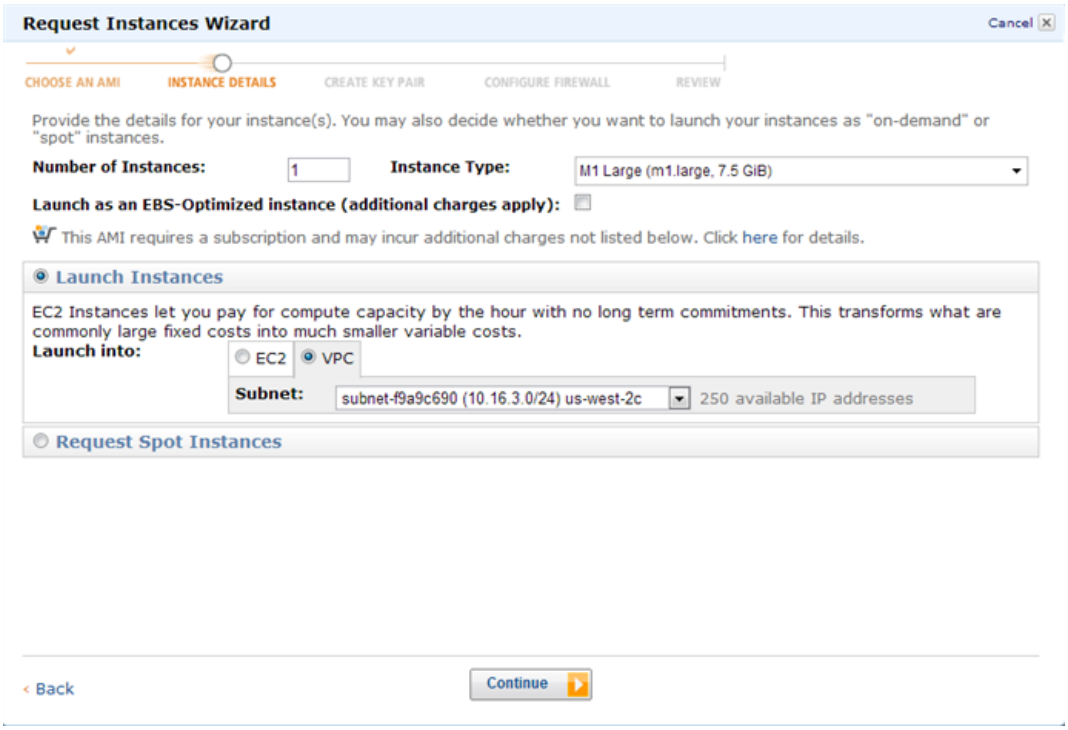
11. On the search result page, click Citrix Branch Repeater for CloudBridge.

12. On the Citrix Branch Repeater for CloudBridge page, click Continue.

13. On the Launch with EC2 Console tab, click Launch with EC2 Console for the region where you want to launch Citrix Branch Repeater AMI.



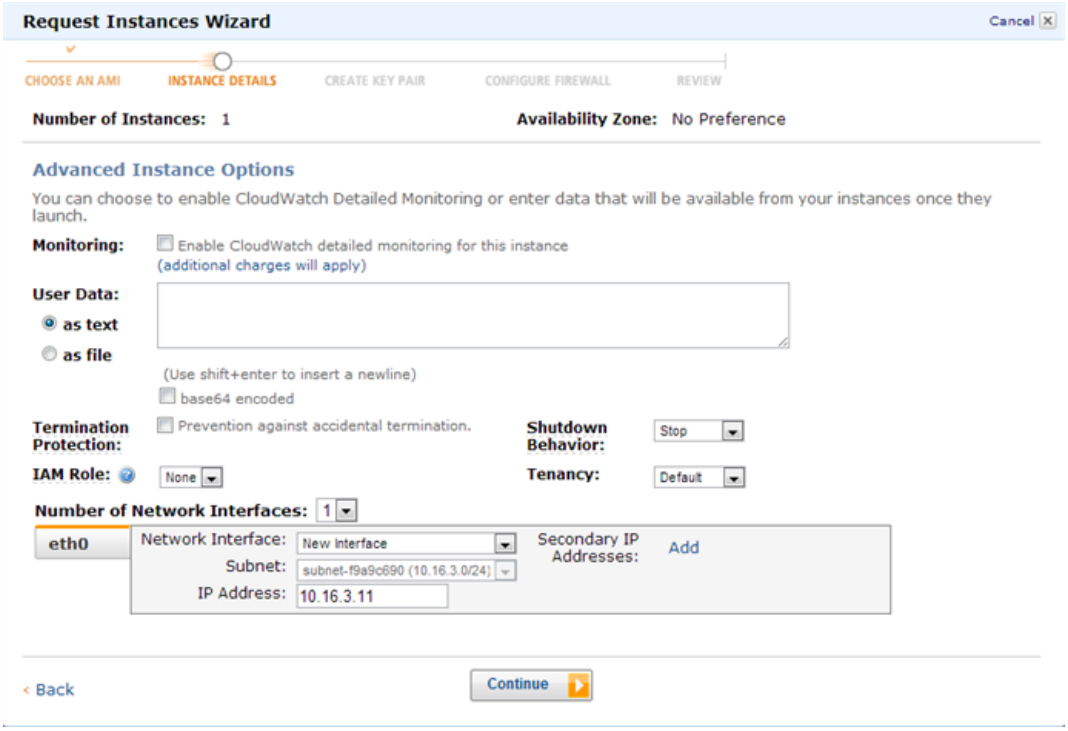
14. On the Request Instance Wizard page, type 1 in the Number of Instances text box, and from the Instance Type drop-down list, select Large (m1.large, 7.5GIB).



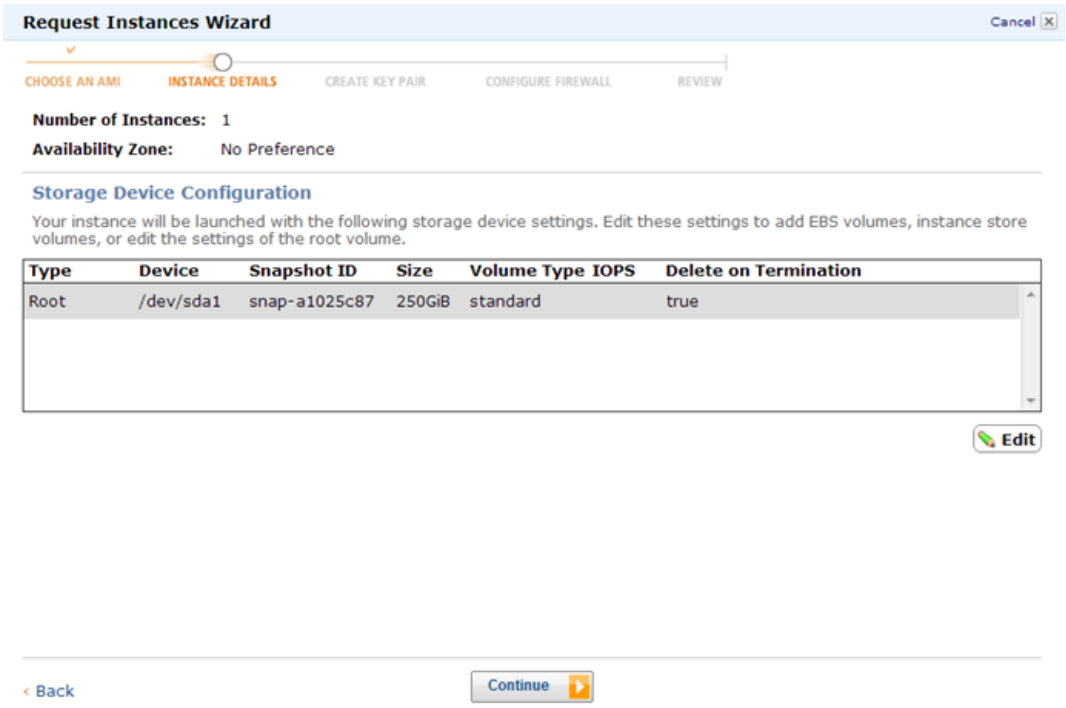
15. In the Launch Instances section, click the VPC tab. Then, from the Subnet drop-down list, select the private network subnet, and then click Continue.

16. On the next page, in the Advanced Instance Options section, verify the value for Number of Network Interfaces and eth0 details, such as Network Interface, Subnet, and IP Address, and then click Continue.

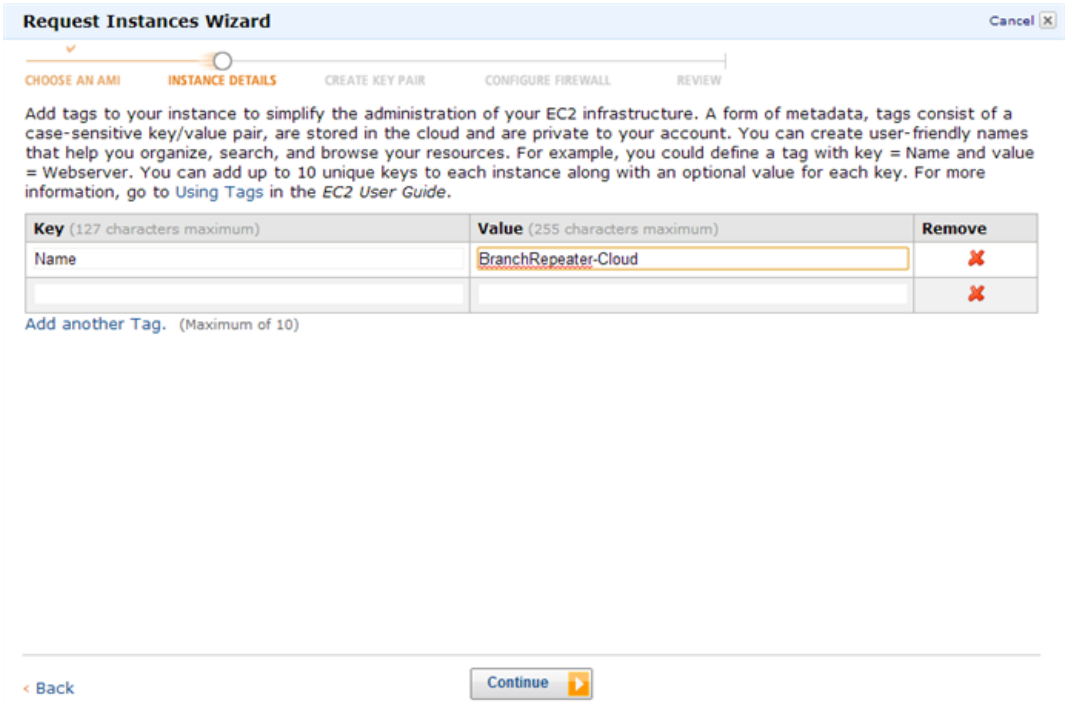
    Note: Branch Repeater AMI is not supported with more than one network interface. Therefore, the value of Number of Network Interfaces field should be set only to 1.



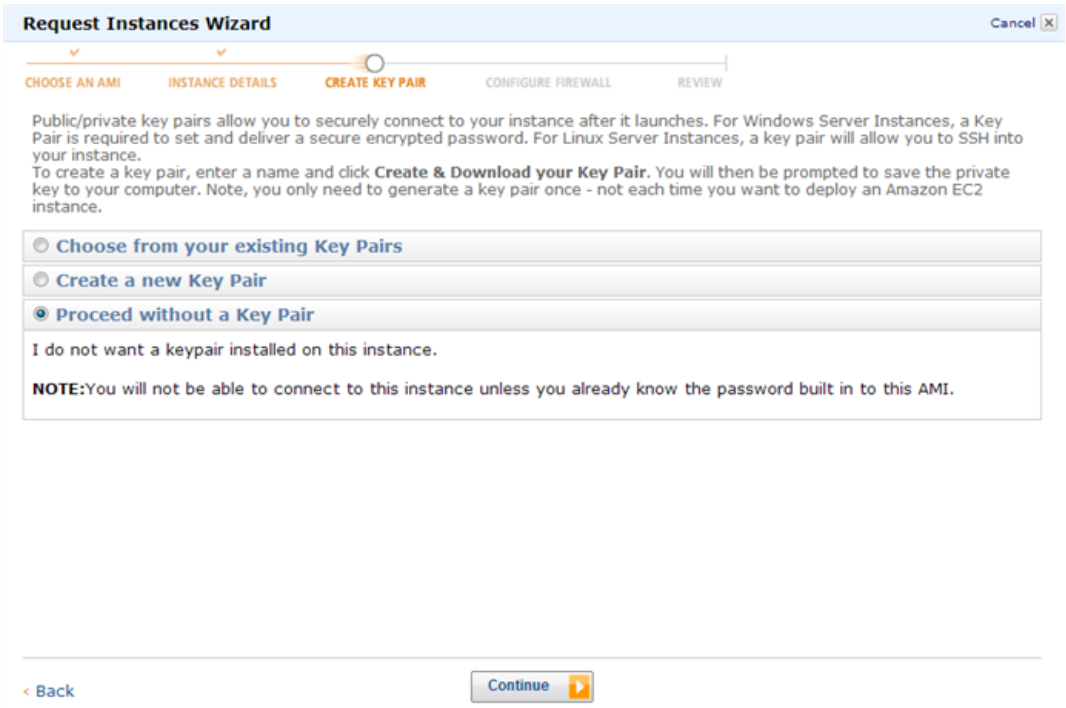
17. On the Request Instances Wizard page, verify the storage device configuration information and click Continue.



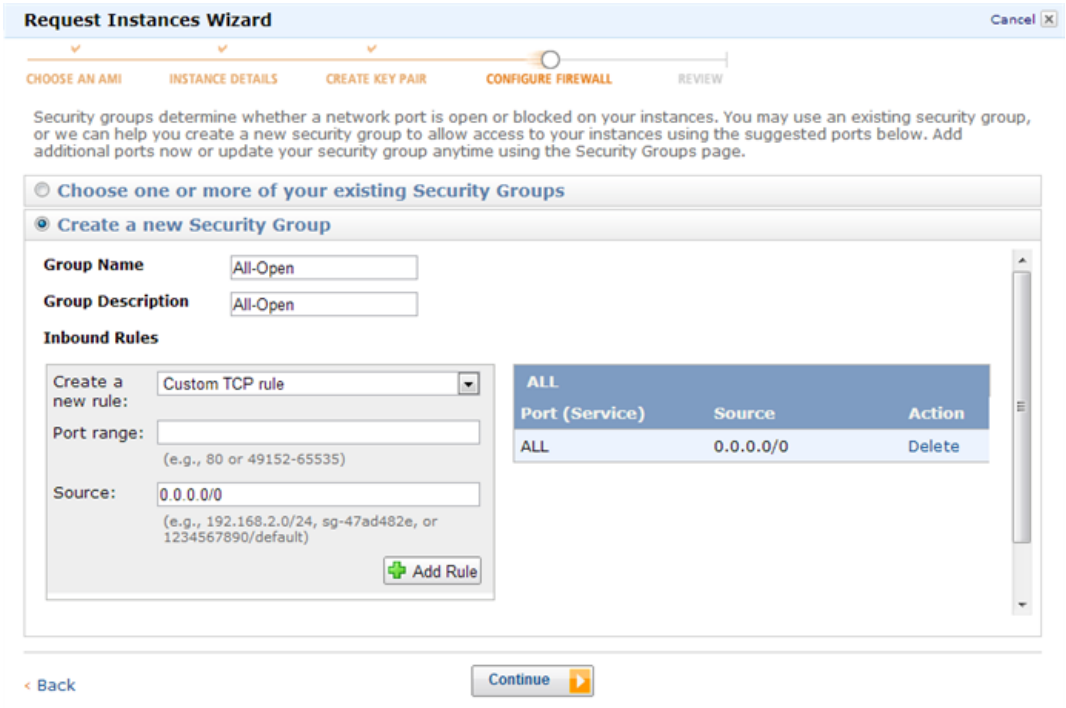
18. On the Request Instances Wizard page, enter a name for the EC2 instance in the Value text box, and then click Continue.



19. On the Request Instances Wizard page, select Proceed without a Key Pair, and then click Continue.

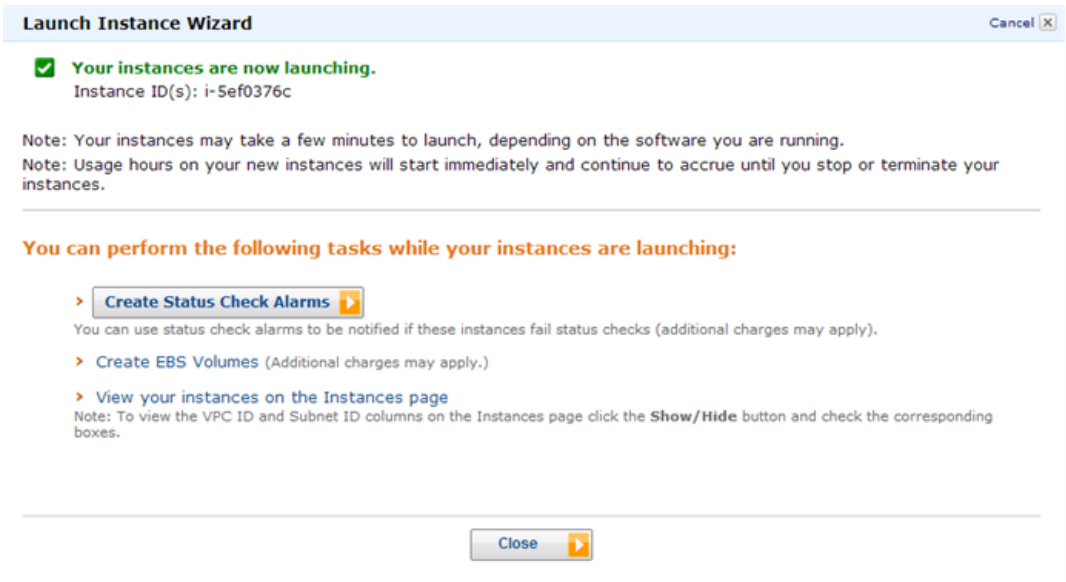


20. On the Request Instances Wizard page, select Create a new Security Group, then create a group that allows all the traffic to pass from the list, and then click Continue.



21. On the Request Instances Wizard page, verify the EC2 instance configuration details, and then click Launch to launch the EC2 instance.

22. Click Close to close the Launch Instance Wizard dialog box. The new EC2 instance is launched successfully.



Disabling the Source/Destination Check Feature

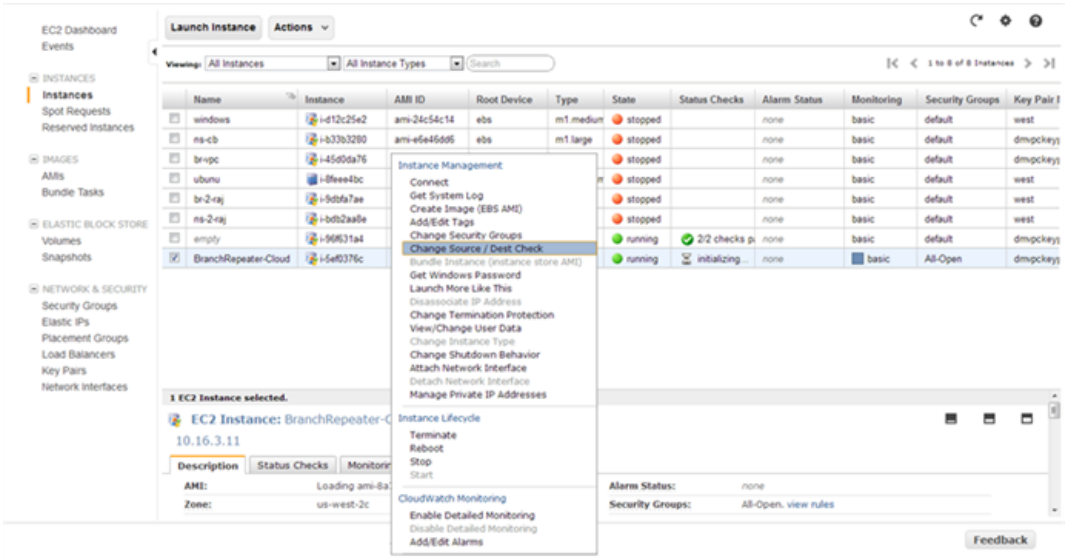
You must disable the Source/Destination check feature of Branch Repeater AMI instance for it to work properly on AWS.

To disable the Source/Destination check feature

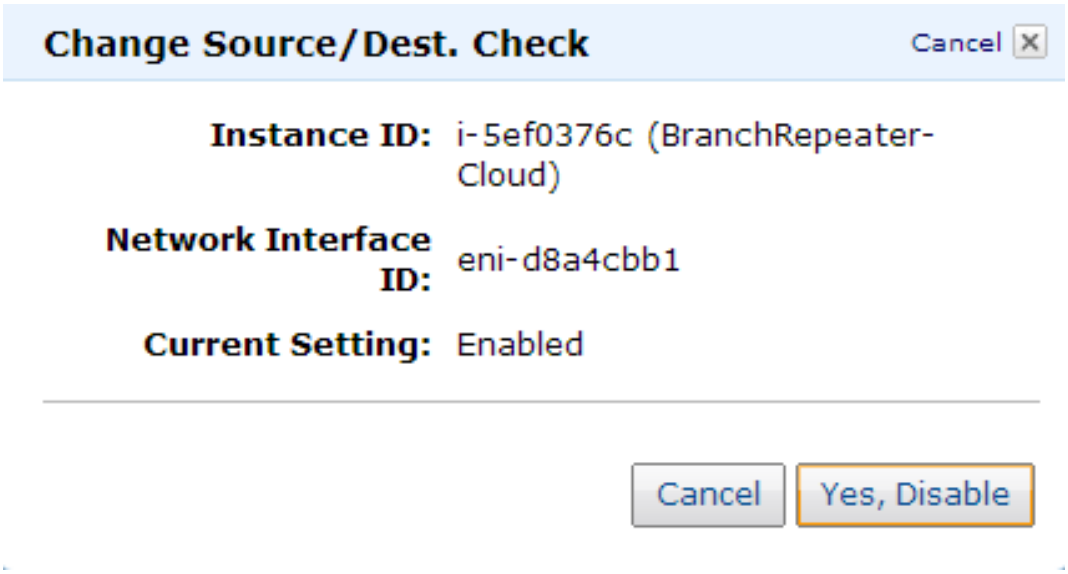
1. On the Amazon EC2 Console Dashboard page, in the navigation pane, click instances. The new EC2 instance should appear in the My Instances list.

2. Select the new EC2 instance. The instance details appear in the EC2 Instances pane.

3. Right-click the new EC2 instance and then select Change Source/Dest Check from the popup menu.



4. In the Change Source / Dest. Check dialog box, click Yes, Disable to disable the feature.

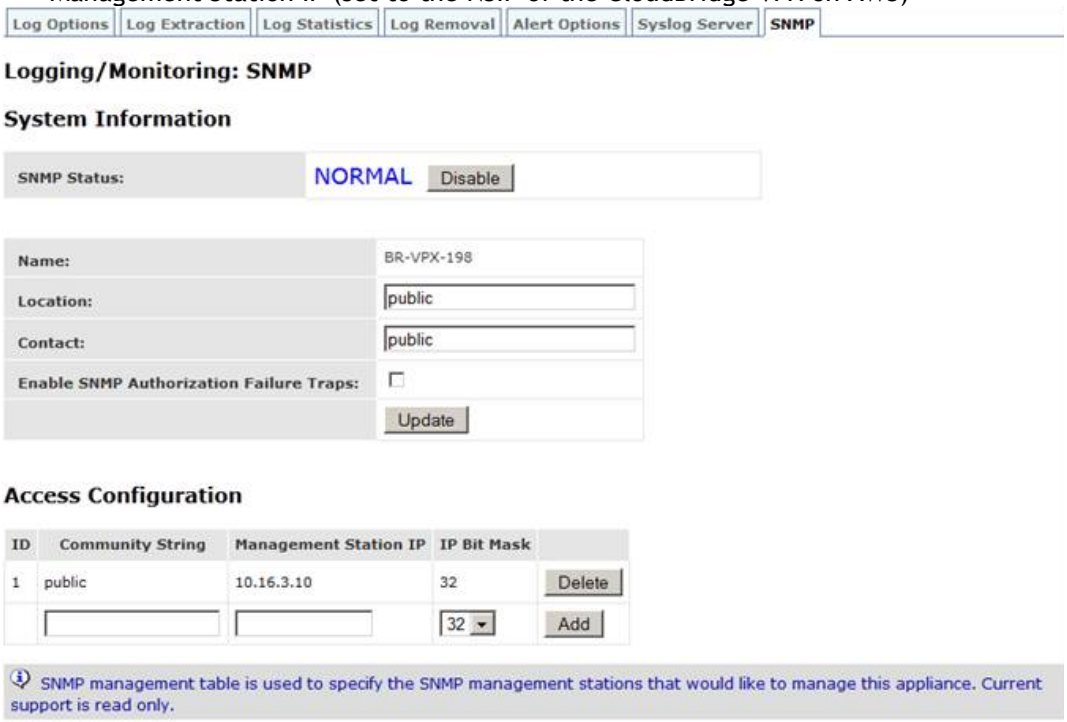


Configuring SNMP Monitoring on the Branch Repeater AMI on AWS

You must enable SNMP monitoring on the Branch Repeater AMI on AWS. Also, you must grant SNMP monitoring access to the paired CloudBridge VPX on AWS by adding its NSIP on the Branch Repeater AMI instance.

To configure SNMP monitoring on the Branch Repeater AMI by using the Branch Repeater graphical user interface

1. In the navigation pane, expand Configuration, and then click Logging/Monitoring.
2. In the details pane, click the SNMP tab.
3. In the System Information section, in the SNMP Status row, click Enable. This action enables SNMP monitoring on the Branch Repeater AMI instance.
4. In the Access Configuration section, add SNMP monitoring access to CloudBridge VPX appliance by setting the following parameters:
   - Community String (set to the string public)
   - Management Station IP (set to the NSIP of the CloudBridge VPX on AWS)



5. Click Add.

Limitations and Usage Guidelines for Branch Repeater AMI Instances on AWS

- High Availability setup for Branch Repeater AMI instances is not supported.
- Branch Repeater AMI instance in Group Mode is not supported.
- Branch Repeater plug-ins are not supported.
- Tagged VLAN is not supported because of the inherent limitation of AWS.
- Traffic shaping is not supported.
- You may create only an m1.large Branch Repeater AMI instance on AWS.
- IP address/gateway/subnet assignment using the Branch Repeater management user interface is not supported.
- Console access is not available for Branch Repeater AMI instance on AWS.
- It is not possible to install licenses on a Branch Repeater AMI instance on AWS. The Branch Repeater AMI instance is automatically licensed and rate limiting is controlled by the CloudBridge instance, which is paired with the Branch Repeater AMI instance.
- While configuring the Branch Repeater instance, you may not change the disk size, which has a default value of 250 GB. A higher capacity disk does not increase the available Disk Based Compression (DBC) cache size.

Setting up the Branch Repeater Appliance in the Datacenter

Before you set up a Branch Repeater virtual appliance (VPX) or physical appliance in the datacenter, provision the virtual appliance or rack mount the hardware appliance.

For instructions for rack mounting a Branch Repeater physical appliance, or provisioning a Branch Repeater VPX instance, see Branch Repeaters.

These setup instructions assume that the Branch Repeater in the datacenter is deployed in one-arm mode. References to an *appliance* apply to virtual appliances (VPX) as well as physical appliances.

After you have installed and completed the initial configuration of the Branch Repeater appliance, configure the interfaces on the NetScaler and Branch Repeater appliances so that they can communicate with each other. Also configure the virtual inline and TCP Maximum Segment Size (MSS) settings on the Branch Repeater appliance.

Configuring the Network at the Datacenter

By default, the first and second interfaces on the Branch Repeater appliance are bridged. Configure one network interface on the NetScaler appliance and the first network interface on the Branch Repeater appliance to be part of the client subnet. For the second interface on the Branch Repeater appliance, do the following (assuming a one-arm configuration):

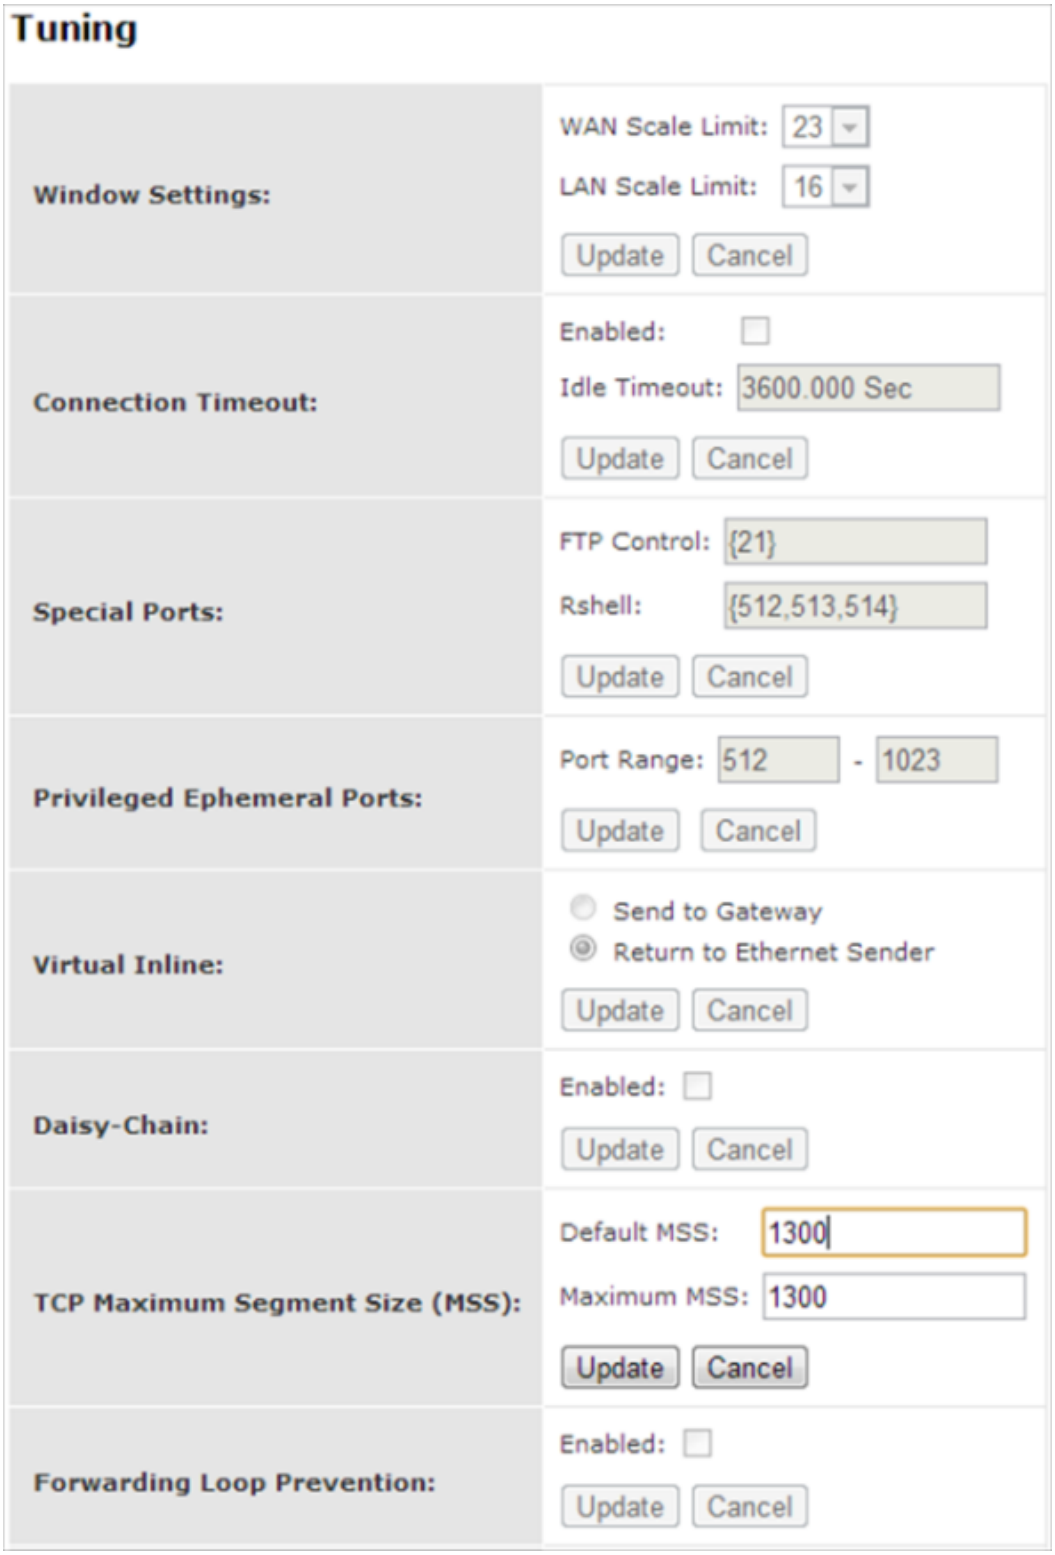
- If the Branch Repeater appliance is a physical appliance, do not connect the interface to the network.
- If the Branch Repeater appliance is a virtual appliance, configure a dummy internal network. Make sure that the second of the bridged ports is the only interface in the dummy internal network.

Configuring the TCP MSS and Virtual Inline Settings on the Branch Repeater

The configuration on the Branch Repeater appliance (either a physical appliance or a virtual appliance) in the datacenter must match the configuration on the Branch Repeater instance in the Amazon VPC. Branch Repeater AMI instances on AWS have a preconfigured value of 1300 for both the default and maximum values of TCP Maximum Segment Size (MSS). Additionally, the Virtual Inline option should be set to Return to Ethernet Sender, so that packets are returned to the CloudBridge appliance. Therefore, you must configure these settings on the datacenter Branch Repeater appliance.

To configure the TCP MSS and Virtual Inline settings on a Branch Repeater appliance in the datacenter

1. Log on to the Branch Repeater appliance in the datacenter.
2. From the Configuration menu, click Tuning.



3. On the Tuning page, do the following:

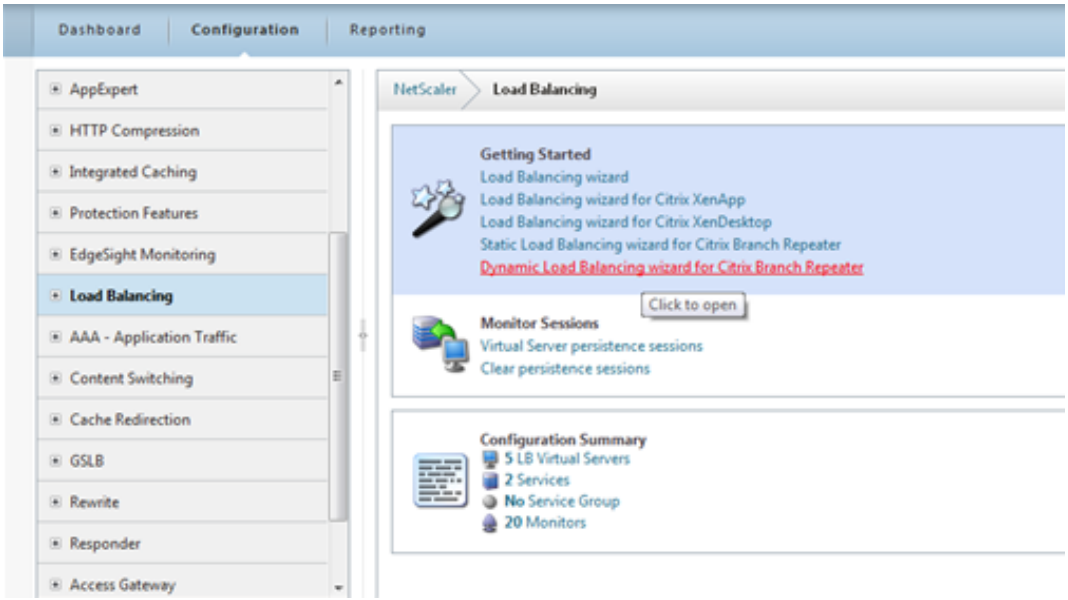
   - In the Virtual Inline row, select Return to Ethernet Sender, and then click Update.
   - In the TCP Maximum Segment Size (MSS) row, in the Default MSS and Maximum MSS boxes, enter 1300, and then click Update.

Redirecting Traffic to the Branch Repeater Appliances from the CloudBridge Appliance

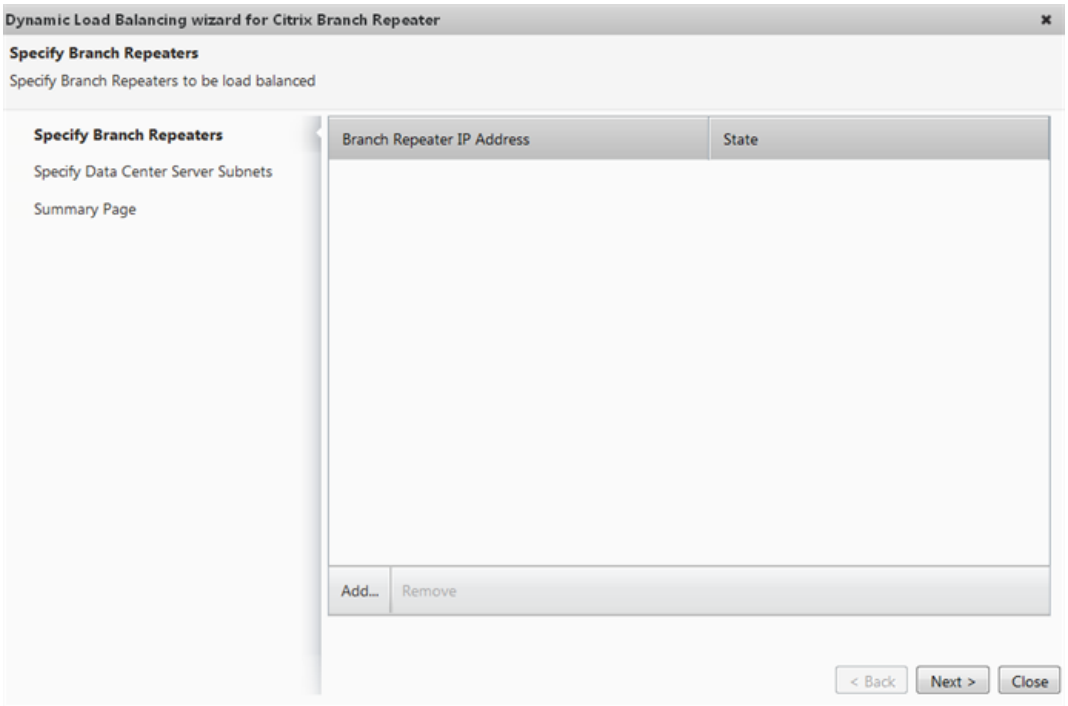
On the CloudBridge appliances in the datacenter and in the Amazon VPC, specify the Branch Repeater appliance as a service by using the Dynamic Load Balancing wizard for Citrix Branch Repeater. The wizard automatically creates a service and two virtual servers on the CloudBridge appliance.

To configure redirection of traffic to Branch Repeater appliances by using the CloudBridge configuration utility

1. In the left pane, click Load Balancing. Then, in the right pane, click Dynamic Load Balancing wizard for Citrix Branch Repeater.

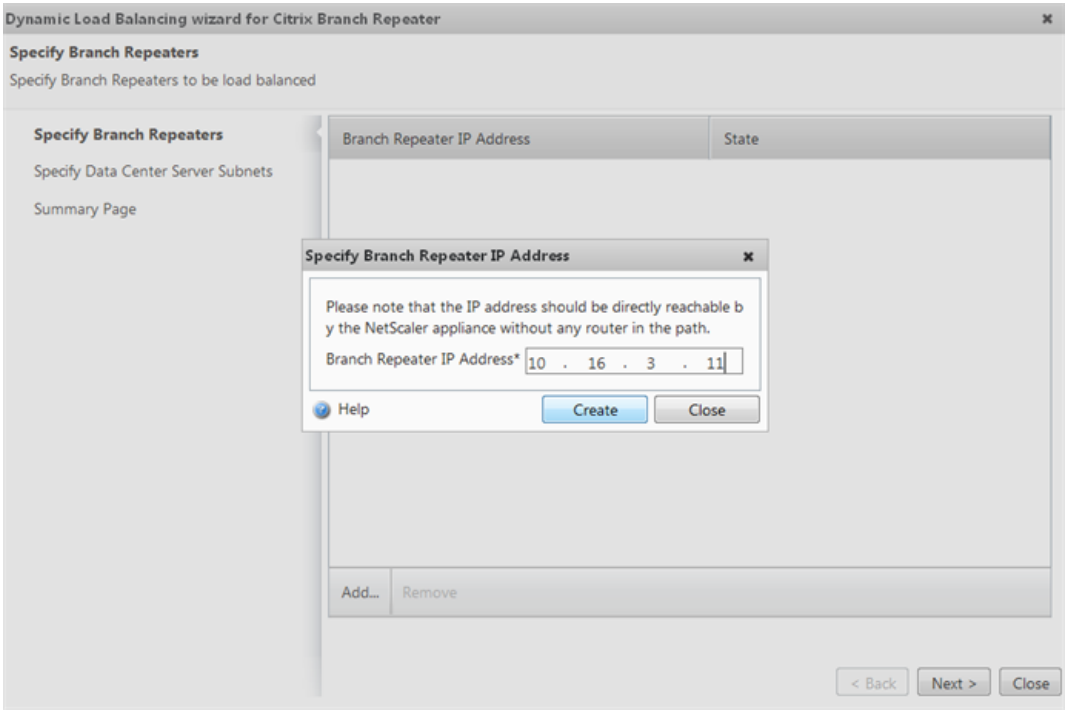


The Dynamic Load Balancing wizard for Citrix Branch Repeater appears.



2. In the wizard, on the Specify Branch Repeaters page, click Add.

3. In the Specify IP Address dialog box, enter the IP address of a Branch Repeater appliance, click Create, and then click Close.

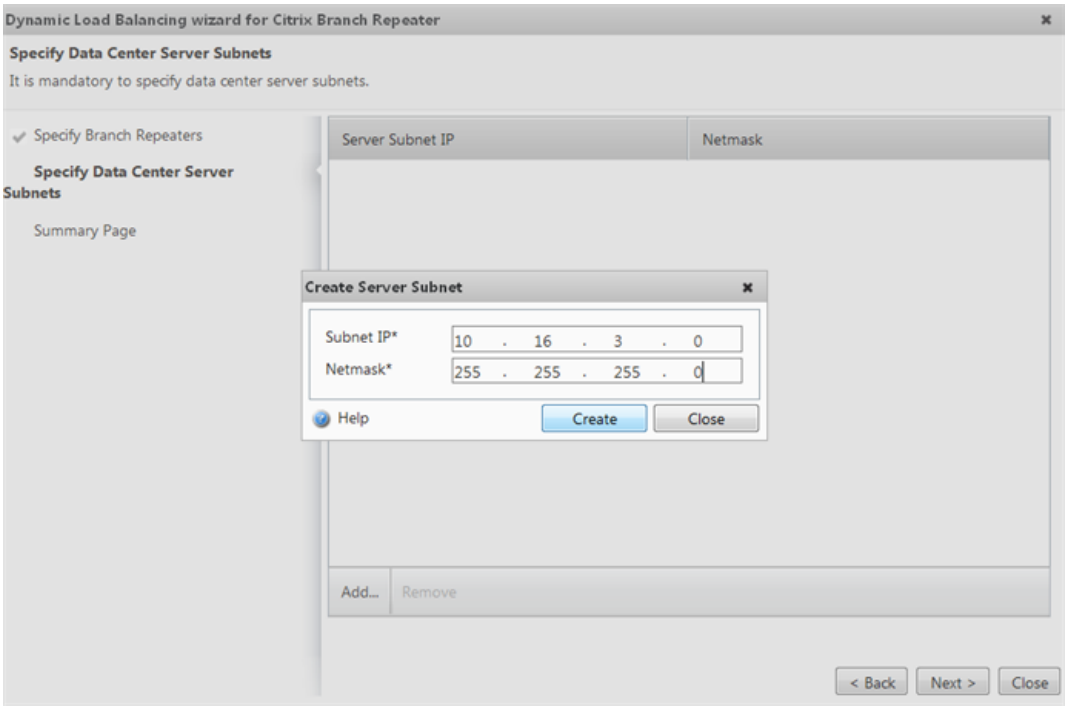


4. Click Next.

5. On the Specify Data Center Server Subnets page, click Add. In the Create Server Subnet dialog box, set the following parameters:

   - Subnet IP – The IP address of the subnet in which the servers reside.

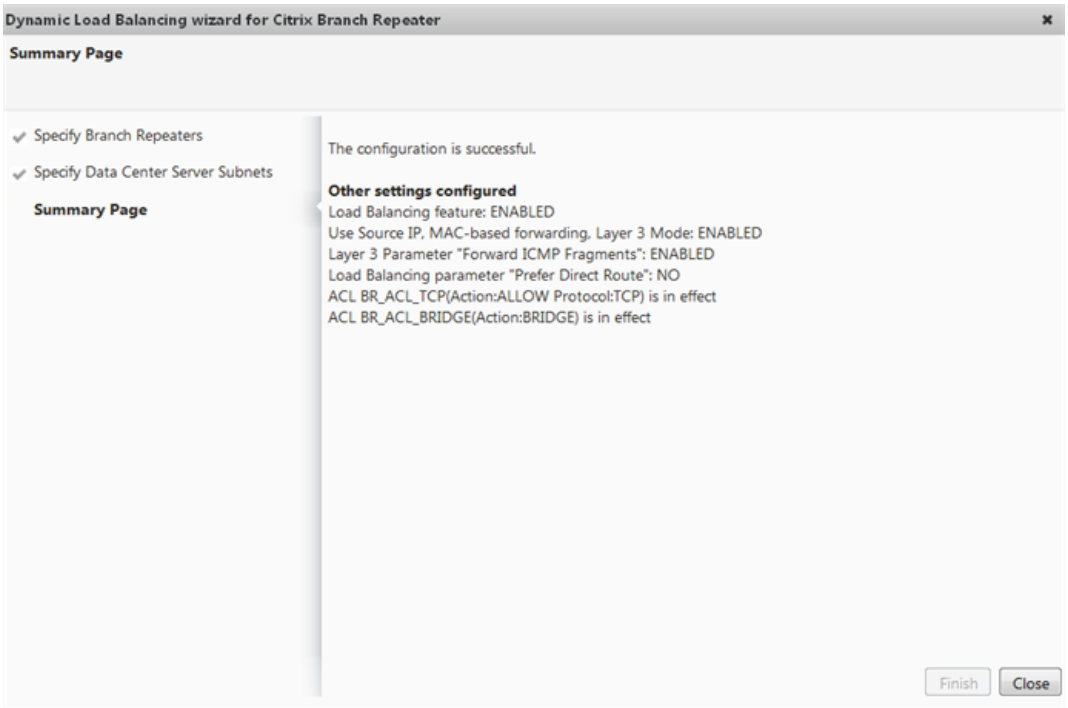
   - Mask – The subnet mask.



6. Repeat steps 5-6 until you have added all of the server subnets, and then click Close.

7. Click Next and click Finish.

8. The Summary page displays additional settings that are added automatically to complete the Branch Repeater load balancing configuration on the CloudBridge appliance.



9. Click Close.

(Advanced Configuration) Accelerating Encrypted MAPI, Signed SMB, SSL Traffic and Branch Repeater Joining to Windows domain

To accelerate encrypted MAPI, signed SMB, and SSL traffic, you have to perform the following steps:

- Add a route to the server farm in the AWS VPC route table.
- Set listen policies for the virtual servers, which represent the Branch Repeater AMI, on the CloudBridge VPX on AWS.

To add a route to the server farm in the AWS VPC route table

1. On the Amazon EC2 Console Dashboard page, in the navigation pane, click instances.
2. Select the CloudBridge VPX instance. The instance details are displayed in the EC2 Instances pane.
3. 
   In the EC2 Instances pane, select the CloudBridge VPX instance and then click edocs Interface (for example, eth2) that faces the Branch Repeater AMI on AWS, and note the Interface ID from the Network Interface pop-up window.
4. Click Services, and then click VPC.
5. 
   In the Navigation pane, click Route Tables to list all the VPC route tables. Select a VPC route table in the Route Tables pane to list the route table details in the Route Table Selected pane.
6. In the Route Table Selected pane, on the Routes tab, add a new row at the bottom of the table and, in the Destination column, type the subnet for the server farm.
7. From the select a target drop-down list, select Enter Network Interface Id.

8. 
   In the Select an Interface dialog box, select the network interface Id that you had noted earlier, and then click OK.

9. 
   Click Add to add the new route to the VPC route table.

Now, you need to set the following listen policies for the virtual servers BR_LB_VS_DYN_1 and BR_LB_VS_DYN_2.

Virtual servers	Parameters to be modified	Value to be set for the parameter
BR_LB_VS_DYN_1	Listen Policy	sys.vserver("BR_LB_VS_DYN_1").state.eq(up)&&client.tcp.repeater_option.exists&&client.ip.src.eq(<IP address of the Branch Repeater>).not For example, sys.vserver("BR_LB_VS_DYN_1").state.eq(up)&&client.tcp.repeater_option.exists&&client.ip.src.eq(10.16.3.11).not

BR_LB_VS_DYN_2	Listen Policy	sys.vserver("BR_LB_VS_DYN_2").state.eq(up)&&client.ip.src.eq(<IP address of the Branch Repeater appliance>).not For example, sys.vserver("BR_LB_VS_DYN_2").state.eq(up)&&client.ip.src.eq(10.16.3.11).not

To set listen policies for the virtual servers to which the Branch Repeater service is bound by using the CloudBridge command line

At the command prompt, type:

set lb vserver <name> -listenpolicy <expression>

Example

> set lb vserver BR_LB_VS_DYN_1 -listenpolicy sys.vserver("BR_LB_VS_DYN_1").state.eq(up)&&client.tcp.repe
Done

> set lb vserver BR_LB_VS_DYN_2 -listenpolicy sys.vserver("BR_LB_VS_DYN_2").state.eq(up)&&client.ip.src.e
Done

Note: On AWS, for pairing a Branch Repeater AMI with a CloudBridge VPX, you use the Dynamic Load Balancing wizard for Citrix Branch Repeater on the CloudBridge VPX. The wizard creates the following entities on the CloudBridge VPX:

Entity Name	Entity Type	Description
BR_LB_SVC_DYN_<IP address of the Branch Repeater appliance> For example, BR_LB_SVC_DYN _ 192.0.2.30	Service	A service representing the Branch Repeater appliance.
BR_LB_VS_DYN_1 and BR_LB_VS_DYN_2	Virtual server	Virtual servers to entertain different types of traffic for the Branch Repeater appliance. The service (for example, BR_LB_SVC_DYN_10.16.3.11) representing the Branch Repeater appliance is bound to both the virtual servers.

Parameter Descriptions (of commands listed in the CLI procedure)

set lb vserver

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Troubleshooting Branch Repeaters in a CloudBridge tunnel Setup

The Branch Repeater Release Notes provides rough guidelines on the maximum number of connections and the optimized throughput for Branch Repeater in a CloudBridge tunnel deployment.

As Branch Repeater appliance approaches the limit, you may observe un-accelerated connections on the web console of the Branch Repeater on the client side. These connections bypass the Branch Repeater on the server side and do not show up on its web console.

On the server side, you need to perform the following steps on the CloudBridge appliance to which the Branch Repeater is paired. These settings should lead to reduced number of un-accelerated connections which in turn results in optimization of even more TCP traffic.

#	Steps	Entity Name	Parameters to be modified	Value to be set for the parameter
1	Modify the Retries and Failure Retries parameters of the default monitor named PING	PING	Retries	33
			Failure Retries	32
2	Bind the PING Monitor to the service (for example, BR_LB_SVC_DYN_192.0.2.30) representing the Branch Repeater appliance.	BR_LB_MONITOR_DYN BR_LB_SVC_DYN_<IP address of the Branch Repeater appliance> For example, BR_LB_MONITOR_DYN BR_LB_SVC_DYN_ 10.16.3.11	NA	NA
3	Unbind the monitor named BR_LB_MONITOR_DYN from the service (for example, BR_LB_SVC_DYN_10.16.3.11) representing the Branch Repeater appliance.	BR_LB_MONITOR_DYN BR_LB_SVC_DYN_<IP address of the Branch Repeater appliance> For example, BR_LB_MONITOR_DYN BR_LB_SVC_DYN_ 10.16.3.11	NA	NA

To set the Retries and Failure Retries parameters of the monitor PING by using the CloudBridge command line

At the command prompt, type:

set lb monitor <MonitorName> <MonitorType> -retries <integer> -failureRetries <integer>

Example

```
> set lb monitor PING ping -retries 33 -failureRetries 32
 Done
```

To bind the monitor PING to the Branch Repeater service by using the CloudBridge command line

At the command prompt, type:

bind service <name> -monitorName <string>

Example

```
> bind service BR_LB_SVC_DYN_10.16.3.11 -monitorName PING
 Done
```

To unbind the default Branch Repeater monitor from Branch Repeater service by using the CloudBridge command line

At the command prompt, type:

unbind service <name> -monitorName <string>

Example

```
> unbind service BR_LB_SVC_DYN_10.16.3.11 -monitorName BR_LB_MONITOR_DYN
 Done
```

Note: On AWS, for pairing a Branch Repeater AMI with a CloudBridge VPX, you use the Dynamic Load Balancing wizard for Citrix Branch Repeater on the CloudBridge VPX. The wizard creates the following entities on the CloudBridge VPX:

Entity Name	Entity Type	Description
BR_LB_SVC_DYN_<IP address of the Branch Repeater appliance> For example, BR_LB_SVC_DYN _ 192.0.2.30	Service	A service representing the Branch Repeater appliance.
BR_LB_MONITOR_DYN BR_LB_SVC_DYN_<IP address of the Branch Repeater appliance> For example, BR_LB_MONITOR_DYN BR_LB_SVC_DYN_ 192.0.2.30	Monitor	A monitor bound to the service (for example, BR_LB_SVC_DYN_10.16.3.11) representing the Branch Repeater appliance.

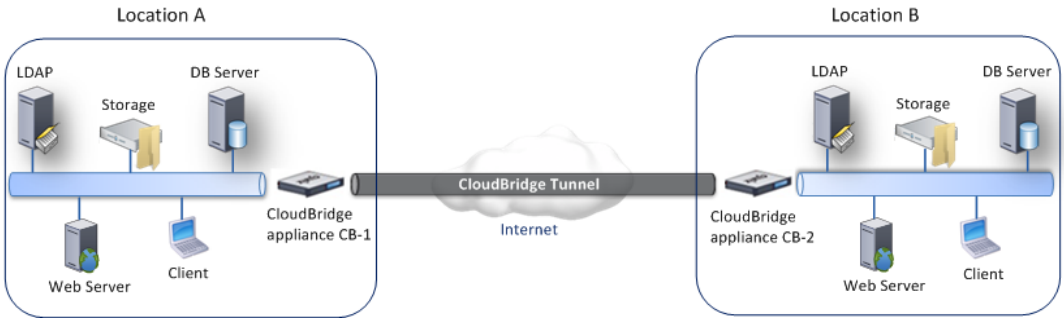
CloudBridge Tunnel Diagnostics and Troubleshooting

The following figure shows a CloudBridge tunnel between two CloudBridge appliances.



If you have problems with a CloudBridge tunnel configuration, make sure that all prerequisites were observed before the tunnel was set up. If they were, the problem might be with the tunnel end-point IP addresses, a NAT configuration, the way the tunnel was set up, or with the data traffic.

Prerequisites for Configuring a Cloudbridge Tunnel

Before you begin configuring a CloudBridge tunnel, make sure that you complete the following tasks:

- **Configure firewalls to allow UDP and ESP traffic** - Configure firewalls, deployed on the network edge of each of the CloudBridge tunnel end points, as follows:
  - If no NAT device is deployed before each of the CloudBridge tunnel end points, that is, the public IP addresses of both the tunnel end points are directly accessible to each other, you must configure the firewall to allow the following:
    - Any UDP packets for port 500
    - Any ESP (IP protocol number 50) packets
  - If a NAT device is deployed before any or each of the CloudBridge tunnel end points, that is, the public IP addresses of at least one tunnel end point is not directly accessible to the other, you must configure the firewall to allow the following:
    - Any UDP packets for port 500
    - Any UDP packets for port 4500
    - Any ESP (IP protocol number 50) packets
- **Test connectivity** - Before configuring the CloudBridge tunnel, make sure that the IP address of each CloudBridge tunnel end point is accessible from the other end point. If you have configured the firewalls to allow UDP packets for ports 500 and 4500, and ICMP traffic is allowed through the firewalls, you should be able to ping the IP address at one end point of the tunnel from the IP address at the other end point.

  On each of the tunnel end points, at the command line interface, type the following command:

  ping -**S** <LocalTunnelEndpoint-IP> <RemoteTunnelEndpoint-IP>

  If above ping is not successful, use any public IP address to verify Internet connectivity.

  ping -S <LocalTunnelEndPtIP> <PublicIP>

  If this ping is also unsuccessful, check your routing or Internet connectivity.

- **Enable the CloudBridge feature** - Make sure that the CloudBridge feature is enabled on NetScaler appliances, if they are used as tunnel end points, and that the license is active.

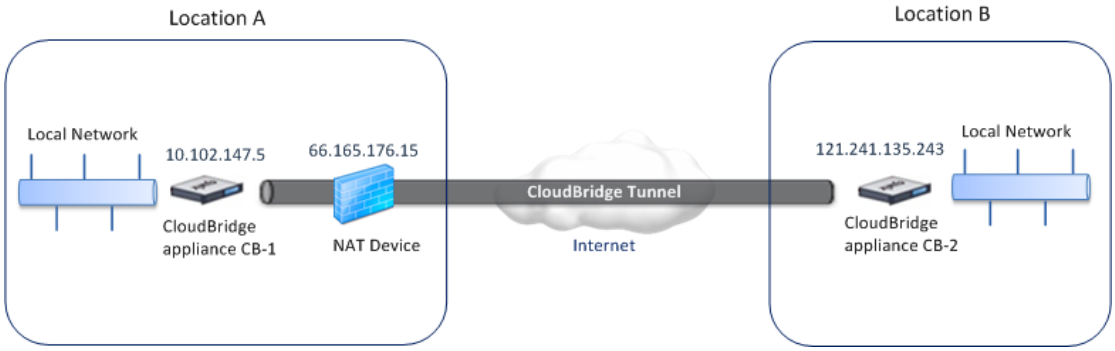
Points to Consider when Configuring a CloudBridge Tunnel with a NAT Device

For configuring a CloudBridge tunnel, consider the following points:

- You must not deploy any dynamic NAT device before a CloudBridge tunnel end point. At least one of the CloudBridge appliances must be directly connected or behind a static NAT device.
- Make sure that the IP tunnel entity configured on each CloudBridge appliance specifies the correct IP address of the appliance at the other end point. If one of the CloudBridge appliances is behind a static NAT device, the IP tunnel entity on the peer tunnel end point (the peer CloudBridge appliance) must specify the remote tunnel end-point IP as the IP address of the NAT device, not the IP address of the CloudBridge appliance that is behind the NAT device.

Examples

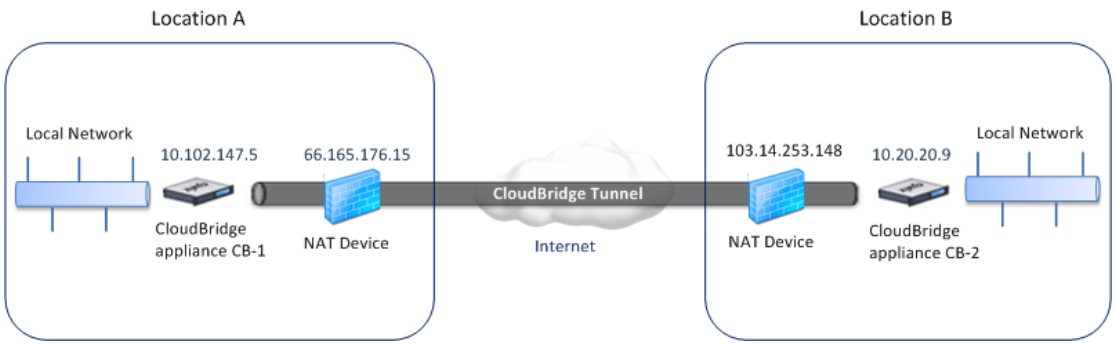
Consider the following deployment, where a NAT device is deployed in front of CloudBridge appliance CB-2:



The remote IP address and the local IP parameters of the IP tunnel entity configuration on CB-1 and CB-2 are as follows:

CloudBridge appliance	Remote IP	Local IP
CB-1	121.241.135.243	10.102.147.5
CB-2	66.165.176.15	121.241.135.243

Consider the following deployment, where a NAT device is deployed in front of both CloudBridge appliances CB-1 and CB-2:



The remote IP and the local IP parameters of the IP tunnel entity configuration on CB-1 and CB-2 are as follows:

CloudBridge appliance	Remote IP	Local IP
CB-1	103.14.253.148	10.102.147.5
CB-2	66.165.176.15	10.20.20.9

Troubleshooting a CloudBridge Tunnel

If your CloudBridge tunnel does not function properly, the issue could be with tunnel establishment or with the data traffic. If you are unsure which type of problem you have, look for an error message in the log file and see if the error message is in the list of tunnel-establishment issues. If you do not find your error message, check the list of possible issues related to data traffic.

Issues Related to Tunnel Establishment

After the requirements for configuring the IPSec tunnel are met and the CloudBridge tunnel is configured, if the status of the tunnel is not UP, look for debugging information in the iked.log file on one or both CloudBridge appliances configured as the tunnel end points.

On either appliance, type the following command at the CloudBridge shell prompt:

cat /tmp/iked.debug | tee /var/iked.log

The following table lists some common errors and their solutions.

Error Log Message	Possible Cause	Solution
retransmission count exceeded the limit **log message example** 2013-02-04 15:47:52 [PROTO_ERR]: ikev2.c:616:ikev2_timeout(): 3:5.5.5.2[500] - 5.5.5.1[500]:0x0:retransmission count exceeded the limit	The tunnel on the other end is not yet configured, or firewall routing issues are preventing the exchange of IKE related packets (UDP port 500/4500).	· If the tunnel on the other end point is not configured, configure it. · If the tunnel settings (IKE Version, Encryption/Hash Algorithm, PSK/certificates) on one end point do not match those on the other end point, no proposal is agreed upon between the end points. Specify the same settings on both end points. · After you configure a CloudBridge tunnel between two end points, if the IP tunnel entity in an end point does not enter the UP state within a few minutes, remove the IP tunnel entity and add it again. One minute is usually sufficient for tunnel establishment if both ends are Citrix CloudBridge appliances. · If none of the above measures correct the problem, configure, between the same end points, another CloudBridge that uses only the GRE protocol. Configure the firewalls on both ends to allow GRE (protocol number 47) packets. Verify that you are able to ping the network at one end of CloudBridge tunnel from the other end.

authentication failure **Log message example** *2013-02-04 16:05:16 [PROTO_ERR]: ikev2_auth.c:615:ikev2_verify(): 8:5.5.5.2[500] - 5.5.5.1[500]:0x8104290:authentication failure*	The IPSec authentication parameters (PSK or the public and private key) are set to incorrect values.	· Configure the authentication parameters correctly on both CloudBridge appliances.
failed to find a socket for retransmission or couldn't find configuration **Log message example** 2013-02-04 15:47:44 [INTERNAL_ERR]: isakmp.c:1844:isakmp_retransmit(): failed to find a socket for retransmission 2013-01-10 21:21:46 [PROTO_ERR]: ikev1.c:950:isakmp_ph1begin_r(): couldn't find configuration .	The tunnel IP address is not yet available for IKE purposes, or the tunnel does not exist.	· Remove the IP tunnel entities on both tunnel end points and add them again. · If another IP tunnel entity exists, with Local IP set to the same IP address but with IPSec profile set to NONE, remove these two tunnel entities and add them again. First add the one with a valid IPSec profile, and then add the one with IPSec profile NONE. · Verify that the IP address is available for IKE purposes, by typing the following commands at the CloudBridge shell prompt: · **ifconfig** -**a** | **grep**<LocalTunnelEndPoint-IP> **Example** root@ns# ifconfig -a | grep 5.5.5.2 *inet 5.5.5.2 netmask 0xffffff00 broadcast 5.5.5.255* · **netstat | grepudp | grep** <LocalTunnelEndPoint-IP> **Example** root@ns# netstat | grepudp | grep 5.5.5.2 *udp4 0 0 5.5.5.2.sae-urn *.* udp4 0 0 5.5.5.2.isakmp *.**

The source port and destination ports shown in the /tmp/iked.debug are other than port 500. That is: src=<srcip>[<srcPort != 500>] dst=<dst tip>[<dstPort != 500>]) **Log message example** 2013-02-04 16:08:59 [INFO]: ike_pfkey.c:490:sadb_log_add(): SADB_UPDATE ul_proto=255 src=5.5.5.1[4500] dst=5.5.5.2[4500] satype=ESP samode=transport spi=0x055fdd6d authtype=HMAC-SHA-256 enctype=AES-CBC lifetime soft time=25741 bytes=0 hard time=28800 bytes=0	At least one of the CloudBridge end points is deployed behind a NAT device	· See Points to Consider when Configuring a CloudBridge Tunnel with a NAT Device for proper IP configuration for configuring a CloudBridge tunnel. · Make sure that UDP traffic is unblocked and the IPSec tunnel configuration is correct on both CloudBridge instances, as described in Prerequisites and Points to Consider when Configuring a CloudBridge Tunnel with a NAT Device.

Issues Related to Data Traffic

If the data in the CloudBridge tunnel are not exchanged properly between the tunnel end points, do the following.

- For a CloudBridge tunnel that uses GRE and IPSec protocols:
  - Make sure that L2 mode is enabled on both of the CloudBridge tunnel end points. To enable L2 mode, type the following command at the CloudBridge command prompt.

    enable mode L2

  - If one of the CloudBridge tunnel end points is a CloudBridge virtual appliance (VPX) and is provisioned on a VMware ESXi hypervisor, make sure that **Promiscuous mode** is set to **Accept** for the vSwitch associated with the CloudBridge VPX appliance.

  - If a VLAN is extended through a CloudBridge tunnel, verify one-to-one mapping on the extended VLAN entity on each of the tunnel end points .

  - Make sure that the IP tunnel entity is bound to the correct netbridge entity in each of the tunnel end points.

  - Verify that the ARP entry for the peer CloudBridge tunnel end point exists on the local tunnel end point, by typing the following command at the CloudBridge command prompt.

    show arp

    If the output shows an incomplete ARP entry, bidirectional traffic is not flowing through the tunnel. If bidirectional traffic is flowing, the ARP entry shows the name of tunnel interface for the devices on the other side of the tunnel.

  - Remove the IP tunnel entities from both tunnel end points and add them again with the same parameters, but with the IPSec profile set to NONE, so that the tunnel uses only the GRE protocol.

    After verifying the following in the IP tunnel (that uses GRE protocol), configure the tunnel with IPSec parameters by specifying a valid IPSec profile to the respective IP tunnel entities on each of the tunnel end points.

    - Proper PING or TCP flow through the tunnel

    - Proper flow of data traffic through the tunnel

    After the configured tunnel (that uses GRE and IPSec protocols) is in UP state, if the data traffic does not flow properly through the tunnel, and if a NAT device was deployed in front of any or both of the tunnel end points, analyze the ingress and egress packets on the NAT devices
- If a CloudBridge appliance is used as Router or Gateway.
  - Make sure that L3 mode is enabled on the CloudBridge appliance. To enable L3 mode, run the following command in the CloudBridge command line.

enable mode L3

- If subnets are bound to a netbridge entity, make sure that correct IP tunnel entity is also bound to the netbridge.

- Run the following command in the CloudBridge command line to see where the packets (Input and Output)are getting dropped:

  stat ipsec counters

- Make sure that the correct routes are configured on both the tunnel end points.

- If no NAT device is deployed in front of the CloudBridge appliance, make sure that the firewalls are configured to allow any ESP (IP protocol number 50) packets and any UDP packets for port 4500.

If none of the above measures result in successful exchange of traffic between the tunnel end points, contact Citrix Technical Support.

Checklist before Contacting Citrix Technical Support

For a speedy resolution, make sure that you have the following items ready before contacting Citrix Technical Support.

- ·Details of the deployment and network topology.
- Log file collected by typing the following command at the CloudBridge shell prompt.

  cat /tmp/iked.debug | tee /var/log/iked.log
- Tech support bundle captured by typing the following command at the CloudBridge command prompt.

  show techsupport
- Packet traces captured on both CloudBridge tunnel end points. To start a packet trace, type the following command at the CloudBridge command prompt.

  start nstrace-size 0

  To stop packet trace, type the following command at the CloudBridge command prompt.

  stop nstrace
- Output of the following command typed at the CloudBridge command prompt.

  show arp

Known Issues

IKE re-keying, which is renegotiation of new cryptographic keys between the CloudBridge tunnel end points to establish new SAs, is not supported. When the Security Associations (SAs) expire, the tunnel goes into the DOWN state. Therefore, you must set a very large value for the lifetimes of SAs.

EdgeSight Monitoring for NetScaler

Citrix EdgeSight for NetScaler is an application to monitor end-user experience with Web applications served in a NetScaler environment. The EdgeSight Monitoring application uses the HTML Injection feature of the NetScaler to provide data with which you can compare the performance of various Web applications across geographical locations.

For EdgeSight monitoring, register the NetScaler appliance with EdgeSight and enable applications in the NetScaler. The EdgeSight application processes the data and displays the information after aggregating it. You can view the data as charts, graphs, or tables.

When EdgeSight monitoring is enabled on a virtual server, NetScaler injects scripts into the responses sent to the clients. Execution or insertion of these scripts does not affect the response to the client. Data injected by the NetScaler is collected by the EdgeSight server through data collector services.

EdgeSight is an agentless application. The EdgeSight server from which you can monitor the user-experience is referred to as *EdgeSight UI server*.

Use the wizard to register the NetScaler appliance with the EdgeSight UI server, select the data collector services, and configure the rate at which data is injected into the response. For more information on the wizard, see "Configuring EdgeSight Monitoring."

Note: The EdgeSight UI server has a data collector and a Web site. For better scalability, you can install multiple data collectors.

To use EdgeSight monitoring, enable EdgeSight monitoring on the load balancing or content switching virtual servers associated with the selected applications. For instructions, see "Enabling an Application for EdgeSight Monitoring. "

Configuring EdgeSight Monitoring for NetScaler

The configuration utility provides a wizard to assist you with configuration. The wizard for the configuration of EdgeSight monitoring for NetScaler guides you through the configuration procedure in simple steps. The wizard takes care of the following tasks:

- Enable the EdgeSight Monitoring (HTML Injection) feature.
- Specify the rate and frequency for injecting data.
- Bind the EdgeSight server/data collector services to the load balancing virtual server on the NetScaler.
- Enable the Web applications for EdgeSight monitoring.

Note: You can configure rate or frequency. If you specify the rate to be x, data is injected once after every x responses sent by the service. For example, if you specify the rate to be 500, NetScaler injects the data into the 1st response, 501st response, 1002nd response, and so on. If you specify frequency to be y, data is injected once in every y milliseconds.

To access the wizard from the NetScaler configuration utility and configure EdgeSight Monitoring

1. In the navigation pane, click EdgeSight Monitoring.
2. Click EdgeSight for NetScaler Wizard.
3. Follow the instructions presented by the wizard.

To configure EdgeSight monitoring from the command line interface and configure EdgeSight Monitoring

The following example shows the CLI commands executed for configuring EdgeSight monitoring for a NetScaler appliance.

Enabling an Application for EdgeSight Monitoring

EdgeSight monitoring makes it possible to monitor the performance of an application from the end user's perspective.

Note: To enable an application to be monitored, EdgeSight monitoring must be enabled on the virtual servers.

EdgeSight monitoring is possible only if the response from the physical server is not compressed. Therefore, make sure that Compression is enabled globally on the NetScaler. When you use the wizard to configure EdgeSight monitoring, the wizard takes care of enabling compression and other necessary processing.

Note: Before enabling EdgeSight monitoring on a virtual server, make sure that you completed the configuration of EdgeSight monitoring through the wizard.

To enable EdgeSight monitoring on a load balancing or content switching virtual server by using the NetScaler configuration utility

1. In the navigation pane, expand Load Balancing and click Virtual Servers.
2. Select the virtual server, or multiple virtual servers, and then click Enable EdgeSight Monitoring.
3. If you want the NetScaler to compress responses after receiving them from the server, select the Compress response at NetScaler before sending it to the client check box.
4. Select the Export EdgeSight statistics to AppFlow check box.
5. From the Appflow Action drop-down list, select the AppFlow action.

   The AppFlow action defines the list of AppFlow collectors to which it exports EdgeSight Monitoring statistics. If you have selected multiple load balancing virtual servers, the same AppFlow action will be configured in the responder policies bound to them.

   Note: You can later change the AppFlow action configured for each of the selected Load Balancing virtual server individually, if required.
6. Click OK.

To enable EdgeSight monitoring on a load balancing or content switching virtual server by using the command line interface

The following example shows the CLI commands executed for enabling EdgeSight monitoring on a virtual server.

Example

Jun 9 22:56:13 <local0.info> 10.102.113.114 06/10/2011:02:56:13 GMT ns PPE-2 : UI CMD_EXECUTED 266 : User nsroot - Remote_ip 10.101.254.143 - Command "show lb vserver guilb" - Status "Success"

Jun 9 22:56:14 <local0.info> 10.102.113.114 06/10/2011:02:56:14 GMT ns PPE-2 : UI CMD_EXECUTED 270 : User nsroot - Remote_ip 10.101.254.143 - Command "bind lb vserver guilb -weight 1 -policyName __ESNS_PREBODY_POLICY" - Status "Success"

Jun 9 22:56:15 <local0.info> 10.102.113.114 06/10/2011:02:56:15 GMT ns PPE-2 : UI CMD_EXECUTED 271 : User nsroot - Remote_ip 10.101.254.143 - Command "bind lb vserver guilb -weight 1 -policyName __ESNS_POSTBODY_POLICY" - Status "Success"

Jun 9 22:56:15 <local0.info> 10.102.113.114 06/10/2011:02:56:15 GMT ns PPE-2 : UI CMD_EXECUTED 272 : User nsroot - Remote_ip 10.101.254.143 - Command "bind lb vserver guilb -weight 1 -policyName __ESNS_RESPONDER_POLICY -priority 2147483647 -gotoPriorityExpression END" - Status "Success"

Jun 9 22:56:15 <local0.info> 10.102.113.114 06/10/2011:02:56:15 GMT ns PPE-2 : UI CMD_EXECUTED 273 : User nsroot - Remote_ip 10.101.254.143 - Command "bind lb vserver guilb -weight 1 -policyName __ESNS_REWRITE_POLICY -priority 2147483647 -gotoPriorityExpression END -type REQUEST" - Status "Success"

Jun 9 22:56:15 <local0.info> 10.102.113.114 06/10/2011:02:56:15 GMT ns PPE-2 : UI CMD_EXECUTED 274 : User nsroot - Remote_ip 10.101.254.143 - Command "show ns feature" - Status "Success"

Accessing the EdgeSight Monitoring Interface from NetScaler

You can view the data presented by the EdgeSight monitoring application from the NetScaler appliance. The configuration utility of the NetScaler displays a login screen to access the EdgeSight UI server and upon successful login, displays the data.

To access EdgeSight for NetScaler by using the NetScaler configuration utility

1. In the navigation pane, click EdgeSight Monitoring.
2. Click Access EdgeSight for NetScaler.
3. Enter the credentials for accessing the EdgeSight UI server. For more information on viewing the reports, see *EdgeSight Administration Guide* at "http://support.citrix.com/article/CTX126418"

Variables Injected for EdgeSight Monitoring for NetScaler

For monitoring the end-user experience in the NetScaler environment, NetScaler injects scripts into the responses sent to the clients. A predefined set of variables are used in the scripts and the variables are evaluated at runtime. The following table describes the variables.

Table 1. Variables for Monitoring the NetScaler Performance

Name	Type	JavaScript type	Comment
SYS.IID	128-bit GUID structure	Windows format GUID	This is a GUID that uniquely identifies each NetScaler. The value of this variable remains constant across reboots. It is valid in both prebody and postbody.
HTTP.XID	128-bit GUID structure	Windows format GUID	This is a GUID that uniquely identifies each HTTP transaction (request/response). This variable is guaranteed to be unique even if the NetScaler is rebooted. It is valid in both the prebody and postbody.
SYS.UPTIME	32-bit integer	10-digit number	Gives the time in seconds, offset to UTC, that the NetScaler has been up. It is valid in both prebody and postbody.
HTTP.REQ.RECEIVE_TIME_BEG	64-bit integer	20-digit number	Gives the time, in microseconds, when NetScaler received the first byte of a client request. It is valid in both prebody and postbody.

HTTP.REQ.RECEIVE_TIME_END	64-bit integer	20-digit number	Gives the time, in microseconds, when NetScaler received the last byte of a client request. It is valid in both the prebody and postbody.
HTTP.REQ.SEND_TIME_BEG	64-bit integer	20-digit number	Gives the time, in microseconds, when NetScaler forwarded the first byte of a request to the back-end server. It is valid in both prebody and postbody.
HTTP.REQ.SEND_TIME_END	64-bit integer	20-digit number	Gives the time, in microseconds, when NetScaler forwarded the last byte of a request to the back-end server. It is valid in both prebody and postbody.
HTTP.RES.RECEIVE_TIME_BEG	64-bit integer	20-digit number	Gives the time, in microseconds, when NetScaler received the first byte of a response from the back-end server. It is valid in both prebody and postbody.
HTTP.RES.RECEIVE_TIME_END	64-bit integer	20-digit number	Gives the time, in microseconds, when NetScaler received the last byte of a response from the back-end server. It is valid only in postbody.
HTTP.RES.SEND_TIME_BEG	64-bit integer	20-digit number	Gives the time, in microseconds, when NetScaler forwarded the first byte of response to the client. It is valid in both prebody and postbody.

HTTP.RES.SEND_TIME_END	64-bit integer	20-digit number	Gives the time, in microseconds, when NetScaler forwarded the last byte of a response to the client. It is valid only in postbody.
SYS.VSERVER	String (147 characters)	20-digit number	Gives the name, IP address, and port number of the virtual server that load balanced the request. It is valid in both prebody and postbody.
SYS.VSERVICE	String (147 characters)	20-digit number	Gives the name, IP address, and port number of the physical server that serviced the request. It is valid in both prebody and postbody.

Flex Tenancy

Flex Tenancy™ is a Citrix NetScaler methodology that allows you to tune a group of NetScaler VPX instances to the unique characteristics and needs of individual applications in a complex Web 2.0 setup.

As the Web becomes the de-facto way of delivering application services, the number of web applications that enterprises and service providers must support has been growing at a very fast pace. Not only are the technical requirements of each web application different, but also in most large environments, the applications are owned and controlled by different constituencies/organizations. This leads to the need to offer the Application Delivery Controller (ADC) functionality as a shared service to multiple tenants.

Understanding the Flex Tenancy Architecture

In a typical Flex Tenancy set-up, NetScaler physical and virtual appliances can be used together in a two-tier architecture with each tier dedicated to managing specific actions. This:

- provides flexibility for how application delivery services are deployed and managed
- makes it much easier to shuffle applications and their associated application delivery resources on-demand without risking the stability of the entire network
- reduces costs

The Flex Tenancy architecture segments web application delivery services into two tiers:

- shared-network-service flex tier
- application-specific tenant tier

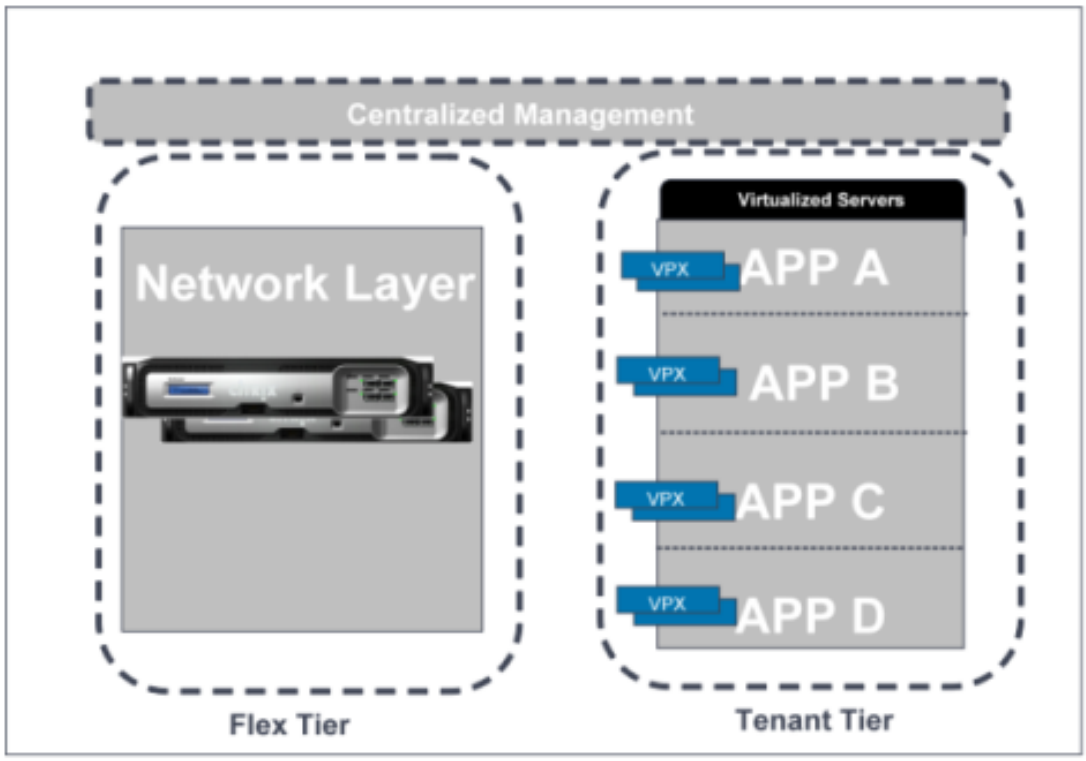

Figure 1. Flex Tenancy Architecture

The Flex Tier

The flex tier runs at the edge of the data center or an enterprise network. The flex tier generally performs application delivery services and associated policies that are common and applied to all applications. Examples of such services could include:

- SSL offload
- SSL VPN
- DoS mitigation
- GSLB
- Certain types of redirects
- Content Switching

Since the policies are common and shared, there is no reason to try and partition them across multiple NetScaler instances dedicated per specific application. Indeed, partitioning at the flex tier is counterproductive as it leads to duplication of effort and the associated possibility of configuration errors during change management. Therefore, the flex tier should be physically centralized on as few NetScaler instances as possible. In all but the smallest environments this will generally lead to NetScaler MPX physical appliances being used at the flex tier.

The Tenant Tier

The tenant tier runs logically close to the applications, with each tenant (whether a tenant is an application, a line of business, or a customer) getting its own NetScaler instance. The tenant tier isolates the application delivery needs that vary by application - like server load balancing, caching, compression and application firewall protection - per application.

Since the policies - and thus the NetScaler configurations - differ by application, there is no inherent configuration benefit to centralizing multiple applications onto a single NetScaler. In fact, there are significant configuration isolation, separation of duties and capacity planning benefits of dedicating appliances on an app-by-app basis.

Centralized Management

One potential downside to dedicating NetScaler instances to specific applications is "appliance sprawl". In Flex Tenancy architectures, the vast majority of most instances will be NetScaler VPX virtual appliances. Therefore, the physical challenges (e.g., racking, cabling) associated with appliance sprawl don't exist. Citrix Command Center is used to provide centralized FCAPS (fault, configuration, accounting, performance, security) management of both the flex and the tenant tiers.

Building a Flex Tenancy Solution

The Flex Tenancy architecture is applicable to any high volume environment where:

- multiple tenants share a common infrastructure
- there is a core set of shared application delivery services that are common to all tenants
- each tenant also has its own specific web application delivery needs and requirements

The two most prevalent examples of this kind of environment are:

- hosting/managed services providers that want to offer dedicated load balancing/application delivery services to their customers
- an enterprise IT organization that models itself as an “internal service provider” to support multiple lines-of-business and business applications.

In each case, the core architecture is similar. However, the deployment architecture and the management of the overall system will likely vary based upon the very different business needs of each case.

Enterprise IT as an Internal Service Provider

Many enterprise IT organizations model themselves as internal service providers supporting the different needs of the different lines-of-business. Building "private clouds" to support enterprise applications is the latest phase of this trend.

An enterprise typically hosts a variety of applications that may be independent of each other.

These applications:

- require their own application server pools
- typically need customized ADC policies and tuning
- have their own distinct change management requirements and windows

The challenge facing the groups managing the web application delivery infrastructure is to support different and increasingly complex applications and at the same time scale so that they can support an ever increasing number of applications.

Achieving application performance in this environment depends upon coordination between network teams and the various application teams. Application tuning requires knowledge of the application and in many cases should be responsibility of the application team. Maintaining network performance and availability requires knowledge of various networking protocols and hardware management and therefore becomes the responsibility of the network team.

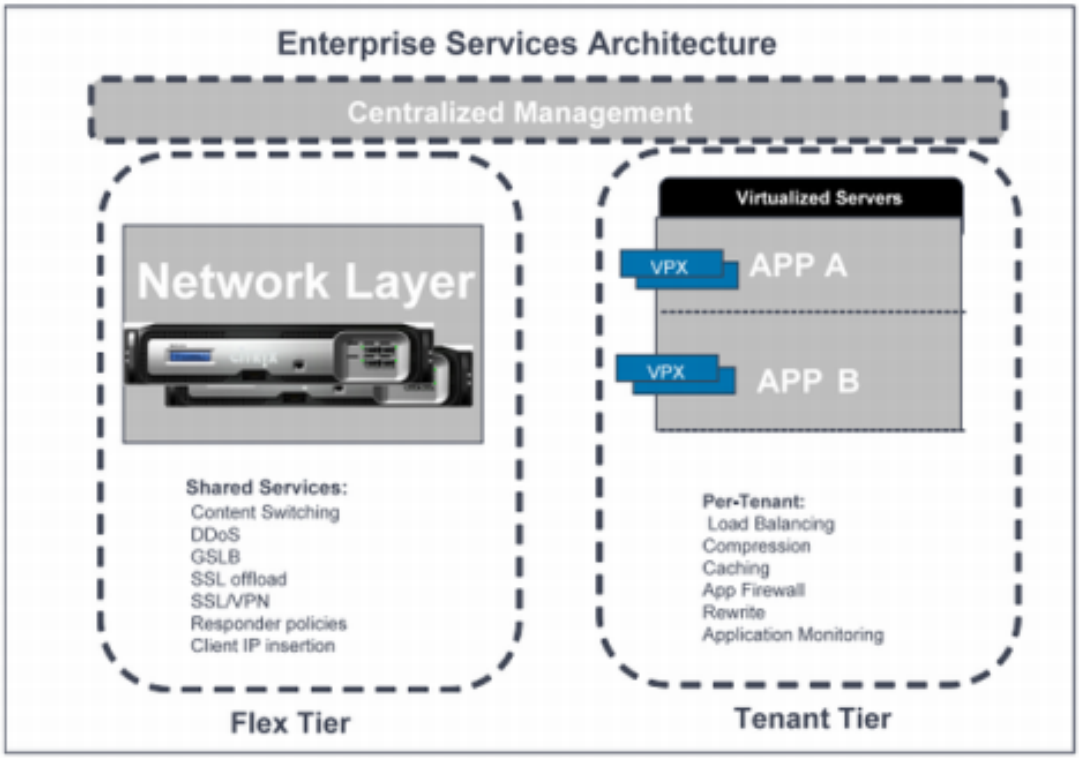
Sharing the same device between both teams creates manageability challenges for an organization. For example, consider an application administrator wanting to upgrade to upgrade the ADC take advantage of new functionality. If the ADC is shared by other applications, the administrator must coordinate with all these teams to initiate change control for his change.

Moreover, any changes to the ADC will need to be tested with every other application. As the number of applications grows, this model becomes exponentially complex.

The Flex Tenancy architecture addresses these issues. Since no other applications run on the tenant instance:

- it can be upgraded based solely on the needs of its hosted app
- there is no need to qualify the version upgrade against other applications
- there is no concern that using the new functionality will impact other app performance

Figure 1. Architecture of an enterprise service solution



There are three possible administrative approaches using Flex Tenancy:

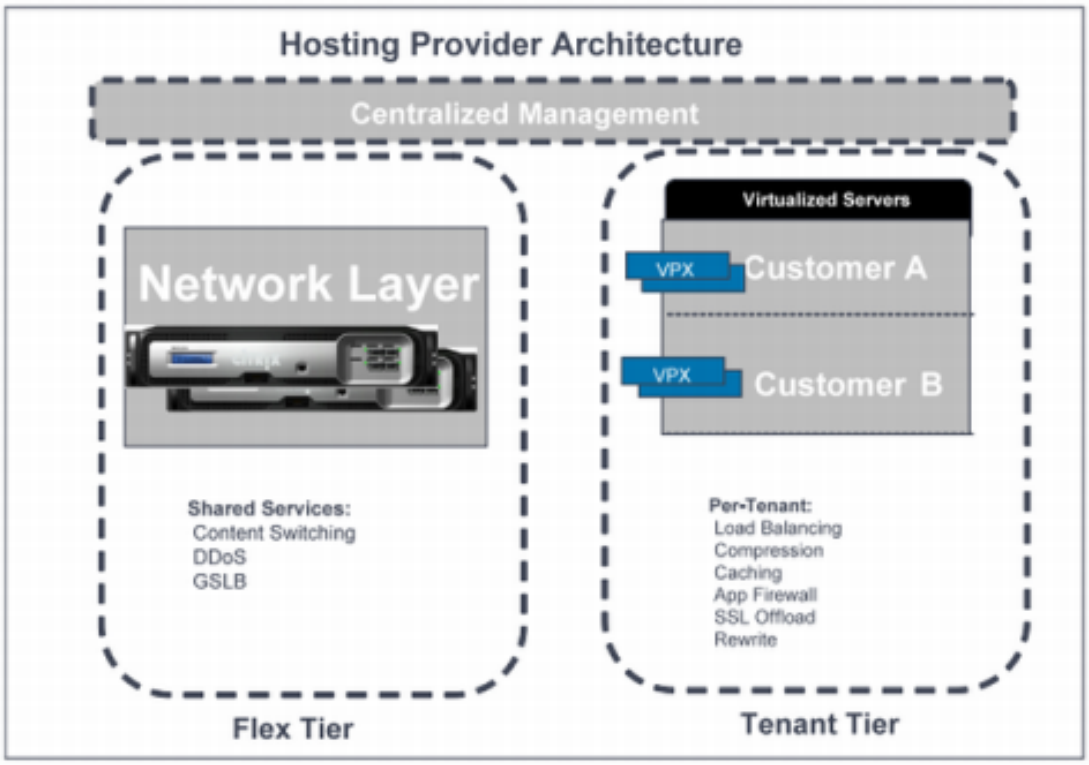
1. The central IT organization can retain full administrative control over both the flex and tenant tiers.

2. The central IT organization can retain full control over the flex tier, but delegate management rights of the tenant instances to individual app teams.

3. The central IT team can retain full control over the flex tier, retain control over certain elements of the tenant tier (e.g., certain IP addressing, ensuring it can retain “root access”) but delegate control of other functionality to app teams.

The ability to tune the application delivery fabric to individual applications enables IT organizations to maximize the performance of their applications and to scale the number of applications they provide to their stakeholders without significant increase in costs.

Hosting provider solution



A hosting provider provides space on a server they own and Internet connectivity for the applications hosted on that server. These servers are typically hosted in a data center. Load balancing is a frequently requested "add-on" services customers ask for. Additionally, advanced L7 services such as compression, application firewall and caching provide additional revenue opportunities for the hosting provider.Figure 1. Architecture of a hosting provider solution

The biggest challenge in this environment is managing and delivering application delivery services for a wide variety of customers, each with varying requirements. Trying to manage these services on a shared device can lead to performance bottlenecks, change management conflicts and ultimately a loss of business. Also, many customers will want admin rights to control the load balancing services used for their hosted back-end servers.

Flex Tenancy solution can be very useful in this scenario. A hosting provider can use the flex tier to run services common to the entire data center. These include global server load balancing (GSLB) which would provide data center redundancy, denial of service protection (DoS), and segregate traffic to the tenant tier using content switching policies.

At the tenant tier each tenant is provisioned, and can manage its own, dedicated NetScaler instances.

One of the primary services of this tier is to load balance requests to the backend servers. In addition, this tier may also perform SSL offload. This is usually a flex tier service, but in a hosting environment it may be offloaded to the tenant tier if the hosting business model

supports customers owning and managing their own certificates.

Tenant tier is also used to apply a variety of complex application policies to tune application performance. For example, a customer can define caching policies to cache objects of a certain application only for ten seconds while other application objects could be cached for a longer duration. Customers can also define rewrite policies, application firewall policies, compression policies and application level monitoring policies.

In this environment, flex tier can comprise of one or more MPX devices while the tenant tier could comprise of a combination of VPX and MPX devices. Citrix provides Command Center to manage these devices.

Since VPX is a virtual appliance, network administrators can easily create a workflow, using commercial or in-house data center automation tools, to bring up additional NetScaler VPX instances and servers online to support the increased load. NetScaler also provides extensive API that can be used to integrate into the work flow automation tools used in hosting/managed services infrastructures. Network administrators can also use the Citrix Command Center in conjunction to propagate the relevant NetScaler configurations to these newly started NetScaler VPX instances.

The division of services amongst the tiers and the ability to manage them through Command Center and NetScaler APIs enables a hosting provider to scale performance of his application delivery fabric and to streamline his operations.

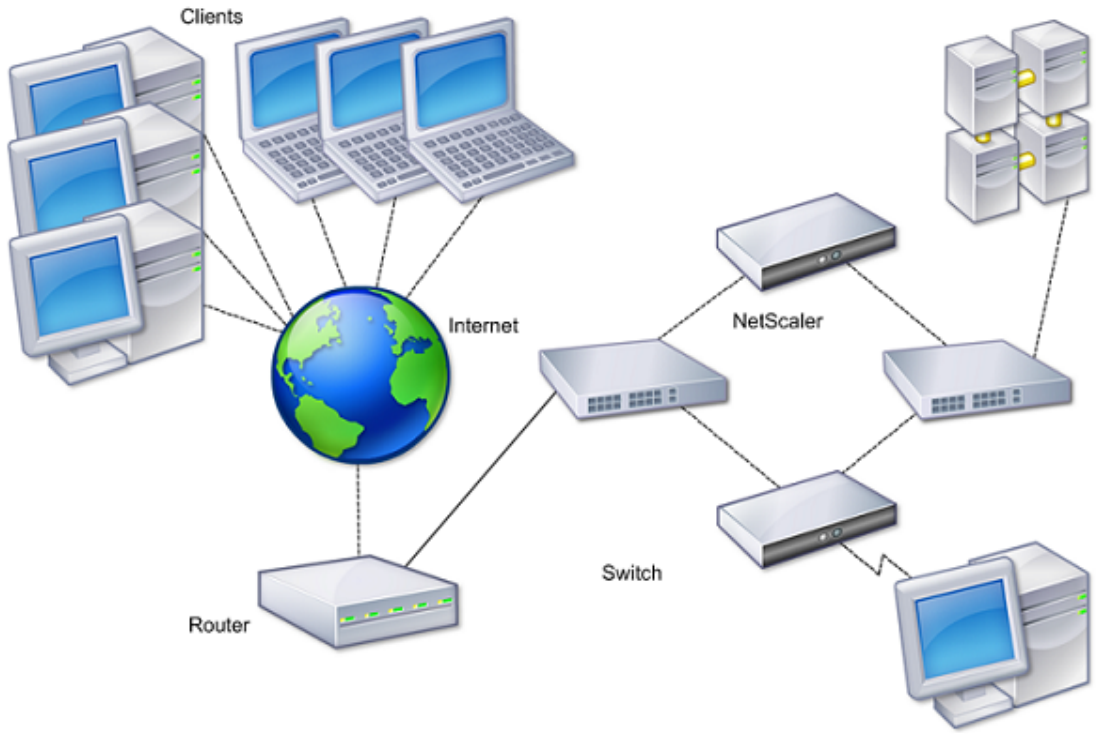
High Availability

A high availability (HA) deployment of two Citrix® NetScaler® appliances can provide uninterrupted operation in any transaction. With one appliance configured as the primary node and the other as the secondary node, the primary node accepts connections and manages servers while the secondary node monitors the primary. If, for any reason, the primary node is unable to accept connections, the secondary node takes over.

The secondary node monitors the primary by sending periodic messages (often called heartbeat messages or health checks) to determine whether the primary node is accepting connections. If a health check fails, the secondary node retries the connection for a specified period, after which it determines that the primary node is not functioning normally. The secondary node then takes over for the primary (a process called failover).

After a failover, all clients must reestablish their connections to the managed servers, but the session persistence rules are maintained as they were before the failover.

With Web server logging persistence enabled, no log data is lost due to the failover. For logging persistence to be enabled, the log server configuration must carry entries for both systems in the log.conf file.



The following figure shows a network configuration with an HA pair.Figure 1. NetScaler Appliances in a High Availability Configuration

To configure HA, you might want to begin by creating a basic setup, with both nodes in the same subnet. You can then customize the intervals at which the nodes communicate health-check information, the process by which nodes maintain synchronization, and the

propagation of commands from the primary to the secondary. You can configure fail-safe mode to prevent a situation in which neither node is primary. If your environment includes devices that do not accept NetScaler gratuitous ARP messages, you should configure virtual MAC addresses. When you are ready for a more complex configuration, you can configure HA nodes in different subnets.

To improve the reliability of your HA setup, you can configure route monitors and create redundant links. In some situations, such as when troubleshooting or performing maintenance tasks, you might want to force a node to fail over (assign primary status to the other node), or you might want to force the secondary node to stay secondary or the primary node to stay primary.

Considerations for a High Availability Setup

Note the following requirements for configuring systems in an HA setup:

- In an HA configuration, the primary and secondary NetScaler appliances should be of the same model. Different NetScaler models are not supported in an HA pair (for example, you cannot configure a 10010 model and a 7000 model as an HA pair).
- In an HA setup, both nodes must run the same version of NetScaler, for example, nCore/nCore or classic/classic. If the nodes are running NetScaler classic and you want to migrate to NetScaler nCore of the same NetScaler release, prop and sync are not supported during the migration process. Once migration is complete, prop and sync are auto-enabled. The same applies if you migrate from NetScaler nCore to NetScaler classic.
- Entries in the configuration file (ns.conf) on both the primary and the secondary system must match, with the following exceptions:
  - The primary and the secondary systems must each be configured with their own unique NetScaler IP addresses (NSIPs.)
  - In an HA pair, the node ID and associated IP address of one node must point to the other node. For example, if you have nodes NS1 and NS2, you must configure NS1 with a unique node ID and the IP address of NS2, and you must configure NS2 with a unique node ID and the IP address of NS1.
- If you create a configuration file on either node by using a method that does not go directly through the GUI or the CLI (for example, importing SSL certificates, or changing to startup scripts), you must copy the configuration file to the other node or create an identical file on that node.
- Initially, all NetScaler appliances are configured with the same RPC node password. RPC nodes are internal system entities used for system-to-system communication of configuration and session information. For security, you should change the default RPC node passwords.

  One RPC node exists on each NetScaler. This node stores the password, which is checked against the password provided by the contacting system. To communicate with other systems, each NetScaler requires knowledge of those systems, including how to authenticate on those systems. RPC nodes maintain this information, which includes the IP addresses of the other systems, and the passwords they require for authentication.

  RPC nodes are implicitly created when adding a node or adding a Global Server Load Balancing (GSLB) site. You cannot create or delete RPC nodes manually.

  Note: If the NetScaler appliances in a high availability setup are configured in one-arm mode, you must disable all system interfaces except the one connected to the switch or hub.
- For an IPv6 HA configuration, the following considerations apply:

- You must install the IPv6PT license on both NetScaler appliances.
- After installing the IPv6PT license, enable the IPv6 feature by using the configuration utility or the command line interface.
- Both NetScaler appliances require a global NSIP IPv6 address. In addition, network entities (for example, switches and routers) between the two nodes must support IPv6.

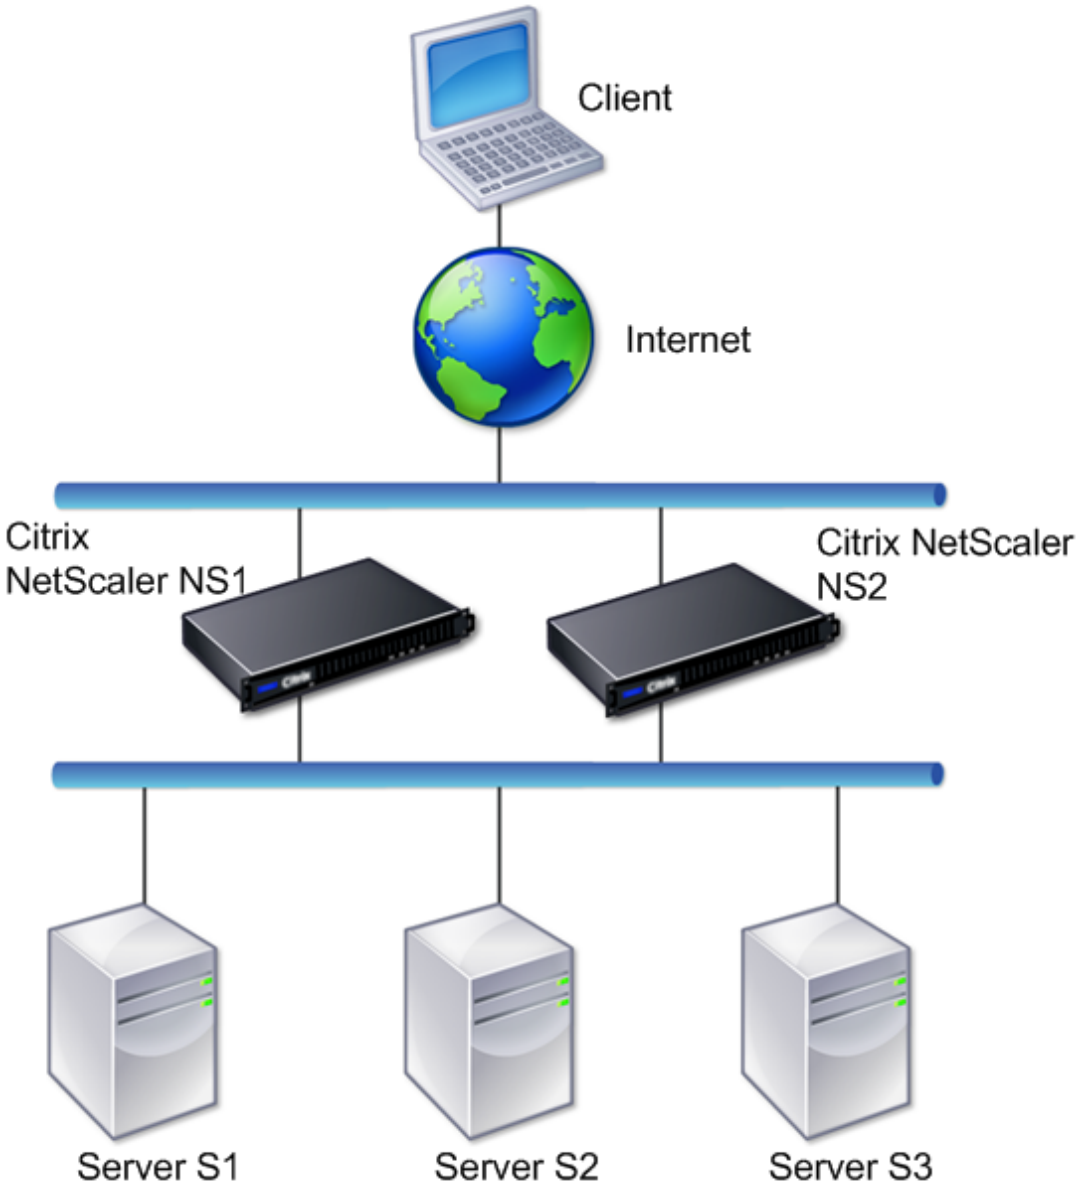
Configuring High Availability

To set up a high availability configuration, you create two nodes, each of which defines the other's NetScaler IP (NSIP) address as a remote node. Begin by logging on to one of the two NetScaler appliances that you want to configure for high availability, and add a node. Specify the other appliance's NetScaler IP (NSIP) address as the address of the new node. Then, log on to the other appliance and add a node that has the NSIP address of the first appliance. An algorithm determines which node becomes primary and which becomes secondary.

Note: The configuration utility provides an option that avoids having to log on to the second appliance.

The following figure shows a simple HA setup, in which both nodes are in same subnet.

Figure 1. Two NetScaler Appliances Connected in a High Availability Configuration



Client
Internet
Citrix
NetScaler NS1
Citrix NetScaler
NS2
Server S1
Server S2
Server S3

Adding a Remote Node

To add a remote NetScaler appliance as a node in a high availability setup, you specify a unique node ID and the appliance's NSIP. The maximum number of node IDs in an HA setup is 64. When you add an HA node, you must disable the HA monitor for each interface that is not connected or not being used for traffic. For CLI users, this is a separate procedure.

Note: To ensure that each node in the high availability configuration has the same settings, you should synchronize your SSL certificates, startup scripts, and other configuration files with those on the primary node.

To add a node by using the command line interface

At the command prompt, type:

- add ha node <id> <IPAddress>
- show ha node

Example

```
> add ha node 3 1000:0000:0000:0000:0005:0600:700a:888b
```

To disable an HA monitor by using the command line interface

At the command prompt, type:

- set interface <ifNum> [-haMonitor (**ON** | **OFF**)]
- show interface <ifNum>

Example

```
> set interface 1/3 -haMonitor OFF
 Done
```

To add a remote node by using the configuration utility

Navigate to System > High Availability and, on the Nodes tab, add a new remote node, or edit an existing node.

Parameter Descriptions (of commands listed in the CLI procedure)

add ha node

show ha node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

set interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Disabling or Enabling a Node

You can disable or enable only a secondary node. When you disable a secondary node, it stops sending heartbeat messages to the primary node, and therefore the primary node can no longer check the status of the secondary. When you enable a node, the node takes part in the high availability configuration.

To disable or enable a node by using the command line interface

At the command prompt, type one of the following commands:

- set ha node -hastatus DISABLED
- set ha node -hastatus ENABLED

To disable or enable a node by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. In the High Availability Status list, select ENABLED (Actively Participate in HA) or DISABLED (Do not participate in HA).

Parameter Descriptions (of commands listed in the CLI procedure)

set ha node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Removing a Node

If you remove a node, the nodes are no longer in high availability configuration.

To remove a node by using the command line interface

At the command prompt, type:

rm ha node <id>

Example

```
> rm ha node 2
  Done
```

To remove a node by using the configuration utility

Navigate to System > High Availability and, on the Nodes tab, delete the node.

Note: You can use the Network Visualizer to view the NetScaler appliances that are configured as a high availability (HA) pair and perform high availability configuration tasks. For more information, see " Using the Network Visualizer."

Parameter Descriptions (of commands listed in the CLI procedure)

rm ha node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring the Communication Intervals

The hello interval is the interval at which the heartbeat messages are sent to the peer node. The dead interval is the time interval after which the peer node is marked DOWN if heartbeat packets are not received. The heartbeat messages are UDP packets sent to port 3003 of the other node in an HA pair.

To set the hello and dead intervals by using the command line interface

At the command prompt, type:

- set HA node [-helloInterval <msecs>] [-deadInterval <secs>]
- show HA node <id>

To set the hello and dead intervals by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Set the following parameters:
    - Hello Interval (msecs)
    - Dead Interval (secs)

Parameter Descriptions (of commands listed in the CLI procedure)

set HA node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show HA node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Synchronization

Synchronization is a process of duplicating the configuration of the primary node on the secondary node. The purpose of synchronization is to ensure that there is no loss of configuration information between the primary and the secondary nodes, regardless of the number of failovers that occur. Synchronization uses port 3010.

Synchronization is triggered by either of the following circumstances:

- The secondary node in an HA setup comes up after a restart.
- The primary node becomes secondary after a failover.

Automatic synchronization is enabled by default. You can also force synchronization.

Disabling or Enabling Synchronization

Automatic HA synchronization is enabled by default on each node in an HA pair. You can enable or disable it on either node.

To disable or enable automatic synchronization by using the command line interface

At the command prompt, type:

- set HA node -haSync DISABLED
- set HA node -haSync ENABLED

To disable or enable synchronization by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Under HA Synchronization, clear or select the Secondary node will fetch the configuration from Primary option.

Parameter Descriptions (of commands listed in the CLI procedure)

set HA node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Forcing the Secondary Node to Synchronize with the Primary Node

In addition to automatic synchronization, the NetScaler supports forced synchronization. You can force the synchronization from either the primary or the secondary node. When you force synchronization from the secondary node, it starts synchronizing its configuration with the primary node.

However, if synchronization is already in progress, forced synchronization fails and the system displays a warning. Forced synchronization also fails in any of the following circumstances:

- You force synchronization on a standalone system.
- The secondary node is disabled.
- HA synchronization is disabled on the secondary node.

To force synchronization by using the command line interface

At the command prompt, type:

force HA sync

To force synchronization by using the configuration utility

1. Navigate to System > High Availability.
2. On the Nodes tab, click Force Synchronization.

Parameter Descriptions (of commands listed in the CLI procedure)

force HA sync

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Synchronizing Configuration Files in a High Availability Setup

In a high availability setup, you can synchronize various configuration files from the primary node to the secondary node.

To perform the synchronization, you can use the command line interface or the configuration utility at either the primary or the secondary node. Files located on the secondary that are specific to the secondary (not present on the primary) are not deleted during the synchronization.

To synchronize files in a high availability setup by using the command line interface

At the command prompt, type:

sync HA files <mode>

Example

```
> sync HA files all
 Done
```

To synchronize files in a high availability setup by using the configuration utility

Navigate to System > Diagnostics and, in the Utilities group, click Start HA files synchronization.

Parameter Descriptions (of commands listed in the CLI procedure)

sync HA files

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Command Propagation

In an HA setup, any command issued on the primary node propagates automatically to, and is executed on, the secondary before it is executed on the primary. If command propagation fails, or if command execution fails on the secondary, the primary node executes the command and logs an error. Command propagation uses port 3010.

In an HA pair configuration, command propagation is enabled by default on both the primary and secondary nodes. You can enable or disable command propagation on either node in an HA pair. If you disable command propagation on the primary node, commands are not propagated to the secondary node. If you disable command propagation on the secondary node, commands propagated from the primary are not executed on the secondary node.

Note: After reenabling propagation, remember to force synchronization.

If synchronization occurs while you are disabling propagation, any configuration-related changes that you make before the disabling of propagation takes effect are synchronized with the secondary node. This is also true for cases where propagation is disabled while synchronization is in progress.

To disable or enable command propagation by using the command line interface

At the command prompt, type:

- set HA node -haProp DISABLED
- set HA node -haProp ENABLED

To disable or enable command propagation by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Clear or select the Primary node will propagate configuration to the Secondary option.

Parameter Descriptions (of commands listed in the CLI procedure)

set HA node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Fail-Safe Mode

In an HA configuration, fail-safe mode ensures that one node is always primary when both nodes fail the health check. This is to ensure that when a node is only partially available, backup methods are enabled to handle traffic as best as possible. The HA fail-safe mode is configured independently on each node.

The following table shows some of the fail-safe cases. The NOT_UP state means that the node failed the health check yet it is partially available. The UP state means that the node passed the health check.

Table 1. Fail-Safe Mode Cases

Node A (Primary) Health State	Node B (Secondary) Health State	Default HA Behavior	Fail-Safe Enabled HA Behavior	Description
NOT_UP(failed last)	NOT_UP (failed first)	A (Secondary), B (Secondary)	A (Primary), B (Secondary)	If both nodes fail, one after the other, the node that was the last primary remains primary.
NOT_UP (failed first)	NOT_UP(failed last)	A (Secondary), B (Secondary)	A(Secondary), B(Primary)	If both nodes fail, one after the other, the node that was the last primary remains primary.
UP	UP	A (Primary), B (Secondary)	A (Primary), B (Secondary)	If both nodes pass the health check, no change in behavior with fail-safe enabled.
UP	NOT_UP	A(Primary), B(Secondary)	A (Primary), B (Secondary)	If only the secondary node fails, no change in behavior with fail-safe enabled.
NOT_UP	UP	A(Secondary), B(Primary)	A(Secondary), B(Primary)	If only the primary fails, no change in behavior with fail-safe enabled.
NOT_UP	UP (STAYSECONDARY)	A (Secondary), B (Secondary)	A (Primary), B (Secondary)	If the secondary is configured as STAYSECONDARY, the primary remains primary even if it fails.

To enable fail-safe mode by using the command line interface

At the command prompt, type:

set HA node [-failSafe (**ON** | **OFF**)]

Example

set ha node -failsafe ON

To enable fail-safe mode by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Under Fail-Safe Mode, select the Maintain one Primary node even when both nodes are unhealthy option.

Parameter Descriptions (of commands listed in the CLI procedure)

set HA node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Virtual MAC Addresses

A Virtual MAC address (VMAC) is a floating entity shared by the primary and the secondary nodes in an HA setup.

In an HA setup, the primary node owns all of the floating IP addresses, such as the MIPs, SNIPs, and VIPs. The primary node responds to Address Resolution Protocol (ARP) requests for these IP addresses with its own MAC address. As a result, the ARP table of an external device (for example, an upstream router) is updated with the floating IP address and the primary node's MAC address.

When a failover occurs, the secondary node takes over as the new primary node. It then uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it acquired from the primary. However, the MAC address that the new primary advertises is the MAC address of its own interface.

Some devices (notably a few routers) do not accept the GARP messages generated by the NetScaler appliance. As a result, some external devices retain the old IP to MAC mapping advertised by the old primary node. This can result in a site going down.

You can overcome this problem by configuring a VMAC on both nodes of an HA pair. Both nodes then possess identical MAC addresses. Therefore, when failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

To create a VMAC, you need to first create a Virtual Router ID (VRID) and bind it to an interface. (In an HA setup, you need to bind the VRID to the interfaces on both nodes.) Once the VRID is bound to an interface, the system generates a VMAC with the VRID as the last octet.

Configuring IPv4 VMACs

When you create a IPv4 VMAC address and bind it to a interface, any IPv4 packet sent from the interface uses the VMAC address that is bound to the interface. If there is no IPv4 VMAC bound to an interface, the interface's physical MAC address is used.

The generic VMAC is of the form 00:00:5e:00:01:<VRID>. For example, if you create a VRID with a value of 60 and bind it to an interface, the resulting VMAC is 00:00:5e:00:01:3c, where 3c is the hex representation of the VRID. You can create 255 VRIDs with values from 1 to 255.

Creating or Modifying an IPv4 VMAC

You create an IPv4 virtual MAC by assigning it a virtual router ID. You can then you bind the VMAC to an interface. You cannot bind multiple VRIDs to the same interface. To verify the VMAC configuration, you should display and examine the VMACs and the interfaces bound to the VMACs.

To add a VMAC by using the command line interface

At the command prompt, type:

- add vrID <id>
- bind vrid <id> -ifnum <interface_name>
- show vrID

Example

```
> add vrID 100
 Done
> bind vrid 100 -ifnum 1/1 1/2 1/3
 Done
```

To unbind interfaces from a VMAC by using the command line interface

At the command prompt, type:

- unbind vrid <id> -ifnum <interface_name>
- show vrID

To configure a VMAC by using the configuration utility

Navigate to Network > VMAC and, on the VMAC tab, add a new VMAC, or edit an existing VMAC.

Parameter Descriptions (of commands listed in the CLI procedure)

add vrID

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind vrid

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show vrID

unbind vrid

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Removing an IPv4 VMAC

To remove an IPv4 virtual MAC, you delete its virtual router ID.

To remove an IPv4 VMAC by using the command line interface

At the command prompt, type:

rm vrid <id>

Example

rm vrid 100s

To remove an IPv4 VMAC by using the configuration utility

Navigate to Network > VMAC and, on the VMAC tab, delete the IPv4 VMAC.

Parameter Descriptions (of commands listed in the CLI procedure)

rm vrid

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring IPv6 VMAC6s

The NetScaler supports VMAC6 for IPv6 packets. You can bind any interface to a VMAC6, even if an IPv4 VMAC is bound to the interface. Any IPv6 packet sent from the interface uses the VMAC6 bound to that interface. If there is no VMAC6 bound to an interface, an IPv6 packet uses the physical MAC.

Creating or Modifying a VMAC6

You create an IPv6 virtual MAC by assigning it an IPv6 virtual router ID. You can then you bind the VMAC to an interface. You cannot bind multiple IPv6 VRIDs to an interface. To verify the VMAC6 configuration, you should display and examine the VMAC6s and the interfaces bound to the VMAC6s.

To add a VMAC6 by using the command line interface

At the command prompt, type:

- add vrID6 <id>
- bind vrID6 <id> -ifnum <interface_name>
- show vrID6

Example

```
> add vrID6 100
Done
> bind vrID6 100 -ifnum 1/1 1/2 1/3
 Done
```

To unbind interfaces from a VMAC6 by using the command line interface

At the command prompt, type:

- unbind vrID6 <id> -ifnum <interface_name>
- show vrID6

To configure a VMAC6 by using the configuration utility

Navigate to Network > VMAC and, on the VMAC6 tab, add a new VMAC6, or edit an existing VMAC6.

Parameter Descriptions (of commands listed in the CLI procedure)

add vrID6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind vrID6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

unbind vrID6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Removing a VMAC6

To remove an IPv4 virtual MAC, you delete its virtual router ID.

To remove a VMAC6 by using the command line interface

At the command prompt, type:

rm vrid6 <id>

Example

rm vrid6 100s

To remove a VMAC6 by using the configuration utility

Navigate to System > Network > VMAC and, on the VMAC6 tab, delete the virtual router ID.

Parameter Descriptions (of commands listed in the CLI procedure)

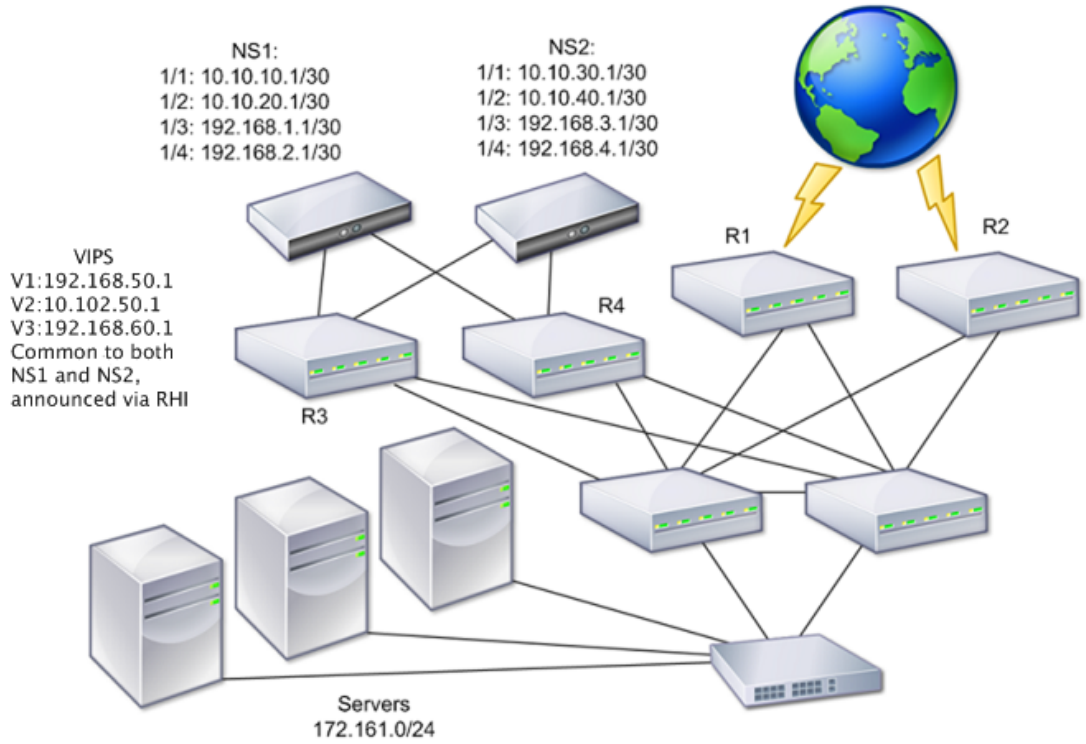
rm vrid6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring High Availability Nodes in Different Subnets

The following figure shows an HA deployment with the two systems located in different subnets:

Figure 1. High Availability over a Routed Network



In the figure, the systems NS1 and NS2 are connected to two separate routers, R3 and R4, on two different subnets. The NetScaler appliances exchange heartbeat packets through the routers. This configuration could be expanded to accommodate deployments involving any number of interfaces.

Note: If you use static routing on your network, you must add static routes between all the systems to ensure that heartbeat packets are sent and received successfully. (If you use dynamic routing on your systems, static routes are unnecessary.)

If the nodes in an HA pair reside on two separate networks, the primary and secondary node must have independent network configurations. This means that nodes on different networks cannot share entities such as MIPs, SNIPs, VLANs, and routes. This type of configuration, where the nodes in an HA pair have different configurable parameters, is known as Independent Network Configuration (INC) or Symmetric Network Configuration (SNC).

The following table summarizes the configurable entities and options for an INC, and shows how they must be set on each node.

Table 1. Behavior of NetScaler Entities and Options in an Independent Network Configuration

NetScaler entities	Options
IPs (NSIP/MIP/SNIPs)	Node-specific. Active only on that node.
VIPs	Floating.
VLANs	Node-specific. Active only on that node.
Routes	Node-specific. Active only on that node. Link load balancing routes are floating.
ACLs	Floating (Common). Active on both nodes.
Dynamic routing	Node-specific. Active only on that node. The secondary node should also run the routing protocols and peer with upstream routers.
L2 mode	Floating (Common). Active on both nodes.
L3 mode	Floating (Common). Active on both nodes.
Reverse NAT (RNAT)	Node-specific. RNAT with VIP, because NATIP is floating.

As in configuring HA nodes in the same subnet, to configure HA nodes in different subnets, you log on to each of the two NetScaler appliances and add a remote node representing the other appliance.

Adding a Remote Node

When two nodes of an HA pair reside on different subnets, each node must have a different network configuration. Therefore, to configure two independent systems to function as an HA pair, you must specify INC mode during the configuration process.

When you add an HA node, you must disable the HA monitor for each interface that is not connected or not being used for traffic. For CLI users, this is a separate procedure.

To add a node by using the command line interface

At the command prompt, type:

- add ha node <id> <IPAddress> -inc ENABLED
- show ha node

Example

```
> add ha node 3 10.102.29.170 -inc ENABLED
 Done
> add ha node 3 1000:0000:0000:0000:0005:0600:700a:888b
  Done
```

To disable an HA monitor by using the command line interface

At the command prompt, type:

- set interface <ifNum> [-haMonitor (**ON** | **OFF**)]
- show interface <ifNum>

Example

```
> set interface 1/3 -haMonitor OFF
 Done
```

To add a remote node by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, add a new remote node.
2. Make sure to select the Turn off HA monitor on interfaces/channels that are down and Turn on INC (Independent Network Configuration) mode on self mode options.

Parameter Descriptions (of commands listed in the CLI procedure)

add ha node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ha node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

set interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Removing a Node

If you remove a node, the nodes are no longer in high availability configuration.

To remove a node by using the command line interface

At the command prompt, type:

rm ha node <id>

Example

```
> rm ha node 2
  Done
```

To remove a node by using the configuration utility

Navigate to System > High Availability and, on the Nodes tab, delete the node.

Note: You can use the Network Visualizer to view the NetScaler appliances that are configured as a high availability (HA) pair and perform high availability configuration tasks. For more information, see " Using the Network Visualizer."

Parameter Descriptions (of commands listed in the CLI procedure)

rm ha node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Route Monitors

You can use route monitors to make the HA state dependent on the internal routing table, whether or not the table contains any dynamically learned or static routes. In an HA configuration, a route monitor on each node watches the internal routing table to make sure that a route entry for reaching a particular network is always present. If the route entry is not present, the state of the route monitor changes to DOWN.

When a NetScaler appliance has only static routes for reaching a network, and you want to create a route monitor for the network, you must enable monitored static routes (MSR) for the static routes. MSR removes unreachable static routes from the internal routing table. If MSR is disabled on static routes, an unreachable static route can remain in the internal routing table, defeating the purpose of having the route monitor.

Route Monitors are supported both in non-INC and INC mode.

Route Monitors in HA in non-INC mode	Route Monitors in HA in INC mode
Route monitors are propagated by nodes and exchanged during synchronization.	Route monitors are neither propagated by nodes nor exchanged during synchronization.
Route monitors are active only in the current primary node.	Route monitors are active on both the primary and the secondary node.
The NetScaler appliance always displays the state of a route monitor as UP irrespective of the whether the route entry is present or not in the internal routing table.	The NetScaler appliance displays the state of the route monitor as DOWN if the corresponding route entry is not present in the internal routing table.

A route monitor starts monitoring its route after 180 seconds in the following cases [This is done to allow dynamic routes to get learnt, which may take 180 secs]: · reboot · failover · set route6 command for v6 routes · set route msr enable/disable command for v4 routes. · adding a new route monitor	-

Route monitors are useful in a non-INC mode HA configuration where you want the non-reachability of a gateway from a primary node to be one of the conditions for HA failover.

Consider an example of a non-Inc mode HA setup in a two-arm topology that has NetScaler appliances NS1 and NS2 in the same subnet, with router R1 and switches SW1, SW2, and SW3.

Because R1 is the only router in this setup, you want the HA setup to failover whenever R1 is not reachable from the current primary node. You can configure a route monitor (say, RM1 and RM2, respectively) on each of the nodes to monitor the reachability of R1 from that node.

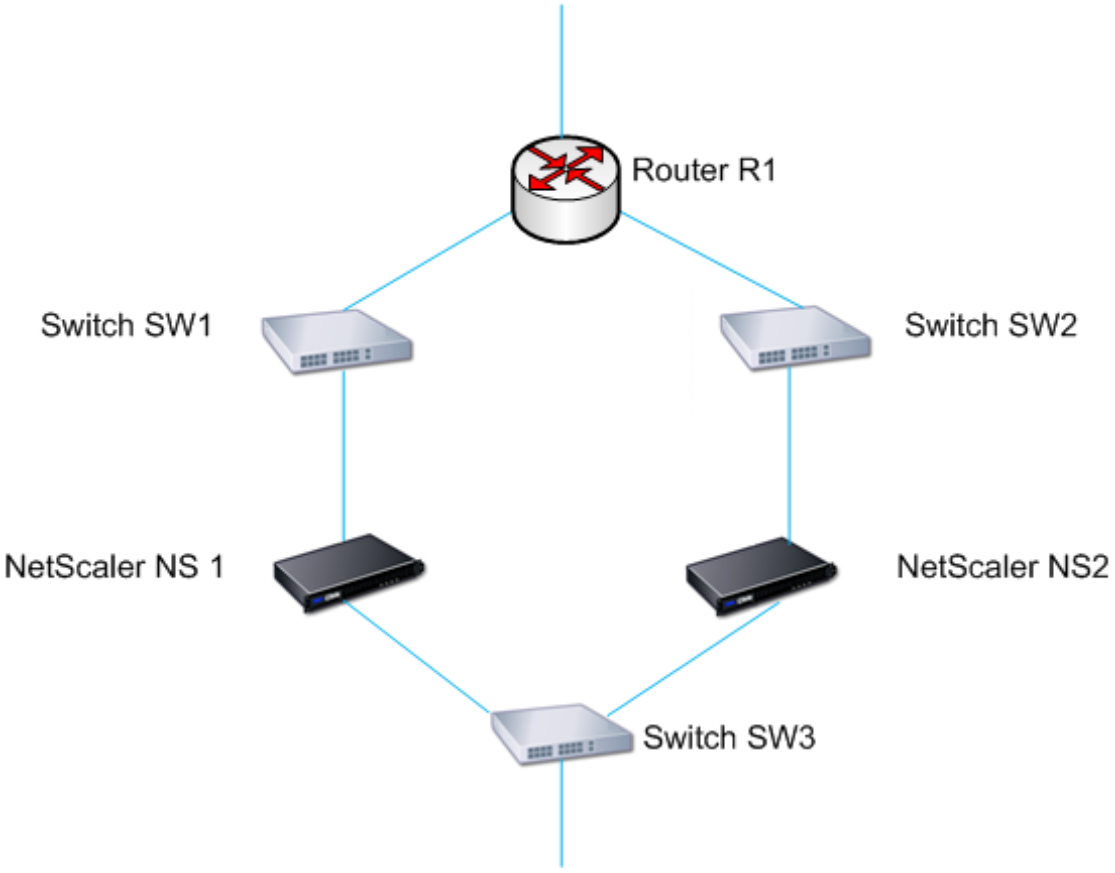


Figure 1.

With NS1 as the current primary node, the execution flow is as follows:

1. Route monitor RM1 on NS1 monitors NS1's internal routing table for the presence of a route entry for router R1. NS1 and NS2 exchange heartbeat messages through switch SW1 or SW3 at regular intervals.

2. If switch SW1 goes down, the routing protocol on NS1 detects that R1 is not reachable and therefore removes the route entry for R1 from the internal routing table. NS1 and NS2 exchanges heartbeat messages through switch SW3 at regular intervals.

3. Detecting that the route entry for R1 is not present in the internal routing table, RM1 initiates a failover. If route to R1 is down from both NS1 and NS2, failover happens every 180 seconds till one of the appliances is able to reach R1 and restore the connectivity.

Adding a Route Monitor to a High Availability Node

A single procedure creates a route monitor and binds it to an HA node.

To add a route monitor by using the command line interface

At the command prompt, type:

- bind HA node <id> (-routeMonitor <ip_addr|ipv6_addr> [<netmask>])
- show HA node

Example

```
> bind HA node 0 -routeMonitor 10.102.71.0 255.255.255.0
 Done
> bind HA node 0 -routeMonitor 1000:0000:0000:0000:0005:0600:700a:888b
 Done
```

To add a route monitor by using the configuration utility

Navigate to System > High Availability and, on the Route Monitors tab, click Configure.

Parameter Descriptions (of commands listed in the CLI procedure)

bind HA node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show HA node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Removing Route Monitors

To remove a route monitor by using the command line interface

At the command prompt, type:

- unbind HA node <id> (-routeMonitor <ip_addr|ipv6_addr> [<netmask>])
- show ha node

Example

unbind HA node 3 -routeMonitor 10.102.71.0 255.255.255.0
unbind HA node 3 -routeMonitor 1000:0000:0000:0000:0005:0600:700a:888b

To remove a route monitor by using the configuration utility

Navigate to System > High Availability and, on the Route Monitors tab, delete the route monitor.

Parameter Descriptions (of commands listed in the CLI procedure)

unbind HA node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ha node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Limiting Failovers Caused by Route Monitors in non-INC mode

In an HA configuration in non-INC mode, if route monitors fail on both nodes, failover happens every 180 seconds until one of the nodes is able to reach all of the routes monitored by the respective route monitors.

However, for a node, you can limit the number of failovers for a given interval by setting the Maximum Number of Flips and Maximum Flip Time parameters on the nodes. When either limit is reached, no more failovers occur, and the node is assigned as primary even if any route monitor fails on that node. If the node is then able to reach all of the monitored routes, the next monitor failure triggers resetting of the Maximum Number of Flips and Maximum Flip Time parameters on the node and starting the time specified in the Maximum Flip Time parameter.

These parameters are set independently on each node and therefore are neither propagated nor synchronized.

Note: This feature is supported only on NetScaler 9.3.e.

Parameters for limiting the number of failovers

Maximum Number of Flips (maxFlips)

Maximum number of failovers allowed, within the Maximum Flip Time interval, for the node in HA in non INC mode, if the failovers are caused by route-monitor failure.

Maximum Flip Time (maxFlipTime)

Amount of time, in seconds, during which failovers resulting from route-monitor failure are allowed for the node in HA in non INC mode.

To limit the number of failovers by using the command line interface

At the command prompt, type:

- `set HA node [-maxFlips < positive_integer>] [-maxFlipTime <positive_integer>]`
- `show HA node [< id>]`

Example

```
> set ha node -maxFlips 30 -maxFlipTime 60
 Done
> sh ha node
1) Node ID: 0
 IP: 10.102.169.82 (NS)
 Node State: UP
 Master State: Primary
 Fail-Safe Mode: OFF
```

```
 INC State: DISABLED
 Sync State: ENABLED
 Propagation: ENABLED
 Enabled Interfaces : 1/1
 Disabled Interfaces : None
 HA MON ON Interfaces : 1/1
 Interfaces on which heartbeats are not seen :None
 Interfaces causing Partial Failure:None
 SSL Card Status: NOT PRESENT
 Hello Interval: 200 msecs
 Dead Interval: 3 secs
 Node in this Master State for: 0:4:24:1
 (days:hrs:min:sec)
2) Node ID: 1
 IP: 10.102.169.81
 Node State: UP
 Master State: Secondary
 Fail-Safe Mode: OFF
 INC State: DISABLED
 Sync State: SUCCESS
 Propagation: ENABLED
 Enabled Interfaces : 1/1
 Disabled Interfaces : None
 HA MON ON Interfaces : 1/1
 Interfaces on which heartbeats are not seen : None
 Interfaces causing Partial Failure: None
 SSL Card Status: NOT PRESENT

Local node information:
 Configured/Completed Flips: 30/0
 Configured Flip Time: 60
 Critical Interfaces: 1/1

Done
```

To limit the number of failovers by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the local node.
2. Set the following parameters:
   - Maximum Number of Flips
   - Maximum Flip Time

Configuring FIS

Link redundancy is a way to prevent failover by grouping interfaces so that, when one interface fails, other functioning interfaces are still available. The link redundancy feature allows you to group the two interfaces into a failover interface set (FIS), which prevents the failure of a single link from causing failover to the secondary system unless all of the interfaces on the primary system are nonfunctional.

Each interface in an FIS maintains independent bridge entries. HA MON interfaces that are not bound to an FIS are known as critical interfaces (CI) because if any of them fails, failover is triggered.

Creating or Modifying an FIS

To add an FIS and bind interfaces to it by using the command line interface

At the command prompt, type:

- add fis <name>
- bind fis <name> <ifnum> ...
- show fis <name>

Example

```
> add fis fis1
 Done
> bind fis fis1 1/3 1/5
 Done
```

An unbound interface becomes a critical interface (CI) if it is enabled and HA MON is on.

To unbind an interface from an FIS by using the command line interface

At the command prompt, type:

- unbind fis <name> <ifnum> ...
- show fis <name>

Example

```
> unbind fis fis1 1/3
 Done
```

To configure an FIS by using the configuration utility

Navigate to System > High Availability and, on the Failover Interface Set tab, add a new FIS, or edit an existing FIS.

Parameter Descriptions (of commands listed in the CLI procedure)

add fis

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind fis

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show fis

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

unbind fis

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Removing an FIS

When the FIS is removed, its interfaces are marked as critical interfaces.

To remove an FIS by using the command line interface

At the command prompt, type:

rm fis <name>

Example

```
> rm fis fis1
  Done
```

To remove an FIS by using the configuration utility

Navigate to System > High Availability and, on the Failover Interface Set tab, delete the FIS.

Parameter Descriptions (of commands listed in the CLI procedure)

rm fis

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Understanding the Causes of Failover

The following events can cause failover in an HA configuration:

1. If the secondary node does not receive a heartbeat packet from the primary for a period of time that exceeds the dead interval set on the secondary. (See Note: 1.)
2. The primary node experiences a hardware failure of its SSL card.
3. The primary node does not receive any heartbeat packets on its network interfaces for three seconds.
4. On the primary node, a network interface that is not part of a Failover Interface Set (FIS) or a Link Aggregation (LA) channel and has the HA Monitor (HAMON) enabled, fails. (See Note: 2.)
5. On the primary node, all interfaces in an FIS fail. (See Note: 2.)
6. On the primary node, an LA channel with HAMON enabled fails. (See Note: 2.)
7. On the primary node, all interfaces fail (see Note: 2). In this case, failover occurs regardless of the HAMON configuration.
8. On the primary node, all interfaces are manually disabled. In this case, failover occurs regardless of the HAMON configuration.
9. You force a failover by issuing the force failover command on either node.
10. A route monitor that is bound to the primary node goes DOWN.

Note: 1. For more information about setting the dead interval, see Configuring the Communication Intervals. Possible causes for a node not receiving heartbeat packets from a peer node include:

- A network configuration problem prevents heartbeats from traversing the network between the HA nodes.
- The peer node experiences a hardware or software failure that causes it to freeze (hang), reboot, or otherwise stop processing and forwarding heartbeat packets.

Note: 2. In this case, fail means that the interface was enabled but goes to the DOWN state, as can be seen from the show interface command or from the configuration utility. Possible causes for an enabled interface to be in the DOWN state are LINK DOWN and TXSTALL.

Forcing a Node to Fail Over

You might want to force a failover if, for example, you need to replace or upgrade the primary node. You can force failover from either the primary or the secondary node. A forced failover is not propagated or synchronized. To view the synchronization status after a forced failover, you can view the status of the node.

A forced failover fails in any of the following circumstances:

- You force failover on a standalone system.
- The secondary node is disabled.
- The secondary node is configured to remain secondary.

The NetScaler appliance displays a warning message if it detects a potential issue when you run the force failover command. The message includes the information that triggered the warning, and requests confirmation before proceeding.

You can force a failover on a primary node, secondary node, and when nodes are in listen mode.

- **Forcing Failover on the Primary Node**.

  If you force failover on the primary node, the primary becomes the secondary and the secondary becomes the primary. Forced failover is possible only when the primary node can determine that the secondary node is UP.

  If the secondary node is DOWN, the force failover command returns the following error message: "Operation not possible due to invalid peer state. Rectify and retry."

  If the secondary system is in the claiming state or inactive, it returns the following error message: "Operation not possible now. Please wait for system to stabilize before retrying."

- **Forcing Failover on the Secondary Node**.

  If you run the force failover command from the secondary node, the secondary node becomes primary and the primary node becomes secondary. A force failover can occur only if the secondary node’s health is good and it is not configured to stay secondary.

  If the secondary node cannot become the primary node, or if secondary node was configured to stay secondary (using the STAYSECONDARY option), the node displays the following error message: "Operation not possible as my state is invalid. View the node for more information."

- **Forcing Failover When Nodes Are in Listen Mode**.

  When the two nodes of an HA pair are running different versions of the system software, the node running the higher version switches to the listen mode. In this mode, neither command propagation nor synchronization works.

Before upgrading the system software on both nodes, you should test the new version on one of the nodes. To do this, you need to force a failover on the system that has already been upgraded. The upgraded system then takes over as the primary node, but neither command propagation or synchronization occurs. Also, all connections need to be re-established.

To force failover on a node by using the command line interface

At the command prompt, type:

force HA failover

To force failover on a node by using the configuration utility

Navigate to System > High Availability and, on the Nodes tab, click Force Failover.

Parameter Descriptions (of commands listed in the CLI procedure)

force HA failover

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Forcing the Secondary Node to Stay Secondary

In an HA setup, the secondary node can be forced to stay secondary regardless of the state of the primary node.

For example, suppose the primary node needs to be upgraded and the process will take a few seconds. During the upgrade, the primary node may go down for a few seconds, but you do not want the secondary node to take over; you want it to remain the secondary node even if it detects a failure in the primary node.

When you force the secondary node to stay secondary, it will remain secondary even if the primary node goes down. Also, when you force the status of a node in an HA pair to stay secondary, it does not participate in HA state machine transitions. The status of the node is displayed as STAYSECONDARY.

Forcing the node to stay secondary works on both standalone and secondary nodes. On a standalone node, you must use this option before you can add a node to create an HA pair. When you add the new node, the existing node continues to function as the primary node, and the new node becomes the secondary node.

Note: When you force a system to remain secondary, the forcing process is not propagated or synchronized. It affects only the node on which you run the command.

To force the secondary node to stay secondary by using the command line interface

At the command prompt, type:

set ha node -hastatus STAYSECONDARY

To force the secondary node to stay secondary by using the configuration utility

Navigate to System > High Availability, on the Nodes tab, open the local node, and select STAY SECONDARY.

Parameter Descriptions (of commands listed in the CLI procedure)

set ha node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Forcing the Primary Node to Stay Primary

In an HA setup, you can force the primary node to remain primary even after a failover. You can enable this option either on a primary node in an HA pair or on a standalone system.

On a standalone system, you must run this command before you can add a node to create an HA pair. When you add the new node, it becomes the primary node. The existing node stops processing traffic and becomes the secondary node in the HA pair.

To force the primary node to stay primary by using the command line interface

At the command prompt, type:

set ha node -hastatus STAYPRIMARY

To force the primary node to stay primary by using the configuration utility

Navigate to System > High Availability, on the Nodes tab, open the local node, and select STAY PRIMARY.

Parameter Descriptions (of commands listed in the CLI procedure)

set ha node

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Understanding the High Availability Health Check Computation

The following table summarizes the factors examined in a health check computation:

- State of the CIs
- State of the FISs
- State of the route monitors

The following table summarizes the health check computation.

Table 1. High Availability Health Check Computation

FIS	CI	Route monitor	Condition
N	Y	N	If the system has any CIs, all of those CIs must be UP.
Y	Y	N	If the system has any FISs, all of those FISs must be UP.
Y	Y	Y	If the system has any route monitors configured, all monitored routes must be present in the FIS.

Troubleshooting High Availability Issues

Certain conditions can cause improper synchronization between nodes or incorrect configuration on the secondary node.

- **Improper synchronization of VLAN configuration in high availability systems**. In HA pairs, synchronization does not work properly if only one node has a VLAN configured. To prevent this problem, configure your VLANs after you configure your appliances as an HA pair, and be sure to configure them both.

- **Retrieving a lost configuration**. If the primary node is unable to send the configuration to the secondary node due to a network error, the secondary node may not have an accurate configuration and may not behave correctly if a failover occurs. If this happens, you can retrieve the current configuration from the configuration backup on the hard disk of the primary appliance. The operating system saves the last four copies of the ns.conf file in the /nsconfig directory as ns.conf.0, ns.conf.1, ns.conf.2, and ns.conf.3. The ns.conf.0 file contains the current configuration.

To retrieve the current system configuration

1. Exit the CLI to FreeBSD by typing the following command and pressing the Enter key:

   > shell

   The FreeBSD shell prompt appears, as shown below.

   #

2. Copy the latest backup file to /nsconfig/ns.conf by using the following command:

   ```
   # cp ‘ls -t /nsconfig/ns.conf.? | head -1` /nsconfig/ns.conf
   ```

If you perform a configuration using the NSConfig utility, it is not propagated. If you create a configuration using NSconfig, you must repeat the configuration steps separately for each node in an HA pair.

High Availability

What are the various ports used to exchange the HA-related information between the nodes in an HA configuration?

In an HA configuration, both nodes use the following ports to exchange HA related information:

- UDP Port 3003, to exchange heartbeat packets.
- Port 3010, for synchronization and command propagation.

What are the conditions that trigger synchronization?

Synchronization is triggered by any of the following conditions:

- The incarnation number of the primary node, received by the secondary, does not match that of the secondary node.

  Note: Both nodes in an HA configuration maintain a counter called *incarnation number*, which counts the number of configurations in the node's configuration file. Each node sends its incarnation number to each other node in the heartbeat messages. The incarnation number is not incremented for the following commands:

  1. All HA configuration related commands. For example, add ha node, set ha node, and bind ha node.
  2. All Interface related commands. For example, set interface and unset interface.
  3. All channel-related commands. For example, add channel, set channel, and bind channel.
- The secondary node comes up after a restart.
- The primary node becomes secondary after a failover.

What configurations are not synced or propagated in an HA configuration in INC or non-INC mode?

The following commands are neither propagated nor synced to the secondary node:

- All node specific HA configuration commands. For example, add ha node, set ha node, and bind ha node.
- All Interface related configuration commands. For example, set interface and unset interface.
- All channel related configuration commands. For example, add channel, set channel, and bind channel.

What configurations are not synced nor propagated in an HA configuration in INC mode?

The following configurations are not synced or propagated. Each node has its own.

- MIPs

- SNIPs
- VLANs
- Routes (except LLB routes)
- Route monitors
- RNAT rules (except any RNAT rule with VIP as the NAT IP)
- Dynamic routing configurations.

Does a configuration added to the secondary node get synchronized on the primary?

No, a configuration added to the secondary node is not synchronized to the primary.

What could be the reason for both nodes claiming to be the primary in an HA configuration?

The most likely reason is that the primary and secondary nodes are both healthy but the secondary does not receive the heartbeat packets from the primary. The problem could be with the network between the nodes.

Does an HA configuration run into any issues if you deploy the two nodes with different system clock settings?

Different system-clock settings on the two nodes can cause the following issues:

- The time stamps in the log file entries do not match. This situation makes it difficult to analyze the log entries for any issues.
- After a failover, you might have problems with any type of cookie based persistence for load balancing. A significant difference between the times can cause a cookie to expire sooner than expected, resulting in termination of the persistence session.
- Similar considerations apply to any time related decisions on the nodes.

What are the conditions for failure of the *force HA sync* command?

Forced synchronization fails in any of the following circumstances:

- You force synchronization when synchronization is already in progress.
- You force synchronization on a standalone NetScaler appliance.
- The secondary node is disabled.
- HA synchronization is disabled on the current secondary node.
- HA propagation is disabled on the current primary node and you force synchronization from the primary.

What are the conditions for failure of the *sync HA files* command?

Synchronizing configuration files fail in either of the following circumstances:

- On a standalone system.

- With the secondary node disabled.

In an HA configuration, if the secondary node takes over as the primary, does it switch back to secondary status if the original primary comes back online?

No. After the secondary node takes over as the primary, it remains as primary even if the original primary node comes back online again. To interchange the primary and secondary status of the nodes, run the *force failover* command.

What are the conditions for failure of the *force failover* command?

A forced failover fails in any of the following circumstances:

- You force failover on a standalone system.
- The secondary node is disabled.
- The secondary node is configured to remain secondary.
- The primary node is configured to remain primary.
- The state of the peer node is unknown.

Networking

The following topics provide a conceptual reference and instructions for configuring the various networking components on the NetScaler appliance.

IP Addressing	Learn the various types of NetScaler-owned IP addresses and how to create, customize, and remove them.
Interfaces	Configure some of the basic network configurations that must be done to get started.
Access Control Lists (ACLs)	Configure the different types of Access Control Lists and how to create, customize, and remove them.
IP Routing	Learn and configure the routing functionality of the NetScaler appliance, both static and dynamic.
Internet Protocol version 6 (IPv6)	Learn how the NetScaler appliance supports IPv6.
Traffic Domains	Learn and configure traffic domains to segment network traffic for different applications.

IP Addressing

Before you can configure the NetScaler appliance, you must assign the NetScaler IP Address (NSIP), also known as the Management IP address. You can also create other NetScaler-owned IP addresses for abstracting servers and establishing connections with the servers. In this type of configuration, the appliance serves as a proxy for the abstracted servers. You can also proxy connections by using network address translations (INAT and RNAT). When proxying connections, the appliance can behave either as a bridging (Layer 2) device or as a packet forwarding (Layer 3) device. To make packet forwarding more efficient, you can configure static ARP entries. For IPv6, you can configure neighbor discovery (ND).

Configuring NetScaler-Owned IP Addresses

The NetScaler-owned IP Addresses—NetScaler IP Address (NSIP), Virtual IP Addresses (VIPs), Subnet IP Addresses (SNIPs), Mapped IP Addresses (MIPs), and Global Server Load Balancing Site IP Addresses (GSLBIPs)—exist only on the NetScaler appliance. The NSIP uniquely identifies the NetScaler on your network, and it provides access to the appliance. A VIP is a public IP address to which a client sends requests. The NetScaler terminates the client connection at the VIP and initiates a connection with a server. This new connection uses a SNIP or a MIP as the source IP address for packets forwarded to the server. If you have multiple data centers that are geographically distributed, each data center can be identified by a unique GSLBIP.

You can configure some NetScaler-owned IP addresses to provide access for management applications.

Configuring the NetScaler IP Address (NSIP)

The NetScaler IP (NSIP) address is the IP address at which you access the NetScaler for management purposes. The NetScaler can have only one NSIP, which is also called the Management IP address. You must add this IP address when you configure the NetScaler for the first time. If you modify this address, you must reboot the NetScaler. You cannot remove an NSIP address. For security reasons, NSIP should be a non-routable IP address on your organization's LAN.

Note: Configuring the NetScaler IP address is mandatory.

To create the NetScaler IP address by using the command line interface

At the command prompt, type:

- set ns config [-IPAddress <ip_addr> -netmask <netmask>]
- show ns config

Example

```
> set ns config -ipaddress 10.102.29.170 -netmask 255.255.255.0
 Done
```

To configure the NetScaler IP address by using the configuration utility

1. In the navigation pane, click System.
2. On the System Information tab, click Setup Wizard.
3. In the Setup Wizard dialog box, click Next.
4. Under System Configuration, set the following parameters:
   - IP Address
   - Netmask
5. Follow the instructions in the Setup Wizard to complete the configuration.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns config

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns config

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring and Managing Virtual IP (VIP) Addresses

Configuration of a virtual server IP (VIP) address is not mandatory during initial configuration of the NetScaler ADC. When you configure load balancing, you assign VIP addresses to virtual servers.

For more information about configuring a load balancing setup, see "Load Balancing."

In some situations, you need to customize VIP attributes or enable or disable a VIP address. A VIP address is usually associated with a virtual server, and some of the VIP attributes are customized to meet the requirements of the virtual server. You can host the same virtual server on multiple NetScaler appliances residing on the same broadcast domain, by using ARP and ICMP attributes. After you add a VIP (or any IP address), the NetScaler sends, and then responds to, ARP requests. VIPs are the only NetScaler-owned IP addresses that can be disabled. When a VIP address is disabled, the virtual server using it goes down and does not respond to ARP, ICMP, or L4 service requests.

As an alternative to creating VIP addresses one at a time, you can specify a consecutive range of VIP addresses.

To create a VIP address by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.59 255.255.255.0 -type VIP
 Done
```

To create a range of VIP addresses by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>

- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.[60-64] 255.255.255.0 -type VIP
ip "10.102.29.60" added
ip "10.102.29.61" added
ip "10.102.29.62" added
ip "10.102.29.63" added
ip "10.102.29.64" added
 Done
```

Parameters for configuring VIP addresses

ipAddress (IP Address)

Unique identification used to represent an entity. This is a required parameter.

netmask (Netmask)

Subnet mask associated with the IP address. This is a required parameter.

type (Type)

Type of the IP address. Specify **VIP**.

arp (ARP)

Use Address Resolution Protocol (ARP) to map IP addresses to the corresponding hardware addresses. Possible values: Enabled, Disabled. Default: Enabled.

icmpresponse (ICMP Response)

NetScaler sends ICMP responses to PING requests according to this value. The user network applications that use ICMP are PING and TRACEROUTE. This parameter can be set only if type is set as VIP. Possible values: NONE, ONE_VSERVER, ALL_VSERVERS, and VSVR_CNTRLD. Default value: NONE.

- When you select NONE, NetScaler always responds (even when the virtual server is DOWN).
- When you select ONE_VSERVER, NetScaler responds if at least one virtual server on this IP address is UP.
- When you select ALL_VSERVERS, NetScaler responds only if all the virtual servers on this IP address are UP.
- When you select VSVR_CNTRLD, the behavior depends on the ICMP VSERVER RESPONSE setting on the virtual server.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, NetScaler responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds even if one virtual server set to ACTIVE is UP.

arpresponse (ARP Response)

NetScaler appliance sends ARP responses according to this value. This parameter can be set only if type is set as VIP. Possible values: NONE, ONE_VSERVER. Default value: NONE.

- When you select NONE, NetScaler always responds (even when the virtual server is DOWN).
- When you select ONE_VSERVER, NetScaler responds if at least one virtual server on this IP address is UP.
- When you select ALL_VSERVERS, NetScaler responds only if all the virtual servers on this IP address are UP.

vServer (Virtual Server)

Apply the vserver attribute to this IP address. Possible values: Enabled, Disabled. Default: Enabled.

state (State)

State of the VIP. Possible values: Enabled, Disabled. Default: Enabled.

To configure a VIP address by using the configuration utility

Navigate to Network > IPs > IPV4s, and add a new IP address or edit an existing address.

To create a range of VIP addresses by using the configuration utility

1. Navigate to Network > IPs > IPV4s.
2. Click Add Range.

To enable or disable an IPv4 VIP address by using the command line interface

At the command prompt, type one of the following sets of commands to enable or disable a VIP and verify the configuration:

- enable ns ip <IPAddress>
- show ns ip <IPAddress>
- disable ns ip <IPAddress>
- show ns ip <IPAddress>

Example

```
> enable ns ip 10.102.29.79
 Done
> show ns ip 10.102.29.79

        IP: 10.102.29.79
        Netmask: 255.255.255.255
        Type: VIP
        state: Enabled
        arp: Enabled
        icmp: Enabled
        vserver: Enabled
        management access: Disabled
          telnet: Disabled
          ftp: Disabled
          ssh: Disabled
          gui: Disabled
          snmp: Disabled
        Restrict access: Disabled
        dynamic routing: Disabled
        hostroute: Disabled
 Done
> disable ns ip 10.102.29.79
 Done
> show ns ip 10.102.29.79

        IP: 10.102.29.79
        Netmask: 255.255.255.255
        Type: VIP
        state: Disabled
        arp: Enabled
        icmp: Enabled
        vserver: Enabled
        management access: Disabled
          telnet: Disabled
          ftp: Disabled
          ssh: Disabled
          gui: Disabled
          snmp: Disabled
        Restrict access: Disabled
        dynamic routing: Disabled
        hostroute: Disabled

 Done
```

To enable or disable a VIP address by using the configuration utility

1. Navigate to Network > IPs > IPV4s.
2. Select the VIP address, and click Enable or Disable.

Configuring ARP response Suppression for Virtual IP addresses (VIPs)

You can configure the NetScaler appliance to respond or not respond to ARP requests for a Virtual IP (VIP) address on the basis of the state of the virtual servers associated with that VIP.

For example, if virtual servers V1, of type HTTP, and V2, of type HTTPs, share VIP address 10.102.29.45 on a NetScaler appliance, you can configure the appliance to not respond to any ARP request for VIP 10.102.29.45 if both V1 and V2 are in the DOWN state.

The following three options are available for configuring ARP-response suppression for a virtual IP address.

- **NONE**. The NetScaler appliance responds to any ARP request for the VIP address, irrespective of the state of the virtual servers associated with the address.
- **ONE VSERVER**. The NetScaler appliance responds to any ARP request for the VIP address if at least one of the associated virtual servers is in UP state.
- **ALL VSERVER**. The NetScaler appliance responds to any ARP request for the VIP address if all of the associated virtual servers are in UP state.

Following table shows the sample behavior of NetScaler appliance for a VIP configured with two virtual servers:

Associated virtual servers for a VIP	**STATE 1**	**STATE 2**	**STATE 3**	**STATE 4**
NONE				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	Yes	Yes	Yes
ONE VSERVER				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	Yes	Yes	No
ALL VSERVER				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN

Respond to an ARP request for this VIP?	Yes	No	No	No

Consider an example where you want to test the performance of two virtual servers, V1 and V2, which have the same VIP address but are of different types and are each configured on NetScaler appliances NS1 and NS2. Let's call the shared VIP address *VIP1*.

V1 load balances servers S1, S2, and S3. V2 load balances servers S4 and S5.

On both NS1 and NS2, for VIP1, the ARP suppression parameter is set to ALL_VSERVER. If you want to test the performance of V1 and V2 on NS1, you must manually disable V1 and V2 on NS2, so that NS2 does not respond to any ARP request for VIP1.

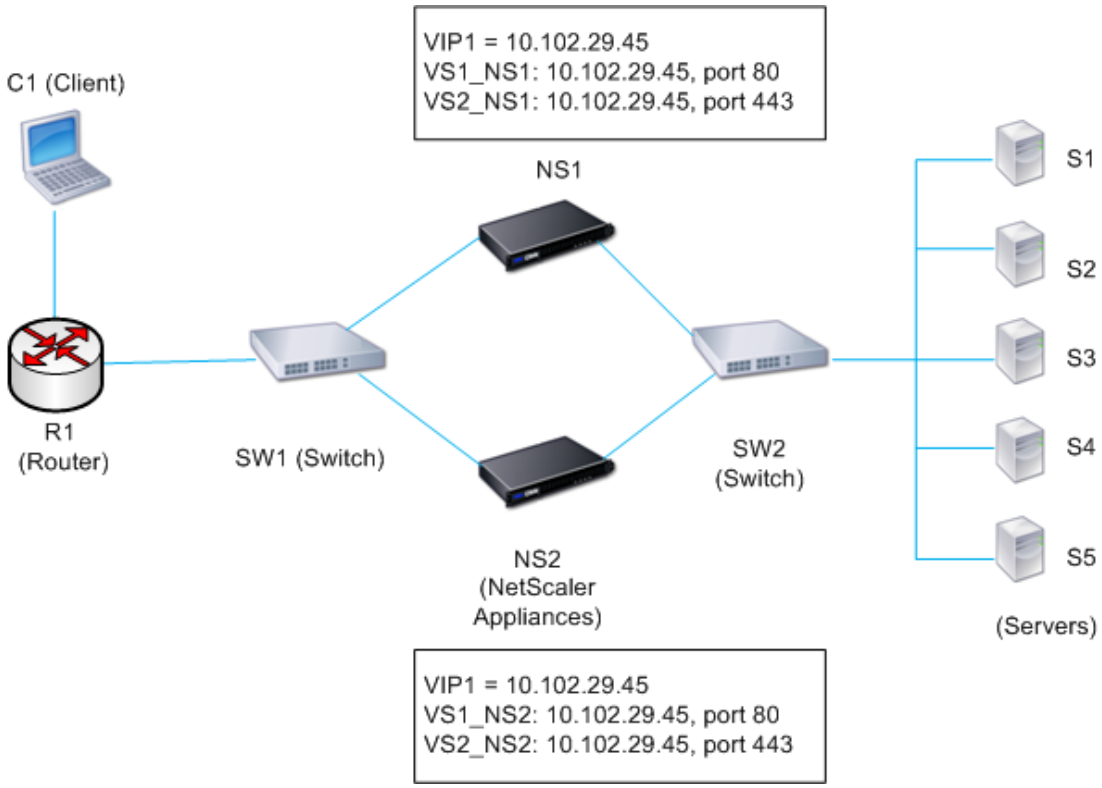

Figure 1.

The execution flow is as follows:

1. Client C1 sends a request to V1. The request reaches R1.
2. R1 does not have an APR entry for the IP address (VIP1) of V1, so R1 broadcasts an ARP request for VIP1.
3. NS1 replies with source MAC address MAC1 and source IP address VIP1. NS2 does not reply to the ARP request.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table, and R1 updates the ARP entry with MAC1 and VIP1.
5. R1 forwards the packet to address VIP1 on NS1.

6. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP or MIP addresses and S2. When S2 sends a response to the client, the response returns by the same path.

7. Now you want to test the performance of V1 and V2 on NS2, so you enable V1 and V2 on NS2 and disable them on NS1. NS2 now broadcasts an ARP message for VIP1. In the message, MAC2 is the source MAC address and VIP1 is the source IP address.

8. SW1 learns the port number for reaching MAC2 from the ARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS2. R1 updates its ARP table.

9. Now suppose the ARP entry for VIP1 times out in the ARP table of R1, and client C1 sends a request for V1. Because R1 does not have an APR entry for VIP1, it broadcasts an ARP request for VIP1.

10. NS2 replies with a source MAC address and VIP1 as the source IP address. NS1 does not reply to the ARP request.

To configure ARP response suppression by using the command line interface

At the command prompt, type:

- set ns ip -arpResponse <arpResponse>]
- show ns ip <IPAddress>

Example

```
> set ns ip 10.102.29.96 -arpResponse ALL_VSERVERS
 Done
```

To configure ARP response suppression by using the configuration utility

1. Navigate to Network > IPs > IPV4s.

2. Open an IP address entry and select the type of ARP Response.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns ip

Configuring Subnet IP Addresses (SNIPs)

A subnet IP address (SNIP) is a NetScaler owned IP address that is used by the NetScaler ADC to communicate with the servers.

The NetScaler ADC uses the subnet IP address as a source IP address to proxy client connections to servers. It also uses the subnet IP address when generating its own packets, such as packets related to dynamic routing protocols, or to send monitor probes to check the health of the servers.

Depending on your network topology, you might have to configure one or more SNIPs for different scenarios. Following are three typical scenarios in which you have to configure SNIPs:

- Using SNIPs for a Directly Connected Server Subnet
- Using SNIPs for Server Subnets Connected through a Router
- Using SNIPs for Multiple Server Subnets (VLANs) on an L2 Switch

To configure a SNIP address on a NetScaler ADC, you add the SNIP address and then enable global Use Subnet IP (USNIP) mode.

As an alternative to creating SNIPs one at a time, you can specify a consecutive range of SNIPs.

To configure a SNIP address by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.203 255.255.255.0 -type SNIP
 Done
```

To create a range of SNIP addresses by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.[205-209] 255.255.255.0 -type SNIP
ip "10.102.29.205" added
ip "10.102.29.206" added
ip "10.102.29.207" added
ip "10.102.29.208" added
ip "10.102.29.209" added
 Done
```

To enable or disable USNIP mode by using the command line interface

At the command prompt, type one of the following commands:

- enable ns modeUSNIP
- disable ns modeUSNIP

To configure a SNIP address by using the configuration utility

Navigate to Network > IPs > IPV4s, and add a new SNIP address or edit an existing address.

To create a range of SNIP addresses by using the configuration utility

1. Navigate to Network > IPs > IPV4s.
2. Click Add Range.

To enable or disable USNIP mode by using the command line interface

At the command prompt, type one of the following commands:

- enable ns mode `USNIP`
- disable ns mode `USNIP`

To enable or disable USNIP mode by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change modes.
2. Select or clear the Use Subnet IP option.

disable ns mode

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Using SNIPs for a Directly Connected Server Subnet

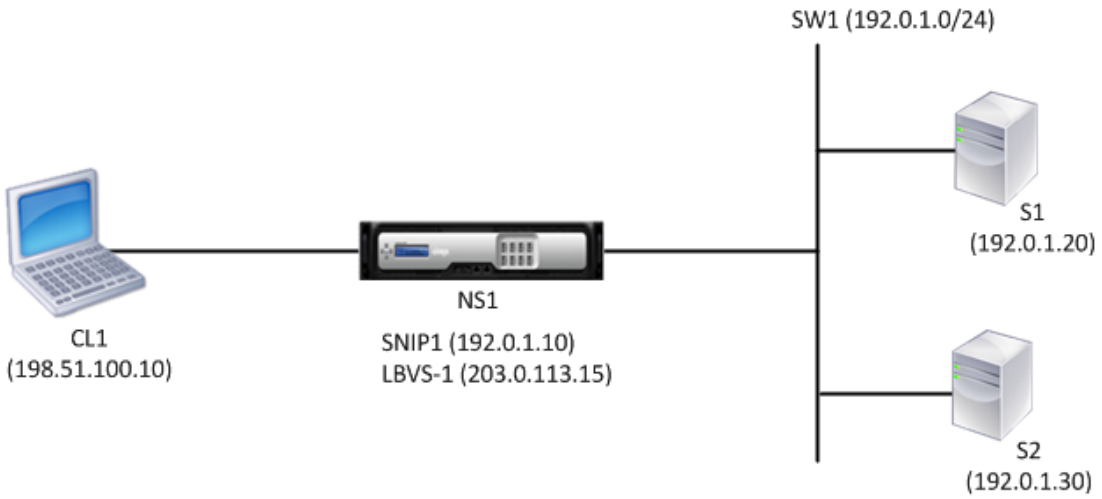
To enable communication between the NetScaler and a server that is either connected directly to the NetScaler or connected through only an L2 switch, you must configure a subnet IP address that belongs to the subnet of the server. You must configure at least one subnet IP address for each directly connected subnet, except for the directly connected management subnet that is connected through NSIP.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on NetScaler ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to the same subnet.

SNIP address SNIP1, which belongs to the same subnet as S1 and S2, is configured on NS1. As soon as SNIP1 is configured, NS1 broadcasts ARP packets for SNIP1.

Services SVC-S1 and SVC-S2 on NS1 represent S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for S1 and S2 to resolve IP-to-MAC mapping. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about configuring load balancing on a NetScaler ADC, see Load Balancing.



Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
    - Source IP = IP address of the client (198.51.100.10)
    - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.

3. LBVS1's load balancing algorithm selects server S2.

4. Because S2 is directly connected to NS1, and SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP1 and S2.

5. NS1 sends the request packet to S2 from SNIP1. The request packet has:

   - Source IP = SNIP1 (192.0.1.10)

   - Destination IP = IP address of S2 (192.0.1.30)
6. S2’s response returns by the same path.

Using SNIPs for Server Subnets Connected through a Router

To enable communication between the NetScaler ADC and servers in subnets connected through a router, you must configure at least one subnet IP address that belongs to the subnet of the directly connected interface to the router. The ADC uses this subnet IP address to communicate with servers in subnets that can be reached through the router.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on NetScaler ADC NS1 is used to load balance servers S1, S2, S3, and S4, which are connected to NS1 through router R1.

S1 and S2 belong to same subnet, 192.0.2.0/24, and are connected to R1 through L2 switch SW1. S3 and S4 belong to a different subnet, 192.0.3.0/24, and are connected to R1 through L2 switch SW2.

NetScaler ADC NS1 is connected to router R1 through subnet 192.0.1.0/24. SNIP address SNIP1, which belongs to the same subnet as the directly connected interface to the router (192.0.1.0/24), is configured on NS1. NS1 uses this address to communicate with servers S1 and S2, and with servers S3 and S4.

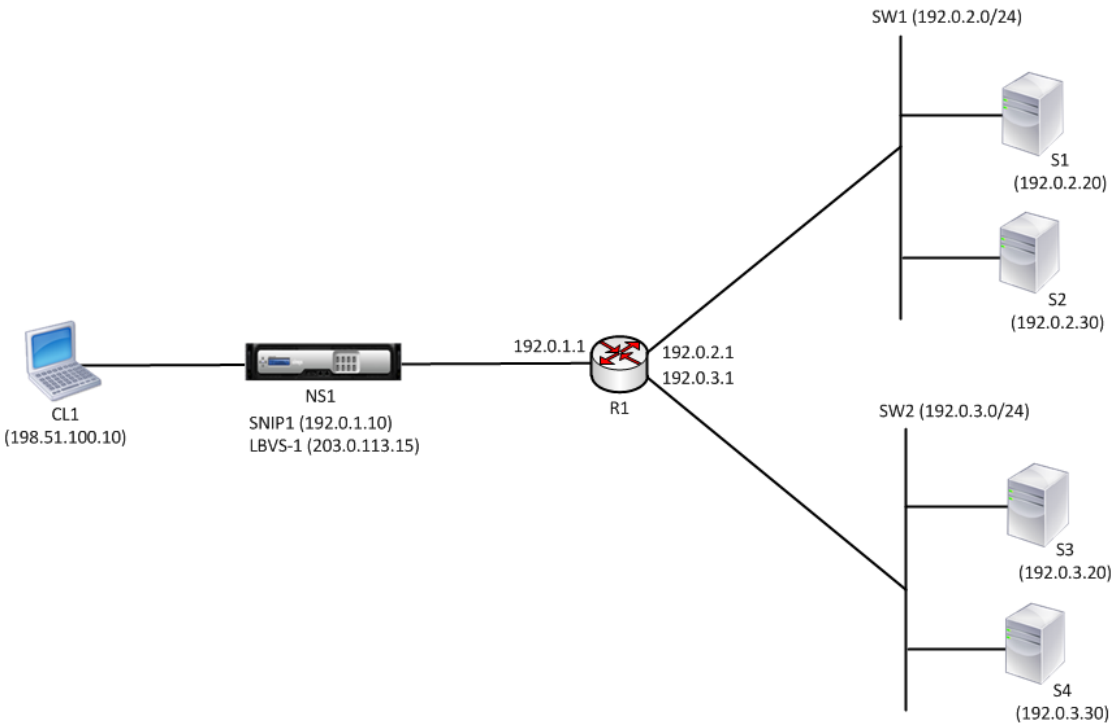
For more information about configuring load balancing on a NetScaler ADC, see Load Balancing.

As soon as address SNIP1 is configured, NS1 broadcasts ARP announcement packets for SNIP1.

NS1's routing table consists of route entries for S1, S2, S3, and S4 through R1. These route entries are either static route entries or advertised by R1 to NS1, using dynamic routing protocols.

Services SVC-S1, SVC-S2, SVC-S3, and SVC-S4 on NS1 represent servers S1, S2, S3, and S4. NS1 finds, in its routing tables, that these servers are reachable through R1. NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about IP routing on a NetScaler ADC, see IP Routing.



Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   - Source IP = IP address of the client (198.51.100.10)
   - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S3.
4. NS1 checks its routing table and finds that S3 is reachable through R1. SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as router R1, NS1 opens a connection between SNIP1 and S3 through R1.
5. NS1 sends the request packet to R1 from SNIP1. The request packet has:
   - Source IP address = SNIP1 (192.0.1.10)
   - Destination IP address = IP address of S3 (192.0.3.20)
6. The request reaches R1, which checks its routing table and forwards the request packet to S3.
7. S3’s response returns by the same path.

Using SNIPs for Multiple Server Subnets (VLANs) on an L2 Switch

When you have multiple server subnets (VLANs) on an L2 switch that is connected to a NetScaler ADC, you must configure at least one SNIP address for each of the server subnets, so that the NetScaler ADC can communicate with these server subnets.

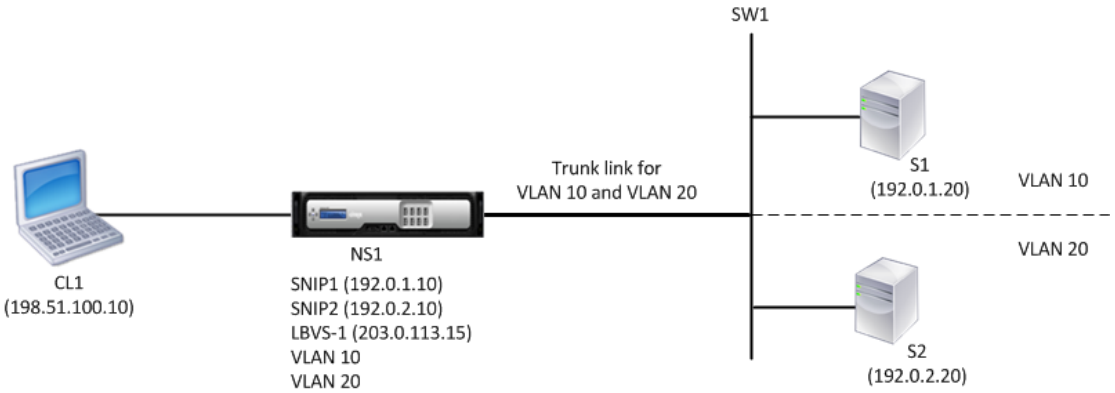
Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on NetScaler ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to different subnets and are part of VLAN 10 and VLAN20, respectively. The link between NS1 and SW1 is a trunk link and is shared by VLAN10 and VLAN20.

For more information about configuring load balancing on a NetScaler ADC, see Load Balancing.

Subnet IP addresses SNIP1 (for reference purposes only) and SNIP2 (for reference purposes only) are configured on NS1. NS1 uses SNIP1 (on VLAN 10) to communicate with server S1, and SNIP2 (on VLAN 20) to communicate with S2. As soon as SNIP1 and SNIP2 are configured, NS1 broadcasts ARP announcement packets for SNIP1 and SNIP2.

For more information about configuring VLANs on a NetScaler ADC, see Configuring VLANs.

Services SVC-S1 and SVC-S2 on NS1 represent servers S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for them. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals to check their health. NS1 sends monitoring probes to S1 from address SNIP1, and to S2 from address SNIP2.



Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
    - Source IP = IP address of the client (198.51.100.10)
    - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.

3. LBVS1's load balancing algorithm selects server S2.

4. Because S2 is directly connected to NS1, and SNIP2 (192.0.2.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP2 and S2.

   Note: If S1 is selected, NS1 opens a connection between SNIP1 and S1.

5. NS1 sends the request packet to S2 from SNIP2. The request packet has:

   - Source IP = SNIP1 (192.0.2.10)

   - Destination IP = IP address of S2 (192.0.2.20)
6. S2’s response returns by the same path.

Configuring Mapped IP Addresses (MIPs)

Mapped IP addresses (MIP) are used for server-side connections. A MIP can be considered a default Subnet IP (SNIP) address, because MIPs are used when a SNIP is not available or Use SNIP (USNIP) mode is disabled.

If the mapped IP address is the first in the subnet, the NetScaler appliance adds a route entry, with this IP address as the gateway to reach the subnet. You can create or delete a MIP during run time without rebooting the appliance.

As an alternative to creating MIPs one at a time, you can specify a consecutive range of MIPs.

The following diagram shows the use of the MIP and SNIP addresses in a NetScaler appliance that connects to the backend servers across the subnets.

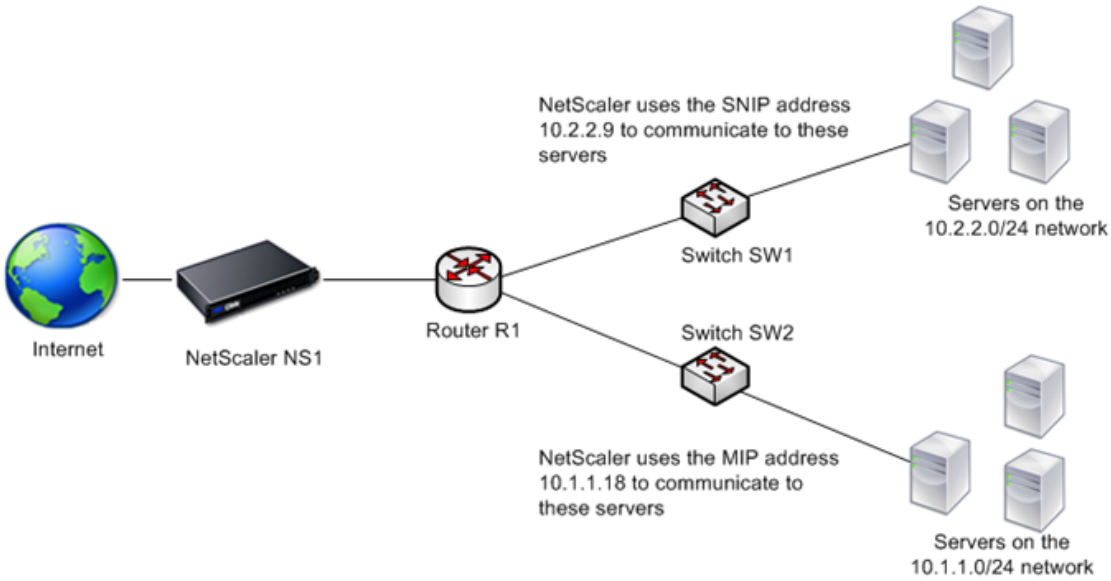


Figure 1. MIP and SNIP addresses

In the setup, if the NetScaler appliance and the backend servers are in the 10.1.1.0/24 subnet, then the appliance uses the MIP address to communicate to the servers. However, if the setup has backend servers on additional subnets, such as 10.2.2.0/24, and there is no router between the NetScaler appliance and the subnet, then you can configure a SNIP address that has a range of 10.2.2.x/24, such as 10.2.2.9 in this case, to communicate to the additional subnet.

You can enable to NetScaler appliance to use MIP to communicate the additional subnet. However, if the setup has a Firewall application between the appliance and the server, then the Firewall might prevent the traffic other than 10.2.2.0/24. In such cases, you need a SNIP address to communicate to the servers.

To create a MIP address by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.171 255.255.255.0 -type MIP
 Done
```

To create a range of MIP addresses by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.[173-175] 255.255.255.0 -type MIP
ip "10.102.29.173" added
ip "10.102.29.174" added
ip "10.102.29.175" added
Done
```

To configure a MIP address by using the configuration utility

Navigate to Network > IPs > IPV4s, and add a new MIP address or edit an existing address.

To create a range of MIP addresses by using the configuration utility

1. Navigate to Network > IPs > IPV4s.
2. Click Add Range.

Parameter Descriptions (of commands listed in the CLI procedure)

add ns ip

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns ip

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring GSLB Site IP Addresses (GSLBIP)

A GSLB site IP (GSLBIP) address is an IP address associated with a GSLB site. It is not mandatory to specify a GSLBIP address when you initially configure the NetScaler appliance. A GSLBIP address is used only when you create a GSLB site.

For more information about creating a GSLB site IP address, see "Global Server Load Balancing."

Removing a NetScaler-Owned IP Address

You can remove any IP address except the NSIP. The following table provides information about the processes you must follow to remove the various types of IP addresses. Before removing a VIP, remove the associated virtual server.

Table 1. Implications of Removing a NetScaler-Owned IP Address

IP address type	Implications
Subnet IP address (SNIP)	If IP address being removed is the last IP address in the subnet, the associated route is deleted from the route table. If the IP address being removed is the gateway in the corresponding route entry, the gateway for that subnet route is changed to another NetScaler-owned IP address.
Mapped IP address (MIP)	If a SNIP exists, you can remove the MIPs. The NetScaler uses NSIP and SNIPs to communicate with the servers when the MIP is removed. Therefore, you must also enable use SNIP (USNIP) mode. For information about enabling and disabling USNIP mode, see "Configuring Subnet IP Addresses (SNIPs)."
Virtual Server IP address (VIP)	Before removing a VIP, you must first remove the vserver associated with it. For information about removing the vserver, see "Load Balancing."
GSLB-Site-IP address	Before removing a GSLB site IP address, you must remove the site associated with it. For information about removing the site, see "Global Server Load Balancing."

To remove an IP address by using the command line interface

At the command prompt, type:

rm ns ip <IPaddress>

Example

```
rm ns ip 10.102.29.54
```

To remove an IP address by using the configuration utility

Navigate to Network > IPs > IPV4s, delete the IP address.

Configuring Application Access Controls

Application access controls, also known as management access controls, form a unified mechanism for managing user authentication and implementing rules that determine user access to applications and data. You can configure MIPs and SNIPs to provide access for management applications. Management access for the NSIP is enabled by default and cannot be disabled. You can, however, control it by using ACLs.

For information about using ACLs, see "Access Control Lists (ACLs)."

The NetScaler appliance does not support management access to VIPs.

The following table provides a summary of the interaction between management access and specific service settings for Telnet.

Management Access	Telnet (State Configured on the NetScaler)	Telnet (Effective State at the IP Level)
Enable	Enable	Enable
Enable	Disable	Disable
Disable	Enable	Disable
Disable	Disable	Disable

The following table provides an overview of the IP addresses used as source IP addresses in outbound traffic.

Application/ IP	NSIP	MIP	SNIP	VIP
ARP	Yes	Yes	Yes	No
Server side traffic	No	Yes	Yes	No
RNAT	No	Yes	Yes	Yes
ICMP PING	Yes	Yes	Yes	No
Dynamic routing	Yes	No	Yes	Yes

The following table provides an overview of the applications available on these IP addresses.

Application/ IP	NSIP	MIP	SNIP	VIP
SNMP	Yes	Yes	Yes	No
System access	Yes	Yes	Yes	No

You can access and manage the NetScaler by using applications such as Telnet, SSH, GUI, and FTP.

Note: Telnet and FTP are disabled on the NetScaler for security reasons. To enable them, contact the customer support. After the applications are enabled, you can apply the controls at the IP level.

To configure the NetScaler to respond to these applications, you need to enable the specific management applications. If you disable management access for an IP address, existing connections that use the IP address are not terminated, but no new connections can be initiated.

Also, the non-management applications running on the underlying FreeBSD operating system are open to protocol attacks, and these applications do not take advantage of the NetScaler appliance's attack prevention capabilities.

You can block access to these non-management applications on a MIP, SNIP, or NSIP. When access is blocked, a user connecting to a NetScaler by using the MIP, SNIP, or NSIP is not be able to access the non-management applications running on the underlying operating system.

To configure management access for an IP address by using the command line interface

At the command prompt, type:

set ns ip <IPAddress> -mgmtAccess <value> -telnet <value> -ftp <value> -gui <value> -ssh <value> -snmp <value> -restrictAccess (ENABLED | DISABLED)

Example

```
> set ns ip 10.102.29.54 -mgmtAccess enabled -restrictAccess ENABLED
 Done
```

To enable management access for an IP address by using the configuration utility

1. Navigate to Network > IPs > IPV4s.
2. Open an IP address entry, and select the Enable Management Access control to support the below listed applications option.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns ip

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

How the NetScaler Proxies Connections

When a client initiates a connection, the NetScaler appliance terminates the client connection, initiates a connection to an appropriate server, and sends the packet to the server. The appliance does not perform this action for service type UDP or ANY.

For more information about service types, see "Load Balancing."

You can configure the NetScaler to process the packet before initiating the connection with a server. The default behavior is to change the source and destination IP addresses of a packet before sending the packet to the server. You can configure the NetScaler to retain the source IP address of the packets by enabling Use Source IP mode.

How the Destination IP Address Is Selected

Traffic sent to the NetScaler appliance can be sent to a virtual server or to a service. The appliance handles traffic to virtual servers and services differently. The NetScaler terminates traffic received at a virtual server IP (VIP) address and changes the destination IP address to the IP address of the server before forwarding the traffic to the server, as shown in the following diagram.

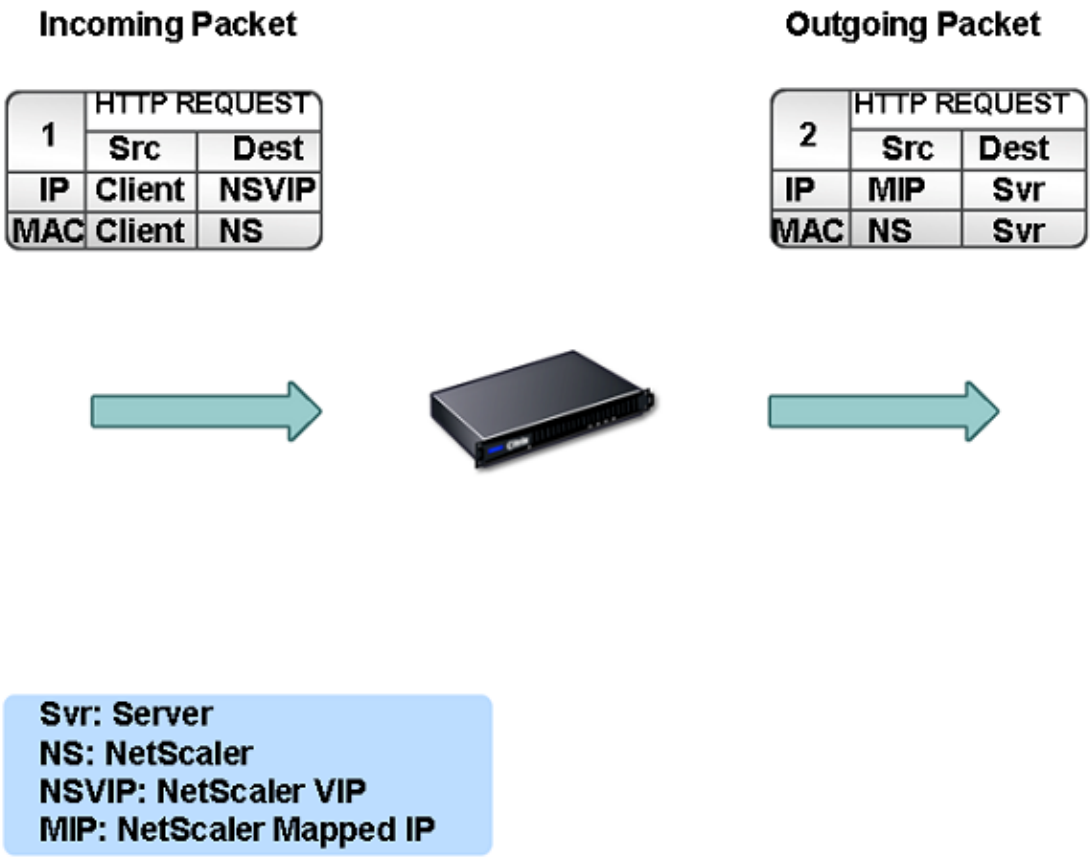

Figure 1. Proxying Connections to VIPs

Packets destined for a service are sent directly to the appropriate server, and the NetScaler does not modify the destination IP addresses. In this case, the NetScaler functions as a proxy.

How the Source IP Address Is Selected

When the NetScaler appliance communicates with the physical servers or peer devices, by default, it does not use the IP address of the client. NetScaler maintains a pool of mapped IP addresses (MIPs) and subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address of a connection to the physical server. Depending on the subnet in which the physical server is placed, NetScaler decides whether a MIP should be used or SNIP.

Note: If the Use Source IP (USIP) option is enabled, NetScaler uses the IP address of the client.

Enabling Use Source IP Mode

When the NetScaler appliance communicates with the physical servers or peer devices, by default, it uses one of its own IP addresses as the source IP. The appliance maintains a pool of mapped IP addresses (MIPs) and subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address for a connection to the physical server. The decision of whether to select a MIP or a SNIP depends on the subnet in which the physical server resides.

If necessary, you can configure the NetScaler appliance to use the client's IP address as source IP. Some applications need the actual IP address of the client. The following use cases are a few examples:

- Client's IP address in the web access log is used for billing purposes or usage analysis.
- Client's IP address is used to determine the country of origin of the client or the originating ISP of the client. For example, many search engines such as Goggle provide content relevant to the location to which the user belongs.
- The application must know the client's IP address to verify that the request is from a trustworthy source.
- Sometimes, even though an application server does not need the client's IP address, a firewall placed between the application server and the NetScaler may need the client's IP address for filtering the traffic.

Enable Use Source IP mode (USIP) mode if you want NetScaler to use the client's IP address for communication with the servers. By default, USIP mode is disabled. USIP mode can be enabled globally on the NetScaler or on a specific service. If you enable it globally, USIP is enabled by default for all subsequently created services. If you enable USIP for a specific service, the client's IP address is used only for the traffic directed to that service.

As an alternative to USIP mode, you have the option of inserting the client's IP address (CIP) in the request header of the server-side connection for an application server that needs the client's IP address.

In earlier NetScaler releases, USIP mode had the following source-port options for server-side connections:

- Use the client's port. With this option, connections cannot be reused. For every request from the client, a new connection is made with the physical server.
- Use proxy port. With this option, connection reuse is possible for all requests from the same client. Before NetScaler release 8.1 this option imposed a limit of 64000 concurrent connections for all server-side connections.

In the later NetScaler releases , if USIP is enabled, the default is to use a proxy port for server-side connections and not reuse connections. Not reusing connections may not affect the speed of establishing connections.

By default, the Use Proxy Port option is enabled if the USIP mode is enabled.

For more information about the Use Proxy Port option, see "Using the Client Port When Connecting to the Server."

Note: If you enable the USIP mode, it is recommended to enable the Use Proxy Port option.

The following figure shows how the NetScaler uses IP addresses in USIP mode.

Figure 1. IP Addressing in USIP Mode

Recommended Usage

Enable USIP in the following situations:

- Load balancing of Intrusion Detection System (IDS) servers
- SMTP load balancing
- Stateless connection failover
- Sessionless load balancing
- If you use the Direct Server Return (DSR) mode

Note: When USIP is required in the one-arm mode installation of the NetScaler appliance, make sure that the server's gateway is one of the IP addresses owned by the NetScaler. For more information about NetScaler owned IP addresses, see "Configuring NetScaler owned IP addresses."

- If you enable USIP, set the idle timeout for server connections to a value lower than the default value, so that idle connections are cleared quickly on the server side.

  For more information about setting an idle time-out value, "Load Balancing."

- For transparent cache redirection, if you enable USIP, enable L2CONN also.
- Because HTTP connections are not reused when USIP is enabled, a large number of server-side connections may accumulate. Idle server connections can block connections for other clients. Therefore, set limits on maximum number of connections to a service. Citrix also recommends setting the HTTP server time-out value, for a service on which

USIP is enabled, to a value lower than the default, so that idle connections are cleared quickly on the server side.

To globally enable or disable USIP mode by using the command line interface

At the command prompt, type one of the following commands:

- enable ns mode USIP
- disable ns mode USIP

To enable USIP mode for a service by using the command line interface

At the command prompt, type:

set service <name>@ -usip (**YES** | **NO**)

Example

set service Service-HTTP-1 -usip YES

To globally enable or disable USIP mode by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change modes.
2. Select or clear the Use Source IP option.

To enable USIP mode for a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, select the service for which you want to enable the USIP mode, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Under Settings, select the Use Source IP check box.
5. Click OK.

Configuring Network Address Translation

Network address translation (NAT) involves modification of the source and/or destination IP addresses and/or the TCP/UDP port numbers of IP packets that pass through the NetScaler appliance. Enabling NAT on the appliance enhances the security of your private network, and protects it from a public network such as the Internet, by modifying your networks source IP addresses when data passes through the NetScaler. Also, with the help of NAT entries, your entire private network can be represented by a few shared public IP addresses. The NetScaler supports the following types of network address translation:

- Inbound NAT (INAT), in which the NetScaler replaces the destination IP address in the packets generated by the client with the private IP address of the server.
- Reverse NAT (RNAT), in which the NetScaler replaces the source IP address in the packets generated by the servers with the public NAT IP addresses.

Configuring INAT

When a client sends a packet to a NetScaler appliance that is configured for Inbound Network Address Translation (INAT), the appliance translates the packet's public destination IP address to a private destination IP address and forwards the packet to the server at that address.

The following configurations are supported:

- **IPv4-IPv4 Mapping**: A public IPv4 address on the NetScaler appliance listens to connection requests on behalf of a private IPv4 server. The NetScaler appliance translates the packet's public destination IP address to the destination IP address of the server and forwards the packet to the server at that address.
- **IPv4-IPv6 Mapping**: A public IPv4 address on the NetScaler appliance listens to connection requests on behalf of a private IPv6 server. The NetScaler appliance creates an IPv6 request packet with the IP address of the IPv6 server as the destination IP address.
- **IPv6-IPv4 Mapping**: A public IPv6 address on the NetScaler appliance listens to connection requests on behalf of a private IPv4 server. The NetScaler appliance creates an IPv4 request packet with the IP address of the IPv4 server as the destination IP address.
- **IPv6-IPv6 Mapping**: A public IPv6 address on the NetScaler appliance listens to connection requests on behalf of a private IPv6 server. The NetScaler appliance translates the packet's public destination IP address to the destination IP address of the server and forwards the packet to the server at that address.

When the appliance forwards a packet to a server, the source IP address assigned to the packet is determined as follows:

- If use subnet IP (USNIP) mode is enabled and use source IP (USIP) mode is disabled, the NetScaler uses a subnet IP address (SNIP) as the source IP address.
- If USNIP mode is disabled and USIP mode is disabled, the NetScaler uses a mapped IP address (MIP) as the source IP address.
- If USIP mode is enabled, and USNIP mode is disabled the NetScaler uses the client IP (CIP) address as the source IP address.
- If both USIP and USNIP modes are enabled, USIP mode takes precedence.
- You can also configure the NetScaler to use a unique IP address as the source IP address, by setting the proxyIP parameter.
- If none of the above modes are enabled and a unique IP address has not been specified, the NetScaler attempts to use a MIP as the source IP address.
- If both USIP and USNIP modes are enabled and a unique IP address has been specified, the order of precedence is as follows: USIP-unique IP-USNIP-MIP-Error.

To protect the NetScaler from DoS attacks, you can enable TCP proxy. However, if other protection mechanisms are used in your network, you may want to disable them.

You can create, modify, or remove an INAT entry.

To create an INAT entry by using the command line interface

At the command prompt, type the following commands to create an INAT entry and verify its configuration:

- add inat <name> <publicIP> <privateIP> [-tcpproxy (ENABLED | DISABLED)] [-ftp (ENABLED | DISABLED)] [-usip (ON | OFF)] [-usnip (ON | OFF)] [-proxyIP <ip_addr|ipv6_addr>]
- show inat [<name>]

Example

```
> add inat ip4-ip4 172.16.1.2 192.168.1.1 -proxyip 10.102.29.171
 Done
```

To modify an INAT entry by using the command line interface

To modify an INAT entry, type the set inat command, the name of the entry, and the parameters to be changed, with their new values.

To remove an INAT configuration by using the command line interface

At the command prompt, type:

rm inat <name>

Example

```
> rm inat ip4-ip4
 Done
```

To configure an INAT entry by using the configuration utility

Navigate to Network > Routes > INAT, and add a new INAT entry or edit an existing INAT entry.

To remove an INAT configuration by using the configuration utility

Navigate to Network > Routes > INAT, delete the INAT configuration.

Coexistence of INAT and Virtual Servers

If both INAT and RNAT are configured, the INAT rule takes precedence over the RNAT rule. If RNAT is configured with a network address translation IP (NAT IP) address, the NAT IP address is selected as the source IP address for that RNAT client.

The default public destination IP in an INAT configuration is the virtual IP (VIP) address of the NetScaler device. Virtual servers also use VIPs. When both INAT and a virtual server use the same IP address, the Vserver configuration overrides the INAT configuration.

Following are a few sample configuration setup scenarios and their effects.

Case	Result
You have configured a virtual server and a service to send all data packets received on a specific NetScaler port to the server directly. You have also configured INAT and enabled TCP. Configuring INAT in this manner sends all data packets received through a TCP engine before sending them to the server.	All packets received on the NetScaler, except those received on the specified port, pass through the TCP engine.
You have configured a virtual server and a service to send all data packets of service type TCP, that are received on a specific port on the NetScaler, to the server after passing through the TCP engine. You have also configured INAT and disabled TCP. Configuring INAT in this manner sends the data packets received directly to the server.	Only packets received on the specified port pass through the TCP engine.
You have configured a virtual server and a service to send all data packets received to either of two servers. You are attempting to configure INAT to send all data packets received to a different server.	The INAT configuration is not allowed.
You have configured INAT to send all received data packets directly to a server. You are attempting to configure a virtual server and a service to send all data packets received to two different servers.	The vserver configuration is not allowed.

Stateless NAT46 Translation

The stateless NAT46 feature enables communication between IPv4 and IPv6 networks through IPv4 to IPv6 packet translation, and vice versa, without maintaining any session information on the NetScaler appliance.

For a stateless NAT46 configuration, the appliance translates an IPv4 packet to IPv6 or an IPv6 packet to IPv4 as defined in RFCs 6145 and 2765.

Note: This feature is supported only on NetScaler 10.e and later.

A stateless NAT46 configuration on the NetScaler appliance has the following components:

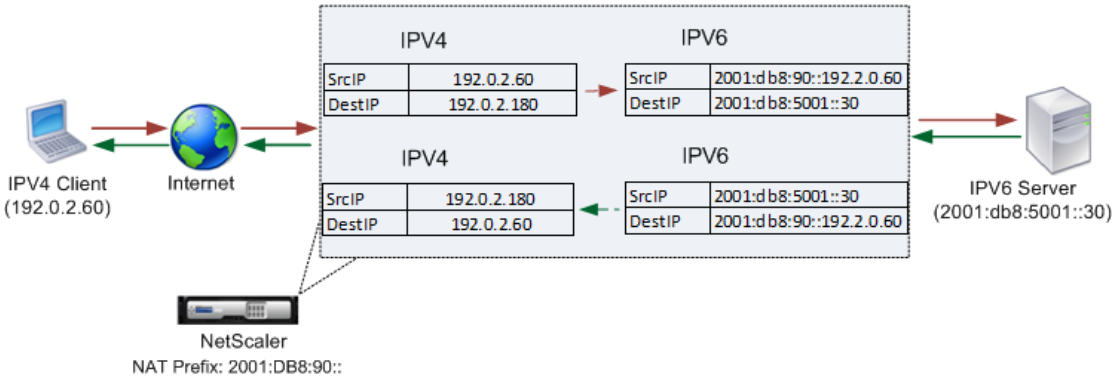
- **IPv4-IPv6 INAT entry**—An INAT entry defining a 1:1 relationship between an IPv4 address and an IPv6 address. In other words, an IPv4 address on the appliance listens to connection requests on behalf of an IPv6 server. An IPv4 request packet for this IPv4 address is translated into an IPv6 packet, and then the IPv6 packet is sent to the IPv6 server.

  The appliance translates an IPv6 response packet into an IPv4 response packet with its source IP address field set as the IPv4 address specified in the INAT entry. The translated packet is then sent to the client.

- **NAT46 IPv6 prefix**—A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance. During IPv4 packet to IPv6 packet translation, the appliance sets the source IP address of the translated IPv6 packet to a concatenation of the NAT46 IPv6 prefix [96 bits] and the IPv4 source address [32 bits] that was received in the request packet.

  During IPv6 packet to IPv4 packet translation, the appliance sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

Consider an example in which an enterprise hosts site www.example.com on server S1, which has an IPv6 address. To enable communication between IPv4 clients and IPv6 server S1, NetScaler appliance NS1 is deployed with a stateless NAT46 configuration that includes an IPv4-IPv6 INAT entry for server S1, and a NAT46 Prefix. The INAT entry includes an IPv4 address at which the appliance listens to connection requests from IPv4 clients on behalf of the IPv6 server S1.



The following table lists the settings used in this example:

Entities	Name	Value
IP address of the client	Client_IPv4 (for reference purposes only)	192.0.2.60
IPv6 address of the server	Sevr_IPv6 (for reference purposes only)	2001:DB8:5001::30
IPv4 address defined in the INAT entry for IPv6 server S1	Map-Sevr-IPv4 (for reference purposes only)	192.0.2.180
IPv6 prefix for NAT 46 translation	NAT46_Prefix (for reference purposes only)	2001:DB8:90::

Following is the traffic flow in this example:

1. IPv4 Client CL1 sends a request packet to the Map-Sevr-IPv4 (192.0.2.180) address on the NetScaler appliance.

2. The appliance receives the request packet and searches the NAT46 INAT entries for the IPv6 address mapped to the Map-sevr-IPv4 (192.0.2.180) address. It finds the Sevr-IPv6 (2001:DB8:5001::30) address.

3. The appliance creates a translated IPv6 request packet with:

   - Destination IP address field = Sevr-IPv6 = 2001:DB8:5001::30

   - Source IP address field = Concatenation of NAT Prefix (First 96 bits) and Client_IPv4 (last 32 bits) = 2001:DB8:90::192.0.2.60
4. The appliance sends the translated IPv6 request to Sevr-IPv6.

5. The IPv6 server S1 responds by sending an IPv6 packet to the NetScaler appliance with:

   - Destination IP address field = Concatenation of NAT Prefix (First 96 bits) and Client_IPv4 (last 32 bits)= 2001:DB8:90::192.0.2.60

   - Source IP address field = Sevr-IPv6 = 2001:DB8:5001::30
6. The appliance receives the IPv6 response packet and verifies that its destination IP address matches the NAT46 prefix configured on the appliance. Because the destination address matches the NAT46 prefix, the appliance searches the NAT46 INAT entries for the IPv4 address associated with the Sevr-IPv6 address (2001:DB8:5001::30). It finds the Map-Sevr-IPv4 address (192.0.2.180).

7. The appliance creates an IPv4 response packet with:

   - Destination IP address field = The NAT46 prefix stripped from the destination address of the IPv6 response = Client_IPv4 (192.0.2.60)

   - Source IP address field = Map-Sevr-IPv4 address (192.0.2.180)
8. The appliance sends the translated IPv4 response to client CL1.

Configuring Stateless NAT46

Creating the required entities for stateless NAT46 configuration on the NetScaler appliance involves the following procedures:

1. Create an IPv4-IPv6 mapping INAT entry with stateless mode enabled.
2. Add a NAT46 IPv6 prefix.

To configure an INAT mapping entry by using the command line interface

At the command prompt, type:

- add inat <name> <publicIPv4> <privateIPv6> -mode STATELESS
- show inat <name>

To add an NAT46 prefix by using the command line interface

At the command prompt, type:

- set inatparam -nat46v6Prefix <ipv6_addr|*>
- show inatparam

Example

```
 > add inat exmpl-com-stls-nat46 192.0.2.180
2001:DB8:5001::30 -mode stateless
Done

> set inatparam -nat46v6Prefix 2001:DB8:90::/96
Done
```

To configure an INAT mapping entry by using the configuration utility

1. Navigate to Network > Routes > INAT.
2. Add a new INAT entry, or edit an existing INAT entry.
3. Set the following parameters:
   - Name*
   - Public IP Address*
   - Private IP Address* (Select the IPv6 check box and enter the address in IPv6 format.)
   - Mode (Select Stateless from the drop down list.)

   * A required parameter

To add a NAT46 prefix by using the configuration utility

Navigate to Network, in the Settings group, click Change IPv6 settings, and set the IPv6 NAT Prefix parameter.

Parameter Descriptions (of commands listed in the CLI procedure)

add inat

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show inat

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Setting Global Parameters for Stateless NAT46

The appliance provides some optional global parameters for stateless NAT46 configurations.

To set global parameters for stateless NAT46 by using the command line interface

At the command prompt, type:

- set inatparam [-nat46IgnoreTOS (YES | NO)] [-nat46ZeroCheckSum (ENABLED | DISABLED)] [-nat46v6Mtu <positive_integer>] [-nat46FragHeader (ENABLED | DISABLED)]
- show inatparam

Example

```
> set inatparam -nat46IgnoreTOS YES -nat46ZeroCheckSum DISABLED -nat46v6Mtu 1400 -nat46FragHeader
 Done
```

To set global parameters for stateless NAT46 by using the configuration utility

Navigate to Network, in the Settings group, click Change IPv6 settings.

Limitations of Stateless NAT46

The following limitations apply to stateless NAT46:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv4 packets is not supported.
- Translation of multicast packets is not supported.
- Translation of destination option headers and source routing headers is not supported.
- Translation of fragmented IPv4 UDP packets that do not contain UDP checksum is not supported.

Stateful NAT64 Translation

The stateful NAT64 feature enables communication between IPv4 clients and IPv6 servers through IPv6 to IPv4 packet translation, and vice versa, while maintaining session information on the NetScaler appliance.

A stateful NAT64 configuration on the NetScaler appliance has the following components:

- **NAT64 rule**— An entry consisting of an ACL6 rule and a netprofile, which consists of a pool of NetScaler owned SNIP Addresses.
- **NAT64 IPv6 Prefix**— A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance.

  Note: Currently the NetScaler appliance supports only one prefix to be used commonly with all NAT 64 rules.

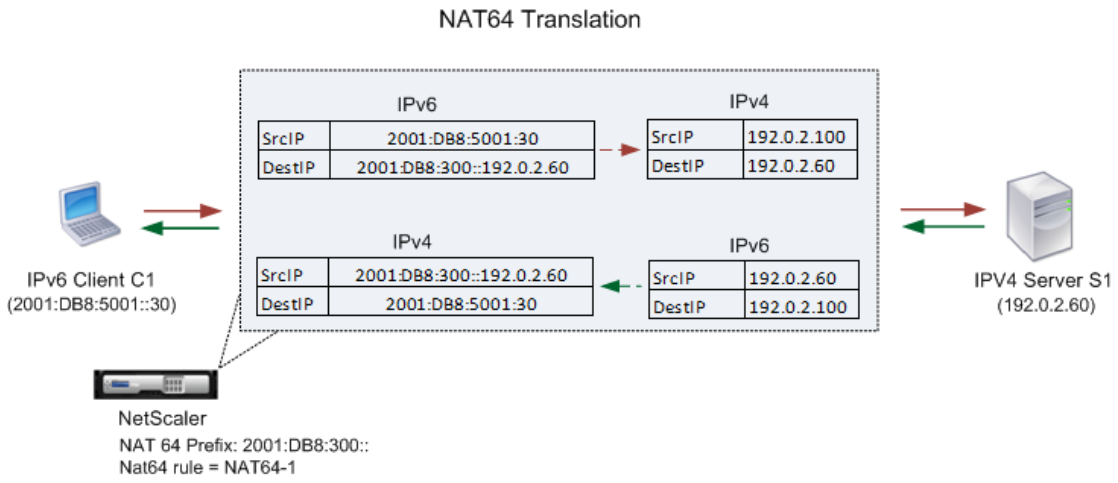
The NetScaler appliance considers an incoming IPv6 packet for NAT64 translation when all of the following conditions are met:

- The incoming IPv6 packet matches the ACL6 rule bound to a NAT64 rule.
- The destination IP address of the IPv6 packet matches the NAT64 IPv6 prefix.

When an IPv6 request packet received by the NetScaler appliance matches an ACL6 defined in a NAT64 rule and the destination IP of the packet matches the NAT64 IPv6 prefix, the NetScaler appliance considers the IPv6 packet for translation.

The appliance translates this IPv6 packet to an IPv4 packet with a source IP address matching one of the IP address bound to the netprofile defined in the NAT64 rule, and a destination IP address consisting of the last 32 bits of the destination IPv6 address of the IPv6 request packet. The NetScaler appliance creates a NAT64 session for this particular flow and forwards the packet to the IPv4 server. Subsequent responses from the IPv4 server and requests from the IPv6 client are translated accordingly by the appliance, on the basis of information in the particular NAT64 session.

Consider an example in which an enterprise hosts site www.example.com on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, NetScaler appliance NS1 is deployed with a stateful NAT64 configuration that includes a NAT64 rule and a NAT64 prefix. A mapped IPv6 address of server S1 is formed by concatenating the NAT64 IPv6 prefix [96 bits] and the IPv4 source address [32 bits]. This mapped IPv6 address is then manually configured in the DNS servers. The IPv6 clients get the mapped IPv6 address from the DNS servers to communicate withIPv4 server S1.



The following table lists the settings used in this example:

Entities	Name	Value
IPv6 address of client CL1	Client_IPv6 (for reference purposes only)	2001:DB8:5001::30
IPv4 address of server S1	Sevr_IPv4 (for reference purposes only)	192.0.2.60
IPv6 prefix for NAT64 translation	NAT64_Prefix (for reference purposes only)	2001:DB8:300::
Mapped IPv6 address (NAT64_Prefix + Sevr_IPv4) of server S1 for IPv6 clients to reach server S1	Map-Sevr-IPv6 (for reference purposes only)	2001:DB8:300::192.0.2.60
ACL6 rule	ACL6-1	· Action = ALLOW · Source IP address =2001:DB8:5001::30
IPset	IPset-1	IP addresses bound (of type SNIPs) = 192.0.2.100 and 192.0.2.102
Netprofile	Netprofile-1	Source IP address = IPset-1
NAT64 rule	NAT64-1	ACL6 rule = ACL6-1 Netprofile = Netprofile-1

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a request packet to Map-Sevr-IPv6 (2001:DB8:300::192.0.2.60) address.

2. The NetScaler appliance receives the request packet. If the request packet matches the ACL6 defined in the NAT64 rule, and the destination IP address of the packet matches the NAT64 IPv6 prefix, the NetScaler considers the IPv6 packet for translation.

3. The appliance creates a translated IPv4 request packet with:

- Destination IP address field containing the NAT64 prefix stripped from the destination address of the IPv6 request (Sevr_IPv4 = 192.0.2.60)

- Source IP address field containing one of the IPv4 address bound to Netprofile-1(in this case, 192.0.2.100)

4. The NetScaler appliance creates a NAT64 session for this flow and sends the translated IPv4 request to server S1.

5. IPv64 server S1 responds by sending an IPv4 packet to the NetScaler appliance with:

   - Destination IP address field containing 192.0.2.100

   - Source IP address field containing the address ofSevr_IPv4(192.0.2.60)
6. The appliance receives the IPv4 response packet, searches all the session entries, and finds that the IPv6 response packet matches the NAT64 session entry created in step 4. The appliance considers the IPv4 packet for translation.

7. The appliance creates a translated IPv6 response packet with:

   - Destination IP address field=Client_IPv6=2001:DB8:5001::30

   - Source IP address field = Concatenation of NAT64 Prefix (First 96 bits) and Sevr_IPv4 (last 32 bits) =2001:DB8:300::192.0.2.60
8. The appliance sends the translated IPv6 response to client CL1.

Limitations of Statelful NAT64

The following limitations apply to stateful NAT64 translation:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv6 packets is not supported.
- Translation of multicast packets is not supported.
- Packets of Stream Control Transmission Protocol (SCTP), Datagram Congestion Control Protocol (DCCP), and IPSec, are not translated.

Configuring Stateful NAT64

Creating the required entities for stateful NAT64 configuration on the NetScaler appliance involves the following procedures:

1. Add an ACL6 rule with action ALLOW.
2. Add an ipset, which binds multiple IP addresses.
3. Add a netprofile and bind the ipset to it. If you want to bind only one IP address, you need not create an ipset entity. In that case, bind the IP address directly to the netprofile.
4. Add a NAT64 rule, which includes binding the ACl6 rule and the netprofile to the NAT 64 rule.
5. Add a NAT64 IPv6 prefix.

To add an ACL6 rule by using the command line interface

At the command prompt, type:

- add ns acl6 <acl6name> <acl6action> ...

To add an IPset and bind multiple IPs to it by using the command line interface

At the command prompt, type:

- add ipset <name>
- bind ipset <name> <IPaddress …>

To add a netprofile by using the command line interface

At the command prompt, type:

- add netprofile <name> -srcIP <IPaddress or IPset>

To add a NAT64 rule by using the command line interface

At the command prompt, type:

- add nat64 <name> <acl6name> -netProfile <string>

To add a NAT64 prefix by using the command line interface

At the command prompt, type:

- set ipv6 -natprefix <ipv6_addr|*>

Example

```
> add acl6 ACL6-1 ALLOW -srcIPv6 2001:DB8:5001::30
Done
```

```
> apply acls6
 Done

> add ip 192.0.2.100 255.255.255.0 -type SNIP
 Done

> add ip 192.0.2.102 255.255.255.0  -type SNIP
 Done

> add ipset IPset-1
 Done

> bind ipset IPset-1 192.0.2.100 192.0.2.102
IPAddress "192.0.2.100" bound
IPAddress "192.0.2.102" bound
 Done

> add netprofile Netprofile-1 -srcIP IPset-1
 Done

> add nat64 NAT64-1 ACL6-1 -netprofile Netprofile-1
 Done

> set ipv6 -natprefix 2001:DB8:300::/96
 Done
```

To add a NAT64 rule by using the configuration utility

Navigate to Network > Routes > NAT64, and a new NAT64 rule, or edit an existing rule.

To add a NAT64 prefix by using the configuration utility

Navigate to Network, in the Settings group, click Change IPv6 settings, and set the IPv6 NAT Prefix parameter.

Configuring RNAT

In Reverse Network Address Translation (RNAT), the NetScaler appliance replaces the source IP addresses in the packets generated by the servers with public NAT IP addresses. By default, the appliance uses a Mapped IP address (MIP) as the NAT IP address. You can also configure the appliance to use a unique NAT IP address for each subnet. You can also configure RNAT by using Access Control Lists (ACLs). Use Source IP (USIP), Use Subnet IP (USNIP), and Link Load Balancing (LLB) modes affect the operation of RNAT. You can display statistics to monitor RNAT.

Note: The ephemeral port range for RNAT on the NetScaler appliance is 1024-65535.

You can use either a network address or an extended ACL as the condition for an RNAT entry:

- **Using a Network address.** When you use a network address, RNAT processing is performed on all of the packets coming from the specified network.
- **Using Extended ACLs.** When you use ACLs, RNAT processing is performed on all packets that match the ACLs. To configure the NetScaler appliance to use a unique IP address for traffic that matches an ACL, you must perform the following three tasks:

  1. Configure the ACL.
  2. Configure RNAT to change the source IP address and Destination Port.
  3. Apply the ACL.

  The following diagram illustrates RNAT configured with an ACL.

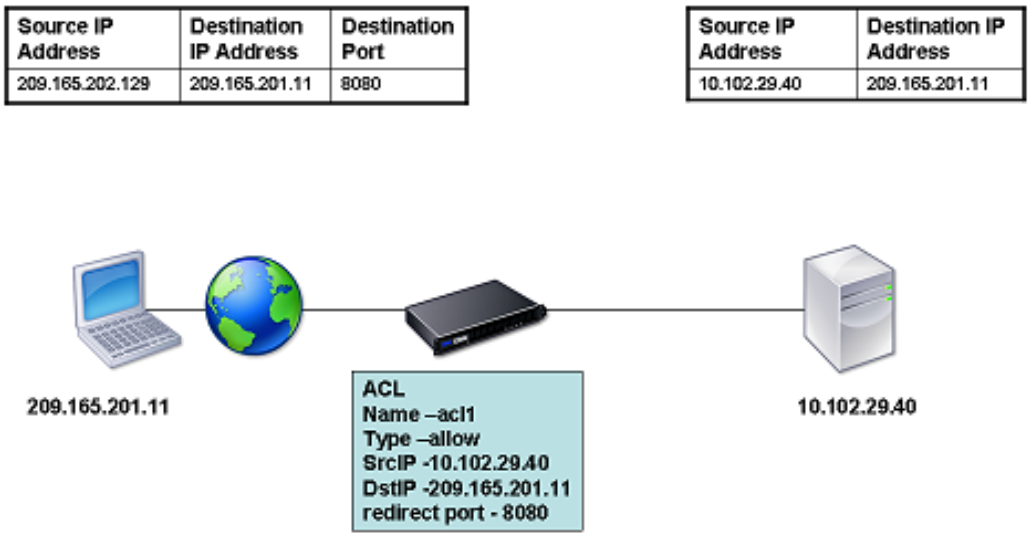

Figure 1. RNAT with an ACL

You have the following basic choices for the type of NAT IP address:

- **Using a MIP or SNIP as the NAT IP Address.** When using a MIP as the NAT IP address, the NetScaler appliance replaces the source IP addresses of server-generated packets with the a MIP. Therefore, the MIP address must be a public IP address. If Use Subnet IP (USNIP) mode is enabled, the NetScaler can use a subnet IP address (SNIP) as the NAT IP address.

- **Using a Unique IP Address as the NAT IP Address.** When using a unique IP address as the NAT IP address, the NetScaler appliance replaces the source IP addresses of server-generated packets with the unique IP address specified. The unique IP address must be a public NetScaler-owned IP address. If multiple NAT IP addresses are configured for a subnet, NAT IP selection uses the round robin algorithm.

  This configuration is illustrated in the following diagram.

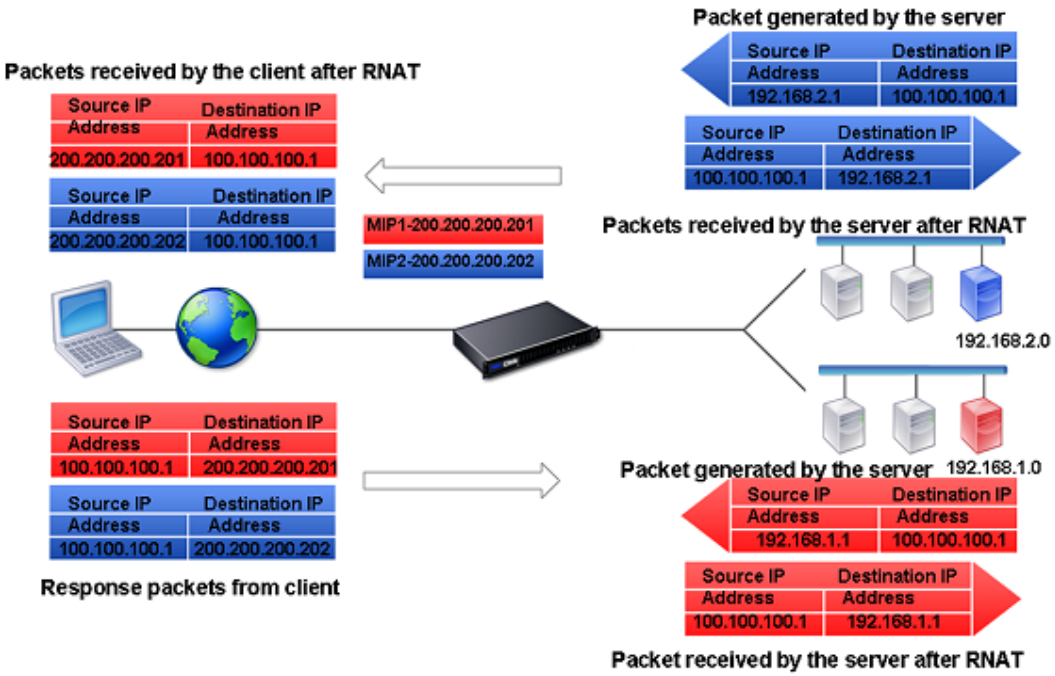

Figure 2. Using a Unique IP Address as the NAT IP Address

Creating an RNAT Entry

The following instructions provide separate command-line procedures for creating RNAT entries that use different conditions and different types of NAT IP addresses. In the configuration utility, all of the variations can be configured in the same dialog box, so there is only one procedure for configuration utility users.

To create an RNAT entry by using the command line interface

At the command prompt, type one the following commands to create, respectively, an RNAT entry that uses a network address as the condition and a MIP or SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a MIP or SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:

- set rnat <IPAddress> <netmask>
- set rnat IPAddress <netMask> -natip <NATIPAddress>
- set rnat <aclname> [-redirectPort <port>]
- set rnat <aclname> [-redirectPort <port>] -natIP <NATIPAddress>

  Use the following command to verify the configuration:

- show rnat

Examples

A network address as the condition and a MIP or SNIP as the NAT IP address:

```
> set rnat 192.168.1.0 255.255.255.0
 Done
```

A network address as the condition and a unique IP address as the NAT IP address:

```
> set rnat 192.168.1.0 255.255.255.0 -natip 10.102.29.50
 Done
```

If instead of a single NAT IP address you specify a range, RNAT entries are created with all the NetScaler-ow

```
> set rnat 192.168.1.0 255.255.255.0  -natIP 10.102.29.[50-110]
 Done
```

An ACL as the condition and a MIP or SNIP as the NAT IP address:

```
> set rnat acl1
 Done
```

An ACL as a condition and a unique IP address as the NAT IP address:

```
> set rnat acl1  -natIP 209.165.202.129
Done
```

If instead of a single NAT IP address you specify a range, RNAT entries are created with all the NetScaler-ow

```
> set rnat acl1  -natIP 10.102.29.[50-70]
 Done
```

To create an RNAT entry by using the configuration utility

1. Navigate to Network > Routes > RNAT.
2. Click Configure RNAT.

Parameter Descriptions (of commands listed in the CLI procedure)

set rnat

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show rnat

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Monitoring RNAT

You can display RNAT statistics to troubleshoot issues related to IP address translation.

To view RNAT statistics by using the command line interface

At the command prompt, type:

stat rnat

Example

```
> stat rnat

RNAT summary
                        Rate (/s)          Total
Bytes Received                0                0
Bytes Sent                    0                0
Packets Received              0                0
Packets Sent                  0                0
Syn Sent                      0                0
Current RNAT sessions         --               0
 Done
>
```

The following tables describes the statistics associated with RNAT and RNAT IP.

Table 1. RNAT Statistics

Statistic	Description
Bytes received	Bytes received during RNAT sessions
Bytes sent	Bytes sent during RNAT sessions
Packets received	Packets received during RNAT sessions
Packets sent	Packets sent during RNAT sessions
Syn sent	Requests for connections sent during RNAT sessions
Current sessions	Currently active RNAT sessions

To monitor RNAT by using the configuration utility

Navigate to Network > Routes > RNAT, and click Statistics.

Parameter Descriptions (of commands listed in the CLI procedure)

stat rnat

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

RNAT in USIP, USNIP, and LLB Modes

Before configuring a RNAT rule, consider the following points:

- When RNAT and Use Source IP (USIP) are both configured on the NetScaler appliance, RNAT takes precedence. In other words, the source IP address of the packets, which matches a RNAT rule, is replaced according to the setting in the RNAT rule.
- When RNAT and Use SNIP (USNIP) are configured on the NetScaler appliance, selection of the source IP address is based on the state of USNIP, as follows:
    - If USNIP is off, the NetScaler appliance uses the mapped IP addresses.
    - If USNIP is on, the NetScaler uses a SNIP address as the NAT IP address.

This behavior does not apply when a unique NAT IP address is used.

In a topology where the NetScaler appliance performs both Link Load Balancing (LLB) and RNAT for traffic originating from the server, the appliance selects the source IP address based on the router. The LLB configuration determines selection of the router. For more information about LLB, see "Link Load Balancing."

Configuring RNAT for IPv6 Traffic

Reverse Network Address Translation (RNAT) rules for IPv6 packets are called *RNAT6s*. When an IPv6 packet generated by a server matches the conditions specified in the RNAT6 rule, the appliance replaces the source IPv6 address of the IPv6 packet with a configured NAT IPv6 address before forwarding it to the destination. The NAT IPv6 address is one of the NetScaler owned SNIP6 or VIP6 addresses.

When configuring an RNAT6 rule, you can specify either an IPv6 prefix or an ACL6 as the condition:

- **Using a IPv6 network address**. When you use an IPv6 prefix, the appliance performs RNAT processing on those IPv6 packets whose IPv6 address matches the prefix.
- **Using ACL6s**. When you use an ACL6, the appliance performs RNAT processing on those IPv6 packets that match the conditions specified in the ACL6.

You have one of the following options to set the NAT IP address:

- Specify a set of NetScaler owned SNIP6 and VIP6 addresses for an RNAT6 rule. The NetScaler appliance uses any one of the IPv6 addresses from this set as a NAT IP address for each session. The selection is based on the round robin algorithm and is done for each session.
- Do not specify any NetScaler owned SNIP6 or VIP6 address for an RNAT6 rule. The NetScaler appliance uses any one of the NetScaler owned SNIP6 or VIP6 addresses as a NAT IP address. The selection is based on the next hop network to which an IPv6 packet that matches the RNAT rule is destined.

To create an RNAT6 rule by using the command line interface

At the command prompt, to create the rule and verify the configuration, type:

- add rnat6 <name> (<network> | (<acl6name> [-redirectPort <port>]))
- bind rnat6 <name> <natIP6>@ ...
- show rnat6

To modify or remove an RNAT6 rule by using the command line interface

- To modify an RNAT6 rule whose condition is an ACL6, type the set rnat6 <name> command, followed by a new value for the redirectPort parameter.
- To remove an RNAT6 rule, type the clear rnat6 <name> command.
- show rnat6

To configure an RNAT6 rule by using the configuration utility

Navigate to Network > Routes > RNAT6, and add a new RNAT6 rule, or edit an existing rule.

Parameter Descriptions (of commands listed in the CLI procedure)

add rnat6

bind rnat6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show rnat6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Prefix-Based IPv6-IPv4 Translation

Prefix-based translation is a process of translating packets sent from private IPv6 servers into IPv4 packets, using an IPv6 prefix configured in the NetScaler appliance. This prefix has a length of 96 bits (128-32=96). The IPv6 servers embed the destination IP address of the IPv4 servers or hosts in the last 32 bits of the destination IP address field of the IPv6 packets. The first 96 bits of the destination IP address field are set as the IPv6 NAT prefix.

The NetScaler appliance compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix. If there is a match, the NetScaler appliance generates an IPv4 packet and sets the destination IP address as the last 32 bits of the destination IP address of the matched IPv6 packet. IPv6 packets addressed to this prefix have to be routed to the NetScaler so that the IPv6-IPv4 translation is done by the NetScaler.

In the following diagram, 3ffe::/96 is configured as the IPv6 NAT prefix on NetScaler NS1. The IPv6 host sends an IPv6 packet with destination IP address 3ffe::74.125.91.105. NS1 compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix, and they match. NS1 then generates an IPv4 packet and sets the destination IP address as 74.125.91.105.

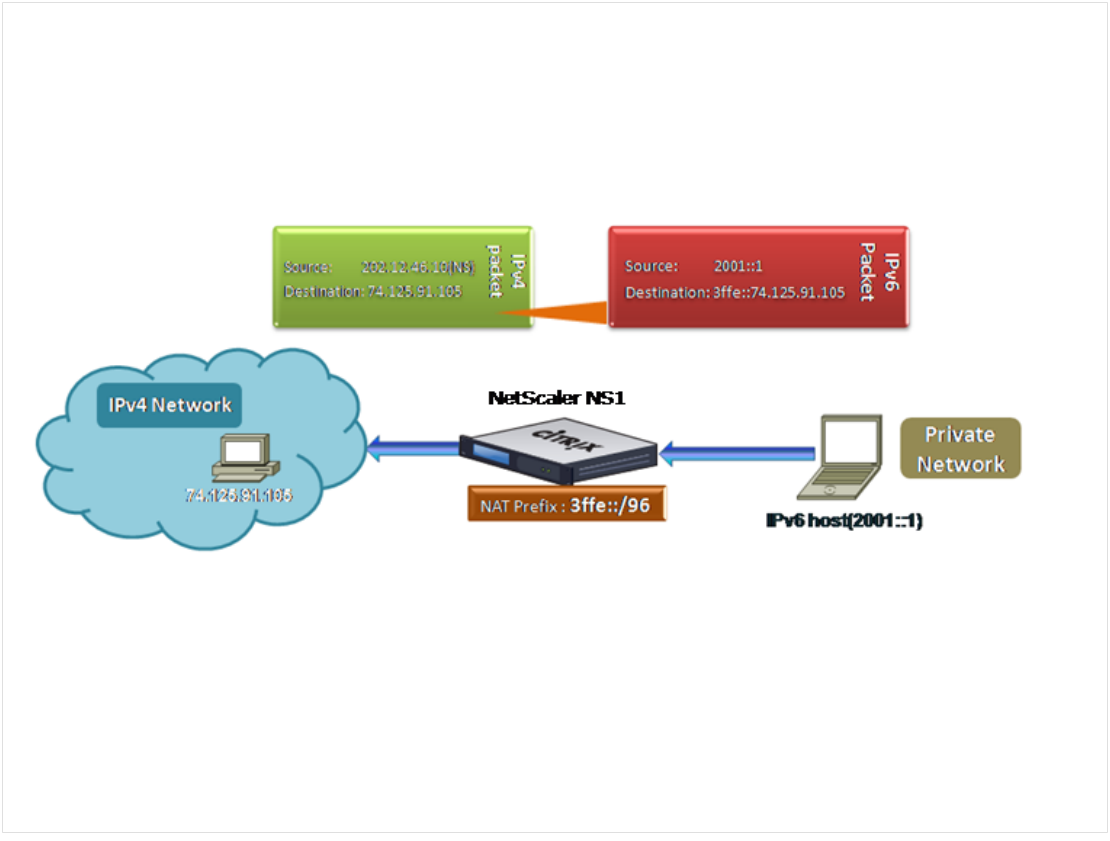

Figure 1. IPv6-IPv4 Prefix-Based Translation

To configure prefix-based IPv6-IPv4 translation by using the command line interface

At the command prompt, type the following commands to set a NAT prefix and verify its configuration:

- set ipv6 [-natprefix <ipv6_addr|*>]
- show ipv6

Example

```
> set ipv6 -natprefix 3ffe::/96
 Done
```

To configure prefix-based IPv6-IPv4 translation by using the configuration utility

Navigate to Network, in the Settings group, click Change IPv6 settings, and set the IPv6 NAT Prefix parameter.

Parameter Descriptions (of commands listed in the CLI procedure)

set ipv6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ipv6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Static ARP

You can add static ARP entries to and remove static ARP entries from the ARP table. After adding an entry, you should verify the configuration. If the IP address, port, or MAC address changes after you create a static ARP entry, you must remove or manually adjust the static entry. Therefore, creating static ARP entries is not recommended unless necessary.

To add a static ARP entry by using the command line interface

At the command prompt, type:

- add arp -IPAddress <ip_addr> -mac<mac_addr> -ifnum <interface_name>
- show arp <IPAddress>

Example

```
> add arp -ip 10.102.29.6 -mac 00:24:e8:73:ca:ec -ifnum 1/1
 Done
```

To remove a static ARP entry by using the command line interface

At the command prompt, type the rm arp command and the IP address.

To add a static ARP entry by using the configuration utility

Navigate to Network > ARP Table, and a new ARP entry.

Parameter Descriptions (of commands listed in the CLI procedure)

add arp

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show arp

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Setting the Timeout for Dynamic ARP Entries

You can globally set an aging time (time-out value) for dynamically learned ARP entries. The new value applies only to ARP entries that are dynamically learned after the new value is set. Previously existing ARP entries expire after the previously configured aging time.

You can specify an ARP time-out value of from 1 through 1200 seconds.

To set the time-out for dynamic ARP entries by using the command line interface

At the command prompt, type the following commands to set the time-out for dynamic ARP entries and verify its configuration:

- set arpparam -timeout <positive_integer>]
- show arpparam

Example

```
> set arpparam -timeout 500
 Done
```

To set the time-out for dynamic ARP entries to its default value by using the command line interface

At the command prompt, type the following commands to set the time-out for dynamic ARP entries to its default value and verify its configuration:

- unset arpparam
- show arpparam

Example

```
> unset arpparam
 Done
```

To set the time-out for dynamic ARP entries by using the configuration utility

Navigate to Network, in the Settings group, click Configure ARP Global Parameters, and set the ARP Table Entry Timeout parameter.

Parameter Descriptions (of commands listed in the CLI procedure)

set arpparam

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show arpparam

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

unset arpparam

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Neighbor Discovery

Neighbor discovery (ND) is one of the most important protocols of IPv6. It is a message-based protocol that combines the functionality of the Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Router Discovery. ND allows nodes to advertise their link layer addresses and obtain the MAC addresses or link layer addresses of the neighboring nodes. This process is performed by the Neighbor Discovery protocol (ND6).

Neighbor discovery can perform the following functions:

Router Discovery

Enables a host to discover the local routers on an attached link and automatically configure a default router.

Prefix Discovery

Enables the host to discover the network prefixes for local destinations.

Note: Currently, the NetScaler does not support Prefix Discovery.

Parameter Discovery

Enables a host to discover additional operating parameters, such as MTU and the default hop limit for outbound traffic.

Address Autoconfiguration

Enables hosts to automatically configure IP addresses for interfaces both with and without stateful address configuration services such as DHCPv6. The NetScaler does not support Address Autoconfiguration for Global IPv6 addresses.

Address Resolution

Equivalent to ARP in IPv4, enables a node to resolve a neighboring node's IPv6 address to its link-layer address.

Neighbor Unreachability Detection

Enables a node to determine the reachability state of a neighbor.

Duplicate Address Detection

Enables a node to determine whether an NSIP address is already in use by a neighboring node.

Redirect

Equivalent to the IPv4 ICMP Redirect message, enables a router to redirect the host to a better first-hop IPv6 address to reach a destination.

Note: The NetScaler does not support IPv6 Redirect.

To enable neighbor discovery, you create entries for the neighbors.

Adding IPv6 Neighbors

Adding IPv6 neighbors enables neighbor discovery.

To add an IPv6 neighbor by using the command line interface

At the command prompt, type:

- add nd6 <neighbor> <mac> <ifnum> [-vlan <integer>]
- show nd6

Example

```
> add nd6 2001::1 00:04:23:be:3c:06 1/1 –vlan 1
 Done
> show nd6
  Neighbor              MAC-Address(Vlan, Interface)      State       TIME
  --------              ----------------------------      -----     --------
1) ::1                  00:d0:68:0b:58:da(   1,  LO/1)   REACHABLE     PERMANENT
2) fe80::2d0:68ff:fe0b:58da 00:d0:68:0b:58:da(   1,  LO/1)   REACHABLE     PERMANENT
3) 2001::1                00:04:23:be:3c:06(   1,   1/1)   REACHABLE       STATIC
 Done
```

Neighbor Discovery Parameters

neighbor

IPv6 neighbor entry. Mandatory.

mac

Unique address assigned to identify the network appliance. Mandatory.

ifnum

The interface on which the MAC resides. Mandatory.

vlan

Virtual LAN (VLAN) that the neighbor is part of.

To add an IPv6 neighbor by using the configuration utility

Navigate to Network > IPv6 Neighbors, and add a new IPv6 neighbor.

Parameter Descriptions (of commands listed in the CLI procedure)

add nd6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show nd6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Removing IPv6 Neighbors

To remove a neighbor discovery entry by using the command line interface

At the command prompt, type:

rm nd6 <Neighbor> -vlan <VLANID>

Example

rm nd6 3ffe:100:100::1 -vlan 1

To remove all neighbor discovery entries by using the command line interface

At the command prompt, type:

clear nd6

To remove a neighbor discovery entry by using the configuration utility

Navigate to Network > IPv6 Neighbors, delete the IPv6 neighbor.

To remove all neighbor discovery entries by using the configuration utility

Navigate to Network > IPv6 Neighbors, and click Clear.

Parameter Descriptions (of commands listed in the CLI procedure)

rm nd6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

clear nd6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring IP Tunnels

An IP Tunnel is a communication channel, that can be created by using encapsulation technologies, between two networks that do not have a routing path. Every IP packet that is shared between the two networks is encapsulated within another packet and then sent via the tunnel.

The NetScaler appliance implements IP Tunneling in the following ways:

- NetScaler as an Encapsulator (Load Balancing with DSR mode)
- NetScaler as a Decapsulator

NetScaler as an Encapsulator (Load Balancing with DSR Mode)

Consider an organization that has multiple data centers across different countries, where the NetScaler maybe at one location and the back-end servers are located in a different country. In essence, the NetScaler and the back-end servers are on different networks and are connected via a router.

When you configure Direct Server Return (DSR) on this NetScaler, the packet sent from the source subnet is encapsulated by the NetScaler and sent via a router and tunnel to the appropriate back-end server. The back-end server decapsulates the packet and responds directly to the client, without allowing the packet to pass via the NetScaler.

NetScaler as a Decapsulator

Consider an organization having multiple data centers each having NetScalers and back-end servers. When a packet is sent from data center A to data center B it is usually sent via an intermediary, say a router or another NetScaler. The NetScaler processes the packet and then forwards the packet to the back-end server. However, if an encapsulated packet is sent, the NetScaler must be able to decapsulate the packet before sending it to the back-end servers. To enable the NetScaler to function as a decapsulator, a tunnel is added between the router and the NetScaler. When the encapsulated packet, with additional header information, reaches the NetScaler, the data packet is decapsulated i.e. the additional header information is removed, and the packet is then forwarded to the appropriate back-end servers.

The NetScaler can also be used as a decapsulator for the Load Balancing feature, specifically in scenarios when the number of connections on a vserver exceeds a threshold value and all the new connections are then diverted to a back-up vserver.

Creating IP Tunnels

To create an IP tunnel by using the command line interface

At the command prompt type:

- add iptunnel <name> <remote> <remoteSubnetMask> <local> -type -protocol (ipoverip | GRE) -ipsecprofile <name>
- show iptunnel

To remove an IP tunnel by using the command line interface

To remove an IP tunnel, type the rm iptunnel command and the name of the tunnel.

Parameters for creating an IP tunnel

name

Name of the IP Tunnel. This alphanumeric string is required and cannot be changed after the service group is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

remoteIp

A public IPv4 address of the remote NetScaler appliance used to set up the tunnel.

remoteSubnetMask

Subnet mask of the remote IP address of the tunnel.

localIp

A public IPv4 address of the local NetScaler appliance used to set up the tunnel. Possible values: Auto, MIP, SNIP, and VIP. Default: Auto.

protocol

The protocol to be used in setting up the IP tunnel. Select GRE for using the Generic Routing Encapsulation (GRE) protocol to set up a GRE tunnel.

ipsecProfileName

Name of the IPSec profile that is used for securing communication in the GRE tunnel.

To create an IP Tunnel by using the configuration utility

Navigate to Network > IP Tunnels, add a new IP tunnel.

To create an IPv6 tunnel by using the command line interface

At the command prompt type:

- add ip6tunnel <name> <remoteIp> <local>
- show ip6tunnel

To remove an IPv6 tunnel by using the command line interface

To remove an IPv6 tunnel, type the rm ip6tunnel command and the name of the tunnel.

Parameters for creating an IPv6 tunnel

name (Name)

A name for the IPv6 Tunnel. This alphanumeric string is required and cannot be changed after the service group is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

remoteIp (Remote IP)

An IPv6 address of the remote NetScaler appliance used to set up the tunnel.

localIp (Local IP Type)

An IPv6 address of the local NetScaler appliance used to set up the tunnel. Possible values: SNIP6 and VIP6. Default: Auto.

To create an IPv6 Tunnel by using the configuration utility

Navigate to Network > IP Tunnels > IPv6 Tunnels, and add a new IPv6 tunnel.

Customizing IP Tunnels Globally

By globally specifying the source IP address, you can assign a common source IP address across all tunnels. Also, because fragmentation is CPU-intensive, you can globally specify that the NetScaler appliance drop any packet that requires fragmentation. Alternatively, if you would like to fragment all packets as long as a CPU threshold value is not reached, you can globally specify the CPU threshold value.

To globally customize IP tunnels by using the command line interface

At the command prompt, type the following commands to globally customize IP tunnels and verify the configuration:

- set ipTunnelParam -srcIP <sourceIPAddress> -srcIPRoundRobin (YES | NO)-dropFrag [YES | NO] -dropFragCpuThreshold <Positive integer>
- show ipTunnelParam

Example

```
> set iptunnelparam –srcIP 12.12.12.22 -dropFrag Yes –dropFragCpuThreshold 50
 Done
> set iptunnelparam -srcIPRoundRobin YES -dropFrag Yes –dropFragCpuThreshold 50
 Done
```

Note: To create a new MIP or SNIP address to use as the global source IP address, use the add ns ip command before you type the set iptunnelparam command.

To globally customize IP tunnels by using the configuration utility

Navigate to Network, in the Settings group, click IPv4 Tunnel Global Settings.

1. Navigate to Network.
2. In the details pane, in the Settings group, click IPv4 Tunnel Global Settings.
3. In the Configure IP Tunnel Global Parameters dialog box, set the parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
4. Click OK and then click Close.

To globally customize IPv6 tunnels by using the command line interface

At the command prompt, type the following commands to globally customize IPv6 tunnels and verify the configuration:

- set ip6tunnelparam -srcIP <IPv6Address> -srcIPRoundRobin (YES | NO)-dropFrag [YES | NO] -dropFragCpuThreshold <Positive integer>
- show ip6tunnelparam

Note: To create a new VIP6 or SNIP6 address to use as the global source IP address, use the add ns ip6 command before you type the set ip6tunnelparam command.

To globally customize IPv6 tunnels by using the configuration utility

Navigate to Network, in the Settings group, click IPv6 Tunnel Global Settings.

Interfaces

Before you begin configuring interfaces, decide whether your configuration can use MAC-based forwarding mode, and either enable or disable this system setting accordingly. The number of interfaces in your configuration is different for the different models of the Citrix NetScaler appliance. In addition to configuring individual interfaces, you can logically group interfaces, using VLANs to restrict data flow within a set of interfaces, and you can aggregate links into channels. In a high availability setup, you can configure a virtual MAC (VMAC) address if necessary. If you use L2 mode, you might want to modify the aging of the bridge table.

When your configuration is complete, decide whether you should enable the system setting for path MTU discovery. NetScaler appliances can be deployed in active-active mode using VRRP. An active-active deployment, in addition to preventing downtime, makes efficient use of all the NetScaler appliances in the deployment. You can use the Network Visualizer tool to view the network configuration of a NetScaler deployment and configure interfaces, channels, VLANs, and bridge groups.

Configuring MAC-Based Forwarding

With MAC-based forwarding (MBF) enabled, when a request reaches the NetScaler appliance, the appliance remembers the source MAC address of the frame and uses it as the destination MAC address for the resulting replies. MAC-based forwarding can be used to avoid multiple-route/ARP lookups and to avoid asymmetrical packet flows. MAC-based forwarding may be required when the NetScaler is connected to multiple stateful devices, such as VPNs or firewalls, because it ensures that the return traffic is sent to the same device that the initial traffic came from.

MAC-based forwarding is useful when you use VPN devices, because it guarantees that all traffic flowing through a VPN passes back through the same VPN device.

The following topology diagram illustrates the process of MAC-based forwarding.

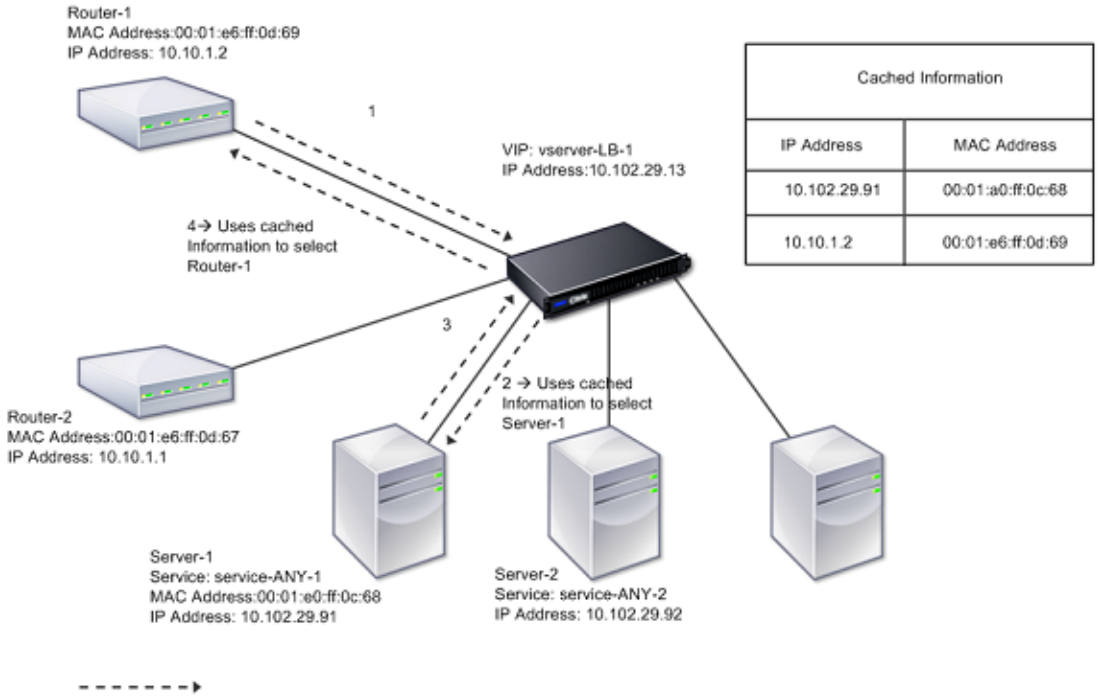

Figure 1. MAC-Based Forwarding Mode

When MAC-based forwarding (MBF) is enabled, the NetScaler caches the MAC address of:

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server replies through the NetScaler appliance, the appliance sets the destination MAC address of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when the NetScaler initiates a

connection, it uses the route and ARP tables for the lookup function. In a direct server return configuration, you must enable MAC-based forwarding.

For more information about direct server return configurations, see "Load Balancing."

Some deployment topologies may require the incoming and outgoing paths to flow through different routers. MAC-based forwarding would break this topology design.

MBF should be disabled in the following situations:

- **When you configure link load balancing.** In this case, asymmetric traffic flows are desirable because of link costs.
- **When a server uses network interface card (NIC) teaming without using LACP (802.1ad Link Aggregation).** To enable MAC-based forwarding in this situation, you must use a layer 3 device between the NetScaler and server.

  Note: MBF can be enabled when the server uses NIC teaming with LACP, because the virtual interface uses one MAC address.
- When firewall clustering is used. Firewall clustering assumes that ARP is used to resolve the MAC address for inbound traffic. Sometimes the inbound MAC address can be a non-clustered MAC address and should not be used for inbound packet processing.

When MBF is disabled, the NetScaler uses L2 or L3 connectivity to forward the responses from servers to the clients. Depending on the route table, the routers used for outgoing connection and incoming connection can be different. In the case of reverse traffic (response from the server):

- If the source and destination are on different IP subnets, the NetScaler uses the route lookup to locate the destination.
- If the source is on the same subnet as the destination, the NetScaler looks up the ARP table to locate the network interface and forwards the traffic to it. If the ARP table does not exist, the NetScaler requests the ARP entries.

To enable or disable MAC-based forwarding by using the command line interface

At the command prompt, type:

- enable ns mode MBF
- disable ns mode MBF

To enable or disable MAC-based forwarding by using the configuration utility

1. Navigate to System > Settings, in the Modes and Features group, click Configure modes.
2. Select or clear the MAC-based forwarding option.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ns mode

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

disable ns mode

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Network Interfaces

Network interfaces in the NetScaler appliance are numbered in <slot>/<port> notation. After configuring your interfaces, you should display the interfaces and their settings to verify the configuration. You can also display this information to troubleshoot a problem in the configuration.

To manage the network interfaces, you might have to enable some interfaces and disable others. You can reset an interface to renegotiate its settings. You can clear the accumulated statistics for an interface. To verify the configuration, you can display the interface settings. You can display the statistics for an interface to evaluate its health.

Setting the Network Interface Parameters

The network interface configuration is neither synchronized nor propagated. For an HA pair, you must perform the configuration on each unit independently.

Network interface parameters include Link Aggregate Control Protocol (LACP) settings. For more information about Link Aggregate Control Protocol (LACP), see "Configuring Link Aggregation Using the Link Aggregate Channel Protocol."

To set the network interface parameters by using the command line interface

At the command prompt, type:

- set interface <id> [-speed <speed>] [-duplex <duplex>] [-flowControl <flowControl>] [-autoneg (DISABLED | ENABLED)] [-haMonitor (ON | OFF)] [(ON | OFF)] [-tagall (ON | OFF)] [-lacpMode <lacpMode>] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT)] [-ifAlias <string>] [-throughput <positive_integer>][-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]

- show interface [<id>]

Example

```
> set interface 1/8 -duplex full
 Done
```

To set the network interface parameters by using the configuration utility

Navigate to Network > Interfaces, select the network interface that you want to modify (for example, 1/8), click Open, and then set the parameters.

1. Navigate to Network > Interfaces, and open the network interface.
2. Set the following parameters:
   - Speed*—speed
   - Duplex*—duplex
   - Flow Control*—flowControl

- Maximum Transmission Unit—mtu
- Auto Negotiation—autoneg
- HA Monitoring—haMonitor
- Tag all VLANs—tagall
- Trunk—trunk
- Alias Name—ifAlias
- Throughput—throughput
- Bandwidth High—bandwidthHigh
- Bandwidth Normal—bandwidthNormal
- LLDP mode*—lldpmode

* A required parameter

Parameter Descriptions (of commands listed in the CLI procedure)

set interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Enabling and Disabling Network Interfaces

By default, the network interfaces are enabled. You must disable any network interface that is not connected to the network, so that it cannot send or receive packets. Disabling a network interface that is connected to the network in a high availability setup can cause failover.

For more information about high availability, see "High Availability."

To enable or disable a network interface by using the command line interface

At the command prompt, type one of the following pairs of commands to enable or disable an interface and verify the setting:

- enable interface <interface_num>
- show interface <interface_num>
- disable interface <interface_num>
- show interface <interface_num>

Example

```
> enable interface 1/8
 Done
> show interface 1/8
      Interface 1/8 (Gig Ethernet 10/100/1000 MBits) #2
      flags=0x4004000 <ENABLED, DOWN, BOUND to LA/1, down, autoneg, 802.1q>
      MTU=1514, MAC=00:d0:68:15:fd:3d, downtime 906h58m40s
      Requested: media UTP, speed AUTO, duplex FULL, fctl OFF, throughput 0
      RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
      TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
      NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
      Bandwidth thresholds are not set.
Done
```

To enable or disable a network interface by using the configuration utility

1. Navigate to Network > Interfaces.
2. Select the network interface, and click Enable or Disable.

Parameter Descriptions (of commands listed in the CLI procedure)

enable interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

disable interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Resetting Network Interfaces

Network interface settings control properties such as duplex and speed. To renegotiate the settings of a network interface, you must reset it.

To reset a network interface by using the command line interface

At the command prompt, type the following commands to reset an interface and verify the setting:

- reset interface <interface_num>
- show interface <interface_num>

Example

```
> reset interface 1/8
 Done
```

To reset a network interface by using the configuration utility

1. Navigate to Network > Interfaces.
2. Select the network interface, and click Reset Interface.

Parameter Descriptions (of commands listed in the CLI procedure)

reset interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Monitoring a Network Interface

You can display network interface statistics to monitor parameters such as packets sent and packets received, throughput, Link Aggregate Control Protocol (LACP) data units, and errors, and use the information to check the health of the network interface. You can clear the statistics of a network interface to monitor its statistics from the time the statistics are cleared.

To display the statistics of the network interfaces by using the command line interface

At the command prompt, type:

stat interface <interface_num>

To display the statistics of an Interface by using the configuration utility

Navigate to Network > Interfaces, select the network interface, and click StatisticsInterface Statistics.

To clear a network interface's statistics by using the command line interface

At the command prompt, type:

clear interface <interface_num>

Example

```
> clear interface 1/8
 Done
```

To clear a network interface's statistics by using the configuration utility

1. Navigate to Network > Interfaces.
2. Select the network interface, and click Clear Statistics.

Parameter Descriptions (of commands listed in the CLI procedure)

stat interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

clear interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Forwarding Session Rules

By default, the NetScaler appliance does not create session entries for traffic that it only forwards (L3 mode). For a case in which a client request that the appliance forwards to a server results in a response that has to return by the same path, you can create a forwarding-session rule. A forwarding-session rule creates forwarding-session entries for traffic that originates from or is destined for a particular network and is forwarded by the NetScaler. You can create forwarding session rules for IPv4 traffic as well as IPv6 traffic.

When configuring an IPv4 forwarding-session rule, you can specify either an IPv4 network address or an extended ACL as the condition for identifying IPv4 traffic for which to create a forwarding-session entry:

- **Network address**. When you specify an IPv4 network address, the appliance creates forwarding sessions for IPv4 traffic whose source or destination matches the network address.
- **Extended ACL rule**. When you specify an extended ACL rule, the appliance creates forwarding sessions for IPv4 traffic that matches the conditions specified in the extended ACL rule.

When configuring an IPv6 forwarding-session rule, you can specify either an IPv6 prefix or an ACL6 as the condition for identifying IPv6 traffic for which to create a forwarding-session entry:

- **IPv6 prefix**. When you specify an IPv6 prefix, the appliance creates forwarding sessions for IPv6 traffic whose source or destination matches the IPv6 prefix.
- **ACL6 rule**. When you specify an ACL6 rule, the appliance creates forwarding sessions for IPv6 traffic that matches the conditions specified in the ACL6 rule.

To create an IPv4 forwarding session rule by using the command line interface

At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:

- add forwardingSession <name> [<network> <netmask>] | [-aclname <string>] -connfailover (ENABLED | DISABLED)
- show forwardingSession

Example

A network address as the condition:

```
> add forwardingSession fs-nw-1 10.102.105.51 255.255.255.255
 Done
```

An ACL as the condition:

```
> add forwardingSession fs-acl-1 acl1
 Done
```

To configure an IPv4 forwarding session rule by using the configuration utility

Navigate to Network > Forwarding Sessions, add a new IPv4 forwarding session, or edit an existing forwarding session.

To create an IPv6 forwarding session rule by using the command line interface

At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:

- add forwardingSession <name> [<IPv6 prefix>] | [-acl6name <string>]
- show forwardingSession

Example

An IPv6 prefix as the condition:

```
> add forwardingSession fsv6-pfx-1 3ffe::/64
 Done
```

An ACL6 rule as the condition:

```
> add forwardingSession fsv6-acl6-1 –acl6name ACL6-FS
 Done
```

To configure an IPv6 forwarding session rule by using the configuration utility

Navigate to Network > Forwarding Sessions, add a new IPv6 forwarding session, or edit an existing forwarding session.

Parameter Descriptions (of commands listed in the CLI procedure)

add forwardingSession

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show forwardingSession

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Understanding VLANs

A NetScaler appliance supports Layer 2 port and IEEE 802.1q tagged VLANs. VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface as a part of multiple VLANs by using IEEE 802.1q tagging.

You can configure VLANs and bind them to IP subnets. The NetScaler then performs IP forwarding between these VLANs (if it is configured as the default router for the hosts on these subnets).

The NetScaler supports the following types of VLANs:

Port-Based VLANs. The membership of a port-based VLAN is defined by a set of network interfaces that share a common, exclusive Layer 2 broadcast domain. You can configure multiple port-based VLANs. By default, all network interfaces on the NetScaler are members of VLAN 1.

If you apply 802.1q tagging to the port, the network interface belongs to a port-based VLAN. Layer 2 traffic is bridged within a port-based VLAN, and Layer 2 broadcasts are sent to all members of the VLAN if Layer 2 mode is enabled. When you add an untagged network interface as a member of a new VLAN, it is removed from its current VLAN.

Default VLAN. By default, the network interfaces on the NetScaler are included in a single, port-based VLAN as untagged network interfaces. This VLAN is the default VLAN. It has a VLAN ID (VID) of 1. This VLAN exists permanently. It cannot be deleted, and its VID cannot be changed.

When you add a network interface to a to a different VLAN as an untagged member, the network interface is automatically removed from the default VLAN. If you unbind a network interface from its current port-based VLAN, it is added to the default VLAN again.

Tagged VLANs. 802.1q tagging (defined in the IEEE 802.1q standard) allows a networking device (such as the NetScaler) to add information to a frame at Layer 2 to identify the VLAN membership of the frame. Tagging allows network environments to have VLANs that span multiple devices. A device that receives the packet reads the tag and recognizes the VLAN to which the frame belongs. Some network devices do not support receiving both tagged and untagged packets on the same network interface—in particular, Force10 switches. In such cases, you need to contact customer support for assistance.

The network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of one VLAN only (its native VLAN). This network interface transmits the frames for the native VLAN as untagged frames. A network interface can be a part of more than one VLAN if the other VLANs are tagged.

When you configure tagging, be sure to match the configuration of the VLAN on both ends of the link. The port to which the NetScaler connects must be on the same VLAN as the NetScaler network interface.

Note: This VLAN configuration is neither synchronized nor propagated, therefore you must perform the configuration on each unit in an HA pair independently.

Applying Rules to Classify Frames

VLANs have two types of rules for classifying frames:

Ingress rules. Ingress rules classify each frame as belonging only to a single VLAN. When a frame is received on a network interface, the following rules are applied to classify the frame:

- If the frame is untagged, or has a tag value equal to 0, the VID of the frame is set to the port VID (PVID) of the receiving interface, which is classified as belonging to the native VLAN. (PVIDs are defined in the IEEE 802.1q standard.)
- If frame has a tag value equal to FFF, the frame is dropped.
- If the VID of the frame specifies a VLAN of which the receiving network interface is not a member, the frame is dropped. For example, if a packet is sent from a subnet associated with VLAN ID 12 to a subnet associated with VLAN ID 10, the packet is dropped. If an untagged packet with VID 9 is sent from the subnet associated with VLAN ID 10 to a network interface PVID 9, the packet is dropped.

Egress Rules. The following egress rules are applied:

- If the VID of the frame specifies a VLAN of which the transmission network interface is not a member, the frame is discarded.
- During the learning process (defined by the IEEE 802.1q standard), the Src MAC and VID are used to update the bridge lookup table of the NetScaler.
- A frame is discarded if its VID specifies a VLAN that does not have any members. (You define members by binding network interfaces to a VLAN.)

VLANs and Packet Forwarding on the NetScaler

The forwarding process on the NetScaler appliance is similar to that on any standard switch. However, the NetScaler performs forwarding only when Layer 2 mode is on. The key features of the forwarding process are:

- Topology restrictions are enforced. Enforcement involves selecting each network interface in the VLAN as a transmission port (depending on the state of the network interface), bridging restrictions (do not forward on the receiving network interface), and MTU restrictions.
- Frames are filtered on the basis of information in the bridge table lookup in the forwarding database (FDB) table of the NetScaler. The bridge table lookup is based on the destination MAC and the VID. Packets addressed to the MAC address of the NetScaler are processed at the upper layers.
- All broadcast and multicast frames are forwarded to each network interface that is a member of the VLAN, but forwarding occurs only if L2 mode is enabled. If L2 mode is disabled, the broadcast and multicast packets are dropped. This is also true for MAC addresses that are not currently in the bridging table.
- A VLAN entry has a list of member network interfaces that are part of its untagged member set. When forwarding frames to these network interfaces, a tag is not inserted

in the frame.

- If the network interface is a tagged member of this VLAN, the tag is inserted in the frame when the frame is forwarded.

When a user sends any broadcast or multicast packets without the VLAN being identified, that is, during duplicate address detection (DAD) for NSIP or ND6 for the next hop of the route, the packet is sent out on all the network interfaces, with appropriate tagging based on either the Ingress and Egress rules. ND6 usually identifies a VLAN, and a data packet is sent on this VLAN only. Port-based VLANs are common to IPv4 and IPv6. For IPv6, the NetScaler supports prefix-based VLANs.

Configuring a VLAN

You can implement VLANs in the following environments:

- Single subnet
- Multiple subnets
- Single LAN
- VLANs (no tagging)
- VLANs (802.1q tagging)

If you configure VLANs that have only untagged network interfaces as their members, the total number of possible VLANs is limited to the number of network interfaces available in the NetScaler. If more IP subnets are required with a VLAN configuration, 802.1q tagging must be used.

When you bind a network interface to a VLAN, the network interface is removed from the default VLAN. If the network interfaces need to be a part of more than one VLAN, you can bind the network interfaces to the VLANs as tagged members.

You can configure the NetScaler to forward traffic between VLANs at Layer 3. In this case, a VLAN is associated with a single IP subnet. The hosts in a VLAN that belong to a single subnet use the same subnet mask and one or more default gateways connected to that subnet. Configuring Layer 3 for a VLAN is optional. Layer 3 is used for IP forwarding (inter-VLAN routing). Each VLAN has a unique IP address and subnet mask that define an IP subnet for the VLAN. In an HA configuration, this IP address is shared with the other NetScaler appliances. The NetScaler forwards packets between configured IP subnets (VLANs).

When you configure the NetScaler, you must not create overlapping IP subnets. Doing so impedes Layer 3 functionality.

Each VLAN is a unique Layer 2 broadcast domain. Two VLANs, each bound to separate IP subnets, cannot be combined into a single broadcast domain. Forwarding traffic between two VLANs requires a Layer 3 forwarding (routing) device, such as the NetScaler appliance.

Creating or Modifying a VLAN

To configure a VLAN, you create a VLAN entity, and then bind network interfaces and IP addresses to the VLAN. If you remove a VLAN, its member interfaces are added to the default VLAN.

To create a VLAN by using the command line interface

At the command prompt, type:

add vlan <id> [-aliasName <string>] [-ipv6DynamicRouting (ENABLED|DISABLED)]

Example

> add vlan 2 –aliasName “Network A”
Done

To bind an interface to a VLAN by using the command line interface

At the command prompt, type:

bind vlan <id> -ifnum <slot/port>

Example

> bind vlan 2 -ifnum 1/8
Done

To bind an IP address to a VLAN by using the command line interface

At the command prompt, type:

bind vlan <id> -IPAddress <IPAddress> <netMask>

Example

```
> bind vlan 2 -IPAddress 10.102.29.54 255.255.255.0
 Done
```

To remove a VLAN by using the command line interface

At the command prompt, type:

rm vlan <id>

To configure a VLAN by using the configuration utility

1. Navigate to Network > VLANs, add a new VLAN, or edit an existing VLAN.
2. To bind an IP address to a VLAN, under IP Bindings, select the Active option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The Type column displays the IP address type (such as mapped IP, virtual IP, or subnet IP) for each IP address in the IP Address column.
3. To bind a network interface to a VLAN, under Interface Bindings, select the Active option corresponding to the interface that you want to bind to the VLAN.

Parameter Descriptions (of commands listed in the CLI procedure)

add vlan

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind vlan

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

rm vlan

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Monitoring VLANS

You can display VLAN statistics such as packets received, bytes received, packets sent, and bytes sent, and use the information to identify anomalies and or debug a VLAN.

To view the statistics of a VLAN by using the command line interface

At the command prompt, type:

stat vlan <vlanID>

Example

stat vlan 2

To view the statistics of a VLAN by using the configuration utility

1. Navigate to Network > VLANs.
2. Select the VLAN, and click Statistics.

Parameter Descriptions (of commands listed in the CLI procedure)

stat vlan

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring VLANs in an HA Setup

VLAN configuration for a high-availability setup requires that the NetScaler appliances have the same hardware configuration, and the VLANs configured on them must be mirror images.

The correct VLAN configuration is implemented automatically when the configuration is synchronized between the NetScaler appliances. The result is identical actions on all the appliances. For example, adding network interface 0/1 to VLAN2 adds this network interface to VLAN 2 on all the appliances participating in the high-availability setup.

Note: If you use network-interface-specific commands in an HA setup, the configurations you create are not propagated to the other NetScaler appliance. You must perform these commands on each appliance in an HA pair to ensure that the configuration of the two appliances in the HA pair remains synchronized.

Configuring VLANs on a Single Subnet

Before configuring a VLAN on a single subnet, make sure that Layer 2 Mode is enabled.

The following figure shows a single subnet environment

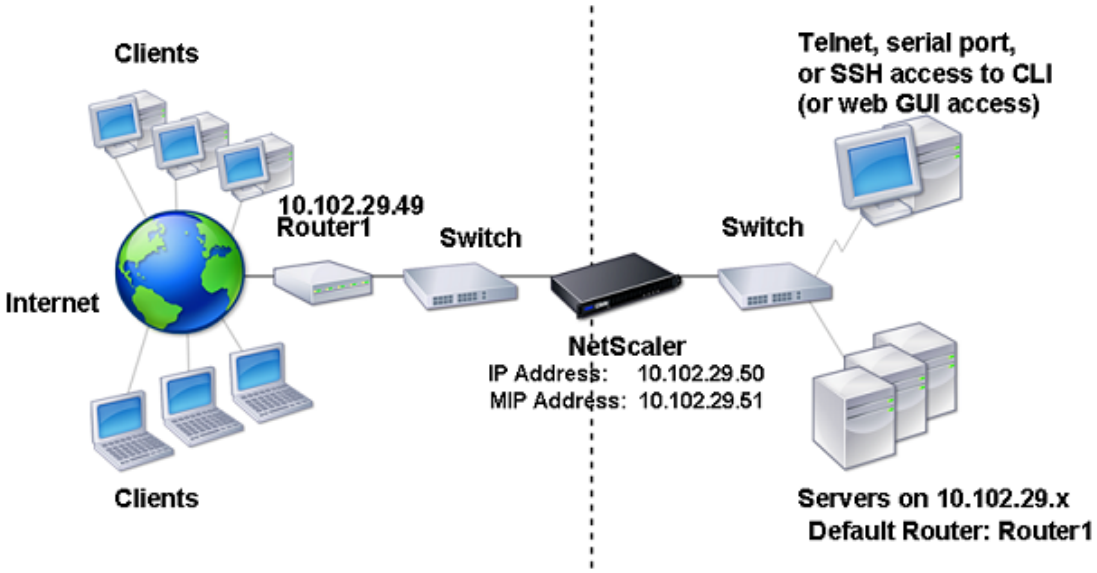

Figure 1. VLAN on a Single Subnet

In the above figure:

1. The default router for the NetScaler and the servers is Router 1.
2. Layer 2 mode must be enabled on the NetScaler for the NetScaler to have direct access to the servers.
3. For this subnet, a virtual server can be configured for load balancing on the NetScaler.

To configure a VLAN on a single subnet, follow the procedures described in "Creating or Modifying a VLAN." VLAN configuration parameters are not required, because the network interfaces are members of this VLAN.

Configuring VLANs on Multiple Subnets

To configure a single VLAN across multiple subnets, you must add a VIP for the VLAN and configure the routing appropriately. The following figure shows a single VLAN configured across multiple subnets.

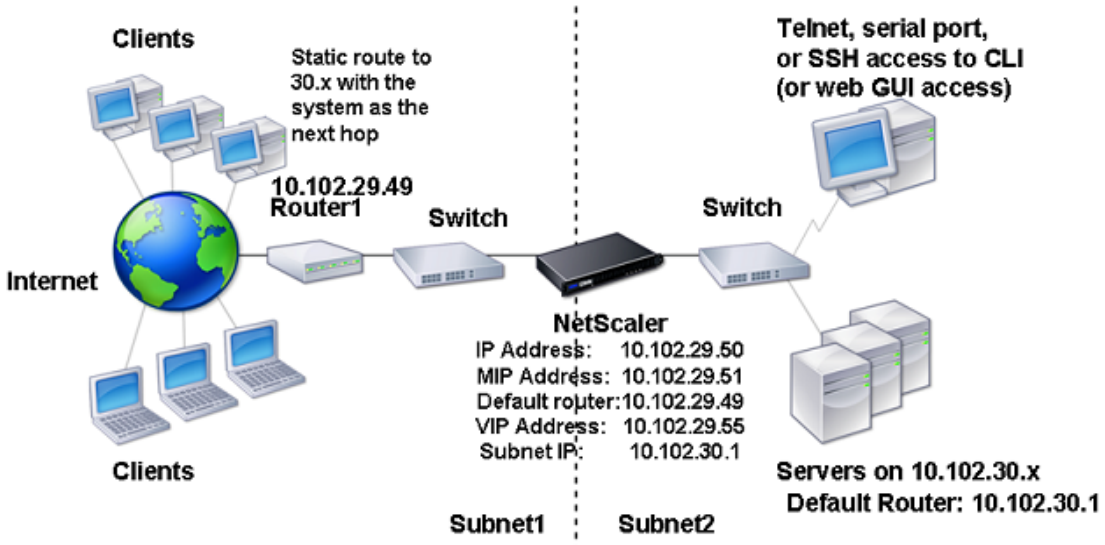

Figure 1. Multiple Subnets in a Single VLAN

To configure a single VLAN across multiple subnets, perform the following tasks:

1. Disable Layer 2 mode. For the procedure to disable Layer 2 mode, see "Enabling and Disabling Layer 2 Mode."

2. Add a VIP.

   For the procedure to add a VIP, see "Configuring and Managing Virtual IP Addresses (VIPs)."

3. Configure RNAT ID.

   For the procedure to configure the RNAT ID, see "Configuring RNAT."

Configuring Multiple Untagged VLANs across Multiple Subnets

In environments with multiple untagged VLANs across multiple subnets, a VLAN is configured for each IP subnet. A network interface is bound to one VLAN only. The following figure shows this configuration.

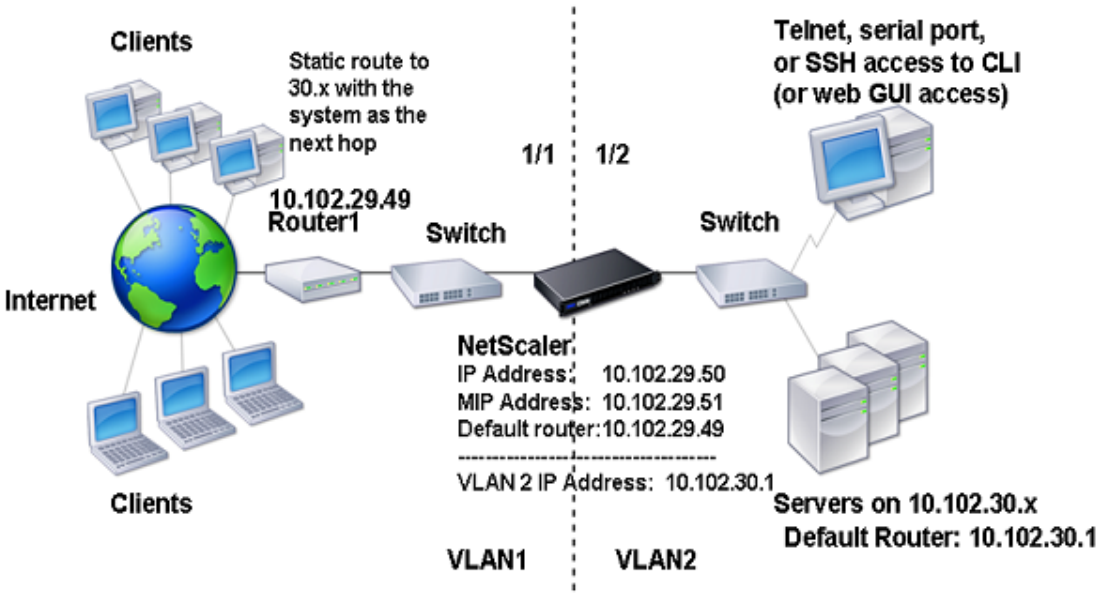

Figure 1. Multiple Subnets with VLANs - No Tagging

To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.

   For the procedure to create a VLAN, see "Creating or Modifying a VLAN."

2. Bind the 1/2 network interface of the NetScaler to VLAN 2 as an untagged network interface.

   For the procedure to bind a network interface to a VLAN, see "Creating or Modifying a VLAN."

3. Bind the IP address and subnet mask to VLAN 2.

   For the procedure to bind a network interface to a VLAN, see "Creating or Modifying a VLAN."

Configuring Multiple VLANs with 802.1q Tagging

For multiple VLANs with 802.1q tagging, each VLAN is configured with a different IP subnet. Each network interface is in one VLAN. One of the VLANs is set up as tagged. The following figure shows this configuration.

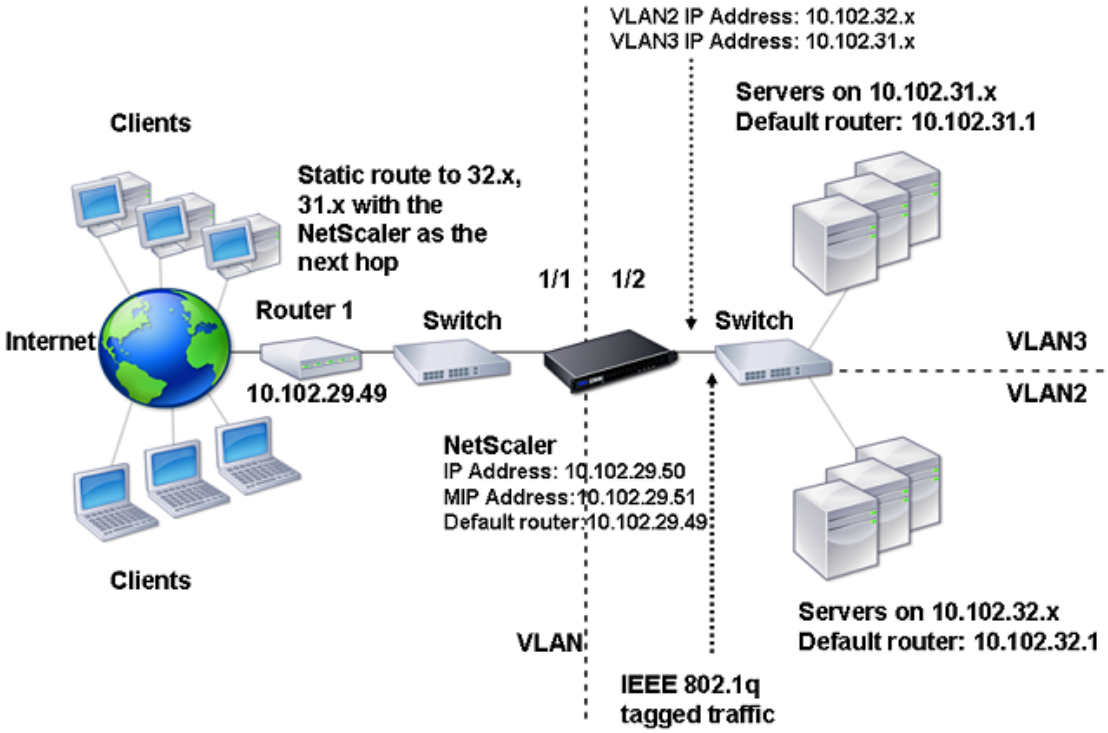

Figure 1. Multiple VLANs with IEEE 802.1q Tagging

To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.

   For the procedure to create a VLAN, see "Creating or Modifying a VLAN."

2. Bind the 1/2 network interface of the NetScaler to VLAN 2 as an untagged network interface.

   For the procedure to bind a network interface to a VLAN, see "Creating or Modifying a VLAN."

3. Bind the IP address and netmask to VLAN 2.

   For the procedure to bind an IP address to a VLAN, see "Creating or Modifying a VLAN."

4. Add VLAN 3.

   For the procedure to create a VLAN, see "Creating or Modifying a VLAN."

5. Bind the 1/2 network interface of the NetScaler to VLAN 3 as a tagged network interface.

   For the procedure to bind a network interface to a VLAN, see "Creating or Modifying a VLAN."

   For the procedure to bind a tagged network interface, see "Creating or Modifying a VLAN."

6. Bind the IP address and netmask to VLAN 3.

   For the procedure to bind an IP address to a VLAN, see "Creating or Modifying a VLAN."

Configuring NSVLAN

NSVLAN is a VLAN to which the NetScaler management IP (NSIP) address's subnet is bound. The NSIP subnet is available only on interfaces that are associated with NSVLAN. By default, NSVLAN is VLAN1, but you can designate a different VLAN as NSVLAN. If you do so, you must reboot the NetScaler appliance for the change to take effect. After the reboot, NSIP subnet traffic is restricted to the new NSVLAN.

The traffic from the NetScaler IP subnet can be tagged (802.1q) with the VLAN ID specified for NSVLAN. You must configure the attached switch interface to tag and allow this same VLAN ID on the connected interface.

If you remove your NSVLAN configuration, the NSIP subnet is automatically bound to VLAN1, restoring the default NSVLAN.

To configure NSVLAN by using the command line interface

At the command prompt, type:

- set ns config -nsvlan <positive_integer> -ifnum <interface_name> ... [-tagged (YES|NO)]
- show ns config

Note: The configuration takes effect after the NetScaler appliance is rebooted.

Example

```
> set ns config -nsvlan 300 -ifnum 1/1 1/2 1/3 -tagged NO
 Done

> save config
 Done
```

To restore the default NSVLAN configuration by using the command line interface

At the command prompt, type:

- unset ns config -nsvlan
- show ns config

Example

```
> unset ns config -nsvlan
 Done
```

To configure NSVLAN by using the configuration utility

Navigate to System > Settings, in the Settings group, click Change NSVLAN Settings.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns config

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns config

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

unset ns config

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Bridge Groups

Typically, when you want to merge two or more VLANs into a single domain, you change the VLAN configuration on all the devices in the separate domains. This can be a tedious task. To more easily merge multiple VLANs into a single broadcast domain, you can use bridge groups.

The bridge groups feature works the same way as a VLAN. Multiple VLANS can be bound to a single bridge group, and all VLANs bound to same bridge group form a single broadcast domain. You can bind only Layer 2 VLANs to a bridge group. For Layer 3 functionality, you must assign an IP address to a bridge group.

In Layer 2 mode, a broadcast packet received on an interface belonging to a particular VLAN is bridged to other VLANs that belong to the same bridge group. In the case of a unicast packet, the NetScaler appliance searches its bridge table for the learned MAC addresses of all the VLANs belonging to same bridge group.

In Layer 3 forwarding mode, an IP subnet is bound to a bridge group. The NetScaler accepts incoming packets belonging to the bound subnet and forwards the packets only on VLANs that are bound to the bridge group.

IPv6 routing can be enabled on a configured bridge group.

To add a bridge group and bind VLANs by using the command line interface

To add a bridge group and bind VLANs and verify the configuration, type the following commands:

- add bridgegroup <id> [-ipv6DynamicRouting (ENABLED | DISABLED)]
- show bridgegroup <id>
- bind bridgegroup <id> -vlan <positive_integer>
- show bridgegroup <id>

Example

```
> add bridgegroup 12
 Done
```

To remove a bridge group by using the command line interface

At the command prompt, type:

rm bridgegroup <id>

Example

rm bridgegroup 12

To configure a bridge group by using the configuration utility

Navigate to Network > Bridge Groups, add a new bridge group, or edit an existing bridge group.

Parameter Descriptions (of commands listed in the CLI procedure)

add bridgegroup

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show bridgegroup

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind bridgegroup

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

rm bridgegroup

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring VMACs

The primary and secondary nodes in a high availability (HA) setup share the Virtual MAC address (VMAC) floating entity. The primary node owns the floating IP addresses (such as MIP, SNIP, and VIP) and responds to ARP requests for these IP addresses with its own MAC address. Therefore, the ARP table of an external device, such as an upstream router, is updated with the floating IP address and the MAC address of the primary node.

When a failover occurs, the secondary node takes over as the new primary node. The former secondary node uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it had learned from the old primary node. The MAC address that the new primary node advertises is the MAC address of its own network interface. Some devices (a few routers) do not accept these GARP messages. Therefore, these external devices retain the IP address-to-MAC address mapping that the old primary node had advertised. This can result in a GSLB site going down.

Therefore, you must configure a VMAC on both nodes of an HA pair. This means that both nodes have identical MAC addresses. When a failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

For the procedures to configure a VMAC, see "High Availability."

Configuring Link Aggregation

Link aggregation combines data coming from multiple ports into a single high-speed link. Configuring link aggregation increases the capacity and availability of the communication channel between the NetScaler appliance and other connected devices. An aggregated link is also referred to as a "channel." You can configure the channels manually, or you can use Link Aggregation Control Protocol (LACP). You cannot apply LACP to a manually configured channel, nor can you manually configure a channel created by LACP.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. (That is, the network interface parameters are ignored.) A network interface can be bound only to one channel.

When a network interface is bound to a channel, it drops its VLAN configuration. When network interfaces are bound to a channel, either manually or by LACP, they are removed from the VLANs that they originally belonged to and added to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you bind the network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then bind them to a channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them back to VLAN 2.

Configuring Link Aggregation Manually

When you create a link aggregation channel, its state is DOWN until you bind an active interface to it. You can modify a channel at any time. You can remove channels, or you can enable/disable them.

To create a link aggregation channel by using the command line interface

At the command prompt, type:

- add channel <id> [-ifnum <interfaceName> ...] [-state (ENABLED | DISABLED)] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor (ON | OFF)][-tagall (ON | OFF)] [-ifAlias <string>] [-throughput <positive_integer>] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]
- show channel

Example

add channel LA/1 -ifnum 1/8
show channels

To bind an interface to or unbind an interface from an existing link aggregation channel by using the command line interface

At the command prompt, type one of the following commands:

- bind channel <id> <interfaceName>
- unbind channel <id> <interfaceName>

Example

bind channel LA/1 1/8

To modify a link aggregation channel by using the command line interface

At the command prompt, type the set channel command, the channel ID, and the parameters to be changed, with their new values.

To configure a link aggregation channel by using the configuration utility

Navigate to Network > Channels, add a new channel, or edit an existing channel.

To remove a link aggregation channel by using the command line interface

Important: When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

At the command prompt, type:

rm channel <id>

Example

```
> rm channel LA/1
 Done
```

To remove a link aggregation channel by using the configuration utility

Important: When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

Navigate to Network > Channels, select the channel that you want to remove and click Remove.

Parameter Descriptions (of commands listed in the CLI procedure)

add channel

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show channel

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind channel

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

unbind channel

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

rm channel

Configuring Link Aggregation by Using the Link Aggregation Control Protocol

The Link Aggregation Control Protocol (LACP) enables network devices to exchange link aggregation information by exchanging LACP Data Units (LACPDUs). Therefore, you cannot enable LACP on network interfaces that are members of a channel that you created manually.

When using LACP to configure link aggregation, you use different commands and parameters for modifying link aggregation channels than you do for creating link aggregation channels. To remove a channel, you must disable LACP on all interfaces that are part of the channel.

Note: In an High Availability configuration, LACP configurations are neither propagated nor synchronized.

Creating Link Aggregation Channels

For creating a link aggregation channel by using LACP, you need to enable LACP and specify the same LACP key on each interface that you want to be the part of the channel. For example, if you enable LACP and set the LACP Key to 3 on interfaces 1/1 and 1/2, a link aggregation channel LA/3 is created and interfaces 1/1 and 1/2 are automatically bound to it.

Note: When enabling LACP on a network interface, you must specify the LACP Key.

By default, LACP is disabled on all network interfaces.

To create an LACP channel by using the command line interface

At the command prompt, type:

- set interface <id> [-lacpMode <lacpMode>] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT)]
- show interface [<id>]

To create an LACP channel by using the configuration utility

Navigate to Network > Interfaces, open the network interface, and set the parameters.

Parameter Descriptions (of commands listed in the CLI procedure)

set interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Modifying Link aggregation Channels

After you have created an LACP channel by specifying interfaces, you can modify properties of the channel.

To modify an LACP channel using the command line interface

At the command prompt, type:

- set channel <id> [-ifnum <interfaceName> ...] [-state (ENABLED | DISABLED)] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor (ON | OFF)] [-ifAlias <string>] [-throughput <positive_integer>] [-tagall (ON | OFF)] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]
- show channel

Example

```
> set channel LA/3 -state ENABLED -speed 10000
 Done
```

To modify an LACP channel by using the configuration utility

Navigate to Network > Channels, and modify an existing LACP channel.

Parameter Descriptions (of commands listed in the CLI procedure)

set channel

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show channel

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Removing a Link Aggregation Channel

To remove a link aggregation channel that was created by using LACP, you need to disable LACP on all the interfaces that are part of the channel.

To remove an LACP channel by using the command line interface

At the command prompt, type:

- set interface <id> -lacpMode Disable
- show interface [<id>]

To remove an LACP channel by using the configuration utility

Navigate to Network > Interfaces, open the network interface, and clear the Enable LACP option.

Parameter Descriptions (of commands listed in the CLI procedure)

set interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

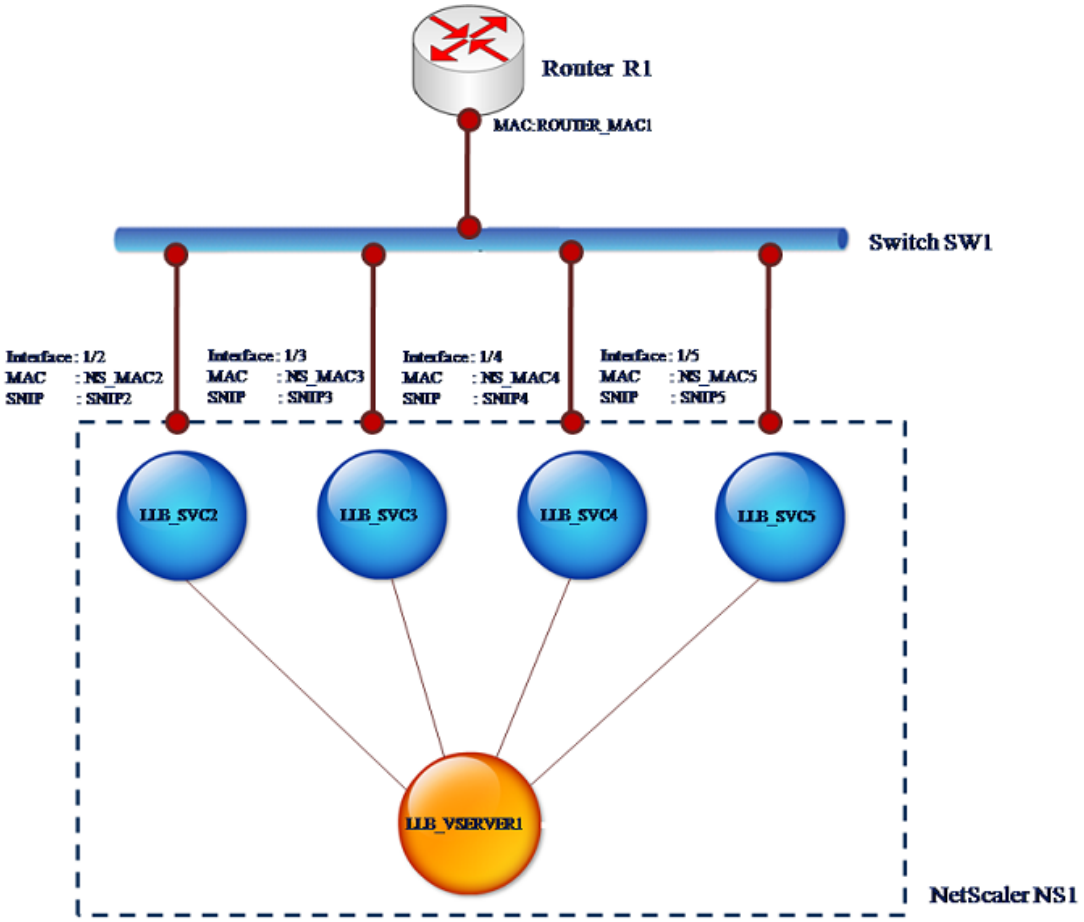
show interface

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Binding an SNIP address to an Interface

You can now bind a NetScaler owned SNIP address to an interface without using Layer 3 VLANs. Any packets related to the SNIP address will go only through the bound interface.

This feature can be useful in a scenario where the upstream switch does not support Link Aggregation channels and you want the NetScaler appliance to load balance traffic, originated from a server, across the four links to the upstream switch as shown in the following illustration.



The following tables describe the example settings for the scenario:

Entity	Name	Value

SNIP addresses on NS1	SNIP2 (for reference purpose only)	10.10.10.2
	SNIP3 (for reference purpose only)	10.10.10.3
	SNIP4 (for reference purpose only)	10.10.10.4
	SNIP5 (for reference purpose only)	10.10.10.5
LLB virtual server on NS1	LLB_VSERVER1	-
Transparent monitor on NS1	TRANS_MON	-
LLB services on NS1	LLB_SVC2	10.10.10.240
	LLB_SVC3	10.10.10.120
	LLB_SVC4	10.10.10.60
	LLB_SVC5	10.10.10.30
MAC address of interface 1/2 on NS1	NS_MAC_2 (for reference purpose only)	00:e0:ed:0f:bc:e0
MAC address of interface 1/3 on NS1	NS_MAC_3 (for reference purpose only)	00:e0:ed:0f:bc:df
MAC address of interface 1/4 on NS1	NS_MAC_4 (for reference purpose only)	00:e0:ed:0f:bc:de
MAC address of interface 1/5 on NS1	NS_MAC_5 (for reference purpose only)	00:e0:ed:1c:89:53
IP address of Router R1	Router_IP (for reference purpose only)	10.10.10.1
MAC address of interface of R1	ROUTER_MAC1 (for reference purpose only)	00:21:a1:2d:db:cc

To configure the example settings

1. Add four different SNIPs in different subnet ranges. This is for ARP to be resolved on four different links. For more information on creating a SNIP address, see "Configuring Subnet IP Addresses (SNIPs)."

   Command Line Interface example

   ```
   > add ns ip 10.10.10.2 255.255.255.0 -type SNIP
    Done
   > add ns ip 10.10.10.3 255.255.255.128 –type SNIP
   Done
   > add ns ip 10.10.10.4 255.255.255.192 –type SNIP
   Done
   > add ns ip 10.10.10.5 255.255.255.224 –type SNIP
   Done
   ```

2. Add four different dummy services in the added SNIP subnets. This is to ensure that the traffic is sent out with source IP as one of the four configured SNIPs. For more information on creating a service, see "Configuring Services."

   Command Line Interface example

   ```
   > add service LLB_SVC2 10.10.10.240 any *
    Done
   > add service LLB_SVC3 10.10.10.120 any *
    Done
   > add service LLB_SVC4 10.10.10.60 any *
    Done
   > add service LLB_SVC5 10.10.10.30 any *
    Done
   ```

3. Add a transparent ping monitor for monitoring the gateway. Bind the monitor to each of the configured dummy services. This is to make the state of the services as UP. For more information on creating a transparent monitor, see "Creating and Binding a Transparent Monitor."

   Command Line Interface example

   ```
   > add monitor TRANS_MON ping -destIP 10.10.10.1 -transparent YES
    Done
   > bind monitor TRANS_MON LLB_SVC2
    Done
   > bind monitor TRANS_MON LLB_SVC3
    Done
   > bind monitor TRANS_MON LLB_SVC4
    Done
   > bind monitor TRANS_MON LLB_SVC5
    Done
   ```

4. Add a link load balancing (LLB) virtual server and bind the dummy services to it. For more information on creating an LLB virtual server, see "Configuring an LLB Virtual Server and Binding a Service."

   Command Line Interface example

   ```
   > add lb vserver LLB_VSERVER1 any
    Done
   > set lb vserver LLB_VSERVER1 -lbmethod ROUNDROBIN
    Done
   > bind lb vserver LLB_VSERVER1 LLB_SVC2
    Done
   > bind lb vserver LLB_VSERVER1 LLB_SVC2
    Done
   > bind lb vserver LLB_VSERVER1 LLB_SVC2
    Done
   > bind lb vserver LLB_VSERVER1 LLB_SVC2
    Done
   ```

5. Add the LLB virtual server as the default LLB route. For more information on creating an LLB route see "Configuring an LLB Route."

   Command Line Interface example

   ```
   > add lb route 0.0.0.0 0.0.0.0  LLB_VSERVER1
    Done
   ```

6. Add an ARP entry for each of the dummy services with the MAC address of the gateway. This way the gateway is reachable through these dummy services. For more information on adding an ARP entry, see "Configuring Static ARP."

   Command Line Interface example

   ```
   > add arp -ipaddress 10.10.10.240 -mac 00:21:a1:2d:db:cc -ifnum 1/2
    Done
   > add arp -ipaddress 10.10.10.120 -mac 00:21:a1:2d:db:cc -ifnum 1/3
    Done
   > add arp -ipaddress 10.10.10.60 -mac 00:21:a1:2d:db:cc -ifnum 1/4
    Done
   > add arp -ipaddress 10.10.10.30 -mac 00:21:a1:2d:db:cc -ifnum 1/5
    Done
   ```

7. Bind a specific interface to an SNIP by adding an ARP entry for each of these SNIPs. This is to ensure that the response traffic will reach the same interface through which the request went out. For more information on adding an ARP entry, see "Configuring Static ARP."

   Command Line Interface example

```
> add arp -ipAddress 10.10.10.2 -mac 00:e0:ed:0f:bc:e0 -ifnum 1/2
 Done
> add arp -ipAddress 10.10.10.3 -mac 00:e0:ed:0f:bc:df -ifnum 1/3
 Done
> add arp -ipAddress 10.10.10.4 -mac 00:e0:ed:0f:bc:de -ifnum 1/4
 Done
> add arp -ipAddress 10.10.10.5 -mac 00:e0:ed:1c:89:53 -ifnum 1/5
 Done
```

Monitoring the Bridge Table and Changing the Aging time

NetScaler appliance bridges frames on the basis of bridge table lookup of the destination MAC address and the VLAN ID. However, the appliance performs forwarding only when Layer 2 mode is enabled.

The bridge table is dynamically generated, but you can display it, modify the aging time for the bridge table, and view bridging statistics.

All the MAC entries in the bridge table are updated with the aging time.

To change the aging time by using the command line interface

At the command prompt, type:

- set bridgetable -bridgeAge <positive_integer>
- show bridgetable

Example

```
> set bridgetable -bridgeage 70
 Done
```

To change the aging time by using the configuration utility

1. Navigate to Network > Bridge Table.
2. Click Change Ageing Time, and set the Ageing Time (seconds) parameter.

To view the statistics of a bridge table by using the command line interface

At the command prompt, type:

stat bridge

To view the statistics of a bridge table by using the configuration utility

Navigate to Network > Bridge Table, select the MAC address, and click Statistics.

Parameter Descriptions (of commands listed in the CLI procedure)

set bridgetable

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show bridgetable

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

stat bridge

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Understanding NetScaler Appliances in Active-Active Mode Using VRRP

An active-active deployment, in addition to preventing downtime, makes efficient use of all the NetScaler appliances in the deployment. In active-active deployment mode, the same VIPs are configured on all NetScaler appliances in the configuration, but with different priorities, so that a given VIP can be active on only one appliance at a time.

Note: This feature is supported only on NetScaler nCore builds.

The active VIP is called the master VIP, and the corresponding VIPs on the other NetScaler appliances are called the backup VIPs. If a master VIP fails, the backup VIP with the highest priority takes over and becomes the master VIP. All the NetScaler appliances in an active-active deployment use the Virtual Router Redundancy Protocol (VRRP) protocol to advertise their VIPs and the corresponding priorities at regular intervals.

NetScaler appliances in active-active mode can be configured so that no NetScaler is idle. In this configuration, different sets of VIPs are active on each NetScaler. For example, in the following diagram, VIP1, VIP2, VIP3, and VIP4 are configured on appliances NS1, NS2, and NS3. Because of their priorities, VIP1 and VIP 2 are active on NS1, VIP3 is active on NS2 and VIP 4 is active on NS3. If, for example, NS1 fails, VIP1 on NS3 and VIP2 on NS2 become active.

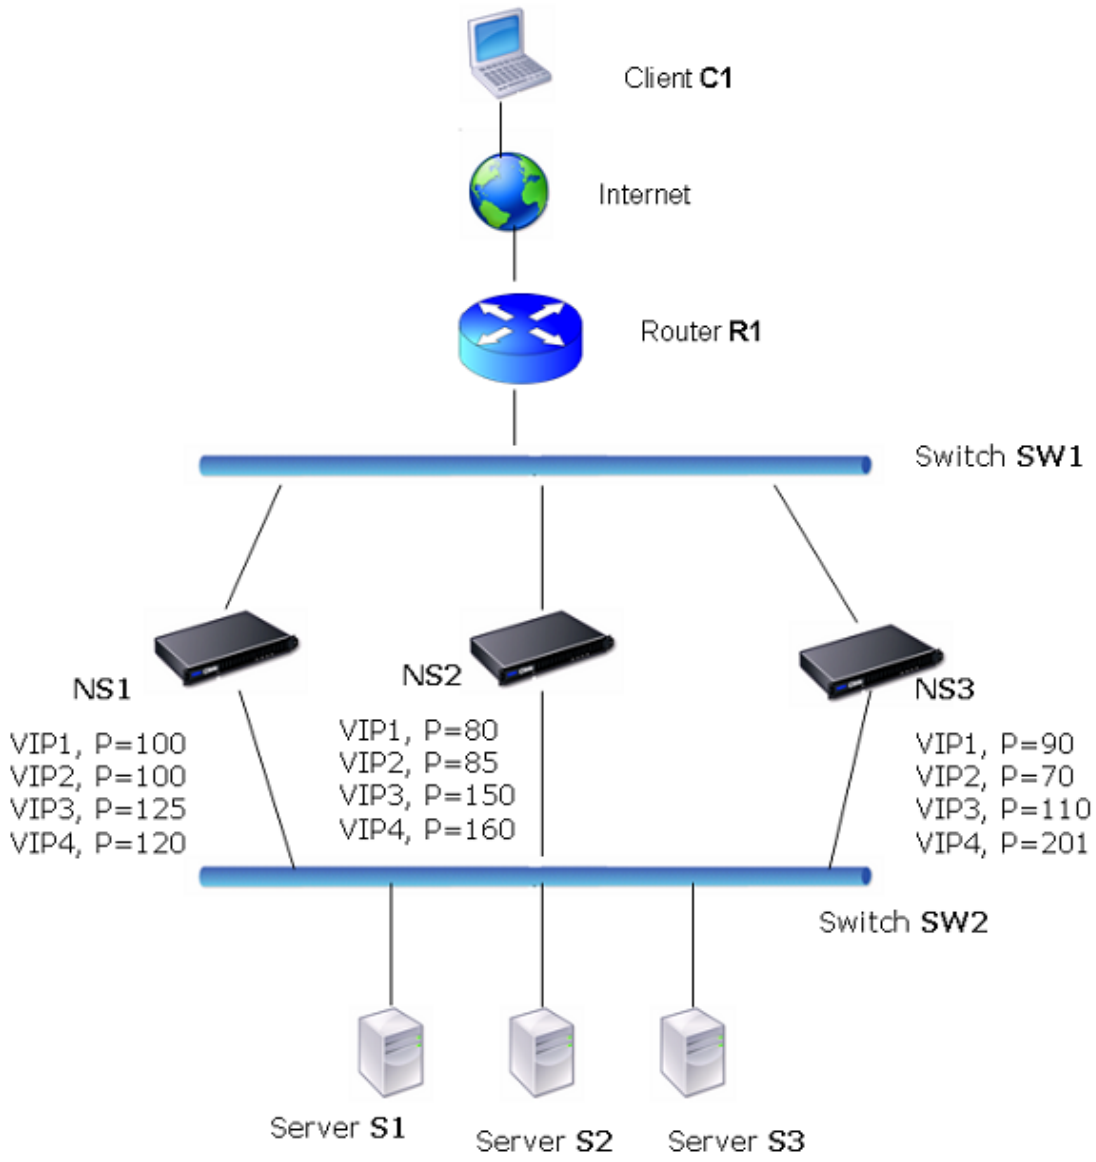


Figure 1. An Active-Active Configuration

The NetScaler appliances in the above diagram process traffic as follows:

1. Client C1 sends a request to VIP1. The request reaches R1.
2. R1 does not have an APR entry for VIP1, so it broadcasts an ARP request for VIP1.
3. VIP1 is active in NS1, so NS1 replies with a source MAC address as the VMAC (for example VMAC1) associated with VIP1, and VIP1 as the source IP address.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table.
5. R1 updates the ARP entry with VMAC1 and VIP1.
6. R1 forwards the packet to the VIP1 on NS1.

7. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP or MIP addresses and S2.

8. S2 replies to the SNIP or MIP on the NetScaler.

9. NS1 sends S2's reply to the client. In the reply, NS1 inserts MAC address of the physical interface as the source MAC address and VIP1 as the source IP address.

10. Should NS1 fail, the NetScaler appliances use the VRRP protocol to select the VIP1 with the highest priority. In this case, VIP1 on NS3 becomes active, and the following two steps update the active-active configuration.

11. NS3 broadcasts a GARP message for VIP1. In the message, VMAC1 is the source MAC address and VIP1 is the source IP address.

12. SW1 learns the new port for VMAC1 from the GARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS3. R1 updates its ARP table.

The priority of a VIP can be modified by health tracking. If you enable health tracking, you should make sure that preemption is also enabled, so that a VIP whose priority is lowered can be preempted by another VIP.

In some situations, traffic might reach a backup VIP. To avoid dropping such traffic, you can enable sharing, on a per-node basis, as you create an active-active configuration. Or you can enable the global send to master option. On a node on which sharing is enabled, it takes precedence over send to master.

Health Tracking

Base priority (BP-range 1-255) ordinarily determines which VIP is the master VIP, but effective priority (EP) can also affect the determination.

For example, if a VIP on NS1 has a priority of 101 and same VIP on NS2 has a priority of 99, the VIP on NS1 is active. However, if two vservers are using the VIP on NS1 and one of them goes DOWN, health tracking can reduce the EP of VIP on NS1. VRRP then makes the VIP on NS2 the active VIP.

Following are the health tracking options for modifying EP:

- **NONE.** No tracking. EP = BP

- **ALL.** If all virtual servers are UP, then EP = BP. Otherwise, EP = 0.

- **ONE.** If at least one virtual server is UP, then EP = BP. Otherwise, EP = 0.

- **PROGRESSIVE.** If ALL virtual servers are UP, then EP = BP. If ALL virtual servers are DOWN then EP = 0. Otherwise EP = BP (1 - K/N), where N is the total number of virtual servers associated with the VIP and k is the number of virtual servers that are down.

Note: If you specify a value other than NONE, preemption should be enabled, so that the backup VIP with the highest priority becomes active if the priority of the master VIP is downgraded.

Preemption

Preemption of an active VIP by another VIP that attains a higher priority is enabled by default, and normally should be enabled. In some cases, however, you may want to disable it. Preemption is a per-node setting for each VIP.

Preemption can occur in the following situations:

- An active VIP goes down and a VIP with a lower priority takes its place. If the VIP with the higher priority comes back online, it preempts the currently active VIP.
- Health tracking causes the priority of a backup VIP to become higher than that of the active VIP. The backup VIP then preempts the active VIP.

Sharing

In the event that traffic reaches a backup VIP, the traffic is dropped unless the sharing option is enabled on the backup VIP. This behavior is a per node setting for each VIP and is disabled by default.

In the figure "An Active-Active Configuration," VIP1 on NS1 is active and VIP1 VIPs on NS2 and NS3 are backups. Under certain circumstances, traffic may reach VIP1 on NS2. If Sharing is enabled on NS2, this traffic is processed instead of dropped.

Configuring Active-Active Mode

On each NetScaler appliance that you want to deploy in active-active mode, you must add a VMAC and bind the VMAC to a VIP. The VMAC for a given VIP must be same on each appliance. For example, if VIP 10.102.29.5, is created on the appliances, a virtual router ID must be created on each NetScaler and bound to VIP 10.102.29.5 on each NetScaler. When you bind a VMAC to a VIP, the NetScaler sends VRRP advertisements to each VLAN that is bound to that VIP. The VMAC can be shared by different VIPs configured on the same NetScaler.

Adding a VMAC

To add a VMAC for an active-active configuration, you create a virtual router ID. To bind a VMAC to a VIP, you associate the VMAC's virtual router ID with the VIP.

To add a VMAC by using the command line interface

At the command prompt, type:

add vrID <value> -priority <value> -preemption (ENABLED|DISABLED) -sharing (ENABLED | DISABLED) -tracking (NONE|ONE|ALL|PROGRESSIVE)

Example

add vrID 125 -priority 100 -sharing ENABLED -tracking ONE

To add a VMAC by using the configuration utility

1. Navigate to Network > VMAC, on the VMAC tab, add a new VMAC, or edit an existing VMAC.
2. Set the following parameters:
   - Virtual Router ID
   - Priority
   - Tracking
   - Preemption
   - Sharing

To bind a VMAC by using the command line interface

At the command prompt, type:

set ns ip <VIP address> -vrid <value>

Example

```
set ns ip 10.102.29.5 -vrid 125
```

To bind a VMAC to a VIP by using the NetScaler configuration utility

1. Navigate to Network > IPs, on the IPV4s tab, open the VIP address that you want to bind to a VMAC.
2. In the Virtual Router Id drop down box, select a virtual router ID.

Parameter Descriptions (of commands listed in the CLI procedure)

add vrID

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

set ns ip

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Send to Master

Usually, the traffic destined to a VIP reaches the NetScaler appliance on which the VIP is active, because an ARP request with the VIP and a VMAC on that appliance has reached the upstream router. But in some cases, such as static routes configured on the upstream router for the VIP subnet, or a topology that blocks this route, the traffic can reach a NetScaler appliance on which the VIP is in backup state. If you want this appliance to forward the data packets to the appliance on which the VIP is active, you need to enable the send to master option. This behavior is a per node setting and is disabled by default.

For example, in the following diagram, VIP1 is configured on NS1, NS2, and NS3 and is active on NS1. Under certain circumstances, traffic for VIP1 (active on NS1) may reach VIP1 on NS3. When the send to master option is enabled on NS3, NS3 forwards the traffic to NS1 through NS2 by using route entries for NS1.

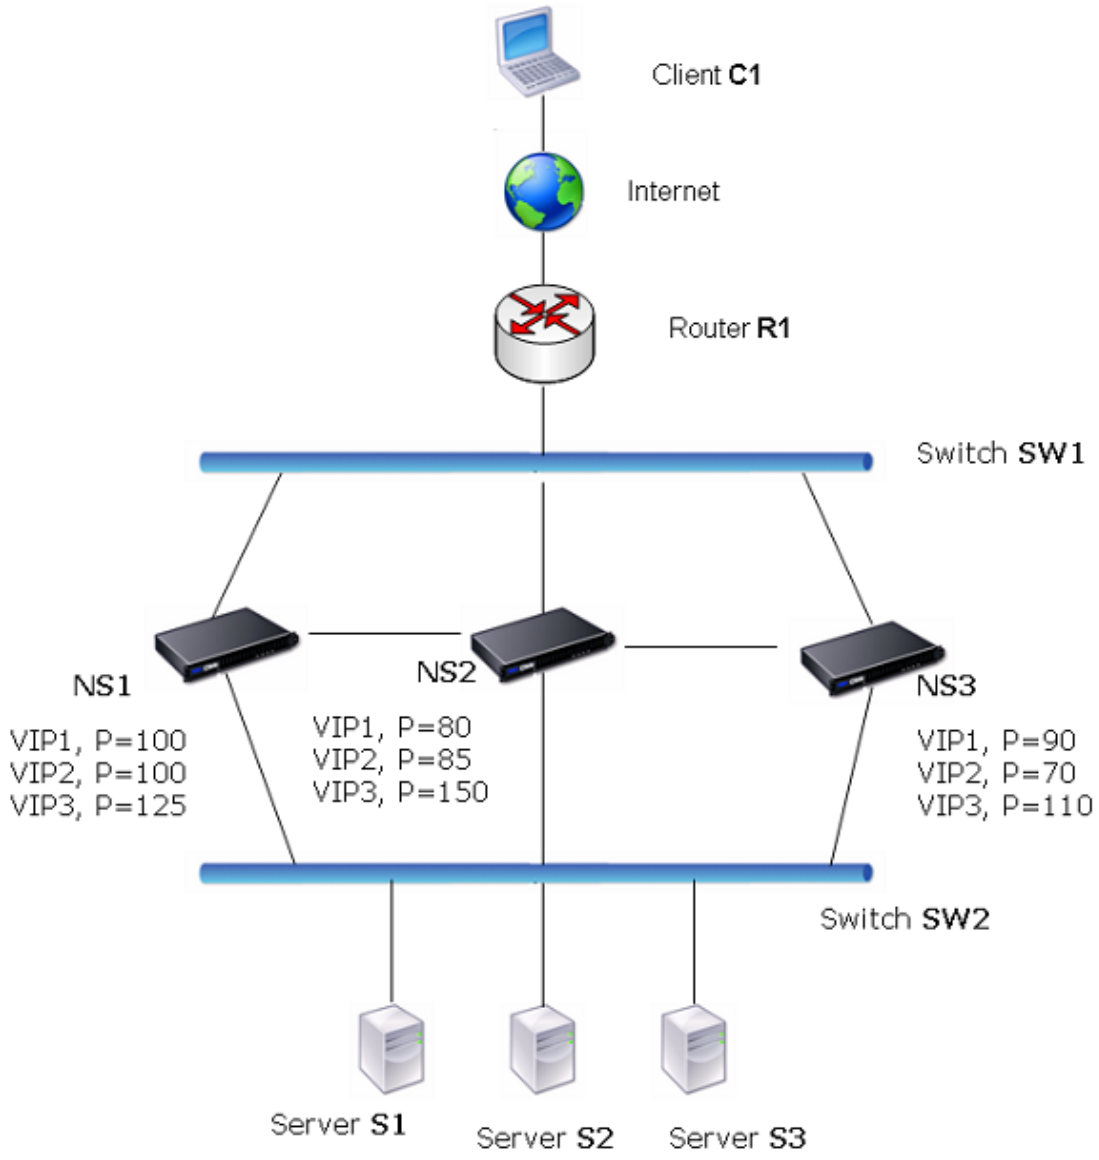

Figure 1. An Active-Active Configuration with Send to Master Option Enabled

To enable send to master by using the command line interface

At the command prompt, type:

set vrIDParam -sendToMaster (ENABLED|DISABLED)

Example

```
> set vrIDParam -sendToMaster ENABLED
 Done
```

To enable send to master by using the configuration utility

1. Select the Send to Master option.

Parameter Descriptions (of commands listed in the CLI procedure)

set vrIDParam

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

An Active-Active Deployment Scenario

Following is an example of a possible active-active deployment scenario.

In the following diagram, VIP1, VIP 2 and VIP3 are configured on all three appliances, NS1, NS2, and NS3. Base Priorities for each VIPs are as shown in the diagram. Health tracking is disabled for each VIP. The priorities of VIPs are set so that VIP1, VIP2, and VIP3 are active on NS3. If NS3 fails, VIP1, VIP2, and VIP3 become active on NS1.

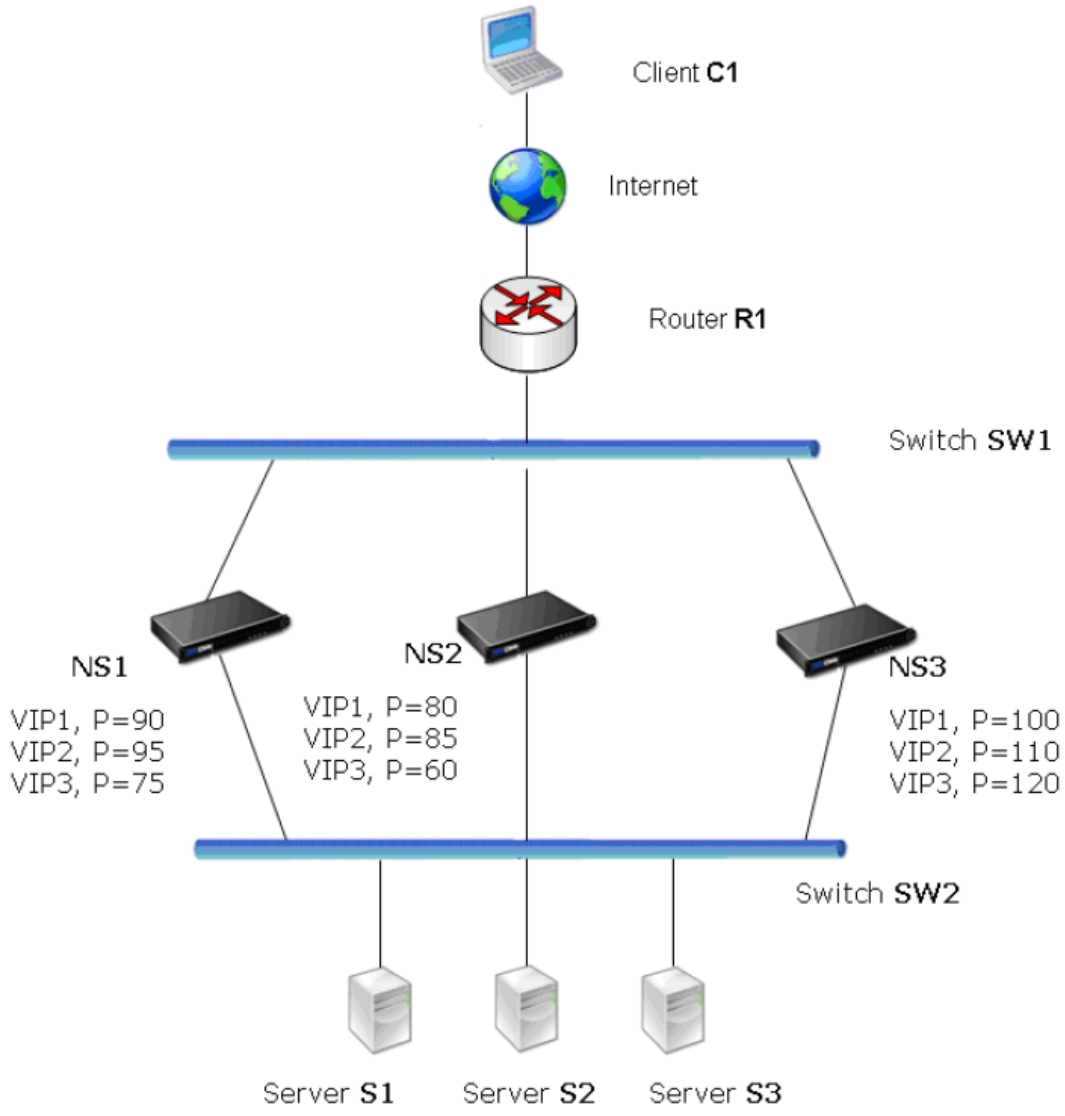

Figure 1. An Active-Active Deployment Scenario

Using the Network Visualizer

The Network Visualizer is a tool that you can use to view the network configuration of a NetScaler node, including the network configuration of the nodes in a high availability (HA) deployment. You can also modify the configuration of VLANs, interfaces, channels, and bridge groups, and perform HA configuration tasks.

In an HA deployment, you can both view and configure network entities on the node to which you are logged on, but you can view the details of only the network entities that are configured on the peer node. However, you can perform certain tasks, such as viewing details and statistics of the peer node and forcing a failover.

When you are logged on to a standalone appliance, you can use the Network Visualizer to do the following:

- View a consolidated graphical summary of key network components, such as VLANs, interfaces, channels, and bridge groups. You can also view the individual details of various network components.
- Modify appliance settings.
- Add, modify, and enable and disable interfaces and channels that are configured on the NetScaler appliance.
- Add and modify VLANs and bridge groups.
- Configure an HA deployment (add a node).
- View node details, node statistics, and statistics for VLANs and interfaces.
- Copy the properties of a network entity to a document or spreadsheet.

When you are logged on to an appliance in an HA deployment, you can perform the above tasks only on the appliance to which you are logged on. Following are additional tasks that you can perform in the Network Visualizer when you are logged on to one of the appliances in an HA pair:

- View the configuration details and high availability details of both nodes in an HA pair.
- Perform HA configuration tasks, such as synchronization and force failover.
- Remove the peer node from the HA configuration.
- View statistics for the peer node.
- Copy the properties of the peer node to a document or spreadsheet.

To open the Network Visualizer

1. In the navigation pane, expand Network.
2. In Monitor Connections, click Network Visualizer.

To locate a VLAN or bridge group in the Visualizer

1. Open the Network Visualizer, and then do the following:
   - To locate a VLAN or bridge group, in the Search text field, begin typing the ID of the VLAN or the bridge group that you want to locate.

     Alternatively, begin typing the IP address of a bound subnet or the ID of a bound interface. The VLANs or bridge groups whose names match the typed characters are highlighted.

     To highlight multiple entities simultaneously, separate the IDs and IP addresses with white spaces. Entities whose IDs or IP addresses match any of the typed IDs and IP addresses are highlighted.
   - To clear the Search field, click the x adjacent to the field.

To modify the network settings of the appliance by using the Visualizer

1. Open the Network Visualizer and click the icon representing the appliance to which you are logged on.
2. In Related Tasks, click Open.

To add a channel by using the Visualizer

1. Open the Network Visualizer and click a network interface.
2. In Related Tasks, click Add Channel.

To add a VLAN by using the Visualizer

1. Open the Network Visualizer, click the appliance to which you are logged on, and then do one of the following:
   - Click an existing VLAN, and then, in Related Tasks, click Add.
   - Click an existing bridge group, and then, in Related Tasks, click Add VLAN.

To add a bridge group by using the Visualizer

1. Open the Network Visualizer, click the appliance to which you are logged on, and then do one of the following:

   - Click an existing bridge group, and then, in Related Tasks, click Add.
   - Click an existing VLAN, and then, in Related Tasks, click Add Bridge Group.

To modify the settings of an interface or channel by using the Visualizer

1. Open the Network Visualizer and click the interface whose settings you want to modify.
2. In Related Tasks, click Open.

To enable or disable an interface or channel by using the Visualizer

1. Open the Network Visualizer and click the interface or channel that you want to enable or disable.
2. In Related Tasks, do one of the following.

   - To enable the interface or channel, click Enable.
   - To disable the interface or channel, click Disable.

To remove a configured channel, VLAN, or bridge group by using the Visualizer

1. Open the Network Visualizer and click the channel, VLAN, or bridge group that you want to remove from the configuration.
2. In Related Tasks, click Remove.

To view statistics for a node, channel, interface, or VLAN by using the Visualizer

1. Open the Network Visualizer and click the node, interface, or VLAN whose statistics you want to view.
2. In Related Tasks, click Statistics.

To set up an HA deployment by using the Visualizer

1. Open the Network Visualizer and click the appliance.
2. In Related Tasks, click HA Setup.

To force the secondary node to take over as the primary by using the Visualizer

1. Open the Network Visualizer and click one of the nodes.
2. In Related Tasks, click Force Failover.

To synchronize the secondary node's configuration with the primary node by using the Visualizer

1. Open the Network Visualizer and click one of the nodes.
2. In Related Tasks, click Force Synchronization.

To remove the peer node from the HA configuration

1. Open the Network Visualizer and click the peer node.
2. In Related Tasks, click Remove.

To copy the properties of a node or network entity by using the Visualizer

1. Open the Network Visualizer and click the appliance or network entity whose properties you want to copy to a document or spreadsheet.
2. In Related Tasks, click Copy Properties.

Access Control Lists

Access Control Lists (ACLs) filter IP traffic and secure your network from unauthorized access. An ACL consists of a set of conditions that the NetScaler® appliance uses to allow or deny access. Consider a small organization that consists of 3 departments, Finance, HR, and Documentation, where no department wants another to access its data. The administrator of the organization can configure ACLs on the NetScaler to allow or deny access. When the NetScaler receives a data packet, it compares the information in the data packet with the conditions specified in the ACL and allows or denies access. The NetScaler supports simple ACLs, extended ACLs, and ACL6s. If both simple and extended ACLs are configured, incoming packets are compared to the simple ACLs first.

Simple ACLs filter packets on the basis of their source IP address and, optionally, their destination port and/or their protocol. Any packet that has the characteristics specified in the ACL is dropped. You can create up to 200,000 simple ACLs.

Extended ACLs filter data packets on the basis of various parameters, such as source IP address, source port, action, and protocol. An extended ACL defines the conditions that a packet must satisfy for the NetScaler to process the packet, bridge the packet, or drop the packet. These actions are known as "processing modes." You can create up to 10,000 extended ACLs.

The processing modes are:

- ALLOW - The NetScaler processes the packet.
- BRIDGE - The NetScaler bridges the packet to the destination without processing it.
- DENY - The NetScaler drops the packet.

The NetScaler processes an IP packet directly when both of the following conditions exist:

- ACLs are configured on the NetScaler.
- The IP packet does not match any of the ACLs.

Simple ACL6s filter IPv6 packets on the basis of their source IPv6 address and, optionally, their destination port and/or their protocol. Any packet that has the characteristics specified in the simple ACL6 is dropped. You can create up to 200,000 simple ACL6s.

ACL6s are ACLs created specifically for IPv6 addresses. ACL6s filter packets on the basis of packet parameters, such as source IP address, source port, action, and so on. An ACL6 defines the condition that a packet must satisfy for the NetScaler to process the packet, bridge the packet, or drop the packet. These actions are known as "processing modes." You can create up to 8,000 ACL6s.

The processing modes are:

- ALLOW - The NetScaler processes the packet.
- BRIDGE - The NetScaler bridges the packet to the destination without processing it.

- DENY - The NetScaler drops the packet.

The NetScaler processes an IP packet directly when both of the following conditions exist:

- ACL6s are configured on the NetScaler.
- The IP packet does not match any of the ACL6s.

ACL Precedence

An IPv4 packet that matches the conditions specified in a simple ACL is dropped. If the packet does not match any simple ACL, the NetScaler compares the packet's characteristics to those specified in any configured extended ACLs. If the packet matches an extended ACL, the NetScaler applies the action specified in the Extended ACL, as shown in the following diagram.

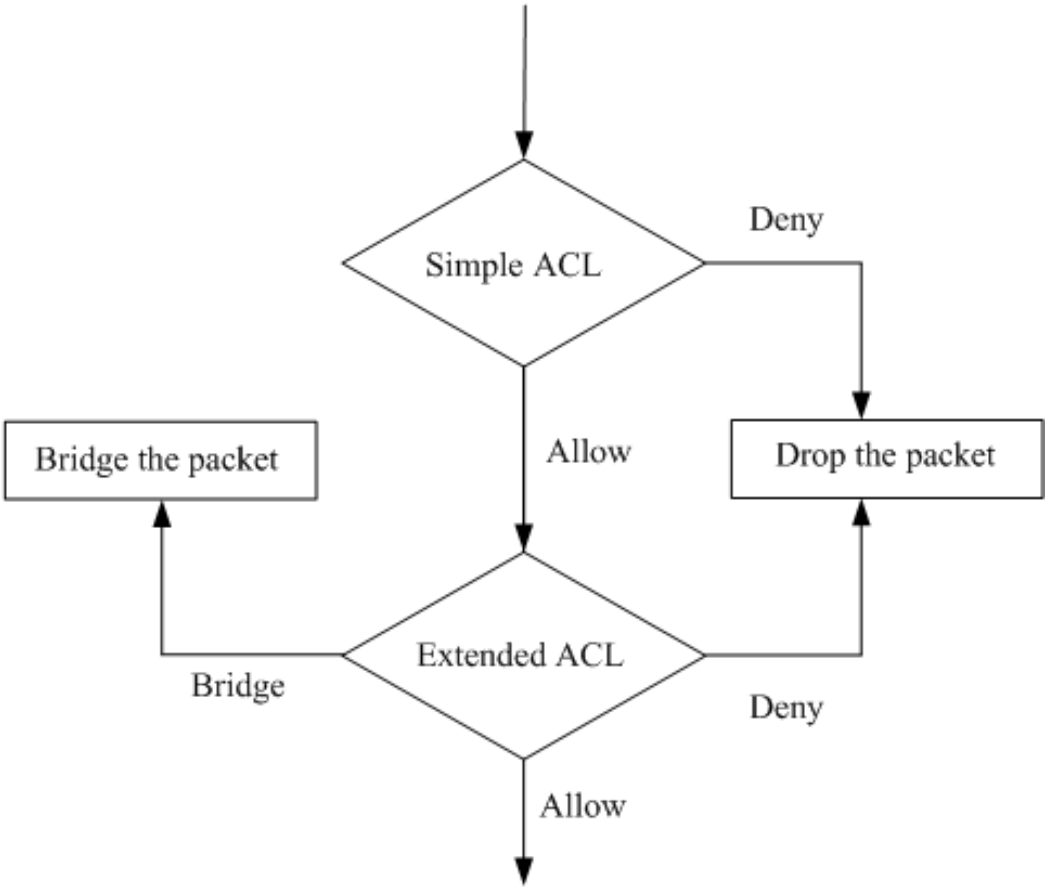

Figure 1. Simple and Extended ACLs Flow Sequence

IPv6 packets are compared only to ACL6s.

Configuring Simple ACLs

A simple ACL, which uses few parameters, cannot be modified once created. When creating a simple ACL, you can specify a time to live (TTL), in seconds, after which the ACL expires. ACLs with TTLs are not saved when you save the configuration. You can also remove a simple ACL manually. You can display simple ACLs to verify their configuration, and you can display statistics to monitor their performance.

Creating Simple ACLs

Use either of the following procedures to create a simple ACL.

To create a simple ACL by using the command line interface

At the command prompt, type the following commands to add an ACL and verify the configuration:

- add ns simpleacl <aclname> DENY -srcIP <ip_addr> [-destPort<port> -protocol (TCP | UDP)] [-TTL <positive_integer>]
- show ns simpleacl [<aclname>]

Example

```
> add simpleacl rule1 DENY -srcIP 10.102.29.5 -TTL 600
 Done
```

To create a simple ACL by using the configuration utility

Navigate to Network > ACLs and, on the Simple ACLs tab, add a new simple ACL.

Parameter Descriptions (of commands listed in the CLI procedure)

add ns simpleacl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns simpleacl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Monitoring Simple ACLs

You can display the simple ACL statistics, which include the number of hits, the number of misses, and the number of simple ACLs configured.

To view simple ACL statistics by using the command line interface

At the command prompt, type:

stat ns simpleacl

Example

```
>stat ns simpleacl

                        Rate (/s)          Total
Deny SimpleACL hits           0                0
SimpleACL hits                0                0
SimpleACL misses              0               11
SimpleACLs count             --                1
 Done
```

The following table describes statistics you can display for simple ACLs.

Table 1. Simple ACL Statistics

Statistic	Indicates
Deny SimpleACL hits	Packets dropped because they match deny simple ACL
SimpleACL hits	Packets matching a simple ACL
SimpleACL misses	Packets not matching any simple ACL
SimpleACL count	Number of simple ACLs configured

To display simple ACL statistics by using the configuration utility

Navigate to Network > ACLs, on the Simple ACLs tab, select the ACL, and click Statistics.

Parameter Descriptions (of commands listed in the CLI procedure)

stat ns simpleacl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Removing Simple ACLs

If you need to modify a simple ACL, you must remove it and create a new one.

To remove a single simple ACL by using the command line interface

At the command prompt, type:

- rm ns simpleacl <aclname>
- show ns simpleacl

To remove all simple ACLs by using the command line interface

At the command prompt, type:

- clear ns simpleacl
- show ns simpleacl

To remove a single simple ACL by using the configuration utility

Navigate to Network > ACLs and, on the Simple ACLs tab, delete the simple ACL.

To remove all simple ACLs by using the configuration utility

Navigate to Network > ACLs and, on the Simple ACLs tab, click Clear.

Parameter Descriptions (of commands listed in the CLI procedure)

rm ns simpleacl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns simpleacl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

clear ns simpleacl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Extended ACLs

To configure extended ACLs, many users first create extended ACLs and then modify them.

For any of the following actions to take effect, they must be applied, by clicking the Commit button:

- Activate
- Remove
- Disable
- Change the Priority

Other actions include:

- Configure logging
- Verify the configuration
- Monitor ACL statistics

Note: If you configure both simple and extended ACLs, simple ACLs take precedence over extended ACLs.

Parameters of Extended ACLs can be configured during creation. Additionally, the following actions can be performed on Extended ACLs: Modify, Remove, Apply, Disable, Enable and Renumber the priority of Extended ACLs.

You can collect statistics of packets using Extended ACLs by enabling logging.

Creating and Modifying an Extended ACL

To create an extended ACL by using the command line interface

At the command prompt, type:

- add ns acl <aclname> <aclaction> [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-TTL <positive_integer>] [-srcMac <mac_addr>] [(-protocol <protocol> [-established]) | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-icmpType <positive_integer> [-icmpCode <positive_integer>]] [-priority <positive_integer>] [-state (ENABLED | DISABLED)] [-logstate (ENABLED | DISABLED) [-ratelimit <positive_integer>]]

- show ns acl [<aclname>]

Example

```
> add ns acl restrict DENY -srcport 45-1024 -destIP 192.168.1.1 -protocol TCP
 Done
```

To configure an extended ACL by using the configuration utility

Navigate to Network > ACLs and, on the Extended ACLs tab, add a new extended ACL, or edit an existing extended ACL.

Parameter Descriptions (of commands listed in the CLI procedure)

add ns acl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns acl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Applying an Extended ACL

After you create or modify an extended ACL, you must activate it by using one of the following procedures. These procedures reapply all the ACLs.

For example, if you have created the ACLs rule1 through rule10, and then you create an ACL called rule11, and apply it, all of the ACLs (rule1 through rule11) are applied afresh.

If a session has a DENY ACL related to it, that session is terminated.

To apply an ACL by using the command line interface

At the command prompt, type:

- apply ns acls
- show ns acl

To apply an ACL by using the configuration utility

1. Navigate to Network > ACLs.
2. On the Extended ACLs tab, click Apply.

Parameter Descriptions (of commands listed in the CLI procedure)

apply ns acls

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns acl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Disabling and Enabling Extended ACLs

By default, ACLs are enabled. This means when ACLs are applied, the NetScaler appliance compares incoming packets against the ACLs.

Disable an ACL if it will not be used for a certain period. After the ACLs are applied, the NetScaler does not compare incoming packets against disabled ACLs.

To disable or enable an extended ACL by using the command line interface

At the command prompt, type one of the following pairs of commands to disable or enable an ACL and verify the result:

- disable ns acl <aclname>
- show ns acl [<aclname>]
- enable ns acl <aclname>
- show ns acl [<aclname>]

Example

```
> disable ns acl restrict
 Done

> show ns acl restrict
        Name: restrict                  Action: DENY     Hits: 0
        srcIP
        destIP = 192.168.1.1
        srcMac:                      Protocol: TCP
        srcPort =  45-1024               destPort
        Vlan:                        Interface:
        Active Status: DISABLED             Applied Status: NOTAPPLIED
        Priority: 10                 NAT: NO
        TTL:
        Log Status: DISABLED
 Done

> enable ns acl restrict
 Done

> show ns acl restrict
        Name: restrict                  Action: DENY     Hits: 0
        srcIP
        destIP = 192.168.1.1
```

```
        srcMac:                     Protocol: TCP
        srcPort =  45-1024             destPort
        Vlan:                      Interface:
        Active Status: ENABLED             Applied Status: APPLIED
        Priority: 10                NAT: NO
        TTL:
        Log Status: DISABLED
Done
```

To disable or enable an extended ACL by using the configuration utility

1. Navigate to Network > ACLs.
2. On the Extended ACLs tab, select the extended ACL, and click Enable or Disable.

Parameter Descriptions (of commands listed in the CLI procedure)

disable ns acl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns acl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

enable ns acl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Renumbering the priority of Extended ACLs

The renumber procedure resets the priorities of the ACLs to multiples of 10. The priority (an integer value) defines the order in which the NetScaler appliance evaluates ACLs. All priorities are multiples of 10, unless you configure a specific priority to an integer value. When you create an ACL without specifying a priority, the NetScaler automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the ACL, the NetScaler performs an action. If the packet does not match the condition defined by the ACL, the NetScaler compares the packet against the ACL with the next-highest priority.

Consider the following example. Two ACLs, rule1 and rule2, are automatically assigned priorities 20 and 30 when they are created. You need to add a third ACL, rule3, to be evaluated immediately after rule1. Rule3 must have a priority between 20 and 30. In this case, you can specify the priority as 25. Later, you can easily renumber the ACLs with priorities that are multiples of 10, without affecting the order in which the ACLs are applied.

To renumber the ACLs by using the command line interface

At the command prompt, type:

renumber ns acls

To renumber the ACLs by using the configuration utility

Navigate to Network > ACLs and, on the Extended ACLs tab, click Renumber Priority (s).

Parameter Descriptions (of commands listed in the CLI procedure)

renumber ns acls

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Extended ACL Logging

You can configure the NetScaler appliance to log details for packets that match an extended ACL. In addition to the ACL name, the logged details include packet-specific information such as the source and destination IP addresses. The information is stored either in the syslog file or in the nslog file, depending on the type of global logging (syslog or nslog) enabled.

Logging can be enabled at both the global level and the ACL level. The global setting takes precedence.

For more information about enabling logging globally, see "Audit Logging."

To optimize logging, when multiple packets from the same flow match an ACL, only the first packet's details are logged, and the counter is incremented for every packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the following parameters:

- Source IP address
- Destination IP address
- Source port
- Destination port
- Protocol

If the packet is not from the same flow, or if the time duration is beyond the meantime, a new flow is created. Mean time is the time during which packets of the same flow do not generate additional messages (although the counter is incremented).

Note: The total number of different flows that can be logged at any given time is limited to 10,000.

To configure ACL Logging by using the command line interface

At the command prompt, type the following commands to configure logging and verify the configuration:

- set ns acl <aclName> [-logState (ENABLED | DISABLED)] [-rateLimit <positive_integer>]
- show ns acl [<aclName>]

Example

```
> set ns acl restrict -logstate ENABLED -ratelimit 120
Warning: ACL modified, apply ACLs to activate change

> apply ns acls
Done
```

To configure ACL Logging by using the configuration utility

1. Navigate to Network > ACLs and, on the Extended ACLs tab, open the extended ACL.
2. Set the following parameters:
   - Log State
   - Log Rate Limit

Parameter Descriptions (of commands listed in the CLI procedure)

set ns acl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns acl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Monitoring the Extended ACL

You can display statistics for monitoring the performance of an extended ACL.

To display the statistics of an extended ACL by using the command line interface

At the command prompt, type:

stat ns acl

Example

```
>stat ns acl rule1

ACL: rule1
                          Rate (/s)          Total
Hits for this ACL                 0              0
 Done
```

The following table lists the statistics associated with extended ACLs and their descriptions.

Table 1. Extended ACL Statistics

Statistic	Specifies
Allow ACL hits	Packets matching ACLs with processing mode set to ALLOW. NetScaler processes these packets.
NAT ACL hits	Packets matching a NAT ACL, resulting in a NAT session.
Deny ACL hits	Packets dropped because they match ACLs with processing mode set to DENY.
Bridge ACL hits	Packets matching a bridge ACL, which in transparent mode bypasses service processing.
ACL hits	Packets matching an ACL.
ACL misses	Packets not matching any ACL.

To display the statistics of an extended ACL by using the configuration utility

Navigate to Network > ACLs, on the Extended ACLs tab, select the extended ACL, and click Statistics.

Parameter Descriptions (of commands listed in the CLI procedure)

stat ns acl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Removing Extended ACLs

You can remove a single extended ACL or all extended ACLs.

To remove a single extended ACL by using the command line interface

At the command prompt, type:

- rm ns acl <aclName>
- show ns acl

To remove all extended ACLs by using the command line interface

At the command prompt, type:

- clear ns acls
- show ns acl

To remove a single extended ACL by using the configuration utility

Navigate to Network > ACLs and, on the Extended ACLs tab, delete the extended ACL.

To remove all extended ACLs by using the configuration utility

Navigate to Network > ACLs and, on the Extended ACLs tab, click Clear.

Parameter Descriptions (of commands listed in the CLI procedure)

rm ns acl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns acl

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

clear ns acls

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Simple ACL6s

A simple ACL6, which uses few parameters, cannot be modified once created. Instead, you must remove the simple ACL6 and create a new one. When creating a simple ACL6, you must specify its name, and a source IP address value against which to match packets. Optionally, you can specify a destination port and a time to live (TTL) value. A TTL is the number of seconds after which the simple ACL6 expires. ACL6s with TTLs are not saved when you save the configuration. Simple ACL6s can traverse the extension headers (if present) of all the incoming IPv6 packets to identify the layer 4 protocol and take a specified action.

Creating Simple ACL6s

To create a simple ACL6, you must specify its name and source IP address. You can also specify a destination port and time to live (TTL).

To create a simple ACL6 by using the command line interface

At the command prompt, type the following commands to create a simple ACL6 and verify the configuration:

- add ns simpleacl6 <aclname> DENY -srcIPv6 <ipv6_addr|null> [-destPort<port> -protocol (TCP | UDP)] [-TTL <positive_integer>]
- show ns simpleacl6 [<aclname>]

Example

> add ns simpleacl6 rule1 DENY –srcIPv6 3ffe:192:168:215::82 -destPort 80 -Protocol TCP -TTL 9000
Done

To create a simple ACL6 by using the configuration utility

Navigate to Network > ACLs and, on the Simple ACL6s tab, add a new simple ACL6.

To remove a single simple ACL6 by using the command line interface

At the command prompt, type:

- rm ns simpleacl6 <aclname>

- show ns simpleacl6

To remove all simple ACL6s by using the command line interface

At the command prompt, type:

- clear ns simpleacl6
- show ns simpleacl6

To remove one or all simple ACL6s by using the configuration utility

1. Navigate to Network > ACLs.
2. Do one of the following:
   - On the Simple ACL6s tab, select the simple ACL6, and delete it.
   - To remove all simple ACL6s, click Clear.

Monitoring Simple ACL6s

You can display the following simple ACL6 statistics:

Table 1. Simple ACL6 Statistics

Statistic	Indicates
Deny simpleACL6 hits	Packets dropped because they match a simple deny ACL6
Simple ACL6 hits	Packets matching a simple ACL6
Simple ACL6 misses	Packets not matching any simple ACL6
Simple ACL6 count	Number of simple ACL6s configured

To display simple ACL6 statistics by using the command line interface

At the command prompt, type:

stat ns simpleacl6

To display simple ACL6 statistics by using the configuration utility

Navigate to Network > ACLs, on the Simple ACL6s tab, select the simple ACL6, and click Statistics.

Parameter Descriptions (of commands listed in the CLI procedure)

add ns simpleacl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

rm ns simpleacl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

clear ns simpleacl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns simpleacl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

stat ns simpleacl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring ACL6s

ACL6s can be configured during creation. Additionally, the following actions can be performed on ACL6s: Modify, Apply, Disable, Enable, Renumber and Remove the priority of ACL6s. Log files of ACL6s can be configured to collect statistics of packets. If a packet matches the condition defined by the ACL6, the NetScaler performs an action. If the packet does not match the condition defined by the ACL6, the NetScaler compares the packet against the ACL6 with the next-highest priority. ACL6s can traverse the extension headers (if present) of all the incoming IPv6 packets to identify the layer 4 protocol and take a specified action.

Creating and Modifying ACL6s

To create an ACL6 by using the command line interface

At the command prompt, type:

- add ns acl6 <acl6name> <acl6action> [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>] [-TTL <positive_integer>] [-srcMac <mac_addr>] [(-protocol <protocol> [-established]) | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-icmpType <positive_integer> [-icmpCode <positive_integer>]] [-priority <positive_integer>] [-state (ENABLED | DISABLED)]

- show ns acl6 [<acl6name>]

Example

Example
> add ns acl6 rule6 DENY -srcport 45-1024 -destIPv6 2001::45 -protocol TCP
 Done

To modify or remove an ACL6 by using the command line interface

- To modify an ACL6, type the set ns ACL6 command, the name of the ACL6, and the parameters to be changed, with their new values.

- To remove an ACL6, type the rm ns ACL6 command and the name of the <entity>.

To configure an ACL6 by using the configuration utility

Navigate to Network > ACLs and, on the ACL6s tab, add a new ACL6, or edit an existing ACL6.

Parameter Descriptions (of commands listed in the CLI procedure)

add ns acl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns acl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Applying ACL6s

After you create an ACL6, you must activate it. The following procedures reapply all the ACL6s.

For example, if you have created the ACL6s rule1 through rule10, and then you create an ACL6 called rule11 and apply it, all of the ACL6s (rule1 through rule11) are applied afresh.

If a session has a DENY ACL related to it, the session is destroyed.

You must apply one of the following procedures after every action you perform on an ACL6 (for example, after disabling an ACL6). However, you can add or modify more than one ACL6 and apply all of them at the same time.

Note: ACL6s created on the NetScaler do not work until they are applied.

To apply ACL6s by using the command line interface

At the command prompt, type:

apply ns acls6

To apply ACL6s by using the configuration utility

1. Navigate to Network > ACLs.
2. On the ACL6s tab, click Apply.

Parameter Descriptions (of commands listed in the CLI procedure)

apply ns acls6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Enabling and Disabling ACL6s

By default, ACL6s are enabled. Therefore, after the ACL6s are applied, the NetScaler appliance compares incoming packets against the configured ACL6s.

If an ACL6 is not required to be part of the lookup table but needs to be retained in the configuration, it must be disabled before the ACL6s are applied. After the ACL6s are applied, the NetScaler does not compare incoming packets against disabled ACL6s.

To disable or enable an ACL6 by using the command line interface

At the command prompt, type:

- enable ns acl6 <acl6name>
- show ns acl6 [<acl6name>]
- disable ns acl6 <acl6name>
- show ns acl6 [<acl6name>]

Note: ACL6s created on the NetScaler do not work until they are applied.

Example

```
> enable ns acl6 rule6
 Done

> show ns acl6 rule6
      Name: rule6                    Action: DENY
      srcIPv6
      destIPv6 = 2001::45
      srcMac:                      Protocol: TCP
      srcPort =  45-1024               destPort
      Vlan:                       Interface:
      Active Status: ENABLED             Applied Status: NOTAPPLIED
      Priority: 10                 Hits: 0
      TTL:
 Done

> disable ns acl6 rule6
 Done

> show ns acl6 rule6
      Name: rule6                    Action: DENY
      srcIPv6
```

```
        destIPv6 = 2001::45
        srcMac:                      Protocol: TCP
        srcPort =  45-1024               destPort
        Vlan:                       Interface:
        Active Status: DISABLED            Applied Status: NOTAPPLIED
        Priority: 10                Hits: 0
        TTL:
Done
```

To disable or enable an ACL6 by using the configuration utility

1. Navigate to Network > ACLs.
2. On the ACL6s tab, select the ACL6, and click Enable or Disable.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ns acl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns acl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

disable ns acl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Renumbering the Priority of ACL6s

The renumber procedure resets the priorities of the ACL6s to multiples of 10. The priority (an integer value) defines the order in which the NetScaler appliance evaluates ACL6s. All priorities are multiples of 10, unless you configure a specific priority to an integer value. When you create an ACL6 without specifying a priority, the NetScaler automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the ACL6, the NetScaler performs an action. If the packet does not match the condition defined by the ACL6, the NetScaler compares the packet against the ACL6 with the next-highest priority.

Consider the following example. Two ACL6s, rule1 and rule2, are automatically assigned priorities 20 and 30 when they are created. You need to add a third ACL, rule3, to be evaluated immediately after rule1. Rule3 must have a priority between 20 and 30. In this case, you can specify the priority as 25. Later, you can easily renumber the ACL6s with priorities that are multiples of 10, without affecting the order in which the ACL6s are applied.

To renumber the priorities of the ACL6s by using the command line interface

At the command prompt, type:

renumber ns acls6

Example

```
> renumber ns acls6
Done
```

To renumber the priority of ACL6s by using the configuration utility

Navigate to Network > ACLs and, on the ACL6s tab, click Renumber Priority (s).

Parameter Descriptions (of commands listed in the CLI procedure)

renumber ns acls6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Monitoring ACL6s

You can display statistics for monitoring the performance of an ACL6.

To display the statistics for an ACL6s by using the command line interface

At the command prompt, type:

stat ns acl6 <acl6name>

The following table lists the statistics associated with ACL6s and their descriptions.

Table 1. ACL6 Statistics

Statistic	Specifies
Allow ACL6 hits	Packets matching IPv6 ACLs with processing mode set to ALLOW. The NetScaler processes these packets.
NAT ACL6 hits	Packets matching a NAT ACL6, resulting in a NAT session.
Deny ACL6 hits	Packets dropped because they match IPv6 ACLs with processing mode set to DENY.
Bridge ACL6 hits	Packets matching a bridge IPv6 ACL, which in transparent mode bypasses service processing.
ACL6 hits	Packets matching an IPv6 ACL.
ACL6 misses	Packets not matching any IPv6 ACL.

To display the statistics for an ACL6 by using the configuration utility

Navigate to Network > ACLs, on the ACL6s tab, select the ACL6, and click Statistics.

Parameter Descriptions (of commands listed in the CLI procedure)

stat ns acl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Removing ACL6s

You can remove a single ACL6 or all ACL6s.

To remove an ACL6 by using the command line interface

At the command prompt, type:

- rm ns acl6 <acl6name>
- show ns acl6

To remove all ACL6s by using the command line interface

At the command prompt, type:

clear ns acls6

To remove an ACL6 by using the configuration utility

Navigate to Network > ACLs and, on the ACL6s tab, delete the ACL6.

To remove all ACLs by using the configuration utility

Navigate to Network > ACLs and, on the ACL6s tab, click Clear.

Parameter Descriptions (of commands listed in the CLI procedure)

rm ns acl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show ns acl6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

clear ns acls6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Terminating Established Connections

For a simple ACL, the NetScaler appliance blocks any new connections that match the conditions specified in the ACL. The appliance does not block any packets related to existing connections that were established before the ACL was created.

However, you can immediately terminate the established connections by running a flush operation from the command line interface or the configuration utility.

Flush can be useful in the following cases:

- You receive a list of blacklisted IP addresses and want to completely block those IP addresses from accessing the NetScaler appliance. In this case, you create simple ACLs to block any new connections from these IP addresses, and then run flush to terminate any existing connections.
- You want to terminate a large number of connections from a particular network without taking the time to terminate them one by one.

When you run flush, the appliance searches through all of its established connections and terminates those that match conditions specified in any of the simple ACLs configured on the appliance.

Note: If you plan to create more than one simple ACL and flush existing connections that match any of them, you can minimize the effect on performance by first creating all of the simple ACLs and then running flush only once.

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the command line interface

At the command prompt, type:

```
flush simpleacl -estSessions
```

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the configuration utility

Navigate to Network > ACLs and, on the Simple ACLs tab, click Flush.

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the command line interface

At the command prompt, type:

```
flush simpleacl6 -estSessions
```

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the configuration utility

Navigate to Network > ACLs and, on the Simple ACL6s tab, click Flush.

IP Routing

NetScaler appliances support both dynamic and static routing. Because simple routing is not the primary role of a NetScaler, the main objective of running dynamic routing protocols is to enable route health injection (RHI), so that an upstream router can choose the best among multiple routes to a topographically distributed virtual server.

Most NetScaler implementations use some static routes to reduce routing overhead. You can create backup static routes and monitor routes to enable automatic switchover in the event that a static route goes down. You can also assign weights to facilitate load balancing among static routes, create null routes to prevent routing loops, and configure IPv6 static routes. You can configure policy based routes (PBRs), for which routing decisions are based on criteria that you specify.

Configuring Dynamic Routes

When a dynamic routing protocol is enabled, the corresponding routing process monitors route updates and advertises routes. Routing protocols enable an upstream router to use the equal cost multipath (ECMP) technique to load balance traffic to identical virtual servers hosted on two standalone NetScaler appliances. Dynamic routing on a NetScaler appliance uses three routing tables. In a high-availability setup, the routing tables on the secondary appliance mirror those on the primary.

The NetScaler supports the following protocols:

- Routing Information Protocol (RIP) version 2
- Open Shortest Path First (OSPF) version 2
- Border Gateway Protocol (BGP)
- Routing Information Protocol next generation (RIPng) for IPv6
- Open Shortest Path First (OSPF) version 3 for IPv6
- ISIS Protocol

You can enable more than one protocol simultaneously.

Routing Tables in the NetScaler

In a NetScaler appliance, the NetScaler kernel routing table, the FreeBSD kernel routing table, and the NSM FIB routing table each hold a different set of routes and serve a different purpose. They communicate with each other by using UNIX routing sockets. Route updates are not automatically propagated from one routing table to another. You must configure propagation of route updates for each routing table.

NS Kernel Routing Table

The NS kernel routing table holds subnet routes corresponding to the NSIP and to each SNIP and MIP. Usually, no routes corresponding to VIPs are present in the NS kernel routing table. The exception is a VIP added by using the `add ns ip` command and configured with a subnet mask other than 255.255.255.255. If there are multiple IP addresses belonging to the same subnet, they are abstracted as a single subnet route. In addition, this table holds a route to the loopback network (127.0.0.0) and any static routes added through the command line interface (CLI). The entries in this table are used by the NetScaler in packet forwarding. From the NetScaler CLI, they can be inspected with the `show route` command.

FreeBSD Routing Table

The sole purpose of the FreeBSD routing table is to facilitate initiation and termination of management traffic (telnet, ssh, etc.). In a NetScaler appliance, these applications are tightly coupled to FreeBSD, and it is imperative for FreeBSD to have the necessary information to handle traffic to and from these applications. This routing table contains a route to the NSIP subnet and a default route. In addition, FreeBSD adds routes of type `WasCloned(W)` when the NetScaler establishes connections to hosts on local networks. Because of the highly specialized utility of the entries in this routing table, all other route updates from the NS kernel and NSM FIB routing tables bypass the FreeBSD routing table. Do not modify it with the `route` command. The FreeBSD routing table can be inspected by using the `netstat` command from any UNIX shell.

Network Services Module (NSM) FIB

The NSM FIB routing table contains the advertisable routes that are distributed by the dynamic routing protocols to their peers in the network. It may contain:

Connected routes

IP subnets that are directly reachable from the NetScaler. Typically, routes corresponding to the NSIP subnet and subnets over which routing protocols are enabled are present in NSM FIB as connected routes.

Kernel routes

All the VIP addresses on which the -hostRoute option is enabled are present in NSM FIB as kernel routes if they satisfy the required RHI Levels. In addition, NSM FIB contains any static routes configured on the NetScaler CLI that have the - advertise option enabled. Alternatively, if the NetScaler is operating in Static Route Advertisement (SRADV) mode, all static routes configured on the NetScaler CLI are present in NSM FIB. These static routes are marked as kernel routes in NSM FIB, because they actually belong to the NS kernel routing table.

Static routes

Normally, any static route configured in VTYSH is present in NSM FIB. If administrative distances of protocols are modified, this may not always be the case. An important point to note is that these routes can never get into the NS kernel routing table.

Learned routes

If the NetScaler is configured to learn routes dynamically, the NSM FIB contains routes learned by the various dynamic routing protocols. Routes learned by OSPF, however, need special processing. They are downloaded to FIB only if the fib-install option is enabled for the OSPF process. This can be done from the router-config view in VTYSH.

High Availability Setup

In a high availability setup, the primary node runs the routing process and propagates routing table updates to the secondary node. The routing table of the secondary node mirrors the routing table on the primary node.

Non-Stop Forwarding

After failover, the secondary node takes some time to start the protocol, learn the routes, and update its routing table. But this does not affect routing, because the routing table on the secondary node is identical to the routing table on the primary node. This mode of operation is known as non-stop forwarding.

Black Hole Avoidance Mechanism

After failover, the new primary node injects all its VIP routes into the upstream router. However, that router retains the old primary node's routes for 180 seconds. Because the router is not aware of the failover, it attempts to load balance traffic between the two nodes. During the 180 seconds before the old routes expire, the router sends half the traffic to the old, inactive primary node, which is, in effect, a black hole.

To prevent this, the new primary node, when injecting a route, assigns it a metric that is slightly lower than the one specified by the old primary node.

Interfaces for Configuring Dynamic Routing

To configure dynamic routing, you can use either the configuration utility or a command-line interface. The NetScaler supports two independent command-line interfaces: the NetScaler CLI and the Virtual Teletype Shell (VTYSH). The NetScaler CLI is the appliance's native shell. VTYSH is exposed by ZebOS. The NetScaler routing suite is based on ZebOS, the commercial version of GNU Zebra.

Note: Citrix recommends that you use VTYSH for all commands except those that can be configured only on the NetScaler CLI. Use of the NetScaler CLI should generally be limited to commands for enabling the routing protocols, configuring host route advertisement, and adding static routes for packet forwarding.

Parameter Descriptions (of commands listed in the CLI procedure)

add ns ip

show route

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring RIP

Routing Information Protocol (RIP) is a Distance Vector protocol. The NetScaler supports RIP as defined in RFC 1058 and RFC 2453. RIP can run on any subnet.

After enabling RIP, you need to configure advertisement of RIP routes. For troubleshooting, you can limit RIP propagation. You can display RIP settings to verify the configuration.

Enabling and Disabling RIP

Use either of the following procedures to enable or disable RIP. After you enable RIP, the NetScaler appliance starts the RIP process. After you disable RIP, the appliance stops the RIP process.

To enable or disable RIP routing by using the command line interface

At the command prompt, enter one of the following commands to enable or disable RIP:

- enable ns feature RIP
- disable ns feature RIP

To enable or disable RIP routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the RIP Routing option.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ns feature

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

disable ns feature

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Advertising Routes

RIP enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertisement enables an upstream router to track network entities located behind the NetScaler.

To configure RIP to advertise routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`router rip`	Start the RIP routing process and enter configuration mode for the routing process.
`redistribute static`	Redistribute static routes.
`redistribute kernel`	Redistribute kernel routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router rip
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Parameter Descriptions (of commands listed in the CLI procedure)

VTYSH

Limiting RIP Propagations

If you need to troubleshoot your configuration, you can configure listen-only mode on any given interface.

To limit RIP propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`router rip`	Start the RIP routing process and enter configuration mode for the routing process.
`passive-interface` < vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example

>VTYSH
NS# configure terminal
NS(config)# router rip
NS(config-router)# passive-interface VLAN0

Parameter Descriptions (of commands listed in the CLI procedure)

VTYSH

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Verifying the RIP Configuration

You can display the routing table and other RIP settings.

To view the RIP settings by using the VTYSH command line

At the command prompt, type the following commands in the following order:

Command	Specifies
VTYSH	Display VTYSH command prompt.
`sh rip`	Display updated RIP routing table.
`sh rip interface <vlan_name>`	Displays RIP information for the specified VLAN.

Example

```
NS# VTYSH
NS# sh rip
NS# sh rip interface VLAN0
```

Configuring OSPF

The NetScaler supports Open Shortest Path First (OSPF) Version 2 (RFC 2328). The features of OSPF on the NetScaler are:

- If a vserver is active, the host routes to the vserver can be injected into the routing protocols.
- OSPF can run on any subnet.
- Route learning advertised by neighboring OSPF routers can be disabled on the NetScaler.
- The NetScaler can advertise Type-1 or Type-2 external metrics for all routes.
- The NetScaler can advertise user-specified metric settings for VIP routes. For example, you can configure a metric per VIP without special route maps.
- You can specify the OSPF area ID for the NetScaler.
- The NetScaler supports not-so-stubby-areas (NSSAs). An NSSA is similar to an OSPF stub area but allows injection of external routes in a limited fashion into the stub area. To support NSSAs, a new option bit (the N bit) and a new type (Type 7) of Link State Advertisement (LSA) area have been defined. Type 7 LSAs support external route information within an NSSA. An NSSA area border router (ABR) translates a type 7 LSA into a type 5 LSA that is propagated into the OSPF domain. The OSPF specification defines only the following general classes of area configuration:
    - Type 5 LSA: Originated by routers internal to the area are flooded into the domain by AS boarder routers (ASBRs).
    - Stub: Allows no type 5 LSAs to be propagated into/throughout the area and instead depends on default routing to external destinations.

After enabling OSPF, you need to configure advertisement of OSPF routes. For troubleshooting, you can limit OSPF propagation. You can display OSPF settings to verify the configuration.

Enabling and Disabling OSPF

To enable or disable OSPF, you must use either the command line interface or the configuration utility. When OSPF is enabled, the NetScaler starts the OSPF process. When OSPF is disabled, the NetScaler stops the OSPF routing process.

To enable or disable OSPF routing by using the command line interface

At the command prompt, type one of the following commands:

1. enable ns feature OSPF
2. disable ns feature OSPF

To enable or disable OSPF routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the OSPF Routing option.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ns feature

disable ns feature

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Advertising OSPF Routes

OSPF enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure OSPF to advertise routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
`configure terminal`	Enters global configuration mode.
`router OSPF`	Start OSPF routing process and enter configuration mode for the routing process.
`network A.B.C.D/M area <0-4294967295>`	Enable routing on an IP network.
`redistribute static`	Redistribute static routes.
`redistribute kernel`	Redistribute kernel routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router OSPF
NS(config-router)# network 10.102.29.0/24 area 0
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Configuring BGP

The NetScaler appliance supports BGP (RFC 4271). The features of BGP on the NetScaler are:

- The NetScaler advertises routes to BGP peers.
- The NetScaler injects host routes to virtual IP addresses (VIPs), as determined by the health of the underlying virtual servers.
- The NetScaler generates configuration files for running BGP on the secondary node after failover in an HA configuration.
- This protocol supports IPv6 route exchanges.

After enabling BGP, you need to configure advertisement of BGP routes. For troubleshooting, you can limit BGP propagation. You can display BGP settings to verify the configuration.

Prerequisites for IPv6 BGP

Before you begin configuring IPv6 BGP, do the following:

- Make sure that you understand the IPv6 BGP protocol.
- Install the IPv6PT license on the NetScaler appliance.
- After installing the IPv6PT license, enable the IPv6 feature.

Enabling and Disabling BGP

To enable or disable BGP, you must use either the command line interface or the configuration utility. When BGP is enabled, the NetScaler appliance starts the BGP process. When BGP is disabled, the appliance stops the BGP process.

To enable or disable BGP routing by using the command line interface

At the command prompt, type one of the following commands:

- enable ns feature BGP
- disable ns feature BGP

To enable or disable BGP routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the BGP Routing option.

Advertising IPv4 Routes

You can configure the NetScaler appliance to advertise host routes to VIPs and to advertise routes to downstream networks.

To configure BGP to advertise IPv4 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`router BGP` < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
`Neighbor` < IPv4 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the link local IPv4 address of the neighbor in the specified autonomous system.
`Address-family ipv4`	Enter address family configuration mode.
`Neighbor` < IPv4 address> activate	Exchange prefixes for the IPv4 router family between the peer and the local node by using the link local address.
`redistribute kernel`	Redistribute kernel routes.
`redistribute static`	Redistribute static routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router BGP 5
NS(config-router)# Neighbor a1bc::102 remote-as 100
NS(config-router)# Address-family ipv4
NS(config-router-af)# Neighbor 10.102.29.170 activate
NS(config-router)# redistribute kernel
NS(config-router)# redistribute static
```

Advertising IPv6 BGP Routes

Border Gateway Protocol (BGP) enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure BGP to advertise IPv6 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`router BGP` < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
`Neighbor` < IPv6 address> remote-as < as-number>	Update the IPv6 BGP neighbor table with the link local IPv6 address of the neighbor in the specified autonomous system.
`Address-family ipv6`	Enter address family configuration mode.
`Neighbor` < IPv6 address> activate	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address.
`redistribute kernel`	Redistribute kernel routes.
`redistribute static`	Redistribute static routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router BGP 5
NS(config-router)# Neighbor a1bc::102 remote-as 100
NS(config-router)# Address-family ipv6
NS(config-router-af)# Neighbor a1bc::102 activate
NS(config-router)# redistribute kernel
NS(config-router)# redistribute static
```

Parameter Descriptions (of commands listed in the CLI procedure)

VTYSH

Verifying the BGP Configuration

You can use VTYSH to display BGP settings.

To view the BGP settings using the VTYSH command line

At the command prompt, type:

VTYSH
You are now in the VTYSH command prompt. An output similar to the following appears:
NS170#
At the VTYSH command prompt, type:
NS170# sh ip BGP
NS170# sh BGP
NS170# sh ip BGP neighbors
NS170# sh ip BGP summary
NS170# sh ip BGP route-map <map-tag>

Configuring IPv6 RIP

IPv6 Routing Information Protocol (RIP) or RIPng is a Distance Vector protocol. This protocol is an extension of RIP to support IPv6. After enabling IPv6 RIP, you need to configure advertisement of IPv6 RIP routes. For troubleshooting, you can limit IPv6 RIP propagation. You can display IPv6 RIP settings to verify the configuration.

Prerequisites for IPv6 RIP

Before you begin configuring IPv6 RIP, do the following:

- Make sure that you understand the IPv6 RIP protocol.
- Install the IPv6PT license on the NetScaler appliance.
- Enable the IPv6 feature.

Enabling IPv6 RIP

You can enable or disable IPv6 RIP by using VTYSH. After you enable IPv6 RIP, the NetScaler starts the IPv6 RIP daemon. After you disable IPv6 RIP, the NetScaler stops the RIP daemon.

To enable IPv6 RIP by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`ns IPv6-routing`	Start IPv6 dynamic routing daemon.
`interface < vlan_name>`	Enter VLAN configuration mode.
`router ipv6 RIP`	Start IPv6 RIP routing process on the VLAN.

Example

```
> VTYSH
NS# configure terminal
NS(config)# ns IPv6-routing
NS(config)# interface vlan0
NS(config-if)# router ipv6 RIP
```

Parameter Descriptions (of commands listed in the CLI procedure)

Configuring IPv6 OSPF

IPv6 OSPF or OSPF version 3 (OSPF v3) is a link state protocol that is used to exchange IPv6 routing information. After enabling IPv6 OSPF, you need to configure advertisement of IPv6 OSPF routes. For troubleshooting, you can limit IPv6 OSPF propagation. You can display IPv6 OSPF settings to verify the configuration.

Prerequisites for IPv6 OSPF

Before you begin configuring IPv6 OSPF, do the following:

- Make sure that you understand the IPv6 OSPF protocol.
- Install the IPv6PT license on the NetScaler appliance.
- Enable the IPv6 feature.

Enabling IPv6 OSPF

To enable IPv6 OSPF, you must use the VTYSH command line. When IPv6 OSPF is enabled, the NetScaler appliance starts the IPv6 OSPF daemon. When IPv6 OSPF is disabled, the appliance stops the IPv6 OSPF daemon.

To enable IPv6 OSPF by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`ns IPv6-routing`	Start IPv6 dynamic routing process.
`interface < vlan_name>`	Enter the VLAN configuration mode.
`ipv6 router OSPF area <area-id>`	Start IPv6 OSPF routing process on a VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# ns IPv6-routing
NS(config)# interface vlan0
NS(config-if)# ipv6 router OSPF area 3
```

Configuring ISIS

The NetScaler appliance supports the Intermediate System-to-Intermediate System (IS-IS or ISIS) dynamic routing protocol. This protocol supports IPv4 as well as IPv6 route exchanges. IS▫IS is a link state protocol and is therefore less prone to routing loops. With the advantages of faster convergence and the ability to support larger networks, ISIS can be very useful in Internet Service Provider (ISP) networks.

Prerequisites for configuring ISIS

Before you begin configuring ISIS, do the following:

- Make sure that you understand the ISIS protocol.
- For IPV6 routes, enable:
  - IPv6 protocol translation feature.
  - IPv6 Dynamic Routing option on the VLANs on which you want to run ISIS protocol.

Enabling ISIS

Use either of the following procedures to enable the ISIS routing feature on the NetScaler appliance.

To enable ISIS routing by using the command line interface

At the command prompt, type:

```
enable ns feature ISIS
```

To enable ISIS routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the ISIS Routing option.

Creating an ISIS Routing Process and Starting It on a VLAN

To create an ISIS routing process, you must use the VTYSH command line.

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Creates an ISIS routing process and configuration mode for the routing process.
net XX....XXXX.YYYY.YYYY.YYYY.00	Specifies a NET value for the routing process, where: · · XX. .. .XXXX is the Area Address (can be 1-13 bytes) · · YYYY.YYYY.YYYY is the System ID (6 bytes) · · 00 is the N-selector (1 byte) A NET value can be 8 to 20 bytes in length. The last byte is always the n-selector, and must be zero. The n-selector indicates that there is no transport entity and means that the packet is for the routing software of the appliance. The six bytes directly preceding the n-selector are the system ID. The system ID length is fixed and cannot be changed. The system ID must be unique throughout each area (Level 1) and throughout the backbone (Level 2). The bytes preceding the system ID are the area ID, which can be from 1 to 13 bytes in length. A maximum of three NETs per routing process are allowed with different area ID, but the system ID should be the same for all NETs.
is-type (level-1|level-1-2|level-2-only)	Sets the ISIS routing process to the specified level of routing. Default: level-1-2.
ns IPv6-routing	Starts the IPv6 dynamic routing daemon.
interface <vlan_name>	Enters the VLAN configuration mode.
ip router ISIS	Enables the ISIS routing process on the VLAN for IPv4 route exchanges.
ipv6 router ISIS	Enables the ISIS routing process on the VLAN for IPv6 route exchanges.

Example

```
> VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# net 15.aabb.ccdd.0097.00
```

```
NS(config-router)# is-type level-1
NS(config-router)# exit
NS(config)# ns IPv6-routing
NS(config)# interface vlan0
NS(config-if)#  ip router isis 11
NS(config-if)# ipv6 router isis 11
```

Advertising Routes

Route advertisement enables an upstream router to track network entities located behind the NetScaler appliance.

To configure ISIS to advertise routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Starts the ISIS routing instance and enter configuration mode for the routing process.
redistribute connected (level-1|level-1-2|level-2)	Redistributes connected routes, where · **level-1** : Redistribute connected routes into Level-1. · **level-1-2** : Redistribute connected routes into Level-1 and Level-2. · **level-2** : Redistribute connected routes into Level-2.
redistribute kernel(level-1|level-1-2|level-2)	Redistributes kernel routes, where: · **level-1** : Redistribute kernel routes into Level-1. · **level-1-2** : Redistribute kernel routes into Level-1 and Level-2. · **level-2** : Redistribute kernel routes into Level-2.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# redistribute connected level-1
NS(config-router)# redistribute kernel level-1
```

Limiting ISIS Propagations

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given VLAN.

To limit ISIS propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router isis [tag]	Enters the configuration mode for the routing process.
passive-interface <*vlan_name*>	Suppresses routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# passive-interface VLAN0
```

Parameter Descriptions (of commands listed in the CLI procedure)

VTYSH

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Verifying the ISIS Configuration

You can use VTYSH to display the ISIS routing table and ISIS information for a specified VLAN.

To view the ISIS settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Description
VTYSH	Displays the VTYSH command prompt.
show ip isis route	Displays updated IPv4 ISIS routing table.
show ipv6 isis route	Displays updated IPv6 ISIS routing table.
sh isis interface <*vlan_name*>	Displays IPv6 ISIS information for the specified VLAN.

Example

```
NS# VTYSH
NS#  show ip isis route
NS#  show ipv6 isis route
NS# sh isis interface VLAN0
```

Installing Routes to the NetScaler Routing Table

The NetScaler appliance can use routes learned by various routing protocols after you install the routes in the appliance's routing table.

To install various routes to the internal routing table by using the VTYSH command line

At the command prompt, type the following commands as appropriate for the routes that you want to install:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`ns route-install Default`	Install IPv4 default routes to the internal routing table.
`ns route-install RIP`	Install IPv4 RIP specific routes to the internal routing table.
`ns route-install BGP`	Install IPv4 BGP specific routes to the internal routing table.
`ns route-install OSPF`	Install IPv4 OSPF specific routes to the internal routing table.
`ns route-install IPv6 Default`	Install IPv6 default routes to the internal routing table.
`ns route-install IPv6 RIP`	Install IPv6 RIP specific routes to the internal routing table.
`ns route-install IPv6 BGP`	Install IPv6 BGP specific routes to the internal routing table.
`ns route-install IPv6 OSPF`	Install IPv6 OSPF specific routes to the internal routing table.

Example

```
>VTYSH
NS# configure terminal
NS# ns route-install Default
NS(config)# ns route-install RIP
NS(config)# ns route-install BGP
NS(config)# ns route-install OSPF
NS# ns route-install IPv6 Default
```

```
NS(config)# ns route-install IPv6 RIP
NS(config)# ns route-install IPv6 BGP
NS(config)# ns route-install IPv6 OSPF
```

Parameter Descriptions (of commands listed in the CLI procedure)

VTYSH

Configuring Static Routes

Static routes are manually created to improve the performance of your network. You can monitor static routes to avoid service disruptions. Also, you can assign weights to ECMP routes, and you can create null routes to prevent routing loops.

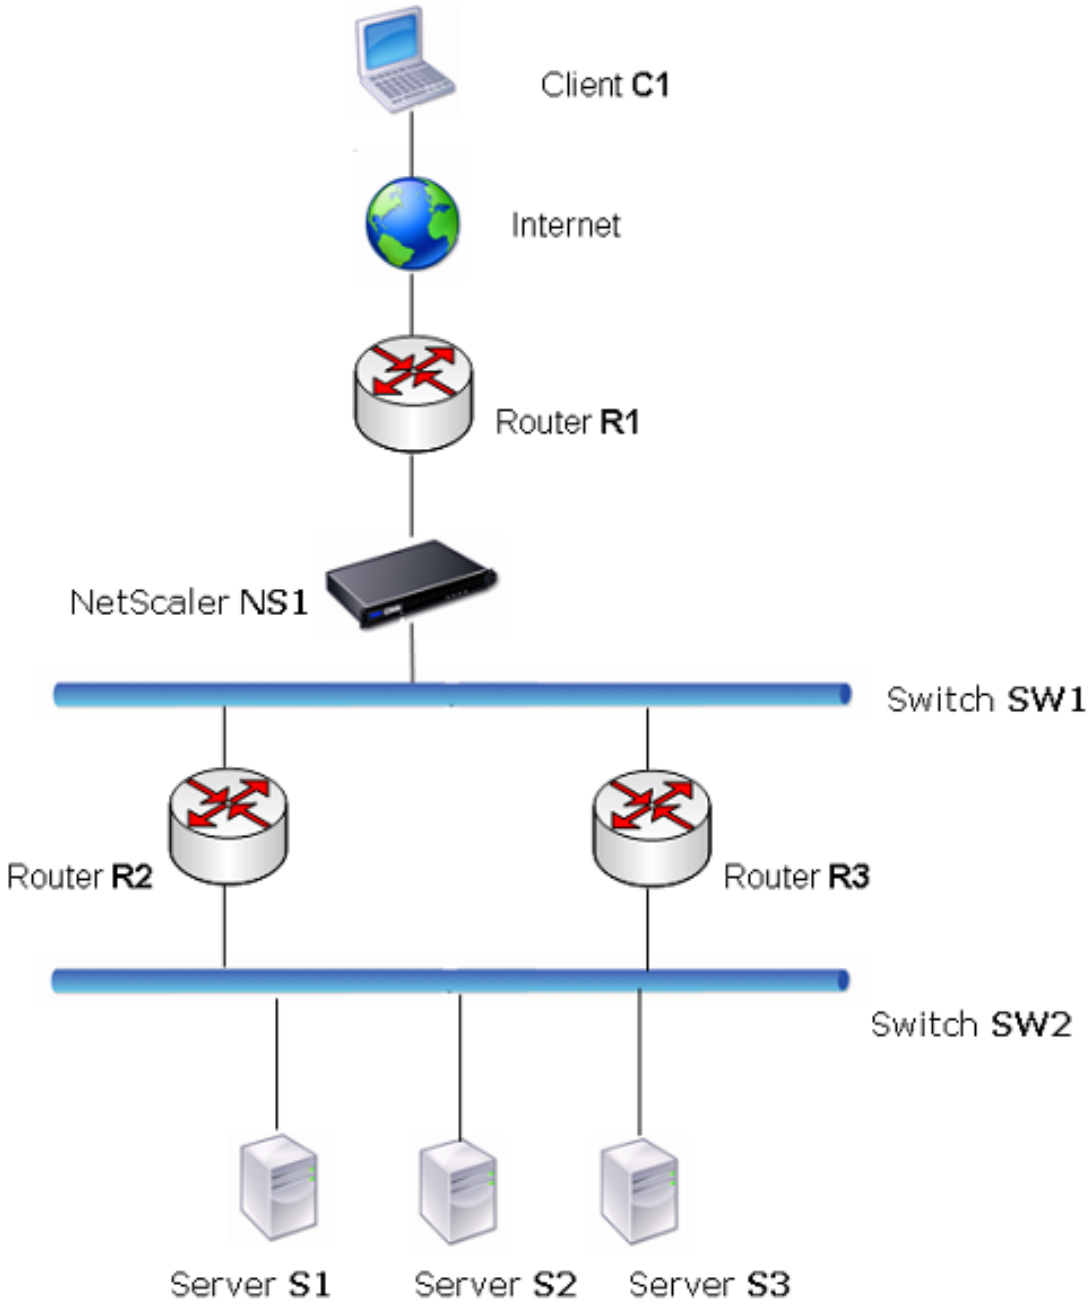
Monitored Static Routes

If a manually created (static) route goes down, a backup route is not automatically activated. You must manually delete the inactive primary static route. However, if you configure the static route as a monitored route, the NetScaler appliance can automatically activate a backup route.

Static route monitoring can also be based on the accessibility of the subnet. A subnet is usually connected to a single interface, but it can be logically accessed through other interfaces. Subnets bound to a VLAN are accessible only if the VLAN is up. VLANs are logical interfaces through which packets are transmitted and received by the NetScaler. A static route is marked as DOWN if the next hop resides on a subnet that is unreachable.

Note: In a high availability (HA) setup, the default value for monitored state routes (MSRs) on the secondary node is UP. The value is set to avoid a state transition gap upon failover, which could result in dropping packets on those routes.

Consider the following simple topology, in which a NetScaler is load balancing traffic to a site across multiple servers.



Router R1 moves traffic between the client and the NetScaler appliance. The appliance can reach servers S1 and S2 through routers R2 or R3. It has two static routes through which to reach the servers' subnet, one with R2 as the gateway and another with R3 as the gateway. Both these routes have monitoring enabled. The administrative distance of the static route with gateway R2 is lower than that of the static route with gateway R3. Therefore, R2 is preferred over R3 to forward traffic to the servers. Also, the default route on the NetScaler points to R1 so that all Internet traffic exits properly.

If R2 fails while monitoring is enabled on the static route, which uses R2 as the gateway, the NetScaler marks it as DOWN. The NetScaler now uses the static route with R3 as the gateway and forwards the traffic to the servers through R3.

The NetScaler supports monitoring of IPv4 and IPv6 static routes. You can configure the NetScaler to monitor an IPv4 static route either by creating a new ARP or PING monitor or by using existing ARP or PING monitors. You can configure the NetScaler to monitor an IPv6 static route either by creating a new Neighbor discovery for IPv6 (ND6) or PING monitor or by using the existing ND6 or PING monitors.

Weighted Static Routes

When the NetScaler appliance makes routing decisions involving routes with equal distance and cost, that is, Equal Cost Multi-Path (ECMP) routes, it balances the load between them by using a hashing mechanism based on the source and destination IP addresses. For an ECMP route, however, you can configure a weight value. The NetScaler then uses both the weight and the hashed value for balancing the load.

Null Routes

If the route chosen in a routing decision is inactive, the NetScaler appliance chooses a backup route. If all the backup routes become inaccessible, the appliance might reroute the packet to the sender, which could result in a routing loop leading to network congestion. To prevent this situation, you can create a null route, which adds a null interface as a gateway. The null route is never the preferred route, because it has a higher administrative distance than the other static routes. But it is selected if the other static routes become inaccessible. In that case, the appliance drops the packet and prevents a routing loop.

Configuring IPv4 Static Routes

You can add a simple static route or a null route by setting a few parameters, or you can set additional parameters to configure a monitored or monitored and weighted static route. You can change the parameters of a static route. For example, you might want to assign a weight to an unweighted route, or you might want to disable monitoring on a monitored route.

To create a static route by using the command line interface

At the command prompt, type the following commands to create a static route and verify the configuration:

- add route <network> <netmask> <gateway>[-cost <positive_integer>] [-advertise (DISABLED | ENABLED)]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

Example

```
> add route 10.102.29.0 255.255.255.0 10.102.29.2 -cost 2 -advertise ENABLED
 Done
```

To create a monitored static route by using the command line interface

At the command prompt, type the following commands to create a monitored static route and verify the configuration:

- add route <network> <netmask> <gateway> [-distance <positive_integer>] [-weight <positive_integer>][-msr (ENABLED | DISABLED) [-monitor <string>]]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

Example

```
> add route 10.102.29.0 255.255.255.0 10.102.29.3 -distance 5 -weight 6 -msr ENBLED -monitor PING
 Done
```

To create a null route by using the command line interface

At the command prompt type:

- `add route` <network> <netmask> null
- show route <network> <netmask>

Example

```
> add route 10.102.29.0 255.255.255.0 null
 Done
```

To remove a static route by using the command line interface

At the command prompt, type:

rm route <network> <netmask> <gateway>

Example

```
> rm route 10.102.29.0 255.255.255.0 10.102.29.3
 Done
```

To configure a static route by using the configuration utility

Navigate to Network > Routes and, on the Basic tab, add a new static route, or edit an existing static route.

To remove a route by using the configuration utility

Navigate to Network > Routes and, on the Basic tab, delete the static route.

Parameter Descriptions (of commands listed in the CLI procedure)

add route

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

show route

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

rm route

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring IPv6 Static Routes

You can configure a maximum of six default IPv6 static routes. IPv6 routes are selected on the basis of whether the MAC address of the destination device is reachable. This can be determined by using the IPv6 Neighbor Discovery feature. Routes are load balanced and only source/destination-based hash mechanisms are used. Therefore, route selection mechanisms such as round robin are not supported. The next hop address in the default route need not belong to the NSIP subnet.

To create an IPv6 route by using the command line interface

At the command prompt, type the following commands to create an IPv6 route and verify the configuration:

- add route6 <network> <gateway> [-vlan <positive_integer>]
- show route6 [<network> [<gateway>]

Example

```
> add route6 ::/0 FE80::67 -vlan 5
 Done
```

To create a monitored IPv6 static route by using the command line interface

At the command prompt, type the following commands to create a monitored IPv6 static route and verify the configuration:

- add route6 <network> <gateway> [-msr (ENABLED | DISABLED) [-monitor <string>]
- show route6 [<network> [<gateway>]

Example

```
> add route6 ::/0 2004::1 -msr ENABLED -monitor PING
 Done
```

To remove an IPv6 route by using the command line interface

At the command prompt, type:

rm route6 <network> <gateway>

Example

```
> rm route6 ::/0 FE80::67
 Done
```

To configure an IPv6 route by using the configuration utility

Navigate to Network > Routes and, on the IPV6 tab, add a new IPv6 route, or edit an existing IPv6 route.

To remove an IPv6 route by using the configuration utility

Navigate to Network > Routes and, on the IPV6 tab, delete the IPv6 route.

Parameter Descriptions (of commands listed in the CLI procedure)

add route6

rm route6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring Policy-Based Routes

Policy-based routing bases routing decisions on criteria that you specify. A policy-based route (PBR) specifies criteria for selecting packets and, typically, a next hop to which to send the selected packets. For example, you can configure the NetScaler appliance to route outgoing packets from a specific IP address or range to a particular next hop router. Each packet is matched against each configured PBR, in the order determined by the specified priorities, until a match is found. If no match is found, or if the matching PBR specifies a DENY action, the NetScaler applies the routing table for normal destination-based routing.

A PBR bases routing decisions for the data packets on parameters such as source IP address, source port, destination IP address, destination port, protocol, and source MAC address. A PBR defines the conditions that a packet must satisfy for the NetScaler to route the packet. These actions are known as "processing modes." The processing modes are:

- ALLOW - The NetScaler sends the packet to the designated next-hop router.
- DENY - The NetScaler applies the routing table for normal destination-based routing.

The NetScaler process PBRs before processing the RNAT rules.

You can create PBRs for outgoing IPv4 and IPv6 traffic.

Many users begin by creating PBRs and then modifying them. To activate a new PBR, you must apply it. To deactivate a PBR, you can either remove or disable it. You can change the priority number of a PBR to give it a higher or lower precedence.

Configuring a Policy-Based Routes (PBR) for IPv4 Traffic

Configuring PBRs involves the following tasks:

- Create a PBR.
- Apply PBRs.
- (Optional) Disable or enable a PBR.
- (Optional) Renumber the priority of the PBR.

Creating or Modifying a PBR

You cannot create two PBRs with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR. The priority (an integer value) defines the order in which the NetScaler appliance evaluates PBRs. When you create a PBR without specifying a priority, the NetScaler automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR, the NetScaler performs an action. If the packet does not match the condition defined by the PBR, the NetScaler compares the packet against the PBR with the next highest priority.

Instead of sending the selected packets to a next hop router, you can configure the PBR to send them to a link load balancing virtual server to which you have bound multiple next hops. This configuration can provide a backup if a next hop link fails.

Consider the following example. Two PBRs, p1 and p2, are configured on the NetScaler and automatically assigned priorities 20 and 30. You need to add a third PBR, p3, to be evaluated immediately after the first PBR, p1. The new PBR, p3, must have a priority between 20 and 30. In this case, you can specify the priority as 25.

To create a PBR by using the command line interface

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> |-protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-state (ENABLED | DISABLED)]

- show ns pbr

Example

> add ns pbr pbr1 allow -srcip 10.102.37.252 -destip 10.10.10.2 -nexthop 10.102.29.77
 Done

To modify the priority of a PBR by using the command line interface

At the command prompt, type the following commands to modify the priority and verify the configuration:

- set ns pbr <name> [-action (ALLOW | DENY)] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-state (ENABLED | DISABLED)]

- show ns pbr [<name>]

Example

```
> set ns pbr pbr1 -priority 23
 Done
```

To remove one or all PBRs by using the command line interface

At the command prompt, type one of the following commands:

- rm ns pbr <name>

- clear ns pbrs

Example

```
> rm ns pbr pbr1
 Done
> clear ns PBRs
 Done
```

To create a PBR by using the configuration utility

Navigate to Network > PBRs, on the PBRs tab, add a new PBR, or edit an existing PBR.

To remove one or all PBRs by using the configuration utility

Navigate to Network > PBRs, on the PBRs tab, delete the PBR.

rm ns pbr

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

clear ns pbrs

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Applying a PBR

You must apply a PBR to activate it. The following procedure reapplies all PBRs that you have not disabled. The PBRs constitute a memory tree (lookup table). For example, if you create 10 PBRs (p1 - p10), and then you create another PBR (p11) and apply it, all of the PBRs (p1 - p11) are freshly applied and a new lookup table is created. If a session has a DENY PBR related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR. For example, you must follow this procedure after disabling a PBR.

Note: PBRs created on the NetScaler appliance do not work until they are applied.

To apply a PBR by using the command line interface

At the command prompt, type:

apply ns PBRs

To apply a PBR by using the configuration utility

1. Navigate to Network > PBRs.
2. On the PBRs tab, select the PBR, and click Apply.

Parameter Descriptions (of commands listed in the CLI procedure)

apply ns PBRs

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Enabling or Disabling PBRs

By default, the PBRs are enabled. This means that when PBRs are applied, the NetScaler appliance automatically compares incoming packets against the configured PBRs. If a PBR is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBRs are applied. After the PBRs are applied, the NetScaler does not compare incoming packets against disabled PBRs.

To enable or disable a PBR by using the command line interface

At the command prompt, type one of the following commands:

- enable ns pbr <name>
- disable ns pbr <name>

Examples

```
> enable ns PBR pbr1
 Done
> show ns PBR pbr1
1)      Name: pbr1
        Action: ALLOW                   Hits: 0
        srcIP = 10.102.37.252
        destIP = 10.10.10.2
        srcMac:                      Protocol:
        Vlan:                       Interface:
        Active Status: ENABLED              Applied Status: APPLIED
        Priority: 10
        NextHop: 10.102.29.77

 Done

> disable ns PBR pbr1
Warning: PBR modified, use 'apply pbrs' to commit this operation
> apply pbrs
 Done
> show ns PBR pbr1
1)      Name: pbr1
        Action: ALLOW                   Hits: 0
        srcIP = 10.102.37.252
        destIP = 10.10.10.2
        srcMac:                      Protocol:
        Vlan:                       Interface:
        Active Status: DISABLED             Applied Status: NOTAPPLIED
        Priority: 10
```

```
        NextHop: 10.102.29.77
Done
```

To enable or disable a PBR by using the configuration utility

1. Navigate to Network > PBRs.
2. On the PBRs tab, select the PBR, and click Enable or Disable.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ns pbr

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

disable ns pbr

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Renumbering PBRs

You can automatically renumber the PBRs to set their priorities to multiples of 10.

To renumber PBRs by using the command line interface

At the command prompt, type:

renumber ns pbrs

To renumber PBRs by using the configuration utility

Navigate to Network > PBRs, on the PBRs tab, and click Renumber Priority (s).

Parameter Descriptions (of commands listed in the CLI procedure)

renumber ns pbrs

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Use Case - PBR with Multiple Hops

Consider a scenario in which two PBRs, PBR1 and PBR2, are configured on NetScaler appliance NS1. PBR1 routes all the outgoing packets, with source IP address as 10.102.29.30, to next hop router R1. PBR2 routes all the outgoing packets, with source IP address as 10.102.29.90, to next hop router R2. R3 is another next hop router connected to NS1.

If router R1 fails, all the outgoing packets that matched against PBR1 are dropped. To avoid this situation, you can specify a link load balancing (LLB) virtual server in the next hop field while creating or modifying a PBR. Multiple next hops are bound to the LLB virtual server as services (for example R1, R2, and R3). Now, if R1 fails, all the packets that matched against PBR1 are routed to R2 or R3 as determined by the LB method configured on the LLB virtual server.

The NetScaler appliance throws an error if you attempt to create a PBR with an LLB virtual server as the next hop in the following cases:

- Adding another PBR with the same LLB virtual server.
- Specifying a nonexistent LLB virtual server.
- Specifying an LLB virtual server for which the bound services are not next hops.
- Specifying an LLB virtual server for which the LB method is not set to one of the following:
  - LEASTPACKETS
  - LEASTBANDWIDTH
  - DESTIPHASH
  - SOURCEIPHASH
  - WEIGHTDRR
  - SRCIPDESTIP_HASH
  - LTRM
  - CUSTOM LOAD
- Specifying an LLB virtual server for which the LB persistence type is not set to one of the following:
  - DESTIP
  - SOURCEIP
  - SRCDSTIP

The following table lists the names and values of the entities configured on the NetScaler appliance:

Table 1. Sample Values for Creating Entities

Entity Type	Name	IP Address
Link load balancing virtual server	LLB1	NA
Services (next hops)	Router1	1.1.1.254
	Router2	2.2.2.254
	Router3	3.3.3.254
PBRs	PBR1	NA
	PBR2	NA

To implement the configuration described above, you need to:

1. Create services Router1, Router2, and Router3 that represent next hop routers R1, R2, and R3.
2. Create link load balancing virtual server LLB1 and bind services Router1, Router2, and Router3 to it.
3. Create PBRs PBR1 and PBR2, with next hop fields set as LLB1 and 2.2.2.254 (IP address of the router R2), respectively.

To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port>
- show service <name>

Example

```
> add service Router1 1.1.1.254 ANY *
 Done
> add service Router2 2.2.2.254 ANY *
 Done
> add service Router3 3.3.3.254 ANY *
 Done
```

To create a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create a link load balancing virtual server and bind a service by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType>
- bind lb vserver < name> <serviceName>
- show lb vserver < name>

Example

```
> add lb vserver LLB1 ANY
 Done
> bind lb vserver LLB1 Router1 Router2 Router3
 Done
```

To create a link load balancing virtual server and bind a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.

   Note: Make sure that **Directly Addressable** is unchecked.

2. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

To create a PBR by using the command line interface

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-nextHop <nextHopVal>]
- show ns pbr

Example

```
> add pbr PBR1 ALLOW -srcIP 10.102.29.30 -nextHop LLB1
 Done
> add pbr PBR2 ALLOW -srcIP 10.102.29.90 -nextHop 2.2.2.254
 Done
```

To create a PBR by using the configuration utility

Navigate to Network > PBRs, on the PBRs tab, add a new PBR.

Configuring a Policy-Based Routes (PBR6) for IPv6 Traffic

Configuring PBR6s involves the following tasks:

- Create a PBR6.
- Apply PBR6s.
- (Optional) Disable or enable a PBR6.
- (Optional) Renumber the priority of the PBR6.

Creating or Modifying a PBR6

You cannot create two PBR6s with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR6. The priority (an integer value) defines the order in which the NetScaler appliance evaluates PBR6s. When you create a PBR6 without specifying a priority, the NetScaler automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR6, the NetScaler performs an action. If the packet does not match the condition defined by the PBR6, the NetScaler compares the packet against the PBR6 with the next highest priority.

To create a PBR6 by using the command line interface

At the command prompt, type:

- add ns pbr6 <name> <action> [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>] [-srcMac <mac_addr>] [-protocol <protocol> |-protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-state (ENABLED | DISABLED)] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-nextHop <nextHopVal>] [-nextHopVlan <positive_integer>]
- show ns pbr

To modify or remove a PBR6 by using the command line interface

To modify a PBR6, type the set pbr6 <name> command and the parameters to be changed, with their new values.

To remove one or all PBR6s by using the command line interface

At the command prompt, type one of the following commands:

- rm ns pbr6 <name>
- clear ns pbr6

To create or modify a PBR6 by using the configuration utility

Navigate to Network > PBRs and, on the PBR6s tab, add a new PBR6, or edit an existing PBR6.

To remove one or all PBR6s by using the configuration utility

Navigate to Network > PBRs > PBR6s and, on the PBR6s tab, delete the PBR6.

Parameter Descriptions (of commands listed in the CLI procedure)

add ns pbr6

show ns pbr

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

rm ns pbr6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

clear ns pbr6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Applying PBR6s

You must apply a PBR6 to activate it. The following procedure reapplies all PBR6s that you have not disabled. The PBR6s constitute a memory tree (lookup table). For example, if you create 10 PBR6s (p6_1 - p6_10), and then you create another PBR6 (p6_11) and apply it, all of the PBR6s (p6_1 - p6_11) are freshly applied and a new lookup table is created. If a session has a DENY PBR6 related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR6. For example, you must follow this procedure after disabling a PBR6.

Note: PBR6s created on the NetScaler appliance do not work until they are applied.

To apply PBR6s by using the command line interface

At the command prompt, type:

apply ns PBR6

To apply PBR6s by using the configuration utility

1. Navigate to Network > PBRs.
2. On the PBR6s tab, select the PBR6, and click Apply.

Parameter Descriptions (of commands listed in the CLI procedure)

apply ns PBR6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Enabling or Disabling a PBR6

By default, the PBR6s are enabled. This means that when PBR6s are applied, the NetScaler appliance automatically compares outgoing IPv6 packets against the configured PBR6s. If a PBR6 is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBR6s are applied. After the PBR6s are applied, the NetScaler does not compare incoming packets against disabled PBR6s.

To enable or disable a PBR6 by using the command line interface

At the command prompt, type one of the following commands:

- enable ns pbr <name>
- disable ns pbr <name>

To enable or disable a PBR6 by using the configuration utility

1. Navigate to Network > PBRs.
2. On the PBR6s tab, select the PBR6, and click Enable or Disable.

Parameter Descriptions (of commands listed in the CLI procedure)

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

disable ns pbr

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Renumbering PBR6s

You can automatically renumber the PBR6s to set their priorities to multiples of 10.

To renumber PBR6s by using the command line interface

At the command prompt, type:

renumber ns pbr6

To renumber PBR6s by using the configuration utility

Navigate to Network > PBRs, on the PBR6s tab, click Renumber Priority (s).

Parameter Descriptions (of commands listed in the CLI procedure)

renumber ns pbr6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Troubleshooting Routing Issues

To make your troubleshooting process as efficient as possible, begin by gathering information about your network. You need to obtain the following information about the NetScaler appliance and other systems in the Network:

- Complete Topology diagram, including interface connectivity and intermediate switch details.
- Running Configuration. You can use the `show running` command to get the running configuration for ns.conf and ZebOS.conf.
- Output of the `History` command, to determine whether any configuration changes were made when the issue arose.
- Output of the `Top` and `ps -ax` commands, to determine whether any routing daemon is over utilizing the CPU or is misbehaving.
- Any routing related core files in /var/core - nsm, bgpd, ospfd, or ripd. Check the time stamp to see if they are relevant.
- dr_error.log and dr_info.log files from /var/log.
- Output of the `date` command and time details for all relevant systems. Print dates across all devices one after another, so that the times on the log messages can be correlated with various events.
- Relevant ns.log, newnslog files.
- Configuration files, log files and command history details from upstream and downstream routers.

Generic Routing FAQs

Users typically have the following questions about how to troubleshoot generic routing issues:

- How do I save the config files?

  The `write` command from VTYSH saves only ZebOS.conf. Run the save ns config command from NetScaler CLI to save both ns.conf and ZebOS.conf files.

- If I have configured both a static default route and a dynamically learned default route, which is the preferred default route?

  The dynamically learned route is the preferred default route. This behavior is unique to default routes. However, in case of the Network Services Module (NSM), unless the administrative distances are modified, a statically configured route in the RIB is preferred over a dynamic route. The route that is downloaded to the NSM FIB is the static route.

- How do I block the advertisement of default routes?

  After release 7.0, the default route is not injected into ZebOS.

  However, if you are working with 7.0 or an earlier release, you must apply a suitable route map with the

  However, if you are working with 7.0 or an earlier release, you must apply a suitable route map with the `redistribute kernel` command for each protocol to block default route advertisement. For example:

```
ns(config)#access-list 1 deny 0.0.0.0
ns(config)#access-list 2 permit any
ns(config)#route-map redist-kernel permit 5
ns(config-route-map)#match ip address 1
ns(config)#route-map redist-kernel permit 10
ns(config-route-map)#match ip address 2
ns(config-route-map)#q
ns(config)#router ospf 1
ns(config-router)#redistribute kernel route-map redist-kernel
ns(config-router)#q
ns(config)#q
ns#show route-map
route-map redist-kernel, permit, sequence 5
  Match clauses:
    ip address 1
  Set clauses:
route-map redist-kernel, permit, sequence 10
  Match clauses:
    ip address 2
```

```
  Set clauses:
ns#show access-list
Standard IP access list 1
   deny 0.0.0.0
Standard IP access list 2
   permit any
ns#
```

- How do I view the debug output of networking daemons?

  You can write debugging output from networking daemons to a file by entering the following `log file` command from the global configuration view in VTYSH:

  ```
  ns(config)#log file /var/ZebOS.log
  ```

  With release 8.1, you can direct debug output to the console by entering the `terminal monitor` command from VTYSH user view:

  ```
  ns#terminal monitor
  ```

- How do I collect cores of running daemons?

  You can use the gcore utility to collect cores of running daemons for processing by gdb. This might be helpful in debugging misbehaving daemons without bringing the whole routing operation to a standstill.

  ```
  gcore [-s] [-c core] [executable] pid
  ```

  The -s option temporarily stops the daemon while gathering the core image. This is a recommended option, because it guarantees that the resulting image shows the core in a consistent state.

  ```
  root@ns#gcore -s -c nsm.core /netscaler/nsm 342
  ```

- How do I run a batch of ZebOS commands?

  You can run a batch of ZebOS commands from a file by entering the `VTYSH -f` <file-name> command. This does not replace the running configuration, but appends to it. However, by including commands to delete the existing configuration in the batch file and then add those for the new, desired configuration, you can use this mechanism to replace a specific configuration:

  ```
  !
  router bgp 234
  network 1.1.1.1 255.255.255.0
  ```

```
!
route-map bgp-out2 permit 10
 set metric 9900
 set community 8602:300
!
```

Troubleshooting OSPF-Specific Issues

Before you start debugging any OSPF specific issue, you must collect information from the NetScaler appliance and all systems in the affected LAN, including upstream and downstream routers. To begin, enter the following commands:

1. show interface from both nscli and VTYSH
2. `show ip ospf interface`
3. `show ip ospf neighbor detail`
4. show ip route
5. `show ip ospf route`
6. `show ip ospf database summary`
    a. If there are only few LSAs in the database, then enter `show ip ospf database router`, `show ip ospf database A`. network, `show ip ospf database external`, and other commands to get the full details of LSAs.
    b. If there are a large number of LSAs in the database, enter the `show ip ospf database self-originated` command.
7. show ip ospf
8. show ns ip. This ensures that the details of all VIPs of interest are included.
9. Get the logs from peering devices and run the following command:

```
gcore -s -c xyz.core /netscaler/ospfd <pid>
```

Note: The `gcore` command is non-disruptive.

Collect additional information from the NetScaler as follows:

1. Enable logging of error messages by entering the following command from the global configuration view in VTYSH:

```
ns(config)#log file /var/ospf.log
```

2. Enable debugging ospf events and log them by using the following command:

```
ns(config)#log file /var/ospf.log
```

Enable debug ospf lsa packet only if the number of LSAs in the database is relatively small (< 500).

Parameter Descriptions (of commands listed in the CLI procedure)

show interface

show ns ip

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Internet Protocol version 6 (IPv6)

A NetScaler appliance supports both server-side and client-side IPv6 and can therefore function as an IPv6 node. It can accept connections from IPv6 nodes (both hosts and routers) and from IPv4 nodes, and can perform Protocol Translation (RFC 2765) before sending traffic to the services. You have to license the IPv6 feature before you can implement it.

The following table lists some of the IPv6 features that the NetScaler appliance supports.

Table 1. Some Supported IPv6 Features

IPv6 features
IPv6 addresses for SNIPs (NSIP6, VIP6, and SNIP6)
Neighbor Discovery (Address Resolution, Duplicated Address Detection, Neighbor Unreachability Detection, Router Discovery)
Management Applications (ping6, telnet6, ssh6)
Static Routing and Dynamic routing (OSPF)
Port Based VLANs
Access Control Lists for IPv6 addresses (ACL6)
IPv6 Protocols (TCP6, UDP6, ICMP6)
Server Side Support (IPv6 addresses for vservers, services)
USIP (Use source IP) and DSR (Direct Server Return) for IPv6
SNMP and CVPN for IPv6
HA with native IPv6 node address
IPv6 addresses for MIPs
Path-MTU discovery for IPv6

The following table lists NetScaler components that support IPv6 addresses and provides references to the topics that document the components.

Table 2. NetScaler Components That Support IPv6 Addresses and the Corresponding Documentation

NetScaler component	Topic that documents IPv6 support
Network	Adding, Customizing, Removing, Removing all, and Viewing routes.
SSL Offload	Creating IPv6 vservers for SSL Offload
SSL Offload	Specifying IPv6 SSL Offload Monitors
SSL Offload	Creating IPv6 SSL Offload Servers
Load Balancing	Creating IPv6 vservers for Load Balancing
Load Balancing	Specifying IPv6 Load Balancing Monitors

Load Balancing	Creating IPv6 Load Balancing Servers
DNS	Creating AAAA Records

You can configure IPv6 support for the above features after implementing the IPv6 feature on your NetScaler appliance. You can configure both tagged and prefix-based VLANs for IPv6. You can also map IPv4 addresses to IPv6 addresses.

Implementing IPv6 Support

IPv6 support is a licensed feature, which you have to enable before you can use or configure it. If IPv6 is disabled, the NetScaler does not process IPv6 packets. It displays the following warning when you run an unsupported command:

"Warning: Feature(s) not enabled [IPv6PT]"

The following message appears if you attempt to run IPv6 commands without the appropriate license:

"ERROR: Feature(s) not licensed"

After licensing the feature, use either of the following procedures to enable or disable IPv6.

To enable or disable IPv6 by using the command line interface

At the command prompt, type one of the following commands:

- enable ns feature ipv6pt
- disable ns feature ipv6pt

To enable or disable IPv6 by using the configuration utility

1. Navigate to System > Settings, in the Modes and Features group, click Configure Advanced Features.
2. Select or clear the IPv6 Protocol Translation option.

Parameter Descriptions (of commands listed in the CLI procedure)

enable ns feature

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

disable ns feature

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

VLAN Support

If you need to send broadcast or multicast packets without identifying the VLAN (for example, during DAD for NSIP, or ND6 for the next hop of the route), you can configure the NetScaler appliance to send the packet on all the interfaces with appropriate tagging. The VLAN is identified by ND6, and a data packet is sent only on the VLAN.

For more information about ND6 and VLANs, see "Configuring Neighbor Discovery."

Port-based VLANs are common for IPv4 and IPv6. Prefix-based VLANs are supported for IPv6.

Simple Deployment Scenario

Following is an example of a simple load balancing set-up consisting of an IPv6 vserver and IPv4 services, as illustrated in the following topology diagram.

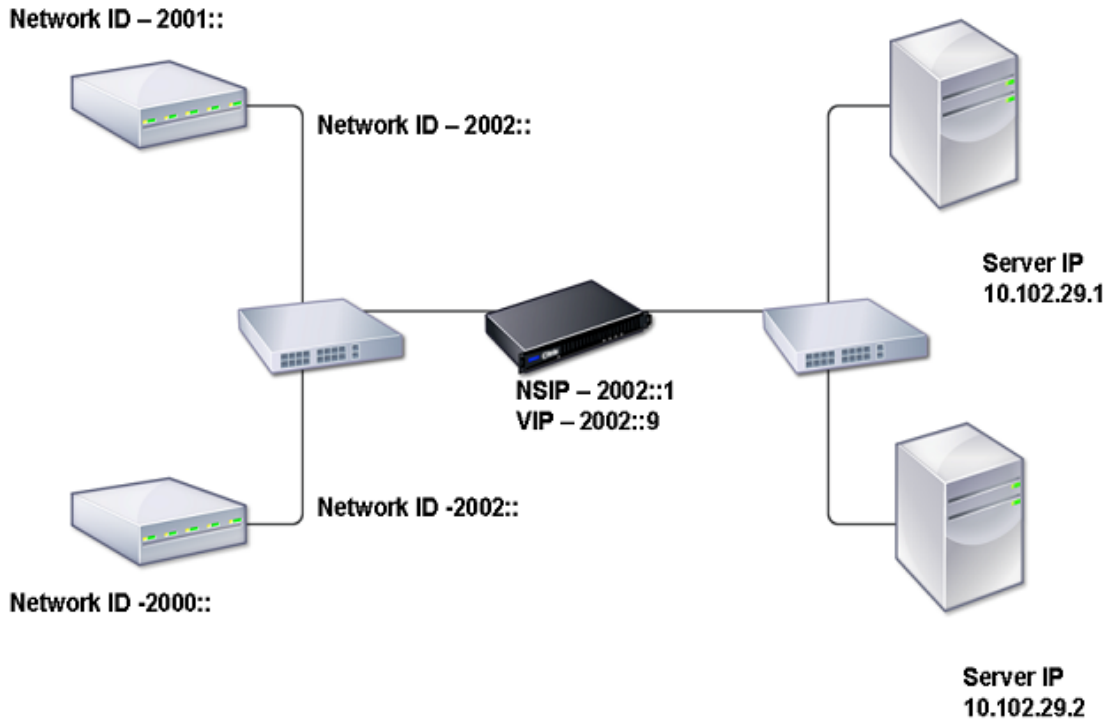

Figure 1. IPv6 Sample Topology

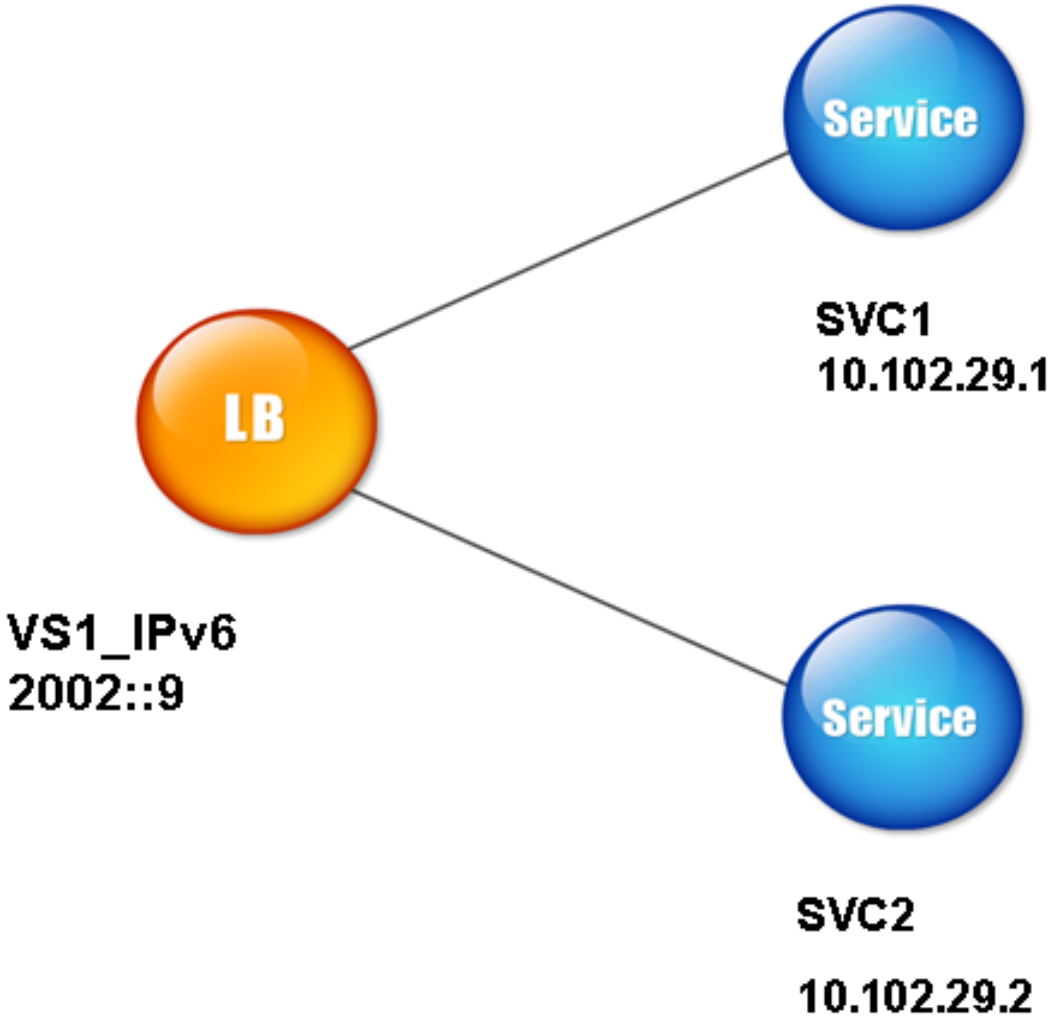
The following table summarizes the names and values of the entities that must be configured on the NetScaler.

Table 1. Sample Values for Creating Entities

Entity type	Name	Value
LB Vserver	VS1_IPv6	2002::9
Services	SVC1	10.102.29.1
	SVC2	10.102.29.2



The following figure shows the entities and values of the parameters to be configured on the NetScaler. Figure 2. IPv6 Entity Diagram

To configure this deployment scenario, you need to do the following:

1. Create an IPv6 service.
2. Create an IPv6 LB vserver.
3. Bind the services to the vserver.

To create IPv4 services by using the command line interface

At the command prompt, type:

add service <Name> <IPAddress> <Protocol> <Port>

Example

add service SVC1 10.102.29.1 HTTP 80
add service SVC2 10.102.29.2 HTTP 80

To create IPv4 services by using the configuration utility

Navigate to Load Balancing > Services, click Add, and then set the following parameters:

- Service Name
- IP Address
- Protocol
- Port

To create IPv6 vserver by using the command line interface

At the command prompt, type:

add lb vserver <Name> <IPAddress> <Protocol> <Port>

Example

add lb vserver VS1_IPv6 2002::9 HTTP 80

To create IPv6 vserver by using the configuration utility

1. Set the following parameters:
   - Name
   - Protocol
   - IP Address Type
   - IP Address
   - Port

To bind a service to an LB vserver by using the command line interface

At the command prompt, type:

bind lb vserver <name> <service>

Example

bind lb vserver VS1_IPv6 SVC1

The vservers receive IPv6 packets and the NetScaler performs Protocol Translation (RFC 2765) before sending traffic to the IPv4-based services.

To bind a service to an LB vserver by using the configuration utility

1. Navigate to Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers page, select the vserver for which you want to bind the service (for example, VS1_IPv6).
3. Click Open.
4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box corresponding to the service that you want to bind to the vserver (for example, SVC1).
5. Click OK.
6. Repeat Steps 1-4 to bind the service (for example, SVC2 to the vserver).

Parameter Descriptions (of commands listed in the CLI procedure)

add service

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

add lb vserver

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind lb vserver

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Host Header Modification

When an HTTP request has an IPv6 address in the host header, and the server does not understand the IPv6 address, you must map the IPv6 address to an IPv4 address. The IPv4 address is then used in the host header of the HTTP request sent to the vserver.

To change the IPv6 address in the host header to an IPv4 address by using the command line interface

At the command prompt, type:

set ns ip6 <IPv6Address> -map <IPAddress>

Example

set ns ip6 2002::9 -map 200.200.200.200

To change the IPv6 address in the host header to an IPv4 address by using the configuration utility

1. Navigate to Network > IPs and, on the IPV6s tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:0:9, and click Open.
2. In the Mapped IP text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns ip6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

VIP Insertion

If an IPv6 address is sent to an IPv4-based server, the server may not understand the IP address in the HTTP header, and may generate an error. To avoid this, you can map an IPv4 address to the IPv6 VIP and enable VIP insertion.

To configure a mapped IPv6 address by using the command line interface

At the command prompt, type:

set ns ip6 <IPv6Address> -map <IPAddress>

Example

```
> set ns ip6 2002::9 -map 200.200.200.200
 Done
```

To configure a mapped IPv6 address by using the configuration utility

1. Navigate to Network > IPs, on the IPV6s tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:0:9, and click Open.
2. In the Mapped IP text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

Use either of the following procedures to enable insertion of an Ipv4 VIP address and port number in the HTTP requests sent to the servers.

To enable VIP insertion by using the command line interface

At the command prompt, type:

set lb vserver <name> -insertVserverIPPort <Value>

Example

```
> set lb vserver VS1_IPv6 -insertVserverIPPort ON
 Done
```

To enable VIP insertion by using the configuration utility

1. In the Advanced tab, under Traffic Settings, in the Vserver IP Port Insertion drop-down list box, select VIPADDR.
2. In the Vserver IP Port Insertion text box, type the vip header.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns ip6

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

set lb vserver

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Traffic Domains

Traffic domains are a way to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments within a NetScaler appliance. An application belonging to a specific traffic domain communicates with entities and processes traffic within that domain. The traffic belonging to one traffic domain cannot cross the boundary of another traffic domain.

Benefits of using Traffic Domains

The main benefits of using traffic domains on a NetScaler appliance are the following:

- **Use of duplicate IP addresses in a Network**. Traffic domains allow you to use duplicate IP address on the network. You can assign the same IP address or network address to multiple devices on a network, or multiple entities on a NetScaler appliance, as long as each of the duplicate address belongs to a different traffic domain.
- **Use of Duplicate entities on the NetScaler appliance**. Traffic domains also allow you to use duplicate NetScaler feature entities on the appliance. You can create entities with the same settings as long as each entity is assigned to a separate traffic domain.

  Note: Duplicate entities with same name is not supported.
- **Multitenancy**. Using traffic domains, you can provide hosting services for multiple customers by isolating each customer's type of application traffic within a defined address space on the network.

A traffic domain is uniquely identified by an identifier, which is an integer value. Each traffic domain needs a VLAN or a set of VLANs. The isolation functionality of the traffic domain depends on the VLANs bound to the traffic domain. More than one VLAN can be bound to a traffic domain, but the same VLAN cannot be a part of multiple traffic domains. Therefore, the maximum number of traffic domains that can be created depends on the number of VLANS configured on the appliance.

Default Traffic Domain

A NetScaler appliance has a preconfigured traffic domain, called the *default traffic domain*, which has an ID of 0. All factory settings and configurations are part of the default traffic domain. You can create other traffic domains and then segment traffic between the default traffic domain and each of the other traffic domains. You cannot remove the default traffic domain from the NetScaler appliance. Any feature entity that you create without setting the traffic domain ID is automatically associated with the default traffic domain.

Note: Some features and configurations are supported only in the default traffic domain. They do not work in nondefault traffic domains. For a list of the features supported in all traffic domains, see "Supported NetScaler Features in Traffic Domains."

How Traffic Domains Work

As an illustration of traffic domains, consider an example in which two traffic domains, with IDs 1 and 2, are configured on NetScaler appliance NS1.

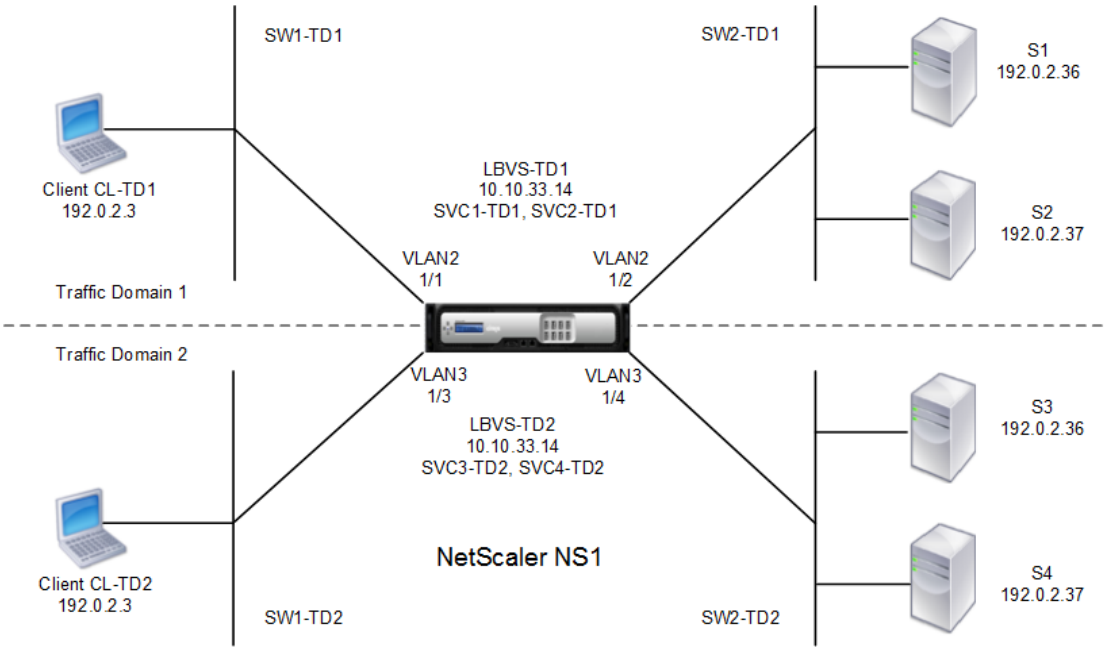
In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the NetScaler appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. Servers S1 and S2 are connected to NS1 through L2 switch SW2-TD1. Client CL-TD1 is on a private network connected to NS1 through L2 switch SW1-TD1. SW1-TD1 and SW2-TD1 are connected to VLAN 2 of NS1. VLAN 2 is bound to traffic domain 1, which means that client CL-TD1 and servers S1 and S2 are part of traffic domain 1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the NetScaler appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. Servers S3 and S4 are connected to NS1 through L2 switch SW2-TD2. Client CL-TD2 is on a private network connected to NS1 through L2 switch SW1-TD2. SW1-TD2 and SW2-TD2 are connected to VLAN 3 of NS1. VLAN 3 is bound to traffic domain 2, which means that client CL-TD2 and servers S3 and S4 are part of traffic domain 2.

On the NetScaler appliance, entities LBVS-TD1 and LBVS-TD2 share the same settings, including the IP address. The same is true for SVC1-TD1 and SVC3-TD2, and for SVC2-TD1 and SVC4-TD2. This is possible because these entities are in different traffic domains.

Similarly, servers S1 and S3, S2 and S4 share the same IP address, and clients CL-TD1 and CL-TD2 each have the same IP address.

Figure 1. How traffic domains work



The following table lists the settings used in the example.

Entity	Name	Details
Settings in traffic domain 1		
VLANs bound to traffic domain 1	VLAN 2	VLAN Id: 2 Interfaces bound: 1/1, 1/2
Client connected to TD1	CL-TD1 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD1	LBVS-TD1	IP address: 192.0.2.15
Service bound to virtual server LBVS-TD1	SVC1-TD1	IP address: 192.0.2.36
	SVC2-TD1	IP address: 192.0.2.37
SNIP	SNIP-TD1 (for reference purposes only)	IP address: 192.0.2.27
Settings in traffic domain 2		
VLAN bound to traffic domain 2	VLAN 3	VLAN Id: 3 Interfaces bound: 1/3, 1/4
Client connected to TD2	CL-TD2 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD2	LBVS-TD2	IP address: 192.0.2.15
Service bound to virtual server LBVS-TD2	SVC3-TD2	IP address: 192.0.2.36
	SVC4-TD2	IP address: 192.0.2.37
SNIP in TD2	SNIP-TD2 (for reference purposes only)	IP address: 192.0.2.29

Following is the traffic flow in traffic domain 1:

1. Client CL-TD1 broadcasts an ARP request for the IP address of 192.0.2.15.
2. The ARP request reaches NS1 on interface 1/1, which is bound to VLAN 2. Because VLAN 2 is bound to traffic domain 1, NS1 updates the ARP table of traffic domain 1 for the IP address of client CL-TD1.
3. Because the ARP request is received on traffic domain 1, NS1 looks for an entity configured on traffic domain 1 that has an IP address of 192.0.2.15. NS1 finds that a load balancing virtual server LBVS-TD1 is configured on traffic domain 1 and has the IP address 192.0.2.15.
4. NS1 sends an ARP response with the MAC address of interface 1/1.
5. The ARP reply reaches CL-TD1. CL-TD1 updates its ARP table for the IP address of LBVS-TD1 with the MAC address of interface 1/1 of NS1.
6. Client CL-TD1 sends a request to 192.0.2.15. The request is received by LBVS-TD1 on port 1/1 of NS1.
7. LBVS-TD1's load balancing algorithm selects server S2, and NS1 opens a connection between a SNIP in traffic domain 1 (192.0.2.27) and S2.

8. S2 replies to SNIP 192.0.2.27 on NS1.

9. NS1 sends S2's reply to client CL-TD1.

Following is the traffic flow in traffic domain 2:

1. Client CL-TD2 broadcasts an ARP request for the IP address of 192.0.2.15.

2. The ARP request reaches NS1 on interface 1/3, which is bound to VLAN 3. Because VLAN 3 is bound to traffic domain 2, NS1 updates traffic-domain 2's ARP-table entry for the IP address of client CL-TD2, even though an ARP entry for the same IP address (CL-TD1) is already present in the ARP table of traffic domain 1.

3. Because the ARP request is received in traffic domain 2, NS1 searches traffic domain 2 for an entity that has an IP address of 192.0.2.15. NS1 finds that load balancing virtual server LBVS-TD2 is configured in traffic domain 2 and has the IP address 192.0.2.15. NS1 ignores LBVS-TD1 in traffic domain 1, even though it has the same IP address as LBVS-TD2.

4. NS1 sends an ARP response with the MAC address of interface 1/3.

5. The ARP reply reaches CL-TD2. CL-TD2 updates its ARP table entry for the IP address of LBVS-TD2 with the MAC address of interface 1/3 of NS1.

6. Client CL-TD2 sends a request to 192.0.2.15. The request is received by LBVS-TD2 on interface 1/3 of NS1.

7. LBVS-TD2's load balancing algorithm selects server S3, and NS1 opens a connection between a SNIP in traffic domain 2 (192.0.2.29) and S3.

8. S2 replies to SNIP 192.0.2.29 on NS1.

9. NS1 sends S2's reply to client CL-TD2.

Supported NetScaler Features in Traffic Domains

The NetScaler features in the following list are supported in all traffic domains.

Supported features in traffic domains	
· ARP table	· Persistency
· ND6 table	· Service
· Bridge table	· Servicegroup
· All types of IPv4 and IPv6 addresses	· Policies (*)
· IPv4 and IPv6 routes	· PING
· ACL and ACL6	· TRACEROUTE
· PBR & PBR6	· PMTU
· INAT	· High Availability (connection mirroring is not supported)
· RNAT	· Cookie Persistency
· MSR	· MSS
· MSR6	· Logging
· Net profiles	· Priority Queuing
· SNMP MIBs	· Surge Protection
· Fragmentation	· HTTP DOSP (*)
· Monitors	· Load balancing (all types of load balancing virtual servers except of type TFTP)
· Content Switching	
· Cache Redirection	

Any NetScaler feature not listed above is supported only in the default traffic domain.
Traffic domains are not supported in a cluster configuration.

Configuring Traffic Domains

Configuring a traffic domain on the NetScaler appliance consists of the following tasks:

- **Add VLANs.** Create VLANs and bind specified interfaces to them.
- **Create a traffic domain entity and bind VLANs to it.** This involves the following two tasks:
  - Create a traffic domain entity uniquely identified by an ID, which is an integer value.
  - Bind the specified VLANs to the traffic domain entity. All the interfaces that are bound to the specified VLANs are associated with the traffic domain. More than one VLAN can be bound to a traffic domain, but a VLAN cannot be a part of multiple traffic domains.
- **Create feature entities on the traffic domain**. Create the required feature entities in the traffic domain. The CLI commands and configuration dialog boxes of all the supported features in a nondefault traffic domain include a parameter called a *traffic domain identifier* (td). When configuring a feature entity, if you want the entity to be associated with a particular traffic domain, you must specify the td. Any feature entity that you create without setting the td is automatically associated with the default traffic domain.

To give you an idea of how feature entities are associated with a traffic domain, this topic covers the procedures for configuring all the entities mentioned in the figure titled "How traffic domains work."

The command line interface has two commands for these two tasks, but the configuration utility combines them in a single dialog box.

To create a VLAN and bind interfaces to it by using the command line interface

At the command prompt, type:

- add vlan <id>
- bind vlan <id> -ifnum <slot/port>
- show vlan <id>

To create a traffic domain entity and bind VLANs to it by using the command line interface

At the command prompt, type:

- add ns trafficdomain <td>
- bind ns trafficdomain <td> -vlan <id>
- show ns trafficdomain <td>

To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> -td <id>
- show service <name>

To create a load balancing virtual server and bind services to it by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType> <IPAddress> <port> -td <id>
- bind lb vserver <name> <serviceName>
- show lb vserver <name>

To create a VLAN by using the configuration utility

Navigate to Network > VLANs, click Add, and set the parameters.

To create a traffic domain entity by using the configuration utility

Navigate to Network > Traffic Domains, click Add, and in the Create Traffic Domain dialog box, set the parameters.

To create a service by using the configuration utility

Navigate to Load Balancing > Services, click Add, and set the parameters.

To create a load balancing virtual server by using the configuration utility

Navigate to Load Balancing > Virtual Servers, click Add, and set the parameters.

Web Interface

The Web Interface on Citrix NetScaler appliances is based on Java Server Pages (JSP) technology and provides access to Citrix XenApp and Citrix XenDesktop applications. Users access resources through a standard Web browser or by using the Citrix XenApp plug-in.

The Web Interface runs as a service on port 8080 on the NetScaler appliance. To create Web Interface sites, Java is executed on Apache Tomcat Web server version 6.0.35 on the NetScaler appliance. The Web Interface sites provide user access to the XenApp and XenDesktop resources, which include applications, content, and desktops.

The Web Interface installation includes installing the Web Interface tar file and JRE tar file on the NetScaler appliance. To configure the Web Interface, you create a Web Interface site and bind one or more XenApp or XenDesktop farms to it.

How Web Interface Works

The following figure illustrates a basic Web interface session.

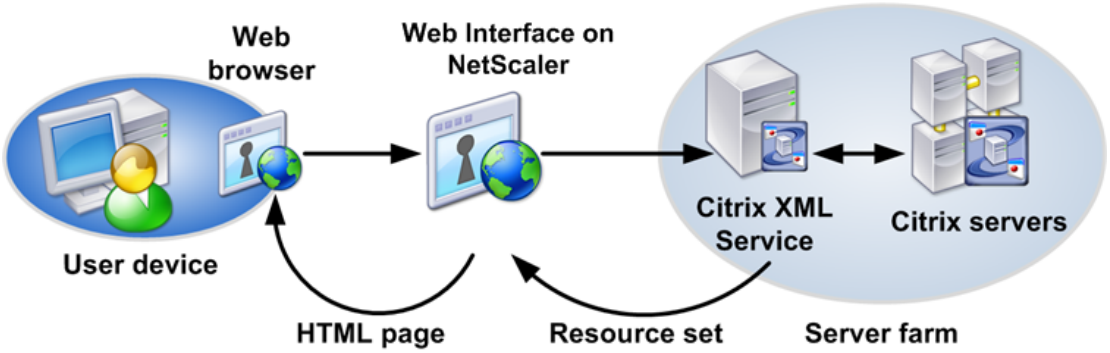

Figure 1. *A Basic Web Interface Session*

Following is a typical set of interactions among a user device, a NetScaler running the Web interface, and a server farm.

1. A user authenticates to the Web interface through a Web browser or by using the XenApp plug-in.
2. The Web interface reads the user's credentials and forwards the information to the Citrix XML Service running on servers in the server farm.
3. The Citrix XML Service on the designated server retrieves from the servers a list of resources that the user can access. These resources constitute the user's resource set and are retrieved from the Independent Management Architecture (IMA) system.
4. The Citrix XML Service then returns the user's resource set to the Web interface running on the NetScaler.
5. The user clicks an icon that represents a resource on the HTML page.
6. The Web interface queries the Citrix XML Service for the least busy server.
7. The Citrix XML Service returns the address of this server to the Web interface.
8. The Web interface sends the connection information to the Web browser.
9. The Web browser initiates a session with the server.

Prerequisites

The following prerequisites are required before you begin installing and configuring the Web interface.

- XenApp or XenDesktop farms are set up and running in your environment. For more information about XenApp, see the XenApp documentation at http://edocs.citrix.com/. For more information about XenDesktop, see the XenDesktop farms documentation at http://edocs.citrix.com/.
- Conceptual knowledge of the Web interface. For more information about Web interface running on a server, see the Web interface documentation at http://edocs.citrix.com/.

Installing the Web Interface

To install the Web interface, you need to install the following files:

- **Web interface tar file**. The setup file for installing the Web interface on the NetScaler appliance. This tar file also includes Apache Tomcat Web server version 6.0.35. The file name has the following format: nswi-<version number>.tgz (for example, nswi-1.5.tgz).

- **JRE tar file**. The JRE tarball. You can use the Diablo Latte JRE version 1.6.0-7 for 64-bit FreeBSD 6.x/amd64 platform available on FreeBSD Foundation Web site at http://www.freebsdfoundation.org/java/java16. Alternatively, you can use OpenJDK6 package for FreeBSD 6.x/amd63. You can download openjdk6-b17_2.tbz from https://citrix.sharefile.com/d/c85aeefcc05643f8.

Note: On a high availability setup, when installing the web interface with tar files (web interface and JRE) that are already available on the appliance, ensure that the files are available in the same location on both the primary and secondary appliances; otherwise, the web interface will not be installed on the secondary appliance.

Copy the tar files to a local workstation or to the /var directory of the appliance.

These files install all the Web interface components and JRE on the hard drive and configure automatic startup of the Tomcat Web server with Web interface at appliance startup time. Both tar files are internally expanded in the /var/wi directory on the hard drive.

Note: After installing web interface on the appliance and before creating a web interface site, you must place the client plugin in the appliance by using the appropriate Upload Plugins utility provided on the web interface details pane.

To install the Web interface and JRE tar files by using the command line interface

At the command prompt, type:

install wi package -wi <URL> -jre <URL>

Examples

> install wi package -wi sftp://username:password@10.102.29.12/var/nswi-1.5.tgz -jre <url>

> install wi package -wi ftp://username:password@10.102.29.15/var/nswi-1.5.tgz -jre <url>

To install the Web interface and JRE tar files by using the configuration utility

In the navigation pane, click Web Interface, and select Install Web Interface, and then specify the install path for web interface tar file and JRE tar file.

Parameter Descriptions (of commands listed in the CLI procedure)

install wi package

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

Configuring the Web Interface

To configure the web interface, you create a web interface site and bind one or more XenApp or XenDesktop farms to it. You then configure the web interface to work behind an HTTP or an HTTPS virtual server or Access Gateway.

- **Using an HTTP or an HTTPS virtual server**. You create an HTTP or an HTTPS virtual server on the NetScaler appliance and bind the web interface service, running on port 8080 of the NetScaler appliance, to the virtual server. Clients on the LAN use the virtual server IP address to access the web interface. When using this access method, the URL format for the web interface site is as follows:

  ```
  <HTTP or HTTPS>://<HTTP or HTTPS vserver IP address>:<vserver port number>/<web interface site path>
  ```

  The following access methods are available for clients accessing the web interface site when it is configured using an HTTP or an HTTPS virtual server:

  - **Direct**. Actual address of a XenApp or XenDesktop server is sent to the clients.
  - **Alternate**. Alternate address of a XenApp or XenDesktop server is sent to the clients.
  - **Translated**. Translated address, from the defined internal addresses to external addresses and ports mapping table, is sent to the clients from a specified network. When you use this option, you have to define internal address to external address and port mappings.
- **Using Access Gateway**. You associate the web interface site with Access Gateway. You associate the web interface site with Access Gateway. Remote clients use the Access Gateway URL to access the web interface site. With this access method, the URL format for the web interface site is as follows:

  ```
  HTTPS://<Access Gateway URL>/<web interface site path>
  ```

  The following access methods are available for clients accessing the web interface site when it is configured using an Access Gateway:

  - **Gateway Direct**. Actual address of a XenApp or XenDesktop server is sent to Access Gateway.
  - **Gateway Alternate**. Alternate address of a XenApp server is sent to Access Gateway. You cannot use this mode to access XenDesktop servers.
  - **Gateway Translated**. Translated address, from the defined internal addresses to external addresses and ports mapping table, is sent to Access Gateway. When you use this option, you have to define internal address to external address and port mappings.

Configuring a Web Interface Site for LAN Users Using HTTP

In this scenario, user and the Web interface setup are on the same enterprise LAN. The enterprise has both a XenApp and a XenDesktop farm. Users access the Web interface by using an HTTP vserver. The Web interface exposes its own login page for authentication. The vserver IP address is used to access the Web interface.

The following figure illustrates the Web interface running on the NetScaler appliance NS1. A Web interface site WINS1 is created and a XenApp farm XA1 and a XenDesktop farm XD1 are bound to it. An HTTP vserver HTTP_WI is also created. Client C1 uses the IP address of the HTTP_WI vserver to access the WINS1 site.

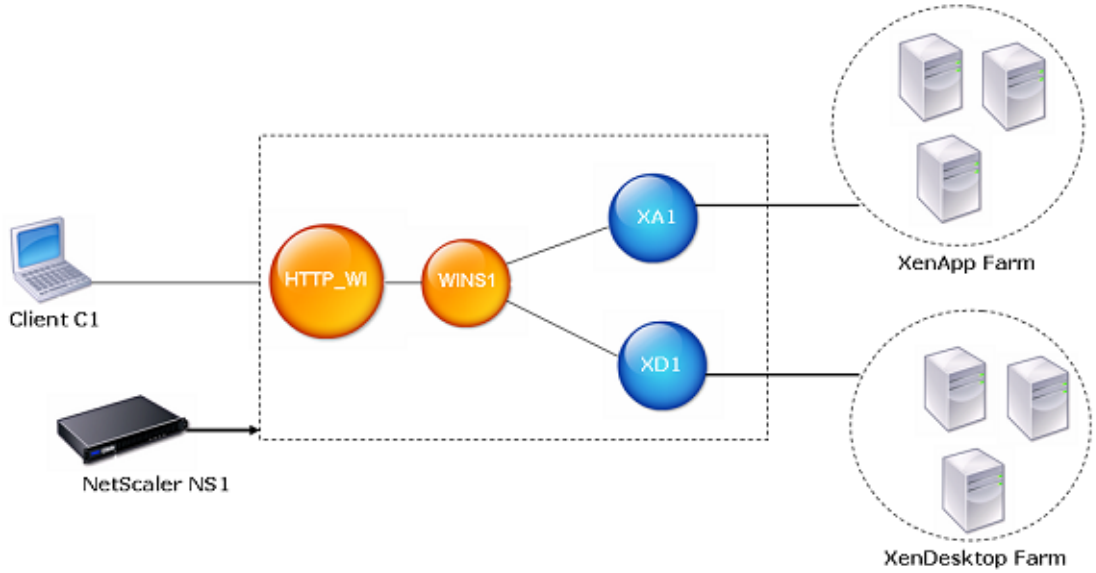

Figure 1. A Web Interface Site Configured for LAN Users Using HTTP

To configure a Web interface site for LAN users using HTTP by using the configuration utility

1. In the navigation pane, click Web Interface.
2. In the details pane, click Web Interface Wizard.
3. On the wizard Introduction page, click Next.
4. On the wizard Configure Web Interface Site page, configure the following parameters:
   - Site Path* (You cannot change the name of an existing Web interface site.)
   - Site Type
   - Published Resource Type
   - Kiosk Mode
   - Authentication Methods
   - Login Title
   - Web Session Timeout
   - Enable access through receiver client

   * A required parameter.
5. In Default Access Methods, select the Direct or Alternate or Translated option and configure the following parameters:
   - Virtual Server
   - Protocol (select **HTTP**)
   - IP Address
   - Port

   Note:

   When you create the HTTP vserver by using the configuration utility, the configuration utility automatically creates a service, which logically represents the Web interface service running on the NetScaler appliance, and binds the service to the HTTP virtual server.

   For more information about services and virtual servers, see the "Traffic Management."
6. Click Next.
7. On the wizard's Configure Access Methods page, do one of the following:
   - To set an access method for a client IP address or network, click Add.

- To change the access method for a client IP address or network, select the association, and then click Open.

8. In the Configure Access Method dialog box, configure the following parameters:

   - Client IP Address* (You cannot change this parameter after setting it.)
   - Netmask (You cannot change this parameter after setting it.)
   - Access Method

   * A required parameter.

   Note: Before you configure access method based on the client IP address, you must enable USIP mode on the web interface service to make the client's IP address available with the web interface.

9. Click Next.
10. On the wizard's Configure Address Translations page, click Add for adding a mapping between an Internal IP address and an external IP address.

    Note: The Configure Address Translations page appears on the wizard when you set the Translated access method for a Client's IP address or network.

11. In the Configure Address Translations dialog box, configure the following parameters:

    - Internal IP Address
    - Internal Port
    - External IP Address
    - External Port
    - Access Type

    * A required parameter.

12. Click Next.
13. On the wizard's Configure XenApp/XenDesktop Farm page, do one of the following:

    - To add a XenApp or XenDesktop farm, click Add.
    - To modify an existing XenApp or XenDesktop farm, select the farm, and then click Open.

14. In the Create XenApp/XenDesktop Farm or Configure XenApp/XenDesktop Farm dialog box, configure the following parameters:

    - Name* (You cannot change the name of an existing XenApp or XenDesktop farm.)
    - XML Service Addresses*
    - XML Service Port
    - Transport

- Load Balance

* A required parameter.

15. Click Next, and then click Finish.

16. Verify that the Web interface site you configured is correct by selecting the site and viewing the Details section at the bottom of the pane. To view the Web interface site, in the navigation pane, expand System, expand Web Interface, and then click Sites.

To configure a Web interface site for LAN users using HTTP by using the command line interface

1. Add a Web interface site. Set Direct or Alternate or Translated for the defaultAccessMethod parameter. At the command prompt, type:

   add wi site <sitePath> -siteType (XenAppWeb | XenAppServices) -publishedResourceType (Online | Offline | DualMode) -kioskMode (ON | OFF) -wiAuthenticationMethods (Explicit | Anonymous) -webSessionTimeout <positive_integer> -defaultAccessMethod <defaultAccessMethod> -loginTitle <string>

   Example

   > add wi site WINS1 -siteType XenAppWeb -publishedResourceType Online -kioskMode ON -defaultAccess

2. (Optional) Set an access method for a Client's IP address or network. At the command prompt, type:

   bind wi site <sitePath> -accessMethod <accessMethod> -clientIpAddress <ip_addr> -clientNetMask <netmask>

3. If you have set the Translated access method for a Client's IP address or network then provide Internal IP and external IP address mappings. At the command prompt, type:

   bind wi site <sitePath> -translationInternalIp <ip_addr> -translationInternalPort <port|*> -translationExternalIp <ip_addr> -translationExternalPort <port|*> [-accessType <accessType>]

4. Bind XenApp or XenDesktop farms to the Web interface site. At the command prompt, type:

   bind wi site <sitePath> <farmName> <xmlServerAddresses> -xmlPort <value> -transport (HTTP | HTTPS) -loadBalance (ON | OFF)

   Example

   > bind wi site WINS1 XA1 10.102.46.6 -xmlPort 80 -transport HTTP -LoadBalance OFF
   > bind wi site WINS1 XD1 10.102.46.50 -xmlPort 80 -transport HTTP -LoadBalance OFF

5. Create a service that is a logical representation of the Web interface service running on the NetScaler appliance. At the command prompt, type:

   add service <name> <IP address> <serviceType> <port>

   Example

   > add service WI_Loopback_Service 127.0.0.1 HTTP 8080

6. Add an HTTP vserver. At the command prompt, type:

   add lb vserver <virtualServerName> <protocol> <IPAddress> <port>

   Example

> add lb vserver HTTP_WI HTTP 10.102.29.5 80

7. Bind the Web interface service to the HTTP vserver. At the command prompt, type:

   bind lb vserver <virtualServerName> <serviceName>

   Example

   > bind lb vserver HTTP_WI WI_Loopback_Service

Configuring a Web Interface Site for LAN Users Using HTTPS

In this scenario, user accounts and the Web interface setup are on the same enterprise LAN. Users access the Web interface by using an SSL-based (HTTPS) vserver. The Web interface exposes its own login page for authentication. SSL offloading is done by this vserver on the NetScaler. The vserver IP address is used to access the Web interface instead of the NetScaler IP address (NSIP).

The following figure illustrates the Web interface running on the NetScaler appliance NS1. A Web interface site WINS1 is created and a XenApp farm XA1 and a XenDesktop farm XD1 are bound to it. An HTTPS vserver HTTPS_WI is also created. Client C1 uses the IP address of the HTTPS_WI vserver to access the WINS1 site.

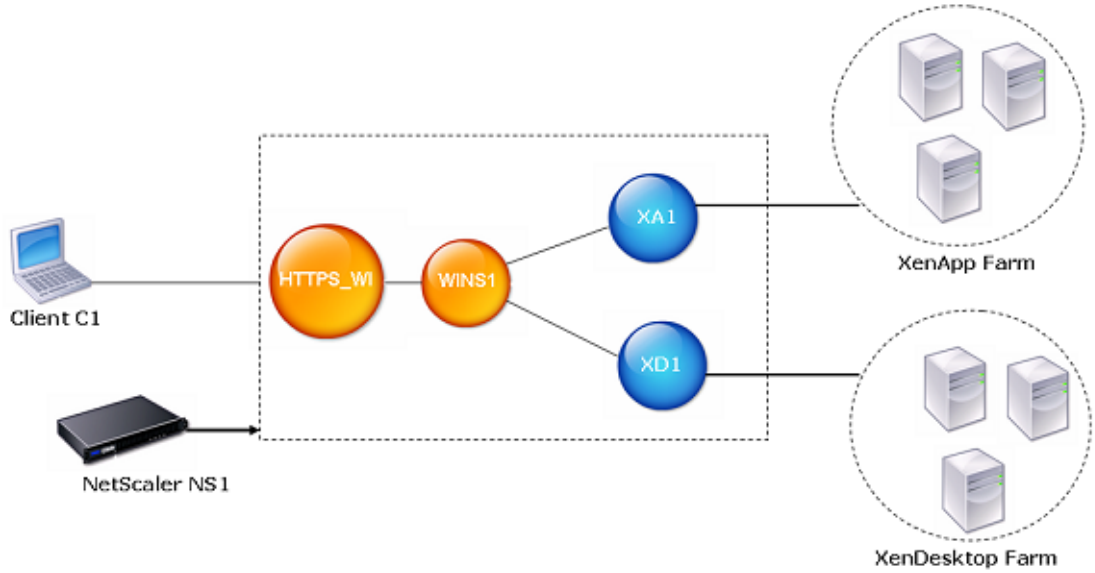

Figure 1. A Web Interface Site Configured for LAN Users Using HTTPS

To configure a Web interface site for LAN users using HTTPS by using the configuration utility

1. In the navigation pane, click Web Interface.
2. In the details pane, click Web Interface Wizard.
3. On the wizard Introduction page, click Next.
4. On the wizard Configure Web Interface Site page, configure the following parameters:
   - Site Path* (You cannot change the name of an existing Web interface site.)
   - Site Type
   - Published Resource Type
   - Kiosk Mode
   - Authentication Methods
   - Login Title
   - Web Session Timeout
   - Enable access through receiver client

   * A required parameter.
5. In Default Access Methods, select the Direct or Alternate or Translated option and configure the following parameters:
   - Virtual Server
   - Protocol (select **HTTPs**)
   - IP Address
   - Port

   Note:

   When you create the HTTPS vserver by using the configuration utility, the configuration utility automatically creates a service, which logically represents the Web interface service running on the NetScaler appliance, and binds the service to the HTTPS virtual server.

   For more information about services and virtual servers, see the "Traffic Management."
6. Click Next.
7. On the wizard's Specify a server Certificate page, you create or specify an existing SSL certificate-key pair. The SSL certificate-key pair is automatically bound to the HTTPS vserver.

For more information, see "Binding an SSL Certificate Key Pair to the Virtual Server."

8. Click Next.
9. On the wizard's Configure Access Methods page, do one of the following:
   - To set an access method for a client IP address or network, click Add.
   - To change the access method for a client IP address or network, select the association, and then click Open.
10. In the Configure Access Method dialog box, configure the following parameters:
    - Client IP Address* (You cannot change this parameter after setting it.)
    - Netmask (You cannot change this parameter after setting it.)
    - Access Method

    * A required parameter.

    Note: Before you configure access method based on the client IP address, you must enable USIP mode on the web interface service to make the client's IP address available with the web interface.
11. Click Next.
12. On the wizard's Configure Address Translations page, click Add for adding a mapping between an Internal IP address and an external IP address.

    Note: The Configure Address Translations page appears on the wizard when you set the Translated access method for a Client's IP address or network.
13. In the Configure Address Translations dialog box, configure the following parameters:
    - Internal IP Address
    - Internal Port
    - External IP Address
    - External Port
    - Access Type

    * A required parameter.
14. On the wizard's Configure XenApp/XenDesktop Farm page, do one of the following:
    - To add a XenApp or XenDesktop farm, click Add.
    - To modify an existing XenApp or XenDesktop farm, select the farm, and then click Open.
15. In the Create XenApp/XenDesktop Farm or Configure XenApp/XenDesktop Farm dialog box, configure the following parameters:
    - Name* (You cannot change the name of an existing XenApp or XenDesktop farm.)
    - XML Service Addresses*

- XML Service Port
- Transport
- Load Balance

* A required parameter.

16. Click Next, and then click Finish.
17. Verify that the Web interface site you configured is correct by selecting the site and viewing the Details section at the bottom of the pane. To view the Web interface site, in the navigation pane, expand System, expand Web Interface, and then click Sites.

To configure a Web interface site for LAN users using HTTPS by using the command line

1. Add a Web interface site. Set Direct or Alternate or Translated for the defaultAccessMethod parameter. At the command prompt, type:

   add wi site <sitePath> -siteType (XenAppWeb | XenAppServices) -publishedResourceType (Online | Offline | DualMode) -kioskMode (ON | OFF) -wiAuthenticationMethods (Explicit | Anonymous) -webSessionTimeout <positive_integer> -defaultAccessMethod <defaultAccessMethod> -loginTitle <string>

   Example

   > add wi site WINS1 -siteType XenAppWeb -publishedResourceType Online -kioskMode ON -defaultAccess

2. (Optional) Set an access method for a Client's IP address or network. At the command prompt, type:

   bind wi site <sitePath> -accessMethod <accessMethod> -clientIpAddress <ip_addr> -clientNetMask <netmask>

3. If you have set the Translated access method for a Client's IP address or network then provide Internal IP and external IP address mappings. At the command prompt, type:

   bind wi site <sitePath> -translationInternalIp <ip_addr> -translationInternalPort <port|*> -translationExternalIp <ip_addr> -translationExternalPort <port|*> [-accessType <accessType>]

4. Bind XenApp or XenDesktop farms to the Web interface site. At the command prompt, type:

   bind wi site <sitePath> <farmName> <xmlServerAddresses> -xmlPort <value> -transport (HTTP | HTTPS) -loadBalance (ON | OFF)

   Example

   > bind wi site WINS1 XA1 10.102.46.6 -xmlPort 80 -transport HTTP -LoadBalance OFF
   > bind wi site WINS1 XD1 10.102.46.50 -xmlPort 80 -transport HTTP -LoadBalance OFF

5. Create a service that is a logical representation of the Web interface service running on the NetScaler appliance. At the command prompt, type:

   add service <name> <IPAddress> <serviceType> <port>

   Example

   > add service WI_Loopback_Service 127.0.0.1 HTTP 8080

6. Add an HTTPS vserver. At the command prompt, type:

   add lb vserver <name>@ <protocol> <IPAddress> <port>

   Example

> add lb vserver HTTPS_WI SSL 10.102.29.3 443

7. Bind the Web interface service to the HTTPS vserver. At the command prompt, type:

   bind lb vserver <name>@ <serviceName>

   Example

   > bind lb vserver HTTPS_WI WI_Loopback_Service

8. Create an SSL certificate key pair. At the command prompt, type:

   add ssl certkey <certificate-KeyPairName> -cert <certificateFileName> -key <privateKeyFileName>

   Example

   > add ssl certkey SSL-Certkey-1 -cert /nsconfig/ssl/test1.cer -key /nsconfig/ssl/test1

9. Bind the SSL certificate key pair to the HTTPS vserver. At the command prompt, type:

   bind ssl vserver <vserverName> -certkeyName <certificate- KeyPairName>

   Example

   > bind ssl vserver HTTPS_WI -certkeyName SSL-Certkey-1

10. Add a rewrite action. At the command prompt, type:

    add rewrite action <name> <type> <target> [<stringBuilderExpr>] [(-pattern <expression>]

    Example

    > add rewrite action Replace_HTTP_to_HTTPS INSERT_AFTER "HTTP.RES.HEADER(\"Location\").Value(0).R

11. Create a rewrite policy and bind the rewrite action to it. At the command prompt, type:

    add rewrite policy <name> <rule> <action>

    Example

    > add rewrite policy rewrite_location "HTTP.RES.STATUS == 302 && HTTP.RES.HEADER(\"Location\").Valu

12. Bind the rewrite policy to the HTTPS vserver. At the command prompt, type:

    bind lb vserver <VserverName> -policyname <rewritePolicyName> -priority <value> -type response

    Example

    > bind lb vserver HTTPS_WI -policyname rewrite_location -priority 10 -type response

Configuring a Web Interface Site for Remote Users Using Access Gateway

In this scenario, user accounts and the Web interface setup are on different networks. Users access a Web interface site by using the Access Gateway URL. SmartAccess is automatically enabled.

The following figure illustrates the Web interface running on the NetScaler appliance NS1. A Web interface site WINS1 is created and a XenApp farm XA1 and a XenDesktop XD1 are bound to it. An Access Gateway VPN vserver AGEE_WI is also configured. The client uses the Access Gateway URL of the AGEE_WI to access the WINS1 site.

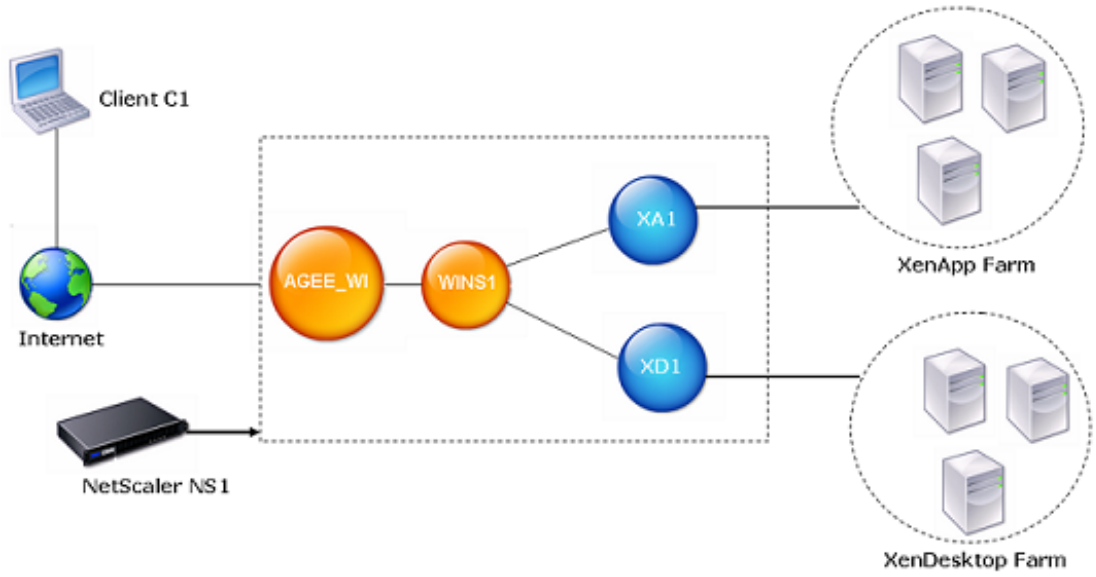

Figure 1. A Web Interface Site Configured for Remote Users Using Access Gateway

To configure a Web interface site for remote users using Access Gateway by using the configuration utility

1. In the navigation pane, click Web Interface.
2. In the details pane, click Web Interface Wizard.
3. On the wizard Introduction page, click Next.
4. On the wizard Configure Web Interface Site page, configure the following parameters:
   - Site Path* (You cannot change the name of an existing Web interface site.)
   - Site Type
   - Published Resource Type
   - Kiosk Mode
   - Authentication Methods
   - Login Title
   - Web Session Timeout
   - Enable access through receiver client

   * A required parameter.
5. In Default Access Methods, select the Gateway Direct or Gateway Alternate or Gateway Translated option and configure the following parameters:
   - Authentication Point
   - Access Gateway URL
   - Add DNS Entry
   - Trust SSL Certificate
   - STA Server URL
   - STA Server URL (2)
   - Session Reliability
   - Use two STA Servers
6. Click Next.
7. On the wizard's Configure Access Methods page, do one of the following:
   - To set an access method for a client IP address or network, click Add.

- To change the access method for a client IP address or network, select the association, and then click Open.

8. In the Configure Access Method dialog box, configure the following parameters:
   - Client IP Address* (You cannot change this parameter after setting it.)
   - Netmask (You cannot change this parameter after setting it.)
   - Access Method

   * A required parameter.

   Note: Before you configure access method based on the client IP address, you must enable USIP mode on the web interface service to make the client's IP address available with the web interface.
9. Click Next.
10. On the wizard's Configure Address Translations page, click Add for adding a mapping between an Internal IP address and an external IP address.

    Note: The Configure Address Translations page appears on the wizard when you set the Translated access method for a Client's IP address or network.
11. In the Configure Address Translations dialog box, configure the following parameters:
    - Internal IP Address
    - Internal Port
    - External IP Address
    - External Port
    - Access Type

    * A required parameter.
12. Click Next.
13. On the wizard's Configure XenApp/XenDesktop Farm page, do one of the following:
    - To add a XenApp or XenDesktop farm, click Add.
    - To modify an existing XenApp or XenDesktop farm, select the farm, and then click Open.
14. In the Create XenApp/XenDesktop Farm or Configure XenApp/XenDesktop Farm dialog box, configure the following parameters:
    - Name* (You cannot change the name of an existing XenApp or XenDesktop farm.)
    - XML Service Addresses*
    - XML Service Port
    - Transport

- Load Balance

* A required parameter.

15. Click Next, and then click Finish.

16. Verify that the Web interface site you configured is correct by selecting the site and viewing the Details section at the bottom of the pane. To view the Web interface site, in the navigation pane, expand System, expand Web Interface, and then click Sites.

To configure a Web interface site for remote users using Access Gateway by using the command line interface

1. Add a Web interface site. Set GatewayDirect or GatewayAlternate or GatewayTranslated for the defaultAccessMethod parameter. At the command prompt, type:

   add wi site <sitePath> <agURL> <staURL> -sessionReliability (ON | OFF) -useTwoTickets (ON | OFF) -secondSTAURL <string> -authenticationPoint (WebInterface | AccessGateway) -siteType (XenAppWeb | XenAppServices) -publishedResourceType (Online | Offline | DualMode) -kioskMode (ON | OFF)-wiAuthenticationMethods (Explicit | Anonymous) -webSessionTimeout <positive_integer> -defaultAccessMethod <defaultAccessMethod> -loginTitle <string>

   Example

   > add wi site WINS1 https://ag.mycompany.com http://ag.staserver.com -sessionReliability OFF -auther

2. (Optional) Set an access method for a Client's IP address or network. At the command prompt, type:

   bind wi site <sitePath> -accessMethod <accessMethod> -clientIpAddress <ip_addr> -clientNetMask <netmask>

3. If you have set the Translated access method for a Client's IP address or network then provide Internal IP and external IP address mappings. At the command prompt, type:

   bind wi site <sitePath> -translationInternalIp <ip_addr> -translationInternalPort <port|*> -translationExternalIp <ip_addr> -translationExternalPort <port|*> [-accessType <accessType>]

4. Bind XenApp or XenDesktop farms to the Web interface site. At the command prompt, type:

   bind wi site <sitePath> <farmName> <xmlServerAddresses> -xmlPort <value> -transport (HTTP | HTTPS) -loadBalance (ON | OFF)

   Example

   > bind wi site WINS1 XA1 10.102.46.6 -xmlPort 80 -transport HTTP -LoadBalance OFF
   > bind wi site WINS1 XD1 10.102.46.50 -xmlPort 80 -transport HTTP -LoadBalance OFF

Parameter Descriptions (of commands listed in the CLI procedure)

add wi site

Using Smart Card Authentication for Web Interface through Access Gateway

The web interface on the NetScaler appliance supports single sign-on with a smart card through Access Gateway. You log on to Access Gateway by using a valid client certificate, either served from the local certificate store or from a smart card. After successful authentication, you are redirected to the web interface.

Requirements

- Make sure that you install the latest web interface tar file (nswi-1.5.tgz). This tar file provides support for smart card authentication.
- You must configure Delegation on the Active Directory. Follow the **Active Directory Configuration** section under **Procedure**, as described in the article at http://support.citrix.com/article/CTX124603.

To use smart card authentication for a web interface site through Access Gateway by using the configuration utility

1. In the navigation pane, click Web Interface.
2. In the details pane, click Web Interface Wizard.
3. On the wizard Introduction page, click Next.
4. On the wizard Configure Web Interface Site page, configure the following parameters:
   - Site Type
   - Site Path
   - Published Resource Type
   - Authentication Methods
   - Login Title
   - Language
   - Web Session Timeout
   - Kiosk Mode
5. Select GatewayDirect as the Default Access Method.
6. Select Access Gateway as the Authentication Point.
7. Select or create a Access Gateway Vserver. For more information, see "http://support.citrix.com/proddocs/topic/access-gateway-10/agee-config-settings-ag-wizard-tsk.html."
8. Click Settings to set the ICA mode, SSO, and WIhome.
9. Select SmartCard as the Access Gateway Authentication Method.
10. Click the SmartCard Settings link to configure certificate-based authentication on Access Gateway. You can skip these steps if certificate-based authentication is already configured on Access Gateway. In the Smart Card Settings wizard do the following:
    a. Specify the CA certificate. Install a CA certificate or use an already installed certificate for the Access Gateway virtual server to authenticate the client certificate.
    b. Configure authentication policies. Create a certificate-based authentication policy and bind it to Access Gateway vserver as follows:
       i. Click Insert Policy. In the Policy Name column, select New Policy.
       ii. In the Create Authentication Policy dialog box, specify a name for the policy, select Authentication Type as CERT, and click New.

iii. In the Create Authentication Server dialog box, specify the server Name and the User Name Field and click Create.

iv. Bind the policy to the Access Gateway Vserver with **ns_true** as expression and default priority.

c. Configure SSL-based client authentication with Client Certificate set as Optional.

d. Click Finish.

11. Continue with the wizard as described in "Configuring a Web Interface Site for Remote Users Using Access Gateway."

To use smart card authentication for a web interface site through Access Gateway by using the command line interface

At the command prompt, type:

add wi site <sitePath> <agURL> <staURL> -authenticationPoint AccessGateway -agAuthenticationMethod SmartCard -defaultAccessMethod GatewayDirect

Additionally, smart card support on web interface requires certificate-based authentication on the Access GatewayAdditionally, smart card support on web interface requires certificate-based authentication on the Access Gateway. If you do not have certificate-based authentication already configured on the Access Gateway vserver, do the following:

1. Configure an Access Gateway vserver and bind the server and CA certificate to it.

   add vpn vserver <*vpnvserver_name*> SSL <*AccessGateway_VIP*> <*port*>

   bind ssl vserver <*vpnvserver_name*> -certkeyName <*Server_Cert_Key_Pair*>

   bind ssl vserver <*vpnvserver_name*> -certkeyName <*Root_Cert_as_CKP*> -CA

   set ssl vserver <*vpnvserver_name*> -clientAuth ENABLED -clientCert Optional

   add dns nameserver <*dns_server_ip*>

2. Configure a certificate-based authentication policy and bind itcertAction_name to the Access Gateway vserver.

   add authentication certAction <certAction_name> -userNameField <string>

   add authentication certPolicy <*certPolicy_name*> <*rule*> <*certAction_name*>

   bind vpn vserver <vserver_name> -policy <*certPolicy_name*>

3. Configure the web interface site in ICA proxy mode through a session policy and then bind it to Access Gateway vserver.

add vpn sessionAction <*sessionAction_name*> -defaultAuthorizationAction ALLOW -SSO ON -wihome "<WI_URL>" -wiPortalMode NORMAL -icaproxy ON

add vpn sessionPolicy <*sessionPolicy_name*> <*rule*> <*sessionAction_name*>

bind vpn vserver <*vpnvserver_name*> -policyName <*sessionPolicy_name*>

bind vpn vserver <*vpnvserver_name*> -staServer *"<sta_server_url>"*

Parameter Descriptions (of commands listed in the CLI procedure)

Using the WebInterface.conf Dialog Box

The WebInterface.conf dialog box in the configuration utility displays the content of the webinterface.conf file for a Web Interface site.

You can do the following from this dialog box:

- Edit the WebInterface.conf file and save the changes.
- Search the file's content for instances of a text string.
- Easily save the WebInterface.conf file to your local computer.

To search a string in the webinterface.conf file by using the configuration utility

1. In the navigation pane, expand Web Interface, and then click Sites, select the web interface site, and click WebInterface.conf.
2. In the WebInterface.conf dialog box, use the following controls:
    - Find. Displays the following search options that you can use to find one or more instances of a text string in a configuration:
        - Look for. Provides a space for you to type the text string that you want to locate in the configuration. As you type the text, the first instance is displayed. If the word you are looking for is not in the file, the Look for text box will change color.
        - Next. Finds and highlights the next occurrence of the text string you typed in Look for.
        - Previous. Finds and highlights the previous occurrence of the text string you typed in Look for.
        - Mark All. Highlights all instances of the text string at one time you typed in Look for. Scroll to review each highlighted instance.

To save the content of the webinterface.conf to your local system by using the configuration utility

1. In the navigation pane, expand Web Interface, and then click Sites, click WebInterface.conf and select Save output text to a file.

Using the config.xml Dialog Box

The Config.xml dialog box in the configuration utility displays the content of the config.xml file for a Web Interface site of site type XenApp/XenDesktop Services Site.

You can do the following from this dialog box:

- Edit the config.xml file and save the changes.
- Search the file's content for instances of a text string.
- Easily save the config.xml file to your local computer.

To search a string in the config.xml file by using the configuration utility

1. In the navigation pane, expand Web Interface, and then click Sites, select XenApp/XenDesktop services site, and click Config.xml.
2. In the Config.xml dialog box, use the following controls:
    - Find. Displays the following search options that you can use to find one or more instances of a text string in a configuration:
        - Look for. Provides a space for you to type the text string that you want to locate in the configuration. As you type the text, the first instance is displayed. If the word you are looking for is not in the file, the Look for text box will change color.
        - Next. Finds and highlights the next occurrence of the text string you typed in Look for.
        - Previous. Finds and highlights the previous occurrence of the text string you typed in Look for.
        - Mark All. Highlights all instances of the text string at one time you typed in Look for. Scroll to review each highlighted instance.

To save the content of the config.xml to the local system by using the configuration utility

1. In the navigation pane, expand Web Interface, and then click Sites, select XenApp/XenDesktop Services Site.
2. Click Config.xml and select Save output text to a file.

Traffic Management

2015-05-17 05:04:23 UTC

Contents

Traffic Management

The following topics cover configuration and installation information for NetScaler traffic management features.

Cache Redirection	Analyzes incoming requests and forwards the requests for already cached data to cache servers. Dynamic HTTP requests and non-cacheable requests are forwarded to the origin servers. Cache redirection is a policy-based feature.
Content Switching	Analyzes client requests and redirects the requests to specific servers on the basis of geographical area, authorization credentials, and device from which the request was initiated.
DataStream	Ensures optimal distribution of traffic from the application and web servers to the database servers. Enables you to segment traffic according to information in the SQL query and on the basis of database names, user names, character sets, and packet size.
Domain Name System	Provides authoritative domain name server (ADNS server) functionality for a domain. The NetScaler appliance functions as a DNS end resolver and forwarder, and also helps in name resolution when fully qualified domain names are not configured.
Firewall Load Balancing	Distributes the traffic across multiple firewalls, providing fault tolerance, increased throughput, and high availability.
Global Server Load Balancing	Enables disaster recovery and ensures continuous availability of applications by protecting against points of failure in a wide area network (WAN).
Link Load Balancing	Load balances outbound traffic across multiple Internet connections to transmit packets seamlessly over the best possible link.
Load Balancing	Distributes user requests for web pages and other protected applications across multiple servers to prevent server overloading and failure. Load balancing also provides fault tolerance.
SSL Offload and Acceleration	Offloads SSL processing from a server to the NetScaler appliance to accelerate SSL transactions.
Web 2.0 Push	Offloads connection management from Web 2.0 servers. Instead of having to maintain a long-lived connection to each client, a Web 2.0 server can maintain a single connection to the NetScaler appliance. The appliance relays the server's data to waiting clients over the connections that it maintains with them.

Cache Redirection

In a typical deployment, different clients ask web servers for the same content repeatedly. To relieve the origin web server of processing each request, a NetScaler® appliance with cache redirection enabled can serve this content from a cache server instead of from the origin server.

The NetScaler analyzes incoming requests, sends requests for cacheable data to cache servers, and sends non-cacheable requests and dynamic HTTP requests to origin servers.

Cache redirection is a policy-based feature. By default, requests that match a policy are sent to the origin server, and all other requests are sent to a cache server. For testing or maintenance, you might want to skip policy evaluation and direct all requests to the cache or to the origin server.

You can combine content switching with cache redirection to cache selective content and serve content from specific cache servers for specific types of requested content.

A NetScaler configured for cache redirection can be deployed at the edge of a network, in front of the origin server, or anywhere along the network backbone. In an edge deployment, commonly used by Internet Service Providers (ISPs), cable companies, content delivery distribution networks, and enterprise networks, the NetScaler resides directly in front of the clients. In a server-side deployment, the NetScaler is closer to the origin servers.

Cache redirection is used most commonly with the HTTP service type, but it also supports the secure HTTPS protocol.

Cache Redirection

In a typical deployment, different clients ask web servers for the same content repeatedly. To relieve the origin web server of processing each request, a NetScaler® appliance with cache redirection enabled can serve this content from a cache server instead of from the origin server.

The NetScaler analyzes incoming requests, sends requests for cacheable data to cache servers, and sends non-cacheable requests and dynamic HTTP requests to origin servers.

Cache redirection is a policy-based feature. By default, requests that match a policy are sent to the origin server, and all other requests are sent to a cache server. For testing or maintenance, you might want to skip policy evaluation and direct all requests to the cache or to the origin server.

You can combine content switching with cache redirection to cache selective content and serve content from specific cache servers for specific types of requested content.

A NetScaler configured for cache redirection can be deployed at the edge of a network, in front of the origin server, or anywhere along the network backbone. In an edge deployment, commonly used by Internet Service Providers (ISPs), cable companies, content delivery distribution networks, and enterprise networks, the NetScaler resides directly in front of the clients. In a server-side deployment, the NetScaler is closer to the origin servers.

Cache redirection is used most commonly with the HTTP service type, but it also supports the secure HTTPS protocol.

Cache Redirection Policies

A cache redirection virtual server applies cache redirection policies to each incoming request. By default, if a request matches one of the configured policies, it is considered non-cacheable, and the NetScaler appliance sends it to the origin server. Other requests are sent to a cache server. This behavior can be reversed, so that requests that match configured cache redirection policies are sent to cache servers.

The NetScaler provides a set of policies for cache redirection. If these built-in policies are not adequate for your deployment, you can configure user-defined cache redirection policies.

Note: Once you have determined which built-in cache redirection policies to use, or have created user-defined policies, proceed with configuring cache redirection. To use this feature, you must configure at least one cache redirection virtual server, and, for normal operation, you must bind at least one cache redirection policy to that virtual server.

Displaying the Built-in Cache Redirection Policies

You can display the available cache redirection polices by using the command line interface or the configuration utility.

To display the built-in cache redirection policies by using the command line interface

At the command prompt, type:

show cr policy [<policyName>]

Example

```
> show cr policy
1)      Cache-By-Pass RULE: NS_NON_GET          Policy:bypass-non-get
2)      Cache-By-Pass RULE: (NS_CACHECONTROL_NOSTORE || NS_CACHECONTROL_NOCACHE || NS_HEADER_
3)      Cache-By-Pass RULE: (NS_EXT_CGI || NS_EXT_ASP || NS_EXT_EXE || NS_EXT_CFM || NS_EXT_EX || N
4)      Cache-By-Pass RULE: NS_URL_TOKENS       Policy:bypass-urltokens
5)      Cache-By-Pass RULE: (NS_HEADER_COOKIE && NS_EXT_NOT_GIF && NS_EXT_NOT_JPEG)     Policy:byp
 Done
>
```

To display the built-in cache redirection policies by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Policies. The configured cache redirection policies appear in the details pane.

2. Select one of the configured policies to view details.

Configuring a Cache Redirection Policy

A cache redirection policy includes one or more expressions (also called *rules*). Each expression represents a condition that is evaluated when the client request is compared to the policy.

You do not explicitly configure actions for cache redirection policies. By default, the NetScaler considers any request that matches a policy to be non-cacheable and directs the request to the origin server instead of the cache.

Cache redirection uses the *classic policy* format. Each policy has a name and includes an expression or a set of expressions that are combined by using logical operators.

To add a cache redirection policy by using the command line interface

At the command prompt, type the following commands to add a cache redirection policy and verify the configuration:

- add cr policy <policyName> -rule <expression>
- show cr policy [<policyName>]

Examples

Policy with a simple expression:

```
> add cr policy Policy-CRD-1 -rule "REQ.HTTP.URL != /*.jpeg"
 Done
> show cr policy Policy-CRD-1
        Cache-By-Pass RULE: REQ.HTTP.URL != '/*.jpeg'   Policy:Policy-CRD-1
 Done
>
```

Policy with a compound expression:

```
> add cr policy Policy-CRD-2 -rule "REQ.HTTP.METHOD == POST && (REQ.HTTP.URL == /*.cgi || REQ.HTTP.U
 Done
> show cr policy Policy-CRD-2
        Cache-By-Pass RULE: REQ.HTTP.METHOD == POST && (REQ.HTTP.URL == '/*.cgi' || REQ.HTTP.URL != '/
 Done
>
```

Policy that evaluates a header:

```
> add cr policy Policy-CRD-3 -rule "REQ.HTTP.HEADER If-Modified-Since EXISTS"
 Done
> show cr policy Policy-CRD-3
        Cache-By-Pass RULE: REQ.HTTP.HEADER If-Modified-Since EXISTS    Policy:Policy-CRD-3
 Done
>
```

To modify or remove a cache redirection policy by using the command line interface

- To modify a cache redirection policy, use the set cr policy command, which is just like using the add cr policy command, except that you enter the name of an existing policy.
- To remove a policy, use the rm cr policy command, which accepts only the <name> argument. You can only remove a cache redirection policy that is not bound to a cache redirection virtual server. If the policy is bound to a virtual server, you must first unbind the policy, and then remove it from the NetScaler.

For details on unbinding a cache redirection policy, see "Unbinding a Policy from a Cache Redirection Virtual Server."

Parameters for creating a cache redirection policy

policyName

Name of the cache redirection policy. This is a mandatory parameter, and the value cannot be changed after the policy is created.

rule

An expression that the NetScaler evaluates to identify non-cacheable requests. Can consist of multiple expressions joined by `AND` and `OR` operators.

To configure a cache redirection policy with a simple expression by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Policies.
2. In the details pane, click Add.
3. In the Create Cache Redirection Policy dialog box, in the Name* text box, type the name of the policy, and then in the Expression area, click Add.
4. To configure a simple expression, enter the expression. Following is an example of an expression that checks for a .jpeg extension in a URL:
   - Expression Type-General
   - Flow Type -REQ
   - Protocol -HTTP
   - Qualifier -URL
   - Operator - !=
   - Value* - /*.jpeg

   The simple expression in the following example checks for an If-Modified-Since header in a request:
   - Expression Type -General
   - Flow Type -REQ
   - Protocol -HTTP
   - Qualifier -HEADER
   - Operator -EXISTS
   - Header Name -If-Modified-Since
5. When you are finished entering the expression, click OK or Create, and then click Close.

To configure a cache redirection policy with a compound expression by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Policies.
2. In the details pane, click Add.
3. In the Name text box, enter a name for the policy.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), and underscore (_) symbols. You should choose a name that will make it easy for others to tell what type of content this policy was created to detect.

4. Choose the type of compound expression that you want to create. Your choices are:

   - **Match Any Expression**. The policy matches the traffic if one or more individual expressions match the traffic.
   - **Match All Expressions**. The policy matches the traffic only if every individual expression matches the traffic.
   - **Tabular Expressions**. Switches the Expressions list to a tabular format with three columns. In the rightmost column, you place one of the following operators:
     - The AND [&&] operator, to require that, to match the policy, a request match both the current expression and the following expression.
     - The OR [||] operator, to require that, to match the policy, a request match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.

     You can also group expressions in nested subgroups by selecting an existing expression and clicking one of the following operators:

     - The BEGIN SUBGROUP [+ ( ] operator, which tells the NetScaler appliance to begin a nested subgroup with the selected expression. (To remove this operator from the expression, click -(.)
     - The END SUBGROUP [+)] operator, which tells the NetScaler appliance to end the current nested subgroup with the selected expression. (To remove this operator from the expression, click -) .)
   - **Advanced Free-Form**. Switches off the Expressions Editor entirely and turns the Expressions list into a text area in which you type your compound expression. This is both the most powerful and the most difficult method of creating a policy expression, and is recommended only for those thoroughly familiar with the NetScaler classic expressions language.

     For more information about creating classic expressions in the Advanced Free-Form text area, see "Configuring Classic Policies and Expressions".

     Caution: If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression

editing mode unless you are sure that is what you want to do.

5. If you chose Match Any Expression, Match All Expressions, or Tabular Expressions, click Add to display the Add Expression dialog box.

   You should leave the expression type set to General for cache redirection policies.

6. In the Flow Type drop-down list, choose a flow type for your expression.

   The flow type determines whether the policy examines incoming or outgoing connections. You have two choices:

   - **REQ**. Configures the NetScaler appliance to examine incoming connections, or requests.
   - **RES**. Configures the appliance to examine outgoing connections, or responses.

7. In the Protocol drop-down list, choose a protocol for your expression.

   The protocol determines the type of information that the policy examines in the request or response. Depending upon whether you chose REQ or RES in the previous drop-down list, either all four of the following choices, or three of them, are available:

   - **HTTP**. Configures the appliance to examine the HTTP header.
   - **SSL**. Configures the appliance to examine the SSL client certificate. Available only if you chose REQ (requests) in the previous drop-down list.
   - **TCP**. Configures the appliance to examine the TCP header.
   - **IP**. Configures the appliance to examine the source or destination IP.

8. Choose a qualifier for your expression from the Qualifier drop-down list.

   The contents of the Qualifier drop-down list depend on which protocol you chose. The following table describes the choices available for each protocol.

   Table 1. Cache Redirection Policy Qualifiers Available for Each Protocol

Protocol	Qualifier	Definition
HTTP	METHOD	The HTTP method used in the request.

	URL	The contents of the URL header.
	URLTOKENS	The URL tokens in the HTTP header.
	VERSION	The HTTP version of the connection.
	HEADER	The header portion of the HTTP request.
	URLLEN	The length of the contents of the URL header.
	URLQUERY	The query portion of the contents of the URL header.
	URLQUERYLEN	The length of the query portion of the URL header.
SSL	CLIENT.CERT	The SSL client certificate as a whole.
	CLIENT.CERT.SUBJECT	The contents of the client certificate subject field.
	CLIENT.CERT.ISSUER	The client certificate issuer.
	CLIENT.CERT.SIGALGO	The signature algorithm used in the client certificate.
	CLIENT.CERT.VERSION	The client certificate version.
	CLIENT.CERT.VALIDFROM	The date from which the client certificate is valid. (The start date.)
	CLIENT.CERT.VALIDTO	The date after which the client certificate is no longer valid. (The end date.)
	CLIENT.CERT.SERIALNUMBER	The client certificate serial number.
	CLIENT.CIPHER.TYPE	The encryption method used in the client certificate.
	CLIENT.CIPHER.BITS	The number of significant bits in the encryption key.
	CLIENT.SSL.VERSION	The SSL version of the client certificate.

TCP	SOURCEPORT	The source port of the TCP connection.
	DESTPORT	The destination port of the TCP connection.
	MSS	The maximum segment size (MSS) of the TCP connection.
IP	SOURCEIP	The source IP of the connection.
	DESTIP	The destination IP of the connection.

9. Choose the operator for your expression from the Operator drop-down list.

   Your choices depend on the qualifier you chose in the previous step. The complete list of operators that can appear in this drop-down list is:

   - == . Matches the following text string exactly.
   - != . Does not match the following text string.
   - > . Is greater than the following integer.
   - CONTAINS . Contains the following text string.
   - CONTENTS . The contents of the designated header, URL, or URL query.
   - EXISTS . The specified header or query exists.
   - NOTCONTAINS . Does not contain the following text string.
   - NOTEXISTS . The specified header or query does not exist.

   If you want this policy to operate on requests sent to a specific Host, you can leave the default, the equals (==) sign.

10. If the Value text box is visible, type the appropriate string or number into the text box.

    For example, if you want this policy to select requests sent to the host `shopping.example.com`, you would type that string in the Value text box.

11. If you chose HEADER as the qualifier, type the header you want in the Header Name text box.

12. Click OK to add your expression to the Expression list.

13. Repeat steps 4 through 11 to create additional expressions.

14. Click Close to close the Add Expression dialog box and return to the Create Cache Redirection Policy dialog box.

Built-in Cache Redirection Policies

The NetScaler appliance provides built-in cache redirection policies that handle typical cache requests. These policies are based on HTTP methods, the URL or URL tokens of the incoming request, the HTTP version, or the HTTP headers in the request and their values.

Built-in cache redirection policies can be directly bound to a virtual server and do not need further configuration.

Cache redirection policies use the simpler of two NetScaler expressions languages, called *classic expressions*. For a complete description of classic expressions and how to configure them, see http://support.citrix.com/article/CTX132362.

The NetScaler provides the following built-in cache redirection policies

built in Policy Name	Description
bypass-non-get	Bypass the cache if the request uses an HTTP method other than GET.
bypass-cache-control	Bypass the cache if the request header contains a Cache-Control: no-cache or Cache-Control: no-store header, of if the HTTP request contains a pragma header.
bypass-dynamic-url	Bypass the cache if the URL suggests that the content is dynamic, as indicated by the presence of any of the following extensions: · cgi · asp · exe · cfm · ex · shtml · htx Also bypass the cache if the URL starts with any of the following: · /cgi-bin/ · /bin/ · /exec/
bypass-urltokens	Bypass the cache because the request is dynamic, as indicated by one of the following tokens in the URL: ?, !, or =.

bypass-cookie	Bypass the cache for any URL that has a cookie header and an extension other than .gif or .jpg.

Cache Redirection Configurations

Depending on your deployment and network topology, you can configure one of the following types of cache redirection:

- **Transparent**. A transparent cache can reside on a variety of points along a network backbone to alleviate traffic along the delivery route. In transparent mode, the cache redirection virtual server intercepts all traffic flowing to the NetScaler appliance and applies cache redirection policies to determine whether content should be served from the cache or from the origin server.

- **Forward proxy**. A forward proxy cache server resides on the edge of an enterprise LAN and faces the WAN. In the forward proxy mode, the cache redirection virtual server resolves the hostname of the incoming request by using a DNS server and forwards requests for non-cacheable content to the resolved origin servers. Cacheable requests are sent to the configured cache servers.

- **Reverse proxy**. Reverse proxy caches are configured for specific origin servers. Incoming traffic directed to the reverse proxy, can either be served from a cache server or be sent to the origin server with or without modification to the URL.

Configuring Transparent Redirection

When you configure transparent cache redirection, the NetScaler appliance evaluates all traffic it receives, to determine whether it is cacheable. This mode alleviates traffic along the delivery route and is often used when the cache server resides on the backbone of an ISP or carrier.

By default, cacheable requests are sent to a cache server, and non-cacheable requests to the origin server. For example, when the NetScaler appliance receives a request that is directed to a web server, it compares the HTTP headers in the request with a set of policy expressions. If the request does not match the policy, the appliance forwards the request to a cache server. If the response does match a policy, the appliance forwards the request, unchanged, to the web server.

For details on how to modify this default behavior, see "Directing Policy Hits to the Cache instead of the Origin."

To configure transparent redirection, first enable cache redirection and load balancing, and configure edge mode. Then, create a cache redirection virtual server with a wildcard IP address (*), so that this virtual server can receive traffic coming to the NetScaler on any IP address the appliance owns. To this virtual server, bind cache redirection policies that describe the types of requests that should not be cached. Then, create a load balancing virtual server that will receive traffic from the cache redirection virtual server for cacheable requests. Finally, create a service that represents a physical cache server and bind it to the load balancing virtual server.

Enabling Cache Redirection and Load Balancing

The NetScaler cache redirection and load balancing features are not enabled by default. They must be enabled before any cache redirection configuration can take effect.

To enable cache redirection and load balancing by using the command line interface

At the command prompt, type the following command to enable cache redirection and load balancing and verify the settings:

- enable ns feature `cr lb`
- show ns feature

Example

```
> enable ns feature cr lb
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)   Web Logging              WL               ON
 2)   Surge Protection         SP               ON
 3)   Load Balancing           LB               ON
 4)   Content Switching         CS               ON
 5)   Cache Redirection         CR               ON
 6)   Sure Connect

         ...
         ...
         ...

 23)   HTML Injection           HTMLInjection       ON
 24)   NetScaler Push           push                OF
 Done
>
```

To enable cache redirection and load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. To enable cache redirection, in the details pane, under Modes and Features, click Configure advanced features.
    a. In Configure Advanced Features dialog box, select the check box next to the Cache Redirection, and then click OK.
    b. In Enable/Disable Feature(s)? dialog box, click Yes.
3. To enable load balancing, in the details pane, under Modes and Features, click Configure basic features.
    a. In Configure Basic Features dialog box, select the check box next to the Load Balancing, and then click OK.
    b. In Enable/Disable Feature(s)? dialog box, click Yes.

Configuring Edge Mode

When deployed at the edge of a network, the NetScaler appliance dynamically learns about the servers on that network. Edge mode enables the appliance to dynamically learn about up to 40,000 HTTP servers and proxy TCP connections for these servers.

This mode turns off collection of statistics for the dynamically learned services and is typically used in transparent deployments for cache redirection.

To enable edge mode by using the command line interface

At the command prompt, type the following commands to enable edge mode and verify the setting:

- enable ns mode Edge
- show ns mode

Example

```
> enable ns mode edge
 Done

> show ns mode

      Mode                    Acronym          Status
      -------                 -------          ------
        ...
        ...
        ...
 6)   MAC-based forwarding       MBF              ON
 7)   Edge configuration         Edge             ON
 8)   Use Subnet IP              USNIP            OFF
        ...
        ...
        ...

 Done
>
```

Parameters for enabling edge mode

Mode

The name of the mode to be enabled. This is a mandatory argument.

To enable edge mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In Configure Modes dialog box, select the check box next to the Edge Configuration, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

Configuring a Cache Redirection Virtual Server

By default, a cache redirection virtual server forwards cacheable requests to the load balancing virtual server for the cache, and forwards non-cacheable requests to the origin server (except in a reverse proxy configuration, in which non-cacheable requests are sent to a load balancing virtual server). There are three types of cache redirection virtual servers: transparent, forward proxy, and reverse proxy.

A transparent cache redirection virtual server uses an IP address of * and a port number, usually 80, that can accept HTTP traffic sent to any IP address that the NetScaler represents. As a result, you can configure only one transparent cache redirection virtual server. Any additional cache redirection virtual servers that you configure must be forward proxy or reverse proxy redirection servers.

To add a cache redirection virtual server in transparent mode by using the command line interface

At the command prompt, type the following commands to add a cache redirection virtual server and verify the configuration:

- add cr vserver <name> <serviceType> [<IPAddress> <port>] [-cacheType <cacheType>] [-redirect <redirect>] [-cacheVserver <string>]
- show cr vserver [<name>]

Example

```
add cr vserver Vserver-CRD-1 HTTP * 80 -cacheType TRANSPARENT -redirect POLICY -cacheVserver Vserver-L
> show cr vserver Vserver-CRD-1
      Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
      State: UP  ARP:DISABLED
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default:       Content Precedence: RULE       Cache: TRANSPARENT
      On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF
 Done
>
```

To modify or remove a cache redirection virtual server by using the command line interface

- To modify a virtual server, use the set cr vserver command, which is just like using the add cr vserver command, except that you enter the name of an existing virtual server.
- To remove a virtual server, use the rm cr vserver command, which accepts only the <name> argument.

Parameters for adding a cache redirection virtual server

name

Name of the cache redirection virtual server. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Can be changed after the cache redirection virtual server is created. You should choose a name that helps identify the type of service being added. Maximum length of the name can be 127 characters.

serviceType

The type of data that the virtual server will handle. For typical web traffic, the protocol is HTTP. Possible Values: HTTP, SSL.

IPAddress

The IP address of the virtual server that you are adding. For transparent cache redirection, assign an asterisk (*) as the IP address, so that the virtual server listens on all IP addresses configured on the NetScaler.

port

The port number on which the virtual server receives traffic.

cacheType

The type of cache redirection you are configuring. Possible values: TRANSPARENT, REVERSE, FORWARD.

redirect

The redirect method to be used. Possible values: CACHE, ORIGIN, POLICY.

For normal operation, specify POLICY based redirection and bind appropriate cache redirection policies to the virtual server.

cacheVserver

The name of a load balancing virtual server to which this redirection virtual server sends cache requests.

To add a cache redirection virtual server in transparent mode by using the configuration utility

1. In the navigation pane, click Cache Redirection, and then click Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Cache Redirection) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for adding a cache redirection virtual server” as shown:
   - Name*—name
   - Port*—port

   * A required parameter
4. In the Protocol drop-down list, select a supported protocol (for example, **HTTP**). If the virtual server is to receive traffic on a port other than the standard port for the selected protocol, enter a new value in the Port field.
5. Click the Advanced tab.
6. Verify that Cache Type is set to TRANSPARENT and Redirect is set to POLICY.
7. If you have already configured load balancing virtual servers for cache redirection, select a virtual server from the Cache Server drop-down list.
8. Click Create, and then click Close. The Cache Redirection Virtual Servers pane displays the new virtual server.
9. Select the new cache redirection virtual server to display the details of its configuration.

Binding Policies to the Cache Redirection Virtual Server

Cache redirection policies are not automatically bound to the cache redirection virtual server. A policy based cache redirection virtual server cannot function unless you bind at least one policy to it.

To bind policies to a cache redirection virtual server by using the command line interface

At the command prompt, type:

- bind cr vserver <name> -policyName <string>
- show cr vserver [<name>]

Example

```
> bind cr vserver Vserver-CRD-1 -policyName bypass-cache-control
 Done
> bind cr vserver Vserver-CRD-1 -policyName bypass-dynamic-url
 Done
> bind cr vserver Vserver-CRD-1 -policyName bypass-urltokens
 Done
> bind cr vserver Vserver-CRD-1 -policyName bypass-cookie
 Done

> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: UP  ARP:DISABLED
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default:        Content Precedence: RULE        Cache: TRANSPARENT
        On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF

1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: bypass-dynamic-url
3)      Cache bypass  Policy: bypass-urltokens
4)      Cache bypass  Policy: bypass-cookie
 Done
>
```

Parameters for binding policies to a cache redirection virtual server

name

The name of the cache redirection virtual server you are binding the policy to.

policyName

The name of the policy being bound to the cache redirection virtual server. The policy must already be created on the NetScaler appliance before it is bound.

To bind a user-defined policy to a cache redirection virtual server by using the configuration utility

1. In the navigation pane, expand Cache Redirection and click Virtual Servers.
2. Click the virtual server that you want to configure, and click Open.
3. On the Policies tab, select type of the policy and then click Insert Policy.
4. Under Policy Name column, select the policy that you want to bind.
5. Click OK.

Unbinding a Policy from a Cache Redirection Virtual Server

When you unbind a policy from the cache redirection virtual server, the NetScaler appliance no longer applies the policy when evaluating client requests.

To unbind a policy from a cache redirection virtual server by using the command line interface

At the command prompt, type:

- unbind cr vserver <name> -policyName <string>
- show cr vserver [<name>]

Example

```
unbind cr vserver Vserver-CR-1 -policyName bypass-non-get
> show cr vserver Vserver-CRD-1
      Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
      State: UP  ARP:DISABLED
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default:       Content Precedence: RULE       Cache: TRANSPARENT
      On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF

1)     Cache bypass  Policy: bypass-cache-control
 Done
>
```

To unbind a user-defined policy from a cache redirection virtual server by using the configuration utility

1. In the navigation pane, expand Cache Redirection and click Virtual Servers.
2. Click the virtual server that you want to configure, and then click Open.
3. On the Policies tab, under Policy Name, select the policy that you want to unbind.
4. Click Unbind Policy, and then click OK.

Creating a Load Balancing Virtual Server

The cache redirection virtual server on the NetScaler appliance can send requests to either a cache server farm, if the request is cacheable, or to the origin server farm if the request is not cacheable.

Each cache server is represented on the appliance by a service, which is bound to a load balancing virtual server that receives requests from the cache redirection virtual server and forwards those requests to the servers.

For details on configuring load balancing virtual servers and other configuration options, see "Load Balancing."

To create a load balancing virtual server by using the command line interface

At the command prompt, type the following commands to create a load balancing virtual server and verify the configuration:

- add lb vserver <name> <serviceType> [<IPAddress>] [<port>]
- show lb vserver [<name>]

Example

```
> add lb vserver Vserver-LB-CR HTTP 10.102.20.30 80
 Done
> show lb vserver Vserver-LB-CR
        Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
        State: DOWN
        Last state change was at Fri Jul  2 08:47:52 2010
        Time since last state change: 0 days, 00:00:08.470
        Effective State: DOWN
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        No. of Bound Services :  0 (Total)       0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE
        Vserver IP and Port insertion: OFF
        Push: DISABLED  Push VServer:
        Push Multi Clients: NO
        Push Label Rule: none
 Done
>
```

Parameters for creating a load balancing virtual server

name

The name of the virtual server being created.

serviceType

The type of traffic the virtual server will be receiving. For all web traffic, create virtual servers of type HTTP or, for secure Web traffic, HTTPS.

IPAddress

The IP address of the virtual server. This is the IP address that will receive incoming traffic.

port

The port number on which the incoming traffic will be received.

To create a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for creating a load balancing virtual server" as shown:
   - Name*-name
   - IP Address*- IPAddress
   - Port*-port

   * A required parameter
4. In the Protocol* drop down list, select a supported protocol (for example, **HTTP**). If the virtual server is to receive traffic on a port other than the well-known port for the selected protocol, enter a new value in the Port field.
5. Click Create, and then click Close. The Load Balancing Virtual Servers pane displays the new virtual server.

Configuring an HTTP Service

On the NetScaler appliance, a service represents a physical server on the network. In the transparent cache redirection configuration, the service represents the cache server. Cacheable requests are sent by the cache redirection virtual server to the load balancing virtual server, which in turn forwards each request to the correct service, which passes it on to the cache server.

To configure an HTTP service by using the command line interface

At the command prompt, type the following commands to create an HTTP service and verify the configuration:

- add service <name> <IP> <serviceType> <port> -cacheType <cacheType>
- show service [<name>]

Example

```
> add service Service-HTTP-1 10.102.29.40 HTTP 80 -cacheType TRANSPARENT
 Done
> show service Service-HTTP-1
      Service-HTTP-1 (10.102.29.40:80) - HTTP
      State: DOWN
      Last state change was at Fri Jul  2 09:14:17 2010
      Time since last state change: 0 days, 00:00:13.820
      Server Name: 10.102.29.40
      Server ID : 0   Monitor Threshold : 0
      Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
      Use Source IP: NO
      Client Keepalive(CKA): NO
      Access Down Service: NO
      TCP Buffering(TCPB): NO
      HTTP Compression(CMP): YES
      Idle timeout: Client: 180 sec   Server: 360 sec
      Client IP: DISABLED
      Cache Type: TRANSPARENT Redirect Mode:
      Cacheable: NO
      SC: OFF
      SP: ON
      Down state flush: ENABLED

1)     Monitor Name: tcp-default
            State: DOWN     Weight: 1
            Probes: 3       Failed [Total: 3 Current: 3]
            Last response: Failure - Time out during TCP connection establishment stage
```

```
                Response Time: N/A
 Done
>
```

To modify or remove a service by using the command line interface

- To modify a service, use the set service command, which is just like using the add service command, except that you enter the name of an existing service.
- To remove a service, use the rm service command, which accepts only the <name> argument.

Parameters for adding an HTTP service

name

The name of the service you are configuring. The name can begin with a letter, a number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should choose a name that helps identify the type of service being added. (Cannot be changed after the service has been created.)

IP

The physical IP address of the server that the service you are configuring represents. Make sure that the server is reachable by the NetScaler.

port

The port number on which the service sends and receives data to and from the server.

serviceType

The type of data that will be transferred between the NetScaler and the server. Typically, for web server caches, the serviceType is HTTP.

cacheType

The type of cache redirection you are configuring.

To add an HTTP service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for adding an HTTP service" as shown:
   - Service Name*—name
   - Server*— IP
   - Port*—port

   * A required parameter
4. In the Protocol* drop-down list, select a supported protocol (for example, **HTTP**).
5. Click Create, and then click Close.

Binding/Unbinding a Service to/from a Load Balancing Virtual Server

You must bind a service to the load balancing virtual server. This enables the load balancer to forward the request to the server that the service represents. If your configuration changes, you can unbind a service from the load balancing virtual server.

To bind a service to a load balancing virtual server by using the command line interface

At the command prompt, type:

- bind lb vserver <name> <serviceName>
- show lb vserver [<name>]

Example

```
> bind lb vserver vserver-LB-CR service-HTTP-1
 Done
> show lb vserver Vserver-LB-CR
        Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
        State: DOWN
        Last state change was at Fri Jul  2 08:47:52 2010
        Time since last state change: 0 days, 00:42:25.610
        Effective State: DOWN
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        No. of Bound Services :  1 (Total)       0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE
        Vserver IP and Port insertion: OFF
        Push: DISABLED  Push VServer:
        Push Multi Clients: NO
        Push Label Rule: none

1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
 Done
>
```

To unbind a service from a load balancing virtual server by using the command line interface

To unbind a service, use the unbind lb vserver command instead of bind lb vserver.

Parameters for binding/unbinding a service to/from a load balancing virtual server

name

The virtual server name from which the service will be bound/unbound. This is a mandatory argument. Maximum Length: 127

serviceName

The service name (created with the addService command) that will be unbound. Maximum Length: 127

To bind/unbind a service from a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server from which you want to bind/unbind the service, and then click Open.
3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

Disabling the Use the Proxy Port Setting for Transparent Caching

If the use source IP (USIP) option is disabled on a cache service configured on the NetScaler appliance, the appliance forwards client requests to the cache service by using a NetScaler-owned subnet IP (SNIP) address or mapped IP (MIP) address as the source IP address and a random port as the source port. The randomly selected port is called the proxy port.

However, if you want to configure a fully transparent cache (a cache configuration in which the cache service receives the client's IP address and port number), you must not only enable the USIP option, either globally or on the cache service, but also disable the Use Proxy Port setting, either globally or on the cache service. Disabling the Use Proxy Port setting enables the appliance to use the client's source port as the source port when it connects to the cache service, and ensures a fully transparent cache configuration.

For more information about configuring the Use Proxy Port option globally or on a service, see "Configuring the Source Port for Server-Side Connections."

Assigning a Port Range to the NetScaler

Sharing of the client IP address may create a conflict that makes network devices, such as routers, cache servers, origin servers, and other NetScaler appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

A method to solve this problem is to assign a source port range to the NetScaler appliance. This allotment enables network devices to unambiguously identify the NetScaler appliance that sent the request.

To assign a source port range to a NetScaler appliance by using the command line interface

At the command prompt, type:

set ns param -crPortRange <startPortNumber-endPortNumber>

Parameters for assigning source port range

startPortNumber

Lower limit of the port range

endPortNumber

Upper limit of the port range

The range should be from 1024 through 65535.

To assign a source port range to a NetScaler appliance by using the NetScaler configuration utility

1. In the navigation pane, click System, and then click Settings.
2. In the Settings group, click the Change global system settings link.
3. In the Cache Redirection Port Range group, specify the port range for the NetScaler by typing a port number for Start Port and a port number for End Port.
4. Click OK.

Enabling Load Balancing Virtual Servers to Redirect Requests to Cache

If a load balancing virtual server is configured to listen on a particular IP address and port combination, it takes precedence over the cache redirection virtual server for any requests destined for that address-port combination. Therefore, the cache redirection virtual server does not process those requests.

If you want to override this functionality and let the cache redirection virtual server decide whether the request should be served from the cache or not, configure the particular load balancing virtual server to be cacheable.

Such a configuration is typically used when an ISP uses a NetScaler appliance at the edge of its network and all traffic flows through the appliance.

To enable load balancing virtual servers to redirect requests to the cache by using the command line interface

At the command prompt, type:

- set lb vserver <name> [-cacheable (YES | NO)]
- show lb vserver [<name>]

Example

```
set lb vserver Vserver-LB-CR –cacheable YES
> show lb vserver vserver-LB-CR
        Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
        State: DOWN
        Last state change was at Fri Jul  2 08:47:52 2010
        Time since last state change: 0 days, 01:05:51.510
        Effective State: DOWN
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        No. of Bound Services :  1 (Total)       0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE
        Cacheable: YES  PQ: OFF SC: OFF
        Vserver IP and Port insertion: OFF
```

```
    Push: DISABLED  Push VServer:
    Push Multi Clients: NO
    Push Label Rule: none

1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
 Done
```

For transparent cache redirection, the NetScaler intercepts all traffic and evaluates every request to determine whether it is cacheable. Non-cacheable requests are sent unchanged to the origin server.

When using transparent cache redirection, you may want to turn off cache redirection for load balancing virtual servers that always direct traffic to origin servers.

To turn off caching for a load balancing virtual server by using the command line interface

To turn off caching for a load balancing virtual, use the unset lb vserver command instead of set lb vserver. Specify a value of NO value for the **-cacheable** parameter**.**

To enable or disable load balancing virtual servers to redirect requests to the cache by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server from which you want to enable/disable the caching, and then click Open.
3. On the Advanced tab, select/clear Cache Redirection check box.
4. Click OK.

Configuring Forward Proxy Redirection

A forward proxy is a single point of contact for a client or group of clients. In this configuration, the NetScaler appliance redirects non-cacheable requests to an origin server and redirects cacheable requests to either a forward proxy cache or a transparent cache.

When the NetScaler is configured as a forward proxy, users must modify their browsers so that the browser sends requests to the forward proxy instead of the destination servers.

A forward proxy cache redirection virtual server on the NetScaler compares the request with a policy for caching. If the request is not cacheable, the NetScaler queries a DNS load balancing virtual server for resolution of the destination, and then sends the request to the origin server. If the request is cacheable, the NetScaler forwards the request to a load balancing virtual server for the cache.

The NetScaler relies on a host domain name or IP address in the request's HOST header to determine the requested destination. If there is no HOST header in the request, the appliance inserts a HOST header based on the destination IP address in the request.

Typically, the NetScaler appliance acts as a forward proxy in an enterprise LAN. In such a configuration, the appliance resides at the edge of an enterprise LAN and intercepts client requests before they are fanned out to the WAN. Configuring the appliance in the forward proxy mode reduces traffic on the WAN.

To configure forward proxy cache redirection, first enable load balancing and cache redirection on the NetScaler. Then, configure a DNS load balancing virtual server and associated services. Also configure a load balancing virtual server and bind to it appropriate services for the cache. Configure a forward proxy cache redirection virtual server and bind the DNS and load balancing virtual servers to it. You must also configure caching policies and bind them to the cache redirection virtual server. To complete the setup, configure the client browsers to use the forward proxy.

For details on how to enable cache redirection and load balancing on the NetScaler, see "Enabling Cache Redirection and Load Balancing."

For details on how to create a load balancing virtual server, see "Creating a Load Balancing Virtual Server."

For details on how to configure services that represent the cache server, see "Configuring an HTTP Service."

For details on how to bind the service to a virtual server, see "Binding Services to the Virtual Server."

For details on how to create a forward proxy cache redirection server, see "Configuring a Cache Redirection Virtual Server", and create a virtual server of type TRANSPARENT or FORWARD.

For details on binding cache redirection policies to the cache redirection virtual server, see "Configuring a Cache Redirection Policy."

Creating a DNS Service

A DNS service is a representation, on the NetScaler appliance, of a physical DNS server in the network. A DNS load balancing virtual server sends DNS requests to the DNS server in the network through such a service.

To create a DNS service by using the command line interface

At the command line, type the following commands to create a DNS service and verify the configuration :

- add service <name> <IP> <serviceType> <port>
- show service [<name>]

Example

```
add service Service-DNS-1 10.102.29.41 DNS 53
show service Service-DNS-1
        Service-DNS-1 (10.102.29.41:53) - DNS
        State: DOWN
        Last state change was at Fri Jul  2 10:14:32 2010
        Time since last state change: 0 days, 00:00:13.550
        Server Name: 10.102.29.41
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): NO
        HTTP Compression(CMP): NO
        Idle timeout: Client: 120 sec   Server: 120 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED

1)      Monitor Name: ping-default
                State: DOWN     Weight: 1
                Probes: 3       Failed [Total: 3 Current: 3]
                Last response: Failure - Probe timed out.
                Response Time: 2000.0 millisec
 Done
```

Parameters for creating a DNS service

name

The name of the service you are configuring. The name can begin with a letter, a number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should choose a name that helps identify the type of service being added. (Cannot be changed after the service has been created.)

IP

The physical IP address of the server that the service you are configuring represents. Make sure that the server is reachable by the NetScaler.

port

The port number on which the service sends and receives data to and from the server.

serviceType

The type of data that will be transferred between the NetScaler and the server. Typically, for DNS service, the serviceType is DNS.

To add an DNS service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for creating a DNS service" as shown:
   - Service Name*—name
   - Server*—IP
   - Port*—port

   * A required parameter
4. In the Protocol* drop down list, select a supported protocol (for example, **DNS**).
5. Click Create, and then click Close.

Creating a DNS Load Balancing Virtual Server

The DNS virtual server enables the forward proxy to perform DNS resolution before forwarding a client request to an origin server. The DNS load balancing virtual server is associated with the DNS service that represents the physical DNS server on the network.

To create a DNS load balancing virtual server by using the command line interface

At the command line, type the following commands to create a DNS load balancing virtual server and verify the configuration:

- add lb vserver <name> <serviceType>
- show lb vserver [<name>]

Example

```
> add lb vserver Vserver-DNS-1 DNS
 Done
> show lb vserver Vserver-DNS-1
        Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
        State: DOWN
        Last state change was at Fri Jul  2 10:32:28 2010
        Time since last state change: 0 days, 00:00:08.10
        Effective State: DOWN  ARP:DISABLED
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  0 (Total)       0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE
 Done
>
```

Parameters for creating a DNS load balancing virtual server

name

The name of the virtual server being created.

serviceType

The type of traffic the virtual server will be receiving.

To create a DNS load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, in the Name box, type a name for the virtual server.
4. In the Protocol* drop down list, select a supported protocol (for example, **DNS**).
5. Click Create, and then click Close. The DNS Virtual Servers pane displays the new virtual server.

Binding the DNS Service to the Virtual Server

For the DNS server to respond to DNS requests, the service representing the DNS server must be bound to the DNS virtual server.

To bind the DNS service to the load balancing virtual server:

At the command prompt, type the following commands to bind the DNS service to the load balancing virtual server and verify the configuration:

- bind lb vserver <name> <serviceName>
- show lb vserver <name>

Example

```
> bind lb vserver Vserver-DNS-1 Service-DNS-1
 Done
> show lb vserver Vserver-DNS-1
        Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
        State: DOWN
        Last state change was at Fri Jul  2 10:32:28 2010
        Time since last state change: 0 days, 00:12:16.80
        Effective State: DOWN  ARP:DISABLED
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  1 (Total)       0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE

1) Service-DNS-1 (10.102.29.41: 53) - DNS State: DOWN   Weight: 1
 Done
>
```

To unbind a DNS service from the load balancing virtual server:

Use the unbind lb vserver command instead of bind lb vserver.

Parameters for Binding/Unbinding a DNS service to/from a load balancing virtual server

name

The name of the virtual server to/from which the service will be bound/unbound. This is a mandatory argument. Maximum Length: 127

serviceName

The name of the service (created with the addService command) that will be bound or unbound. Maximum Length: 127

To Bind/Unbind a DNS service to/from a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server to/from which you want to bind/unbind the DNS service, and then click Open.
3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

Configuring a Client Web Browser to Use a Forward Proxy

When you configure the NetScaler appliance as forward proxy cache redirection virtual server in the network, you must configure the client Web browser to send requests to the forward proxy. Typically, when you use a forward proxy, the only route to the servers in the network is through the forward proxy.

Refer the documentation for your browser to configure the browser to use a forward proxy. Specify the IP address and port number of the forward proxy cache redirection virtual server for this configuration.

Configuring Reverse Proxy Redirection

A reverse proxy resides in front of one or more Web servers and shields the origin server from client requests. Often, a reverse proxy cache is a front-end for all client requests to a server. An administrator assigns a reverse proxy cache to a specific origin server. This is unlike transparent and forward proxy caches, which cache frequently requested content for all requests to any origin server, and the choice of a server is based on the request.

Unlike a transparent proxy cache, the reverse proxy cache has its own IP address and can replace destination domains and URLs in a non-cacheable request with new destination domains and URLs.

You can deploy reverse proxy cache redirection at the origin-server side or at the edge of a network. When deployed at the origin server, the reverse proxy cache redirection virtual server is a front-end for all requests to the origin server.

In the reverse proxy mode, when the NetScaler receives a request, a cache redirection virtual server evaluates the request and forwards it to either a load balancing virtual server for the cache or a load balancing virtual server for the origin. The incoming request can be transformed by changing the host header or the host URL before they it is sent to the backend server.

To configure reverse proxy cache redirection, first enable cache redirection and load balancing. Then, configure a load balancing virtual server and services to send cacheable requests to the cache servers. Also configure a load balancing virtual server and associated services for the origin servers. Then, configure a reverse proxy cache redirection virtual server and bind relevant cache redirection policies to it. Finally, configure mapping policies and bind them to the reverse proxy cache redirection virtual server.

The mapping policies have an associated action that enables the cache redirection virtual server to forward any non-cacheable request to the load balancing virtual server for the origin.

Be sure to create the default cache server destination.

For details on how to enable cache redirection and load balancing on the NetScaler, see "Enabling Cache Redirection and Load Balancing."

For details on how to create a load balancing virtual server, see "Creating a Load Balancing Virtual Server."

For details on how to configure services that represent the cache server, see "Configuring an HTTP Service."

For details on how to bind the service to a virtual server, see "Binding Services to the Virtual Server."

For details on how to create a reverse proxy cache redirection server, see "Configuring a Cache Redirection Virtual Server", and create a virtual server of type REVERSE.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see "Binding Policies to the Cache Redirection Virtual Server."

Configuring Mapping Policies

If an incoming request is non-cacheable, the reverse-proxy cache redirection virtual server replaces the domain and URL in the request with the domain and URL of a target origin server and forwards the request to the load balancing virtual server for the origin.

A mapping policy enables the reverse proxy cache redirection virtual server to replace the destination domain and URL and forward the request to the load balancing virtual server for the origin.

A mapping policy must first translate the domain and the URL, and then pass the request on to the origin load balancing virtual server.

A mapping policy can map a domain, a URL prefix, and a URL suffix, as follows:

- Domain mapping: You can map a domain without a prefix or suffix. The domain mapping is the default mapping for the virtual server (for example, mapping www.mycompany.com to www.myrealcompany.com).
- Prefix mapping: You can replace a specified pattern prefixed as part of the URL (for example, mapping www.mycompany.com/sports/index.html to www.mycompany.com/news/index.html).
- Suffix mapping: You can replace the file suffix in the URL (for example, mapping www.mycompany.com/sports/index.html to www.mycompany.com/sports/index.asp).

The source and the destination strings being mapped must be similar. If you specify a source domain, you must specify a destination domain, and if you specify a source suffix, you must specify a destination suffix. Similarly, if you specify an exact URL from the source, the target URL must also be an exact URL.

Once you configure mapping policies for the reverse proxy mode, you must bind them to the cache redirection virtual server.

You can use combinations of the source URL, target URL, and source and target domains to configure all three types of domain mapping.

To configure a mapping policy for reverse proxy mode by using the command line interface

At the command prompt, type the following command to add a policy map and verify the configuration:

- add policy map <mapPolicyName> -sd <string> [-su <string>] [-td <string>] [-tu <string>]
- show policy map [<mapPolicyName>]

Example

The following command maps a domain in a client request to a target domain:

```
> add policy map myMappingPolicy -sd www.mycompany.com -td www.myrealcompany.com
 Done
> show policy map myMappingPolicy
1)      Name: myMappingPolicy
       Source Domain: www.mycompany.com       Source Url:
       Target Domain: www.myrealcompany.com    Target Url:
 Done
>
```

Following is an example of mapping a URL suffix to a different URL suffix:

```
> add policy map myOtherMappingPolicy -sd www.mycompany.com -td www.myrealcompany.com -su /news
 Done
> show policy map myOtherMappingPolicy
1)      Name: myOtherMappingPolicy
       Source Domain: www.mycompany.com       Source Url: /news.html
       Target Domain: www.myrealcompany.com    Target Url: /realnews.html
 Done
>
```

Parameters for creating a mapping policy

mapPolicyName

The name of the map policy you are creating.

sd

The publicly known source domain name. This is the domain name with which a client request arrives at a reverse proxy virtual server for cache redirection.

su

The source URL. Specify all or part of the source URL, in the following format: `/ [[prefix] [*]] [.suffix]`

td

The domain name sent to the server. The source domain name is replaced with this name.

tu

The target URL. Specify the target URL in the following format: `/ [[prefix] [*]] [.suffix]`

To configure a mapping policy for reverse proxy mode by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Map Policies.
2. In the details pane, click Add.
3. In the Create Map Policy dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for creating a mapping policy" as shown:
   - Name*- mapPolicyName
   - Source Domain*-sd
   - Target Domain*-td
   - Source URL-su
   - Target URL-tu

   * A required parameter
4. Click Create, and then click Close. The Map pane displays the new mapping policy.

To bind the mapping policy to the cache redirection virtual server by using the command line interface

At the command prompt, type the following commands to bind the mapping policy to the cache redirection virtual server and verify the configuration:

- bind cr vserver <name> -policyName <string> [<targetVserver>]
- show cr vserver <name>

Example

```
> bind cr vserver Vserver-CRD-3 -policyName myMappingPolicy Vserver-LB-CR
 Done
> show cr vserver Vserver-CRD-3
      Vserver-CRD-3 (10.102.29.50:88) - HTTP  Type: CONTENT
      State: UP
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Default: Vserver-LB-CR  Content Precedence: RULE       Cache: REVERSE
      On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
      Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF

1)     Policy:        Target: Vserver-LB-CR   Priority: 0     Hits: 0
1)     Map: myMappingPolicy Target: Vserver-LB-CR
 Done
```

>

To bind the mapping policy to the cache redirection virtual server by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.
2. In the details pane, select the virtual server from which you want to bind the mapping policy, and then click Open.
3. In the Configure Virtual Server(Cache Redirection), on the Policies tab, select Map, and then click Insert Policy.
4. In the Policy Name column, select the policy from drop down list.
5. In the Target column, click the down arrow, and then select the vserver from drop down list.
6. Click OK.

Selective Cache Redirection

Selective cache redirection sends requests for particular types of content, for example, images, to one cache server or group of cache servers and sends other types of content to a different cache server or group of cache servers. You can configure advanced cache redirection in transparent, reverse proxy, or forward proxy modes.

In selective cache redirection, the NetScaler appliance intercepts a client request and forwards non-cacheable requests to the original destination in the client request. For cacheable requests, the appliance sends the requests to the destination cache server that can serve content of a specific content type.

Selective cache redirection involves configuring content switching policies in addition to cache redirection policies. The NetScaler first evaluates the cache redirection policies that are bound to the cache redirection virtual server. If a request matches a cache redirection policy, the cache redirection virtual server sends the request to the origin server or a load balancing virtual server for the origin. If no cache redirection policies match the request, the NetScaler evaluates the content switching policies bound to the cache redirection virtual server. If a content switching policy matches the request, the cache redirection virtual server redirects the request to a load balancing virtual server for the cache.

To configure selective cache redirection, first enable cache redirection, load balancing, and content switching on the NetScaler appliance. Then, configure a load balancing virtual server for the cache and an associated HTTP service. After this, configure a cache redirection virtual server and bind both the cache redirection and content switching policies to it. Once you have bound the policies, you can configure the virtual server to give precedence to either rule based or URL based content-switching policies.

When configured for transparent mode cache redirection in an edge deployment topology, the NetScaler sends all cacheable HTTP traffic to a transparent cache farm. Clients access the Internet through the NetScaler, which is configured as a Layer 4 switch that receives traffic on port 80.

The NetScaler can direct requests for images (for example, .gif and .jpg files) to one server in the transparent cache farm, and all other requests for static content to other servers in the farm. For this configuration, you configure content switching policies to send images to the image cache and send all other cacheable content to a default cache.

Note: The configuration described here is for transparent selective cache redirection. Therefore, it does not require a load balancing virtual server for the origin, as would a reverse proxy configuration.

To configure this type of selective cache redirection, first enable cache redirection, load balancing, and content switching. Then, configure a load balancing virtual server for the cache and configure an associated HTTP service. Then, configure a cache redirection virtual server and create and bind both cache redirection and content switching policies to this virtual server.

For details on how to enable cache redirection and load balancing on the NetScaler, see "Configuring Cache Redirection."

Enabling Content Switching

To configure selective cache redirection, after you enable both the load balancing and cache redirection features on the NetScaler, you must enable content switching.

To enable content switching by using the command line interface

At the command prompt, type:

- enable ns feature CS
- show ns feature

Example

```
> enable ns feature cs
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)   Web Logging             WL               ON
 2)   Surge Protection        SP               ON
 3)   Load Balancing          LB               ON
 4)   Content Switching        CS               ON
 5)   Cache Redirection        CR               ON
       ...
       ...
       ...
23)   HTML Injection          HTMLInjection    ON
24)   NetScaler Push          push             OFF
Done
```

To enable cache redirection and load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure basic features.
3. In Configure Basic Features dialog box, select the check box next to the Content Switching, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

Configuring a Load Balancing Virtual Server for the Cache

Create a load balancing virtual server and an HTTP service for each type of cache server that will be used. For example, if you want to serve JPEG files from one cache server and GIF files from another cache server, and use a third cache server for the rest of the content, create an HTTP service and virtual server for each of the three types of cache servers. Then bind each service to its respective virtual server.

For details on how to create a load balancing virtual server, see "Creating a Virtual ServerCreating a Virtual Server."

For details on how to configure services that represent the cache server, see "Configuring an HTTP Service."

For details on how to bind the service to a virtual server, see "Binding/Unbinding a Service to/from a Load Balancing Virtual Server."

For details on how to create a transparent proxy cache redirection server, see "Configuring a Cache Redirection Virtual Server", and create a virtual server of type TRANSPARENT.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see "Binding Policies to the Cache Redirection Virtual Server."

Configuring a Cache Redirection Policy for a Specific Type of Content

To identify requests that contain a .gif or .jpeg extension as cacheable, you configure a cache redirection policy and bind it to the cache redirection virtual server.

Note: If a request matches a policy, the NetScaler appliance forwards it to the origin server. As a result, in the following procedure, you configure policies to match requests that do *not* have ".gif" or ".jpeg" extensions.

To configure cache redirection for a specific type of content, configure a policy that uses a simple expression, as described in "Configuring a Cache Redirection Policy."

Configuring Policies for Content Switching

You must create a content switching policy to identify specific types of content to be cached in one cache server or farm and identify other types of content to serve from another cache server or farm. For example, you can configure a policy to determine the location for image files with .gif and .jpeg extensions.

After defining the content switching policy, you bind it to a cache redirection virtual server and specify a load balancing virtual server. Requests that match the policy are forwarded to the named load balancing virtual server. Requests that do not match the content switching policy are forwarded to the default load balancing virtual server for the cache.

For more details about the content switching feature and configuring content switching policies, see "Content Switching."

You must first create the content switching policy and then bind it to the cache redirection virtual server.

To create a content switching policy by using the command line interface

At the command line, type:

- add cs policy <policyName> [-url <string> | -rule <expression>]
- show cs policy [<policyName>]

Examples

```
> add cs policy Policy-CS-JPEG -rule "REQ.HTTP.URL == '/*.jpeg'"
 Done
> show cs policy Policy-CS-JPEG
        Rule: REQ.HTTP.URL == '/*.jpeg'         Policy: Policy-CS-JPEG
        Hits: 0
 Done
>

> add cs policy Policy-CS-GIF -rule "REQ.HTTP.URL == '/ *.gif'"
 Done
> show cs policy Policy-CS-GIF
        Rule: REQ.HTTP.URL == '/ *.gif'         Policy: Policy-CS-GIF
        Hits: 0
 Done
>

> add cs policy Policy-CS-JPEG-URL -url /*.jpg
 Done
```

```
> show cs policy Policy-CS-JPEG-URL
        URL: /*.jpg     Policy: Policy-CS-JPEG-URL
        Hits: 0
 Done
>

> add cs policy Policy-CS-GIF-URL -url /*.gif
 Done
> show cs policy Policy-CS-GIF-URL
        URL: /*.gif     Policy: Policy-CS-GIF-URL
        Hits: 0
 Done
>
```

Parameters for creating a content switching policy

policyName

Name of the content switching policy. This is a mandatory parameter, and the value cannot be changed after the policy is created.

url

The URL, with wildcards. Specify the string value in this format: // [[prefix] [*]] [.suffix]
Maximum value: 208

rule

An expression that the NetScaler evaluates to identify non-cacheable requests. Can consist of multiple expressions joined by `AND` and `OR` operators.

To create a URL-based content switching policy by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.
4. Select the URL radio button.
5. In the Value text box, type the string value (for example, **/sports**).
6. Click Create and click Close. The policy you created appears in the Content Switching Policies page.

To create a rule-based content switching policy by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.
4. Select the Expression radio button, and then click Configure.
5. In the Create Expression dialog box, choose the expression syntax that you want to use.
   - If you want to use default syntax, accept the default and proceed to the next step.
   - If you want to use classic syntax, click Switch to Classic Syntax.

   The Expression portion of the dialog box changes to match your choice. The default syntax Expression view has fewer elements than does the classic syntax Expression view. In the default syntax Expression view, instead of a preview window, a button provides access to an expression evaluator. The evaluator evaluates the expression you entered, to verify that it is valid, and displays an analysis of the expression's effect.
6. Enter your policy expressions.
   - If you are using classic syntax and need further instructions, see "Configuring Classic Policies and Expressions."
   - If you are using the default syntax and need further instructions, see "Configuring Default Syntax Expressions: Getting Started."
7. Click Create and click Close. The policy you created appears in the Content Switching Policies pane.

To bind the content switching policy to a cache redirection virtual server by using the command line interface

At the command prompt, type the following commands to bind the content switching policy to a cache redirection virtual server and verify the configuration:

- bind cs vserver <name> <targetVserver> [-policyName <string>]
- show cs vserver [<name>]

Example

```
> bind cs vserver Vserver-CR-1 lbcachejpeg -policyName Policy-CS-JPEG
 Done
> bind cs vserver Vserver-CR-1 lbcachegif -policyName Policy-CS-GIF
```

```
 Done
> show cs vserver Vserver-CR-1
        Vserver-CR-1 (10.102.29.60:80) - HTTP   Type: CONTENT
        State: UP
        Last state change was at Fri Jul  2 12:53:45 2010
        Time since last state change: 0 days, 00:00:58.920
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        State Update: DISABLED
        Default:        Content Precedence: RULE
        Cacheable: YES
        Vserver IP and Port insertion: OFF
        Case Sensitivity: ON
        Push: DISABLED  Push VServer:
        Push Label Rule: none

1)      Policy: Policy-CS-JPEG  Target: lbcachejpeg     Priority: 0     Hits: 0
2)      Policy: Policy-CS-GIF   Target: lbcachegif      Priority: 0     Hits: 0
 Done
>
```

Parameters for binding a content switching policy to a cache redirection virtual server

name

The name of the cache redirection virtual server to which you are binding the content switching policy.

targetVserver

The name of the load balancing virtual server to which cacheable requests that match the content switching policy are sent.

policyName

The name of the content switching policy that decides the cache server to which cacheable content of a specific type is sent.

Note: You are binding the content switching policy to a cache redirection virtual server and not to a content switching virtual server, even though you are using the ' bind cs vserver ' command.

To bind the content switching policy to a cache redirection virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the policy (for example, **Vserver-CS-1**), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, click CSW, and then click Insert Policy.
4. In the Policy Name column, select the policy that you want to configure for the content switching virtual server.
5. In the Target column, click the green arrow, and select the target load balancing virtual server from the list.
6. Click OK.

Configuring Precedence for Policy Evaluation

You can configure a content switching policy based on either a rule, which is a generic configuration to accommodate various content types, or a URL, which is more specific and defines exactly the type of content that has to be sent to a particular cache server. Essentially, the same content can be defined by either a rule based policy or a URL based policy.

Once you bind content switching policies of either type to a cache redirection virtual server, you can configure the virtual server to give precedence to either rule based or URL based policies. This will, in turn, decide which servers the particular requests are directed to.

To configure precedence for policy evaluation, use the precedence parameter, which specifies the type of policy (URL or RULE) that takes precedence on the content redirection virtual server.

Possible values: RULE, URL

Default value: RULE

To configure precedence for policy evaluation by using the command line interface

At the command prompt, type the following commands to configure precedence for policy evaluation and verify the configuration:

- set cr vserver <name> [-precedence (RULE | URL)]
- show cr vserver <name>

Example

```
> set cr vserver Vserver-CRD-1 -precedence URL
 Done
> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: UP  ARP:DISABLED
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default:        Content Precedence: URL Cache: TRANSPARENT
        On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF
```

```
1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: Policy-CRD
 Done
>
```

To configure precedence for policy evaluation by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure precedence, (for example, **Vserver-CS-1**), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, next to Precedence, click Rule or URL, and then click OK.

Administering a Cache Redirection Virtual Server

To administer a cache redirection virtual server, you need to view cache redirection statistics. You might need to enable or disable cache redirection servers, or direct policy hits to the cache instead of the origin. Administrative tasks also include backing up a cache redirection virtual server and managing client connections.

Viewing Cache Redirection Virtual Server Statistics

You can view properties of a cache redirection virtual server and statistics on the traffic that has passed through a cache redirection virtual server. You can also view the cache redirection virtual servers and policies that you have bound to load balancing virtual servers.

To view statistics for a specific cache redirection virtual servers, use the name parameter to specify the name of the virtual server for which statistics will be displayed. Otherwise, statistics for all cache redirection virtual servers are displayed. Maximum Length: 127

To view statistics for a cache redirection virtual server by using the command line interface

At the command prompt, type:

stat cr vserver [<name>]

Example

```
> stat cr vserver Vserver-CRD-1

Vserver Summary
                    IP  port    Protocol       State
Vser...CRD-1        0.0.0.0   80        HTTP          UP

VServer Stats:
                              Rate (/s)             Total
Requests                              0                 0
Responses                             0                 0
Request bytes                         0                 0
Response bytes                        0                 0

To view statistics for a cache redirection virtual server by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to view statistics, (for example, **Vserver-CRD-1**), and then click Statistics.

Omit the server name to display basic statistics for all cache redirection virtual servers. Include the server name to display detailed statistics for that virtual server, including number and size of requests and responses that pass through the virtual server

To view the statistics of a cache redirection virtual server by using the monitoring and dashboard utilities

1. To view the statistics by using the monitoring utilities, click the Monitoring tab.
2. In the Select Group drop-down menu, choose CR Virtual Servers. A list of cache redirection virtual servers appears.
3. To view the statistics by using the dashboard utilities, click the Dashboard tab.
4. Click Applet Client or Web Start Client next to Statistical Utility.
5. In the Select Group drop-down menu, choose CR Virtual Servers. The dashboard displays summary statistics for the cache redirection virtual servers.
6. To see a chart of virtual server activity, click Chart. A graphical representation of the virtual server statistics appears.

Enabling or Disabling a Cache Redirection Virtual Server

When you create a cache redirection virtual server, it is enabled by default. If you disable a cache redirection virtual server, its state changes to OUT OF SERVICE and it stops redirecting cacheable client requests. However, the NetScaler appliance continues to respond to ARP and ping requests for the IP address of this virtual server.

To Enable or Disable a cache redirection virtual servers by using the command line interface

At the command line, type one of the following commands:

- enable cr vserver <name>
- show cr vserver <name>
- disable cr vserver <name>
- show cr vserver <name>

Examples

```
> enable cr vserver Vserver-CRD-1
 Done
> show cr vserver Vserver-CRD-1
       Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
       State: UP  ARP:DISABLED
       Client Idle Timeout: 180 sec
       Down state flush: ENABLED
       Disable Primary Vserver On Down : DISABLED
       Default:        Content Precedence: URL Cache: TRANSPARENT
       On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
       Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF

1)     Cache bypass  Policy: bypass-cache-control
2)     Cache bypass  Policy: Policy-CRD
 Done
>

> disable cr vserver Vserver-CRD-1
 Done
> show cr vserver Vserver-CRD-1
       Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
       State: OUT OF SERVICE  ARP:DISABLED
```

```
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default:        Content Precedence: URL Cache: TRANSPARENT
        On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF

1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: Policy-CRD
 Done
>
```

To Enable or Disable a cache redirection virtual servers by using the configuration utility

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.
3. In the details pane, select the virtual server that you want to enable or disable, (for example, **Vserver-CRD-1**), and then click Statistics.
4. In the Proceed dialog box, click Yes.

Directing Policy Hits to the Cache Instead of the Origin

By default, when a request matches a policy, the NetScaler appliance forwards the request either to the origin server directly, or to a load balancing virtual server for the origin, depending on how you have configured cache redirection.

You can change the default behavior so that when a request matches a policy, the request is forwarded to a load balancing virtual server for the cache.

To change the destination for a policy hit to the origin or the cache, use the onPolicyMatch parameter, which specifies where to send requests that match the cache redirection policy.

The valid options are:

1. CACHE - Directs all matching requests to the cache.

2. ORIGIN - Directs all matching requests to the origin server.

Note: For this option to work, you must select the cacheredirection type as POLICY.

Possible values: CACHE, ORIGIN

Default value: ORIGIN

To change the destination for a policy hit to the origin or the cache by using the command line interface

At the command prompt, type the following commands to change the destination for a policy hit and verify the configuration:

- set cr vserver <name> [-onPolicyMatch (ORIGIN | CACHE)]

- show cr vserver <name>

Example

```
